Care has been taken to confirm the accuracy of the information presented and to describe generally accepted practices. However, the authors, editors, and publisher are not responsible for errors or omissions or for any consequences from application of the information in this book and make no warranty, expressed or implied, with respect to the currency, completeness, or accuracy of the contents of the publication. Application of this information in a particular situation remains the professional responsibility of the practitioner.

The authors, editors, and publisher have exerted every effort to ensure that drug selection and dosage set forth in this text are in accordance with current recommendations and practice at the time of publication. However, in view of ongoing research, changes in government regulations, and the constant flow of information relating to drug therapy and drug reactions, the reader is urged to check the package insert for each drug for any change in indications and dosage and for added warnings and precautions. This is particularly important when the recommended agent is a new or infrequently employed drug.

Some drugs and medical devices presented in this publication have Food and Drug Administration (FDA) clearance for limited use in restricted research settings. It is the responsibility of health care providers to ascertain the FDA status of each drug or device planned for use in their clinical practice.

The publishers have made every effort to trace copyright holders for borrowed material. If they have inadvertently overlooked any, they will be pleased to make the necessary arrangements at the first opportunity.

To purchase additional copies of this book, call our customer service department at (800) 638-3030 or fax orders to (301) 223-2320. International customers should call (301) 223-2300.

Visit Lippincott Williams & Wilkins on the Internet: at LWW.com. Lippincott Williams & Wilkins customer service representatives are available from 8:30 am to 6 pm, EST.

WS: To Susan, David, Charlie, Brandie, Mitchell, Caroline, and Chloe

LB: To my mom and dad, Deasue and Louis. Thank you for all of the intangibles

PB: For Nishan, at the beginning

EC: In Memory of Dr. Ed Baik Chung and Dr. Okhyung Kang and Dennis, Marissa and Emma Lee

DF: To Marisa, Elias, Henry, and Isabel

KML: To my mother Joan

PM: To my family and patients

MM: To my wonderful family. Thanks for all your support

RT: To Sarah, Meghan, Lauren, and my many teachers and mentors

PREFACE

This sixth edition of *The 5-Minute Pediatric Consult* attests to the continuing value to the readers of the content and innovative format. A sixth edition! Wow! I look back on the history of this text and now website with pride and much pleasure. When the first edition was proposed in 1995, the new format of the 5-Minute series intrigued me. The innovative design, fitting well into the evolving computer technology, first Personal Digital Assistants and then the internet, has led to wide acceptance of this presentation that provides easy access to important information. The popularity of *The 5-Minute Pediatric Consult* is a testimony to the excellent work of the authors and editors who write the chapters, and to the editorial and production staff who transform the pages into the final book and website.

This edition contains many chapters rewritten by a group of new authors as well as refinement of all chapters. There are a number of new topics written by child psychiatrists such as separation anxiety, substance abuse, and obsessive compulsive disorders. My thanks to Pace Duckett for recruiting these authors. We added new topics such as narcolepsy, dental trauma, fragile X syndrome, thoracic insufficiency syndrome, and vaccine reactions.

I have been fortunate to have a team of associate editors, many have been on this project for all six editions, while others joined us later but continued the high level of professionalism and dedication to this book. I appreciate the efforts of Lou Bell, Peter Bingham, Esther Chung, David Friedman, Kathy Loomes, Petar Mamula, Maria Mascarenhas, and Ronn Tanel. My gratitude to all of them for their efforts to continue the reputation of high quality known in *The 5-Minute Pediatric Consult*. One of the principles for working on this project is it should be fun. I know it has been enjoyable for me. As the internet and notebooks become more popular, my old fashioned bias for real books will continue despite the prediction that books will be obsolete in the future. I hope not.

Being involved in many ways with educating medical students at Penn and residents at Children's Hospital of Philadelphia, and visiting many hospitals, I was able to see firsthand how this book was helpful to trainees, primary care pediatricians, and nurses, and thus, justifying the name of *The 5-Minute Pediatric Consult*. The spread of the book to other countries in many translations was gratifying and exceeded my initial expectations.

At a recent medical school reunion, I was struck by the memories of my classmates who all shared similar experience in the 4 years of school but had quite a diverse record of recollections that they entered into the reunion booklet. One of my memories was the experience at grand rounds where the chief of medicine related the story that he asked his mentor and previous chief of medicine to continue to come to grand rounds and participate in the department's activities. The older doctor agreed with the proviso that when he began to repeat himself and show some major memory defects, that he would get a tap on the shoulder as an indicator of it was time to step off the stage. The former chief did

not want to be remembered as the old man with a poor memory who stayed too long. One day he got a tap on his shoulder; he knew what that meant. Our memories of him remain positive. On the other hand, our former chief of pediatrics would sleep through grand rounds and when prodded to answer a question, he began to talk about his favorite disease, even though it was not the topic of the session; so much for his reputation. These contrasting observations have helped form some of my professional philosophies. I always made sure that I did not stay too long, mainly to allow for the next generation to have opportunities that I was fortunate to have in my career. Therefore, with this sixth edition, I am retiring from editorship of *The 5-Minute Pediatric Consult* and look to the future of the book under the new team.

Before I go, I do want to express my appreciation and special thanks to Cheryl Polchenko, managing editor and a good pal, who has held all the pieces together and assured the completion of these editions. In every group there is a special person who quietly stands out, Cheryl is that person. *Grazie mille!* Likewise, that staff at Wolters Kluwer Health (that was Lippincott that was Williams & Wilkins). My friends and associates at Wolters Kluwer Health made working on this project a great pleasure. Thanks to Sonya Seigafuse, Rebecca Gaertner, and Nicole Walz who worked on the sixth edition and to Tim Hiscock, Katie Millet, and Joyce Murphy from the past editions. I appreciate them being so helpful. Sandhya Joshi headed the production team that turned the manuscripts into this book. *Molte grazie* to all of them.

At this time of reflection, I also want to acknowledge people, most of whom are no longer with us but their influence on me remains. First my parents who were book lovers and set a great example for the joys of reading and the value of education. Then my teachers, mentors, and colleagues including Willis Hunt, an eccentric but lovable biology teacher, Isaac Starr, my research mentor who showed that one could be a first rate scientist as well as a gentleman (I loved his advice that "all the easy things have been done already."), Harold Farmer, a general internist who demonstrated an enthusiasm for teaching and for delving into medical history, and Francis Wood who set the example that excellent medical care has to be combined with compassionate doctor-patient communication. My fond memories of training at Children's Hospital of Philadelphia include my mentors: David Cornfeld, John Hope, Bob Kaye, Alfred Bongiovani, Bill Rashkind, and Henry Cecil as well as colleagues, Mike Genel, Tom Moshang, Bill Sharrar, Fred Burg, and Ed Chaney, all great friends. A special recognition of Bruce Tempest, former roommate, source of many good insights, both medical and cultural and an integral part of helping medical students learn firsthand about Navajo culture. Of course, I value the lessons from patients and families who taught me the most about patient care. Thanks to all.

WILLIAM SCHWARTZ, MD
Philadelphia 2012

CONTRIBUTING AUTHORS

Nicholas S. Abend, MD

Assistant Professor of Neurology and Pediatrics
Perelman School of Medicine at the University of Pennsylvania
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Division of Plastic Surgery
Perelman School of Medicine at the
University of Pennsylvania and the
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Cynthia R. Jacobstein, MD, MSCE

Assistant Professor of Clinical Pediatrics
Department of Pediatrics
Division of Emergency Medicine
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Douglas Jacobstein, MD

Attending Physician
Division of Pediatric Gastroenterology and
Nutrition
Sinai Hospital of Baltimore
Baltimore, Maryland

Irfan Jafree, MD

Electrophysiology Fellow
Department of Neurology
University of Vermont College of Medicine
Burlington, Vermont

**John Lynn Jefferies, MD, MPF, FACC,
FAAP**

Associate Professor
Pediatric Cardiology
Director
Advanced Heart Failure, Cardiomyopathy,
and Ventricular Assist Device Programs
Co-Director
Cardiovascular Genetics
Associate Director
Heart Institute Research Core
Cincinnati Children's Hospital Medical
Center
University of Cincinnati
Cincinnati, Ohio

Anne K. Jensen, BA

Medical Student
Division of Ophthalmology
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Payal S. Kadia, MD

Fellow
Pediatric Emergency Medicine
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Binita M. Kamath, MBBChir, MRCP, MTR

Staff Physician
Division of Gastroenterology, Hepatology
and Nutrition
The Hospital for Sick Children
Associate Scientist
Research Institute
Assistant Professor
University of Toronto
Toronto, Canada

Robert D. Karch, MD, MPH, FAAP

Director
Pediatric Hospital Medicine
Nemours Children's Hospital
Orlando, Florida

Sara Karjoo, MD

Pediatric Gastroenterology, Hepatology
and Nutrition
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Michael D. Keller, MD

Division of Allergy/Immunology
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Andrea Kelly, MD, MSCE

Assistant Professor of Pediatrics
Division of Endocrinology & Diabetes
Children's Hospital of Philadelphia
Perelman School of Medicine at the
University of Pennsylvania
Philadelphia, Pennsylvania

Janice Anne Kelly, MD

Clinical Associate Professor of Pediatrics
University of Pennsylvania
Division of Gastroenterology and Nutrition
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Judith Kelsen, MD

Assistant Professor of Pediatrics
The Children's Hospital of Philadelphia
Division of Gastroenterology
Philadelphia, Pennsylvania

Shellie M. Kendall, MD

Clinical Fellow
Pediatric Cardiology
University of California, San Francisco
San Francisco, California

Melissa Kennedy, MD

Attending Physician
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Hans B. Kersten, MD

Associate Professor of Pediatrics
St. Christopher's Hospital for
Children
Drexel University College of Medicine
Philadelphia, Pennsylvania

Leslie Kersun, MD, MSCE

Inpatient Medical Director
Division of Oncology
The Children's Hospital of
Philadelphia
Assistant Professor of Pediatrics
Perelman School of Medicine at the
University of Pennsylvania
Philadelphia, Pennsylvania

Jason Y. Kim, MD, MSCE

Division of Infectious Diseases
The Children's Hospital of
Philadelphia
Assistant Professor of Clinical
Pediatrics
Perelman School of Medicine
Philadelphia, Pennsylvania

Terry Kind, MD, MPH

Associate Professor of Pediatrics
Director
Pediatric Medical Student Education
Department of Community Pediatric
Health
Children's National Medical Center
The George Washington University
Washington, DC

Jeremy King, DO

Pediatric Gastroenterologist
Kapiolani Medical Specialists
Assistant Professor
Pediatrics
John A. Burns School of Medicine
Honolulu, Hawaii

Matthew P. Kirschen, MD

Pediatrics
Stanford, California

Thomas F. Kolon, MD

Associate Professor of Urology
Perelman School of Medicine at the
University of Pennsylvania
Program Director
Pediatric Urology Fellowship
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Sanjeev V. Kothare, MD

Division of Epilepsy & Clinical
Neurophysiology
Associate Professor
Department of Neurology
Harvard Medical School
Interim Medical Director
Center for Pediatric Sleep Disorders
Fellowship Director
Pediatric Sleep Medicine Training
Program
Children's Hospital Boston
Boston, Massachusetts

Renee K. Kottenhahn, MD, FAAP

Clinical Associate Professor of Pediatrics
Jefferson Medical College of Thomas
Jefferson University
Philadelphia, Pennsylvania
Associate Director
Pediatric Practice Program and Attending
Physician
Department of Pediatrics
Christiana Care Health Services
Wilmington, Delaware

Wendy J. Kowalski, MD

Attending Neonatologist
Department of Neonatology
Lehigh Valley Hospital
Allentown, Pennsylvania

Richard M. Kravitz, MD

Associate Professor of Pediatrics
Medical Director
Pediatric Sleep Laboratory
Department of Pediatrics
Duke University Medical Center
Durham, North Carolina

Matthew P. Kronman, MD, MSCE

Assistant Professor, Division of Infectious
Diseases
Department of Pediatrics
University of Washington/Seattle
Children's Hospital
Seattle, Washington

Julie You Kwon, MD

Division of Ophthalmology
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Michele P. Lambert, MD, MTR

Assistant Professor of Pediatrics at the
Children's Hospital of Philadelphia
Division of Hematology
Perelman School of Medicine at the
University of Pennsylvania
Philadelphia, Pennsylvania

David R. Langdon, MD

Clinical Director
Division of Endocrinology
Children's Hospital of Philadelphia
Clinical Associate Professor
University of Pennsylvania School of
Medicine
Philadelphia, Pennsylvania

Judith B. Larkin, MD, FAAP

Instructor in Pediatrics
Nemours Pediatrics, Philadelphia
Thomas Jefferson University Hospital
Philadelphia, Pennsylvania
A. I. duPont Hospital for Children
Wilmington, Delaware

Christopher LaRosa, MD

A. I. duPont Hospital for Children
Wilmington, Delaware

Jerry G. Larrabee, MD

Division Chief
Pediatric Primary Care
Department of Pediatrics
University of Vermont
Burlington, Vermont

Dale Young Lee, MD

Fellow
Pediatric Gastroenterology, Hepatology,
and Nutrition
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Rebecca K. Lehman, MD

Assistant Professor
Department of Neurosciences
Division of Pediatric Neurology
Medical University of South Carolina
Charleston, South Carolina

Alycia Leiby, MD

Goryeb Children's Hospital/Atlantic
Health System
Pediatric Gastroenterology and Nutrition
Morristown, New Jersey

Diva D. De León, MD

Assistant Professor of Pediatrics
Division of Endocrinology/Diabetes
The Children's Hospital of Philadelphia
Perelman School of Medicine at the
University of Pennsylvania
Philadelphia, Pennsylvania

Daniel H. Leung, MD

Assistant Professor of Pediatrics
Gastroenterology, Hepatology, and
Nutrition
Texas Children's Hospital
Baylor College of Medicine
Medical Director
Viral Hepatitis Clinic
Houston, Texas

Leonard J. Levine, MD

Assistant Professor of Pediatrics
Department of Pediatrics
Drexel University College of
Medicine
Attending Physician
Division of Adolescent Medicine
St. Christopher's Hospital for
Children
Philadelphia, Pennsylvania

Lorraine E. Levitt Katz, MD

Associate Professor
Division of Endocrinology
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Norman Lewak, MD

Clinical Professor of Pediatrics
University of California, San Francisco
San Francisco, California

Daniel J. Licht, MD

Assistant Professor of Neurology and
Pediatrics
Division of Neurology
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Henry Lin, MD

Fellow
Pediatric Gastroenterology, Hepatology,
and Nutrition
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Rochelle G. Lindemeyer, DMD

Attending Dentist
Director
Pediatric Dentistry Residency
Program
Department of Dentistry
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Steven Liu, MD

Pediatric Gastroenterologist
Children's Center for Digestive
Healthcare
Atlanta, Georgia

Kathleen M. Loomes, MD

Associate Professor of Pediatrics
Perelman School of Medicine at the
University of Pennsylvania
Division of Gastroenterology, Hepatology
and Nutrition
The Children's Hospital of
Philadelphia
Philadelphia, Pennsylvania

Alexander Lowenthal, MD

Senior Echocardiography Fellow
Lucile Packard Children's Hospital at
Stanford
Palo Alto, California

Sheela N. Magge, MD, MSCE

Assistant Professor of Pediatrics
University of Pennsylvania Perelman
School of Medicine
Division of Endocrinology and
Diabetes
The Children's Hospital of
Philadelphia
Philadelphia, Pennsylvania

Shannon Manzi, PharmD

Team Leader, Emergency Services
Department of Pharmacy
Children's Hospital Boston
Boston, Massachusetts

Petar Mamula, MD

Associate Professor of Pediatrics
University of Pennsylvania Perelman
School of Medicine
Division of Gastroenterology, Hepatology
and Nutrition
The Children's Hospital of
Philadelphia
Philadelphia, Pennsylvania

Yang Mao-Draayer, MD, PhD

Associate Professor
Department of Neurology
University of Michigan
Ann Arbor, Michigan

Bradley S. Marino, MD, MPP, MSCE

Associate Professor of Pediatrics
University of Cincinnati College of
Medicine
Director
Heart Institute Research Core
Director
Heart Institute Neurodevelopmental
Clinic
Attending Physician
Cardiac Intensive Care Unit
Divisions of Cardiology and Critical Care
Medicine
Cincinnati Children's Hospital Medical
Center
Cincinnati, Ohio

Jennifer A. Markowitz, MD

Department of Neurology
Children's Hospital of Boston
Boston, Massachusetts

Jonathan Markowitz, MD, MSCE

Director
Children's Center for Digestive Health
Greenville, South Carolina

Maria R. Mascarenhas, MBBS

Associate Professor of Pediatrics at the
University of Pennsylvania
Division of Gastroenterology, Hepatology
and Nutrition
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Kiran Maski, MD

Instructor
Department of Neurology
Children's Hospital Boston
Boston, Massachusetts

Oscar Henry Mayer, MD

Division of Pulmonology
The Children's Hospital of
Philadelphia
Assistant Professor of Clinical
Pediatrics
Perelman School of Medicine of the
University of Pennsylvania
Philadelphia, Pennsylvania

Erin E. McGintee, MD

Attending Physician
Allergy and Immunology
ENT and Allergy Associates, LLP
East Hampton, New York

Susan McKamy, PharmD, BCPS

Assistant Clinical Professor
Department of Clinical Pharmacy
School of Pharmacy
University of California, San Francisco
San Francisco, California
Clinical Lead Pharmacist
Miller Children's Hospital of Long Beach
Long Beach, California

Heather McKeag, MD

Assistant Professor of Pediatrics
Tufts University School of Medicine
Department of Pediatrics
Floating Hospital for Children at Tufts
Medical Center
Boston, Massachusetts

Lisa Mcleod, MD

Department of Pediatrics
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Maureen McMahon, MD

Instructor
Department of Pediatrics
Jefferson Medical College
Philadelphia, Pennsylvania
Pediatrician
Department of Pediatrics
A.I. duPont Hospital for Children
Wilmington, Delaware

Hugh J McMillan, MD, MSc

Assistant Professor of Pediatrics
Division of Neurology
Children's Hospital of Eastern Ontario
Ottawa, Ontario

Margaret M. McNamara, MD

Associate Professor of Pediatrics
University of California San Francisco
San Francisco, California

William McNett, MD

Associate Professor
Pediatrics
Jefferson Medical College
Philadelphia, Pennsylvania

Avani S. Mehta, MD

Fellow
Pediatric Emergency Medicine
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Devendra I. Mehta, MBBS, MSc, MRCP

Assistant Professor
Department of Pediatrics
Thomas Jefferson University
Pediatric Gastroenterologist
Department of Pediatrics
Nemours Children's Clinic
Orlando, Florida

Michelle E. Melicosta, MD, FAAP

U.S. Army Health Center
Wiesbaden, Germany

Heather L. Meluskey, BS, BSN, RN

Pulmonary Hypertension Nurse
Coordinator
Department of Cardiology
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Calies Menard-Katcher, MD

Division of Gastroenterology, Hepatology
and Nutrition
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Jondavid Mentee, MD

Assistant Professor of Pediatrics
Children's Hospital Los Angeles
Keck School of Medicine
Los Angeles, California

Laura M. Mercer-Rosa, MD, MSCE

Assistant Professor in Pediatrics
Perelman School of Medicine
University of Pennsylvania
Philadelphia, Pennsylvania

Kevin E. C. Meyers, MBBCh

Associate Professor of Pediatrics
Nephrology Division
Department of Pediatrics
The Children's Hospital of Philadelphia
University of Pennsylvania
Philadelphia, Pennsylvania

Edmund A. Milder, MD

Fellow
Pediatric Infectious Diseases
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania
Medical Corps
United States Navy

Carol A. Miller, MD

Clinical Professor
Pediatrics
University of California San Francisco
School of Medicine
San Francisco, California

Monte D. Mills, MD

Director
Division of Ophthalmology
The Children's Hospital of Philadelphia
Associate Professor
Ophthalmology
Perelman School of Medicine, University
of Pennsylvania
Philadelphia, Pennsylvania

Jane E. Minturn, MD, PhD

Division of Oncology
The Children's Hospital of Philadelphia
Assistant Professor of Pediatrics
Perelman School of Medicine at the
University of Pennsylvania
Philadelphia, Pennsylvania

Sabina Mir, MBBS

Pediatric Gastroenterology, Hepatology
and Nutrition
Texas Children's Hospital
Baylor College of Medicine
Houston, Texas

Rakesh D. Mistry, MD, MS

Assistant Professor of Pediatrics
University of Pennsylvania School of
Medicine
Attending Physician
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Kimberly Molina, MD

Assistant Professor of Pediatrics
Division of Pediatric Cardiology
University of Utah
Salt Lake City, Utah

Divya Moodalbail, MD

Pediatric Nephrology Fellow
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Sogol Mostoufi-Moab, MD, MSCE

Assistant Professor of Pediatrics
Divisions of Oncology and Endocrinology
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Amanda Muir, MD

Fellow
Department of Gastroenterology,
Hepatology and Nutrition
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Frances M. Nadel, MD, MSCE

Associate Professor, Clinical Pediatrics
Department of Pediatrics
Perelman School of Medicine at the
University of Pennsylvania
Attending Physician
Division of Emergency Medicine
Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Luz I. Natal-Hernandez, MD

Pediatric Cardiology
UCSF Medical Center
San Francisco, California

Jane Nathanson, MD

Pediatric Resident
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Seth L. Ness, MD, PhD

Director
Medical Leader
Neuroscience Therapeutic Area
Janssen Research and Development LLC
Janssen Pharmaceutical Companies of
Johnson & Johnson
Titusville, New Jersey

Jason G. Newland, MD, Med

Associate Professor of Pediatrics
Children's Mercy Hospitals & Clinics
University of Kansas City, Missouri

Jessica Newman, DO

Fellow
Division of Infectious Diseases
Department of Internal Medicine
University of Kansas Medical Center
Kansas City, Kansas

The 5-Minute Pediatric Consult

SIXTH EDITION

ABDOMINAL MASS

Rose C. Graham

BASICS

DEFINITION

An unusually enlarged abdominal or retroperitoneal organ (i.e., hepatomegaly, splenomegaly, or enlarged kidney) or a defined fullness in the abdominal cavity not directly associated with an abdominal organ.

EPIDEMIOLOGY

- 60% of abdominal masses in children are due to organomegaly.
- 40% of abdominal masses in children are due to anomalies of development, neoplasms, or inflammatory conditions.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- **Stomach**
 - Gastroparesis
 - Duplication
 - Foreign body/bezoar
 - Gastric torsion
 - Gastric tumor (lymphoma, sarcoma)
- **Intestine**
 - Feces (constipation)
 - Meconium ileus
 - Duplication
 - Volvulus
 - Intussusception
 - Intestinal atresia or stenosis
 - Malrotation
 - Inflammatory bowel disease complications (abscess, phlegmon)
 - Appendiceal or Meckel diverticulum abscess
 - Toxic megacolon
 - Lymphoma, adenocarcinoma
 - Carcinoid
 - Foreign body
 - Duodenal hematoma (trauma)
- **Liver**
 - Hepatomegaly due to intrinsic liver disease:
 - Hepatitis (viral, autoimmune)
 - Metabolic disorders (Wilson disease, glycogen storage disease)
 - Congenital hepatic fibrosis
 - Cystic disease (Caroli disease)
 - Tumor (hepatic adenoma, hepatoblastoma, hepatocellular carcinoma or diffuse neoplastic process such as lymphoma)
 - Vascular tumor (hamartoma, hemangioma, hemangioendothelioma)
 - Vascular obstruction/congestion (Budd–Chiari syndrome, congestive heart failure)
 - Focal nodular hyperplasia
- **Spleen**
 - Storage disease (Gaucher, Niemann–Pick)
 - Langerhans cell histiocytosis
 - Leukemia
 - Hematologic (hemolytic disease, sickle cell disease, hereditary spherocytosis/elliptocytosis)
 - Wandering spleen

- **Pancreas**
 - Pseudocyst (trauma)
 - Pancreatoblastoma
- **Gallbladder/biliary tract**
 - Choledochal cyst
 - Hydrops
 - Obstruction (stone, stricture, trauma)
- **Kidney**
 - Multicystic dysplastic kidney
 - Hydronephrosis/ureteropelvic obstruction
 - Polycystic disease
 - Wilms tumor
 - Renal vein thrombosis
 - Cystic nephroma
 - Mesoblastic nephroma
- **Bladder**
 - Posterior urethral valves
 - Neurogenic bladder
- **Adrenal**
 - Adrenal hemorrhage
 - Adrenal abscess
 - Neuroblastoma
 - Pheochromocytoma
- **Uterus**
 - Pregnancy
 - Hematocolpos
 - Hydrometrocolpos
- **Ovary**
 - Cysts (dermoid, follicular)
 - Torsion
 - Germ cell tumor
- **Peritoneal**
 - Ascites
 - Teratoma
- **Abdominal wall**
 - Umbilical/inguinal/ventral hernia
 - Omphalocele/gastroschisis
 - Trauma (rectus hematoma)
 - Tumor (fibroma, lipoma, rhabdomyosarcoma)
- **Omentum/mesentery**
 - Cysts
 - Mesenteric fibromatosis
 - Mesenteric adenitis
 - Tumors (liposarcoma, leiomyosarcoma, fibrosarcoma, mesothelioma)
- **Other**
 - Lymphangioma
 - Fetus in fetu
 - Sacrococcygeal teratoma

APPROACH TO THE PATIENT

When evaluating a pediatric abdominal mass, an organized approach is paramount in determining its etiology.

- **Phase 1:** Determine the location of the abdominal mass and its association with intra-abdominal organs via a thorough and careful abdominal examination.
- **Phase 2:** Perform diagnostic tests:
 - Ultrasound is the most efficient way to start the evaluation.

Hints for Screening Problems

- In neonates, a palpable liver edge can be normal; the total liver span is most important.
- In infants, a full bladder is often mistaken for an abdominal mass.
- In infants, most abdominal masses are of renal origin and nonmalignant.
- Severe constipation in older children and adolescents can present as a large, hard mass extending from the pubis past the umbilicus.
- Gastric distention should be considered in all children who present with a tympanic epigastric mass.

HISTORY

- **Question:** Weight loss?
- **Significance:** Tumor, inflammatory bowel disease
- **Question:** Fever?
- **Significance:** Abscess, malignancy
- **Question:** Jaundice?
- **Significance:** Liver/biliary disease
- **Question:** Hematuria or dysuria?
- **Significance:** Renal disease
- **Question:** Vomiting?
- **Significance:** Intestinal obstruction
- **Question:** Frequency and quality of bowel movements?
- **Significance:** Constipation, intussusception, compression of bowel by mass
- **Question:** Bleeding or bruising?
- **Significance:** Coagulopathy
- **Question:** History of abdominal trauma?
- **Significance:** Pancreatic pseudocyst, duodenal hematoma
- **Question:** Sexual activity?
- **Significance:** Pregnancy
- **Question:** Age of patient?
- **Significance:**
 - Often a helpful clue in investigating the cause of the abdominal mass
 - In neonates, the most common origin of abdominal masses is the genitourinary system (cystic kidney disease, hydronephrosis).
 - In infants and preschool-aged children, the most common malignant tumors are Wilms tumor and neuroblastoma.
 - In adolescent-aged girls, ovarian disorders, hematocolpos, and pregnancy are more common causes of abdominal masses.

PHYSICAL EXAM

- **Finding:** General appearance?
- **Significance:** Ill-appearance or cachexia point toward infection or malignancy.
- **Finding:** Location of abdominal mass?
- **Significance:**
 - Left lower quadrant: Constipation, ovarian process, ectopic pregnancy
 - Left upper quadrant: Anomaly of the kidney or splenomegaly
 - Right lower quadrant: Abscess (inflammatory bowel disease), intestinal phlegmon, appendicitis, intussusception, ovarian process, ectopic pregnancy
 - Right upper quadrant: Involves liver, gallbladder, biliary tree, or intestine
 - Epigastric: Abnormality of the stomach (bezoar, torsion), pancreas (pseudocyst), or enlarged liver
 - Suprapubic: Pregnancy, hydrometrocolpos, hematocolpos, posterior urethral valves
 - Flank: Renal disease (cystic kidney, hydronephrosis, Wilms tumor)
- **Finding:** Characteristics of abdominal mass?
- **Significance:** Mobility, tenderness, firmness, smoothness, and/or irregularity of the surface of the mass can provide clues to its significance.
- **Finding:** Hard and immobile mass?
- **Significance:** Tumor
- **Finding:** Extension of mass across midline or into pelvis?
- **Significance:** Tumor, hepatomegaly, splenomegaly
- **Finding:** Percussion of mass?
- **Significance:** Dullness indicates a solid mass; tympany indicates a hollow viscus.
- **Finding:** Shifting dullness, fluid wave?
- **Significance:** Ascites
- **Finding:** Skin exam?
- **Significance:** Bruising and petechiae may occur with coagulopathy related to liver disease and malignant infiltration of bone marrow; café au lait spots are associated with neurofibromas.
- **Finding:** Lymphadenopathy or lymphadenitis?
- **Significance:** Systemic process either malignant or infectious

DIAGNOSTIC TESTS & INTERPRETATION

- **Test:** CBC
- **Significance:** Anemia or hemolysis
- **Test:** Chemistry panel
- **Significance:**
 - Renal disease: BUN and creatinine levels
 - Liver disease (bilirubin, ALT, AST, alkaline phosphatase, GGT, albumin, PT/PTT)
 - Gallbladder disease (bilirubin, GGT)
 - Pancreatic disease: Amylase/lipase levels
 - Intestinal disease: Hypoalbuminemia
- **Test:** Uric acid and lactate dehydrogenase levels
- **Significance:** Elevated in the setting of rapid cell turnover of solid tumors

Imaging

- Plain abdominal radiographs:
 - Rule out intestinal obstruction, identify calcifications, fecal impaction.
- Abdominal ultrasound:
 - Can usually identify the origin of the mass and differentiate between solid and cystic tissue; disadvantages are operator variability and a limited exam when bowel gas obscures underlying abdominal tissues.
- CT scan:
 - Can provide more detail when there is overlying gas or bone; if malignancy is suspected should do chest, abdomen, and pelvis CT.
- MRI:
 - Vascular lesions of liver, major vessels, and tumors
- Radioisotope cholescintigraphy (HIDA) scan:
 - Liver, gallbladder
 - Meckel scan can identify gastric mucosa contained within a Meckel diverticulum or intestinal duplication.
- Voiding cystourethrography or intravenous urography:
 - Wilms tumor, cystic kidney disease, posterior urethral valves, hydronephrosis
- Upper GI study and barium enema:
 - May be of benefit when the mass involves the intestine

TREATMENT

General Measures

- Immediate hospitalization for patients who present with an abdominal mass and signs and/or symptoms of intestinal obstruction
- Initial diagnostic studies should include an abdominal ultrasound and a surgical or oncological consultation as indicated.
- The remaining causes of abdominal masses require urgent care and timely evaluation and referral to appropriate specialists.

ISSUES FOR REFERRAL

Except for the diagnosis of constipation, the presence of an abdominal mass requires immediate attention, and diagnostic studies should be performed expeditiously at a facility capable of diagnosing pediatric disorders.

Admission Criteria

- Immediate hospitalization for patients who present with an abdominal mass and signs and/or symptoms of intestinal obstruction (intussusception, volvulus, gastric torsion, bezoar, foreign body):
 - Toxic megacolon
 - Ovarian torsion
 - Ectopic pregnancy
 - Biliary obstruction (stone, hydrops)
 - Fever
 - Pancreatitis (pseudocyst)
- The remaining causes of abdominal masses require urgent care and timely evaluation and referral to appropriate specialists.

CODES

ICD9

- 789.1 Hepatomegaly
- 789.2 Splenomegaly
- 789.30 Abdominal or pelvic swelling, mass, or lump, unspecified site

ICD10

- R16.0 Hepatomegaly, not elsewhere classified
- R16.1 Splenomegaly, not elsewhere classified
- R19.00 Intra-abd and pelvic swelling, mass and lump, unsp site

ABDOMINAL MIGRAINE

Matthew P. Kirschen

Joel Friedlander

BASICS

DESCRIPTION

Recurrent attacks of periumbilical pain with nausea, vomiting, anorexia, headache, and pallor

EPIDEMIOLOGY

Incidence

- Occurs mostly in children, with a mean onset at age 7 year (3–10 years)
- Peak symptoms 10–12 years of age
- More common in girls (3:2)

Prevalence

- May affect as many as 1–4% of children at some point in their lives
- Declining frequency toward adulthood

RISK FACTORS

Genetics

Parents of affected children often have history of migraine headaches and motion sickness.

ETIOLOGY

- May involve neuronal activity originating in the hypothalamus with involvement of the cortex and autonomic nervous system
- Serotonin is implicated, and blockade of serotonin receptors may prevent abdominal migraine.
- May involve some as yet ill-defined local intestinal vasomotor factors

DIAGNOSIS

Rome III criteria—2 episodes within 12 months meeting all of the following criteria:

- Paroxysmal intense periumbilical pain that lasts > 1 hour
- Intervening episodes of health between episodes
- Pain that interferes with activity
- Pain associated with ≥ 2 of the following: Anorexia, nausea, vomiting, headache, photophobia, or pallor
- No evidence of inflammatory, anatomic, metabolic, or neoplastic process

HISTORY

- Pain usually lasts <6 hours.
- Pain can be located anywhere in abdomen, but more often in upper quadrants.
- No abdominal pain between attacks
- Repetition of identical abdominal crises, anywhere from 1 time per week to several times a year
- Migraine in the history of patient or relatives
- Occasionally, other migraine phenomena such as nausea, vomiting, perspiration, body temperature changes, focal paresthesias, radiation of pain to a limb, visual disturbances, or general malaise
- Impaired consciousness (some degree of lethargy may occur)
- Ask about a family history of migraine headache or unexplained bouts of abdominal pain as children.

PHYSICAL EXAM

- Physical exam, including complete neurologic and abdominal exam, is usually unremarkable.
- Complete eye exam including fundoscopic exam should be done to evaluate for papilledema.

DIAGNOSTIC TESTS & INTERPRETATION

- Even if a patient meets most criteria for abdominal migraine, studies as outlined below should be strongly considered to ensure that a more serious disorder does not exist.
- Abdominal migraine is a diagnosis of exclusion.

Lab

- CBC with differential
- ESR and CRP
- Urinalysis
- Pregnancy test
- Amylase and lipase
- Stool hemoccult
- Stool culture
- Lactose breath test for lactose intolerance
- Lead level
- Evaluation for porphyria or familial Mediterranean fever

- Metabolic evaluation (must be performed during a symptomatic period): Urine organic acids, plasma amino acids, ammonia, lactate, blood gas, acylcarnitine profile, imaging

Diagnostic Procedures/Radiologic Imaging

- Obstruction series to assess for intermittent or partial bowel obstruction
- Upper GI to rule out anatomic abnormalities
- US or CT scan to rule out mass lesion or chronic appendicitis
- Renal US to rule out ureteropelvic junction (UPJ) obstruction
- Barium enema (during painful crisis) to rule out intussusception
- EEG may help differentiate between abdominal migraine and epilepsy.
- Visual evoked response (VER) to red and white flashlight: Children with abdominal migraine may display a specific fast-wave activity response.
- Rarely, brain imaging with CT or MRI may be useful for evaluating causes of intermittent hydrocephalus.

DIFFERENTIAL DIAGNOSIS

- Infection:
 - Giardia
- Environmental:
 - Lead intoxication
- Tumors
- Metabolic:
 - Porphyria, lactose intolerance, female carriers of (X-linked) ornithine transcarbamylase (OTC) gene mutation, organic acidemias
- Psychosocial:
 - Functional abdominal pain/irritable bowel syndrome
- Surgical:
 - Appendicitis, intussusception, biliary colic
- Inflammation:
 - Inflammatory bowel disease, peptic ulcer disease, mesenteric adenitis
- GI:
 - Irritable bowel syndrome, gastroesophageal reflux, wandering spleen, cyclical vomiting syndrome, recurrent abdominal pain, functional abdominal pain, constipation, superior mesenteric artery (SMA) syndrome, recurrent pancreatitis

- Anatomic:
 - Meckel diverticulum, UPJ obstruction
- Neurologic:
 - Abdominal epilepsy—but has a shorter duration of pain (minutes), altered consciousness during event, abrupt onset, abnormal discharges in EEG in 80%
 - Temporal lobe epilepsy
 - Intermittent hydrocephalus (possibly secondary to a 3rd ventricle colloid cyst)

ALERT

Because it is usually a diagnosis of exclusion, many patients go through a large workup to rule out other causes of pain, sometimes including laparotomy.

TREATMENT

MEDICATION (DRUGS)

- Medications can be used to abort acute attacks or be taken as daily prophylaxis.
- For most patients, risks of side effects and complications from the use of these medications may outweigh the relief of pain, especially in children who are experiencing infrequent episodes.
- Limited data exist on abortive agents for abdominal migraines; however, several agents have shown benefit in specialty-based clinical practice, including metoclopramide, steroids, intranasal sumatriptan, and NSAIDs (although the latter may be avoided if there are clinical concerns for gastritis or peptic ulcer disease). Consider benzodiazepines (i.e. lorazepam) and antiemetics (i.e. ondansetron) for vomiting predominant symptoms.
- Suggested prophylactic treatments are similar to those for migraine headaches and include tricyclic antidepressants (e.g., amitriptyline), topiramate, propranolol, cyproheptadine, and valproic acid. If EEG or other data point to possible epilepsy, empiric treatment with anticonvulsants may be considered.

ADDITIONAL TREATMENT

General Measures

- Trigger avoidance:
 - An event diary should be kept to identify possible migraine triggers.
 - Avoiding triggers is the most optimal strategy for preventing recurrent attacks:
 - Common triggers include caffeine, nitrites, amines, emotional arousal, travel, prolonged fasting, altered sleep, exercise, and/or flickering lights.
- Cognitive therapies:
 - Behavioral therapies and lifestyle modification (regular sleep, hydration, and exercise) may also be of benefit. Biofeedback in conjunction with other cognitive therapies and/or relaxation programs may be helpful. Assistance from a trained pediatric mental health professional might be necessary.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Most children outgrow abdominal migraine symptoms (~60%) by early adolescence.
- A substantial percentage of patients (~70%) may later develop more typical migraine headaches.
- Although nonspecific EEG changes are seen more commonly among these children, very few go on to develop epilepsy.
- 10% of children who have a diagnosis of migraine headaches have previously suffered from unexplained recurrent abdominal pain.
- Adult migraine headache sufferers experience abdominal pain more frequently than do tension headache sufferers.

PATIENT EDUCATION

- To help child during bouts of pain, allow the child to do whatever makes him or her comfortable—rest, positioning, quiet.
- Whether the patient should be excused from school depends on various factors:
 - Frequency, severity, and duration of pain
 - Age, maturity, and coping skills of the child

CODES

ICD9

346.20 Variants of migraine, not elsewhere classified, without mention of intractable migraine without mention of status migrainosus

ICD10

- G43.101 Migraine with aura, not intractable, with status migrainosus
- G43.109 Migraine with aura, not intractable, without status migrainosus
- G43.111 Migraine with aura, intractable, with status migrainosus

FAQ

- Q: Does this mean my child will develop migraine headaches?
- A: There is no accurate way to predict whether your child will develop migraine headaches.
- Q: I have 2 younger children. What chance do they have of developing abdominal migraines?
- A: Although migraine headaches do tend to run in families, there is no known Mendelian inheritance pattern.
- Q: What can I do to help my child during bouts of pain?
- A: First, allow the child to do whatever makes him or her comfortable. This may mean resting, positioning, or being quiet. Acetaminophen or NSAID based pain relievers may help to a certain degree. Whether the patient should be excused from school depends on various factors such as the frequency, severity, and duration of the pain as well as the age, maturity, and coping skills of the child.

ABDOMINAL PAIN

Kurt A. Brown

BASICS

DEFINITION

A child's complaint of abdominal pain can originate from GI and non-GI causes but also commonly can be the manifestation of referred pain from extra-abdominal sites.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- **Congenital/anatomic**
 - Incarcerated hernia
 - Intussusception
 - Malrotation with volvulus
 - Ovarian torsion
 - Testicular torsion
 - Ureteropelvic junction obstruction
- **Infectious**
 - Cystitis and urinary tract infections
 - Fitz-Hugh–Curtis syndrome
 - Gastroenteritis (bacterial, viral or parasitic)
 - Helicobacter pylori gastritis
 - Mononucleosis
 - Pharyngitis
 - Pelvic inflammatory disease
 - Peritonitis
 - Pneumonia
 - Psoas abscess
 - Sepsis
 - Tubo-ovarian abscess
 - Varicella
- **Toxic, environmental drugs**
 - Anticholinergic drugs
 - Intestinal foreign body
 - Heavy-metal (i.e., lead) ingestion
 - Mushroom poisoning
 - Food poisoning
 - Sympathomimetic drugs
- **Trauma**
 - Child abuse
 - Duodenal hematoma
 - Perforated viscus
 - Splenic hematoma/rupture
- **Tumor**
 - Any tumor, benign or malignant, leading to viscus obstruction
 - Leukemia
 - Lymphoma
 - Wilms tumor
- **Genetic/metabolic**
 - Diabetic ketoacidosis
 - Lactase deficiency

- **Allergic/inflammatory**
 - Appendicitis
 - Cholecystitis
 - Eosinophilic gastroenteritis
 - Henoch–Schönlein purpura
 - Hepatitis
 - Inflammatory bowel disease
 - Intestinal adhesions
 - Mesenteric adenitis
 - Necrotizing enterocolitis
 - Pancreatitis
 - Peptic ulcer or gastritis
 - Esophagitis or duodenitis
- **Functional**
 - Depression
 - Functional abdominal pain
 - Malingering
 - Münchausen syndrome (+/– by proxy)
 - Stress
- **Miscellaneous**
 - Abdominal migraine
 - Cholelithiasis
 - Colic
 - Constipation
 - Dysmenorrhea
 - Ectopic pregnancy
 - Endometriosis
 - Ileus
 - Intestinal pseudo-obstruction
 - Irritable bowel syndrome
 - Lactose intolerance
 - Mittelschmerz
 - Nephrolithiasis
 - Ovarian cyst
 - Pregnancy
 - Porphyrria
 - Sickle cell disease
 - Typhlitis

APPROACH TO THE PATIENT

- **Phase 1:** Careful and complete history and physical exam to narrow this extensive differential diagnosis:
 - Identify emergencies
 - Separate acute pain conditions from chronic pain
- **Phase 2:** Directed laboratory evaluations should be made to support more likely portions of the differential diagnosis.

HISTORY

- **Question:** Location and duration of pain?
- **Significance:** Acute vs. chronic illness
- **Question:** Onset and progression of symptoms?
- **Significance:** Evolution of painful process
- **Question:** Presence of hematochezia?
- **Significance:** Colonic bleeding or massive upper GI bleeding
- **Question:** Abdominal distention?
- **Significance:** Distention of an abdominal viscus by air, stool, or fluid
- **Question:** Radiation of pain?
- **Significance:** Certain entities characteristically have radiation of pain (i.e., pancreatitis to the back, appendicitis to the right lower quadrant).

- **Question:** Pain relieved by bowel movements?
- **Significance:** Etiology may be related to colonic distension (by air or stool) or inflammation (colitis).
- **Question:** Bowel movement pattern: Decrease in frequency or change in caliber?
- **Significance:** Constipation, tumor, or something else?
- **Question:** Relationship to emesis?
- **Significance:** Usually upper intestinal tract obstruction, liver or gall bladder disorders (pain etiology—see Table 1)
- **Question:** Signs and symptoms of abdominal pain?
- **Significance:** The farther the complaint of pain is away from the periumbilical region, the more likely the pain etiology represents organic disease. True nighttime waking with pain is more often correlated with organic disease than functional pain.

PHYSICAL EXAM

- **Finding:** Location of pain?
- **Significance:** See Table 1
- **Finding:** Re-examination by the same health care provider for changing characteristics?
- **Significance:** Evolution of abdominal process
- **Finding:** Rebound tenderness?
- **Significance:** Peritoneal irritation from peritonitis or appendicitis; potential need for surgical intervention
- **Finding:** Rectal examination?
- **Significance:** Peritoneal irritation, further localization of pain, masses, presence and consistency of stool, and/or occult heme

DIAGNOSTIC TESTS & INTERPRETATION

- **Test:** CBC with differential
- **Significance:** Total WBC count is nonspecific and may be a poor indicator of intestinal inflammation. Anemia is seen in lead poisoning, malignancy, and bleeding. Low platelets are seen in hypersplenism.
- **Test:** ESR
- **Significance:** Nonspecific indicator of systemic inflammation, such as inflammatory bowel disease
- **Test:** Urinalysis
- **Significance:** General screen for urinary tract abnormalities, infection, and collagen disease
- **Test:** Comprehensive metabolic panel
- **Significance:** Sodium, potassium, chloride, carbon dioxide, blood urea nitrogen, creatinine, glucose, total protein, albumin, alanine aminotransferase, uric acid, lactate dehydrogenase

TREATMENT

General Measures

- Every effort should be made to ensure that the patient is clinically stable.
- Frequent evaluation of vital signs and physical exam is a means of assessing evolving pain and ensuring that the patient is well enough for potential discharge.

ISSUES FOR REFERRAL

Persistent abdominal pain without clear etiology or chronic GI diseases should be referred to a pediatric gastroenterologist.

Table 1. Classic clinical findings in disorders characterized by abdominal pain

Disorder	Typical clinical picture	Definitive diagnostic test
Peptic ulcer disease	Burning or sharp midepigastric pain that occurs 1–3 hours after meals and is exacerbated by spicy food and relieved by antacids; family history of peptic ulcer disease	Endoscopy
Pancreatitis	Episodic left upper quadrant pain or epigastric that occurs 5–10 minutes after meals, radiates to the back, and is exacerbated by fatty foods	Pancreatic ultrasound or CT scan Serum amylase and lipase level (↑)
Urinary tract infection	Suprapubic pain, burning on urination, urinary frequency, urinary urgency	Urine culture Urinalysis
Renal calculi	Severe periodic cramping pain that occurs in the flank and occasionally radiates to the groin; costovertebral angle tenderness; family history of renal calculi	Urinalysis Renal ultrasound
Periappendiceal abscess	Right lower quadrant pain; rebound and direct tenderness; anorexia and vomiting; fever	Laparoscopy WBC count (↑)
Gallbladder disease	Right upper quadrant pain that occurs 5–10 minutes after meals and is exacerbated by fatty foods; family history of gallstones	Gallbladder ultrasound
Menstrual pain	Cramping suprapubic pain that occurs during the menses	Trial with NSAIDs
Pelvic inflammatory disease	Suprapubic pain	Cervical culture
Functional abdominal pain (irritable bowel syndrome)	Cramping periumbilical pain that is exacerbated by eating and relieved by defecation	Trial with Metamucil
Lactose intolerance	Cramping periumbilical pain that increases following ingestion of dairy products and is accompanied by flatulence and bloating	Trial with a milk-free diet Breath hydrogen study for lactose deficiency
Inflammatory bowel disease	Right lower quadrant cramping and tenderness; anemia; guaiac-positive stool	Colonoscopy Barium enema Upper GI series ESR (↑), platelet count (↑), WBC count (↑)
Esophagitis	Epigastric and substernal pain that is relieved by antacids and exacerbated by lying down; history of iron deficiency; anemia; guaiac-positive stool	Endoscopy
Lead poisoning	Abdominal pain; history of pica; microcytic anemia; basophilic stippling	Serum lead level
Pancreatic pseudocyst	Left upper quadrant pain; recurrent vomiting; history of abdominal pain	Abdominal ultrasound
Sickle cell disease	Periumbilical pain that responds to rest and rehydration	Sickle cell preparation Hemoglobin electrophoresis
Abdominal epilepsy	Periodic severe abdominal pain that is often associated with seizures	Trial with anticonvulsants
Abdominal migraine	Severe abdominal pain; family history of migraine; recurrent headache, fever, and vomiting; unilateral or occipital headache; somatic complaints	Trial with antimigraine medications
Depression	Social withdrawal; decreased activity; irritability; poor attention span; difficulty sleeping	Trial with antidepressant medications
School avoidance	Nonspecific abdominal pain; severe anxiety reaction; pain that is more severe on weekdays and improves on weekends	

CT, computed tomography; ESR, erythrocyte sedimentation rate; GI, gastrointestinal; NSAIDs, nonsteroidal antiinflammatory drugs; UTI, urinary tract infection; WBC, white blood cell; ↑, increased.

ABNORMAL BLEEDING

Char Witmer

BASICS

DEFINITION

Abnormal bleeding may present as:

- Frequent or significant mucocutaneous bleeding (epistaxis, bruising, gum bleeding, or menorrhagia)
- Bleeding in unusual sites such as muscles, joints, or internal organs
- Excessive postsurgical bleeding

ETIOLOGY

Abnormal bleeding can be the result of a coagulation factor deficiency, an acquired or congenital disorder of platelet number or function, or inherited or acquired collagen vascular disorders.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Platelet disorders may be quantitative or qualitative, collagen vascular disorders can be acquired or inherited, and disorders of coagulation factors can be congenital or acquired.

- **Thrombocytopenia: Defective production**
 - Congenital/genetic:
 - Thrombocytopenia with absent radii syndrome
 - Amegakaryocytic thrombocytopenia
 - Fanconi anemia
 - Metabolic disorders
 - Wiskott–Aldrich syndrome
 - Bernard–Soulier syndrome
 - Other rare familial syndromes (e.g., May–Hegglin anomaly)
 - Acquired:
 - Aplastic anemia
 - Drug-associated marrow suppression
 - Virus-associated marrow suppression (e.g., HIV)
 - Chemotherapy
 - Radiation injury
 - Nutritional deficiencies (e.g., vitamin B12 and folate)
 - Marrow infiltration:
 - Neoplasia (e.g., leukemia, neuroblastoma)
 - Histiocytosis
 - Osteopetrosis
 - Myelofibrosis
 - Hemophagocytic syndromes
 - Storage diseases
- **Thrombocytopenia: Increased destruction**
 - Idiopathic thrombocytopenia
 - Neonatal alloimmune thrombocytopenia
 - Maternal autoimmune thrombocytopenia
 - Drug induced (heparin, sulfonamides, digoxin, chloroquine)
 - Sepsis/disseminated intravascular coagulopathy
 - Infection: Viral, bacterial, fungal, rickettsial
 - Microangiopathic process (e.g., thrombotic thrombocytopenic purpura/hemolytic uremic syndrome)
 - Kasabach–Merritt syndrome
 - Hypersplenism

- **Platelet function disorders**

- Storage pool disorders (e.g., dense granule deficiency, Hermansky–Pudlak or Chediak–Higashi syndrome)
- Platelet receptor abnormalities (e.g., Glanzmann thrombasthenia, adenosine 5'-diphosphate receptor defect)
- Drugs (e.g., aspirin, NSAIDs, guaifenesin, antihistamines, phenothiazines, anticonvulsants)
- Uremia
- Paraproteinemia

- **Coagulation disorders**

- Prolongation of activated partial thromboplastin time (aPTT):
 - Deficiency of factor VIII, IX, XI, or XII
 - Acquired inhibitor or lupus anticoagulant
 - Von Willebrand disease (aPTT may be normal)
- Prolongation of prothrombin time (PT):
 - Mild vitamin K deficiency
 - Liver disease, mild to moderate
 - Deficiency of factor VII
 - Factor VII inhibitor
- Prolongation of PT and aPTT:
 - Liver disease, severe
 - Disseminated intravascular coagulopathy
 - Severe vitamin K deficiency
 - Hemorrhagic disease of the newborn
 - Deficiency of factor II, V, or X or fibrinogen
 - Dysfibrinogenemia
 - Hypoprothrombinemia associated with a lupus anticoagulant
- Normal screening laboratory tests:
 - Von Willebrand disease
 - Factor XIII deficiency
 - Alpha-2-antiplasmin deficiency
 - Plasminogen activator inhibitor-I deficiency

- **Vessel wall disorders**

- Congenital:
 - Hereditary hemorrhagic telangiectasia
 - Ehlers–Danlos syndrome
 - Osteogenesis imperfecta
 - Marfan syndrome
- Acquired:
 - Vasculitis (systemic lupus erythematosus, Henoch–Schönlein purpura, and others)
 - Scurvy

APPROACH TO THE PATIENT

- **Phase 1**

- Includes a thorough history and physical exam
- Familial history specifically of bleeding or consanguinity is an important component of this phase.
- Standard screening laboratory tests include PT, aPTT, and platelet count.

- **Phase 2**

- If a bleeding disorder is suspected but the initial screening tests are negative, testing for von Willebrand disease, factor XIII deficiency, and dysfibrinogenemia is warranted.
- Consider platelet aggregation studies.

- **Phase 3**

- Any abnormal screening tests need further evaluation with additional testing to define the specific disorder (e.g., factor assays).

HISTORY

By taking into account the patient's age, sex, clinical presentation, past medical history, and family history, the most likely cause of bleeding can be usually determined.

- **Question:** Sex of patient?
- **Significance:** Hemophilia is X-linked.
- **Question:** Family history of bleeding?
- **Significance:** Suggests an inherited bleeding disorder
- **Question:** Bleeding in unusual places without significant trauma (intracranial, joints)?
- **Significance:** May indicate significant factor deficiency—hemophilia
- **Question:** Several surgeries in the past without bleeding?
- **Significance:** An inherited bleeding disorder is less likely.
- **Question:** Poorly controlled epistaxis?
- **Significance:** Localized trauma (nose-picking) can cause unilateral epistaxis.
- **Question:** Sepsis?
- **Significance:** Suggests disseminated intravascular coagulopathy
- **Question:** Mucocutaneous bleeding (gum bleeding, bruises, epistaxis, menorrhagia)?
- **Significance:** May indicate a platelet disorder or von Willebrand disease
- **Question:** Purpura or petechiae?
- **Significance:** May signify platelet disorders, von Willebrand disease, or vasculitis
- **Question:** Recent medications?
- **Significance:** Aspirin and NSAIDs (e.g., ibuprofen) affect platelet function.
- **Question:** Presence of renal or liver disease?
- **Significance:**
 - Azotemia contributes to bleeding.
 - Liver disease reduces clotting factors.
- **Question:** Severe malnutrition?
- **Significance:** May lead to scurvy, vitamin K deficiency, or decreased hepatic synthesis of coagulation factors
- **Question:** Sudden onset of petechiae?
- **Significance:** May indicate idiopathic thrombocytopenia

PHYSICAL EXAM

- **Finding:** Petechiae in skin and mucous membranes?
- **Significance:** Disorder of platelet number or function, von Willebrand disease, or vasculitis
- **Finding:** Small bruises in unusual places?
- **Significance:** Possible platelet disorder or von Willebrand disease
- **Finding:** Large bruises or palpable bruises?
- **Significance:** Coagulation deficiencies, severe platelet disorders, or von Willebrand disease
- **Finding:** Delayed wound healing?
- **Significance:** Factor XIII deficiency or dysfibrinogenemia
- **Finding:** Purpura localized to lower body (buttocks, legs, ankles)?
- **Significance:** Henoch–Schönlein purpura

DIAGNOSTIC TESTS & INTERPRETATION

- **Test:** Phase 1: Initial laboratory screening
 - Platelet count
 - PT and aPTT
- **Significance:** Screening tests normal, bleeding disorder suspected
- **Test:** Phase 2:
 - Definitive platelet testing includes platelet aggregation and adenosine triphosphate release studies with ristocetin, collagen, thrombin, arachidonic acid, and adenosine 5'-diphosphate.
- **Significance:** Qualitative platelet defect suspected
 - Factor VIII:C
 - Von Willebrand factor antigen (VIIR:Ag)
 - Von Willebrand factor activity (ristocetin cofactor)
 - Von Willebrand factor multimeric analysis—only send after the diagnosis of von Willebrand disease has been established
 - Thrombin time and fibrinogen assay to screen for afibrinogenemia or dysfibrinogenemia
 - Factor XIII deficiency suspected: Factor XIII assay (urea clot lysis study)
- **Significance:** Von Willebrand disease suspected
- **Test:** Phase 3: Discriminating laboratory studies for abnormal phase 1 tests
- **Significance:**
 - When thrombocytopenia is present:
 - Inspection of blood smear (screening for bone marrow diseases)
 - Mean platelet volume (may be normal or elevated in destructive causes, elevated in congenital macrothrombocytopenias, low in Wiskott–Aldrich syndrome)
 - Bone marrow aspiration (rarely necessary)
 - When disseminated intravascular coagulopathy is suspected (infection, liver disease, massive trauma, PT and aPTT prolonged):
 - Fibrinogen
 - D-dimer or fibrin split products
 - Peripheral smear inspection for RBC fragments
 - Prolonged aPTT (inhibitor screen [50:50 mixing study of patient's and normal plasma]):
 - If aPTT fully corrects with mixing, this is consistent with a factor deficiency:
 - Assess for specific factor deficiencies: Factor VIII, IX, XI, XII
 - If partial or no correction after mixing study:
 - Inhibitor is present.
 - Confirmatory test for the presence of a lupus anticoagulant with a platelet-neutralizing procedure or DRVVT
- **Test:** Prolonged PT
- **Significance:**
 - Inhibitor screen should also be considered for prolonged PT.
 - Specific factor levels (VII)
- **Test:** Prolonged PT and aPTT
- **Significance:**
 - Test for disseminated intravascular coagulopathy, liver disease, and fibrinogen disorders, as described previously
 - Vitamin K deficiency, moderate to severe
 - Factor assays: V, X, II (prothrombin), and fibrinogen

CLINICAL PEARLS

- Children with bleeding disorders are more likely to have large bruises (> 5 cm), palpable bruises, and bruises on more than one body part.
- Uncommon sites for bruising for all ages include the back, buttocks, arms, and abdomen.
- The aPTT may be extremely prolonged in patients with deficiencies of the contact factors (prekallikrein, high molecular weight kininogen [HMWK], factor XII). These deficiencies do not result in bleeding.
- Improper specimen collection including heparin contamination or underfilling of the specimen tube can result in artificially prolonged clotting times.
- Do not forget to consider nonaccidental injury as a cause of increased bruising.
- Factor XII deficiency and lupus anticoagulant are not associated with abnormal bleeding.

ALERT

Pitfalls of testing:

- **PFA-100**
 - Low specificity and sensitivity
 - Affected by medications (NSAIDs)
 - Not recommended as a screening test
- **Bleeding time**
 - Prolonged when platelets <100,000/mm³
 - Affected by medications such as aspirin, NSAIDs, antihistamines
 - Does not correlate well with bleeding risk
 - Accurate result depends on proper technique.
 - Not recommended as a screening test
- **PT and aPTT**
 - Normal ranges are age dependent.
 - Polycythemia (hematocrit 65%) or underfilling of the specimen tube may result in a spuriously prolonged result.
 - Heparin contamination results in a spuriously prolonged result.
- **Von Willebrand disease studies**
 - Values fluctuate over time and may be periodically normal in affected individuals.
 - May require repeated testing to make diagnosis

EMERGENCY CARE

- Pressure, elevation, and ice are generally helpful for most bleeding disorders when active bleeding is present.
- More definitive care is dictated by the nature of the underlying hemostatic defect:
 - Platelet transfusions are useful in disorders of thrombocytopenia owing to decreased production and for intrinsic qualitative platelet disorders, but not for immune platelet disorders.
 - Frozen plasma should be used only in severe cases when the exact diagnosis is not readily available but a defect in coagulation is suspected.
- Head injuries in patients with thrombocytopenia or hemophilia require immediate medical attention.

TREATMENT

General Measures

- Pressure on wound
- Elevation
- Topical application of thrombin
- Topical application of clot-activating polymers

CODES

ICD9

- 626.2 Excessive or frequent menstruation
- 782.7 Spontaneous ecchymoses
- 784.7 Epistaxis

ICD10

- D69.1 Qualitative platelet defects
- R04.0 Epistaxis
- R23.3 Spontaneous ecchymoses

FAQ

- Q: What are the proper preoperative screening tests for bleeding disorders prior to elective surgery such as tonsillectomy?
- A: A thorough personal history, familial history, and physical exam are by far the most important screening tests. A bleeding time or PFA-100 is not recommended. A CBC, PT, and aPTT are often requested by the surgeon, but normal results do not ensure that a bleeding complication will not occur. Overall, the sensitivity and specificity of these screening tests is poor.
- Q: Bruising is a normal part of childhood. How does one know when bruising is "too much"?
- A: Small bruises on bony prominences on the front of the body are common in children and probably reflect trauma rather than a bleeding disorder. Children with bleeding disorders are more likely to have large bruises (> 5 cm), palpable (raised) bruises, and bruises on more than one body part. Uncommon sites for bruising for all ages include the back, buttocks, arms, and abdomen.

ACETAMINOPHEN POISONING

Kevin C. Osterhoudt

BASICS

DESCRIPTION

- Acetaminophen poisoning may occur after acute or chronic overdose.
- After acute overdose, a serum acetaminophen level above the treatment line of the Rumack-Matthew acetaminophen poisoning nomogram should be considered possibly hepatotoxic.
- Acetaminophen is sold under many brand names and is often an ingredient in combination pain reliever preparations.
- Serious hepatotoxicity after a single acute overdose by young children is rare compared with that by adolescents.
- Most toddlers with acetaminophen hepatotoxicity suffer repeated supratherapeutic dosing.

EPIDEMIOLOGY

- Analgesics are the most common drugs implicated in poisoning exposures among children younger than 6 years.
- Acetaminophen preparations make up ~48% of all analgesic poisoning exposures reported to poison control centers.

Incidence

In 2003, acetaminophen poisoning was responsible for 1/2 of all adult cases of acute liver failure.

RISK FACTORS

- Depression
- Pain syndromes
- Glutathione depletion: Prolonged vomiting, alcoholism, etc.
- CYP2E1 induction: Alcoholism, isoniazid therapy

GENERAL PREVENTION

- Acetaminophen should be stored with child-resistant caps, out of sight of young children.
- Proper use of acetaminophen products should be taught to patients with pain or fever.

PATHOPHYSIOLOGY

- Most absorbed acetaminophen is metabolized through formation of hepatic glucuronide and sulfate conjugates.
- Some acetaminophen is metabolized by the CYP450 mixed-function oxidase system, leading to the formation of the toxic *N*-acetyl-*p*-benzoquinoneimine (NAPQI).

- NAPQI is quickly detoxified by glutathione under usual circumstances.
- After overdose, metabolic detoxification can become saturated:
 - Drug elimination half-life becomes prolonged.
 - Proportionately more NAPQI is produced.
 - Glutathione supply cannot meet detoxification demand.
 - Hepatotoxicity or renal toxicity may ensue.

ETIOLOGY

- Single acute overdose of >150 mg/kg or 10 g
- Repeated overdose of >100 mg/kg/d, or 6 g/d, for >2 days

COMMONLY ASSOCIATED CONDITIONS

- Acetaminophen is often marketed in combination with other pharmaceuticals, which may complicate a drug overdose situation.
- Adolescents frequently overdose on more than 1 drug preparation.

DIAGNOSIS

HISTORY

- Medical history of pain or fever:
 - Acetaminophen ingestion should be explored in any patient being treated for pain or fever.
- Amount of acetaminophen ingested:
 - A single, acute ingestion of <150 mg/kg (\leq 10 g in adolescents) is unlikely to cause significant toxicity among otherwise healthy individuals.
- Timing of ingestion:
 - Allows application of the Rumack-Matthew nomogram
- Sustained-release preparation:
 - Acetaminophen is now available in sustained-release form.
- Medication list:
 - Use of isoniazid or other CYP2E1 hepatic enzyme inducers may increase risk for toxicity.
- Signs and symptoms:
 - Initially may be clinically silent
 - Vomiting
 - Anorexia

PHYSICAL EXAM

Right upper quadrant tenderness may suggest acetaminophen-induced hepatitis.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Serum acetaminophen level:
 - Allows application of the Rumack-Matthew nomogram after acute overdose
 - Rumack-Matthew nomogram applies only to single, acute acetaminophen overdose scenarios.
- Hepatic transaminases:
 - Aspartate aminotransferase (AST) is the most sensitive of the widely available measures to assess acetaminophen hepatotoxicity and begins to rise 12–24 hours after significant overdose
- Liver and kidney function tests:
 - As the AST rises, it is important to follow liver and kidney function with tests such as serum glucose, prothrombin (PT) and partial thromboplastin (PTT) times, serum creatinine, plasma pH, and serum albumin.
 - The PT and PTT may be slightly elevated owing to direct effect of elevated blood acetaminophen concentrations or *N*-acetylcysteine therapy, without signifying liver injury.
 - The decline of an elevated serum AST may indicate either liver recovery or profound liver failure and must be interpreted in context.
- Salicylate level:
 - May be a coingestant in the setting of analgesic drug overdose

Pathological Findings

Hepatic zone III (centrilobular) necrosis

DIFFERENTIAL DIAGNOSIS

- Infectious hepatitis
- Other drug-induced hepatitis

TREATMENT

MEDICATION (DRUGS)

First Line

- Single acute overdose:
 - Activated charcoal, 1–2 g/kg (maximum 75 g), may be administered if acetaminophen is judged to be present in the stomach or proximal intestine (usually within 2 hours of ingestion).
 - *N*-acetylcysteine should be administered if a serum acetaminophen level obtained >4 hours after overdose falls above the treatment line of the Rumack-Matthew nomogram.
 - Patients presenting to medical care >7 hours after overdose should be given a loading dose of *N*-acetylcysteine while waiting for the serum acetaminophen level result.

- Oral *N*-acetylcysteine dose: 140 mg/kg loading dose, followed by 70 mg/kg maintenance doses q4h (see “FAQ”)
- Intravenous *N*-acetylcysteine dose: 150 mg/kg loading dose over 1 hour, then 12.5 mg/kg/hr for 4 hours, then 6.25 mg/kg/hr (see “FAQ”)
- Repeated supratherapeutic ingestion:
 - Consider *N*-acetylcysteine therapy if:
 - Ingestion of > 100 mg/kg or 6 g/d for consecutive days
 - Patient is symptomatic
 - AST level is elevated
 - Acetaminophen level is higher than would be expected given dosing, and AST level is normal
- Once started, *N*-acetylcysteine therapy should be continued until:
 - The serum acetaminophen level is nondetectable
 - A simultaneous serum AST has not risen, or, if elevated, liver enzymes and liver function are clearly improving

Second Line

- Acetaminophen poisoning and oral *N*-acetylcysteine therapy are emetogenic: Chill and cover the *N*-acetylcysteine. Consider antiemetic therapy with drugs such as metoclopramide and/or ondansetron. Enteral *N*-acetylcysteine may be given slowly via nasogastric or nasoduodenal tube.
- Intravenous *N*-acetylcysteine has been associated with anaphylactoid reactions, which may require cessation or slowing of infusion, antihistamines, corticosteroids, and/or epinephrine.

ADDITIONAL TREATMENT

General Measures

Evaluate for possible polypharmacy overdose.

ISSUES FOR REFERRAL

- Patients with AST approaching 1,000 IU/L should be considered for transfer to a liver transplant center.
- Mental health services should be provided to victims of intentional overdose.

SURGERY/OTHER PROCEDURES

Liver transplant should be considered per transplant center protocols. The King’s College Hospital Criteria include:

- pH <7.30 after resuscitation, or
- PT > 1.8 times control, plus
- Serum creatinine >3.3 mg/dL, plus
- Encephalopathy

IN-PATIENT CONSIDERATIONS

Admission Criteria

- *N*-acetylcysteine therapy
- Psychiatric evaluation warranted

Discharge Criteria

- *N*-acetylcysteine therapy concluded
- No concern for developing liver injury

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Cardiorespiratory monitoring is warranted during intravenous *N*-acetylcysteine therapy.
- Intensive care monitoring is warranted during fulminant hepatic failure.

PATIENT EDUCATION

- Drug administration education should be offered to victims of chronic overdose.
- Home safety education should be provided after pediatric exploratory ingestions.

PROGNOSIS

- Among previously healthy children, hepatotoxicity is rare with single doses <150–200 mg/kg.
- After single acute acetaminophen overdose, likelihood of hepatotoxicity may be determined by using the Rumack-Matthew nomogram.
- *N*-acetylcysteine therapy prevents hepatic failure in >99% of acetaminophen-poisoned patients if administered within 8 hours of overdose.
- *N*-acetylcysteine therapy is less efficacious when administered >8 hours after overdose, but should still be offered.
- Repetitive dosing of >75 mg/kg/d should be evaluated cautiously, especially in the presence of the following:
 - Febrile illness
 - Vomiting or malnourishment
 - Anticonvulsant or isoniazid therapy

COMPLICATIONS

- Hepatic failure
- Renal insufficiency
- Anaphylactoid shock may complicate intravenous *N*-acetylcysteine therapy.

CODES

ICD9

965.4 Acetaminophen poisoning by aromatic analgesics, not elsewhere classified

ICD10

- T39.1X4A Poisoning by 4-Aminophenol derivatives, undetermined, initial encounter
- T39.1X4D Poisoning by 4-Aminophenol derivatives, undetermined, subsequent encounter
- T39.1X4S Poisoning by 4-Aminophenol derivatives, undetermined, sequela

FAQ

- Q: What is “patient-tailored” *N*-acetylcysteine (NAC) therapy?
- A: The duration of *N*-acetylcysteine therapy used to be dependent upon the pharmaceutical form administered, but is now tailored to the patient based on serum acetaminophen level and liver function.
- Q: Should NAC be given PO or IV?
- A: Both seem to be similarly efficacious. Oral administration of NAC is complicated by taste aversion and vomiting. IV NAC may lead to anaphylactoid shock. No cost–benefit studies are available for direct comparison of patient-tailored courses of oral NAC and IV NAC.

ACNE

Marney Gundlach

BASICS

DESCRIPTION

Acne vulgaris is a disorder of pilosebaceous follicles (PSFs). PSFs are found on the face, chest, back, and upper arms. Acne lesions include microcomedones, closed comedones (whiteheads or CCs), open comedones (blackheads or OCs), inflammatory lesions (erythematous papules [Pap], pustules [Pus], nodules [Nod], or cysts), scars, and macules. No universally accepted classification system for acne exists. One scheme is:

	OC/CC	Pap/Pus	Nod/Scars
Mild	+	+/-	+/-
Moderate	+	+	+/-
Severe	+	+	+

Other forms of acne:

- Acne conglobata: Large connecting cysts or abscesses causing severe disfigurement
- Acne fulminans: Severe acne associated with fever, arthritis, and systemic symptoms
- Acne rosacea: In adults; no comedones
- Steroid acne: Uniform papules or pustules seen after using topical or systemic steroids
- Neonatal acne: Inflammatory acne in up to 20% of neonates; resolves without treatment

RISK FACTORS

Genetics

Familial patterns exist, but no inheritance pattern has been demonstrated.

PATHOPHYSIOLOGY

Four factors contribute to PSF obstruction:

- Increased sebum production: Adrenarche causes increased androgen production, which enlarges sebaceous glands and increases sebum production. Production peaks in teens and decreases in 20s.
- Hyperkeratinization: Epithelial cells lining the PSF don't shed well. Cells and sebum obstruct the PSF, creating a microcomedone.
- Proliferation of *Propionibacterium acnes*: Anaerobic, gram-positive diphtheroid colonizes PSFs and produces free fatty acids (FFAs).
- Inflammation
 - *P. acnes* attract neutrophils (PMNs) to PSFs, which ingest bacteria-releasing hydrolytic enzymes. Inflammation caused by enzymes and FFAs damaging follicles
 - Acne severity related to interactions of *P. acnes* with immune mediators, not absolute concentrations of *P. acnes*
 - Educate patients that OCs are due to lipid oxidation and melanin, not dirt.

ETIOLOGY

- Environmental factors (work grease exposure, hair grease use) may increase lesion numbers.
- Friction from athletic helmets, shoulder pads, chin straps, or bra straps may worsen acne.

COMMONLY ASSOCIATED CONDITIONS

- Polycystic ovarian syndrome (PCOS)
- SAPHO syndrome: Synovitis, acne, pustulosis, hyperostosis, and osteitis

- Adrenal tumors
- Late-onset congenital adrenal hyperplasia

DIAGNOSIS

HISTORY

- Age of onset: early or late onset of acne may indicate androgen excess.
- Medications (including some oral contraceptive pills [OCs], lithium, progestin implants, depot medroxyprogesterone, isoniazid, nicotine products, and steroids) may worsen acne.
- Menstrual history: Premenstrual flares may occur owing to androgen effects of progesterone.
- Androgen excess (history of or current)
 - Prepubertal: Early-onset acne or body odor, increased growth, adrenarche or pubarche, genital maturation, or clitoromegaly
 - Postpubertal: Alopecia, hirsutism, truncal obesity, acanthosis nigricans, or irregular menses
- Psychological impact: Ask patients about self-esteem, depression, and suicidal ideations.

PHYSICAL EXAM

- Skin: Note distribution of OCs, CCs, and inflammatory lesions on the face, chest, and back. May diagram facial lesions with global assessment of acne severity (number, size, extent, and scarring). Pomade acne may be seen around hairline.
- Note signs of androgen excess (see "History").

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Consider for patients with early- or late-onset acne, signs of androgen excess, or acne unresponsive to traditional therapy.
- Most boys have normal hormone levels.
- Girls may have increased levels of DHEAS and free testosterone and decreased levels of sex hormone-binding globulin (SHBG). Consider also total testosterone, FSH, and LH for PCOS.
- Lab monitoring while using isotretinoin should include complete blood count, triglycerides, cholesterol, and transaminases.

DIFFERENTIAL DIAGNOSIS

- Adenoma sebaceum
- Gram-negative folliculitis
- Keratosis pilaris

TREATMENT

MEDICATION (DRUGS)

Topical Agents

Patients assume acne should improve with vigorous cleansing of the skin. Instead, this may worsen acne and irritation from topical agents.

- Benzoyl peroxide (BP): Bactericidal, decreases FFAs.
 - Use for mild inflammatory and comedonal acne; or as adjunct with oral or topical antibiotics to prevent antibiotic resistance.
 - Available as lotion, cream, wash, and gel in 2.5–10%; 5% concentration up to twice daily effective for most patients; 10% solution has similar effectiveness as 5% but with increased side effects.
 - Side effects include drying, erythema, burning, peeling, stinging, and rarely contact dermatitis.

Counsel patients that BP may bleach clothing and linens.

- Topical antibiotics (erythromycin, clindamycin, sulfacetamide) decrease concentration of *P. acnes* and inflammatory mediators; may decrease FFAs.
 - Use for mild or moderate inflammatory acne; no comedolytic effects; apply once or twice daily. Do not use as monotherapy.
 - Side effects: Well tolerated but may include drying or irritation; patients may complain about the smell of sulfacetamide.
 - Often combined with BP; combination products are more expensive. Can use separate generic prescriptions of BP and topical antibiotics together
 - Combining with topical retinoid in clinical trials yields faster results and greater clearing than topical antibiotics alone.
- Retinoids promote epithelial shedding from the PSF, promote comedone drainage, prevent new comedone formation (by decreasing obstruction), and are anti-inflammatory.
 - Side effects include erythema, dryness, irritation, initial acne flares, hypo- or hyperpigmentation, and photosensitivity (advise use of sunscreen with SPF 15–30).
 - 1st-line therapy for most patients; may increase penetration of other topical agents by improving cell shedding
 - Treatment started with lowest strength, small amount every 3rd night and increased to nightly application over 3 weeks. Increase concentration as tolerated. Applying at night may decrease photosensitivity.
- Tretinoin
 - Available as cream, gel, and liquid (increasing potency, respectively). Apply to dry skin.
 - Approved for children ≥ 13 years
 - Sporadic reports of congenital malformations have occurred with tretinoin (pregnancy category C); may discuss with women of childbearing age.
- Adapalene
 - Cream, gel, solution, or pledgets
 - Adapalene gel 0.1% is better tolerated than tretinoin gel 0.025%.
 - Approved for children ≥ 13 years
- Tazarotene
 - Cream and gel. Apply to dry skin.
 - More irritating than other retinoids
 - Approved for children ≥ 12 years
 - Teratogenicity concerns; contraindicated in pregnancy (Category X)
- Salicylic acid promotes comedolysis with drying and peeling, effective for comedonal acne:
 - 0.5–5% cream, wash, lotion, or gel once or twice daily
 - Less effective than topical retinoids at preventing new lesions, but less irritating
 - Consider for patients with comedonal acne who cannot use retinoids or who have a large surface area to treat (e.g., back).
- Azelaic acid: Anticomedonal and antibacterial; decreases hyperpigmentation:
 - 20% cream applied twice daily
 - Side effects include itching, burning, tingling, stinging, and erythema.
 - Consider for patients with comedonal acne who cannot use retinoids or who have a large surface area to treat (e.g., back).

Oral Agents

- Oral antibiotics (tetracycline, doxycycline, minocycline): Same as topical antibiotics plus inhibit PMN chemotaxis, decrease inflammation:
 - Tetracycline is cheapest but has least efficacy; also 4×/day dosing
 - Minocycline and doxycycline given 1–2× daily, dosed at 1 mg/kg
 - Use for acne that is moderate to severe, widespread, or treatment resistant.
 - Use with retinoids; do not use alone.
 - Antibiotic resistance may be seen in 25% of patients; limit treatment length. After 12 weeks, may switch to retinoid monotherapy with no change in clinical response.
 - More effective than topical antibiotics, but more systemic effects
- Isotretinoin decreases sebum production, is anti-inflammatory, and reduces *P. acnes*:
 - Used for acne that is recalcitrant or with significant scarring only, given side effects.
 - Dose starts at 0.5 mg/kg/d in 2 divided doses for 4 weeks, and is increased as tolerated up to 1 mg/kg/d; total course usually 15–20 weeks; total cumulative dose should not exceed 120–150 mg/kg.
 - For patients with severely inflamed acne, start at lower dose to prevent initial acne flares or pretreat with oral corticosteroids.
 - FDA-mandated registry (iPledge; see <https://www.ipledgeprogram.com/>) for all patients on isotretinoin; prescribed only by physicians experienced with its use
 - Side effects:
 - Teratogenicity (obtain 2 negative pregnancy tests in women prior to starting)
 - Depression and suicide have been reported in patients on isotretinoin (causality not established, but counsel about this risk).
 - Rare, sporadic reports of serious skin infections including erythema multiforme, Stevens-Johnson syndrome, and toxic epidermal necrolysis
 - Pseudotumor cerebri when combined with tetracycline (contraindicated)
 - Other side effects: Hyperlipidemia, dry skin, headaches, cheilitis, impaired glucose control in diabetics
- OCPs (for women):
 - Combined OCPs work by (1) estrogen increasing SHBG, which decreases free testosterone, decreasing gonadotropin secretion, which decreases ovarian androgen production; and (2) androgen receptor blocking, which prevents dihydrotestosterone (DHT) formation in the PSFs.
 - Suggested as an adjunct for women with moderate to severe acne not responding to topical retinoids
 - Use OCPs with a low-androgen progestin. OCPs shown in RCTs to improve acne:
 - Ethinyl estradiol (35 mcg) and norgestimate
 - Ethinyl estradiol (20 or 30 mcg) and levonorgestrel
 - Ethinyl estradiol (20-30-35 mcg) and norethindrone
 - Ethinyl estradiol (30 mcg) and drospirenone 3 mg
 - Ethinyl estradiol (30 mcg) and chlormadinone 2 mg

- May need 3–6 months to see improvement.
- Side effects include nausea, breast tenderness, weight gain, breakthrough menstrual bleeding, myocardial infarction, ischemic stroke, and DVTs.
- Use caution in girls who smoke tobacco.
- Spironolactone
 - Blocks androgen receptor in sebaceous gland
 - Give 50–150 mg daily.
 - Off-label use, usually in combination with oral antibiotics

ALERT

- *Clostridium difficile* pseudomembranous colitis may occur rarely with topical clindamycin.
- Do not use isotretinoin with tetracycline, minocycline, or doxycycline owing to increased risk of pseudotumor cerebri.
- BP inactivates tretinoin; when used together, apply BP in the morning and tretinoin at night.
- Tetracycline, minocycline, and doxycycline are category D drugs (unsafe in pregnancy).

ADDITIONAL TREATMENT**General Measures**

- Goal is to reduce number and severity of lesions and prevent scarring. Treat until no new lesions form.
- Tell patients that 6–8 weeks (time for microcomedone to mature) are required for clinical improvement.
- Scars warrant aggressive treatment targeting inflammation.
- In general, creams and lotions are less drying than solutions or gels. More-drying formulations may be better for patients with oily skin or for quick-drying prior to applying makeup; less-drying formulations may be needed for patients with sensitive skin/eczema.

COMPLEMENTARY & ALTERNATIVE THERAPIES

- Limited empirical studies on CAM and acne. RCTs of the following showed that they were not as effective as 5% BP, but resulted in less skin irritation:
 - Tea tree oil: A mixture of terpenes and alcohols with antibiotic and antifungal properties; 5% solution may be effective at treating comedonal and inflammatory acne; may be associated with male gynecomastia
 - Gluconolactone 14% solution may be effective on comedonal and inflammatory acne.

**ONGOING CARE****PATIENT EDUCATION**

- <http://www.skincarephysicians.com/acnet/index.html>
- http://www.aap.org/publiced/BR_Teen_Acne.htm

COMPLICATIONS

- Scarring may be permanent.
- Self-esteem: Acne severity correlated to social variables including embarrassment and lack of enjoyment in social activities among teenagers.
- Patients with mild to moderate acne showed clinical depression and >5% suicidal ideation. Depression scores improve in correlation with response to acne treatment.
- Suicide

FAQ

- Q: What treatment is recommended for patients with comedonal and inflammatory acne?
- A: Topical retinoid + topical/oral antibiotic + BP
- Web site with patient FAQs: <http://www.skincarephysicians.com/acnet/FAQ.html>

ACQUIRED HYPOTHYROIDISM

Adda Grimberg

BASICS

DESCRIPTION

Hypothyroidism that occurs after the neonatal period

EPIDEMIOLOGY

Incidence

- May develop at any age
- Autoimmune thyroid disorders occur more frequently in children and adolescents with type 1 diabetes mellitus.

Prevalence

Chronic lymphocytic thyroiditis prevalence correlates with iodine intake; countries with the highest dietary iodine also have the highest prevalence.

RISK FACTORS

Genetics

- Family history of thyroid disease or other autoimmune endocrinopathies increases risk.
- Genetic predisposition in patients with chronic lymphocytic thyroiditis; 30–40% of patients have a family history of thyroid disease, and up to 50% of their 1st-degree relatives have thyroid antibodies.
- Weak associations of chronic lymphocytic thyroiditis with certain human leukocyte antigen haplotypes
- Autoimmune thyroid disease may be part of Schmidt syndrome (type II polyglandular autoimmune disease).
- Genetic syndromes associated with higher incidence of autoimmune thyroiditis:
 - Down syndrome
 - Turner syndrome (especially those with isochromosome Xq)

ETIOLOGY

- Myriad causes (see “Differential Diagnosis”)
- Can result from thyroid gland dysfunction (primary hypothyroidism) or from pituitary/hypothalamic dysfunction leading to understimulation of the thyroid gland (secondary and tertiary hypothyroidism)

COMMONLY ASSOCIATED CONDITIONS

- Vitiligo
- Other autoimmune endocrinopathies
- Pernicious anemia

DIAGNOSIS

HISTORY

- Linear growth failure can be the 1st sign of thyroid dysfunction.
- Declining school performance is a sensitive marker for lethargy and reduced focusing.
- Radiation exposure, history of diabetes, family history of autoimmune disease
- Signs and symptoms:
 - Early primary hypothyroidism can be asymptomatic.
 - Hypothyroid-related symptoms indicate progression from compensated to uncompensated hypothyroidism.
 - Hypothyroidism may be preceded in some cases by temporary hyperthyroidism (Hashitoxicosis).
 - Goiter may be the presenting sign of acquired hypothyroidism; tenderness suggests an infectious process.

PHYSICAL EXAM

- Bradycardia: Thyroid hormone has cardiac effects.
- Short stature (or fall-off on growth curve) and increased upper/lower segment ratio: Euthyroidism is required to maintain normal growth.
- Goiter: Note consistency, symmetry, nodularity, signs of inflammation:
 - May give a clue regarding cause of hypothyroidism
 - May provide a clinical marker to follow during therapy
- Myxedema (water retention) is not limited to subcutaneous tissue; it may also lead to cardiac failure, pleural effusions, and coma.
- Muscle hypertrophy, yet muscle weakness most obvious in arms, legs, and tongue; hypothyroidism causes disordered muscle function.
- Delayed relaxation phase of deep tendon reflexes due to slowed muscle contraction
- Pale, cool, dry, carotenemic skin due to decreased cell turnover
- Increase in lanugo hair in children; can be reversed with treatment
- Sexual development is an important factor.
- Hypothyroidism can be associated with:
 - Delayed puberty (due to low thyroid hormone level)
 - Precocious puberty and galactorrhea (due to elevated TSH)

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- T₄ (low) and TSH (elevated): Elevated TSH with normal T₄ indicates compensated primary hypothyroidism.
- Free T₄: The most sensitive marker for secondary/tertiary hypothyroidism (TSH elevation lost; total T₄ may still be low normal)
- Antithyroglobulin and antimicrosomal (antiperoxidase) antibodies are markers for chronic lymphocytic thyroiditis.
- The following conditions may test false-positive for acquired hypothyroidism:
 - Thyroid-binding globulin deficiency: Low total T₄, but normal free T₄ and TSH
 - Peripheral resistance to thyroid hormone: Normal/high total T₄
 - “Euthyroid sick” syndrome: low T₄ and T₃; normal/low TSH; increased shunting to reverse T₃
- The following tests may be affected in acquired hypothyroidism:
 - Serum creatinine: Elevated due to reduced glomerular filtration rate
 - LDL cholesterol level: Elevated due to decreased LDL receptor expression
 - Creatine kinase: Increased; hypothyroidism is a rare cause of rhabdomyolysis.

Imaging

Head MRI for suspected secondary/tertiary hypothyroidism or pituitary or hypothalamic lesion

DIFFERENTIAL DIAGNOSIS

- Immunologic:
 - Chronic lymphocytic thyroiditis (Hashimoto thyroiditis)
 - Polyglandular autoimmune syndrome (Schmidt syndrome)
- Infectious:
 - Postviral subacute thyroiditis
 - Associated with congenital infections:
 - Rubella
 - Toxoplasmosis
- Environmental:
 - Goitrogen ingestion:
 - Iodides
 - Expectorants
 - Thioureas
- Iatrogenic:
 - Following surgical thyroidectomy for thyroid cancer, hyperthyroidism, or extensive neck tumors
 - Following radioiodine ablative therapy for hyperthyroidism or thyroid cancer
 - Following irradiation to the head or neck for cancer treatment
 - Medications: lithium, amiodarone, iodine contrast dyes, tiratricol (an OTC fat-loss supplement)

- Metabolic:
 - Cystinosis
 - Histiocytosis X
- Congenital:
 - Late-onset congenital-large ectopic gland
- Genetic syndromes:
 - Down syndrome
 - Turner syndrome
- Secondary or tertiary hypothyroidism
 - Hypothalamic or pituitary disease
- Consumptive hypothyroidism:
 - Due to increased type 3 iodothyronine deiodinase activity in hemangiomas

TREATMENT

MEDICATION (DRUGS)

- L-Thyroxine (synthetic thyroid hormone) replacement
- Indicated for the treatment of overt or compensated hypothyroidism
 - 2–5 mcg/kg/d PO, once daily
 - Monitor T₄ and TSH and titrate dose to maintain normalized thyroid function tests.
 - Duration of therapy:
 - Lifetime
 - In 30% of the cases, children with chronic lymphocytic thyroiditis will undergo spontaneous remission.
 - Need for treatment can be reassessed after growth is completed.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Whenever starting medication or adjusting dose, check T₄ and TSH at 4–6 weeks to assess adequacy of the new dose.
- Monitor response to treatment by measuring T₄ and TSH levels to ensure compliance.

PATIENT EDUCATION

Pharmacies in recent years have been recommending that L-thyroxine be administered on an empty stomach. The Drugs and Therapeutics Committee of the Pediatric Endocrine Society recommended that consistency in administration, coupled with regular dose titration to thyroid function tests, is more important than improving absorption by restricting intake to only times of empty stomach.

PROGNOSIS

- If patients are compliant, prognosis is excellent.
- Treated patients often resume growth at a rate greater than normal (catch-up growth).
- In children in whom treatment has been delayed, catch-up growth may not fully normalize height to predicted values.
- Other signs and symptoms resolve at a variable rate.
- Goiters in chronic lymphocytic thyroiditis may not completely regress with treatment (enlargement due to persistent inflammation does not correct, though TSH-mediated hypertrophy will).

COMPLICATIONS

- Most significant complication is impaired linear growth.
- Puberty can also be affected.
- Myxedema coma may occur.
- Encephalopathy of varied clinical presentation has been associated with high titers of thyroid antibodies, especially antimicrosomal; responds well to corticosteroid treatment.

ICD10

E03.4 Atrophy of thyroid (acquired)

FAQ

- Q: What happens if my child forgets a dose?
- A: Give the dose as soon as you remember. If it is the next day, give 2 doses.
- Q: How long will my child have to take these pills?
- A: Probably for life.
- Q: Are there any side effects from the medication?
- A: No. The medication contains only the hormone that your child's thyroid gland is not making. The hormone is made synthetically, so there is also no infectious risk.
- Q: If my child takes twice the dose, will his or her growth catch up faster?
- A: Your child may grow a little faster but will also have adverse effects from having too much thyroid hormone.
- Q: Does the medication have to be taken at any particular time of day?
- A: No, but consistently choosing the same time of day helps to remember to take it. Do not take simultaneously with soy products or raloxifene (an antiestrogen medication) because they can cause malabsorptions of levothyroxine.
- Q: What if my child needs surgery?
- A: Treatment of hypothyroidism such that the patient is euthyroid (normal thyroid status) prior to surgery is preferable whenever possible (only exception is ischemic heart disease requiring surgery). Euthyroid sick syndrome, which is common in very ill patients, should not be treated.

ACUTE DRUG WITHDRAWAL

Robert J. Hoffman

Naomi Dreisinger

BASICS

DESCRIPTION

- Drug withdrawal is a physiologic response to an effectively lowered drug concentration in a patient with tolerance to that drug.
- Withdrawal results in a predictable pattern of symptoms that are reversible if the drug in question or another appropriate substitute is reintroduced.
- Sedative-hypnotic withdrawal is the most common life-threatening withdrawal syndrome in children. This includes withdrawal from barbiturates, benzodiazepines, as well as gamma hydroxybutyrate and similar substances.
- Other substances that are associated with withdrawal syndromes include opioids, selective serotonin reuptake inhibitors, and caffeine.

EPIDEMIOLOGY

- The most common life-threatening withdrawal syndrome, alcohol withdrawal, rarely occurs in children.
- Neonates born to alcohol-dependent mothers are at risk.

RISK FACTORS

Patients receiving sedatives or analgesics capable of causing tolerance are at risk. This is particularly true with infusions or high doses of such substances in previously naïve patients.

GENERAL PREVENTION

- Clinician familiarity with tolerance and withdrawal associated with prescribed medications allows appropriate drug tapering.
- Drug abuse prevention is appropriate for all children.

PATHOPHYSIOLOGY

- Altered CNS neurochemistry is the most important and clinically relevant aspect of withdrawal pathophysiology.
- Under normal conditions, the CNS maintains a balance between excitation and inhibition. While there are several ways to achieve this balance, excitation is constant and actions occur through removal of inhibitory tone.
- Relative to adults and younger children, adolescents are more prone to development of dependence and withdrawal syndromes due to immaturity of their prefrontal cortex.

ETIOLOGY

- Neonates:
 - Maternal alcohol, caffeine, opioid, sedative-hypnotic, or selective serotonin reuptake inhibitor use may result in a neonatal abstinence syndrome.
 - Treatment with caffeine, opioids, or sedative-hypnotics may result in an abstinence syndrome.

- Older children:
 - Subsequent to treatment with caffeine, opioids, or sedative-hypnotics, an abstinence syndrome may result.
 - Substance abuse, particularly opioids, gamma hydroxybutyrate or other sedative-hypnotics may result in an abstinence syndrome.
 - Frequent caffeine or nicotine use may lead to an abstinence syndrome.
- Use of opioid antagonists such as naloxone, naltrexone, and nalmephe are associated with opioid withdrawal.

DIAGNOSIS

- Drug withdrawal is a clinical diagnosis.
- Patients should be evaluated for associated diagnoses such as traumatic injury, pneumonia, etc.

HISTORY

- Typically, a history of substance exposure, either direct exposure or maternal use, will be elicited.
 - Exposure may be to prescribed medication or abusable substances.
 - Substance use by the mother or child might intentionally be concealed.
- The timing of withdrawal varies depending on the half-life of the substance involved.
 - The shorter the half-life, the sooner the onset of withdrawal and typically the more severe withdrawal symptoms.
- Alcohol or sedative-hypnotics:
 - Withdrawal from these may result in tremulousness, diaphoresis, agitation, insomnia, altered mental status, or withdrawal seizures.
 - Baclofen withdrawal is more frequently severe or life-threatening relative to benzodiazepine withdrawal. History of pump manipulation or malfunction should be sought.
- Caffeine:
 - Withdrawal may result in dysphoria, headache, behavioral changes, or agitation.
- Opioids:
 - Nausea, vomiting, diarrhea, irritability, yawning, sleeplessness, diaphoresis, lacrimation, tremor, and hypertonicity may result.
 - Neonates can also have seizures, a high-pitch cry, skin mottling, and excoriation. These latter signs and symptoms are more typical of opioid withdrawal and rarely occur with neonatal alcohol withdrawal.
- Nicotine:
 - Dysphoria, agitation, behavioral changes, and increased appetite may all occur.
- SSRIs:
 - Neonatal withdrawal from SSRIs may result in jitteriness, agitation, crying, shivering, increased muscle tone, breathing and sucking problems, as well as seizure.
 - Children withdrawing from SSRIs may have jitteriness, agitation, dysphoria, behavioral changes, shivering, increased muscle tone, and seizure.

PHYSICAL EXAM

- Vital signs including temperature should be evaluated regularly. Vital sign changes are tachycardia and hypertension may occur concomitantly with acute drug withdrawal.
- Technology-dependent patients, such as children with an intrathecal baclofen pump, should have evaluation of the machine to determine if it is working properly.
- Most cases of substance withdrawal only result in behavioral changes.
- Opioid withdrawal may be accompanied by diaphoresis, mydriasis, yawning, and lacrimation.
- Sedative-hypnotic withdrawal may result in hypertension, tachycardia, hyperthermia, agitation, hallucinations, and seizure.

DIAGNOSTIC TESTS & INTERPRETATION

Imaging

Neuroimaging to rule out intracranial pathology may rarely be indicated.

Diagnostic Procedures/Other

- No routine lab tests are indicated for patients with substance withdrawal.
- Tests necessary to rule out differential diagnoses should be obtained when appropriate.

DIFFERENTIAL DIAGNOSIS

- Hypoglycemia
- Intoxication with sympathomimetics, anticholinergics, theophylline, caffeine, aspirin, or lithium
- Thyroid storm
- Serotonin syndrome
- Neuroleptic malignant syndrome
- Encephalitis
- Meningitis
- Sepsis

TREATMENT

MEDICATION (DRUGS)

- Symptom-triggered treatment has been demonstrated to be superior to fixed-regimen treatment in terms of patient outcome as well as length of stay.
- Patients experiencing withdrawal from benzodiazepines or barbiturates after treatment in a chronic or intensive care setting may be treated by reinstating the drug and then tapering.
- Iatrogenic withdrawal induced by use of opioid antagonists should not be treated by opioid administration.
 - Withdrawal induced by naloxone should abate rapidly due to the brief half-life of naloxone.
 - Withdrawal induced by naltrexone or nalmephe will be much longer lasting. Symptomatic treatment may be indicated.

- There is no fixed quantity of drug to use for any withdrawal syndrome. Each patient requires a unique quantity of drug.
 - Repeated dosing should continue until the symptoms are controlled, at which point maintenance and then tapering can occur.
- Sedative-hypnotic withdrawal:
 - Ideally, withdrawal is treated with the same class of substance, such as benzodiazepine or barbiturate, if not the precise same drug.
 - Benzodiazepines are particularly useful due to the rapid onset of effect.
 - Diazepam has active metabolites that assist in tapering the drug.
 - Propofol is an outstanding medication for treatment of severe alcohol or sedative-hypnotic withdrawal in adults.
 - Propofol may be used in pediatric cases refractory to benzodiazepines and barbiturates.
 - Use is associated with respiratory depression.
 - Clinicians must be capable of airway management and expect airway support to be necessary when propofol is used.
 - Propofol use is safe in children, but rare cases of metabolic acidemia have occurred when prolonged infusions are used. Prolonged use of propofol infusion should be accompanied by close observation for acidemia.
- Opioid withdrawal:
 - Heroin (as well as other opioids) withdrawal is best treated with an opioid of similar potency and equal or longer duration of action.
 - Methadone is a preferred treatment for withdrawal in adolescents and adults, but most neonatologists have limited or no experience with this drug.
 - Paregoric and tincture of opium remain the most commonly used therapies for neonatal withdrawal.
 - Patients who experience opioid withdrawal in the setting of chronic or intensive care may be treated by reinstating infusion or dosing of the drug they were on before withdrawal symptoms and then tapering this, typically by 10% daily.
- Caffeine withdrawal:
 - Caffeine as soft drink or tea taken to treat headache or agitation
 - Neonatal caffeine abstinence symptoms may be treated by reinstating 75–100% of the caffeine dosage that was discontinued. This amount is then tapered, typically by 10% daily.
- Nicotine withdrawal is not typically treated in children.
- Use of nicotine patch, gum, or other delivery methods is used to increase success rate of abstinence rather than for medical management of the withdrawal syndrome.

ADDITIONAL TREATMENT

General Measures

- Initial Stabilization
 - Initial management is aimed at evaluating and supporting airway, breathing, circulation, serum glucose, and ECG. (A, B, C, D, E)
- Supportive care is the most important general principle.
- The illness is managed with intent of close monitoring and addressing issues as they arise.

ISSUES FOR REFERRAL

- Any patient with substance abuse issues should be referred for appropriate psychiatric or drug counseling.
- Most cases of substance withdrawal are best handled by an addiction specialist, medical toxicologist, intensivist, or other clinician experienced with management of withdrawal.

IN-PATIENT CONSIDERATIONS

Admission Criteria

- In-patient treatment for alcohol or sedative-hypnotic withdrawal is mandatory.
- Although withdrawal from opioids and selective serotonin reuptake inhibitors is not life-threatening, admission with initial management as an inpatient is preferable.

IV Fluids

- Maintenance IV fluid may be required in patients who are unable to take PO.
- Dehydration was once a leading cause of death among patients with alcohol withdrawal.

Discharge Criteria

- Inpatients who have been converted from parenteral to oral medications and are controlled with oral medications may be discharged for home tapering.
- Patients who never require parenteral therapy may be discharged with oral replacement medication after consultation with the appropriate specialist.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- If disposition will be discharge, it is crucial to ensure that the patient's condition is stable before discharge.
- If there is any question regarding whether the patient can be appropriately managed as an outpatient, initial in-patient management is preferable.

Patient Monitoring

- Sedative-hypnotic withdrawal or any other withdrawal syndrome with severe symptoms is best cared for with initial cardiopulmonary monitoring until vital sign abnormalities are controlled with appropriate replacement therapy.
- Patients should be closely monitored until vital signs are within acceptable limits.
- Vigilance for agitation or delirium with sedative-hypnotic withdrawal is necessary.
- Vigilance to detect oversedation and respiratory depression is necessary.

PATIENT EDUCATION

Patients or parents should be aware of withdrawal symptoms to be vigilant for detecting future events.

PROGNOSIS

- With appropriate therapy, withdrawal is well tolerated.
- Poor prognostic factors are primarily related to comorbidities.

COMPLICATIONS

Complications of hypertension, tachycardia, hyperthermia, and CNS agitation or seizure may occur with sedative-hypnotic withdrawal.

ACUTE KIDNEY INJURY

Rebecca Ruebner
Lawrence Copelovitch

BASICS

DESCRIPTION

- Acute kidney injury (AKI), previously referred to as acute renal failure (ARF), is defined as any insult to the kidney, with a sudden decrease of normal kidney function that compromises the normal renal regulation of fluid, electrolyte, and acid–base homeostasis.
- In practical terms, AKI is characterized by a reduction in the glomerular filtration rate (GFR) that results in an abrupt increase in the concentrations of serum creatinine and BUN.
- AKI in the most severe cases may lead to irreversible end-stage renal failure.
- In AKI, the urine output is variable: Anuria, oliguria, and in some cases polyuria can all be observed at presentation.
- Oliguria: Urine output <0.5 mL/kg/h in infants or <500 mL/1.73 m²/d in older children
- Anuria: Total cessation of urinary output
- Polyuria: Urine output >2 L/m²/d in infants and children or 3 L/d in adults

EPIDEMIOLOGY

Incidence

- AKI due to acute tubular necrosis (ATN) is commonly seen in hospitalized patients. The combination of ischemia plus nephrotoxic agents (aminoglycosides, amphotericin B, contrast, chemotherapeutic agents) place these patients at increased risk.
- AKI secondary to dehydration, NSAID toxicity, or medication-induced interstitial nephritis is common in the outpatient setting

PATHOPHYSIOLOGY

AKI is commonly precipitated by an ischemic or nephrotoxic event. Initial vasodilatation is followed by intense vasoconstriction, with blood redistributed from the cortex to the juxtamedullary nephrons. Delivery of oxygen to the kidney is impaired, leading to ATN. Intratubular debris and cast formation develop. Tubular fluid leaks backward across the injured tubular membrane, which, in addition to tubular obstruction, causes further hemodynamic changes.

ETIOLOGY

AKI has many causes, which can be subcategorized into 3 groups:

- Prerenal:
 - Decreased perfusion of the kidney secondary either to decreased intravascular volume (e.g., dehydration), decreased effective circulating blood volume (e.g., CHF), or from altered intrarenal hemodynamics (e.g., NSAIDs)
 - Common form of AKI in children
- Postrenal:
 - Obstructive process (either structural or functional)
 - Obstruction can reside in the lower tract or bilaterally in the upper tracts (unless the patient has a single kidney).
 - This form of renal failure is more common in newborns.

- Intrinsic: Disorders that directly affect the kidney. This form can be subcategorized as follows:
 - ATN is the end result of either ischemic- or toxin-mediated damage to the tubules. Ischemic induced ATN is the result of prolonged and severe prerenal AKI, which is no longer immediately reversible with the restoration of appropriate renal perfusion. Toxin-mediated ATN can be caused by many medications (e.g., aminoglycosides), poisons (e.g., mercury), or endogenous toxins (e.g., myoglobinuria).
 - Glomerular disorders include the various forms of acute glomerulonephritis (e.g., postinfectious, rapidly progressive [crescentic]).
 - Vascular lesions compromise glomerular blood flow. Hemolytic-uremic syndrome is the most common disorder that causes intrinsic AKI in children.
 - Interstitial nephritis most often occurs as a result of exposure to medications such as NSAIDs. It may also be associated with infections (e.g., pyelonephritis), systemic diseases, or tumor infiltrates.

DIAGNOSIS

HISTORY

- Previous infection (acute glomerulonephritis), neurogenic bladder, single kidney (obstruction)
- Therapy with nonsteroidal anti-inflammatory agents, β -lactam antibiotics, acyclovir (acute interstitial nephritis), nephrotoxic drugs (e.g., aminoglycosides, amphotericin B, cisplatin [ATN])
- Toxins: Exposure to heavy metals, organic solvents (ATN)
- Gross hematuria: Glomerulonephritis (tea colored), renal calculi (bright red blood)
- Positive family history of hemolytic-uremic syndrome
- Trauma: Crush injury (ATN)
- Review of symptoms: Various systemic symptoms (acute glomerulonephritis)
- Signs and symptoms: Fever, rash (acute interstitial nephritis, acute glomerulonephritis), bloody diarrhea, pallor (hemolytic-uremic syndrome), severe vomiting or diarrhea (prerenal), abdominal pain (obstruction), hemorrhage, shock (ATN), anuria (acute glomerulonephritis, obstruction), polyuria (ATN, acute interstitial nephritis)

PHYSICAL EXAM

- General: Weight and hydration status; shock (i.e., prerenal, ATN), edema (e.g., acute glomerulonephritis), jaundice (i.e., hemolytic-uremic syndrome, ATN)
- Eyes: Uveitis (i.e., acute interstitial nephritis)
- Lungs: Rales (i.e., acute glomerulonephritis)
- Heart: Gallop (i.e., acute glomerulonephritis)
- Abdomen/Pelvis: Mass (i.e., obstruction)
- Skin: Rash (i.e., acute interstitial nephritis, acute glomerulonephritis), petechiae (i.e., hemolytic-uremic syndrome)
- Joints: Arthritis (i.e., acute glomerulonephritis)

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- All patients with AKI should have a urinalysis with microscopic exam, serum chemistries, and a CBC:
 - Urinalysis: Specific gravity (>1.020 suggests prerenal AKI), proteinuria ($>3+$ intrinsic, glomerular AKI), eosinophiluria (acute interstitial nephritis), pyuria (pyelonephritis), granular casts (prerenal, ATN), pigmenturia (ATN), erythrocyte casts (glomerulonephritis acute interstitial nephritis, ATN)
 - Serum chemistries: Hyponatremia, acidosis, hyperkalemia, hyperphosphatemia, hypocalcemia, BUN/creatinine >20 (i.e., prerenal)
 - CBC: Microangiopathic hemolytic anemia, thrombocytopenia (i.e., hemolytic-uremic syndrome), eosinophilia (i.e., acute interstitial nephritis)
- Selected patients require further studies, including serologies, urine electrolytes, imaging, and renal biopsy:
 - Serologies: Hypocomplementemia (acute glomerulonephritis), antineutrophil cytoplasmic antibodies (acute glomerulonephritis), antinuclear antibodies (acute glomerulonephritis)
 - The fractional excretion of sodium (FENa) is a useful urinary index that determines tubular function. $FENa = [(UNa/PNa)/(Ucreat/Pcreat)] \times 100$. The FENa should not be obtained after diuretics are administered. FENa >2 : acute interstitial nephritis, ATN; FENa <1 : hemolytic-uremic syndrome, acute glomerulonephritis, prerenal.

Imaging

- Chest radiograph: Cardiomegaly or pulmonary edema (fluid overload)
- Renal US: Hydronephrosis, trabeculated bladder (i.e., obstruction), increased echogenicity (i.e., ATN, acute interstitial nephritis, acute glomerulonephritis, hemolytic-uremic syndrome), abnormal Doppler study (renal venous thrombosis)

Diagnostic Procedures/Other

Renal biopsy: Indicated in patients with prolonged, unexplained AKI or suspicion for crescentic glomerulonephritis

DIFFERENTIAL DIAGNOSIS

- Chronic kidney disease: Insidious, associated with poor growth, polyuria, rickets, delayed growth, and anemia
- Azotemia (elevated BUN): Hypercatabolic states including corticosteroid therapy or upper GI bleeding
- Elevated creatinine: Caused by rhabdomyolysis, drugs (trimethoprim-sulfa, cimetidine)

TREATMENT

MEDICATION (DRUGS)

- Excretion and evacuation of many medications is influenced by AKI. Careful attention to drug dosing and levels can minimize toxicity.
- Preventive: Mannitol or furosemide therapy to prevent AKI remains controversial. They may be used prophylactically (e.g., amphotericin B, cisplatin, contrast media) or in cases of hemoglobinuria or myoglobinuria to increase urine flow. Physicians consider that this may convert renal failure from oliguric to nonoliguric.

ADDITIONAL TREATMENT

Additional Therapies

- Supportive:
 - Establish an effective circulatory volume. If the patient is in shock, administer fluids (e.g., normal saline, lactated Ringer solution) liberally, even if there is no urine output.
 - Maintain a normal intravascular volume. Carefully monitor urine output, and provide appropriate fluids accordingly. Consider fluid restriction and diuretics if the patient suffers volume overload.
 - Monitor serum potassium levels frequently. Avoid drugs, fluids, or foods containing potassium in patients with oliguria or anuria.
 - Avoid nephrotoxic medications when possible.
 - Hyponatremia is usually due to free water excess and should thus be managed with fluid restriction. Hypertonic saline should be used if only CNS symptoms are present.
 - Hypocalcemia, if mild, may be treated by phosphate restriction. Severe hypocalcemia requires treatment with calcium gluconate (100 mg/kg) given slowly.
 - Severe acidosis (pH <7.2) requires supplementation with bicarbonate. However, this may cause hypernatremia, fluid overload, and symptomatic hypocalcemia.
 - The effect of aggressive nutritional support is controversial, with the exception of use in a significantly malnourished or hypercatabolic child.
 - Hypertension should be treated aggressively if encephalopathy is present.
 - Dialysis or hemofiltration is indicated for refractory acidosis, severe hyperkalemia, volume overload, and uremic symptoms (e.g., pericarditis, lethargy, bleeding diathesis) or for the removal of toxins (e.g., uric acid, salicylate).
- Specific:
 - Each cause of renal failure may necessitate specific treatment, such as fluid resuscitation (i.e., prerenal), urologic intervention (i.e., obstruction), and corticosteroids (i.e., acute interstitial nephritis, some forms of acute glomerulonephritis).

IN-PATIENT CONSIDERATIONS

Initial Stabilization

- If hypovolemic, rapidly establish euvoemia with 0.9% NS boluses.
- If urine output remains low after euvoemia is established, begin fluid restriction (insensibles and urine output).
- In severe hyperkalemia (>6.5 mEq/L), consider:
 - Calcium gluconate (100 mg/kg IV) over 5–10 minutes if severe
 - Glucose (0.5 g/kg) and insulin (0.1 U/kg) IV over 30 minutes
 - Sodium bicarbonate (1–2 mEq/kg) IV over 10–30 minutes if acidotic
 - When administering sodium bicarbonate, monitor serum calcium carefully since the hypocalcemia may worsen.
 - Kayexalate (1 g/kg) PO or PR in sorbitol
 - Furosemide (1–2 mg/kg) if renal function is adequate
 - Hemodialysis or peritoneal dialysis

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Patients usually remain hospitalized until their renal function improves. Long-term follow-up to monitor sequelae is indicated in patients with prolonged anuria.
- The likelihood of recovery from AKI depends on the amount of urine output and the underlying cause.
- Patients with nonoliguric AKI (e.g., toxin-mediated ATN, interstitial nephritis, hemolytic-uremic syndrome) have lower complication rates than those with oliguric AKI.

PROGNOSIS

- Generally, patients with nonoliguric renal failure have a lower mortality rate than patients with oliguria or anuria.
- The mortality rate increases in patients with multisystem organ failure, despite good supportive care.

COMPLICATIONS

- A significant postobstructive diuresis can be seen after treatment for obstructive AKI.
- Fluid overload, resulting in congestive heart failure, hypertension, or hyponatremia
- Hyperkalemia, affecting cardiac function by causing arrhythmias
- Uremia, manifest by mental status changes, increased risk of bleeding, and infection
- Metabolic acidosis
- Hypocalcemia, causing tetany

FAQ

- Q: What is the expected recovery time in patients with AKI who present with anuria?
- A: Recovery time depends on the etiology of the AKI. Children with hemolytic-uremic syndrome may recover in days to weeks. Those with ATN recover days after treatment for the cause. Children whose disorder results from obstruction usually recover as soon as the obstruction is removed.
- Q: When should renal function return to normal?
- A: Renal function may never return to normal in patients with long-standing anuria. In other cases, after recovery occurs, serum creatinine levels return to normal within weeks.
- Q: Which indices should be observed after a patient recovers from AKI?
- A: Patients recovering from AKI should have BP and urinalysis for proteinuria monitored regularly. Serum creatinine should be measured if the course of AKI was prolonged.

ACUTE LYMPHOBLASTIC LEUKEMIA

Susan R. Rheingold

BASICS

DESCRIPTION

- Acute lymphoblastic leukemia (ALL) is a malignant proliferation of white blood cells characterized by an excess of lymphoblasts.
- Risk stratification is based on clinical features at diagnosis (age and WBC count), biologic and cytogenetic characteristics of the lymphoblasts, and response to initial therapy.
- Risk stratification determines therapy intensity and prognosis.
 - Low risk: Favorable cytogenetics (trisomy 4, 10, or t(12;21) (TEL/AML1), age 1–10 years, WBC count <50,000 at diagnosis, precursor B phenotype, and no minimal residual disease (MRD) at end-induction.
 - Standard risk: Age 1–10 years; WBC count <50,000, precursor B phenotype, non-contributory cytogenetics, no extramedullary involvement (CNS or teste), and no minimal residual disease (MRD) at end-induction.
 - High risk: Age 1–10 years with WBC count >50,000; age >10 years regardless of WBC count or phenotype; all T-cell phenotype, extramedullary involvement, and no/very low minimal residual disease (MRD) at end-induction.
- Very high risk: Unfavorable cytogenetics (hypodiploid, MLL), positive minimal residual disease at end of induction/induction failure. Traditionally patients with t(9;22) ALL (Philadelphia +) were considered very high risk but outcomes have improved drastically with targeted molecular therapy.
- Infants <1 year of age at diagnosis have poor outcomes and are treated on intensive infant protocols.

EPIDEMIOLOGY

- ALL is the most common cancer of childhood, accounting for 30% of cancer diagnoses in children ≤15 years of age.
- More common in Caucasians and males

Incidence

- Incidence of ALL is 1/1,700 in children <15 years of age.
- Peak incidence is between 2 and 5 years of age.

RISK FACTORS

- Prior cancer therapy—chemotherapy or radiation.
- Early exposure to viruses (i.e., daycare) appears to be protective.
- Twin with ALL.
- Genetic syndrome listed below.

Genetics

Increased risk of leukemia with the following:

- Trisomy 21 (≤15% risk), Neurofibromatosis type 1, Fanconi anemia, Bloom syndrome, Ataxia Telangiectasia, Schwachman–Diamond syndrome
- Li–Fraumeni p53 Syndrome (Familial cancer syndrome).
- Congenital immunodeficiencies (e.g., Wiskott–Aldrich syndrome).
- 5–25% risk of ALL in monozygotic twin (5% in dizygotic) before 5 years of age

PATHOPHYSIOLOGY

Leukemia cells are derived from a lymphoblastic precursor cell that acquires multiple genetic mutations that lead to rapid clonal proliferation; lack of cell maturation; and resistance to normal cell death processes (apoptosis). This lymphoblastic proliferation leads to overgrowth and the crowding out of normal bone marrow precursors causing ineffective hematopoiesis and infiltration of lymphatic tissue and end-organs

ETIOLOGY

ASSOCIATED CONDITIONS

- Trisomy 21 (Down syndrome)
- Li–Fraumeni Syndrome
- Neurofibromatosis type 1
- Ataxia telangiectasia
- Bloom syndrome
- Immunodeficiencies

DIAGNOSIS

SIGNS AND SYMPTOMS

HISTORY

- Bleeding (cutaneous and mucosal), easy bruising, epistaxis
 - Low platelet count
 - Coagulopathy
- Bone pain, limp, refusal to bear weight:
 - Infiltrative disease of marrow
 - Pathologic fractures
- Fatigue, pallor, headache:
 - Anemia
- Stridor, orthopnea, shortness of breath, wheezing, any respiratory distress:
 - Mediastinal mass, pleural effusion
 - Venous stasis due to hyperleukocytosis
- Oliguria, anuria:
 - Renal failure most likely from tumor lysis syndrome
- Ocular pain, blurred vision, photophobia:
 - Leukemic infiltration of orbit, optic nerve, retina, iris, cornea, or conjunctiva
- Headache, vomiting, seizures, lethargy:
 - Leukemic infiltration CNS
 - Stroke due to hyperleukocytosis

PHYSICAL EXAM

- Pallor
 - Anemia
- Lymphadenopathy (generalized)
 - Infiltration with leukemia
- Hepatosplenomegaly
 - Infiltration with leukemia
- Bone tenderness
 - Bone marrow infiltration, fracture
- Petechiae and purpura, subconjunctival and retinal hemorrhages
 - Thrombocytopenia
- Hypopyon (layering of leukemia cells in anterior chamber of eye)
- Papilledema CNS infiltration
- Painless testicular enlargement in boys
 - Testicular infiltration
- Swelling of the face, orthopnea
 - Superior vena cava (SVC) syndrome in presence of mediastinal mass

- Rash, subcutaneous nodules
 - Leukemic infiltration of skin (leukemia cutis)
 - Petechiae
- Extremity weakness; numbness or tingling
 - Spinal cord compression

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC
 - Increased or decreased WBC count: <10,000/ μ L in 50% of cases, >50,000/ μ L in 20% of cases
 - Hemoglobin <10 g/dL in 80% of cases
 - Thrombocytopenia (platelets <100,000/ μ L) in 75% of cases. Think of ITP if platelets <10,000/ μ L and rest of CBC is normal.
 - Peripheral smear usually shows characteristic leukemic lymphoblasts.
- PT/PTT, DIC panel
- Chemistry panel:
 - Tumor lysis syndrome: elevated uric acid, potassium, and phosphorous with a secondary hypocalcemia.
 - Elevated creatinine secondary to uric acid or calcium phosphate crystal deposition in the renal tubules.
 - Slight abnormality of liver function tests due to leukemic infiltrate
 - Elevated lactic dehydrogenase (LDH)

ALERT

Beware of any machine-generated differential that has a high percentage of atypical lymphocytes. Leukemic blasts can be mistaken for these cell types and the smear should be reviewed by a pathologist or oncologist.

Imaging

- Chest X-ray—5–10% of cases have a mediastinal mass

Diagnostic Procedures/Other

- Bone marrow aspirate and biopsy:
 - Presence of >25% leukemic lymphoblasts is diagnostic.
 - Immunophenotyping, morphology, and cytogenetic studies are diagnostic and prognostic.
- CSF examination for lymphoblasts:
 - >5 blasts/hpf is positive

Pathological Findings

Morphologic confirmation of lymphoblasts in bone marrow with immunophenotyping. May have combinations of:

- Precursor B- CD 10+, 19+, 20+, 22+, TdT +
- Precursor T- CD 2+, 3+, 5+, 7 +, TdT+
- May also have some minimal myeloid marker involvement- CD 13+, 33+, 34+.

DIFFERENTIAL DIAGNOSIS

- Infectious:
 - Pertussis and parapertussis
 - Parvovirus
 - Cytomegalovirus
 - Acute infectious lymphocytosis
 - Infectious mononucleosis (EBV)

- Hematologic:
 - Idiopathic thrombocytopenic purpura
 - Aplastic anemia
 - Evans syndrome
- Rheumatologic:
 - Juvenile idiopathic arthritis
 - Vasculitis
- Malignant conditions:
 - Neuroblastoma with bone marrow involvement
 - Lymphoma with bone marrow involvement
 - Rhabdomyosarcoma
 - Retinoblastoma
 - Acute or chronic myelogenous leukemia
 - Myelodysplastic syndrome
 - Langerhans cell histiocytosis

TREATMENT

ISSUES FOR REFERRAL

Patients suspected of having ALL should be referred as soon as possible to a pediatric oncologist for further evaluation.

INITIAL STABILIZATION

Emergency care is required for the following:

- Hyperleukocytosis
- Spinal cord compression
- Mediastinal mass/SVC syndrome
- Tumor lysis syndrome

GENERAL MEASURES

- Therapy stratified according to risk groups (low, standard, high, and very high). Overall, there are several phases of intensive outpatient therapy followed by a prolonged maintenance (2–3 years).
- Remission Induction [to achieve (<5% blasts in bone marrow, minimal residual disease <0.01%)]:
 - Vincristine (VCR)
 - Prednisone or dexamethasone
 - PEG–Asparaginase
 - Anthracycline—if high-risk
 - Intrathecal chemotherapy
- Consolidation/interim maintenance (focusing on CNS prophylaxis): Weekly intrathecal chemotherapy:
 - Low/average-risk patients get mild oral chemotherapy with weekly VCR and lower dose methotrexate (MTX).
 - Higher risk patients get combinations of more intensive chemotherapy with cyclophosphamide, cytarabine, methotrexate, vincristine, and asparaginase.
- Delayed intensification (further decrease leukemic burden):
 - Combinations of intensive weekly chemotherapy used in higher risk induction and consolidation.
- Very High risk patients, Ph+ ALL, and infants get extra-intensive cycles, including the above chemotherapy at higher doses and etoposide, before starting Maintenance.

- Maintenance:
 - Length varies by protocol
 - Daily oral 6MP and weekly oral MTX
 - Pulses of VCR and glucocorticoid steroids
 - Periodic intrathecal chemotherapy
- Ph+ ALL also gets treated continuously with molecularly targeted oral tyrosine kinase inhibitors (imatinib or dasatinib).
- Patients with CNS involvement, persistent testicular ALL, and higher risk patients may get treated with prophylactic or therapeutic doses of cranial radiation.
- Very high-risk patients are often treated with bone marrow transplant (BMT) when they are in remission.
- Total duration therapy varies but the minimum is 2 years, with a maximum of 3.25 years depending upon sex of patient and protocol.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

At completion of therapy:

- CBC every 3 months for 2 years, then every 4–6 months for 2 years, then yearly visits. Liver and renal function tests every 3–6 months
- Cardiac evaluation yearly
- Endocrine evaluation in children close to puberty
- All survivors should be followed in a pediatric oncology survivorship clinic.

PROGNOSIS

- Morphologic remission post-induction in all risk categories, with presently available therapy, is 98%.
- Long-term survival (overall) approaches 80%.
- Long-term survival in low risk patients is 90–95%; standard risk group is about 85%. Long-term survival in high-risk group is about 60–75%.
- Long-term survival in very high-risk group is 20–50% (often with transplant).

COMPLICATIONS

- Due to disease:
 - Hyperleukocytosis (WBC count > 100,000): Can lead to stroke, respiratory distress
 - Mediastinal mass (usually T-cell lineage): Can lead to cardiorespiratory arrest
 - Tumor lysis syndrome: Can lead to renal failure, cardiac arrhythmias
 - Coagulopathy: Can lead to stroke and hemorrhage
- Relapse: Approximately 20% of patients who obtain a remission will relapse, usually within 5 years of diagnosis. If the relapse occurs while the patient is actively receiving therapy outcome is poor (<20%), even with BMT. If the relapse is > 36 months from diagnosis or isolated to the CNS or testicle, survival is improved (40–70%) with chemotherapy, radiation and/or BMT.
- Potential irreversible toxicity due to therapy:
 - Cranial radiation (XRT): Secondary brain tumors, leukoencephalopathy and deterioration of intellectual functions/learning deficits, growth retardation, decreased bone density
 - L-Asparaginase: thrombosis, stroke
 - Intrathecal chemotherapy: learning disabilities
 - Doxorubicin/daunorubicin: Cardiac toxicity, secondary AML
 - MTX: Stroke, hepatotoxicity
 - Steroids: Avascular necrosis of joints, growth retardation.

CODES

ICD9

- 204.00 Acute lymphoid leukemia, without mention of having achieved remission
- 204.01 Acute lymphoid leukemia, in remission
- 204.02 Acute lymphoid leukemia, in relapse

ICD10

- C91.00 Acute lymphoblastic leukemia not having achieved remission
- C91.01 Acute lymphoblastic leukemia, in remission
- C91.02 Acute lymphoblastic leukemia, in relapse

FAQ

- Q: Can a child on treatment for ALL go to school or leave the house?
- A: Yes. Most centers encourage the child to live a normal life, including school, activities, and travel.
- Q: Will hair fall out and the child be sick for all 3 years on chemotherapy?
- A: The hair usually falls out within a few weeks of initiating therapy and grows back when maintenance therapy begins (6–8 months). Most children feel relatively well during therapy, especially maintenance chemotherapy.
- Q: Does the child need to be isolated from other children?
- A: The most serious infections a child on chemotherapy gets come from bacteria that the child is already colonized with, not community-acquired viruses. That being said, the child should be isolated from any child who has varicella or other known symptomatic infection.

ACUTE MYELOID LEUKEMIA

David T. Teachey

BASICS

DESCRIPTION

- Acute myeloid leukemia (AML) is a block in differentiation and an unregulated proliferation of myeloid progenitor cells.
- Classified according to the World Health Organization (WHO) classification (2008)
- Formerly classified by French-American-British (FAB) classification
- WHO classification based on genetic alterations, whereas FAB based on morphology

EPIDEMIOLOGY

- 7th most common pediatric malignancy
- Leukemia in 1st 4 weeks of life is usually AML
- Ratio of AML to acute lymphoblastic leukemia (ALL) throughout childhood is 1:4.
- Boys and girls are equally affected.

Incidence

- Incidence peaks at 2 years and again at 16 years of age.
- 500 children/year in the US

RISK FACTORS

Genetics

- Only 20–30% of pediatric blasts have a normal karyotype, vs. 40–50% in adults.
- 60% of abnormal karyotypes fall into known subgroups.
- Translocations or duplications of the *MLL* gene at 11q23 and monosomy 7 are found in many cases of therapy-induced AML and carry a poor prognosis.
- Translocations t(8;21), t(15;17), and inv(16) carry a better prognosis.

PATHOPHYSIOLOGY

- Principal defect is a block in the differentiation of primitive myeloid precursor cells
- 2 predominant mechanisms have been identified:
 - Defect at the level of transcriptional activation
 - Defects in the signaling pathway of hematopoietic growth factors. The proto-oncogene Ras is mutated in up to 1/3 of patients with AML.

ETIOLOGY

- Exact cause unknown
- Acquired risk factors:
 - Exposure to benzene
 - Exposure to ionizing radiation
 - Therapy induced, from chemotherapy for a prior malignancy
 - Alkylating agents such as cyclophosphamide, nitrogen mustard, chlorambucil, and melphalan (typically presents several years after therapy)
 - Epipodophyllotoxins such as VP16, VM26 (typically occurs within 2 years after therapy and is characterized by rearrangements involving 11q23)

- Certain congenital syndromes that carry an increased risk of AML:
 - Fanconi anemia
 - Bloom syndrome
 - Neurofibromatosis type I
 - Down syndrome
 - Severe congenital anemia (i.e., Kostmann disease treated with granulocyte colony-stimulating factor)
 - Diamond Blackfan anemia
 - Paroxysmal nocturnal hemoglobinemia
 - Li-Fraumeni syndrome

DIAGNOSIS

HISTORY

Children with AML can present with very few symptoms or with life-threatening sepsis or hemorrhage. Common symptoms include the following:

- Fever: 30–40%
- Pallor: 25%
- Weight loss/anorexia: 22%
- Fatigue: 19%
- Bleeding (i.e., cutaneous, mucosal, menorrhagia): 33%
- Bone or joint pain: 18%

PHYSICAL EXAM

- Signs of anemia:
 - Pallor, fatigue, headache, dyspnea, systolic flow murmur
- Signs of thrombocytopenia:
 - Petechiae, bruising, epistaxis, gingival bleeding
- Signs of infection:
 - Fever
 - Lingering bacterial infections of lung, sinuses, gingiva, perirectal area, skin
- Other exam findings:
 - Hepatomegaly
 - Splenomegaly
 - Lymphadenopathy
 - Gingival hyperplasia
 - Papilledema, cranial nerve palsies (rare)
 - Colorless or slightly purple subcutaneous nodules: “Blueberry muffin” lesions of leukemia cutis (more commonly seen in neonates)

DIAGNOSTIC TESTS & INTERPRETATION

Techniques such as fluorescence in situ hybridization, Southern blotting, and reverse transcriptase–polymerase chain reaction are becoming necessary diagnostic tools for AML.

Lab

- CBC:
 - Anemia, thrombocytopenia, elevated or low total WBC peripheral smear
 - Myeloblasts may be seen.
- Prothrombin time (PT)/partial thromboplastin time (PTT) fibrin split products:
 - Elevated in some cases, especially with acute promyelocytic leukemia (M3)
 - Can have severe, life-threatening disseminated intravascular coagulation (DIC)
- Electrolytes (abnormalities associated with tumor lysis syndrome):
 - Hyperkalemia
 - Hypocalcemia
 - Hyperphosphatemia
 - Hyperuricemia
- CSF analysis for cell count and cytology:
 - > 5 WBC/mm³ is suggestive of CNS disease.
 - 5–15% of cases have CNS involvement at diagnosis.

Diagnostic Procedures/Other

Bone marrow aspirate:

- $> 20\%$ myeloblasts is diagnostic.
- Confirm with immunophenotyping and cytochemistry.

Pathological Findings

- Immunophenotyping:
 - Blasts positive for myeloid-associated surface antigens (CD11b, CD13, CD14, CD15, CD33, or CD36) in 90% of cases
 - Lymphoid markers: T and B cells may be present in 30–60% of pediatric patients.
 - CD41, CD42, and CD61 (megakaryocytic)
- Morphology:
 - Large blasts with low nuclear/cytoplasmic ratio
 - Multiple nucleoli and cytoplasmic granules
- Cytochemistry:
 - Blasts are positive for myeloperoxidase and Sudan black and usually negative for periodic acid–Schiff (PAS) and terminal deoxynucleotide transferase (TdT).

DIFFERENTIAL DIAGNOSIS

- Myeloid blast crisis of chronic myeloid leukemia (Philadelphia chromosome positive)
- ALL
- Leukemoid reaction
- Exaggerated leukocytosis

TREATMENT

MEDICATION (DRUGS)

- Patients are treated with 6–9 months of intensive chemotherapy given in cycles.
- The most effective drugs for remission induction in AML are anthracyclines (e.g., doxorubicin, daunomycin, and mitoxantrone) and cytarabine (Ara-C).
- Etoposide (VP-16), gemtuzumab (anti-CD33 monoclonal antibody), dexamethasone, L-asparaginase, and 6-thioguanine are added in some regimens (remission rate is ~70–85%).
- High rate of remission induction with all-*trans*-retinoic acid in acute promyelocytic leukemia
- Intrathecal Ara-C for CNS prophylaxis

ADDITIONAL TREATMENT

General Measures

- Hydration, alkalinization, and allopurinol during induction
- Rasburicase should be considered in patients with marked elevations in uric acid and renal compromise (contraindicated in patients with G6PD deficiency).
- Blood product support:
 - Avoid products from family members, owing to the possibility of allogeneic bone marrow transplant.
- Broad-spectrum antibiotics and antifungal therapy for fever and neutropenia
- Prophylactic trimethoprim-sulfamethoxazole for *Pneumocystis* infection

Additional Therapies

Allogeneic bone marrow transplant may be the best treatment for AML in 1st remission.

IN-PATIENT CONSIDERATIONS

Initial Stabilization

Children with suspected AML should have immediate evaluation with physical exam, history, and laboratory data including CBC, PT/PTT, electrolytes, calcium, phosphorus, uric acid, and creatinine.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Blood counts monthly for 1st year, every 4 months for the 2nd year, and every 6 months thereafter
- Liver and kidney function tests every 3–6 months
- Cardiac function should be checked every 12 months.
- Endocrine function should be tested in pubertal children.

PROGNOSIS

- 85% achieve remission with intensive chemotherapy.
- ~30–60% achieve long-term survival (>5 years after diagnosis).
- Factors associated with poor prognosis:
 - WBC count > 100,000/mm³
 - Monosomy 7
 - Secondary AML or prior myelodysplastic syndrome
 - FLT3 mutation (FLT3-ITD)
 - Poor initial response to therapy (induction failure or MRD positive [$>0.01\%$] at end of induction)
 - MRD (minimal residual disease): Testing that adds sensitivity to identify lesser quantities of residual leukemia not seen on morphologic exam, using flow cytometry or genetic testing

COMPLICATIONS

- Bleeding (usually secondary to thrombocytopenia)
- DIC occurs in some types of AML, including acute promyelocytic leukemia (M3).
- Treat aggressively with fresh frozen plasma and platelet transfusions.
- Infection:
 - 40% of patients are febrile at diagnosis.
 - Empiric antibiotic therapy must be started after blood cultures are obtained.
- Leukostasis:
 - Intravascular clumping of blasts causing hypoxia, infarction, and hemorrhage
 - Usually with WBC >200,000/mm³
 - Brain and lung are commonly affected organs.
 - Leukapheresis or exchange transfusion may be indicated for patients who are symptomatic with extremely high blast counts.

- Tumor lysis syndrome:
 - Refers to the metabolic consequences from the release of cellular contents of dying leukemic cells
 - Hyperuricemia can lead to renal failure.
 - Hyperkalemia, hyperphosphatemia, and secondary hypocalcemia can be life threatening.
 - Patients should be hydrated with fluid containing bicarbonate and given allopurinol.

CODES

ICD9

205.0 Myeloid leukemia

ICD10

- C92.00 Acute myeloblastic leukemia, not having achieved remission
- C92.01 Acute myeloblastic leukemia, in remission
- C92.02 Acute myeloblastic leukemia, in relapse

FAQ

- Q: Is an indwelling line required for therapy?
- A: Always
- Q: Are repeated hospitalizations likely?
- A: Repeated hospitalizations are needed for chemotherapy and infectious complications.
- Q: Can the child go to school?
- A: May be able to go intermittently during therapy

ADENOVIRUS INFECTION

Jason Newland

Jessica Newman

BASICS

DESCRIPTION

Adenoviruses are ubiquitous, nonenveloped, double-stranded DNA viruses. There are at least 51 human serotypes.

GENERAL PREVENTION

See Table 1.

Table 1. Precautions for hospital patients

Symptoms	Type of Precautions
Respiratory disease	Contact and droplet
Gastrointestinal	Contact
Conjunctivitis	Contact

Oral vaccines have been used by the military.

EPIDEMIOLOGY

- Primary infection usually occurs early in life (by age 10 years) and is, most often, characterized by upper respiratory symptoms.
- Military trainees are especially susceptible to infection, probably due to crowded living conditions.
- Respiratory and enteric infections may occur at any time of year. Epidemics of respiratory disease occur in winter and spring.
- Cause 2–5% of all pediatric respiratory tract infections
- Transmission of respiratory disease occurs via contact with infected secretions.
 - Transmission of enteric adenoviruses is via the fecal–oral route.
- Outbreaks of pharyngo-conjunctival fever have been associated with inadequately chlorinated swimming pools and shared towels.
- One of the most common causes of viral myocarditis in children and adults

Incidence

Peaks between 6 months and 5 years of age

RISK FACTORS

Exposure to adenovirus

PATHOPHYSIOLOGY

Adenoviruses may cause a lytic infection or a chronic/latent infection. In addition, they are capable of inducing oncogenic transformation of cells, although the clinical significance of this observation remains unclear.

ETIOLOGY

Infection with adenovirus

COMMONLY ASSOCIATED CONDITIONS

- Respiratory infections:
 - Upper respiratory tract infections: Otitis media, common cold, pharyngitis
 - Lower respiratory tract infection: Pneumonia, pertussis-like syndrome, croup, necrotizing bronchitis, bronchiolitis
- Pharyngoconjunctival fever:
 - Low-grade fever associated with conjunctivitis, pharyngitis, rhinitis, and cervical adenitis
 - 15% of patients may have meningismus.
 - Increased incidence in summer months
 - Common-source outbreaks most often associated with type 3
- Epidemic keratoconjunctivitis:
 - Bilateral conjunctivitis with preauricular adenopathy
 - May persist for up to 4 weeks
 - Corneal opacities may persist for several months.
 - Associated with types 8, 19, and 37
- Myocarditis preceding viral illness:
 - Present with cardiovascular collapse, CHF, respiratory distress, or ventricular tachycardia
 - Prognosis is poor.
 - High mortality; a large number require transplant, and a portion develop dilated cardiomyopathy
- Hemorrhagic cystitis may cause microscopic or gross hematuria:
 - If present, gross hematuria persists on average for 3 days.
 - Often associated with dysuria and urinary frequency
 - More common in males than females
 - Associated with types 11 and 21
 - Can occur in both immunocompetent and immunocompromised hosts
- Infantile diarrhea:
 - Watery diarrhea associated with fever
 - Symptoms may persist for 1–2 weeks
 - Associated with types 40, 41, and less often 31
- CNS-infection epidemics (associated with outbreaks of respiratory disease) and sporadic cases of encephalitis and meningitis have been observed; often associated with pneumonia
- Immunocompromised hosts:
 - Can cause disseminated disease including pneumonia, hepatitis, and gastroenteritis
 - Fatality rates much higher, up to 75% in hematopoietic stem cell transplant patients
 - Observed in transplanted patients; up to 10% of liver/renal transplant patients
- Miscellaneous: Associated with intussusception (isolated in up to 40% of cases) and fatal congenital infection

DIAGNOSIS

HISTORY

- Fever:
 - Nonspecific
- Rhinitis:
 - Upper respiratory infection (URI)
- Laryngitis, sore throat:
 - URI
- Nonproductive or croupy cough:
 - Respiratory infection
- Headache, myalgias:
 - CNS infection
- Hematuria (gross or microscopic), dysuria, urinary frequency:
 - Hemorrhagic cystitis
- Watery diarrhea:
 - Enteric adenovirus
- Conjunctivitis, rhinitis, exudative pharyngitis, and meningismus:
 - Typical findings of adenovirus

PHYSICAL EXAM FINDINGS

- Pulmonary tachypnea, wheezing, rales:
 - Pneumonia
- Tachycardia, tachypnea, gallop rhythm, hepatomegaly:
 - Myocarditis
- Abdominal tenderness, distention:
 - Gastroenteritis

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC:
 - Leukocytosis or leukopenia, often with left shift in the differential counts
- ESR:
 - Often elevated
- Viral isolation:
 - From nasopharyngeal secretions, urine, conjunctivae, or stool
- Viral identification:
 - Observe viral antigen in infected cells by immunofluorescence, amplify genome by polymerase chain reaction
 - Stool antigen test for serotypes 40/41
 - Highest yield from nasopharyngeal swab or stool
 - Adenovirus PCR may be helpful in narrowing differential diagnosis; especially with regards to the immunocompromised host
- ECG:
 - Low-voltage QRS
 - Low-amplitude or inverted T waves
 - Small or absent Q wave in V₅ and V₆

Imaging

- Echocardiogram:
 - Poor ejection fraction
- Chest X-ray
 - Bilateral patchy interstitial infiltrates (lower lobes) or enlarged heart
 - Cardiomegaly

DIFFERENTIAL DIAGNOSIS

- Respiratory infection:
 - Influenza
 - Parainfluenza
 - Human metapneumovirus
 - Pertussis
 - Mycoplasma pneumoniae
 - Bacterial pneumonia
 - Boca virus
- Pharyngoconjunctival fever:
 - Group A streptococcus
 - Epstein–Barr virus
 - Parainfluenza
 - Enterovirus
 - Measles
 - Kawasaki disease
- Epidemic keratoconjunctivitis:
 - Herpes simplex
 - Chlamydia
 - Enterovirus
- Myocarditis:
 - Enteroviruses
 - Herpes simplex
 - Epstein–Barr virus
 - Influenza
 - Bacterial myocarditis
- Hemorrhagic cystitis:
 - Glomerulonephritis
 - Vasculitis
 - Renal tuberculosis
- Infantile diarrhea:
 - Rotavirus
 - Norwalk agent
 - Astrovirus
 - Salmonella
 - Shigella
 - Campylobacter
- CNS infection:
 - Enterovirus
 - Herpes simplex virus
 - Mycoplasma
 - Bacterial meningitis

**TREATMENT****GENERAL MEASURES**

- Supportive care
- Monitor for secondary bacterial infections
- Avoid steroid-containing ophthalmic ointments

MEDICATION (DRUGS)**First Line**

Cidofovir has been shown to have benefit in immunocompromised patients with disseminated disease. However, a risk of developing a dose-limiting nephrotoxicity exists. Infusion of AdV-specific cytotoxic T cells or IVIG may have some benefit in immunocompromised patients, particularly hematopoietic stem cell transplant patients.

**ONGOING CARE****PROGNOSIS**

Most syndromes are self-limited.

COMPLICATIONS

- Bronchiolitis obliterans (rare)
- Corneal opacities with visual disturbance (usually resolves spontaneously)
- Congestive heart failure
- Dilated cardiomyopathy

**CODES****ICD9**

- 008.62 Enteritis due to adenovirus
- 079.0 Adenovirus infection in conditions classified elsewhere and of unspecified site
- 478.9 Other and unspecified diseases of upper respiratory tract

ICD10

- A08.2 Adenoviral enteritis
- B34.0 Adenovirus infection, unspecified
- J39.8 Other specified diseases of upper respiratory tract

FAQ

- Q: Is there anything one can do to prevent these infections.
- A: Washing hands and avoiding contact with ill persons will help slow the spread of these infections.

ALCOHOL (ETHANOL) INTOXICATION

Ann B. Bruner

BASICS

DESCRIPTION

- Acute ingestion (accidental or intended) of alcohol, resulting in loss of inhibition, often associated with unruly/violent behavior, impaired judgment and/or coordination, diminished alertness/responsiveness, and sedation or coma
- Accidental ingestion is more common in toddlers and younger children.
- Frequency of intentional alcohol use increases with age.
- Alcohol–drug interactions are common because acute intoxication reduces hepatic clearance for other drugs, thereby increasing their serum concentrations.

EPIDEMIOLOGY

Alcohol is 2nd only to caffeine in prevalence and incidence of use among substances of use/abuse.

Prevalence

- > 75% of high school students have had more than 1 drink in their lifetime; 37% had their 1st drink before 8th grade.
- Rates of past 30-day alcohol use in 2009 were 3.5% (12–13 yo), 13.0% (14–15 yo), 26.3% (16–17 yo), 49.7% (18–20 yo), and 70.2% (21–25 yo).
- Nearly 50% of high school students report current alcohol use, and 30% report heavy drinking in the past 30 days (> 5 drinks).
- Underage (12–20 yo) drinkers are 3 times more likely than adults to use illicit drugs with alcohol.
- Almost 1/3 of high school students have ridden in a car with a driver who has been drinking alcohol.
- Rates of driving under the influence are age-related: in 2009, 6.3% of 16–17 yo, 16.6% of 18–20 yo, and 24.8% of 21–25 yo reported driving under the influence in the past year.
- Rates of binge alcohol use (5 or more drinks in 1 day in past 30 days) in 2009 were 1.6% (12–13 yo), 7.0% (14–15 yo), 17.0% (16–17 yo), 34.7% (18–20 yo), and 46.5% (21–25 yo).
- Among full-time enrolled college students (18–22 yo), 63.9% were current drinkers, 43.5% were binge drinkers, and 16.0% were heavy drinkers (5 or more drinks in 1 day on 5 or more days in past 30 days); full-time college students have higher rates of alcohol use than part-time students or young adults not enrolled in college.

RISK FACTORS

Patients with psychiatric conditions are at an increased risk for abuse of alcohol and other drugs.

GENERAL PREVENTION

- Promote family discussions about alcohol use and abuse.
- Provide safety recommendations to prevent accidental ingestions.

PATHOPHYSIOLOGY

- Effects of alcohol ingestion are related to dose, the time in which alcohol was consumed and then absorbed, and the patient's history of alcohol exposure.
- Alcohol absorption, decreased by the presence of food in the stomach and increased if liquid is carbonated, occurs rapidly and largely in the small intestine.
- Minimal quantities of alcohol are excreted in urine, sweat, and breath.
- > 90% of alcohol oxidized in liver follows zero-order kinetics, primarily by alcohol dehydrogenase (ADH) and then acetaldehyde dehydrogenase (ALDH); rate of metabolism is fixed (not related to dose or time) and is proportional to body weight. Ethnic/racial and gender variabilities exist on quantity and efficacy of ADH.
- Ethanol is metabolized by ADH to acetaldehyde, then to acetate, and finally to ketones, fatty acids, or acetone; ketosis and, infrequently, metabolic acidosis can occur.
- Respiratory acidosis can occur secondary to carbon dioxide retention from respiratory depression due to ethanol intoxication.
- Hypoglycemia occurs during acute ethanol intoxication owing to impaired gluconeogenesis resulting from changes in the NADH/NAD⁺ ratio associated with ethanol metabolism.
- Alcohol affects the CNS primarily through the γ -aminobutyric acid (GABA) and glutamate neurotransmitter systems.

ETIOLOGY

Alcoholic beverages (water and ethanol) are produced from fermentation/distillation of sugar from grapes (wine), grains/corn (beer/whiskey), potatoes (vodka), or sugar cane (rum). After distillation, alcohol is mixed into solution to make specific beverages; products are marketed according to alcohol content or "proof," which is twice the percent. Alcohol content ranges from 3–6% (6–12 proof) in beer to 40–75% (80–150 proof) in vodka/rum/whiskey. Alcohol is often consumed concurrently with other substances (licit and illicit), presenting a mixed clinical picture of intoxication.

COMMONLY ASSOCIATED CONDITIONS

- Alcohol is involved in 30% of all drug overdoses.
- A significant percentage of adolescent trauma patients, especially victims of gunshot wounds, have positive toxicology screens for alcohol and other drugs.

DIAGNOSIS

HISTORY

- Medical: Baseline health will affect patient's response to alcohol; diabetics, for example, may have worse hypoglycemia.
- Type and dose of other drugs ingested:
 - Clinical effects of and treatment for other ingestions can vary depending on substance.
 - Polysubstance ingestion is very common.
- Psychiatric history: Evaluate for possible suicidal ideation.
- Gathering details regarding the alcohol consumed (type, amount, and over what time period) may help predict clinical course. For example, blood alcohol concentration (BAC) may continue rising if ingestion occurred recently.
- Intoxication presents clinically with signs ranging from lack of coordination, slurred speech, and confusion (BAC of 20–200 mg/dL) to ataxia and nausea/vomiting (BAC 200–300 mg/dL) to amnesia, seizures, or coma (BAC > 300 mg/dL).

PHYSICAL EXAM

- Bruises, lacerations, and fractures may suggest trauma and raise concern about CNS injury.
- Neurologic exam, including mental status, will assess degree of intoxication and consciousness, including patient's ability to protect his or her airway, and risk for aspiration.
- Tachycardia, hypotension may indicate dehydration.
- Fever may suggest infection.
- Average time for normalization of mental status in intoxicated adults is 3–3.5 hours; patients without clinical improvement in 3 hours should be evaluated for other causes of altered mental status.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Blood alcohol concentration:
 - Generally correlates with clinical picture.
 - In children, signs of intoxication may be present at levels of 50 mg/dL.
 - Serum levels of 600–800 mg/dL can be fatal.
- Blood and/or urine toxicology screen:
 - Most urine toxicology screens do not test for alcohol.
 - Concurrent ingestions are common.
- Acetaminophen level:
 - Usually not part of the general serum toxicology screen
 - Consider if polysubstance ingestion suspected and/or if patient has suicidal ideation
- Serum electrolytes:
 - Alcohol is a diuretic. The associated nausea and vomiting seen with intoxication may result in severe dehydration.
 - Ketosis and, infrequently, metabolic acidosis can occur.
- Serum glucose level: Ethanol inhibits gluconeogenesis and can be associated with hypoglycemia.
- Blood gas can show both respiratory and metabolic acidosis.

DIFFERENTIAL DIAGNOSIS

- Environmental:
 - Other ingestions (overdose of sedatives or illicit drugs, such as benzodiazepines, marijuana, narcotics, lysergic acid diethylamide [LSD], and phencyclidine [PCP])
 - Toxic exposures (ethylene glycol, methanol, carbon monoxide)
 - Head trauma
- Infection
 - Meningitis
 - Encephalitis
 - Sepsis
- Tumor: Brain tumor
- Metabolic:
 - Hypoglycemia
 - Ketoacidosis
 - Hyperammonemia
 - Electrolyte imbalances (hyponatremia, hypernatremia)
- Miscellaneous:
 - Increased intracranial pressure from hydrocephalus, mass, other
 - Stroke

**TREATMENT****MEDICATION (DRUGS)**

IV dextrose as needed for hypoglycemia

ADDITIONAL TREATMENT**General Measures**

- Assess airway, breathing, and circulation (ABC).
- Protect airway: The patient may require intubation and mechanical ventilation.
- Mainstay is supportive therapy, as no specific ethanol antidote exists.
- Appropriate trauma management as needed
- Because alcohol is absorbed rapidly, gastric lavage is indicated only if the patient is seen immediately after ingestion (within minutes).

ISSUES FOR REFERRAL

- Refer to substance abuse specialist (addiction medicine, psychiatrist, or certified addictions counselor) for detailed evaluation and treatment.
- Refer for psychiatric evaluation if depression, anxiety, suicidal ideation, or any other mental health condition is suspected.
- Assess for other risk-taking behaviors, including other substance use, sexual activity, use of motor vehicles while intoxicated, weapon carrying, and delinquency, and their sequelae, including pregnancy, sexually transmitted infections, and violence.

IN-PATIENT CONSIDERATIONS**Initial Stabilization**

Keep patient awake; watch for vomiting as patients are at risk for choking owing to depressed gag reflex.

Admission Criteria

- Unstable vital signs (hypotension)
- Persistent CNS depression/impaired mental status
- Potential severity of comorbid psychiatric conditions (depression/suicidality)
- Inability to contact a parent/guardian

IV Fluids

IV fluids for dehydration and hypotension

Nursing

Observe and monitor vital signs and neurologic status.

Discharge Criteria

- Stable vital signs
- Patient awake, alert, responsive, and oriented
- Decreasing BAC
- Parent/guardian fully informed about patient's alcohol use

**ONGOING CARE****DIET**

NPO secondary to depressed gag reflex

PROGNOSIS

BAC serum levels of 600–800 mg/dL can be fatal.

COMPLICATIONS

- Diuresis and dehydration
- Vasodilation and hypotension
- Vomiting, aspiration, potential respiratory arrest
- Hypoglycemia
- Metabolic acidosis
- Impaired mental status
- Engagement in risk-taking behaviors (e.g., other drug use, unprotected intercourse) while intoxicated
- CNS depression
- Gastritis
- GI bleeding
- Acute pancreatitis
- Motor vehicle collisions associated with driving while intoxicated
- Alcoholism
- Alcohol withdrawal following a period of intoxication in chronic users (symptoms include tachycardia, elevated blood pressure, irritability, nausea, vomiting, and tremor)

**CODES****ICD9**

980.0 Toxic effect of ethyl alcohol

ICD10

- F10.920 Alcohol use, unspecified with intoxication, uncomplicated
- F10.929 Alcohol use, unspecified with intoxication, unspecified
- T51.OX1A Toxic effect of ethanol, accidental (unintentional), initial encounter

FAQ

- Q: How quickly does a person metabolize alcohol?
- A: The liver metabolizes ~10 g of ethanol per hour, which corresponds to a decline in BAC of 18–20 mg/dL/hr.
- Q: What is the legal level of BAC that defines driving under the influence of alcohol?
- A: This varies by state, but generally is between 80 and 100 mg/dL.
- Q: Why do some individuals, particularly of Asian descent, turn red or develop signs of pruritus after ingesting alcohol?
- A: Flushing, pruritus, and nausea are due to high levels of acetaldehyde. Variations in the metabolic activity of dehydrogenase enzymes are associated with factors such as gender, history of alcohol use, and genetics. Decreased ALDH activity, which is more common in Native Americans and Asians, can result in increased levels of acetaldehyde (an estimated 50% of Asians).

ALLERGIC CHILD

Matthew Fogg

BASICS

DEFINITION

- The allergic child tends toward IgE-mediated reactions in response to pollens, molds, environmental allergens, drugs, insect stings, and foods.
- Reactions may manifest as:
 - Eczema
 - Allergic rhinitis
 - Asthma
 - Angioedema
 - Hives
 - Anaphylaxis
- Children may have dark circles under their eyes (allergic shiners) or a nasal crease from the “allergic salute” (upward rubbing of the nose to relieve itch).
- Children inherit the tendency to be allergic, but do not inherit specific allergies.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- **Eyes**
 - Physical and chemical irritants
 - Viral or bacterial infection
- **Nose**
 - Recurrent upper respiratory tract infections
 - Rhinitis medicamentosa: Reaction to nasal sprays
 - Drugs that cause nasal congestion:
 - Oral contraceptives
 - Reserpine
 - Guanethidine
 - Propranolol
 - Thioridazine
 - Tricyclic antidepressants
 - Aspirin
 - Airway irritants:
 - Smoke
 - Environmental pollution
 - Cold air
 - Kartagener syndrome: Sinusitis, bronchiectasis, immobile cilia
 - Cystic fibrosis
 - Sinusitis
- **Lungs**
 - Airway irritants:
 - Smoke
 - Environmental pollution
 - Cold air
 - Gastroesophageal reflux
 - Foreign body aspiration
 - Anatomic defect in airway
 - Cystic fibrosis
 - Kartagener syndrome
 - Immune deficiency
- **Skin**
 - Viral exanthems
 - Autoimmune disorders
 - Physical and chemical irritants

HISTORY

Careful history of seasonal or year-round symptoms and environmental exposures is essential.

Questions best asked systematically in a review of systems format:

- **Ears**
 - Otitis
 - Myringotomy tubes
 - Hearing loss
- **Nasal**
 - Frequent upper respiratory infections
 - Sinusitis
 - Polyps
 - Epistaxis
 - Snoring
 - Sneezing
 - Rhinitis
 - Deviated septum
 - Obstruction
 - Itch
 - Mouth breathing
 - Nasal discharge
- **Throat**
 - Sore throat
 - Throat clearing
 - Postnasal drip
 - Palate itch
 - Tonsillitis
 - Tonsillectomy
 - Croup
- **Chest**
 - Day cough
 - Night cough
 - Sputum production
 - Pain
 - Wheeze
 - Shortness of breath
 - Cyanosis
- **Eyes**
 - Itching
 - Tearing
 - Discharge
 - Swelling
 - Redness
 - Rubbing
- **Skin**
 - Eczema
 - Hives
 - Angioedema
 - Contact dermatitis
 - Seborrheic dermatitis
 - Skin infections
 - Pruritus

Does the child have food or drug allergies?

- **Question:** What type of reaction does the child have?
- **Significance:** Allergy (IgE-mediated reactions resulting in wheezing, allergic rhinitis, hives, angioedema, eczema, or anaphylaxis) or intolerance (nonspecific rash, diarrhea, gas, headache, or hyperactivity)
- **Question:** Ask about food allergy and anaphylaxis?
- **Significance:** Food allergy or history of anaphylaxis is an indication for an EpiPen and lifelong avoidance.
- **Question:** Has the child ever been stung by a bee, and, if so, what was the reaction?
- **Significance:** Systemic reactions are an indication for referral to an allergist for venom desensitization. Venom desensitization can be potentially lifesaving.
- **Question:** Does anyone in the family have hay fever (allergic rhinitis), asthma, or eczema?
- **Significance:** Familial history of atopy increases the likelihood of atopy in other family members.

Regarding the environment:

- **Question:** Does the child's home have a basement, damp areas, or a humidifier?
- **Significance:** Sources of mold spores; humidity also increases dust mite population.
- **Question:** Is there forced air heat?
- **Significance:** Tends to blow allergen-laden dust around the home
- **Question:** Is home cooled by opening windows?
- **Significance:** Lets pollens into the house
- **Question:** Are there any smokers in the home?
- **Significance:** Airway irritants can exacerbate respiratory difficulties.
- **Question:** Are there any pets in the home, at school, or in daycare?
- **Significance:** Animal dander is a common aeroallergen.
- **Question:** Are there many stuffed animals or books in the bedroom?
- Does the bedroom have carpeting?
- Is bedding washed frequently?
- What type of pillow is used?
- Is the mattress encased in plastic?
- **Significance:** Dust mites
- **Question:** Where does the patient spend most of his or her time? Does the patient attend daycare?
- **Significance:** Upper respiratory tract infections can mimic allergies and exacerbate reactive airway disease.

PHYSICAL EXAM

A complete physical exam is essential to rule out systemic disease that can mimic allergies.

- **Finding:** Ocular allergic signs?
- **Significance:**
 - Allergic shiners due to passive congestion in the nose, which impedes the venous return to the vessels under the eyes
 - Cobblestoning of the conjunctiva
 - Dennie-Morgan line, infraorbital folds associated with suborbital edema secondary to atopy
 - Clear stringy discharge
- **Finding:** Nasal allergic signs?
- **Significance:**
 - Pale edematous nasal mucosa
 - Nasal crease across the bridge of nose secondary to repeated upward rubbing of the nose
 - Clear nasal discharge with or without occlusion
- **Finding:** Ear allergic signs?
- **Significance:** Fluid in the middle ear or retracted tympanic membranes may be associated with eustachian tube dysfunction seen with allergic inflammation.
- **Finding:** Throat allergic signs?
- **Significance:** Cobblestoning of posterior pharynx secondary to submucosal lymphoid hyperplasia
- **Finding:** Lung allergic signs?
- **Significance:** Wheezes, rhonchi, decreased air entry, and chronic obstruction can be secondary to allergic responses.
- **Finding:** Skin allergic signs?
- **Significance:** Eczema, hives, angioedema, and dermatographism

DIAGNOSTIC TESTS & INTERPRETATION

- **Test:** Immediate hypersensitivity
- **Significance:**
 - Skin prick tests to suspected allergens based on history (study of choice)
 - Intradermal skin tests for patients who have a negative prick test and a suspicious history pose a greater risk of systemic reactions (environmental allergens only, not for foods)
 - Radioallergosorbent (RAST) tests measure free serum IgE to a specific antigen to which a particular patient may be sensitized—primarily for patients at risk for a severe systemic reaction from skin testing or in whom skin testing is not feasible.
 - Skin tests are preferable to RAST tests in most cases.
 - Do not screen for food allergy with RAST tests without a significant history of reaction. Many false positives will show up leading to inappropriate dietary restriction and parental anxiety.
 - Eosinophils in the blood or respiratory secretions may be indicative of an allergic diathesis
- **Test:** Baseline pulmonary function studies should be obtained on asthmatic children or in children with an allergic history.
- **Significance:** To evaluate for obstructive disease

**TREATMENT****General Measures**

- Specific environmental control (as determined by skin testing)
- Pets should be kept out of the bedroom if a child has allergic stigmata.
- If a child has severe allergies or asthma related to pet exposure, the animal should be removed from the home.
- To keep the dust mite population under control, the bedding should be washed in hot water at least once every 2 weeks, the pillow should be fiber filled, and the mattress should be encased in plastic.

ISSUES FOR REFERRAL

- A patient failing medical management of upper respiratory or ocular allergies with routine antihistamine/decongestant medications may be referred to an allergist who can help identify triggers contributing to the problem.
- Poorly controlled asthma not responding to intermittent inhaled β -agonists or an asthmatic child who is symptomatic between exacerbations, or one who has an atypical pattern of exacerbations.
- Asthma patients with frequent hospitalizations or steroid-dependent asthma patients
- Patients who are absent from school frequently because of allergic or asthmatic symptoms
- Patients with limited activity
- Strong seasonal history of respiratory complaints
- Difficult-to-manage atopic dermatitis
- Recurrent croup
- Food allergy
- History of anaphylaxis
- Egg-allergic patients who require influenza vaccine
- Drug allergy
- Latex allergy

**ONGOING CARE****PROGNOSIS**

- In general, environmental allergies that cause rhinitis and asthma persist into adulthood.
- Most children outgrow food allergies to milk, egg, soy, wheat, and other foods.
- Children may rarely outgrow peanut, tree nut, or shellfish allergy.
- Allergic children have the biologic potential to become sensitized to many environmental allergens; limit exposure to prevent sensitization.

**CODES****ICD9**

- 477.0 Allergic rhinitis due to pollen
- 692.9 Contact dermatitis and other eczema, unspecified cause
- 995.3 Allergy unspecified

ICD10

- J30.1 Allergic rhinitis due to pollen
- L30.9 Dermatitis, unspecified
- T78.40XA Allergy, unspecified, initial encounter

FAQ

- Q: Do children outgrow allergies?
- A: In general, environmental allergies that cause rhinitis and asthma persist into adulthood. However, most children outgrow food allergies to milk, egg, soy, wheat, and other foods. Children may rarely outgrow peanut, tree nut, or shellfish allergy in ~25% cases.
- Q: Can allergic children have the biologic potential to become sensitized to many environmental allergens?
- A: The goal should be to limit exposure to these antigens to prevent sensitization.
- Q: If a parent is allergic to a specific allergen, can the child inherit this allergy?
- A: Children inherit the tendency to be allergic, but they do not inherit specific allergies.
- Q: What treatments are available?
- A: Specific environmental control, as determined by skin testing, antihistamines, topical steroids, and immunotherapy

ALOPECIA (HAIR LOSS)

Hope Rhodes

Terry Kind

BASICS

DEFINITION

- Absence of hair where it normally grows
- Categorized as acquired or congenital
 - Most cases are acquired: Tinea capitis is most common, followed by traumatic alopecia and alopecia areata.
- Also categorized as diffuse or localized
 - Most cases of alopecia are localized and, of these, tinea capitis is the most common.
- Many normal healthy newborns lose their hair in the first few months of life.
 - Hair loss may be exacerbated by friction from bedding/sleep surface, especially in atopic infants.
- Normally, 50–100 hairs are shed and simultaneously replaced every day, on average.
- 90% of alopecia cases are due to the following disorders:
 - Tinea capitis
 - Alopecia areata
 - Traction alopecia
 - Telogen effluvium
 - Alopecia is preceded by a psychologically or physically stressful event 6–16 weeks prior to the onset of hair loss.
 - Growing hairs convert rapidly to resting hairs.

RISK FACTORS

Genetics

- Alopecia areata:
 - Polygenic with variety of triggering factors
 - Family history in 10–42% of cases
 - Males and females equally affected
 - Onset usually before age 30 years
- Monilethrix (also called beaded hair):
 - A rare autosomal dominant disorder

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Consider the most likely diagnoses first.

- **Infectious**
 - Tinea capitis
 - Varicella
 - Syphilis
- **Congenital**
 - Aplasia cutis congenita
 - Incontinentia pigmenti
 - Oculomandibulofacial syndrome (sparse hair, hypoplastic teeth, cataracts, short stature)
 - Goltz syndrome (alopecia, focal dermal hypoplasia, strabismus, nail dystrophy)
 - Triangular alopecia of the frontal scalp
 - Focal dermal hypoplasia
 - Hair-shaft defects (trichodystrophies)
 - Ectodermal dysplasias
 - Nevi
 - Progeria

- **Nutritional**
 - Zinc deficiency
 - Marasmus
 - Kwashiorkor
 - Anorexia nervosa
 - Hypervitaminosis A
 - Celiac disease
- **Endocrinologic**
 - Androgenetic alopecia
 - Hypothyroidism
 - Hyperthyroidism
 - Hypoparathyroidism
 - Hypopituitarism
 - Diabetes mellitus
- **Rheumatologic**
 - Systemic lupus erythematosus
 - Scleroderma
- **Trauma**
 - Traction alopecia
 - Trichotillomania
 - Scalp electrode scar from in utero monitoring
- **Toxin**
 - Radiation
 - Medications (e.g., anticoagulants, antimetabolites)
 - Heavy metals (e.g., arsenic, lead)
- **Toxic exposures**
 - Antimetabolites
 - Anticoagulants
 - Antithyroid medications
 - Lead
 - Arsenic
- **Stress**
 - Trichotillomania
- **Miscellaneous**
 - Alopecia areata (autoimmune)
 - Telogen effluvium
 - Darier disease (keratotic crusted papules, keratosis follicularis)
 - Lichen planus
 - Burn

Commonly Associated Conditions

- May be associated with a genetic, endocrine, or toxin-mediated condition
 - Look for nail, skin, teeth, or gland involvement
- Trichotillomania is frequently associated with a finger-sucking habit.

APPROACH TO THE PATIENT

- Treatment of alopecia is guided by underlying etiology.
- Other than reassurance and waiting, there is no proven effective long-term therapy for alopecia areata. Topical steroids may show short-term benefit. There are no randomized clinical trials on the use of topical immunotherapy or intralesional steroids.
- Caution regarding side effects of all potential treatments

- Topical antifungals alone are not adequate to treat tinea capitis.
- A topical shampoo, such as selenium sulfide or ketoconazole shampoo, is recommended for tinea capitis to decrease fungal shedding and risk of spread to others.

HISTORY

- **Question:** Attempt to classify the alopecia.
- **Significance:** To aid in diagnosis and subsequent treatment plan
- **Question:** Is the loss acquired or congenital? Is the alopecia treatable or likely to be self-limited?
- **Significance:** Consider most likely diagnoses, including tinea capitis, traumatic alopecia, and alopecia areata
- **Question:** Associated abnormalities?
- **Significance:** May be part of a syndrome
- **Question:** Is there an endocrine abnormality or a toxin/medication effect?
- **Significance:** Some of these would require prompt attention.
- **Question:** Assess hair loss.
- **Significance:**
 - Increased amount of hair in the brush or in the shower/tub drain?
 - Does hair appear or feel thinner?
 - Patches of hair loss or broken hairs noted?
- **Question:** Considering trichotillomania?
- **Significance:** Note that patients often deny hair-pulling. Direct confrontation is rarely helpful.

PHYSICAL EXAM

Assess localized vs. diffuse hair loss

- **Finding:** Associated systemic signs or any nonscalp findings?
- **Significance:** May signify a genetic syndrome or endocrine abnormality
- **Finding:** Scalp?
- **Significance:**
 - Alopecia areata: Except for well-demarcated hair loss, scalp appears normal with smooth surface.
 - Tinea capitis: Scalp is often scaly and may be erythematous; areas of hair loss with broken hair stubs. Referred to as “black-dot” alopecia.
- **Finding:** Bizarre configuration and irregular outline of hair loss. Hairs of varying lengths?
- **Significance:** Distinguishes traction/traumatic alopecia from alopecia areata
- **Finding:** Short broken hairs but not black dots?
- **Significance:** Short hairs are usually associated with trichotillomania, whereas black dot alopecia is seen with tinea capitis.
- **Finding:** Frontal, vertex, or bi-temporal decreased hair density in adolescents?
- **Significance:** May be adolescent-onset, androgenetic alopecia

- **Finding:** Hair shaft varies in thickness, with small node-like deformities (like beads), increased breakage, and partial alopecia?
- **Significance:**
 - Monilethrix
 - Other hair-shaft abnormalities with increased fragility include pseudomonilethrix, trichorrhexis, pili torti, pili bifurcati, Menkes kinky hair syndrome, and trichothiodystrophy.
- **Finding:** Nail defects such as dystrophic changes and fine stippling?
- **Significance:**
 - Nail defects are seen in 10–20% of cases of alopecia areata.
 - Nail defects accompanying localized alopecia along with syndactyly, strabismus, and dermal hypoplasia may be found in Goltz syndrome.
 - In ectodermal dysplasias, nails, hair, teeth, or glands may be affected.
- **Finding:** Pubic hair and eyebrow hair loss?
- **Significance:**
 - Found in a form of alopecia areata called “alopecia universalis,” where nearly all body hair is lost (alopecia totalis involves the loss of all scalp hair).
 - Body hair loss such as pubic hair or eyebrow hair may also occur in trichotillomania.

DIAGNOSTIC TESTS & INTERPRETATION

- **Test:** Fungal culture
- **Significance:**
 - Recommended when assessing for tinea capitis as a cause of alopecia
 - Definitive results may take up to several weeks; may treat while awaiting results.
 - Using a cotton-tipped applicator, culturette, toothbrush, or direct plating on Sabouraud dextrose agar, culture will be positive for *Trichophyton tonsurans* in >90% of cases in North America.
 - Less common are *Microsporium canis*, *Microsporium audouinii*, *Trichophyton mentagrophytes*, and *Trichophyton schoenleinii*.
- **Test:** Potassium hydroxide (KOH) exam
- **Significance:**
 - The KOH exam is another way to assess for tinea capitis.
 - Hyphae and spores within hair shaft indicate tinea capitis.
 - With *Microsporium*, spores surround the hair shaft.
 - Endocrine testing
 - With alopecia areata or diffuse alopecia, consider endocrine tests or referral to an endocrinologist or dermatologist for further evaluation.
 - Routine screening for autoimmune disorders is generally not indicated.
- **Test:** Hair-pluck test
- **Significance:**
 - Used to determine the ratio of telogen (resting) to anagen (growing) hairs
 - ~50 hairs are plucked (with 1 firm tug using a hemostat clamped around the hair ~1 cm from the scalp) and examined under the low-power lens of a microscope to determine the percentage of hairs that are telogen and anagen hairs.
 - >25% telogen hairs are indicative of telogen effluvium.

- **Test:** Dermatophyte testing medium (DTM)
- **Significance:**
 - Assessing for tinea capitis
 - Definitive results may take from days to weeks.
 - If dermatophyte colonies grow on the medium, the phenol red indicator in the agar will turn from yellow to red.
- **Test:** Wood's light (lamp) examination
- **Significance:**
 - *M. canis*, *M. audouinii*, or *T. schoenleinii* fluoresces green
 - *T. tonsurans* does not fluoresce
- **Test:** Scalp biopsy
- **Significance:**
 - Can help to distinguish alopecia areata and trichotillomania
 - In alopecia areata, hair follicles become small but continue to produce fine hairs; there is mitotic activity in the matrix, and often inflammation is present.
 - In trichotillomania, follicles are not small. They are usually in a transitional (catagen) phase and no longer produce normal hair shafts. Keratinous debris, fibrosis, and clumps of dark melanin pigment are present. Significant inflammation is absent.
 - In telogen effluvium, follicles remain intact without inflammation.

TREATMENT

MEDICATION (DRUGS)

First Line

- For tinea capitis: Microsize griseofulvin 10–25 mg/kg/d (maximum 1 g) or ultramicrosize griseofulvin 5–15 mg/kg/d (maximum 750 mg) orally once per day for 4–6 weeks. Approved for children >2 years of age.
- For alopecia areata requiring treatment: Topical corticosteroids may be used for isolated patches for short-term benefit.

Second Line

- For tinea capitis: Terbinafine, itraconazole, or fluconazole may be effective, although only terbinafine is FDA approved for this condition.
- For alopecia areata: There is limited evidence for long-term effectiveness of any treatment. For trial of other therapies (intralesional steroid, topical immunotherapy) seek consultation with a dermatologist.

General Measures

- Treatment of alopecia is guided by the underlying cause.
- If alopecia signifies a toxic exposure or an endocrine abnormality, the underlying condition may require prompt diagnosis and treatment.
- Infectious causes of alopecia (such as with tinea capitis) should be treated promptly.
- Most patients with alopecia areata do not need treatment, as regrowth will occur spontaneously.
- Complementary and alternative medicine (CAM)
 - Hypnotherapy, massage, acupuncture, and onion juice are among the complementary therapies that have been tried for conditions like alopecia areata and trichotillomania. Of note, though many patients try CAM for alopecia, more research is needed.

ONGOING CARE

PROGNOSIS

- Tinea capitis, alopecia areata, and traction alopecia:
 - Hair will regrow, may take months
 - There is a poorer prognosis with alopecia universalis. <10% have full recovery.
- Telogen effluvium:
 - Spontaneous regrowth is expected unless the stressful event continues/recurs.
- Alopecia areata may spontaneously remit and then recur.

CODES

ICD9

- 110.0 Dermatophytosis of scalp and beard
- 704.00 Alopecia, unspecified
- 704.01 Alopecia areata

ICD10

- B35.0 Tinea barbae and tinea capitis
- L63.9 Alopecia areata, unspecified
- L65.9 Nonscarring hair loss, unspecified

FAQ

- Q: When can children with tinea capitis return to school?
- A: Once treatment with a systemic antifungal has begun, the child may return to school. A topical shampoo, such as selenium sulfide or ketoconazole shampoo, is recommended to decrease fungal shedding and the risk of spread to others.
- Q: Will the hair grow back?
- A: For the 3 most common causes of childhood alopecia—accounting for 90% of cases; tinea capitis, alopecia areata, and traction alopecia—hair will regrow, but may take months to do so.

ALPHA-1-ANTITRYPSIN DEFICIENCY

Melissa Kennedy
Joshua R. Friedman

BASICS

DESCRIPTION

- α_1 -Antitrypsin deficiency is an autosomal recessive genetic disorder that causes lung and liver disease.
- Classical PiZZ α_1 -antitrypsin deficiency is caused by homozygosity for the autosomal recessive Z mutant allele of α_1 -antitrypsin.
- α_1 -antitrypsin is a 55-kd glycoprotein that is synthesized by the liver and released into the circulation, where it is the main inhibitor of host tissue damage caused by neutrophil proteases.
 - Lung disease begins after the 3rd decade of life and culminates in emphysema.
 - Liver disease may present as neonatal jaundice or in older children with elevated liver enzymes, portal hypertension, or cirrhosis.

EPIDEMIOLOGY

- One of the most common inherited disorders worldwide, although most patients do not have severe disease
- Most common genetic cause of liver disease in children and emphysema in adults

Incidence

- Incidence of the PiZZ genotype is highest in whites in North America, Australia, and Europe, particularly in Scandinavia, the British Isles, Northern France and the Tyrol region of Italy
- In the U.S., the PiZ allele frequency is ~14.5 per 1000, with lower rates among Asians, blacks, and Latinos and higher rates among whites.
- The incidence of classical α_1 -antitrypsin deficiency (PiZZ) is 1 in 1,500 to 1 in 3,500 live births.
- Only ~10% of PiZZ or PiSZ individuals will develop clinically significant liver disease.

Prevalence

- An estimated 70,000–100,000 individuals are affected in North America.
- As many as 25 million people in the U.S. are carriers of a mutant allele.

RISK FACTORS

Genetics

- α_1 -Antitrypsin is a serine protease inhibitor encoded by the *SERPINA1* gene. Classic, or PiZZ α_1 -antitrypsin deficiency is caused by a homozygous point mutation at position 342 in the α_1 -antitrypsin gene encoding a substitution of lysine for glutamate. The 2nd most common mutation, or the S allele, occurs at position 246 and results in the substitution of valine for glutamate. The normal allele is M.
- The Z mutation is associated with the accumulation of α_1 -antitrypsin polymers within the endoplasmic reticulum of hepatocytes. These are not secreted into the circulation, resulting in low serum α_1 -antitrypsin levels. It is unclear whether polymerization causes retention in the endoplasmic reticulum (ER) or vice versa.

- Patients with PiZZ alleles have the most significant findings, with serum levels of α_1 -antitrypsin at levels less than 15% of normal.
- The heterozygous carrier state of the Z allele is found in 1.5–3% of the population and is not by itself a common cause of liver injury, however, it may be a modifier gene for other liver diseases.
- Other intermediate genotypes, PiMS, PiMZ, and PiSS, have not been definitively associated with hepatic disease, although referral center data reports patients with chronic liver disease having a higher frequency of PiMZ than would be predicted by chance.
- Compound heterozygotes with PiSZ phenotype may develop liver disease identical to PiZZ patients.
- Only about 10% of affected individuals experience clinically significant liver disease, indicating that other genetic or environmental factors are important modifiers of the disease.

PATHOPHYSIOLOGY

- Lung disease in PiZZ individuals results from loss of α_1 -antitrypsin function. Excessive activity of destructive enzymes, such as elastase, cathepsin G, and proteinase 3, results in progressive emphysema. This is greatly accelerated by cigarette smoking as well as atmospheric pollutants.
- In contrast, liver disease in α_1 -antitrypsin deficiency is caused by a gain of function in the Z mutant, which results in intracellular retention of the protein and hepatocellular damage.
 - The mutant Z polypeptide is unable to fold correctly after being translocated into the endoplasmic reticulum. As a result, it is retained in the ER where some molecules aggregate to form large polymers, and others are directed to proteolytic degradation pathways. Very few molecules are secreted.

ETIOLOGY

Mutations in the *SERPINA1* gene result in lung disease through unopposed protease activity and in liver disease by intracellular retention of mutant α_1 -antitrypsin.

DIAGNOSIS

HISTORY

- Highly variable presentation in neonates and young children
- Most patients with liver disease will have protracted jaundice during the 1st 8 weeks of life, which may be associated with abdominal distention, poor feeding, poor weight gain, hepatomegaly, and splenomegaly.
- Jaundice usually clears by 1 year of age.
- Normal liver function, continued liver disease, or progression to cirrhosis may follow.

- Presentation of liver disease may also occur during childhood or beyond. Symptoms may include hepatomegaly, failure to thrive, jaundice, or complications of portal hypertension and cirrhosis.
- Fulminant hepatic failure is very rare but has been reported.

PHYSICAL EXAM

Evidence of jaundice, hepatosplenomegaly, abdominal distention, and other stigmata of chronic liver disease

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Elevated total and conjugated bilirubin, elevated serum transaminases, hypoalbuminemia, or coagulopathy.
- Protein electrophoresis to determine the protease inhibitor (Pi) phenotype is the gold standard for diagnosis of α_1 -antitrypsin deficiency.
- Serum levels of α_1 -antitrypsin can be used as a complementary test to compare phenotype results against or to guide work-up before phenotype results are available.
- Quantitative serum α_1 -antitrypsin levels:
 - PiMM: 20–53 mmol/L
 - PiZZ: \leq 2.5–7 mmol/L
 - Pi null/null phenotype: No measurable levels of α_1 -antitrypsin
 - False-negative results may occur because the protein acts as an acute-phase reactant and may rise into the normal range in an ill PiZZ individual.
 - In retrospective studies, low levels of α_1 -antitrypsin had a positive predictive value of 94%, whereas normal levels had a negative predictive value of 100%.
- Confirmation is made by serum protein electrophoresis to determine the allele type.

Imaging

Ultrasound with Doppler study for evaluation of portal hypertension and/or for pretransplantation evaluation if liver failure develops.

Diagnostic Procedures/Other

Definitive diagnosis is made by serum protein electrophoresis to determine the α_1 -antitrypsin phenotype. The diagnosis should be supported by liver biopsy.

Pathological Findings

- Liver biopsy in infants can show a variety of findings including giant cell transformation, lobular hepatitis, steatosis, inflammation, fibrosis, hepatocellular necrosis, bile duct paucity, or bile duct proliferation
- A diagnostic finding is diastase-resistant, periodic acid-Schiff staining globules in hepatocytes, which represent dilated endoplasmic reticulum membranes engorged with polymerized mutant Z-type α_1 -antitrypsin protein.

DIFFERENTIAL DIAGNOSIS

- The differential diagnosis varies with the age at presentation.
- Neonates and infants generally present with jaundice. Other diagnoses to consider in this age group include biliary atresia, anatomic biliary abnormalities, congenital infections, galactosemia, and tyrosinemia. (See "Neonatal Cholestasis and Jaundice" for complete listing.)
- In older children, viral (hepatitis viruses, EBV, and CMV), toxic (ethanol, acetaminophen), metabolic (Wilson disease), and obstructive causes should be considered.

**TREATMENT**

- α_1 -antitrypsin deficiency does not have a specific treatment.
- Management is based on preventing complications of chronic liver disease.
- Cigarette smoking and hepatotoxins must be avoided.
- Liver transplantation is reserved for severe liver disease. In addition to replacing the diseased liver, the transplant graft will secrete normal α_1 -antitrypsin, thereby halting progression of the lung disease.
- Enzyme replacement therapy is used in adults to prevent progression of lung disease. This has no effect on liver disease.
- Screening imaging or α -fetoprotein levels may be monitored due to the concern for an increased risk of hepatocellular carcinoma.
- Annual influenza vaccination and pneumococcal vaccination every 5 years
- Vaccinations against hepatitis A and B

MEDICATION (DRUGS)

- Ursodeoxycholic acid, a choleric agent, can be used at a dose of 20–30 mg/kg/d to manage the cholestasis and pruritus associated with liver disease.
- Augmentation therapy:
 - Pooled human plasma–derived α_1 -antitrypsin has been used to restore circulating levels of the protease inhibitor to levels above the protective threshold.
 - Results in a decrease in the rate of decline in 1-second forced expiratory volume and decreased mortality rate during the period of study
 - Future therapeutics: Various compounds are being investigated for their ability to promote proper folding of the mutant protein, thereby allowing normal secretion and preventing hepatocellular damage. Hepatocyte transplantation and gene therapy strategies are being investigated.

SURGERY/OTHER PROCEDURES

Surgical treatment at this time consists of orthotopic liver transplantation for patients with end-stage liver disease. Disease does not recur following transplantation. For lung disease, volume reduction surgery or lung transplantation may be used.

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

Annual liver and pulmonary function testing

PROGNOSIS

Only 10% of PiZZ and PiSZ individuals will have clinically significant liver disease during childhood; ~50% of the remaining individuals will have mildly elevated aminotransferases as the only liver abnormality. More significant liver disease may develop during late adulthood.

COMPLICATIONS

- Cirrhosis and early-onset lower-lobe emphysema.
- The course of liver disease is highly variable in affected individuals:
 - Jaundice, acholic stools, and hepatomegaly may present during the first weeks of life.
 - Jaundice usually clears by the 4th month and complete resolution of symptoms, chronic liver disease, or the development of cirrhosis may follow.
- Older children may present with manifestations of chronic liver disease or cirrhosis, with evidence of portal hypertension.
- Major dermatologic manifestation:
 - Panniculitis, an inflammation of the fat just beneath the skin, causing the skin to harden and form lumps, patches, or lesions
 - Likely that the damage is initiated by the destructive action of unrestrained neutrophils elastase

E88.01 Alpha-1-antitrypsin deficiency

FAQ

- Do all patients with PiZZ disease get liver involvement?
- A: No. ~10% will have liver disease, and most of these will present with jaundice during the neonatal period. In most of these, the jaundice will resolve during the 1st year of life. The rate of progression of liver disease to cirrhosis in all PiZZ subjects is variable, but overall is low.
- Q: What is the best initial diagnostic test for α_1 -antitrypsin deficiency?
- A: The total serum α_1 -antitrypsin level is an appropriate screening test. In persons with low levels, the diagnosis must be confirmed via protease inhibitor typing.

ALTITUDE ILLNESS

Patrick B. Solari
Paige L. Wright
George A. Woodward

BASICS

DESCRIPTION

- Acute mountain sickness (AMS): Failure to adapt to the hypoxic demands of altitude. Includes a group of clinical signs and symptoms seen in travelers to altitudes > 2,500 m
- Mild mountain sickness: Headache in morning and on exertion, anorexia, nausea, dizziness, vomiting, shortness of breath on exertion, insomnia, irritability, periodic breathing (Cheyne-Stokes respiration), poor performance
- Moderate mountain sickness: Severe headache, lassitude (weariness, indifference, antisocial), weakness, anorexia, nausea, ataxia, decreased urine output, diminished judgment and coordination. Capable of activities with difficulty.
- Severe mountain sickness: Insidious or acute onset, usually 2–4 days after ascent. Can progress to life-threatening situation within hours. Can include pulmonary and cerebral edema.
- High-altitude cerebral edema (HACE): Develops over 1–3 days after ascent, usually preceded by AMS. Headache, vomiting, lassitude, irritability, drowsiness, ataxia, slurred speech, cranial nerve paralysis, hypo- or hyperreflexia, hemiparesis, hemiplegia, mental status changes (confusion, irrationality, depression, disorientation, amnesia, hallucinations, severe nightmares), decreased urine output, seizures, papilledema, coma, death
- High-altitude pulmonary edema (HAPE): Often develops over several days and may be associated with or exacerbated by concurrent viral illness. Initially with dyspnea on exertion, then at rest, decreased exercise capability, dry cough, fatigue, tachypnea, low-grade fever <38.5°C (99.5°F). Develop pink frothy sputum, cyanosis, wheezing, rales, tachycardia, low-grade fever, and orthopnea
- Other altitude-related issues: High-altitude syncope, amnesia, edema (facial and extremity), retinopathy (hemorrhages), pharyngitis and bronchitis, flatus, immune suppression, thrombosis, coagulation abnormalities (thrombotic events), platelet changes, chronic mountain illness (Monge disease, polycythemia), weight loss

RISK FACTORS

- Travel in high-altitude areas
- Rapid ascent
- Underlying medical conditions, such as sickle cell disease, hypertension, sleep apnea, obstructive lung disease, cerebrovascular disease, or concurrent infections.
- Infants younger than 4–6 weeks have immature circulation and could be more susceptible to altitude illness.

GENERAL PREVENTION

- Avoid rapid ascent:
 - Limit ascents to 300 m (1,000 ft) per day above 3,000 m (> 10,000 ft).
- Gradual acclimatization:
 - Do not fly or drive to heights above 3,000 m.
 - Allow at least 24 hours for each 1,000 m (3,300 ft) gained.
 - Exercise is not a substitute for acclimatization (or protection against AMS).

- Early recognition of symptoms (even if minor):
 - Assume symptoms secondary to AMS unless proven otherwise.
 - Go no higher until symptoms resolve.
 - Descend if worsening.
- Climb high, sleep low.
- Avoid alcohol, codeine, sedative-hypnotics, and respiratory depressants.
- Exercise within individual capacity:
 - Avoid heavy exercise after passive ascent for at least 24 hours.

PATHOPHYSIOLOGY

- Complex combination of anatomic factors, as well as physiologic and biochemical responses to hypoxia.
- AMS is thought to be related to rise in intracranial pressure at altitude that is worsened by exertion. Early fluid retention also linked to development of AMS.
- HACE is linked to hypoxia-induced increase in cerebral blood flow and vasogenic edema. Those with a “tight-fitting” brain within the skull may have less ability to buffer edema and may be more susceptible to HACE.
- HAPE is linked to exaggerated pulmonary hypertension, specifically elevated pulmonary artery pressure (PAP) and impaired alveolar fluid clearance. Medications that lower PAP may prevent HAPE.

COMMONLY ASSOCIATED CONDITIONS

Ophthalmologic:

- Retinal vessel engorgement
- Retinal hemorrhages: Usually resolves in 7 to 10 days without symptoms. 100% of people at 6,500 m (21,450 ft)
- Macular hemorrhages: More severe, associated with visual changes
- Ultraviolet keratitis

DIAGNOSIS

HISTORY

- Previous altitude illness:
 - Suggests symptoms in future with ascent to similar altitude
- Altitude where symptoms occurred, method of arrival at altitude, and rate of ascent.
 - Rapid ascent minimizes time for natural acclimatization and increases risk of developing altitude illness.
- Exertion level:
 - Increased exertion on ascent may increase speed of symptom development.
- Medical history, medications, drug or alcohol use:
 - Pre-existing problems such as asthma, sickle cell disease, hypertension, sleep apnea, obstructive or restrictive lung disease, cerebrovascular disease, or concurrent infections, may predispose one to development of altitude illness.

SIGNS AND SYMPTOMS

- See “Description.”
- Symptoms either insidious or acute onset, usually 2–4 days after ascent:
 - Can become life threatening within hours
- Morning headache, progressive with ascent:
 - Suggests HACE
- Insomnia, difficulty falling asleep, frequent waking:
 - Suggests hypoxia, early AMS

- Periodic breathing (hyperpnea to apnea):
 - Suggests moderate to advanced AMS
- GI: Anorexia, nausea, vomiting, abdominal cramps, flatus:
 - Potentially related to ascent
- Pulmonary: Dry cough, shortness of breath, sore throat, dyspnea on exertion and at rest, decreased exercise capability:
 - Potential progression to HAPE
- Neurologic: Lassitude, weariness, indifference, fatigue, irritability, dizziness, ataxia, or weakness:
 - Progression to HACE
- Decreased urine output edema or fluid retention:
 - Indicative of fluid shifts, fluid losses, inadequate replacement, or dehydration

PHYSICAL EXAM

- Normal in early AMS:
 - Abnormalities usually occur after 12–24 hours at altitude (range, 2–96 hours).
- Lake Louise Score (LLS): (0–15)
 - Elevation Gain + Headache + Score >3 is considered diagnostic of AMS.

Score	0	1	2	3
Headache	None	Mild	Mod	Severe
GI	None	Mild upset	Mod upset	Vomiting
Fatigue	None	Mild tired	Mod tired	Incapacitating
Dizziness	None	Mild dizzy	Mod dizzy	Severe dizziness
Sleeping	None	Less sleep	Mod waking	No sleep

- Children’s LLS:
 - Used in preverbal children.
 - To calculate Children’s LLS, combine the Fussiness score with the Symptom score
 - Children’s LLS Score >7 (Fussiness Score >4, Symptom Score >3) is considered diagnostic of AMS.

Fussiness

score	0	3	6
Amount	None	Intermittent	Constant
Intensity	Not fussy	Moderately Fussy	Extremely Fussy

Symptom

score	0	1	2	3
Eating	Norm	Mild	Mod Eating	Not eating; vomiting
Playing	Norm	Mild less	Play less	No play at all
Sleeping	Norm	Mild less	Difficult sleep	Unable to sleep

DIAGNOSTIC TESTS & INTERPRETATION

- ECG: Rule out myocardial etiology of symptoms or consequence of ascent.
- HAPE: May have evidence of RV strain

Lab

- Toxicology screen
- Electrolytes
- Arterial blood gas:
 - Check oxygenation, ventilation, and acid–base status.
- Carbon monoxide level
- CBC:
 - Assess oxygen-carrying capacity of blood.
 - Look for anemia, polycythemia, and platelet abnormalities.

Imaging

- Chest x-ray:
 - Vasocongestion, patchy or diffuse infiltrates, often worse than physical exam suggests.
- Ventilation and perfusion scan:
 - Structural pulmonary assessment
- Brain CT scan:
 - Assess for structural abnormalities and cerebral edema.

DIFFERENTIAL DIAGNOSIS

- Environmental:
 - Alcohol toxicity, hangover, drug effects, hypothermia, carbon monoxide poisoning
- Medical/metabolic:
 - Dehydration, viral illness
- Psychosocial:
 - Exhaustion, sleep deprivation, personality traits (irritability), insomnia

TREATMENT

MEDICATION (DRUGS)

- Acetazolamide (carbonic anhydrase inhibitor):
 - Prevention of AMS:
 - Pediatric dose: 2.5 mg/kg PO q12h
 - Adult dose: PO 125 mg BID
 - Treatment of early AMS
 - Pediatric Dose: 2.5 mg/kg PO q12h
 - Adult dose PO 250 mg BID
 - Caution for those with sulfa allergy.
 - Use in conjunction with (not in place of) gradual ascent, descent if symptomatic
- Dexamethasone (Decadron) PO/IV/IM:
 - Prevention of AMS, HACE:
 - NOT recommend for prophylaxis in pediatrics.
 - Adult dose: 2 mg PO q6h
 - Treatment of AMS, HACE (drug of choice):
 - Pediatric dose: 0.15 mg/kg/dose q6h
 - Adult dose (AMS): 4 mg q6h, (HACE): 8 mg once, then 4 mg q6h
 - Do not use longer than 10 days (glucocorticoid suppression)
- Nifedipine:
 - Prevention and treatment of HAPE:
 - Pediatric dose: 0.5 mg/kg/dose q8h
 - Adult dosage: 20-mg sustained release q8–12h
 - For prevention, start 24 hours prior to ascent and continued for 5 days at altitude.
 - Adjunct to descent, O₂
- Tadalafil:
 - Phosphodiesterase inhibitors, shown to decrease pulmonary artery pressure (PAP) at high altitude and may reduce incidence of HAPE, not studied in children.
 - Prevention of HAPE:
 - Adult dosage: 10 mg PO BID
 - For prevention, start 24 hours prior to ascent and continued for 5 days at altitude.

- Adjunct to descent
- Salmeterol:
 - Long-acting beta-agonist:
 - High dose: 125 mcg q12h (adults)
 - Limited clinical experience
 - Use as adjunct with nifedipine, not as monotherapy.

ADDITIONAL TREATMENT

General Measures

- Mild AMS:
 - Treatment may not be needed.
 - Symptomatic headache relief with ibuprofen, acetaminophen, aspirin, prochlorperazine
 - Temporal artery massage
 - Halt ascent until symptoms improve.
- Moderate to severe AMS:
 - Descent
 - Supplemental oxygen >90% SpO₂ (relieves hypoxia, reduces pulmonary hypertension)
 - Acetazolamide
 - Consider dexamethasone (if allergic to sulfa or cannot take acetazolamide)
 - Vasodilators (nifedipine, morphine)
- HACE:
 - Descend immediately.
 - Supplemental Oxygen to keep SpO₂ >90%
 - Dexamethasone
 - Portable hyperbaric chamber
 - Consider intubation and hyperventilation.
- HAPE:
 - Descend immediately.
 - Supplemental oxygen to keep SpO₂ >90%
 - Acetazolamide
 - Nifedipine
 - B-agonist (Salmeterol, Albuterol)
 - Sildenafil, Tadalafil
 - Consider antibiotics
 - Portable hyperbaric chamber
 - CPAP
 - Knee-chest position with abdominal squeeze
 - Pursed-lip breathing, mask, intubation
 - Symptoms may recur when positive pressure is removed.

IN-PATIENT CONSIDERATIONS

Initial Stabilization

- Suspect AMS
- Stop ascent
- Partial or full descent:
 - Gamow portable hyperbaric chamber may be used until descent arranged.
- Oxygen if available
- Fluids
- Consider acetazolamide
- Avoid alcohol, codeine, sedative-hypnotics:
 - Avoid respiratory depressants

ONGOING CARE

DIET

- Increase fluid and calorie consumption with altitude and exertion.
- Increased carbohydrate diet.
- Avoid alcohol, tobacco, sedatives, and recreational drugs.

PROGNOSIS

- Expect improvement with mild mountain sickness in 1–2 days.
- Moderate mountain sickness clears with descent and acclimation.
- Severe mountain sickness usually clears with descent and therapy.

- Excellent if recognized quickly, ascent stopped, and/or descent and therapy initiated
- Can be poor if symptoms go unrecognized or noted without appropriate descent and therapy

FAQ

- Q: Can one develop AMS at moderate altitudes, such as during a ski vacation?
- A: Yes, although the altitudes encountered rarely lead to the development of severe symptoms in this population.
- Q: Will physical conditioning prior to ascent decrease the risk of developing altitude illness?
- A: No. In fact, better conditioning may inadvertently increase the risk of developing altitude illness, as one may achieve higher altitudes more quickly.
- Q: Are children more likely to develop HAPE than adults?
- A: Children from low altitudes have no greater risk of developing HAPE than adults; however, children who reside at high altitudes are more likely than adults to develop re-entry HAPE.
- Q: Should I give prophylaxis to my child to prevent AMS?
- A: Not usually. Only children with a significant history of AMS or unavoidable significant ascent should be given prophylaxis with acetazolamide. This can often be avoided by good planning with adequate rest and pacing of ascent. Prophylaxis with dexamethasone is not recommended in children.
- Q: Should everyone in whom a headache develops when at a higher than usual altitude be treated with acetazolamide?
- A: Not necessarily. Consider other causes of headaches and other conservative measures like rest and analgesics. The decision to treat should be based on severity of illness and other options available.

AMBLYOPIA

Monte D. Mills

BASICS

DESCRIPTION

Amblyopia is generally classified by cause, with 3 primary types:

- Anisometropic amblyopia: Resulting from asymmetric refractive error and resultant unilateral blurring. This is the most common cause of amblyopia.
- Strabismic amblyopia: Resulting from misalignment of the eyes, and subsequent lack of an image that can be “fused”, or integrated into a single image in the brain. This is most likely with early-onset, constant strabismus. Up to 60% of patients with strabismus will also have amblyopia.
- Deprivation amblyopia: Resulting from optical imperfection (cataract, ptosis, corneal opacity, prolonged patching or bandage), which prevents the formation of a clear image in one or both eyes. Deprivation, especially if it begins early in life, is associated with the most severe amblyopia.

EPIDEMIOLOGY

Amblyopia is the most common cause of unilateral vision loss in children and young adults.

Prevalence

Large population-based studies indicate that 2–5% of the adult population has amblyopia.

PATHOPHYSIOLOGY

- Asymmetric input between the 2 eyes (unilateral cataract, anisometropia, etc.) is more likely to cause amblyopia than symmetrically poor images, due to competitive influences between the 2 eyes. As a result, amblyopia is usually unilateral.
- Bilateral amblyopia may result from severe, symmetric bilateral image degradation such as bilateral cataract, bilateral high ametropia (high refractive error), etc.
- Visual acuity in amblyopic eyes varies from minimal impairment (20/25) to legal blindness (<20/200). Other significant impairments in amblyopic eyes may include reduced contrast sensitivity, reduced or absent binocularity and depth perception, and impaired or distorted spatial perception. Peripheral visual fields are preserved, and vision is never completely lost (no light perception) from amblyopia alone.

DIAGNOSIS

SIGNS AND SYMPTOMS

Poor vision

HISTORY

- Age of onset of vision loss
- Eye trauma, injury, or surgery
- Refractive error or glasses
- Ptosis or ocular occlusion
- Family history of strabismus, anisometropia, or amblyopia

PHYSICAL EXAM

- Visual acuity is the single most significant sign in detection of amblyopia. Vision must be tested in each eye separately, with reliable occlusion (adhesive patch, opaque card, or plastic occluder). Because most amblyopia is monocular, testing vision with both eyes open is inadequate as a screening tool.
- Binocularity tests such as Titmus stereopsis (3D fly) will detect suppression, which is frequently associated with amblyopia.

DIAGNOSTIC TESTS & INTERPRETATION

Vision testing in young children is difficult and, sometimes, unreliable:

- Children must be tested with each eye separately.
- Repeating the tests and adjunctive tests including the Titmus test, cover testing, photoscreening, and Bruchner red reflex test will increase the sensitivity of screening.

Lab

Imaging

Imaging studies of the optic nerves and posterior visual pathways may be useful in selected cases to exclude other causes of vision loss.

DIFFERENTIAL DIAGNOSIS

- Amblyopia is diagnosed by exclusion: Conditions that cause vision loss without easily recognized pathology might be mistaken for amblyopia.
- In children, the differential diagnosis of vision loss in normal-appearing eyes includes the following:
 - Uncorrected refractive error (hyperopia, myopia, astigmatism)
 - Optic nerve hypoplasia
 - Optic atrophy
 - Compressive, toxic or hereditary optic neuropathies
 - Retinopathies, including Leber congenital amaurosis, Stargardt disease, retinitis pigmentosa, and others
 - Central visual impairment (cortical blindness)
 - Glaucoma
 - Factitious or functional causes (hysterical blindness)

TREATMENT

GENERAL MEASURES

- Unilateral amblyopia:
 - Treat underlying cause of vision loss (strabismus, anisometropia, optical opacity) and force preferential use of the amblyopic eye.
 - The classic and most common treatment is occlusion with an adhesive patch worn over the opposite eye for several hours per day.
 - The amount of time of occlusion necessary to reverse amblyopia depends on variables including the severity of amblyopia, cause of amblyopia, age, and other associated ocular conditions.
 - Typically worn, from a few weeks to months
 - Infants and very young children require closer observation to prevent reversing the amblyopia to the previously preferred eye (occlusion amblyopia) from excessive patching.
 - Optical penalization of the opposite eye using topical cycloplegic eyedrops, such as atropine 1%. Recent studies suggest that atropine penalization may be as effective as patching to treat mild or moderate amblyopia.
 - Treatment should be attempted in amblyopic children within the “sensitive period” of birth to 8 years of age. Improvement of vision with treatment of older children has been reported, but is much less likely. Treatment is usually continued until visual acuity is equal to the opposite eye, or no further improvement is seen over several examinations with treatment.
 - The primary risk of treatment is overcorrection, with iatrogenic amblyopia in the occluded opposite eye.
- In strabismic amblyopia, initiation of treatment for amblyopia need not wait for correction of the strabismus. In fact, the stability of the surgical strabismus correction is improved if amblyopia therapy is initiated before surgery:
 - Treatment is usually continued until visual acuity in both eyes is equal, or until vision in the amblyopic eye shows no further improvement after several examinations over a period of time.

ISSUES FOR REFERRAL

Prompt referral of failures and children suspected of poor vision for complete ophthalmic examination is essential for successful amblyopia screening programs.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- In general, the younger the patient, the more intensive the patching therapy, and the milder the amblyopia, the more frequent vision testing is necessary to ensure that vision in the opposite, occluded eye is not harmed.
- Children are clever at finding ways to avoid the temporary vision impairment from patching, and will peek or remove patches frequently.
- In younger children, amblyopia may recur after successful treatment.

PATIENT MONITORING

- Children should be retested frequently, and retreated if vision drops after finishing successful initial treatment.
- Testing should continue at least annually until the child is at least 8 years old.

PATIENT EDUCATION

Because the outcome of amblyopia depends entirely on early detection and treatment within the first few years of life, all children should be screened by monocular recognition visual acuity as early as possible (at the 3- or 4-year well-child visit), and testing should be repeated annually until 8 years of age. Children who are not capable of accurate visual acuity testing by 4 years of age should also be referred for complete evaluation

PROGNOSIS

- After treatment, amblyopia may recur and vision should be retested regularly.
- Patients with strabismus, even if previously treated with glasses or surgery, must be followed for amblyopia.
- Vision loss from amblyopia will persist even after the condition that originally caused the amblyopia has resolved. In some cases, when there is no obvious cause, a history of episodes of anisometropia, occlusion, or strabismus must be considered.

COMPLICATIONS

- Left untreated, amblyopia results in irreversible, uncorrectable vision loss after visual maturity (8–10 years of age).
- Usually the vision loss is unilateral, and the functional effects may be minimal if vision in the remaining eye is normal.
- In bilateral cases, or if other diseases or injury affects the remaining eye, the outcome can be significant functional impairment, including legal blindness.

FAQ

- Q: How long will patching be necessary?
- A: It is not possible to predict exactly how long treatment will be necessary to restore vision. In general, the younger the patient, the milder the impairment, and the more intensive the patching, the more quickly vision is restored. In general, patching is usually continued for 1–4 months in most cases of anisometropic or strabismic amblyopia. Normalization of vision or lack of further improvement is usually the treatment end point.

- Q: Will vision be normal after treatment?
- A: The degree of recovery with amblyopia therapy depends on the density of the amblyopia, the cause, and the age at which treatment is initiated. In almost all children younger than 6–8 years, some visual improvement can be expected with amblyopia treatment, although not all patients will improve to 20/20 vision.
- Q: Will patching eliminate the need for glasses?
- A: No, patching does not influence the outcome of refractive errors (power of glasses, Refractive Error). Glasses may still be needed after patching is completed.
- Q: Will patching for amblyopia improve the strabismus?
- A: No, in most cases patching for amblyopia will not eliminate strabismus or the need for strabismus surgery. However, in most cases it is best to begin amblyopia treatment before surgery, to improve the surgical outcome.
- Q: Is “vision therapy” without patching an effective treatment for strabismus?
- A: Although eye exercises, pleoptics, and other vision therapies have been used to treat amblyopia, none is as effective as patching or other occlusive therapy. Current vision therapy techniques have not been proven to improve amblyopia.
- Q: My child refuses to wear a patch. Are there alternatives to patching?
- A: Yes, optical penalization with glasses, atropine cycloplegic penalization, and even contact lens occlusion can be effective. However, patching is the most reliable and effective treatment. Parental support, encouragement, and reward are essential for treatment compliance.

AMEBIASIS

Jason Kim

BASICS

DESCRIPTION

Clinical syndromes associated with *Entamoeba histolytica* infection

EPIDEMIOLOGY

- Treatment of drinking water
- Hand washing
- Appropriate disposal of human fecal waste
- Use of condoms
- Infection-control measures: Standard precautions are recommended for the hospitalized patient.

Incidence

Amebiasis accounts for 40–50 million cases of colitis worldwide and leads to 40,000–110,000 deaths annually.

Prevalence

- The estimated prevalence in the US is 4% although there have been no recent serosurveys in developed countries.
- Worldwide distribution involving an estimated 10% or more of the world's population. Most common in tropical areas, with infection rates as high as 20–50%. The highest morbidity and mortality are seen in developing countries in Central America, South America, Africa, and Asia.

RISK FACTORS

- The very young, the elderly, and patients with underlying immunosuppression or malnutrition are at highest risk for severe disease.
- Patients in whom the diagnosis should be considered include:
 - Immigrants from or travelers to endemic areas
 - Children with bloody stools or mucus in stools
 - Children with hepatic abscess
 - The febrile child with right upper quadrant pain and tenderness, abdominal pain, or discomfort
 - The child with hepatomegaly, typically without jaundice

PATHOPHYSIOLOGY

- Fecal–oral transmission
- *E. histolytica* is excreted as cysts or trophozoites in the stool of infected patients.
- Ingested cysts are unaffected by gastric acid and become trophozoites that colonize and invade the colon.
- Amebae attach to epithelial cells via a galactose/N-acetylgalactosamine (Gal/GalNAc) binding lectin. The parasite has the ability to lyse human epithelial cells, or kill by inducing apoptosis. Then cytokines and chemokines released attract neutrophils, macrophages, and lymphocytes. The host immune response contributes significantly to the reduction of epithelial integrity.

- Amebas then use cysteine protease to cleave extracellular matrix proteins to invade the submucosal layers.
- Amebas can then disseminate directly from the intestine to the liver in up to 10% of patients. Dissemination from the liver to the lung, heart, brain, and spleen has been described.
- The incubation period is typically 1–3 weeks but can range from a few days to months or years.

ETIOLOGY

- *E. histolytica* is nonflagellated protozoan parasite.
- Other species of the *Entamoeba* family are nonpathogenic, including the morphologically identical *Entamoeba dispar*.

DIAGNOSIS

HISTORY

Intestinal disease may be asymptomatic or have mild symptoms such as abdominal discomfort, flatulence, constipation, and occasionally diarrhea.

PHYSICAL EXAM

- The most common clinical manifestation is intestinal amebiasis.
- Nondysenteric colitis is characterized by intermittent diarrhea and abdominal pain.
- Acute amebic colitis (dysenteric) is associated with grossly bloody stools with mucus, abdominal pain, and tenesmus.

DIAGNOSTIC TESTS & INTERPRETATION

The diagnosis of amebiasis depends on the recognition of typical symptoms and routine laboratory tests.

Lab

- CBC typically reveals a leukocytosis.
- Transaminases are often not elevated.
- Occult blood is detected in stool.
- Stool samples:
 - Isolation and visualization:
 - Serial stool samples, usually 3, are recommended.
 - Samples obtained within 1–2 hours of passage should be examined by wet mount and fixed in formalin and polyvinyl alcohol.
 - Serial stool samples are necessary since cysts may be shed intermittently. 3 serial stool samples will detect up to 70% of patients with amebic colitis and 50% of patients with hepatic abscess.
 - Stool samples should not be contaminated by urine, water, barium, enema substances, laxatives, or antibiotics, since these substances may destroy or interfere with identification of the trophozoites.
 - Microscopy has a sensitivity of <60% and specificity of 10–50% on a single sample.
 - Second-generation stool antigen testing kits (commercially available) also have demonstrated excellent sensitivity and specificity comparable to real time PCR.

Serology:

- Serum antiamebic antibodies are considered an adjunct to diagnosis.
- ~85% of patients with amebic dysentery and 99% of patients with liver amebiasis will have positive serology.
- Molecular testing to differentiate *Entamoeba histolytica* from non-pathogenic *Entamoeba* species is in the research phase.

Imaging

- Ultrasound, CT, or MRI of the liver
- In patients with hepatic amebiasis, chest x-ray may reveal elevation of the right hemidiaphragm.

Diagnostic Procedures/Other

- Note: Amebae are difficult to visualize in abscess aspirates and substantial risk is associated with CT or ultrasound-guided procedures, including bleeding, peritonitis secondary to spillage of amebae, or rupture of echinococcal cysts.
- Colonoscopy

Pathological Findings

- Identification of trophozoites or cysts in the stool
- Colonic or rectal mucosa visualized by colonoscopy reveals ulcerations, and amebae can often be found around these lesions.

DIFFERENTIAL DIAGNOSIS

The diagnosis is often missed in children because the disease is not included in the differential. Because it is not common in the US, amebiasis may initially be misdiagnosed as bacterial dysentery. Differential diagnosis includes the following:

- Infection: *Salmonella* species *Shigella* species, *Campylobacter* species, *Yersinia* species, *Clostridium difficile*, *Escherichia coli* (enteroinvasive and enterohemorrhagic) pyogenic abscess, Echinococcal cyst, inflammatory bowel disease: Crohn disease, ulcerative colitis,
- Miscellaneous: Ischemic colitis, diverticulitis, arteriovenous malformations, hepatoma

TREATMENT

MEDICATION (DRUGS)

First Line

- Asymptomatic intestinal amebiasis: Intraluminal agents:
 - Iodoquinol is the drug of choice. The recommended dosage is 30–40 mg/kg/d (maximum, 1,950 mg) PO in 3 divided doses for 20 days.
- Acute amebic colitis or extraintestinal amebiasis:
 - Metronidazole (a tissue-active agent) 35–50 mg/kg/d PO in 3 divided doses for 10 days (maximum, 2,250 mg/d) plus a course of treatment with an intraluminal active agent (as above). ~1/3 of patients treated with metronidazole alone will relapse.

Second Line

- Asymptomatic intestinal amebiasis:
 - Diloxanide furoate (Furamide) at doses of 20 mg/kg/d (maximum, 1,500 mg/d) PO in 3 divided doses or paromomycin, 25–35 mg/kg/d PO in 3 divided doses for 7 days.
- Acute amebic colitis or extraintestinal amebiasis:
 - One study has reported good efficacy using nitazoxanide in children; however, it was small and combined *E. histolytica* and *E. dispar* into one stratum.
 - However, nitazoxanide shows good activity in vitro against *E. histolytica*.

ADDITIONAL TREATMENT

General Measures

- The goal of treatment is the elimination of tissue-invading trophozoites and intestinal cysts.
- The choice of treatment regimens depends on the clinical presentation.
- Agents that are active against *E. histolytica* are divided into 2 categories: Drugs with activity against intraluminal amebae and drugs with activity against extraintestinal and invasive amebiasis.

SURGERY/OTHER PROCEDURES

Patients with large liver abscesses or who have failed medical therapy should be considered candidates for surgical or percutaneous drainage.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Follow-up stool examination is always necessary to ensure eradication of intestinal amebae.
- For amebic abscesses, drainage should be considered if response to medical therapy has not occurred in 4–5 days.

PROGNOSIS

Clinical improvement is expected within 72 hours of initiation of therapy.

COMPLICATIONS

- Amebic liver abscess:
 - 2nd most common presentation of amebiasis, often not associated with amebic dysentery
- Ameboma:
 - Abdominal mass representing granulation tissue in the colon
- Extraintestinal manifestations of amebiasis are presumed to be a result of direct extension from liver abscesses. These include the following:
 - Pericarditis
 - Pleuropulmonary abscess or empyema
 - Bronchohepatic fistula
 - Genitourinary tract abscess
 - Cerebral abscess
 - Cutaneous amebiasis:
 - This is a rare finding in children, with ~6,510 cases reported in the literature.
 - Shallow painful cutaneous ulcers in the diaper area, usually found in association with amebic colitis or dysentery
 - Epidemiologic studies from countries with high prevalence of amebiasis show an association between amebic diarrhea and poor growth. The negative effect on growth was significantly more deleterious than diarrhea caused either by *Giardia* or *Cryptosporidium*.

AMENORRHEA

Renee K. Kottenhahn
Deborah B. Ehrenthal

BASICS

DESCRIPTION

Amenorrhea is the absence of menstruation. It is divided into 2 categories:

- **Primary amenorrhea** is the failure to begin menstruation by age 16 in girls with otherwise appropriate pubertal development or by age 14 in the absence of secondary sexual characteristics. Evaluation should also be considered if a girl has not menstruated within 2 years of obtaining Tanner IV breast development regardless of her age.
- **Secondary amenorrhea** is the cessation of menstruation for 3 cycles or 6 months in girls and women with previously established regular cycles:
 - Should not be used when referring to girls who are within their 1st 2 years of menarche because regular ovulatory cycles have not yet been established; their periods are unpredictable.
- A regular menstrual cycle is a sign of good health. The absence of menses or disruption of regular cycles once they have been established can result from systemic disease, genetic or anatomic abnormalities, physical or emotional stress, or unrecognized pregnancy. The goal of the evaluation is to identify the underlying cause (see Differential Diagnosis section below)
- Approach to patient:
 - A stepwise approach to the evaluation guided by the history and physical exam is recommended:
 - Phase 1: Exclude pregnancy by urine or serum HCG testing.
 - Phase 2: Obtain a complete history to differentiate between primary and secondary amenorrhea to help identify the underlying cause.
 - Phase 3: Perform a directed physical exam.
 - Phase 4: Initiate stepwise diagnostic testing to assess for causes of amenorrhea.

DIAGNOSIS

HISTORY

- Age of patient:
 - Genetic abnormalities more common in younger patients
 - Premature ovarian failure found with increasing age
- Past and current medical history
 - Prior/current/chronic illness including autoimmune, renal, thyroid, or liver disease; diabetes, or cancer (radiation or chemotherapy), which may be the underlying cause of amenorrhea
- Stressful life events:
 - A diagnosis of exclusion
- Growth and weight changes
 - Consider endocrinopathy, genetic disease, PCOS, rapid weight gain, eating disorder or other chronic disease
- Behavioral:
 - Eating disorder and/or excessive exercise

- Headaches:
 - Assess for visual field defects, dizziness (suggesting pituitary tumor or other intracranial process)
- Reproductive and menstrual history:
 - Age at menarche
 - Menstrual cycles: regularity, flow, duration; characteristics of last menstrual period (normal or abnormal)
 - Sexual history: Sexual activity, prior pregnancy, current or prior contraceptive use (Depo-Provera can cause amenorrhea for up to 18 months)
 - Presence of symptoms of molimina in the past: menstruation associated with breast tenderness, fluid retention, cramping
 - Risk factors for uterine scarring
- Galactorrhea:
 - Spontaneous milky discharge from the breast suggests elevated prolactin or thyroid abnormality, or may be due to manual stimulation, medications, pituitary tumor, or illicit drug use.
- Abdominal or pelvic pain:
 - Cyclic or intermittent abdominal/pelvic pain suggests a uterine anomaly or obstruction.
- Skin and hair:
 - Excess hair growth (inquire about shaving, plucking, or waxing), acne, balding, and acanthosis nigricans are symptoms of androgen excess and suggest PCOS, congenital adrenal hyperplasia (rare), or a tumor (rare).
 - Easy bruising or pigmented striae suggest Cushing syndrome.
- Medications:
 - Hormonal and cytotoxic medications, illicit drugs, antidepressant drugs, and medications such as opiates.

PHYSICAL EXAM

- General appearance, height, and weight with calculation of BMI (body mass index in kg/m^2):
 - Obesity raises suspicion of PCOS or Cushing syndrome.
 - Athleticism or underweight suggests female athlete triad or eating disorder, respectively.
 - Stigmata of Turner syndrome (short stature, web neck, etc.) or other genetic syndrome
 - Abnormal growth pattern suggests endocrinopathy, dietary restriction, chronic disease, or genetic disorder.

- Skin exam:
 - Acne, hirsutism (increased facial hair, midline hair over sternum and lower abdomen), acanthosis nigricans, and balding are suggestive of virilization or PCOS.
 - Bruises or pigmented striae suggest Cushing syndrome.
- Tanner staging and breast exam:
 - Abnormal Tanner stage for chronologic age suggests an endocrine, metabolic, or genetic abnormality.
 - Galactorrhea suggests abnormalities in prolactin or thyroid.
- Thyroid nodule or enlargement:
 - Evaluate for hyperthyroidism or hypothyroidism.
- Abdominal mass:
 - Evaluate for uterine obstruction, tumor.
- Genitourinary exam:
 - Abnormal external genitalia suggests outflow tract abnormalities.
 - Clitoral enlargement is a sign of virilization and raises suspicion for an androgen-secreting tumor or congenital adrenal hyperplasia.
 - The decision to do a digital or speculum pelvic exam should be based on the patient's age/maturity/gynecologic history/and ability to tolerate the exam. An ultrasound may be a helpful adjunct to evaluate anatomy (see below).

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Standard initial testing: pregnancy test, FSH/LH, estradiol, TSH, free T4 prolactin (8 a.m.)
- For primary amenorrhea include genetic testing by checking a karyotype to identify sex chromosome abnormalities.
- If PCOS is suspected or virilization is identified also include total and free testosterone, DHEA-S, and 17-hydroxyprogesterone.
- If Cushing syndrome is suspected consider an overnight dexamethasone suppression test or 24-hour urinary free cortisol excretion.

Imaging

- Imaging should be used selectively.
- Transvaginal or Pelvic ultrasound:
 - Confirm presence of normal müllerian structures (uterus and ovaries) for patients with primary amenorrhea.
 - Exclude ovarian mass, renal abnormalities based on abnormal physical exam or laboratory results.
- MRI of the pituitary gland if indicated based on neurologic symptoms, galactorrhea, and/or laboratory results (elevated prolactin)

Diagnostic Procedures/Other

Progesterone challenge: to be used selectively only after primary evaluation completed

DIFFERENTIAL DIAGNOSIS

- Outflow tract abnormalities:
 - Imperforate hymen, transverse vaginal septum, müllerian agenesis, androgen insensitivity syndrome (testicular feminization)
- Ovarian failure:
 - Chromosomal abnormalities, radiation- or chemotherapy-induced ovarian failure, autoimmune premature ovarian failure, idiopathic premature ovarian failure
- Chronic anovulation:
 - Androgen excess: polycystic ovary syndrome (common), congenital adrenal hyperplasia, ovarian or adrenal tumor
 - Elevated prolactin: Prolactinoma, medications, hypothyroidism, others
 - Low or normal LH/FSH: Chronic or systemic illness, psychological stress, eating disorders, extreme obesity, excessive exercise
 - Thyroid disease
 - Other endocrine abnormality: Pituitary insufficiency, Cushing syndrome
- Medications:
 - Cytotoxic, hormonal contraception, opiates, psychiatric medications, and others
- Pregnancy

**TREATMENT**

- Identification and management of the underlying disorder is key.
- Estrogen/progestin hormonal therapy should not be initiated prior to completing a full evaluation.
- Premature use of hormonal therapy may alter subsequent testing.
- Contraindications to hormone therapy must be ruled out (refer to World Health Organization [WHO] Medical Eligibility Criteria at http://www.who.int/reproductivehealth/publications/family_planning/en/).

ADDITIONAL TREATMENT**Additional Therapies**

Behavioral interventions: A family-based approach is recommended for addressing complex behavior problems or emotional symptoms in an adolescent.

FAQ

- Q: What are the normal benchmarks for evaluating pubertal development in girls?
- A: Normal benchmarks for evaluating pubertal development in girls: Breast development by age 12–13, menarche ~2 years after breast development (by age 14), or menarche within 2 years of achieving Tanner IV breast stage.
- Q: Does a patient who says she has never had sex still need a pregnancy test?
- A: Yes

ANAEROBIC INFECTIONS

Hamid Bassiri

Adam J. Ratner (5th edition)

BASICS

DESCRIPTION

Anaerobic bacteria are organisms capable of growing in a reduced oxygen environment, either exclusively (obligate anaerobes) or in addition to growing in air (facultative anaerobes). Anaerobic bacteria can cause invasive and sometimes serious disease.

EPIDEMIOLOGY

While anaerobic bacteremia is less frequent in children than in adults, some pediatric anaerobic infections are common at certain sites (e.g., chronic otitis media or sinusitis).

- Anaerobic bacteria most commonly found in polymicrobial infections with other anaerobic and aerobic flora.
- Because of their fastidious nature, the ability of microbiology laboratories to identify anaerobic bacteria is highly dependent on proper collection and transport of culture specimens. As a result, anaerobic bacteria can often be missed.
- The most common anaerobes include various genera of gram-negative rods (*Bacteroides*, *Prevotella*, *Porphyromonas*, *Fusobacteria*, *Bilophila*, and *Sutterella*), gram-positive cocci (*Peptostreptococcus*), spore-forming gram-positive bacilli (*Clostridia*), nonspore-forming gram-positive bacilli (*Eubacterium*, *Bifidobacterium*, *Propionibacterium*, *Actinomyces*, and *Lactobacillus*), and gram-negative cocci (*Veillonella*).

RISK FACTORS

Increased risk is associated with impaired host immunity or presence of devitalized tissue (owing to surgery, trauma, vascular insufficiency, diabetes), or presence of foreign bodies.

PATHOPHYSIOLOGY

- Generally occurs when there is a break in a mucocutaneous barrier.
- Numerous virulence factors have been described, including exotoxins (e.g., *Clostridia* spp.), antiphagocytic capsule (e.g., *Bacteroides* spp.), and endotoxins (e.g., *Fusobacterium* spp.)

ETIOLOGY

Anaerobic infections most commonly derive from the normal flora of the oropharynx, skin, intestines, or the female genital tract. Thus, anaerobic infections are often associated with a loss of integrity of anatomic or epithelial barriers at these sites.

COMMONLY ASSOCIATED CONDITIONS

- CNS infections:
 - Brain abscess
 - Subdural empyema
 - Epidural abscess
- Head and neck infections:
 - Sinusitis (generally polymicrobial)
 - Chronic otitis media
 - Ludwig angina (infection of the submandibular space)
 - Cervical adenitis
 - Peritonsillar abscess
 - Dental abscess
 - Gingivitis
 - Actinomycosis of jaw
 - Lemierre disease (septic thrombophlebitis of the internal jugular vein owing to *Fusobacterium*, often resulting in pulmonary abscess formation)
- Pleuropulmonary infections:
 - Aspiration of oral and/or gastrointestinal fluids
 - Pneumonia, abscess formation
 - Secondary to aspirated foreign bodies
 - Actinomycosis
- Peritonitis/peritoneal abscess:
 - Appendiceal abscess
 - Perforated viscus
 - Postoperative complication
 - Trauma-related
 - Actinomycosis
- Cholangitis:
 - Ascending infection may occur following biliary tract surgery (e.g., Kasai procedure).
 - Infection is often polymicrobial.
- Soft tissue infection:
 - Paronychia
 - Pilonidal cyst
 - Crepitant cellulitis
 - Necrotizing fasciitis
 - Gas gangrene (*Clostridium* spp.)
 - Infected decubitus ulcers (may result in contiguous osteomyelitis)
 - Penetrating wounds (may lead to tetanus)
- Infections of the female genital tract:
 - Endometritis or salpingitis
 - Tubo-ovarian or adnexal abscess
 - Pelvic inflammatory diseases
 - Pelvic abscess
 - Bartholin gland, vulvar, or perineal abscess
 - Bacterial vaginosis

- Infected bite wounds:
 - Anaerobes isolated from 50% of human or animal bites
- Bacteremia:
 - Often associated with focal primary site of involvement (gastrointestinal disease, abscess)
- Neonatal infections:
 - Cellulitis at fetal monitoring sites
 - Aspiration pneumonia
 - Omphalitis
 - Conjunctivitis
 - Infant botulism

DIAGNOSIS

Involvement of anaerobic bacteria should be suspected in infections with suppuration, abscess formation, tissue necrosis, or in hosts with systemic disease.

HISTORY

- Impaired mental status:
 - Increased risk of aspiration
- History of thumb sucking:
 - Anaerobes frequently isolated from paronychia
- History of animal or human bites
- Recent surgery or trauma:
 - Poor drainage or devitalized tissue associated with anaerobic infection
- Underlying immunodeficiency or chronic illness:
 - Impaired phagocytic function
- History of pus that is “sterile” (no growth on routine cultures)

PHYSICAL EXAM

- Location of infection:
 - See “Associated Conditions.”
- Poor dentition:
 - Increased colonization of oropharynx with anaerobic organisms
- Necrotic tissue or crepitus
- “Dishwater” pus or discharge with foul odor:
 - Characteristic of anaerobic infections
- Lateral neck pain in association with respiratory distress:
 - Lemierre disease causes septic thrombophlebitis of the internal jugular vein and lung abscess.

DIAGNOSTIC TESTS & INTERPRETATION**Lab**

- Gram stains with unique morphology:
 - Small, pleomorphic gram-negative bacilli (*Bacteroides* spp.); large gram-positive organisms with “boxcar” morphology (*Clostridium* spp.)
- Anaerobic cultures:
 - Should be performed on tissue or aspirated fluid obtained in a sterile fashion from the infected site. Anaerobically collected specimens should be transported to the microbiology laboratory promptly.
 - Do not send swabs for anaerobic cultures.

Imaging

- Radiographs:
 - Air–fluid level, cavity formation, gas in tissue
- CT and/or MRI scans:
 - Often important to define anatomic location and extent of disease

DIFFERENTIAL DIAGNOSIS

- Likely pathogens not recovered from aerobic cultures
- Failure of empiric antibiotic coverage that is not active against anaerobes

**TREATMENT****ADDITIONAL TREATMENT****General Measures**

In general, antimicrobials with the best activity against anaerobes include metronidazole, carbapenems, chloramphenicol, and beta-lactam/beta-lactamase inhibitor combinations. Clindamycin, cephamycins, and antipseudomonal synthetic penicillins also have relatively good range of activity. Penicillin, cephalosporins, tetracyclines, macrolides, aminoglycosides, trimethoprim-sulfamethoxazole, and monobactams have either variable or poor activity against anaerobes and should not be used as empiric therapy. Most fluoroquinolones (except moxifloxacin) also have variable activity. Vancomycin has activity against gram-positive but not gram-negative anaerobes.

Empiric drug therapy:

- CNS infections:
 - Vancomycin + cefotaxime + metronidazole
- Head and neck infections:
 - Ampicillin-sulbactam, amoxicillin-clavulanate, or clindamycin

- Pleuropulmonary infections:
 - Ampicillin-sulbactam, amoxicillin-clavulanate, or clindamycin
- Peritonitis/peritoneal abscess:
 - Ampicillin-sulbactam, ticarcillin-clavulanate, piperacillin-tazobactam, or ceftioxin, or meropenem, imipenem
- Cholangitis:
 - Piperacillin-tazobactam, or meropenem, imipenem
- Soft tissue infection:
 - Site dependent
- Infections of the female genital tract:
 - Site dependent
- Infected bite wounds:
 - Ampicillin-sulbactam, piperacillin-tazobactam, amoxicillin-clavulanate
- Bacteremia:
 - Isolate dependent
- Neonatal infections:
 - Site dependent

COMPLEMENTARY & ALTERNATIVE THERAPIES

- Neutralization of toxins, especially in the case of botulism or tetanus
- Hyperbaric oxygen, although still sometimes used (especially in Clostridial infections), has not been shown to be of proven benefit, although it may help define and demarcate the borders of devitalized tissues.

SURGERY/OTHER PROCEDURES

Effective drainage of abscesses and debridement of devitalized tissue is essential.

**ONGOING CARE****PROGNOSIS**

- Determined by speed with which infection is appropriately treated with antibiotics and/or drainage.
- High rates of mortality associated with clinically apparent anaerobic bacteremia.
- Specific prognosis depends on the bacterial species involved and the status of the patient’s immune system.
- Soft tissue infections caused by *Clostridium* spp. may cause up to 20% mortality despite aggressive therapy.

COMPLICATIONS

Vary with nature of infection, but can include extension of infection to adjacent structures, or development of bacteremia.

ANAPHYLAXIS

Mathew Fogg

BASICS

DESCRIPTION

- Anaphylaxis is an explosive antigen-specific IgE-mediated response resulting in the release of potent biologically active mediators from mast cells and other inflammatory cells. However, non-IgE-mediated direct mast cell degranulation can result in a similar response.
- In fatal anaphylaxis, death may occur from airway obstruction and/or shock. When treating a patient with anaphylaxis, respiratory symptoms and hypotension should be taken very seriously.
- System(s) affected: Heart; lungs; skin; GI tract; upper respiratory tract:
- Any or all of these target organs may be affected.

EPIDEMIOLOGY

Incidence

- 0.4 cases per million individuals annually
- Increased hospital incidence of 0.6 cases per 1,000 patients
- 400–800 deaths annually in the US

RISK FACTORS

Genetics

Atopy can be familial, and atopics are at more risk for anaphylaxis.

PATHOPHYSIOLOGY

- Inducing agents stimulate mast cells to release inflammatory mediators via either an antigen-specific or an antigen-nonspecific manner. These mediators may then act either locally or systemically. Mediator release results are in the table Pathophysiology of Anaphylaxis.

Pathophysiology of anaphylaxis

Pathologic process	Sign or symptom	Putative mediator responsible
Vascular permeability	Urticaria, angioedema, laryngeal edema, abdominal swelling, cramps	Histamine (H1) leukotrienes, prostaglandins
Vasodilation	Flushing, headache	Histamine (H1 and H2), leukotrienes, prostaglandins
Smooth-muscle contraction	Wheezing, gastrointestinal cramps, diarrhea	Histamine (H1), leukotrienes, prostaglandins
Congestion	Rhinorrhea, bronchorrhea	Histamine (H2), prostaglandins, leukotrienes

ETIOLOGY

- IgE mediated:
 - Antibiotics (penicillin and others)
 - Foreign protein agents (insect venom, latex antigens, fire ant venom, blood products, and others)
 - Therapeutic agents (allergen extracts, vaccines, and others)
 - Foods (peanuts, nuts, shellfish, and others)
- Non-IgE-mediated “anaphylactoid” reactions (activates histamine release from mast cells without protein binding to IgE):
 - Radiopaque media
 - Opiates
 - Dextran
 - Vancomycin
 - Polymyxin B
 - Quaternary ammonium muscle relaxants (i.e., methyl scopolamine bromide, homatropine methylbromide, methantheline bromide, and Pro Banthine bromide)

DIAGNOSIS

Decide quickly whether the symptoms the patient is experiencing are consistent with anaphylaxis.

- Phase 1: Initiate therapy for anaphylaxis. This generally includes epinephrine 1:1,000 administered SQ, H1 antihistamines, H2 antihistamines, and rapid volume expansion if necessary.
- Phase 2: Attempt to identify the agent that induced the anaphylactic reaction.

HISTORY

- Reaction time to offending allergen:
 - Anaphylactic reactions usually begin within seconds to minutes after contact with offending antigen. This can help the physician identify the antigen responsible.
- History of anaphylaxis:
 - If so, the patient likely knows the allergen responsible.
 - Efforts should be directed toward allergen avoidance.
- Does the patient have autoinjectable epinephrine?
 - Most deaths from anaphylaxis are associated with delayed administration of epinephrine. Most patients with a history of anaphylaxis should have autoinjectable epinephrine.
- Insect sting:
 - Insect or fire ant venom allergy can result in anaphylaxis. It is important to identify the insect if possible (remember that honeybees leave their stinger at the sting site). Immunotherapy is indicated and effective for anaphylaxis in venom-allergic patients.
- Food allergies:
 - Any food can cause anaphylaxis.
 - Dramatic increase in childhood food allergy in past 15 years
 - Cow’s milk, egg, soy, peanut, wheat, tree nuts, and shellfish are the most common.

Medications:

- Beta-blockers make treatment of anaphylaxis more difficult.
- Alternative medications (glucagon) should be sought in patients with a history of anaphylaxis.
- Signs And Symptoms
 - Consistent with anaphylaxis:
 - Profuse rhinorrhea
 - Urticaria
 - Wheezing
 - Throat tightness
 - Tachycardia
 - Hypotension
 - Any combination of the following symptoms:
 - Cutaneous: Urticaria/angioedema
 - Respiratory: Bronchospasm/laryngeal edema
 - Cardiovascular: Hypotension, arrhythmias, myocardial ischemia
 - GI: Nausea, vomiting, pain, diarrhea
 - Patients commonly describe a sense of impending doom:
 - May be the 1st sign of an impending anaphylactic reaction

PHYSICAL EXAM

- Angioedema:
 - May be noted anywhere during a systemic allergic reaction
 - Much more significant if it involves the lips, tongue, mouth, or larynx (can result in airway obstruction)
- Urticaria:
 - Cutaneous manifestation of a systemic allergic reaction
- Profuse rhinorrhea:
 - May signal upper respiratory tract involvement in a systemic allergic reaction
- Wheezing:
 - Signals lower respiratory tract involvement in a systemic allergic reaction
- Tachycardia and hypotension:
 - Signals cardiovascular involvement in a systemic allergic reaction
 - Tachycardia usually represents a compensatory mechanism in order to maintain the patient’s BP from fluid extravasation.

DIAGNOSTIC TESTS & INTERPRETATION

- Treatment of anaphylaxis should never be withheld while awaiting laboratory confirmation.
- ECG:
 - Anaphylaxis may show rhythm abnormalities, ischemic changes, or infarction on an ECG.

Lab

- Plasma histamine:
 - Plasma histamine is elevated during anaphylaxis, but is difficult to measure because of its extremely short half-life.
 - Useful only in research setting
- Serum tryptase level:
 - Preferred test if available
 - Serum tryptase is elevated during anaphylaxis.
 - Tryptase is elevated for several hours after the onset of anaphylaxis.
 - Tryptase often not elevated in anaphylaxis due to foods

- CBC:
 - Hemoconcentration (as judged by an increased hematocrit or hemoglobin) is common as fluid exits the intravascular space during an anaphylactic reaction.
- Cardiac enzymes:
 - Myocardial ischemia during anaphylaxis may result in a myocardial infarction, and elevated cardiac enzymes.

Note: Skin tests are significantly better than RAST tests for diagnosis of venom and food allergy.

Imaging

Chest radiograph: Bronchospasm associated with anaphylaxis may result in air trapping and hyperinflated lung fields on chest film.

DIFFERENTIAL DIAGNOSIS

- Genetic/metabolic:
 - Hereditary angioedema
 - Systemic mastocytosis
 - Pheochromocytoma
 - Carcinoid
- Allergic/immunologic:
 - Idiopathic
 - Foods
 - Insect stings
 - Drugs
 - Latex
- Nonimmunologic mast cell degranulation
- Exercise-induced (may occur only after ingestion of a specific food)
- Serum sickness
- Miscellaneous:
 - Vasovagal collapse

TREATMENT

MEDICATION (DRUGS)

First Line

- SQ epinephrine 1:1,000 concentration:
 - Infants to adults: 0.01 mg/kg, maximum of 0.5 mg of 1:1,000 solution, repeated q3–5min
 - Early administration of epinephrine is essential.
- Diphenhydramine IV or PO:
 - Children: 5 mg/kg in 3 or 4 divided doses; maximum 300 mg/d
- Ranitidine IV:
 - 2–4 mg/kg in 2 divided doses
 - H2 blockade may be helpful in refractory anaphylaxis.
- Hydrocortisone or another systemic steroid should be started:
 - 1–5 mg/kg/d in 2–4 divided doses
 - thought to prevent a late-phase reaction
 - Of little help during an immediate anaphylactic reaction
 - Glucagon: Second-line treatment for patients with anaphylaxis on a beta-blocker who are not responding to epinephrine.

ADDITIONAL TREATMENT

General Measures

- Maintain airway.
- A tourniquet may be applied (above the injection or sting site) to decrease venous blood return from the site of antigen entry.

- Supplement with oxygen, place in recumbent position, and elevate legs. Patients have increased oxygen consumption during anaphylaxis.
- Maintain BP with volume expanders or pressors. Hypotension is a serious manifestation of anaphylaxis.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patients not admitted to the hospital should be observed for several hours, because late “biphasic” reactions can begin as late as 24 hours after the initial anaphylaxis.

- These patients are at risk for a 2nd episode of anaphylaxis.
- Patients with anaphylaxis should be treated with steroids during the acute treatment, and they should be given a short course of oral corticosteroids to finish at home.
- Must be discharged with autoinjectable epinephrine (this will provide temporary relief so the patient will have time to seek medical assistance).
- Patients must know to seek immediate medical help if symptoms return.

Patient Monitoring

- All patients who have had anaphylaxis should be discharged with epinephrine in an auto-injecting apparatus.
- Note: All patients with anaphylaxis would benefit from consultation with an allergist.
- Factors that may help alert you to make a referral include the following:
 - History of idiopathic anaphylaxis:
 - An allergist can help by testing likely triggers.
 - History of anaphylaxis to insect stings or fire ants:
 - Anaphylaxis to insects or fire ants is an indication for venom desensitization.
 - History of food anaphylaxis:
 - The allergist can assist with an appropriate avoidance diet and support resources.
 - History of latex anaphylaxis:
 - The allergist can assist with strict latex-avoidance precautions, and latex testing if the history is unclear.

PATIENT EDUCATION

All patients should follow up with an allergist.

PROGNOSIS

Excellent, provided the trigger can be avoided

COMPLICATIONS

- Pulmonary edema, pulmonary hemorrhage, and pneumothorax
- Laryngeal edema with or without airway obstruction
- Myocardial ischemia and infarction
- Death may result from asphyxiation from upper airway obstruction or profound shock or both.

CODES

ICD9

- 977.9 Poisoning by unspecified drug or medicinal substance
- 995.0 Other anaphylactic shock, not elsewhere classified
- 995.60 Anaphylactic shock due to unspecified food

ICD10

- T78.00XA Anaphylactic shock due to unspecified food, initial encounter
- T78.2XXA Anaphylactic shock, unspecified, initial encounter
- T78.09XA Anaphylactic shock due to other food products, initial encounter

FAQ

- Q: Can a patient have an anaphylactic reaction on 1st exposure to an allergen?
- A: A patient must have had a previous exposure to the offending allergen for sensitization to occur. Therefore, anaphylactic reactions should not occur on 1st exposure. Remember: Infants can be sensitized in utero and through breast milk and topically; therefore, a baby may react upon “1st” exposure to a food.
- Q: When should the autoinjectable epinephrine be used?
- A: Immediately at the onset of an anaphylactic reaction. It is recommended to use it for any acute allergic reaction other than isolated hives or skin itching.
- Q: Do patients outgrow this condition?
- A: No. Subsequent reactions tend to have a more rapid onset, and tend to be more severe. Children often outgrow food-induced anaphylaxis.
- Q: Who should be referred to an allergist?
- A: All patients who have experienced anaphylaxis would benefit from consultation with an allergist. Patients with anaphylaxis from insect stings, fire ants, and certain antibiotics can be desensitized. In addition, the allergist can be helpful in identifying obscure triggers of anaphylaxis.

ANEMIA OF CHRONIC DISEASE (ANEMIA OF INFLAMMATION)

Michele P. Lambert

BASICS

DESCRIPTION

Anemia that accompanies a variety of systemic diseases, with the common features of chronicity and inflammation. Anemia of chronic disease is more properly called anemia of inflammation (AI) and is the combined result of mildly increased destruction of RBCs, relative erythropoietin resistance, and iron-restricted erythropoiesis.

PATHOPHYSIOLOGY

Typically mild to moderate anemia (Hgb 7–12); develops in the setting of infection, inflammatory disorders, and some malignancies.

- Characterized by inadequate erythrocyte production in the setting of low serum iron and low iron-binding capacity despite normal or increased macrophage iron stores (or increased or normal ferritin as used in clinical practice)
- Typically normochromic, normocytic but, if longstanding, can be hypochromic, microcytic (especially in children)
- Main mechanism appears to be:
 - Iron restriction (limited iron supply to erythropoiesis) Hepcidin is increased by IL-6 and causes depletion of the only known membrane iron transporter (ferroportin) resulting in cellular inability to release stored iron and enterocyte inability to absorb iron.
- Other factors contributing to anemia in various degrees include:
 - Increased red cell destruction
 - Diagnostic phlebotomy or other blood loss
 - Cytokine-mediated interference with erythropoietin signaling
 - Cytokine-mediated suppression of erythropoiesis
 - Cytokines such as interleukin-1 (IL-1) and interleukin-6 (IL-6) can activate ferritin synthesis. The ferritin can lead to sequestration of iron, which eventually is converted into hemosiderin.

ETIOLOGY

Underlying disease process

COMMONLY ASSOCIATED CONDITIONS

- Underlying disease process:
 - Infections, both acute and chronic
 - Inflammatory disease
 - Collagen vascular diseases
 - Malignancies
 - Renal failure
- Anemia of chronic disease often coexists with other causes of anemia, including occult blood loss, hemolysis, dietary iron deficiency, and drug-related marrow suppression

DIAGNOSIS

SIGNS AND SYMPTOMS

- Various abnormal physical findings may be present, depending on the underlying chronic disease process.
- May have mild pallor but will not have signs of circulatory collapse.
- Similar disease can be seen more acutely in the setting of anemia of critical illness (also part of AI).

HISTORY

Anemia develops over the first month of the underlying disease process and then remains fairly stable over time.

PHYSICAL EXAM

- Mild pallor
- Mild tachycardia, may be inapparent at rest
- Very rarely more overt signs of anemia such as flow murmur, gallop or hepatomegaly
- Physical findings of the underlying disease

DIAGNOSTIC TESTS & INTERPRETATION

If only the serum iron is obtained, without other iron studies, the child may be inappropriately diagnosed with iron deficiency.

Lab

- CBC with indices
 - Normocytic, normochromic (can be microcytic, hypochromic when very long standing) anemia with hematocrit rarely <20%
 - Reticulocyte count usually in the normal range, but low for the level of anemia
- Iron studies:
 - Low plasma iron, with low total iron-binding capacity
 - Low transferrin saturation by iron
 - Normal or high ferritin level
- Elevated free erythrocyte protoporphyrin
- Hemosiderin in bone marrow macrophages is increased if bone marrow aspiration is done and the aspirate is viewed with iron stains.
- Albumin and transferrin are both low
- Acute-phase reactants such as C-reactive protein may be elevated.

Diagnostic Procedures/Other

Bone marrow aspiration is generally not indicated.

DIFFERENTIAL DIAGNOSIS

Anemia of chronic disease is often confused with iron-deficiency anemia.

- In anemia of chronic disease:
 - Mild to moderate anemia
 - Mild anisocytosis
 - Usually normochromic, normocytic but can be hypochromic with microcytosis
 - Decreased plasma iron
 - Decreased iron-binding capacity
 - Normal or slightly low transferrin saturation
 - Decreased marrow sideroblasts
 - Normal or elevated reticuloendothelial iron
 - Elevated free erythrocyte protoporphyrin
 - Normal or elevated ferritin
- In iron deficiency:
 - Decreased plasma iron
 - Increased iron-binding capacity
 - Decreased transferrin saturation
 - Decreased marrow sideroblasts
 - Decreased reticuloendothelial iron
 - Increased free erythrocyte protoporphyrin
 - Decreased serum ferritin
- In **both** iron deficiency and anemia of chronic disease:
 - Decreased plasma iron
 - Decreased transferrin saturation
 - Decreased marrow sideroblasts
 - Elevated free erythrocyte protoporphyrin
 - Decreased reticulocyte count
- Tests that help differentiate iron deficiency from anemia of chronic disease:
 - Iron-binding capacity
 - Serum ferritin
 - Reticuloendothelial iron stain in marrow

**TREATMENT****GENERAL MEASURES**

- Iron:
 - Generally, no role for iron therapy unless there is coexisting iron-deficiency anemia. However, recent studies in patients with renal disease have shown improved response to erythropoietin with coadministration of parenteral iron.
- Recombinant human erythropoietin:
 - Effective, but indications for use are still not universally accepted
 - Often used in chronic renal failure
 - Has been used in inflammatory bowel disease, with good results
 - Should be used for more severe and symptomatic anemia in which the underlying disease is likely to be prolonged and difficult to treat
- Treatment should be directed at the underlying disease process.

SPECIAL THERAPY

Transfusion of packed RBCs is sometimes indicated intermittently in severe anemia with hemodynamic compromise.

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

Treatment of underlying disease process may promote slow resolution of associated anemia. Hematocrit increases ~6–8 weeks after start of recombinant human erythropoietin therapy; continues to rise over 6 months.

COMPLICATIONS

If severe, patients may be transfusion dependent and, thus, be at risk for complications associated with packed RBC transfusions.

**CODES****ICD9**

- 281.3 Other specified megaloblastic anemias not elsewhere classified
- 283.0 Autoimmune hemolytic anemias
- 285.29 Anemia of other chronic disease

ICD10

- D53.1 Other megaloblastic anemias, not elsewhere classified
- D59.1 Other autoimmune hemolytic anemias
- D63.8 Anemia in other chronic diseases classified elsewhere

FAQ

- Q: Does anemia that is associated with a chronic disease require further evaluation?
- A: If the anemia fits within the usual expectations for the patient's diagnosis, there is no need to pursue further investigation, except in specific cases. If there is an associated malignancy for which marrow metastasis is possible, a bone marrow aspirate and biopsy should be done. In conditions with malabsorption, nutritional deficiencies, and blood loss should be ruled out.

ANICRYPTOCOCCAL INFECTIONS

Samir S. Shah

BASICS

DESCRIPTION

Cryptococcosis, an opportunistic fungal infection caused by *Cryptococcus neoformans*, may involve several organ systems, including the CNS, lungs, bones, visceral organs, and skin.

EPIDEMIOLOGY

- Most pediatric infections occur in immunocompromised hosts, including those with malignancy, HIV, and solid organ or bone marrow transplantation; 20% of infections requiring hospitalization occur in normal hosts.
- There is no person-to-person spread of the infection.

Incidence

- Occurs in 5–15% of HIV-infected adults, usually with CD4+ lymphocyte counts <50 cells/mm³. Occurs in 0.8–2.3% of HIV-infected children. The lower infection rate in children reflects their lower exposure to sources of *Cryptococcus neoformans*. The overall seroprevalence is 0% in neonates and 4.1% in school-age children, compared to 69% in adults.
- 1–3% of solid-organ transplant recipients develop *Cryptococcus neoformans* infections; typically >1 year after transplantation.

GENERAL PREVENTION

- Most studies on prevention address HIV-infected patients.
- Use of highly active antiretroviral therapy (HAART) prevents most cases of cryptococcosis in HIV-infected patients.
- Primary prophylaxis with fluconazole prevents new-onset cryptococcal disease in HIV-infected patients. However, primary prophylaxis is not routinely recommended except for those with limited access to HAART and those with high levels of antiretroviral drug resistance.
- Maintenance (suppressive) therapy after completion of therapy for cryptococcal infection is recommended for HIV-infected patients. In those with low CD4+ lymphocyte counts, relapse rates are 100% without maintenance antifungal therapy, 18–25% with amphotericin B or itraconazole, and 2–3% with fluconazole.
 - Prophylaxis may be discontinued in patients receiving HAART with CD4+ lymphocytes >100 /mm³ and undetectable viral loads.
- There is no consensus on the duration of fluconazole suppressive therapy after treatment of cryptococcosis in HIV-negative immunocompromised patients. Most experts provide maintenance (suppressive) antifungal therapy with fluconazole PO (6 mg/kg/d) for at least 1 year after the completion of acute treatment and then reassess its ongoing use based on the level of current immunosuppression.

PATHOPHYSIOLOGY

- Primary infection occurs through the inhalation of aerosolized soil particles containing the yeast forms. The skin and gastrointestinal tract are also portals of entry.
- Protective immune response requires specific T-cell-mediated immunity.
- CNS infection with *Cryptococcus neoformans* results from hematogenous dissemination.

COMMONLY ASSOCIATED CONDITIONS

- *Cryptococcus neoformans* is the most common cause of fungal meningitis in the US.
- Disseminated infection occurs more commonly among immunocompromised hosts.
- Concurrent *Pneumocystis carinii* pneumonia was detected in 13% of adults with cryptococcal meningitis.
- Pulmonary involvement is asymptomatic in up to 50% of cases, and disease may be either focal or widespread.
- Bone involvement occurs in 10% of cases of disseminated cryptococcal infection.
- Cutaneous involvement mimics acne-type eruptions that ulcerate and results from hematogenous spread of the organism or from direct extension of bone infection.

DIAGNOSIS

HISTORY

- Cryptococcal meningitis may present as either an indolent infection or acute illness.
- Symptoms of cryptococcal meningitis include headache, malaise, and low-grade fever. Nausea, vomiting, altered mentation, and photophobia are less common. Stiff neck, focal neurologic symptoms (e.g., decreased hearing, facial nerve palsy, or diplopia), and seizures are rare.
- Primary pulmonary cryptococcal disease is not well described in children because most cases are disseminated at the time of diagnosis. 50% of adults have cough or chest pain, and fewer have sputum production, weight loss, fever, and hemoptysis.
- In immunocompromised hosts, the onset of infection is more rapid and the course more severe. Pulmonary involvement is minimal when dissemination occurs quickly.

PHYSICAL EXAM

- None of the presenting signs of cryptococcal infection are sufficiently characteristic to distinguish it from other infections, particularly in immunocompromised patients.
- CNS involvement: Nuchal rigidity, photophobia, and focal neurologic deficits
- Respiratory tract involvement: Cough, tachypnea, grunting, and subcostal or intercostal retractions. Decreased breath sounds or dullness to percussion may be present, or the lung exam may be normal.
- Cutaneous manifestations: Erythematous or verrucous papules, nodules, pustules, acneiform lesions, ulcers, abscesses, or granulomas. Lesions can occur anywhere on the body, but are found most often on the face and neck.
 - Mucocutaneous findings are present in 10–15% of cases of disseminated disease.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Lumbar puncture: Diagnose cryptococcal meningitis:
 - CSF should be sent for cell count and differential; protein; glucose; cultures for bacterial, fungal, and viral pathogens; and cryptococcal antigen (India ink stain is less commonly performed).
 - Examination of the CSF reveals <500 WBC/mm³ (usually <100 WBC/mm³), mostly mononuclear leukocytes, with minimal changes in protein. CSF glucose is <50 mg/dL in ~65% of patients.
 - Budding yeast are seen on India ink stain in 50% of cases.
 - CSF cultures are positive in ~90% of patients.
 - The latex agglutination test for cryptococcal polysaccharide antigen is specific, sensitive, and rapid. Titers $\geq 1:4$ suggest the diagnosis of cryptococcal infection if appropriate controls (to exclude the presence of rheumatoid factor or other nonspecific agglutinins) are negative.
 - HIV-infected patients with pneumonia and CD4+ T-lymphocyte counts <200 cells/mm³ should be evaluated with sputum fungal culture, blood fungal culture, and a serum cryptococcal antigen test. A lumbar puncture to exclude the possibility of occult meningitis should be considered. If any test is positive for *Cryptococcus neoformans*, then a lumbar puncture should be performed to exclude cryptococcal meningitis.
 - Blood culture and serum cryptococcal antigen titers: Diagnose disseminated cryptococcal infection. Serum cryptococcal antigen tests are positive in $>85\%$ of patients with cryptococcal meningitis.
 - Sputum culture: Diagnose cryptococcal pneumonia.
 - Skin or bone biopsy: Diagnose cutaneous or osteoarticular cryptococcal infection.
 - HIV testing: Evaluation for immunodeficiencies, including HIV, is warranted in any patient with cryptococcosis.
 - CBC with differential: May reveal hypereosinophilia (absolute eosinophil count $>1,500$ /mm³)
 - Serum electrolytes: Detect hyponatremia, a complication of cryptococcal meningitis.
- #### Imaging
- Chest x-rays (anteroposterior and lateral): Nodules, diffuse infiltrates, and pleural effusions may be seen in cryptococcal pneumonia.
 - Head CT or MRI: May demonstrate granulomatous lesions (cryptococcomas; ~15% of patients with meningitis) or elevated intracranial pressure. MRI reveals dilation of perivascular spaces in almost half the cases.

DIFFERENTIAL DIAGNOSIS

- Although cryptococcosis occurs most commonly in HIV-infected patients with low CD4+ lymphocyte counts, the diagnosis warrants consideration in all febrile immunocompromised children (e.g., solid-organ transplant, leukemia)
- Meningitis: Viruses and *Mycobacterium tuberculosis*
- Pneumonia: Other pulmonary mycoses, including aspergillosis, histoplasmosis, and blastomycosis. Also consider *Mycoplasma pneumoniae* and *Mycobacterium tuberculosis*.
- Bone: Osteogenic sarcoma
- Cutaneous: Molluscum contagiosum, herpes simplex virus infection, pyoderma gangrenosum, and cellulitis

**TREATMENT****ADDITIONAL TREATMENT****General Measures**

- Clinical management depends on extent of disease and immune status of the host.
- Pulmonary and extrapulmonary disease, HIV-negative, nontransplant:
 - Normal hosts with isolated pulmonary nodules may not need treatment if the serum cryptococcal antigen is negative and the patient is asymptomatic.
 - Patients with symptoms, extensive pulmonary disease, or evidence of extrapulmonary disease require treatment.
 - Fluconazole 6–12 mg/kg/d PO (max 400 mg) for 6–12 months for mild/moderate disease. Alternate regimen: Itraconazole 4–10 mg/kg/d PO (max 400 mg) for 6–12 months (monitor drug levels); or amphotericin B 0.7–1 mg/kg/d PO for 3–6 months.
 - Same as CNS for severe disease
 - Maintenance therapy with fluconazole should be considered for immunocompromised patients (see “Prevention”).
- CNS, HIV-negative, non-transplant:
 - Induction/consolidation: Amphotericin B (0.7–1 mg/kg/d) plus flucytosine (100–150 mg/kg/d PO, divided q6h) for 4 weeks, then fluconazole PO (10–12 mg/kg/d) for a minimum of 8 weeks followed by maintenance therapy with fluconazole PO (6 mg/kg/d) for 6–12 months. Alternate induction/consolidation regimen: Amphotericin B plus flucytosine for 6–10 weeks.
- Pulmonary and extrapulmonary disease, HIV-infected, or transplant:
 - Fluconazole (PO) 6–12 months for mild/moderate disease; same as CNS infection for severe disease.
 - Consider surgical débridement for patients with persistent or refractory pulmonary or bone lesions.
- CNS disease, HIV-infected or transplant:
 - Induction/consolidation: Amphotericin B (IV) plus flucytosine (PO) for at least 2 weeks, followed by fluconazole PO (10–12 mg/kg/d) for at least 8 weeks; consider subsequent suppressive therapy with fluconazole PO (6 mg/kg/d)
 - Intrathecal amphotericin B is very toxic but may be used in refractory cases.

- HIV-infected patients require continuation of antifungal drugs indefinitely because of the high recurrence rate of cryptococcosis.
- Liposomal amphotericin (5 mg/kg/d) or amphotericin B lipid complex (5 mg/kg/d) IV may be substituted for amphotericin B, especially in patients with pre-existing renal dysfunction and those receiving calcineurin inhibitors.
- Flucytosine is used only in combination with amphotericin B and not as a single agent because of the rapid emergence of drug resistance.
- Voriconazole, a new triazole antifungal agent, demonstrates excellent in vitro activity against *Cryptococcus neoformans* but requires clinical study. Caspofungin, a new echinocandin antifungal agent, is not active against *Cryptococcus neoformans*.

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

- Because of the risk of relapse, patients should be seen at 3-month intervals for 12–18 months following treatment. Immunocompromised patients should be evaluated every 2–3 months, even while on suppressive therapy, to monitor clinically for relapse.
- Repeat lumbar punctures documenting a decrease in CSF cryptococcal antigen and sterility of culture are useful in evaluating response to treatment. During therapy for acute meningitis, an unchanged or increased titer of CSF antigen correlates with clinical and microbiologic failure to respond to treatment. Serum antigen titers are not helpful for this purpose.
- Evaluate patients with cryptococcal meningitis for neurologic sequelae.
- HIV-infected patients require suppressive antifungal therapy (see “Prevention”).

PROGNOSIS

- Mortality is rare in patients with isolated pulmonary or cutaneous disease.
- In-hospital mortality is ~20% for cryptococcal meningitis and ~8% for non-CNS cryptococcal infections.
 - In normal hosts with meningitis, poor prognostic factors include serum or CSF cryptococcal titers >1:32 or CSF WBC <20/mm³.
 - In HIV-infected patients with meningitis, poor prognostic factors include hyponatremia, concomitant growth of *Cryptococcus neoformans* from another site, increased intracranial pressure, and any alteration of mental status.
- Up to 40% of patients with cryptococcal meningitis have residual neurologic deficits.
- Relapse rates are high in HIV-infected patients (see “Prevention”).

COMPLICATIONS

- Elevated intracranial pressure with meningitis.
- Pulmonary, cutaneous, and bone involvement may occur (see “Associated Conditions”).
- In solid-organ transplant patients, those receiving tacrolimus immunosuppression are less likely to have CNS involvement and more likely to have skin, soft tissue, or osteoarticular involvement.

**CODES****ICD9**

- 117.5 Cryptococcosis
- 321.0 Cryptococcal meningitis

ICD10

- B45.1 Cerebral cryptococcosis
- B45.9 Cryptococcosis, unspecified

FAQ

- Q: What are the sources of *Cryptococcus* in nature?
- A: Pigeon droppings and soil. Naturally acquired infections occur in lower mammals, especially cats. However, neither animal-to-human nor human-to-human infections have been reported.
- Q: Should all children with *Cryptococcus* be evaluated for immunodeficiency?
- A: Yes.

ANKYLOSING SPONDYLITIS

Timothy Beukelman

Randy Q. Cron

Eric Hanson (5th edition)

BASICS

DESCRIPTION

An inflammatory arthritis that tends to be asymmetric peripherally and involve the insertion of tendons and ligaments and the sacroiliac joints and spine

EPIDEMIOLOGY

- Typically affects adolescent boys
- Much less common in blacks:
 - HLA-B27 occurs in 70–90% of patients, and is present in 8% of whites and 6% of blacks in the general population.

Prevalence

~1/10,000 white boys

RISK FACTORS

Genetics

- HLA-B27 associated
- Usually a family history of a male relative with disease

PATHOPHYSIOLOGY

Inflammatory synovitis of joints and calcification of the anterior and posterior longitudinal ligaments of the spine

ETIOLOGY

Idiopathic

DIAGNOSIS

- Inflammatory back pain (better with exercise, not relieved by rest) of insidious onset that has been present for at least 6 weeks.
- Inactivity stiffness resulting in gelling of peripheral joints and back

HISTORY

- Pain
- Family history

PHYSICAL EXAM

- Sacroiliac tenderness:
 - Indicates site of inflammation
- Pain on direct palpation at insertion of Achilles tendon and plantar fascia at calcaneal insertion (location of entheses):
 - Indicates site of inflammation

DIAGNOSTIC TESTS & INTERPRETATION

- Schober test of lumbar spine flexibility:
 - Mark 15-cm span at mid-lower back at level of iliac crest while patient is standing.
 - Have patient flex back as far as possible.
 - Re-measure span.
 - Abnormal if <5 cm increase in span

Lab

CBC, erythrocyte sedimentation rate (ESR), HLA-B27, rheumatoid factor (RF), and antinuclear antibody (ANA) tests:

- ESR is occasionally not elevated.
- RF and ANA are typically negative.

Imaging

Sacroiliac views:

- Demonstrate evidence of pseudo-widening, erosions, and/or sclerosis, with fusion being a late finding. Because x-ray findings may take years to develop in the presence of disease, MRI is supplanting x-ray as the initial modality to assess SI involvement in some centers.

DIFFERENTIAL DIAGNOSIS

- Caution:
 - Over-diagnosis in HLA-B27–positive individuals in whom other causes for joint swelling should be considered
- Infection:
 - Reactive arthritis caused by enteric pathogens or *Chlamydia* species
 - Whipple disease
 - Intestinal-bypass–associated arthritis
 - Discitis
 - Pott disease
- Tumors:
 - Osteoid osteoma
- Trauma:
 - Traumatic injury causing lower back pain/spasm
 - Herniated disc
- Metabolic:
 - Ochronosis
- Congenital:
 - Kyphosis
- Immunologic:
 - Inflammatory bowel disease–associated arthropathy
 - Oligoarticular juvenile idiopathic arthritis
- Psychologic:
 - Feigning lower back pain/stiffness
- Miscellaneous:
 - Psoriasis-associated arthritis

TREATMENT

MEDICATION (DRUGS)

- NSAIDs:
 - Naproxen
 - Indomethacin
 - Diclofenac
- Disease-modifying drugs:
 - Sulfasalazine
 - Methotrexate
 - Leflunomide
 - Tumor necrosis factor inhibitors

ADDITIONAL TREATMENT

General Measures

- Therapy may need to be lifelong.
- After initiation of therapy, should see some improvement in stiffness, synovitis, and range of motion over weeks to several months

Additional Therapies

Physical therapy:

- Physical therapy is an essential component of treatment.
- Must encourage range-of-motion exercises and avoid prolonged neck flexion.

SURGERY/OTHER PROCEDURES

In advanced cases, total hip replacement, C-spine fusion, and/or spinal wedge osteotomy (the latter if posture is severely affected).

ONGOING CARE

DIET

- Food intake should be good with NSAIDs.
- Ensure folate intake with methotrexate.

PATIENT EDUCATION

Activity:

- As tolerated. In cases of severe/advanced disease, modify behaviors accordingly in consideration of reduced spine flexibility and subsequent risk of serious injury.

PROGNOSIS

Poor if disease remains active for 10 years or more

COMPLICATIONS

- Acute anterior uveitis
- Aortic insufficiency
- Worsening stiffness
- Ankylosis with risk of vertebral subluxation, fracture, and nerve damage, including cauda equina syndrome
- Acute or chronic eye pain
- Chest pain or shortness of breath

CODES

ICD9

720.0 Ankylosing spondylitis

ICD10

- M08.1 Juvenile ankylosing spondylitis
- M45.9 Ankylosing spondylitis of unspecified sites in spine

FAQ

- Q: Should HLA-B27 be checked routinely in boys with back pain?
- A: Detection of HLA-B27 alone should not precipitate an extensive workup because it is so common in the normal healthy population. However, the risk for developing a spondyloarthropathy is 16 times greater than in HLA-B27–negative individuals.
- Q: Can affected individuals play contact sports?
- A: This is probably not a good idea because as the spine fuses, the risk for fracture of the spine (especially the cervical spine) increases. However, children with milder forms of disease, such as enthesitis related arthritis, should not be discouraged.

ANOMALOUS CORONARY ARTERY

Shellie M. Kendall

Geoffrey L. Bird (5th edition)

BASICS

DESCRIPTION

The anomalous coronary artery arises from the pulmonary artery rather than the aorta. Most commonly, the left coronary is the anomalous artery.

EPIDEMIOLOGY

Incidence

Very rare anomaly. Occurs in 0.25% of congenital heart disease.

Prevalence

The majority of patients present in infancy, at around the age of 2 months. The literature contains case reports of patients presenting as old as during the 4th to 7th decades of life.

PATHOPHYSIOLOGY

- In the neonatal period, pulmonary artery pressure is increased owing to elevated pulmonary vascular resistance. Initially this elevated pulmonary artery pressure provides antegrade flow from the pulmonary artery through the anomalous coronary artery. As pulmonary vascular resistance drops, pulmonary artery pressure drops. When the diastolic blood pressure in the pulmonary artery is lower than the myocardial perfusion pressure (diastolic aortic pressure), pulmonary runoff “steals” blood from the myocardium, resulting in myocardial ischemia.
- The fact that the left ventricle is perfused with desaturated blood plays a less important role than the overall perfusion-related imbalance between myocardial oxygen demand and supply.

ETIOLOGY

- Abnormal septation of the conotruncus into the aorta and pulmonary artery
- Persistence of the pulmonary buds and involution of the aortic buds that will eventually form the coronary arteries
- As-yet-unspecified genetic predisposition

DIAGNOSIS

HISTORY

- Typically presents with paroxysms of poor feeding, pallor, tachypnea, and diaphoresis
- Irritability, crying, appearance of being in pain (especially after meals)
- Congestive heart failure
- Can be asymptomatic
- Can be symptomatic in infancy and then gradually improve (with the development of adequate coronary collateralization)
- Older children and adults may have dyspnea, syncope, or angina pectoris
- Sudden death

PHYSICAL EXAM

- Signs of congestive heart failure (e.g., cachexia, tachycardia, tachypnea, lethargy, diaphoresis)
- Loud P₂ component of S
- Gallop rhythm
- Murmur of mitral regurgitation, or a continuous murmur reminiscent of a coronary arteriovenous fistula
- Diagnosis should be entertained in any infant presenting with cardiomegaly or perplexing cardiorespiratory symptoms.

DIAGNOSTIC TESTS & INTERPRETATION

Imaging

- Chest radiograph: Cardiomegaly, pulmonary edema
- Nuclear imaging: Thallium myocardial perfusion imaging shows reduced uptake in ischemic regions.
- Electrocardiography: Anterolateral infarct pattern in an infant (Q in I, aVL, V₄–V₆), abnormal R-wave progression in precordial leads
- Echocardiogram: Attachment of coronary artery to pulmonary artery by 2-dimensional imaging. Doppler interrogation shows flow passing from coronary artery to great artery rather than vice versa.
 - Dilation of the right coronary artery
 - Left ventricular function impairment, wall motion abnormalities, and dilation
 - Mitral regurgitation
 - Echogenic papillary muscles

Diagnostic Procedures/Other

- Cardiac catheterization: Angiographic and hemodynamic parameters may correlate with degree of cardiovascular dysfunction.
 - Low cardiac output
 - High left atrial filling pressures
 - Pulmonary arterial hypertension
- Aortic root angiography shows passage of contrast medium from normally connected right coronary artery to the left coronary arterial system to the pulmonary artery.
- Pulmonary artery angiogram shows reflux of contrast medium into the left coronary artery and/or a “negative wash-in” of unopacified blood flowing from left coronary to pulmonary artery.
- Coronary CT angiography: Excellent diagnostic modality for older patients with slower heart rates allowing better resolution.

DIFFERENTIAL DIAGNOSIS

- Cardiomyopathy
- Mitral valve regurgitation
- Left ventricular failure from other causes
- Colic
- Bronchiolitis

TREATMENT

ADDITIONAL TREATMENT

General Measures

The 1st priority is to safely institute supportive care measures while expeditiously planning for surgical intervention. Medical therapy alone has a very limited role in the current era.

SURGERY/OTHER PROCEDURES

- Direct reimplantation of the left coronary artery into the aorta using a button of pulmonary arterial tissue and/or an extension-tube graft of anterior and posterior pulmonary arterial wall tissue sewn into a narrow cylinder to avoid tension, distortion, and stenosis of the coronary
- Creation of an aortopulmonary window and tunnel that directs blood from aorta to the left coronary ostium (Takeuchi procedure).
- Ligation of the origin of the left coronary artery (to prevent flow runoff into the pulmonary artery or “steal”) is less frequently used, even in very ill infants.
- Ligation of the origin of the left coronary artery and reconstitution of flow with saphenous or internal mammary graft is less frequently used in the current era.

IN-PATIENT CONSIDERATIONS

Initial Stabilization

Attention to basic life support measures (airway, breathing, and circulation) and prompt referral to a pediatric cardiac center. An excess of procedures, interventions, and manipulation is poorly tolerated by this group of patients. Even with the full support of a tertiary care center’s experienced team, these measures are fraught with peril.

ONGOING CARE

PROGNOSIS

- Untreated, 65–85% of those who present in infancy will die before the age of 1 year, usually after 2 months of age (when pulmonary vascular resistance falls).
- Very few of those who present early improve spontaneously.
- Late results after surgery are excellent in many centers. Hospital mortality in larger selected series of these frequently moribund patients is $\leq 5\%$, with very little subsequent attrition.
- Mitral regurgitation usually improves after surgery establishes a patent dual-coronary system, but this may take 6–12 months to be fully realized. Follow-up evaluation is warranted, as mitral regurgitation may progress despite surgery, and valve repair may be required later.

CODES

ICD9

746.85 Coronary artery anomaly

ICD10

- Q24.5 Malformation of coronary vessels
- Q25.8 Other congenital malformations of other great arteries

FAQ

- Q: How do you differentiate crying from the symptoms of myocardial ischemia from crying from colic?
- A: This is not easy, but clinical assessment should manifest the signs of CHF, shock, and low cardiac output, which are decidedly atypical for the usual patient with colic. If the patient is still feeding, the crying in patients with this lesion classically occurs after meals, when blood is shunted to the liver and intestines. This is not a highly sensitive finding, and concern should lead to further objective evaluation.

ANOREXIA NERVOSA

Candice P. Chen

BASICS

DESCRIPTION

DSM-IV criteria:

- Refusal to maintain body weight at or above a minimally normal weight (i.e., weight loss or failure to gain weight during a period of growth leading to maintenance of body weight <85% of expected)
- Intense fear of gaining weight or becoming fat, even though underweight
- Disturbance in the way in which one's body weight, shape, or size is perceived; undue influence of body weight or shape on self-esteem; or denial of seriousness of currently low body weight
- In postmenarchal females, amenorrhea
- Types: Restricting (no binge eating or purging) or binge eating/purging

Reprinted with permission from the *Diagnostic and Statistical Manual of Mental Disorders*, 4th ed., text revision (Copyright 2000). American Psychiatric Association.

EPIDEMIOLOGY

Prevalence

- Typically, adolescent girls or young women, although 5–15% of cases are in male patients
- Estimated 0.5–1% of adolescents have an eating disorder.
- Studies indicate that >50% of children and adolescents presenting with a concern of an eating disorder do not meet the full DSM-IV diagnostic criteria but still require treatment.

RISK FACTORS

More prevalent in industrialized societies; occurs in all US household income levels and major ethnic groups.

- Dieting is a possible risk factor for the future development of an eating disorder.
- Adolescents participating in activities that emphasize maintaining a certain weight (e.g., gymnastics, ballet, ice skating, wrestling) are at increased risk.
- Personality traits such as low self-esteem, difficulty expressing negative emotions, difficulty resolving conflict, and perfectionist tendencies are associated with an increased risk.

Genetics

Family and twin studies indicate a genetic component. A relative of a person with an eating disorder has a 10× greater lifetime risk of developing an eating disorder.

GENERAL PREVENTION

When counseling on obesity, take care not to foster overaggressive dieting. Help children and adolescents build self-esteem while addressing their weight concerns.

PATHOPHYSIOLOGY

- Physical manifestations are generally due to weight loss and malnutrition. In an attempt to conserve energy, the body becomes functionally hypothyroid (euthyroid sick syndrome). Body temperature and heart rate decrease. As cardiac function becomes impaired, orthostasis and hypotension occur. Reduced peripheral circulation causes hair thinning, brittle nails, dry skin, and lanugo.

- Hypothalamic hypogonadism results from malnutrition and stress and causes delayed puberty and amenorrhea. Decreased estrogen and testosterone also contribute to osteoporosis.
- Electrolyte abnormalities generally develop as a result of malnutrition. However, sodium abnormalities may develop owing to dehydration or excess water intake, and hypokalemia may develop secondary to vomiting and/or laxative or diuretic use.

ETIOLOGY

Multifactorial including genetic, neurochemical, psychodevelopmental, and sociocultural factors

COMMONLY ASSOCIATED CONDITIONS

- Depression
- Anxiety disorders
- Substance abuse

DIAGNOSIS

HISTORY

- Question: Have you ever weighed much less than other people thought you should?
 - Patients may try to hide their illness. A negative response does not negate an eating disorder.
- Question: What is the least amount you have weighed in the past year?
 - The reported weight, along with the current height, should be used to calculate a body mass index (BMI).
- Question: Are you afraid of gaining weight?
 - Patients will often report an intense fear of gaining weight.
- Question: How do you think you look?
 - A patient's perceived body image is often distorted. Perceived body image may be significantly misaligned with reality.
- Question in postmenarchal females: Have you ever missed menstrual periods? Have you ever missed 3 in a row?
 - 3 or more missed periods in a row is an indication of amenorrhea.
- Obtain a diet history, including 24-hour diet, history of binge-eating, purging, food restrictions, or calorie counting; use of diuretics, laxatives, diet pills, or emetics; elimination history; exercise history (i.e., how much, intensity); menstrual history; substance use.

PHYSICAL EXAM

- All patients should have a full physical exam with special emphasis on:
 - Vital signs, weight, height, BMI: Patient may have bradycardia, hypotension, orthostasis, or hypothermia; BMI is needed to determine if weight is <85% expected.
 - Physical and sexual growth and development: Patient may be emaciated or have atrophic breasts or delayed puberty.
 - Cardiovascular system: May detect a cardiac arrhythmia, murmur, or evidence of congestive heart failure
 - Dry skin, lanugo, thinning scalp hair, angular stomatitis
 - Salivary gland enlargement or Russell sign (scarring on dorsum of hand): Suggests purging behavior

- Muscular irritability or weakness: May occur with severe malnutrition or use of an emetic
- Evidence of self-injurious behavior: May indicate previous suicide attempts
- All patients need dental exam for enamel erosion and tooth loss due to purging behavior or insufficient calcium intake, respectively.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- All patients with anorexia nervosa:
 - Serum electrolytes, blood urea nitrogen/creatinine: Most are normal, may show dehydration or sodium or potassium abnormalities
 - TSH; if indicated, free T₄, T₃: To rule out thyroid disease
 - CBC with differential: Mild anemia is common due to iron or folate deficiency; WBC count is generally low due to malnutrition.
 - ESR: Generally low due to malnutrition
 - AST, ALT, alkaline phosphatase: Occasionally abnormal due to fatty liver
 - Urinalysis: Evaluate specific gravity to assess for dehydration that may be seen with purging or diuretic use.
 - Malnourished and severely symptomatic patients:
 - Complement component 3a: May indicate nutritional deficiencies when other markers are within normal ranges
 - Serum calcium, magnesium, phosphorous: May all be low; in hospitalized patients follow phosphorous daily to assess for refeeding syndrome.
 - Serum ferritin: May be low
 - Electrocardiogram: May have bradycardia, ST-T wave abnormalities with hypokalemia, increased PR interval and 1st-degree heart block, prolonged QTc
 - 24-hour urine for creatinine clearance: Generally low, normal may indicate azotemia
 - Patients amenorrheic for >6 months:
 - Dual-energy x-ray absorptiometry (DEXA) scan: Evaluates bone density to determine risk of compression fracture and bone loss
 - Nonroutine assessments:
 - Toxicology screen, if suspect substance use
 - Serum amylase, fractionated for salivary gland isoenzyme: If available, with vomiting, will be elevated
 - Serum LH, FSH, prolactin, if persistent amenorrhea with normal weight: LH and FSH will generally be low.
 - β-HCG: Rule out pregnancy.
 - Stool for guaiac, if suspected GI bleed
 - Stool or urine for bisacodyl, emodin, aloë-emodin, and rhein, if suspected laxative abuse
- ### DIFFERENTIAL DIAGNOSIS
- Oncologic: Brain tumor, other cancers
 - Gastroenterologic: Inflammatory bowel disease, celiac disease
 - Endocrinologic: Diabetes mellitus, thyroid disease, hypopituitarism, Addison disease
 - Psychiatric: Depression, obsessive-compulsive disorder, substance abuse
 - Other chronic diseases or infections
 - Superior mesenteric artery syndrome (can also be a consequence of eating disorder)

TREATMENT

MEDICATION (DRUGS)

Medications should be used in conjunction with nutritional and psychosocial treatment, not as the primary or sole modality of treatment. If possible, defer medications until weight has been restored.

- Antidepressants to treat persistent depression or anxiety:
 - SSRIs have the most evidence for efficacy.
 - Do not use bupropion in patients with eating disorders because of an increased risk of seizures in patients with eating disorders.
 - Avoid tricyclic antidepressants and MAOIs owing to potential lethality and toxicity with overdose.
- Consider 2nd-generation and low-potency antipsychotics for select patients with severe symptoms such as severe resistance to gaining weight, severe obsessive thinking, and/or disease denial that approaches delusional status.

ADDITIONAL TREATMENT

Psychosocial treatment:

- Goals: Understand and change behaviors and attitudes related to eating disorder, improve interpersonal and social functioning, address comorbid psychopathology
- Psychotherapy: Individual, family, group. Evidence suggests outcomes are better for family therapy than individual therapy for adolescents.

ISSUES FOR REFERRAL

The treatment of anorexia generally involves a multidisciplinary team, including a pediatrician, a nutritionist, and a psychiatrist. In some areas, patients may also be referred to pediatricians who specialize in eating disorders.

IN-PATIENT CONSIDERATIONS

Admission Criteria

Criteria for inpatient hospitalization:

- Weight <75% ideal body weight or weight loss despite treatment; food refusal; body fat <10%; daytime heart rate <50 bpm; nighttime heart rate <45 bpm; systolic blood pressure <90 mm Hg; orthostatic hypotension; temperature <96°F; arrhythmia
- Additional factors to consider: Suicidality, other psychiatric disorders requiring hospitalization, severe substance use disorder, uncontrolled vomiting, hematemesis, weight close to previous weight where patient became medically unstable

Discharge Criteria

Patient is medically stable. Evidence indicates that patients who reach 90% of their recommended average body weight before discharge have lower readmission rates.

ONGOING CARE

DIET

Nutritional treatment:

- Goals: Restore weight, normalize eating patterns, achieve normal perceptions of hunger and satiety, correct malnutrition
- Establish target weight and rate of weight gain: Goal is weight at which menstruation is restored or normal physical and sexual development resume.
- Usually begin intake at 30–40 kcal/kg/d, may increase to 70–100 kcal/kg/d. Weight gain goal 0.25–1 kg/wk is realistic.
- In severely malnourished patients, avoid refeeding syndrome by starting slowly, generally 1,000–1,600 kcal/d, increasing by 200–400 kcal/d.
- Reserve NG feeds for patients with extreme difficulty recognizing their illness, those refusing treatment, or those with eating-associated guilt.
- Evaluate and treat GI symptoms including constipation, bloating, and abdominal pain. Stool softeners and polyethylene glycol are treatments of choice. Avoid stimulant laxatives.
- Add vitamin and mineral supplements (e.g., phosphorous, calcium); may require acute supplementation.
- When desired weight is achieved, calculate ongoing caloric intake based on weight and activity (usually 40–60 kcal/kg/d).

PATIENT EDUCATION

Help limit physical activity and caloric expenditure if exercise is a significant component of the patient's illness.

PROGNOSIS

Adolescent outcomes are better than adult outcomes. One study following adolescents hospitalized for anorexia nervosa showed 86.3% with partial or complete recovery at 10–15-year follow-up. However, the median time to partial recovery was 57.4 months.

COMPLICATIONS

- Fluid and electrolyte imbalances
- Rapid refeeding of severely malnourished patients (refeeding syndrome) can cause hypophosphatemia, leading to cardiac failure, stupor and coma, and hemolytic anemia.
- Cardiovascular: ECG abnormalities (conduction abnormalities are thought to be the most common proximal cause of death), pericardial effusion; and use of ipecac (an emetic no longer available) was associated with irreversible myocardial damage and diffuse myositis
- GI: Delayed gastric emptying, slow GI motility, bloating, constipation, fatty liver, hypercholesterolemia from abnormal lipoprotein metabolism, and esophagitis or Mallory-Weiss tears from chronic vomiting
- Endocrine: Euthyroid sick syndrome, amenorrhea, osteopenia, growth retardation (may have permanent effects in younger patients)

- Renal: Increased risk of renal stones, polyuria due to abnormal vasopressin secretion; in refeeding, 25% develop peripheral edema due to increased renal sensitivity to aldosterone.
- Hematologic: Anemia, leukopenia, thrombocytopenia
- Neuropsychologic: Cortical atrophy, apathy, poor concentration, cognitive impairment, seizures, peripheral neuropathy

FAQ

- Q: What is the expected inpatient treatment duration?
- A: Duration of hospitalization varies; average is ~5–6 weeks.
- Q: When may the patient return to school?
- A: Generally, weight should be >85% of expected, the student should be medically stable, and the health professional should work with the school administration to ensure a suitable treatment program.
- Q: When may the athlete return to play?
- A: Generally, when weight is >85% of expected, the patient is medically stable, and a suitable treatment plan is in place.

ANTHRAX

Andrew P. Steenhoff

BASICS

DESCRIPTION

Bacillus anthracis is a spore-forming, Gram-positive rod that can cause acute infection (anthrax) in humans and animals.

GENERAL PREVENTION

- Antibiotics are effective against germinating *Bacillus anthracis* but not against the spores. Therefore, if prophylactic antibiotics are stopped prematurely, remaining spores can cause disease when they germinate. This phenomenon of delayed-onset disease does not occur with cutaneous or gastrointestinal exposures.
- Where the threat of transmission of *Bacillus anthracis* spores is deemed credible, decontamination of skin and potential fomites (e.g., clothing) may be considered to reduce the risk for cutaneous and gastrointestinal forms of the disease.
- Anthrax vaccine adsorbed (AVA) is the only licensed human anthrax vaccine in the USA. Primary vaccination consists of subcutaneous injections at 0, 2, and 4 weeks, and 3 booster vaccinations at 6, 12, and 18 months. Annual booster injections are required to maintain immunity. The most common adverse event is injection-site discomfort (e.g., edema, pain, local hypersensitivity).

ALERT

Pulmonary disease caused by anthrax is a hemorrhagic mediastinitis with pleural effusions and not a bronchopneumonia.

EPIDEMIOLOGY

Incidence

- Anthrax is primarily zoonotic. Most naturally acquired anthrax infections are cutaneous (95%). Inhalational (5%) and GI (<1%) forms are particularly rare.
- Prior to October 2001, only 18 cases of inhalational anthrax were reported in the USA during the 20th century.
- No human-to-human spread of inhalational anthrax has been reported.
- Rare cases of human-to-human transmission of cutaneous anthrax have been reported after direct contact with infected skin lesions.
- Anthrax has been used as an agent of bioterrorism.

PATHOPHYSIOLOGY

- After inhalation, wound inoculation, or ingestion, *Bacillus anthracis* spores infect macrophages, germinate, and proliferate.
 - Proliferation occurs at the site of infection and in regional lymph nodes.
 - Replicating bacteria release toxins, leading to edema, hemorrhage, and necrosis.

- Incubation period depends on the route of transmission.
 - Inhalational anthrax: Infection requires inhalation of >8,000 spores; incubation period is 2–60 days.
 - Cutaneous anthrax: Spores enter a cut or abrasion in the skin; incubation period is 1–12 days.
 - Gastrointestinal anthrax: Spores are ingested in undercooked, infected meat; incubation period is 1–7 days; infection occurs in the upper (oropharyngeal lesions) or lower (intestinal lesions) GI tract.
- Hematogenous spread of the bacteria causes infection at other sites, including the CNS, liver, spleen, and kidney.

COMMONLY ASSOCIATED CONDITIONS

If anthrax is intentionally released, physicians must be alert for diseases caused by other potential biologic warfare agents (e.g., plague, tularemia, Q fever, smallpox, and botulism).

DIAGNOSIS

SIGNS AND SYMPTOMS HISTORY

- Inhalational anthrax:
 - Clinical presentation is a 2-stage illness.
 - Initial symptoms are nonspecific and last 1–3 days. They include low-grade fever, dry cough, headache, vomiting, chills, weakness, abdominal pain, and substernal discomfort. This stage may be followed by a brief period of apparent recovery.
 - 2nd-stage symptoms develop abruptly 2–5 days later: fever, hemoptysis, dyspnea, chest pain, and profuse diaphoresis. Death may occur within 1–2 days.
- Cutaneous anthrax:
 - Painless lesions develop on affected areas soon after exposure.
 - Systemic symptoms of fever, malaise, and headache may occur.
- GI anthrax:
 - Oropharyngeal form causes sore throat, dysphagia, and fever.
 - Intestinal form also causes nausea, vomiting, anorexia, severe abdominal pain, and bloody diarrhea.

PHYSICAL EXAM

- Clinical presentation of anthrax in children is varied; rapid diagnosis and effective treatment require recognition of the broad spectrum of clinical presentations
- Inhalational anthrax:
 - Tachypnea, hypoxia, cyanosis
 - Stridor, rales, signs of pleural effusion
 - Hemoptysis, hematemesis, melena

- Cutaneous anthrax:
 - Initial painless, pruritic macule or papule enlarges into a 1–3-cm round ulcer by the second day.
 - 1–3-mm vesicles with clear or serosanguineous fluid surround the ulcer.
 - A painless, depressed, black eschar follows, often with extensive local edema.
 - Over 1–2 weeks, the eschar dries, loosens, and falls off, occasionally with scarring.
 - Painful, regional lymphadenopathy may occur.
- GI anthrax:
 - Unilateral oral or esophageal ulcers, cervical lymphadenopathy
 - Cecal or terminal ileal ulcers (Intestinal anthrax progresses to massive ascites and acute abdomen.)
- Disseminated anthrax (potential complication of any of the above forms of anthrax):
 - Sepsis syndrome: Tachycardia, hypotension, septic shock
 - Meningitis: Meningismus, delirium, obtundation

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Gram-stain smear and culture from vesicular fluid:
 - Diagnose cutaneous anthrax
 - Gram stain reveals large, Gram-positive, boxcar-shaped bacilli.
 - Capsule is visible on polychrome methylene blue stain.
 - *Bacillus anthracis* grows readily on blood agar.
- Anthraxin skin test:
 - Measures anthrax cell-mediated immunity
 - It is positive in 80% of patients within 72 hours of infection and in >95% of cases within 3 weeks.
 - The test was positive in 72% of patients >16 years after recovery.
- Serologic enzyme-linked immunosorbent assay (ELISA):
 - Measures antibodies to the lethal and edema toxins of *Bacillus anthracis*
 - Positive if a single acute-phase titer is >1:32 or if there is a fourfold or greater rise between acute and convalescent titers collected 4 weeks apart
- Polymerase chain reaction, immunohistochemical staining
- Nasopharyngeal swab or induced respiratory secretion culture:
 - Used for epidemiologic investigation
 - The sensitivity, specificity, and predictive value of nasal swab testing are unknown; therefore, this test should not be used to guide the use of postexposure prophylactic antibiotics.
- Blood culture: Patients with cutaneous anthrax may have bacteremia with *Bacillus anthracis* even without significant signs of systemic disease.
- CBC
- Serum electrolytes, glucose, and calcium:
 - Hypokalemia, acidosis, hypoglycemia, and hypocalcemia occurred during experimental anthrax infection in animals.
 - Hemorrhagic meningitis

Imaging

Chest X-ray (or chest CT scan):

- Inhalational anthrax causes a hemorrhagic mediastinitis.
- X-ray shows a widened mediastinum and pleural effusions.
- No infiltrates are present.

DIFFERENTIAL DIAGNOSIS

- The prodromal illness of inhalational anthrax may resemble a lower respiratory tract infection, although upper respiratory infection symptoms are characteristically absent.
- Patients with inhalational anthrax may have a widened mediastinum on chest radiograph which may resemble an aortic aneurysm or bacterial mediastinitis.
- Necrotic skin lesions may resemble plague, tularemia, ecthyma gangrenosum, and brown recluse spider bite.
- GI anthrax may be confused with other infectious causes of enteritis (e.g., *Shigella*, *Salmonella*, *Yersinia*, *Campylobacter*, enterohemorrhagic *Escherichia coli*, *Clostridium difficile*, colitis), intussusception, Meckel diverticulum, and inflammatory bowel disease.

TREATMENT

GENERAL MEASURES

Direct physical contact with a substance alleged to be anthrax:

- Wash exposed skin and articles of clothing with soap and water.
- Administer postexposure prophylaxis until the substance is proved not to be anthrax.
- Contact the public health department or the Centers for Disease Control and Prevention (CDC).

MEDICATION (DRUGS)

- Postexposure prophylaxis: Ciprofloxacin 15 mg/kg (up to 500 mg) or doxycycline 2 mg/kg (up to 100 mg) or levofloxacin 8 mg/kg (up to 250 mg) PO b.i.d. for 60 days. (Pediatric: Use ciprofloxacin for initial prophylaxis. Switch to amoxicillin or penicillin if susceptibility testing permits.)
- Treatment:
 - For all forms of anthrax, begin with IV therapy and switch to oral therapy when clinically appropriate. Treat for 60 days (IV and PO combined).
 - Inhalational or gastrointestinal anthrax: Ciprofloxacin 15 mg/kg (up to 400 mg) or doxycycline 2 mg/kg (up to 100 mg) IV q12h plus clindamycin or rifampin
 - Cutaneous anthrax: Ciprofloxacin or doxycycline IV. (Pediatric: Begin therapy with ciprofloxacin [plus clindamycin or rifampin for inhalational/gastrointestinal anthrax] and convert to penicillin G IV if susceptibility testing permits and when clinical improvement is documented.)

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS PROGNOSIS

- Inhalational anthrax:
 - Case fatality rates were previously estimated to be >85% after symptoms develop. However, early use of appropriate antibiotic therapy appears to improve survival.
 - Survival rate is higher if symptoms develop >30 days after exposure.
- Cutaneous anthrax
 - Case fatality rate is 20% without antibiotic treatment and <1% with antibiotic treatment.
- GI anthrax: Case fatality rate is 25–60%.

COMPLICATIONS

- Antibiotic therapy of cutaneous anthrax limits the likelihood of developing systemic symptoms but does not change the course of the eschar formation.
- Systemic dissemination of inhalational, cutaneous, or gastrointestinal anthrax may lead to sepsis, meningitis, and death.

MISCELLANEOUS

Infection control:

- Immediately notify the hospital epidemiologist, infection control department, or local health department of suspected cases.
- No data suggest that patient-to-patient transmission of inhalational anthrax occurs. Standard barrier isolation precautions are recommended for all hospitalized patients with all forms of anthrax infection. High-efficiency particulate air-filter masks or other measures for airborne precautions are not indicated.
- There is no need to immunize or provide prophylaxis to patient contacts unless they, like the patient, were exposed to the aerosol.
- If anthrax is used as a bioweapon, spores may be detected on environmental surfaces. Inhalational anthrax is unlikely to be caused by secondary aerosolization of these spores.

ICD-9 CODES

- 022.0 Cutaneous anthrax
- 022.1 Pulmonary anthrax
- 022.9 Anthrax, unspecified

ICD10

- A22.0 Cutaneous anthrax
- A22.1 Pulmonary anthrax
- A22.9 Anthrax, unspecified

FAQ

- Q: Does the government have a plan in place if there were mass exposure to anthrax?
- A: Yes. Under emergency plans, the federal government would ship appropriate antibiotics from its stockpile to wherever they are needed.
- Q: Should individuals ask their physicians to write a prescription for ciprofloxacin (or other antibiotic) so they have prophylaxis available?
- A: No. Ciprofloxacin and other antibiotics should not be prescribed unless there is a clearly indicated need. In addition, indiscriminate prescribing and widespread use of ciprofloxacin could hasten the development of drug-resistant organisms.
- Q: Can a person get screened or tested for anthrax?
- A: No screening test is available to determine whether anthrax exposure has occurred. The only way exposure can be determined is through a public health investigation.
- Q: What are the clues to differentiate pulmonary or inhalational anthrax from RSV in children?
- A: Children with pulmonary anthrax display a high WCC with left shift compared to the relatively normal WCC of those with RSV. Blood O₂ levels may be severely depressed in inhalational anthrax.

APLASTIC ANEMIA

Alexis Teplick

Janel L. Kwiatkowski (5th edition)

BASICS

DESCRIPTION

- A heterogeneous disorder within the bone marrow failure syndromes
- Characterized by a marked decrease or absence of blood precursors in the bone marrow and peripheral pancytopenia. The disorder exists in both acquired and congenital forms.

EPIDEMIOLOGY

Incidence

- Annual incidence of 2 new cases per 1 million in US and Europe
- Incidence in Asia is ~3-fold higher than in West, likely owing to environmental exposures or infectious agents.
- ~80% of cases are acquired, and 20% of cases are due to inherited bone marrow failure syndromes.

Prevalence

- Two major age peaks: 15–25 years and >60 years
- Male = female in acquired cases; males may be slightly overrepresented in hereditary cases.

RISK FACTORS

Genetics

- Acquired cases have been associated with specific histocompatibility antigens (human leukocyte antigen-DR2 twice as frequent in aplastic anemia patients as in the unaffected population), as well as with polymorphisms in genes encoding cytokines and with upregulation of the transcription factor T-bet.
- May be associated with heritable conditions including Fanconi anemia, dyskeratosis congenita, and others

PATHOPHYSIOLOGY

- An inciting event, such as infection or medication, provokes an aberrant immune response with oligoclonal expansion of cytotoxic T lymphocytes.
- Aberrant cytokine production by T lymphocytes suppresses hematopoietic cell proliferation and triggers apoptosis of CD34⁺ progenitor cells.
- This results in a marked reduction in the number of hematopoietic stem cells (CD34⁺).
- Stromal (supporting) cells within the bone marrow microenvironment are usually normal.

ETIOLOGY

- Acquired:
 - Idiopathic (70% of cases)
 - Idiosyncratic drug side effects (e.g., chloramphenicol, nonsteroidal anti-inflammatory drugs, antiepileptics, quinacrine, cimetidine)
 - Hepatitis (usually non-A, non-B, and non-C)
 - HIV-1, EBV, human herpes virus-6, CMV
 - Chemicals/toxins such as insecticides (dichlorodiphenyltrichloroethane [DDT], parathion); benzene, carbon tetrachloride
 - Radiation
 - Malnutrition: Kwashiorkor, marasmus, anorexia nervosa
 - Paroxysmal nocturnal hemoglobinuria (PNH)
 - Pregnancy
 - Autoimmune mechanisms
 - Preleukemia, myelodysplastic syndrome (MDS)

- Congenital:
 - Fanconi anemia
 - Dyskeratosis congenita
 - Shwachman-Diamond syndrome
 - Reticular dysgenesis
 - Amegakaryocytic thrombocytopenia
 - Familial

DIAGNOSIS

HISTORY

- Evidence of bone marrow failure:
 - Pallor, lethargy, easy fatigue, weakness, and loss of appetite are signs of anemia. These may not be noticed by patient/parent owing to slow onset of anemia (with compensation).
 - Petechiae, easy and excessive bruising, prolonged epistaxis, gingival bleeding, hematuria, and bloody stools are signs/symptoms of thrombocytopenia.
 - Infections that do not respond to antibiotics, oral ulcers, and gingival hyperplasia may be signs of neutropenia.
- Evidence of cause:
 - Drug or toxin exposure (although usually not identified)
 - History of hepatitis, jaundice, or other viral infections

PHYSICAL EXAM

- Cachexia suggests another etiology, such as malignancy.
- Excessive bruising, petechiae, and pallor as signs of severe thrombocytopenia and anemia. Skin hyper- or hypopigmentation may be seen with Fanconi anemia.
- Oral mucosal ulcerations and bleeding, thrush, palatal petechiae, and gingival hypertrophy as signs of neutropenia and thrombocytopenia
- Tachycardia and systolic ejection murmur from anemia
- Lymphadenopathy and hepatosplenomegaly suggest acute leukemia/malignant process and are not associated with aplastic anemia.
- Perianal ulcerations/infection from neutropenia
- Skeletal anomalies and dysmorphic features may be signs of Fanconi anemia.
- Classic triad of dyskeratosis congenita includes dystrophic nails, lacy reticular pigmentation, and oral leukoplakia (75% of patients with DC will have at least one of these).

DIAGNOSTIC TESTS & INTERPRETATION

Lab

To confirm the diagnosis:

- CBC with differential and reticulocyte count
 - Severe aplastic anemia (at least 2 of the following)
 - Granulocyte count <500/mm³
 - Platelet count <20,000/mm³
 - Reticulocyte count (corrected for hematocrit) <1%
 - Very severe aplastic anemia, as above but granulocyte count <200/mm³
 - Mild or moderate aplastic anemia (hypoplastic anemia), less severe cytopenias

- Supplemental laboratory studies: Liver function tests; hepatitis A, B, and C antibody panel; viral serologies (e.g., Epstein-Barr virus, parvovirus B19 [IgG and IgM], varicella zoster virus, cytomegalovirus, human immunodeficiency virus, human herpes virus-6)

To exclude other causes:

- Bone marrow aspirate for chromosomal analysis to rule out MDS, acute leukemia
- Diepoxybutane chromosome breakage study (on peripheral blood) for Fanconi anemia
- Flow cytometry performed on red cells and granulocytes to exclude PNH
- Telomere length profile to evaluate for dyskeratosis congenita (telomere length extremely short in this disorder)
- Red cell folate and vitamin B₁₂ levels to detect deficiency causing pancytopenia with macrocytosis

Imaging

Usually not needed. Magnetic resonance imaging of thoracic and lumbar spine will show increased fatty infiltration of marrow space; helpful when bone marrow aspirate shows patchy cellularity.

Diagnostic Procedures/Other

Bone marrow aspirate and biopsy

Pathological Findings

Bone marrow aspirate and biopsy in severe aplastic anemia marrow will be hypocellular with fatty infiltration, <25% cellularity on biopsy.

DIFFERENTIAL DIAGNOSIS

- Acute leukemia
- MDS
- PNH
- Folate or B₁₂ deficiency (macrocytic anemia)
- Acute drug reaction with bone marrow suppression
- Acute infection (viral) with bone marrow suppression (e.g., HIV-1, cytomegalovirus, parvovirus B19, EBV)
- Marrow infiltration by malignant tumors (e.g., non-Hodgkin lymphoma, neuroblastoma)
- Hemophagocytic lymphohistiocytosis (i.e., familial erythrophagocytic lymphohistiocytosis)

TREATMENT

MEDICATION (DRUGS)

First Line

Antithymocyte globulin (ATG) and cyclosporine are 1st-line medications for treatment of severe aplastic anemia in those without an HLA-identical sibling donor.

Second Line

For refractory aplastic anemia:

- Repeat course of ATG/cyclosporine
- Stem cell transplantation from unrelated donor
- High-dose cyclophosphamide
- Alemtuzumab (a humanized monoclonal antibody specific for CD52, which is present on lymphocytes) is in clinical trials.

ADDITIONAL TREATMENT**General Measures**

- Bone marrow transplantation:
 - Treatment of choice for patients <40 years of age with severe aplastic anemia and human leukocyte antigen-identical sibling as marrow donor
 - Transplant early; minimize supportive transfusions.
 - Alternative donor bone marrow transplantation should be used only for patients who have failed immunosuppressive therapy.
 - Peripheral blood stem cell and umbilical cord blood regimens are currently being tested.
- Immunosuppressive therapy:
 - ATG and cyclosporine. Growth factors (G-CSF or granulocyte macrophage colony-stimulating factor) are often given if severely neutropenic, although addition of growth factors has not been shown to improve survival.
 - High-dose cyclophosphamide without bone marrow transplantation. This treatment was associated with a greater number of early deaths from infection than was treatment with antithymocyte globulin/cyclosporine.
- Androgens:
 - Used for the treatment of Fanconi anemia
 - Effective in moderate and mild aplastic anemia, particularly if anemia is the most significant cytopenia
- Supportive therapy:
 - Transfusion support: Family donors should not be used (to avoid alloimmunization); use CMV-safe, irradiated, leukodepleted products; minimize number of transfusions.
 - Infectious disease support: Pan culture and institute broad-spectrum parenteral antibiotics for fever/neutropenia; antifungal therapy for persistent fevers. Adding G-CSF may lead to more rapid rise in neutrophil counts, although there are some reports of increased clonal transformation. Maintain good hand washing and oral hygiene. Avoid rectal temperatures. Long-term prophylactic antibiotics are not recommended.

IN-PATIENT CONSIDERATIONS**Initial Stabilization**

- Broad-spectrum antibiotics for febrile neutropenic patients; consider antifungal therapy for patients with prolonged fevers.
- Platelet transfusions for bleeding; maintain platelet count > 10,000/mm³ in nonbleeding adolescent/adult patients (single-donor units, irradiated, leukocyte depleted)
- Red cell transfusions in severely anemic patients should be given slowly, to prevent congestive heart failure (unless anemia is acute and due to blood loss rather than lack of production). Use irradiated, leukocyte-depleted, cytomegalovirus-safe red cell product from unrelated donors.

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

- Time to recovery: Response to medical therapy is not immediate, but most responses to medical therapy, with some degree of blood count recovery, occur within 3 months of treatment. Hematologic recovery may be incomplete, and some patients may remain cyclosporine dependent.
- Signs of recovery include normalization of mean corpuscular volume (MCV) and increasing reticulocyte, neutrophil, and monocyte counts. Full platelet recovery may take months.
- Other:
 - 8–15% risk of MDS and/or myeloid leukemia at 10 years. May be lower in children
 - 15% risk of PNH at 5 years. May be lower in children
 - Risk of relapse or development of clonal bone marrow disorders is higher in patients treated with immunosuppression than in those treated with stem cell transplantation.

DIET

Avoid raw fish and undercooked meats in neutropenic patients.

PROGNOSIS

- In patients with severe aplastic anemia, 80–90% mortality at 2 years if untreated
- Bone marrow transplant from human leukocyte antigen-identical sibling donor:
 - 79% overall survival in children
 - 80–90% survival at 5 years for the young, uninfected, and minimally transfused patient
- Bone marrow transplant from human leukocyte antigen-identical unrelated donor: 30–55% survival (due to older population, frequent graft rejection, more severe graft-versus-host disease, infection from delayed engraftment with prolonged neutropenia)
- Immunosuppressive therapy:
 - 60–80% response rate (initial treatment)
 - Higher response rate in children
- Factors associated with poor outcome:
 - Bleeding at presentation
 - Severe pancytopenia (absolute neutrophil count < 200/mm³, platelet < 20,000/mm³)
 - Prolonged pancytopenia (> 1 month)
 - Active infection at diagnosis
- Relapse:
 - Risk of relapse is 30–40% at 5 years; many respond to salvage therapy.
 - Salvage therapy: 2nd course of immunosuppressive therapy (50% salvage), matched unrelated-donor bone marrow transplantation (30–55% overall survival)

COMPLICATIONS

- Infection: Overwhelming bacterial sepsis and fungal (*Aspergillus*) infections are most frequent cause of death.

- Hemorrhage: Intracranial, especially if refractory to platelet transfusions
- Iron overload secondary to long-term RBC transfusions, with subsequent organ dysfunction if untreated

- D61.09 Other constitutional aplastic anemia
- D61.9 Aplastic anemia, unspecified

FAQ

- Q: Can family members donate blood for a child with aplastic anemia?
- A: This is not recommended, as transfusion with blood products from parents or siblings increases the risk of graft rejection of bone marrow in the setting of a related-donor bone marrow transplant.
- Q: What activities should a child with aplastic anemia avoid?
- A: Patients with low RBC counts should avoid excessive exercise or high-altitude exposure. Patients with low WBC counts are more susceptible to bacterial infections. Patients should avoid dental work, as this may introduce bacteria into the bloodstream through the mouth. Patients with low platelet counts should avoid contact sports (e.g., football, hockey, lacrosse, skiing).
- Q: How does one learn more about experimental therapies for the treatment of aplastic anemia?
- A: Inquiries to the National Institutes of Health (NIH) in Bethesda, Maryland, or to the hematology division of the nearest medical school or National Institutes of Health–designated cancer center should result in information about the availability of experimental therapies.

APPENDICITIS

Melissa Kennedy
Joy Collins
Vera de Matos (5th edition)

BASICS

DESCRIPTION

Acute inflammation of the appendix

EPIDEMIOLOGY

- Most common acute surgical emergency in childhood
- Affects 250,000 people per year in the US
- Peak incidence in 10–19-year-old age group where incidence is 233 per 100,000 children
- Incidence much less in younger children, 1–2/10,000 in children <4 years

PATHOPHYSIOLOGY

- Acute obstruction is caused by obstruction of appendiceal lumen by fecalith, calculi, hyperplastic lymphoid tissue, a worm, or (rarely) a carcinoid tumor.
- Bacteria invade the appendiceal wall at sites of ulceration, producing inflammation.
- Necrosis of appendiceal wall results in perforation with fecal contamination of the peritoneum and localized abscess formation and peritonitis.

DIAGNOSIS

Classic signs and symptoms include right lower quadrant (RLQ) pain, anorexia, nausea, and vomiting.

HISTORY

- Abdominal pain is most common symptom and is virtually always present.
- Classically pain begins in the periumbilical region and then migrates to the right lower quadrant, nausea and vomiting occur next, and fever and leukocytosis occur later.
- Other less specific symptoms include flatulence, diarrhea, change in bowel habits, rectal tenderness, and malaise.
- Patients in the younger age group are more challenging to diagnose as toddlers may not be able to explain onset and location of pain. Delayed diagnosis and perforation is higher in this age group.

PHYSICAL EXAM

- Several findings on the physical exam may indicate appendicitis and peritoneal irritation.
- Pain and tenderness at McBurney point (1.5–2 inches from the anterior superior iliac spine [ASIS] in a line from the umbilicus to the ASIS)
- Rovsing sign is pain in the right lower quadrant with palpation in the left lower quadrant.
- The psoas sign is right lower quadrant pain with passive right hip extension and indicates a retrocecal appendix.
- The obturator sign is right lower quadrant pain with right hip and knee flexion followed by internal rotation of the right hip and indicates a pelvic appendix.
- Other physical exam findings include abdominal rebound tenderness, guarding, and focal tenderness on rectal exam.
- Following perforation, the abdomen becomes rigid and tender with absent bowel sounds.
- Patients are often febrile, tachypneic, and tachycardic.
- Special questions and examining tricks include:
 - Ask patient if the car ride was painful (e.g., going over bumps) as this should elicit peritoneal signs.
 - Palpation of RLQ with stethoscope
 - Jiggling the bed should produce RLQ pain.
 - Pain may be elicited by asking patient to cough or hop on right foot.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC, expect elevated WBC count with left shift
- Urinalysis to exclude urinary tract pathology
- Pregnancy test in females of child-bearing age

Imaging

The diagnosis of appendicitis can often be made without the use of imaging based on history, physical exam, and laboratory studies with a diagnostic accuracy of 80–90% in some studies.

- Abdominal radiograph:
 - Often normal
 - May show fecalith, indistinct psoas margins, cecal wall thickening
 - Air-fluid levels would suggest a small bowel obstruction.
 - Free air or pneumoperitoneum may indicate a perforation.
- Ultrasound:
 - Findings include edema, inflammation, or abscess formation.
 - Diagnostic accuracy depends on the experience of the sonographer.
 - Most specific finding is maximum outer diameter (MOD) of ≥ 7 mm and is associated with a sensitivity of 98.7% and a specificity of 95.4%.
 - Currently initial imaging study of choice for the diagnosis of appendicitis
- CT scan:
 - Findings include fat stranding, abscess or phlegmon, appendicolith when present, and focal cecal thickening.
 - High diagnostic accuracy for diagnosis of appendicitis and may have a higher sensitivity than ultrasound; however, exposure to ionizing radiation is a concern

DIFFERENTIAL DIAGNOSIS

- Infection:
 - Gastroenteritis (e.g., *Yersinia*, *Campylobacter*)
 - Constipation
 - Right lower lobe pneumonia
 - Mesenteric adenitis
 - Typhlitis
 - Urinary tract infection
 - Pelvic inflammatory disease, tubo-ovarian abscess, or ectopic pregnancy
 - Parasitic infection (*Trichuris trichiura*, *Ascaris lumbricoides*)

- Inflammatory:
 - Inflammatory bowel disease exacerbation
 - Anaphylactic purpura
 - Cholecystitis
 - Pancreatitis
 - Diverticulitis
- Genetic/metabolic:
 - Diabetes
 - Sickle cell disease
 - Renal stones
 - Hyponatremia
 - Crohn disease
- Miscellaneous:
 - Function abdominal pain
 - Fecalith
 - Torsion of testes or ovaries
 - Ovarian cyst
 - Endometriosis
 - Small bowel obstruction

TREATMENT

ADDITIONAL TREATMENT

General Measures

- IV fluids to correct hypovolemia, electrolyte abnormalities
- Broad-spectrum antibiotics should be given, and continued for a longer duration if perforation is suspected.
- Nasogastric tube and pain medications may provide comfort preoperatively.

SURGERY/OTHER PROCEDURES

- After the diagnosis is made by a careful history and repeat clinical exam, diagnostic imaging should not delay the surgery.
- Emergency appendectomy: Laparoscopic technique has comparable results to open technique and is associated with faster recovery to daily activity.
- If abscess is present, alternative treatment option is initial nonoperative management with percutaneous abscess drainage and broad-spectrum antibiotics followed by interval appendectomy.

ONGOING CARE

PROGNOSIS

- Recovery is rapid.
- Prognosis excellent without perforation
- Pitfalls:
 - Position of appendix may vary (i.e., location of pain may vary).
 - Retroiliac appendix, poorly localized pain
 - Retrocecal appendix, right upper quadrant (RUQ) pain
 - Appendix in gutter, flank pain
 - Pelvic appendix, pain on rectal exam or diarrhea caused by direct irritation of sigmoid colon
 - Appendicitis progresses rapidly in children; perforation often occurs owing to delayed diagnosis.
 - Pain may resolve briefly following perforation.

COMPLICATIONS

- Mostly seen in cases of perforated appendicitis:
 - Abdominal and pelvic abscesses are also more frequent after a perforated appendicitis (1.3%).
- Intestinal obstruction:
 - In patients with perforated appendicitis paralytic ileus may persist after 3–4 days leading to mechanical obstruction. This usually resolves with nasogastric tube decompression.
 - Patients with perforated appendicitis may develop bowel obstruction 4 weeks after the appendectomy due to adhesive bands, requiring emergency surgery.

ICD10

K37 Unspecified appendicitis

ARTHRITIS, JUVENILE IDIOPATHIC (RHEUMATOID)

Elizabeth Candell Chalom

BASICS

DESCRIPTION

Chronic synovial inflammation of unknown etiology in at least 1 joint, for at least 6 weeks. Age of onset must be <16 years old. In 1997, a new classification system was introduced to classify juvenile idiopathic arthritis (JIA) into 7 subtypes:

- Oligoarticular arthritis affects <5 joints during the 1st 6 months of the disease. Tends to involve large joints, especially the knee. Peak age of onset is 1–6 years; 80% are antinuclear antibody (ANA) positive:
 - Persistent oligoarticular JIA remains in <5 joints.
 - Extended oligoarticular JIA spreads to involve 5 or more joints. Has worse prognosis than persistent oligoarthrits.
- Polyarticular juvenile idiopathic arthritis affects ≥5 joints. Can occur at any age: Peak ages of onset are 1–4 and 7–10 years.
 - Rheumatoid factor positive (RF+) polyarticular juvenile idiopathic arthritis is like adult-onset idiopathic arthritis that occurs in a child. It is often quite aggressive.
 - Rheumatoid factor negative (RF-) polyarticular juvenile idiopathic arthritis is usually less aggressive and easier to control.
- Systemic-onset idiopathic juvenile arthritis:
 - Characterized by high, spiking quotidian or diquotidian fevers and an evanescent pink/salmon-colored macular rash
 - Affected children may also have lymphadenopathy, hepatosplenomegaly, pericarditis, or pleuritis.
 - Arthritis may not appear until weeks to months after the onset of the systemic symptoms.
 - Can occur at any age
- Enthesitis-related arthritis (ERA) generally affects boys, many of whom are human leukocyte antigen (HLA)-B27 positive, in late childhood or adolescence
- Psoriatic arthritis is associated with psoriasis. It often begins in a few joints and then becomes polyarticular. It often involves small joints of hands and feet, as well as knees. Dactylitis is seen in nearly 50% patients.

EPIDEMIOLOGY

Incidence

- Incidence ranges from 1–22/100,000/year
- Affects ~70,000–100,000 children in the US

Prevalence

- Prevalence ranges from 8–150/100,000; varies but is thought to be ~1/1,000
- Girls are affected twice as often as boys, but boys are affected more frequently with ERA.
- ~50% of children with JIA have the oligoarticular type.
- 30% have the polyarticular type.
- 10% have systemic-onset JIA.

RISK FACTORS

Genetics

- Rare in siblings, but many studies have demonstrated increased frequencies of various human leukocyte antigen markers in JIA.
- Each marker may be associated with a different subtype of JIA:
 - Human leukocyte antigen-DR4: RF+ polyarticular JIA
 - Human leukocyte antigen-DR1: Oligoarticular disease without uveitis
 - Human leukocyte antigen-DR5: Oligoarticular JIA with uveitis
 - Human leukocyte antigen-B27: ERA
 - Human leukocyte antigen-A2: Early-onset oligoarticular JIA

DIAGNOSIS

HISTORY

- Morning stiffness that improves after a warm shower/bath or with stretching and mild exercise is common in JIA. Many young children do not complain of pain, but walk with a limp or refuse to walk down stairs in the morning.
- Joints often become sore/painful again in the late afternoon or evening.
- Patients with JIA generally do not complain of severe pain, but rather they avoid using joints that are particularly affected. If a child has severe pain in a joint, especially pain that seems out of proportion to the physical findings, diagnoses other than JIA should be entertained.
- In systemic JIA, the fever curve is important to document. Between fever spikes, the child is often completely afebrile. The rash is evanescent and patients often have a history of fatigue, malaise, and weight loss.

PHYSICAL EXAM

- Arthritis must be present not just arthralgias:
 - May be restricted range of motion in the affected joints and soft tissue contractures as well
- Enthesitis and sacroiliac tenderness are often seen in ERA.
- In systemic JIA, the rash, if present, is almost pathognomonic for this disease.
- Lymphadenopathy and hepatosplenomegaly may be seen in systemic JIA.
- A careful cardiac and pulmonary examination must be done to look for pericarditis and pleuritis.

ALERT

Arthritis must be present for at least 6 weeks before a patient can be diagnosed with JIA. Many viral illnesses can produce joint pain and swelling that mimics JIA but resolves within 4–6 weeks.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- No laboratory finding is diagnostic for JIA.
- Many patients with JIA, especially the polyarticular and systemic types, have elevated sedimentation rates and anemia.
- Antinuclear antibody is a useful test in classifying patients with JIA and determining the risk of uveitis. Positive in:
 - 80% of oligoarticular
 - 40–60% of polyarticular
 - 15–20% of normal population
- Rheumatoid factor will be positive in 15–20% of patients with polyarticular arthritis and usually indicates a more aggressive form of arthritis.

Imaging

- Radiography is often normal early in JIA.
- Later, if arthritis persists, bone demineralization, loss of articular cartilage, erosions, and joint fusion may be seen.

DIFFERENTIAL DIAGNOSIS

- Monoarticular JIA:
 - Septic joint
 - Toxic synovitis
 - Trauma
 - Hemarthrosis
 - Villonodular synovitis
- Monoarticular or oligoarticular JIA:
 - Lyme disease
 - Acute rheumatic fever or poststreptococcal arthritis
 - Viral/postviral arthritis
 - Malignancies
 - Sarcoidosis
 - Inflammatory bowel disease
- Polyarticular JIA:
 - Viral or postviral illness (especially parvovirus)
 - Lyme disease
 - Lupus
- Systemic-onset JIA:
 - Infection
 - Oncologic process (leukemia, lymphoma)
 - Inflammatory bowel disease
 - Lupus

TREATMENT

MEDICATION (DRUGS)

First Line

- Steroids: Intra-articular steroids
 - Triamcinolone hexacetonide injections are often used when there is only 1 or 2 active joints
- Systemic steroids:
 - Systemic steroids are often needed to control flares or with the initial presentation of polyarticular or systemic JIA. Because of the many side effects, patients should be weaned off steroids as soon as possible.
 - Glucocorticoids can be given orally (daily or every other day) or as IV pulses (every 1–8 weeks).
- NSAIDs:
 - First-line therapy for mild JIA
 - If there is no response to the initial NSAID after 4–6 weeks of an adequate dose, a different one should be tried. Patients will often respond differently to the various NSAIDs.
 - If patients experience GI upset or excessive bruising, COX-2 inhibitors may be used. If the arthritis remains active after 2–3 months, a second line treatment should be added.

Second Line

- If NSAIDs are ineffective in controlling the disease, or the patient has moderate to severe arthritis, a second-line agent should be added, such as methotrexate or sulfasalazine.
- Methotrexate: If the arthritis does not respond to NSAIDs, methotrexate is the most common second-line agent for active arthritis in multiple joints. Laboratory values must be monitored closely, in these patients, looking for bone marrow suppression or elevation of transaminase levels.
- Sulfasalazine is most often used in ERA.

Third Line

- Biologic agents are often added when patients do not respond adequately to methotrexate or cannot tolerate its side effects, or the arthritis is severe.
- Antitumor necrosis factor therapy is frequently used: Etanercept is a receptor for tumor necrosis factor that is given SC once or twice a week. Infliximab is a chimeric antibody to tumor necrosis factor that is given IV every 4–8 weeks. Adalimumab is a fully humanized antibody to tumor necrosis factor given SC every other week.
- IL-1 inhibition may work better than TNF inhibition in systemic JIA. Anakinra is a recombinant IL-1 receptor antagonist. It is given as a daily SC injection. Monthly injections with another IL-1 inhibitor are being studied.
- Anti-IL-6 therapy (Tocilizumab) is an IV medication given every other week. It has recently been approved for children with systemic onset JIA.
- Abatacept is a co-stimulation blocker. It blocks the interaction of CD28 on T cells with CD80 and CD86 receptors on antigen presenting cells. It is given IV every 4 weeks. It is currently being tested as a SC injection.
- Rituximab is an antibody to CD20, which is present on all B cells. It is approved for use in adult RA but not in JIA.
- Medications such as cyclophosphamide or thalidomide are sometimes necessary to control severe systemic-onset JIA.

ADDITIONAL TREATMENT

General Measures

- Responses to treatments for juvenile idiopathic arthritis vary tremendously:
 - Some patients may respond to NSAIDs within 1–2 weeks.
 - Others take 4–6 weeks to improve, and some may not respond at all.
 - Steroids usually start to relieve symptoms within a few days.
 - Methotrexate usually takes 4–8 weeks until a benefit is seen.
 - Anti-tumor necrosis factor therapy can start decreasing symptoms in as little as 1–2 weeks, or it may take up to 3 months.
 - Other second-line agents can take up to 16 weeks until the maximum benefit is seen.
- The waxing and waning nature of JIA itself adds to the variability of patient responses to treatments.

Additional Therapies

- Physical and occupational therapy are important in the management of JIA.
- The goal is to maintain range of motion, muscle strength, and function.

ONGOING CARE

PROGNOSIS

- Varies considerably
- Children with oligoarticular JIA usually do well and often go into remission within a few years of starting treatment. They may have flares, however, even up to 10 years after being symptom free and off all medications.
- Patients with polyarticular JIA who are rheumatoid factor positive often develop a severe arthritis that may persist into adulthood.
- Rheumatoid factor-negative polyarticular patients generally do better, and many outgrow their disease.
- 50% of patients with systemic-onset JIA will develop severe chronic polyarticular arthritis.

COMPLICATIONS

- Joint degeneration with loss of articular cartilage
- Soft tissue contractures
- Leg-length discrepancies
- Micrognathia
- Cervical spine dislocations
- Rheumatoid nodules
- Growth retardation
- Uveitis: oligoarticular JIA, especially with a positive antinuclear antibody, is associated with a chronic uveitis, which can lead to loss of vision if not detected early with routine slit-lamp eye examinations. Uveitis may also be seen in polyarticular JIA but it is less common.

- Pericarditis and pleuritis, as well as severe anemia, may develop in patients with systemic-onset JIA.
- Macrophage activation syndrome, or hemophagocytic syndrome:
 - Rare, but potentially lethal complication of systemic-onset JIA, resulting from an overproduction of inflammatory cytokines
 - May present as an acute febrile illness with pancytopenia and hepatosplenomegaly
 - Diagnosis is made by bone marrow aspiration.
 - Treatment is often with high-dose steroids and cyclosporine.

CODES

ICD9

- 714.30 Chronic or unspecified polyarticular juvenile rheumatoid arthritis
- 714.31 Acute polyarticular juvenile rheumatoid arthritis
- 714.32 Pauciarticular juvenile rheumatoid arthritis

ICD10

- M08.3 Juvenile rheumatoid polyarthritis (seronegative)
- M08.89 Other juvenile arthritis, multiple sites
- M08.90 Juvenile arthritis, unspecified, unspecified site

FAQ

- Q: Will the patient outgrow JIA?
- A: Prognosis depends on the type of JIA. In some studies, up to 50% of patients with JIA still had active disease 10 years after diagnosis. Only 15%, however, had any loss of function.
- Q: Will siblings of patients with JIA develop the disease?
- A: Rarely, but it can occur

ASCARIS LUMBRICOIDES

Genevieve L. Buser

Suzanne Dawid (5th edition)

BASICS

DESCRIPTION

Ascaris lumbricoides is a large nematode (roundworm), 15–40 cm in length, which infects humans via eggs found in soil.

EPIDEMIOLOGY

Incidence

- All ages may be affected; however, children are more frequent hosts owing to oral behavior, and tend to have a higher worm burden.
- Ascariasis is more common where sanitation is poor and population dense.
- Eggs are viable in the soil for more than 6 years in temperate climates.

Prevalence

~1/6 of the world's population is infected.

GENERAL PREVENTION

Infection control:

- Sanitary disposal of human excrement, not using human feces as fertilizer and hand washing could eliminate this infection.
- In communities with high *Ascaris* carriage, community-wide recurring administration of anthelmintics is effective.

PATHOPHYSIOLOGY

- Fertilized eggs are ingested from soil contaminated with human feces.
- Larvae are liberated in the small intestine.
- Larvae invade the venous system and travel to the portal circulation, inferior vena cava, and finally, pulmonary capillaries.
- During migration through the pulmonary vessels, an eosinophilic response is evoked.

- Larvae penetrate the alveoli, are expelled by coughing, and swallowed (day 10–14).
- Larvae become adult worms in the small intestine.
- Female worms excrete up to 200,000 eggs per day.
- Fertilized eggs require 2–3 weeks of incubation in soil to become infectious and restart cycle.
- Ingestion to excretion takes 2–3 months.

ETIOLOGY

Children commonly acquire this infection from playing in dirt contaminated with *Ascaris* eggs.

DIAGNOSIS

HISTORY

- Most patients with mild to moderate infections are asymptomatic.
- Moderate to heavy infections may cause malnutrition and non-specific gastrointestinal symptoms.
- History of passage of large worms in the stool or vomitus is suggestive; history of wheezing may precede passage of worms by 2–3 months.
- During the pulmonary migratory stage, larvae cause an inflammatory response (Löeffler's syndrome): Dyspnea, cough, fever, shifting pulmonary infiltrates and eosinophilia.
- During the intestinal phase, symptoms are due to the presence of worms: pain, obstruction (2 per 1000), peritonitis from perforation, and biliary colic, hepatitis or pancreatitis from blockages due to worms.
- Chronic infection can cause nutritive, malabsorptive, and cognitive deficits.

PHYSICAL EXAM

- Chest: May have rales or wheezing if *Ascaris* larvae are in the lungs.
- Abdomen: Auscultate and palpate for signs of obstruction or perforation.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Microscopic examination of stool specimens will demonstrate the characteristic ascarid eggs (round with thick shell).
- During the pulmonary phase, may have peripheral eosinophilia and larvae in sputum, but negative stool examinations.
- Serologic tests are unnecessary and are poorly specific to the diagnosis.

Imaging

- Chest radiograph, if cough is present.
- Abdominal imaging, if abdominal signs or symptoms of obstruction or perforation.

DIFFERENTIAL DIAGNOSIS

- Ascariasis should be considered in the differential diagnosis when a patient presents with pneumonia and peripheral eosinophilia.
- The diagnosis of *Ascaris* infection should be considered whenever intestinal obstruction is seen in an endemic area.
- This infection may be associated with other parasites acquired from contaminated soil: hookworm (*Necator americanus*, *Ancylostoma duodenale*), *Trichuris trichiura*, *Strongyloides stercoralis*, *Toxocara canis*.

TREATMENT

MEDICATION (DRUGS)

First Line

- Oral:
 - Albendazole 400 mg, single dose
 - Mebendazole 100 mg, BID for 3 days
 - Ivermectin 150–200 mcg/kg, single dose
- For children <2 years old, limited studies suggest medications are safe, although not approved for this age group.
 - For children <1 year old, World Health Organization recommends: Albendazole 200 mg, single dose.
- Alternatives (oral):
 - Pyrantel pamoate 11 mg/kg to max 1 g, single dose; side effects
 - Nitazoxanide 7.5 mg/kg to max 500 mg BID for 3 days; less effective
- Piperazine citrate (75 mg/kg/d for 2 days; maximum, 3.5 g) has been used historically for cases of intestinal obstruction (causes worm paralysis), but it is no longer available in the US.

SURGERY/OTHER PROCEDURES

Surgery or endoscopic retrograde cholangiopancreatography may be required for severe intestinal or biliary tract obstruction.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Treatment is highly effective.
- Re-examination of stool specimens 2 weeks after therapy can be considered, but is not essential.
- Reinfection is common in endemic areas, and has led to mass drug administration programs.

Patient Monitoring

Warn parents about passage of worms in stool with treatment.

PROGNOSIS

- Once intestinal infection is detected and treated, the prognosis is excellent.
- If obstructive or respiratory complications have occurred, the prognosis is less favorable.
- The case fatality rate in cases with complications is up to 5%, most from obstruction.

COMPLICATIONS

- Bronchopneumonia may be seen during the pulmonary migrational stage, producing fever, cough, dyspnea, wheeze, eosinophilia, and pulmonary infiltrates (Löeffler's syndrome).
- Heavy infestations may cause abdominal pain, malabsorption, and growth failure.
- Children may experience obstruction (ileocecal), malabsorption, or intussusception.
- Perforation of a viscus or migration into the appendix, biliary, or pancreatic ducts may rarely occur.

ASCITES

Evelyn K. Hsu
Ruben W. Cerri (5th edition)

BASICS

DESCRIPTION

- Ascites is defined as a pathologic accumulation of intraperitoneal fluid:
 - This can be transudative (thin, low protein count and low specific gravity) or exudative (high protein count and specific gravity)
- Peritoneal fluid formation is a dynamic process of production and absorption.
- See Table 1, Analysis of Ascitic Fluid

- Accumulation of fluid occurs with:
 - Inflammatory conditions (e.g., mesenteric adenitis, tuberculosis, pancreatitis, secondary to inflammation of visceral and/or parietal peritoneum)
 - Portal hypertension or obstruction of portal vein flow and/or lymphatic flow by mass, tumor, or external pressure; tumors of abdominal viscera, retroperitoneum, thorax, or mediastinum (often characterized by chylous ascites)

- Infectious: Abscess, tuberculosis, Chlamydia infection, schistosomiasis
- GI: Infarcted bowel, perforation
- Pancreatic: Pancreatitis, ruptured pancreatic duct
- Neoplastic: Lymphoma, neuroblastoma
- Gynecologic: Ovarian tumors, torsion, or rupture
- Miscellaneous: Systemic lupus erythematosus, eosinophilic ascites, chylous ascites, hypothyroidism, ventriculoperitoneal shunt

Table 1. Analysis of ascitic fluid

Condition	Gross appearance	Protein, g/L	Serum-ascites gradient, RBCs, g/dL > 10,000		Include WBC	Other tests
			Cell count			
Cirrhosis	Straw-colored or bile-stained	<25 (95%)	> 1.1	1%	<250 (90%); predominantly mesothelial	
Neoplasm	Straw-colored, hemorrhagic, mucinous, or chylous	> 25 (75%)	< 1.1	20%	> 1,000 (50%); variable cell types	Cytology, cell block, peritoneal biopsy
Tuberculous peritonitis	Clear, turbid, hemorrhagic, chylous	> 25 (50%)	< 1.1	7%	> 1,000 (70%); usually > 70% lymphocytes	Peritoneal biopsy, stain and culture for acid-fast bacilli
Pyogenic peritonitis	Turbid or purulent	If purulent, >25	< 1.1	Unusual	Predominantly polymorphonuclear leukocytes	Positive Gram's stain, culture
CHF	Straw-colored	Variable, 15–53	> 1.1	10%	< 1,000 (90%); usually mesothelial, mononuclear	
Nephrosis	Straw-colored or chylous	<25 (100%)	< 1.1	Unusual	<250; mesothelial, mononuclear	If chylous, ether extraction, Sudan staining
Pancreatic ascites (pancreatitis, pseudocyst)	Turbid, hemorrhagic, or chylous	Variable, often >25	< 1.1	Variable, may be blood-stained	Variable	Increased amylase in ascitic fluid and serum

PATHOPHYSIOLOGY

- Development of ascitic fluid may be sudden or insidious, associated with nonhepatic etiologies, or secondary to acute reduction in hepatocellular function in a marginally compensated liver.
- Intra-abdominal factors (resulting in a net flow of fluid and protein out of the mesenteric capillary bed):
 - Decreased plasma colloid osmotic pressure
 - Increased capillary pressure
 - Increased ascitic colloid osmotic fluid pressure
 - Decreased ascitic fluid hydrostatic pressure

- Primary (congenital) abnormalities of the lymphatics (Milroy disease), congenital neonatal ascites, secondary to abdominal trauma (e.g. ureteral rupture), hematologic diseases (hydrops secondary to hemolysis), congestive heart disease; and lysosomal storage diseases including sialidosis (neuraminidase deficiency), Wolman disease, sialic acid storage disease, GM1 gangliosidosis, Gaucher disease, and Niemann-Pick type C
- Decreased plasma oncotic pressure secondary to hypoalbuminemia (increased losses from renal and GI tract; decreased production in cases of hepatic failure)
- Rupture of intra-abdominal viscus or peritoneal/mesenteric cyst, bowel perforation

ETIOLOGY

- Hepatic: Liver cirrhosis with portal hypertension, chronic liver failure, portal vein occlusion, Budd-Chiari syndrome, lysosomal storage disease
- Renal: Nephrotic syndrome, obstructive uropathy, perforated urinary tract, peritoneal dialysis
- Cardiac: CHF, constrictive pericarditis, inferior vena cava web

DIAGNOSIS

HISTORY

- The etiology for acute decompensation in hepatocellular function (e.g., massive bleeding, sepsis, superimposed infections) should be investigated.
- Use of umbilical catheters in newborn period (increased risk of portal vein thrombosis)
- Evidence of chronic liver disease
- Respiratory distress
- Exposure to hepatotoxins
- Developmental delay or growth failure suggestive of metabolic disease

PHYSICAL EXAM

- Vital signs
- Abdominal circumference
- Weight
- Auscultation of the pericardium
- Neurologic examination to evaluate for encephalopathy

- Skin changes suggestive of chronic liver disease
- Special attention should be directed toward identification of a distended abdomen, fullness in the flanks, inverted umbilicus, and development of hernias, scrotal edema, rectal prolapse, and a prominent anterior wall.
- Techniques to detect free intra-abdominal fluid include presence of a fluid wave or shifting dullness.
- Other physical examination signs include splenomegaly and caput medusae (portal hypertension), cor pulmonale (congestive heart failure), pericardial friction rub (pericarditis), diffuse abdominal pain (peritonitis or visceral perforation), abdominal pain radiating to the back (pancreatitis), lower extremity edema (suggestive of Budd Chiari) and lymphedema (lymphatic obstruction/trauma to the thoracic duct).

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Complete WBC count
- Electrolytes
- Liver function tests: Transaminases, prothrombin time/partial thromboplastin time, total protein, albumin, total and fractionated bilirubin
- Amylase and lipase (to exclude pancreatitis)
- Creatinine and blood urea nitrogen
- Blood cultures
- Urine for specific gravity
- Viral serologies, including hepatitis A, B and C viruses, CMV, EBV, coxsackievirus, enteroviruses
- Plasma amino acids, urine organic acids, lactate/pyruvate (for evaluation for metabolic disease)
- Specific testing for etiologies of chronic liver disease if suspected

Imaging

- Ultrasound of the abdomen with Doppler study to differentiate between free and loculated fluid collection and the presence of intra-abdominal masses as well as to evaluate patency of hepatic and portal vasculature and directionality of flow
- Abdominal computed axial tomography
- Abdominal radiography

Diagnostic Procedures/Other

- Abdominal paracentesis:
 - Safe procedure in the evaluation of etiologies of ascites. The 2 complications are perforation of the bowel and hemorrhage. With sterile conditions, a narrow-bore angiocatheter, usually 15 or 18 gauge, is inserted through the linea alba 2 cm below the umbilicus, using the Z-technique.
 - Done for: Routine studies, including WBC count, culture, LDH, total protein, albumin, glucose, Gram stain, amylase, cholesterol with triglycerides, and cytology
- Calculate serum–ascites albumin gradient (SAAG): (Serum albumin) – (ascites albumin). SAAG ≥ 1.1 g/dL indicates portal hypertension very likely; SAAG < 1.1 g/dL, suspect other causes. These tests require ~ 10 – 20 mL of fluid:
 - When glucose in the ascitic fluid is < 30 mg/dL, tuberculous peritonitis must be excluded.
 - When ascitic amylase is greater than the normal serum amylase, pancreatitis is suggested.

Pathological Findings

Analysis of ascitic fluid:

- The fluid should be examined for its gross appearance; protein content, cell count, and differential cell count should be determined.
- Gram and acid-fast stains and culture should be performed. Cytologic and cell-block examination may disclose an otherwise unsuspected carcinoma or storage disorder.
- See details in Table 1.

DIFFERENTIAL DIAGNOSIS

- Enlarged liver or spleen
- Mesenteric cyst: Does not have shifting dullness when position is changed
- Intestinal obstruction

TREATMENT

ADDITIONAL TREATMENT

General Measures

- The management of the ascites should be directed toward the underlying etiology. In a patient with cirrhosis, accumulation of ascites should be avoided by preventing complications such as sodium and fluid overload, esophageal hemorrhage, spontaneous bacterial peritonitis, hepatorenal syndrome, inferior vena cava obstruction, and renal and cardiac circulatory disturbances.
- Sodium intake should be restricted to 1–2 mEq/kg/d (low-salt diet). Excess sodium in the form of intravenous normal saline should be avoided. For pressure support, colloid is preferred.
- Water should be restricted to 50–75% of maintenance requirements in patients with significant water excess or profound hyponatremia.
- Diuretic therapy, with the goal of reduction of bodyweight by 0.5–1% daily until ascites is resolved. Spironolactone (2–3 mg/kg/d) most effective in cirrhotic patients, in combination with furosemide. When diuretics are used, urine output and serum electrolytes should be closely monitored to prevent prerenal azotemia and decreased effective blood flow to the kidneys

- Refractory ascites: Diuretic-refractory ascites derives from a lack of response to dietary sodium restriction and maximal diuretic therapy. Treatment options:
 - Therapeutic abdominal paracentesis (large-volume paracentesis) should be used only in resistant cases and for tense ascites, because ascitic fluid tends to reaccumulate. Paracentesis of volumes > 1 L should be accompanied by IV infusion of 25% albumin during the procedure.
 - Transjugular intrahepatic portosystemic shunting (TIPS) consists of a metallic stent that bridges the branches of the portal and hepatic veins. May be valuable in cases where portal hypertension is felt to be the underlying etiology of ascitic accumulation.
 - Orthotopic liver transplantation (OLT) is the only curative therapy for refractory ascites from liver disease and the only definitive treatment that has been shown to improve survival.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Weight and effects of diuretics should be assessed closely, with attention to preservation of renal function.
- Urine and serum electrolytes should be monitored.
- Abdominal girth should be measured frequently.
- In cases of infection or peritonitis, a repeat paracentesis should be performed ~48 hours after the initiation of antibiotics for culture and WBC count.

ALERT

- With congenital ascites, evaluate for lysosomal storage diseases.
- When performing paracentesis, make certain that the fluid is ascitic and not intraluminal.
- Ultrasonography may be helpful to determine the location of this fluid.
- With new onset of ascites, make certain to evaluate for abdominal neoplasia.
- With marginally compensated liver disease, attempt to identify the source of the patient's acute decompensation.

PROGNOSIS

Dependent upon the etiology:

- Nephrotic syndrome: Will regress as proteinuria clears
- Liver failure: Will depend upon recovery of liver function
- Cirrhosis (complicated by ascites): Associated with significant morbidity and mortality, related in part to the severe underlying liver disease and in part to the ascites per se. Once ascites appears, the expected mortality rate is ~50% in just 2 years. With liver transplantation, survival is improved dramatically.

COMPLICATIONS

- Infection:
 - Ascitic fluid infection can be classified into 3 categories based on ascitic culture results, polymorphonuclear leukocyte count, and presence or absence of a surgical source of infection
 - An abdominal paracentesis must be performed and ascitic fluid must be analyzed before a confident diagnosis of ascitic fluid infection can be made. The blood culture bottle should be injected with peritoneal fluid at the bedside in order to increase the culture's yield.
 - Spontaneous ascitic fluid infection: Infection of the peritoneal fluid of patients with ascites in the absence of secondary causes, such as bowel perforation or intra-abdominal abscess
- Subtypes:
 - Spontaneous bacterial peritonitis (SBP) (65%)
 - Monomicrobial nonneutrocytic bacterascites (MNB)
 - Culture-negative neutrocytic ascites (CNNA)
- Secondary bacterial peritonitis: An identified intra-abdominal surgically treatable primary source of infection (e.g., perforated gut, perinephric abscess) that usually requires emergency surgical intervention

- Polymicrobial bacterascites: This diagnosis should be suspected when the paracentesis is traumatic or unusually difficult because of ileus, or when stool or air is aspirated into the paracentesis syringe (diagnostic of gut perforation by the paracentesis needle). Antibiotic therapy should be started if there is a high index of suspicion and:
 - Polymorphonuclear leukocytes $<250/\text{mm}^3$: No treatment
 - Polymorphonuclear leukocytes >250 but $<500 \text{ mm}^3$: IV antibiotics if clinical suspicion high; or, wait and retap
 - Polymorphonuclear leukocytes $>500 \text{ mm}^3$: IV antibiotics (e.g., cefotaxime + ampicillin)
 - Polymorphonuclear leukocytes $>500 \text{ mm}^3$: Rule out secondary peritonitis.
- An indication of therapeutic response is a decrease in the neutrophil count in the ascitic fluid by 50% from that detected on presentation. It is appropriate to treat according to sensitivities when cultures are available. The length of therapy depends on clinical response but should be a minimum of 10 days.

- Other complications:
 - Respiratory distress from decreased lung volume and diaphragmatic limitation: Hepatic hydrothorax (large symptomatic pleural effusion that occurs in a cirrhotic patient in the absence of primary cardiopulmonary disease); abdominal wall hernias with rupture; tense ascites with leakage (especially after paracentesis)
- Conservative management consists of appropriate initial therapy for most of these except hernia rupture, which requires surgical reduction.
- Consider prophylactic antibacterial therapy to prevent recurrence

CODES

ICD9

- 457.8 Other noninfectious disorders of lymphatic channels
- 778.0 Hydrops fetalis not due to isoimmunization
- 789.59 Other ascites

ICD10

- I89.8 Other specified noninfective disorders of lymphatic vessels and lymph nodes
- P56.0 Hydrops fetalis due to isoimmunization
- R18.8 Other ascites

FAQ

- Q: What etiologies are likely in cases of congenital ascites?
- A: Lysosomal storage disorders and/or other metabolic diseases should be excluded. If hepatic function is impaired, causes of neonatal liver failure should also be investigated.
- Q: What is the best test to discriminate the type of ascites?
- A: Analysis of the peritoneal fluid collected by abdominal paracentesis is required for this purpose. The serum: Ascites albumin gradient is helpful to discriminate ascites due to portal hypertension from other etiologies.

ASPERGILLOSIS

Michelle Dunn

Theoklis Zaoutis (5th edition)

BASICS

DESCRIPTION

- Applied to the wide variety of illnesses caused by fungi in the genus *Aspergillus*
- Most human disease is caused by *Aspergillus fumigatus*, *Aspergillus flavus*, or *Aspergillus niger*; other *Aspergillus* spp. may occasionally cause disease.

EPIDEMIOLOGY

- *Aspergillus* spp. are saprophytic molds that are ubiquitous and worldwide, growing in soil, grain, dung, bird droppings, and decaying plant matter.
- Spores (conidia) are resistant to desiccation, lightweight, and are easily dispersed in air currents.
- Humans breathe in hundreds of conidia daily, which are handled by alveolar macrophages and neutrophils.
- The main route of transmission is via inhalation of airborne spores; person-to-person spread does not occur.
- The incubation period has not been defined.
- Nosocomial outbreaks have occurred when ventilation or heating systems become contaminated, or when large numbers of spores become airborne during building construction or renovation.

Incidence

The incidence of aspergillosis varies by the type of population. The overall incidence in immunocompromised children is ~0.4%. The incidence in bone marrow transplant patients is higher (4.5%).

RISK FACTORS

Other than those with otomycosis or allergic bronchopulmonary disease, most patients infected with *Aspergillus* are immunocompromised in some way. Patients at risk include those with malignancy, solid-organ transplantation, bone marrow transplantation, chronic steroid therapy, HIV, and congenital immunodeficiencies.

GENERAL PREVENTION

Infection control:

- Hospitalized, immunosuppressed patients are at risk for invasive aspergillosis.
- Environmental measures to control airborne spread of spores in hospitals during construction are indicated.
- Laminar-flow rooms with appropriate filters will significantly decrease contact with airborne conidiospores.

PATHOPHYSIOLOGY

- The most common portal of entry for *Aspergillus* is the respiratory tract; however, damaged skin or operative wounds, the cornea, and the ear can also serve as sites of entry.
 - The development of disease depends on the interaction between the organism (virulence) and the host, specifically host defense mechanisms.
 - *Aspergillus* produces toxic metabolites such as elastase, cytotoxins, endotoxins, phospholipases, and various inhibitors of immune function.
 - *Aspergillus* is an unusual pathogen in immunocompetent patients. The first line of defense in the lungs is the macrophages. Neutrophils are also a key part of the host defense against *Aspergillus*.
- Conditions that alter the normal immunologic mechanisms predispose to invasive aspergillosis. Examples include leukemia (neutropenia), corticosteroids (decreased neutrophil mobilization and macrophage killing), and chronic granulomatous disease (decreased oxidative-mediated killing)

ETIOLOGY

Aspergillus sp., most commonly *Aspergillus fumigatus*

COMMONLY ASSOCIATED CONDITIONS

- Allergic bronchopulmonary aspergillosis (ABPA) is characterized by periodic episodes of wheezing, low-grade fever, eosinophilia on peripheral smear, transient infiltrates on chest radiographic film, and a cough productive of brown mucus plugs. ABPA is thought to represent a hypersensitivity response to *Aspergillus* colonization of the lungs. It occurs most commonly in patients with chronic respiratory disease (i.e., in children with cystic fibrosis or asthma).
- Otomycosis is a localized, noninvasive infection of the external ear seen in healthy hosts. It occurs more commonly in warm, wet climates.
- Sinusitis occurs in both healthy and immunocompromised patients. Healthy patients can present with signs and symptoms of chronic sinusitis or a mass (aspergilloma) in the maxillary or ethmoid sinuses. Immunocompromised patients present with invasive disease characterized by bony destruction with extension to contiguous sites such as the orbit or CNS.
 - Noninvasive pulmonary aspergillomas are pulmonary fungus balls that grow in bronchogenic cysts or other lung cavities without invading lung tissue. They are the most frequent form of pulmonary aspergillosis.
- Invasive pulmonary aspergillosis occurs in the immunocompromised host, most commonly in patients with hematologic malignancy, solid-organ transplants, HIV infection, or other patients receiving long-term immunosuppressive therapy. Invasion of blood vessels by *Aspergillus* leads to infarction, necrosis, and hematogenous dissemination.
- Invasive aspergillosis in immunocompromised hosts can also involve the sinuses, brain, or skin. Rarer infections include endocarditis, meningitis, osteomyelitis, esophagitis, or infection of the eye.

DIAGNOSIS

HISTORY

- Question: Is there a history of chronic otitis externa?
 - Associated with otomycosis
- Question: Is there a history of sinusitis that does not clear?
 - Indolent or noninvasive paranasal sinusitis presents with signs and symptoms of chronic sinusitis that are unresponsive to antibiotic therapy
- Question: Does an asthmatic patient cough up large, dark mucus plugs?
 - ABPA should be considered in the asthmatic patient with a history of expectorating dark mucus plugs, or a history of fleeting pulmonary infiltrates on chest radiography (due to bronchial plugging).
- Question: Is the patient immunocompromised?
 - Immunocompromised patients, especially those with prolonged neutropenia, are at highest risk for invasive aspergillosis. Patients with neutropenia, who are febrile for 1 week despite broad-spectrum antibiotics, are at increased risk of invasive fungal infection.

PHYSICAL EXAM

- Otomycosis is characterized by a mass of black spores (*Aspergillus niger*) that start close to the eardrum and eventually fill the external canal, pain on tragal movement, and occasionally a purulent discharge. It is only rarely an invasive disease.
- Invasive sinus aspergillosis may present with severe pain, proptosis, monocular blindness, and bony destruction on radiographic films, with evidence of direct extension to the anterior fossa or orbit, or with widespread dissemination. The maxillary sinuses are most commonly involved.
- Invasive pulmonary aspergillosis may be indistinguishable from other causes of pneumonia on physical examination. Findings may include fever, tachypnea, rales, hypoxemia, and hemoptysis (secondary to the angioinvasive potential of the organism).

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Initial lab tests

- Isolation of *Aspergillus* sp. by culture is required for definitive diagnosis.
- *Aspergillus* can be recovered from samples of blood, cerebrospinal fluid, sputum, urine, broncho-alveolar lavage sample, or tissue biopsy. Types of specimens collected are guided by history and physical examination.
- *Aspergillus* spp. recovered from cultures of the respiratory tract (e.g., sputum and nasal cultures) are usually a result of colonization in the immunocompetent host but may indicate invasive disease in the immunocompromised host. The positive predictive value may be as high as 80–90% in patients with leukemia or bone marrow transplants.

- Microscopic examination of specially stained tissue samples, or of 10% potassium hydroxide wet-preparation samples, which are positive for branching, septate hyphae are suggestive of *Aspergillus* or other fungal invaders.
- Elevated serum IgE, eosinophilia, *Aspergillus*-specific serum IgE, and an immediate-type skin test response to *Aspergillus* antigen are often present in patients with allergic aspergillosis and are helpful in establishing the diagnosis.
- Radiographic studies may include characteristic findings such as wedge-shaped pleural-based densities or cavities on plain x-rays. Findings on CT scans include the “halo sign” (an area of low attenuation surrounding a nodular lung lesion) initially (caused by edema or bleeding surrounding an ischemic area) and later the “crescent sign” (an air crescent near the periphery of a lung nodule, caused by contraction of infarcted tissue).
- Recent developments in early diagnosis include the use of high-resolution chest CT, new rapid stain techniques and monoclonal antibodies for broncho-alveolar lavage samples, and serum ELISA for *Aspergillus galactomannan*.
- The galactomannan (an *aspergillus* cell wall component) ELISA may be helpful in diagnosing aspergillosis in immunocompromised children even prior to CT changes

DIFFERENTIAL DIAGNOSIS

- Other bacterial and fungal infections in immunocompromised hosts
- Allergic pneumonitis (other causes):
 - Chronic bacterial sinusitis
- Neoplasm

TREATMENT

MEDICATION (DRUGS)

First Line

The newer azole antifungal agent voriconazole is considered primary therapy for invasive aspergillosis. Treatment is generally at least 12 weeks.

Second Line

- Amphotericin B and the lipid-based amphotericin preparations remain appropriate second-line therapeutic options for patients who do not tolerate voriconazole or who are not responding to therapy. For patients in whom amphotericin is being considered, the lipid-based formulations may be preferred as initial therapy in those with marginal renal function or in those receiving other nephrotoxic drugs.
- Caspofungin is also effective second line therapy.
- Itraconazole has been shown to be efficacious in the treatment of mild to moderate aspergillosis. The oral form of itraconazole may be considered as an alternative to amphotericin for prolonged treatment once disease progression has been halted with IV amphotericin therapy.

ADDITIONAL TREATMENT

General Measures

- ABPA is frequently managed with oral steroids. In patients with corticosteroid-dependent ABPA, the addition of itraconazole has been shown to be an effective adjunctive agent. Itraconazole is also used when patients have slow or suboptimal response to steroid therapy, relapse, or steroid toxicity.
- If paranasal sinusitis is noninvasive, surgical drainage or débridement usually results in clearance of the infection.
- Otomycosis (most commonly secondary to *Aspergillus niger*) is often found in association with a bacterial external otitis. Débridement of the external canal and treatment of underlying bacterial external otitis usually produces a good therapeutic response.

SURGERY/OTHER PROCEDURES

Surgical excision, in addition to antifungal medication is sometimes required for localized débridement in invasive disease.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

The course of illness is variable, depending on host immune function and the location and invasiveness of disease.

ALERT

- Any immunocompromised patient with persistent fevers or signs of invasive infection who does not improve on treatment with broad-spectrum antibiotics must be evaluated for fungal infection, and the empiric use of antifungal medications should be considered.
- The rare finding of diffuse nodular pneumonia in children may be indicative of an underlying diagnosis of chronic granulomatous disease and aspergillosis.

PROGNOSIS

- Good in noninvasive disease, such as simple otomycosis or paranasal sinusitis
- Immunosuppressed or severely neutropenic patients may have rapid extension or dissemination of disease; prognosis is often very poor. Early recognition and aggressive treatment and débridement are necessary.

COMPLICATIONS

- Disseminated infection, defined as infection of 2 or more organs, can involve any of the previously discussed sites, as well as the CNS, heart, bones, or skin. Invasiveness depends on the immune state of the host, as well as the period of time and number of spores in the exposure.
- Patients with underlying diseases that predispose them to pulmonary cavitations, blebs, or cysts (such as asthma, chronic bronchitis, tuberculosis, sarcoid, histoplasmosis, and bronchiectasis) may develop an aspergilloma (fungus ball) after seeding their pulmonary secretions with *Aspergillus*. When the mass is large enough to be demonstrated on chest x-ray study, serum levels of IgG antibody to *Aspergillus* are characteristically high. Patients may present with hemoptysis, exacerbation of their underlying disease, or, rarely, invasion or dissemination.

CODES

ICD9

- 117.3 Aspergillosis
- 380.15 Chronic mycotic otitis externa
- 518.6 Allergic bronchopulmonary aspergillosis

ICD10

- B44.81 Allergic bronchopulmonary aspergillosis
- B44.89 Other forms of aspergillosis
- B44.9 Aspergillosis, unspecified

FAQ

- Q: What are rare complications of aspergillosis?
- A: Endocarditis, osteomyelitis, and cutaneous disease
- Q: Does person-to-person spread occur?
- A: No. The principal route of transmission is inhalation of airborne spore

ASPLENIA/HYPOSPLENIA

Matthew J. Ryan

BASICS

DESCRIPTION

Asplenia is the absence of the spleen due to either a congenital anomaly or a surgical procedure. Hyposplenia is defined by the impaired functional capacity of the spleen to prevent bacterial infections.

RISK FACTORS

- Risk of bacteremia is highest in younger children and in the years immediately following splenectomy.
- *Streptococcus pneumoniae* is the most common pathogen-causing septicemia in asplenic children followed by *Haemophilus influenzae*, *Neisseria meningitidis*, *Staphylococcus aureus*, and other streptococci.

PATHOPHYSIOLOGY

- Most patients with hyposplenism have no problems handling antigens. However, if the spleen is minimally functional, problems may develop. The major consequence is an inability to handle infections.
- The spleen is a major component of the reticuloendothelial system; it is important both for antibody synthesis (contains nearly 50% of the B lymphocytes) and removal of opsonized organisms (mononuclear phagocytes). The encapsulated microbes such as pneumococcus, meningococcus, and *Haemophilus* are usually eliminated by this mechanism.
- For patients <4 years of age in whom few alternate routes of bacterial clearance exist, significant pathology can result from impaired splenic function.
- Heterotaxy syndrome should be viewed separately because its prognosis is distinctly unfavorable. Heterotaxy syndrome is characterized by complex congenital heart defects, asplenia or polysplenia, and abdominal heterotaxy.
 - Common associated anomalies include atrioventricular canal defects, conotruncal anomalies, anomalous systemic pulmonary venous connections, and abnormalities of viscerotaxial situs.
 - The embryologic basis is thought to be a disturbance in embryogenesis in the 5th week of development that results in bilateral right-sidedness with abnormal pulmonary lobation in 80% of patients and abdominal heterotaxy in 72%.
 - Heterotaxy syndrome has an incidence of 1:6000 to 1:20,000 live births.

ETIOLOGY

- Secondary to:
 - Surgical splenectomy
 - Congenital asplenia
- In association with certain diseases or illnesses
- For complete list of causes, see "Differential Diagnosis."

DIAGNOSIS

HISTORY

The history taking should be directed toward the differential diagnosis. However, in the apparently healthy child with no identified risk factors who presents with an overwhelming infection with an encapsulated organism, the blood smear should be examined for signs of hyposplenism (see "Lab" below).

PHYSICAL EXAM

- On physical exam, the spleen may be normal, large, or atretic. Therefore, the size of the spleen cannot be used as an indicator of splenic function.
- The size is most closely linked to the underlying etiology.
 - Complete splenic replacement by cysts, neoplasm, or amyloid is an example of hyposplenic splenomegaly.
 - Sequestration crises such as those associated with sickle cell disease and malaria clog the spleen with cellular debris, which results in increased spleen size and decreased function.
 - Sickle cell disease patients typically have splenomegaly early in life as the spleen tends to sequester the abnormal red cells. With time, the spleen slowly auto-infarcts and eventually becomes nonpalpable. Sickle cell patients have impaired splenic function at all stages and should receive prophylactic antibiotics.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- The reduction or absence of splenic function can be determined by specific hematologic changes. Examination of a blood smear is essential to evaluate for signs of decreased splenic function.
- The spleen normally removes intracellular debris such as Howell-Jolly bodies (nuclear remnants), Heinz bodies (denatured hemoglobin), and Pappenheimer bodies (iron granules). Findings of target cells (red cells with a bull's eye center due to excessive membrane relative to the amount of iron and hemoglobin), Howell-Jolly bodies, Heinz bodies, Pappenheimer bodies, and pitted erythrocytes are indicative of hyposplenism or asplenia.
- Pits or pox on the red cell surface are the most sensitive indicator of hyposplenism. These are submembranous vacuoles that can be seen only in wet preparations of red cells fixed in 1% glutaraldehyde and viewed using direct interference-contrast microscopy.
- The ⁵¹Cr-labeled heat-damaged red cells can be used as a measure of the capacity of the spleen to clear particulate matter from the bloodstream.

Imaging

- Ultrasound with Doppler: Useful to assess spleen size and direction of flow in splenic vein and portal vessels.
- CT scan/abdominal MRI: Aids in the detection of polysplenia
- Radionuclide liver/spleen scan: Functional reticuloendothelial cells will be seen with this imaging modality.

DIFFERENTIAL DIAGNOSIS

Diminished splenic function found in:

- Congenital:
 - Isolated congenital asplenia
 - Heterotaxy syndrome
- Hematologic:
 - Sequestration crises (e.g., sickle hemoglobinopathies, essential thrombocytosis, malaria)
 - Sickle cell disease
 - Hereditary hemoglobinopathies

- Autoimmune:
 - Glomerulonephritis
 - Systemic lupus erythematosus
 - Rheumatoid arthritis
 - Sarcoidosis
 - Sjögren syndrome
 - Graves disease
 - Graft-versus-host disease
- Gastrointestinal/hepatic:
 - Celiac disease
 - Inflammatory bowel disease
 - Chronic liver disease/portal hypertension
- Space-occupying lesions:
 - Tumors, such as lymphoma
 - Amyloidosis
 - Cysts
- Postsplenectomy:
 - Trauma
 - Beta-thalassemia
 - Hereditary spherocytosis
- Vascular:
 - Splenic artery occlusion
 - Splenic vein thrombosis
- Miscellaneous:
 - Normal infants
 - Elderly
 - Bone marrow transplant
 - HIV infection
- Splenic irradiation

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Immunization with a pneumococcal conjugate and/or polysaccharide vaccine should be carried out in all patients with hyposplenism. In those patients who will be undergoing a scheduled splenectomy, the *S. pneumoniae*, meningococcus, and *H. influenzae* type b should be given at least 14 days prior to the operation.
- All children between 6 weeks and 59 months of age should receive the 4-dose series of the 13-valent pneumococcal conjugate vaccine (PCV13). A 23-valent pneumococcal polysaccharide vaccine (PPSV23) is available for children >2 years of age. A repeat of the PPSV23 should be administered 5 years after the 1st dose.
- Children should also receive the *Haemophilus influenzae* type b vaccine.
- Tetravalent meningococcal polysaccharide vaccine should be given to all asplenic patients at 2–10 years of age. Meningococcal conjugate vaccine should be administered to adolescents. Revaccination is recommended every 5 years in patients with functional or anatomic asplenia.
- Antimicrobial prophylaxis should be strongly considered in all asplenic children <5 years and for up to 3 years postsplenectomy. Oral penicillin is being replaced by amoxicillin-clavulanic acid, fluoroquinolones, and cefuroxime owing to increasing penicillin resistance.

ALERT

Generally, for patients <4 years, splenectomy is contraindicated because of the risk of developing bacterial infection.

CODES

ICD9

- 289.59 Other diseases of spleen
- 759.0 Anomalies of spleen, congenital

ICD10

- D73.0 Hyposplenism
- Q89.09 Congenital malformations of spleen

FAQ

- Q: What should I do if my child has a fever?
- A: In hyposplenic patients, especially those <4 years of age, all fevers should be taken seriously. Even if the child is being treated with prophylactic penicillin, he or she should be treated for all symptomatic bacterial infections.
- Q: Are there any special times I need to worry about infections?
- A: Asplenic patients receiving dental work or GI endoscopy should be considered on a case-by-case basis. Antibiotic prophylaxis should strongly be considered in asplenic patients undergoing high-risk endoscopic procedures (i.e., sclerotherapy, stricture dilation), as a transient bacteremia can occur in up to 50% of these patients.

ASTHMA

Lee J. Brooks

BASICS

DESCRIPTION

- Characterized by 3 components:
 - Reversible airway obstruction
 - Airway inflammation
 - Airway hyperresponsiveness to a variety of stimuli
- Diagnosis (the 3 “R”s)
 - Recurrence: Symptoms are recurrent.
 - Reactivity: Symptoms are brought on by a specific occurrence or exposure (trigger).
 - Responsive: Symptoms diminish in response to bronchodilator or anti-inflammatory agent.

ALERT

Pitfalls:

- Not recognizing that asthma can manifest as chronic cough; wheezing may not be evident.
- Reluctance to “label” child with having asthma (using terms such as reactive airway disease or bronchitis)
- Frequent antibiotic or cough medicine use to treat asthma symptoms
- “Recurrent pneumonias” often are actually asthma exacerbations; subsegmental atelectasis on chest radiograph misdiagnosed as an infiltrate
- Underreporting of asthma symptoms; beware the child who “doesn’t like to play sports”; he/she may have learned that exercise causes dyspnea.
- Poor adherence with therapy when symptoms are controlled
- Failure to use inhaled medications properly: Inhaled medication use must be taught and reviewed at each visit. A fixed-volume holding chamber should always be used with a pressurized metered-dose inhaler (pMDI), regardless of patient age. pMDIs should be refilled based on the number of doses used, not by estimating contents by shaking or spraying. pMDIs with a built-in dose counter are preferred.

EPIDEMIOLOGY

Incidence

- Most common chronic illness in children
- Death from asthma in children more than tripled from 1979 to 1996, but has been decreasing since then, perhaps owing to better recognition and increased use of anti-inflammatory medications. The incidence of death from asthma does not seem to correlate with severity.

Prevalence

- Wheezing in children is extremely common in the industrialized world (cumulative prevalence, 30–60%).
- In younger children, most episodes occur following viral infections.
- >50% of children who wheeze in early childhood stop wheezing by age 6 years.
- 14% of all young children (40% of those who wheeze during infancy) continue to wheeze.

RISK FACTORS

Genetics

- Children of asthmatics have higher incidence of asthma.
 - 6–7% risk if neither parent has asthma
 - 20% risk if 1 parent has asthma
 - 60% risk if both parents have asthma
- Several genes are known to be associated with the development of atopy and bronchial muscle responsiveness.

GENERAL PREVENTION

- Patient and caregiver education is mandatory to establish provider/caregiver partnership and ensure adherence with treatment plan.
- Every patient/caregiver should be taught that asthma is a chronic, inflammatory condition that can be controlled with proper therapy.
- All medications should be explained and potential risks (side effects) and benefits reviewed.
- A written asthma management plan should be provided, outlining daily therapy and an “action plan” for managing exacerbations of asthma.
- Environmental counseling:
 - Avoid airborne irritants (tobacco smoke, wood stoves, noxious fumes).
 - Minimize dust-mite exposure.
 - Minimize stuffed animals, quilts, books, and clutter.
 - Use dust mite–proof coverings on mattresses, pillows, and box springs.
 - Wash pillows, blankets, and sheets in hot water.
 - Avoid molds by decreasing relative humidity to 50%.
 - Remove pets from child’s bedroom and from house if patient is allergic to the animal.

PATHOPHYSIOLOGY

- Immune and inflammatory responses in the airways are triggered by an array of environmental antigens, irritants, or infectious organisms.
- Atopy and asthma are related.
 - Eosinophilia and the ability to make excess IgE in response to antigen are associated with increased airway reactivity.
 - Asthma is more common in children who have allergic rhinitis and eczema.

- Viral infections, particularly respiratory syncytial virus (RSV), during infancy may play a role in the development of asthma or may modify the severity of asthma.
- Exposure to cigarette smoke and other airway irritants influences the development and severity of asthma.
- Airway is stimulated and primary inflammatory mediators released.
- Airway is invaded by inflammatory cells (mast cells, basophils, eosinophils, macrophages, neutrophils, B and T lymphocytes).
- Inflammatory cells respond to and produce various mediators (cytokines, leukotrienes, lymphokines), augmenting the inflammatory response.
- Airway epithelium is inflamed and becomes disrupted, and basal membrane is thickened.
- Airway smooth muscle is hyperresponsive, and bronchoconstriction ensues.
- Airway smooth muscle hypertrophy and airway epithelial hyperplasia are characteristic chronic changes resulting from poorly controlled asthma.

DIAGNOSIS

HISTORY

- Inquire about these symptoms: Coughing, wheezing, shortness of breath, chest tightness:
 - Frequency of symptoms defines severity.
 - Precipitating factor (trigger)
 - Response to bronchodilator or anti-inflammatory medication
 - Family history of asthma or atopy
- Pattern of symptoms:
 - Perennial versus seasonal
 - Continuous versus acute
 - Duration and frequency of episodes
 - Diurnal variation/nocturnal symptoms
- Do any of the following set off the breathing difficulty?
 - Infections (upper respiratory, sinusitis)
 - Exposure to dust (mites), animal dander, pollen, mold
 - Cold air or weather changes
 - Exercise or play
 - Environmental stimulants (e.g., cigarette smoke, strong odors, pollutants)
 - Emotional factors (e.g., laughing, crying, fear)
 - Drug intake (aspirin, nonsteroidal anti-inflammatory drugs, β -blockers)
 - Food additives
 - Endocrine factors (e.g., menses, pregnancy, thyroid dysfunction)

- Review of systems:
 - Symptoms of complicating factors (gastroesophageal reflux, sinusitis, allergies)
 - Dyspepsia, sour taste (gastroesophageal reflux); throat clearing, purulent nasal discharge, halitosis, cephalgia, or facial pain (sinusitis); nasal itching (“allergic salute”), eye rubbing, sneezing, watery nasal discharge (allergies)
- Impact of asthma:
 - Number of hospitalizations/intensive care unit admissions
 - Number of emergency room visits/doctor’s office visits
 - Asthma attack frequency
 - Number of missed school days/parent workdays
 - Limitation on activity (may be subtle)
 - Number of courses of systemic steroids needed
- Environmental history:
 - Type of home
 - Location of home (urban, suburban, rural)
 - Heating system/air conditioning
 - Use of humidifier
 - Presence of molds, cockroaches, rodents
 - Fireplace
 - Carpeting
 - Stuffed animals
 - Pets
 - Exposure to cigarette smoke

PHYSICAL EXAM

- Pulmonary exam may be normal when asymptomatic.
- Assess work of breathing:
 - Level of distress
 - Intercostal/supraclavicular muscle retractions
- Chest shape (i.e., normal versus barrel shaped)
- Lung auscultation:
 - Wheezing
 - End-expiratory involuntary cough
 - Prolonged expiratory phase
 - Crackles or coarse breath sounds
 - Stridor (indicates extrathoracic airway obstruction)
- Head, eyes, ears, nose, and throat exam: Signs of allergies or sinusitis:
 - Watery or itchy eyes
 - Allergic shiners
 - Dennie lines
 - Nasal congestion
 - Boggy nasal turbinates
 - Nasal polyps
 - Postnasal drip
- General exam (vital signs):
 - Blood pressure (pulsus paradoxus)
 - Respiratory rate (tachypnea)
- Skin: Evidence of eczema
- Extremities: Digital clubbing (very rare in asthma; suggests alternative diagnosis)
- Physical exam trick: Forced-exhalation maneuver to observe for wheezes or for precipitating coughing

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Pulmonary function tests:
 - Essential for the assessment and ongoing care of children with asthma
 - Spirometry measures the degree of airway obstruction and the response to bronchodilators.
 - Values obtained can measure absolute degree of airway obstruction.
 - Serial values can follow progress of disease and response to treatment.
 - Children as young as 4–5 years old can usually perform spirometry with practice.
- Provocational testing:
 - Exercise challenge: Determines effect of exercise on triggering airway obstruction
 - Cold-air challenge: Indirect test of airway hyperresponsiveness
 - Methacholine challenge: A positive test supports the diagnosis of asthma (useful in cases for which history is equivocal and pulmonary function test is normal), measures the degree of airway hyperreactivity
- Allergy evaluation:
 - Blood tests (eosinophil count, IgE level)
 - Skin testing (best test for assessing allergen sensitivity)
 - RAST testing (not as accurate as skin testing)
 - Sputum/nasal examination for presence of eosinophilia
- Other studies:
 - Gastroesophageal reflux evaluation
 - pH probe
 - Milk scan
 - Barium swallow (confirms normal anatomy)
- Peak flow meter (home testing):
 - Measures peak flow rate (PEFR)
 - Effort dependent
 - Assesses central, not peripheral, airway obstruction
 - Used with patients who have poor symptom recognition or labile asthma
 - Dips in peak flow rate precede onset of clinical asthmatic symptoms.
 - Peak flow rate should be performed at least once a day.
 - Peak flow rate values are divided into 3 zones:
 - Green: $\geq 80\%$ of baseline
 - Yellow: 50–80% of baseline
 - Red: 50% of baseline
- Specific peak flow rate guidelines should be individualized for each patient based on the best measurement obtained during a 14-day period when the child is well.

Imaging

- Chest radiograph should be obtained if the diagnosis is uncertain or there is not the expected response to treatment, to rule out congenital lung malformations or obvious vascular malformations:
 - Findings can be normal.
 - Common findings are peribronchial thickening, subsegmental atelectasis, and hyperinflation.
- Sinus CT is useful if symptoms suggest sinusitis.
- Chest CT should be performed if bronchiectasis or anatomic abnormality is suspected.

Diagnostic Procedures/Other

Bronchoscopy can rule out anatomic malformations, foreign bodies, mucous plugging, vocal cord dysfunction, aspiration (lipid-laden macrophages).

DIFFERENTIAL DIAGNOSIS

- Infectious:
 - Pneumonia
 - Bronchiolitis
 - Chlamydia infection
 - Laryngotracheobronchitis
 - Sinusitis
 - Immune deficiency
- Mechanical:
 - Extrinsic airway compression
 - Vascular ring
 - Foreign body
 - Vocal cord dysfunction
 - Tracheobronchomalacia
- Miscellaneous:
 - Cystic fibrosis
 - Bronchopulmonary dysplasia
 - Pulmonary edema
 - Gastroesophageal reflux
 - Recurrent aspiration
 - Bronchiolitis obliterans

TREATMENT

MEDICATION (DRUGS)

- Corticosteroids (anti-inflammatory agents):
 - Most effective anti-inflammatory agents
 - Inhaled: Reduce airway inflammation and hyperresponsiveness more than any other inhaled agents; inhibit production and release of cytokines and arachidonic acid–associated metabolites; enhance β -adrenoreceptor responsiveness; side effects include oral thrush; may minimally affect growth velocity at moderate or high doses
 - Dosage individualized to each patient. Agents vary in topical potency and systemic bioavailability; available as pMDIs, dry-powder inhalers (DPIs), or nebulized. Fluticasone (Flovent) 44, 110, 220 mcg/puff pMDI and 50, 100, 250 mcg DPI; budesonide (Pulmicort) 90, 180 mcg/puff DPI and 250, 500, and 1,000-mcg vials for nebulizer; beclomethasone (Beclivent, Vanceryl, Qvar) 40, 42, 80, 84 mcg/puff; triamcinolone (Azmacort) 100 mcg/puff; flunisolide (AeroBid) 250 mcg/puff; mometasone (Asmanex) 220 mcg DPI
 - Oral: Used for asthma exacerbations or for severe asthma that cannot be otherwise controlled. Exacerbations: Prednisone 1–2 mg/kg/d for 3–7 days or longer; usually tapered if > 7 days of therapy required or if systemic steroids are used frequently. Ongoing therapy: 0.5–1 mg/kg/d daily or every other day for patients with severe asthma. Undesirable side-effect profile. When used daily, assess bone density and for cataract formation at least yearly.
 - IV: Methylprednisolone (Solu-Medrol) 1–2 mg/kg IV q6–12h until improved and able to take oral medication
- Leukotriene modifiers (anti-inflammatory agents):
 - Block the synthesis and/or action of leukotrienes
 - 5-Lipoxygenase inhibitors, zileuton: May cause hepatic dysfunction
 - Leukotriene receptor antagonists: Zafirlukast (10 mg; Accolate) and montelukast (4, 5, and 10 mg; Singulair)
 - Indicated as monotherapy for mild or exercise-induced asthma and in combination with an inhaled corticosteroid for more effective symptom control or using a lower dose of inhaled corticosteroid
- Mast-cell stabilizers
 - Weak anti-inflammatory agents
 - Preparations: Cromolyn sodium; nedocromil sodium (Tilade, available in Canada)
 - Decrease bronchial hyperresponsiveness
 - Can be used prior to exercise for exercise-induced symptoms
 - No significant side effects
 - Inhaled: Nebulizer; MDI

- β_2 -agonists (bronchodilators): Indication is for relief of acute bronchoconstriction (quick-relief medicine); used as needed in people with asthma who have breakthrough symptoms; used prior to exercise in exercise-induced bronchospasm; regular use or overuse associated with worsened control of asthma; routes include inhaled (most effective, metered-dose inhaler or nebulizer) and oral (least effective, most side effects); short-acting (4–6 hours) preparations include albuterol (Ventolin, Proventil, ProAir), terbutaline (Brethaire, Brethine), and metaproterenol (Alupent); a single-isomer preparation of albuterol (Xopenex) may have a slightly longer duration of action and perhaps fewer side effects; longer-acting (up to 12 hours) preparations include salmeterol (Serevent) and formoterol (Foradil) available as pMDI and DPI, can be used daily in conjunction with anti-inflammatory agent for improved symptom control. Fixed combination products of inhaled corticosteroid and a long-acting β -agonist (Advair, Dulera, Symbicort) are available as DPIs and pMDIs.
- There may be an increased risk of asthma-related deaths in patients using long-acting β -agonists (LABA) and it is suggested that LABAs be prescribed only for patients not adequately controlled on other asthma-controller medications or whose disease severity warrants initiation of treatment with 2 maintenance therapies.
 - Theophylline (bronchodilator): 2nd-line agent used when more conventional therapies are unsuccessful; indications are chronic, poorly controlled asthma and nocturnal asthma (if no gastroesophageal reflux); adjunctive therapy with β_2 -drugs and steroids in hospitalized patients in selected cases; route (oral or IV); serum levels must be routinely monitored (therapeutic levels are 10–20 mg/mL). Side effects are seen with increased levels. Many factors affect theophylline levels. Increased levels are seen with erythromycin, ciprofloxacin, cimetidine, viral illnesses, fever. Decreased levels are seen with phenobarbital, phenytoin, rifampin. Sustained-release tablets should not be crushed.
- Anticholinergic agents (bronchodilators): Adjunctive bronchodilators, may be useful in patients who only partially respond to β -agonists; preparations include ipratropium bromide MDI or ampule for nebulization (Atrovent).
- Monoclonal antibodies against IgE (Xolair) can be given as a monthly SC injection in severe asthma patients with moderately high IgE levels.

ISSUES FOR REFERRAL

- A patient who requires hospitalization more than once a year, or who has required intensive care
- A patient who requires frequent bursts of systemic corticosteroids
- A patient whose airway obstruction is not easily reversible
- A patient who has clinical features suggesting another pulmonary process

COMPLEMENTARY & ALTERNATIVE THERAPIES

- Miscellaneous drugs used in severe cases
- Steroid-sparing agents:
 - Troleandomycin (TAO): Macrolide antibiotic; decreases clearance of corticosteroids, thus prolonging the effects of corticosteroids on the lung; lower corticosteroid dosing required
 - Methotrexate: Potent immunosuppressive drug; needs further investigation in children
 - Cyclosporine: Shown to have steroid-sparing effect in adult population with asthma; side effects are significant and may limit use
 - Magnesium sulfate (MgSO₄): Used intravenously as a smooth muscle relaxer in severe acute asthma exacerbation
- Helium:
 - May improve airflow in severe asthma
 - Can improve ventilation and potentially oxygenation
- Immunotherapy:
 - Efficacy in asthma is controversial
 - Most effective if a single antigen can be identified
 - Used only in select cases if medical management and environmental control measures are ineffective

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Long-term follow-up is essential to maintain normal activity and pulmonary function. All patients should use a valved holding chamber with pMDIs, and technique for all inhaled medications should be reviewed regularly.

Patient Monitoring

Signs that may indicate problems: Increased symptoms (cough day or night, wheeze), exercise limitations or symptoms during exercise, decrease in peak flow rate, increasing use of inhaled bronchodilators, subject not improving on enhanced home therapy

DIET

- Avoid foods or food additives (if truly allergic).
- Food-induced asthma is uncommon.

PATIENT EDUCATION

Activity:

- Most patients with asthma can participate fully in sports, even at a high level, with close follow-up. Extra medications such as albuterol and/or cromolyn may be required before vigorous exercise. All athletes should have their quick-relief medications on hand at all times.
- Athletes with asthma may need to report their medications to the governing bodies of their sport.

PROGNOSIS

With proper therapy and good adherence to treatment regimen: Excellent

COMPLICATIONS

Morbidity: Frequent hospitalizations and absence from school. Psychological impact of having a chronic illness. Decline in lung function over time

CODES

ICD9

- 493.00 Extrinsic asthma, unspecified
- 493.92 Asthma, unspecified type, with (acute) exacerbation

ICD10

- J45.901 Unspecified asthma with (acute) exacerbation
- J45.909 Unspecified asthma, uncomplicated

FAQ

- Q: Will my child outgrow his or her asthma?
- A: Family history and allergies affect the ultimate outcome. Wheezing during the 1st 3 years of life is extremely common, with 40–50% of all children wheezing at some time. Many of these children do not develop asthma and “outgrow” their illness by school age. Some patients develop asthma again as young adults.
- Q: Can my child become dependent on asthma medications?
- A: Children do not become “dependent” on these medications as they would with narcotic agents. Daily asthma medications are required to maintain airway patency and to control airway inflammation.
- Q: Will my child be on medications for the rest of his or her life?
- A: This depends on the severity of the asthma. The types, doses, and frequency of asthma medications will change over a patient's lifetime.
- Q: Do inhaled steroids affect patient growth?
- A: There is some transient and slight decrease in growth velocity seen in children who receive moderate-dose inhaled corticosteroids (~0.5 mg/d). Ultimate height does not seem to be affected.

ATAXIA

Sunil Thummala

Susan L. Perlman (5th edition)

BASICS

DESCRIPTION

- Incoordination or clumsiness of movement, disproportionate to weakness
- Most acute ataxias are acquired; chronic ataxias are congenital or hereditary.
- Caused by dysfunction of cerebellum, proprioception, or vestibular system

Clinical presentation:

- Ataxia with fever, rash, GI illness, or recent immunization suggests more benign acute cerebellar ataxia; headache, diplopia, vomiting: More ominous—acute hydrocephalus, tumor, or stroke
- Altered mental status, headache, or seizures raise suspicion for acute disseminated encephalomyelitis (ADEM).
- Brainstem encephalitis: Cranial neuropathies
- Disorders of vestibular pathway: Severe vertigo, nausea, vomiting, and hearing problem
- Toxic/metabolic causes usually alter consciousness.
- Rapidly ascending weakness following infection suggests Guillain Barré (GBS).
- Acute-onset ataxia with diplopia suggests brain stem stroke, tumor.
- Rapidly clearing ataxia with confusion and focal weakness suggests postictal state.
- Headache, visual scintillations, nausea, and dizziness suggest migraine.
- Mitochondrial disorders commonly feature short stature, seizures, retinopathy, heart block, myopathy, and mental retardation.
- Friedreich ataxia is associated with cardiomyopathy, diabetes, scoliosis, pes cavus, and peripheral neuropathy.
- Ataxia telangiectasia: Telangiectasias, frequent bronchopulmonary infection, leukemia/lymphoma, other cancers

EPIDEMIOLOGY

- ~80% of acute ataxias due to postviral, intoxication, GBS.
- ~1 in 1,000 children develops acute ataxia following varicella infection.
- Congenital cerebellar syndromes: Caused by perinatal trauma, vascular events (“ataxic cerebral palsy”). Dandy-Walker syndrome and structural cerebellar abnormalities are rarer.
- Friedreich ataxia: 2–4 in 100,000
- Ataxia with oculomotor apraxia: 5 in 100,000
- Brain gliomas: Common in children

GENERAL PREVENTION

Accidental intoxications, varicella vaccination

PATHOPHYSIOLOGY

- Dysfunction of cerebellum, proprioceptive sensors, and vestibular system causes ataxia.
- Unilateral cerebellar ataxia: Ipsilateral cerebellum or its connections
- The cerebellum can also become the target of autoimmune phenomena.

ETIOLOGY

- Acute-onset ataxias: Postinfectious (ADEM) inflammatory conditions, infection, intoxication, tumors, intracerebral hemorrhage, stroke, trauma, conversion disorder:
 - Intoxication by benzodiazepines, antihistamines, anticonvulsants, lead, CO, alcohol, inhalants
 - Posterior fossa tumors: Medulloblastoma, occult neuroblastoma/opsoclonus-myoclonus-ataxia syndrome
 - Pontine/medullary strokes, strokes involving cerebellum, cerebellar peduncles
 - Acute ataxia with inconsistent findings suggests psychogenic ataxia.
- Episodic: Migraine, seizures, inborn errors of metabolism, familial periodic ataxia (dominant)
- Chronic progressive ataxias: Genetic:
 - Friedreich, ataxia telangiectasia, aminoacidopathies, hexosaminidase A deficiency, abetalipoproteinemia/hypobetalipoproteinemia, Wilson disease, mitochondrial peroxisomal disorders, dominant spinocerebellar ataxias
 - Chiari malformation, Dandy-Walker syndrome, agenesis of cerebellar vermis
- Paraneoplastic: Ataxia may precede opsoclonus/myoclonus due to neuroblastoma/ganglioneuroma.

DIAGNOSIS

HISTORY

- Acute ataxia:
 - History directed to possible intoxication, head trauma, or migraine
 - Recent infection suggests postviral cerebellar ataxia, labyrinthitis, or Guillain-Barré syndrome, ADEM
 - Access to drugs, altered mental status = possible intoxication
 - Recent trauma: Concussion, vertebral dissection/stroke, intracranial bleed
 - History of congenital heart defect: Cerebellar stroke
 - Severe vertigo, nausea, vomiting, hearing problem: Labyrinthitis
- Episodic ataxias:
 - Headache with nausea, visual changes, focal neurologic findings: Migraine syndrome
- Chronic ataxias:
 - Irritability or progressive macrocephaly or cranial neuropathy suggests posterior fossa pathology (e.g., tumor).
 - Multiple system involvement should raise concern for metabolic/genetic causes (mitochondrial disorders, organic acidurias, Friedreich ataxia, ataxia telangiectasia).

PHYSICAL EXAM

- Abnormalities on cranial nerve exam for posterior fossa pathology
- Ataxia proportional to degree of weakness suggests lesion in motor pathway (e.g., myasthenia gravis, GBS).
- Absent DTR: GBS
- Limb dysmetria (appendicular ataxia), dysidiadochokinesis, hypotonia, tremor
- Vermis: Manifests as truncal ataxia, gait ataxia (“drunken” movements), nystagmus, dysarthria, titubation
- Vestibular: Gait ataxia, nystagmus, abnormal Rinne and Weber tests
- Disorders of proprioception: Positive Romberg test, decreased reflexes

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Toxicology screen in acute ataxia; drug levels for specific intoxication
- Lumbar puncture for CSF analysis (for ADEM, GBS, infection)
- EEG if postictal ataxia is a possibility
- Full workup for neuroblastoma in ataxia-opsoclonus/myoclonus: Body CT, MIBG scan, serum ferritin, urine (HVA/VMA)
- Metabolic: Lysosomal hydrolases, ammonia, plasma and CSF lactate, pyruvate, long-chain fatty acids, plasma/urine amino and organic acids
- Low cholesterol: Abetalipoproteinemia
- Elevated α -fetoprotein, decreased serum IgA: Ataxia telangiectasia.
- Genetic tests for Friedreich ataxia, ataxia telangiectasia, and the dominantly inherited spinocerebellar ataxias (many subtypes)
- Mitochondrial screening: Plasma or CSF lactate, genetic testing on blood, muscle biopsy

Imaging

- Radiologic studies are necessary when intoxication has been ruled out. Imaging of brain can help rule out tumor, stroke, or demyelination.
- MRI is superior to CT in most cases; however, if intracranial hemorrhage is a concern a noncontrast CT can quickly confirm diagnosis and aid in treatment

Pathological Findings

Pathology is specific to the underlying etiology, although neurodegenerative cerebellar disease may show only nonspecific loss of Purkinje cells.

DIFFERENTIAL DIAGNOSIS

- Movement disorders (exaggerated physiologic tremor, chorea, athetosis) and limb weakness may be mistakenly diagnosed as ataxia.
- Paretic ataxia: Incoordination proportional to the degree of weakness suggests ataxia (GBS, tick paralysis).
- Psychogenic: Variable effort; no pathologic nystagmus; changing character of tremor, excessive swaying while walking but no fall (astasia-abasia); corrective steps before falling

- Acute ataxia:
 - Intoxication: Depressed mental status; toxicology screen; medications at home
 - Posttraumatic: History/physical findings
 - Postinfectious: Acute cerebellar ataxia (with dysarthria, mild hypotonia)
 - Paraneoplastic: Ataxia may precede opsoclonus/myoclonus due to neuroblastoma/ganglioneuroma.
 - Migraine: Resolves in hours; headache may precede ataxia.
 - Labyrinthitis: Fast phase of nystagmus is unidirectional.
 - ADEM: White matter changes on MRI or CT
 - Acute polyneuropathy: Guillain-Barré syndrome (areflexia, signs of sensory ataxia)
 - Stroke: Focal deficits; abnormal imaging studies
 - Postictal: Rapidly resolving ataxia with negative studies, slowing on EEG; history of convulsion
 - Familial periodic ataxia: Family history
 - Metabolic disorders: Pyruvate dysmetabolism (attacks provoked by febrile illness, associated lactic acidosis), biotinidase deficiency (associated seizures, skin rash)
 - Psychogenic: Variable effort; no pathologic nystagmus; gait is grossly unsteady, corrective steps before falling
- Chronic ataxia:
 - Brain tumor (especially in children <10 years of age): Associated cranial neuropathies, papilledema, headache, pyramidal tract signs
 - Friedreich ataxia: Onset 5–15 years of age, other affected siblings, associated cardiomyopathy, diabetes, polyneuropathy, scoliosis, pes cavus
 - Ataxia telangiectasia: Onset <5 years of age, frequent bronchopulmonary infection, and leukemia/lymphoma (elevated α -fetoprotein)
 - Ataxia with oculomotor apraxia type 1: Onset 2–18 years of age, associated polyneuropathy, chorea, cognitive difficulty (hypoalbuminemia, hypercholesterolemia)
 - Ataxia with oculomotor apraxia type 2: Onset 2–22 years of age, associated polyneuropathy, chorea (elevated α -fetoprotein and CPK)
 - Leukodystrophy: Adreno-, metachromatic, Pelizaeus-Merzbacher (abnormal MRI)
 - Other metabolic diseases: Niemann-Pick type C (bone marrow biopsy); Refsum disease; juvenile-onset Tay-Sachs disease, neuraminidase deficiency (lysosomal disorders); maple syrup urine disease, Hartnup disease (amino acid screen); familial coenzyme Q10 deficiency; familial vitamin E deficiency; cerebral folate transport disorder (low 5-MHTF in CSF)
 - Abetalipoproteinemia: Hypocholesterolemia
 - Mitochondrial disease: Retinopathy, sensorineural hearing loss, diabetes, growth delay, seizures, strokelike episodes, myopathy, elevated pyruvate and lactate levels
 - Congenital disorders of glycosylation
 - Thiamine deficiency
 - Celiac disease
 - Autosomal dominant ataxias
 - Long-term phenytoin use: Primarily adults
 - Rare: Ataxic cerebral palsy, brain dysgenesis, Joubert syndrome, multiple sclerosis, Gerstmann-Sträussler (familial, prion disease)

TREATMENT

- Treatment of individual disorders associated with ataxia is beyond the scope of this chapter.
- Majority of acute ataxias are self-limited, needing only supportive care.
- Treatment depends on underlying condition (e.g., if due to phenytoin toxicity, adjust phenytoin dose).
- Precautions and limitation of activity to decrease injury
- Early identification and management of aspiration
- Steroids, IVIG, plasma exchange for ADEM (limited evidence)
- Brainstem encephalitis: Antibiotics/antiviral coverage until studies are negative
- Immunomodulatory therapies have been tried (steroids, plasma exchange, IVIG) for paraneoplastic ataxia-opsoclonus/myoclonus, which may persist long after therapy for the tumor.
- Epilepsy, migraine preventive therapy
- Acetazolamide may be helpful in familial periodic ataxia.
- Drugs useful for tremor can be helpful for cerebellar tremor.
- Replacement therapies rarely helpful: Vitamin E, thiamine, B₁₂, coenzyme Q10; biotin; folic acid (cerebral folate disorder).
- Physical and occupational therapy, speech therapy, other rehabilitation interventions

ONGOING CARE

PROGNOSIS

- Most acute ataxias are postviral and have good prognosis.
- Acute postinfectious cerebellar ataxia resolves over days to weeks; if imaging studies show demyelination, recovery may take longer.
- Behavioral and learning difficulties may persist in 20% of children with postviral acute cerebellar ataxia.
- Most patients with ADEM recover completely.
- Familial periodic ataxia has benign course.

COMPLICATIONS

- Risks of injuries, aspiration, secondary infections, and depression.
- GBS: Monitor for autonomic instability, respiratory failure
- Ataxia telangiectasia: Immunodeficiency, neoplasia

ALERT

- Inadvertent intoxication with anticonvulsants may not be detected on routine toxin screen.
- MRI: Evaluate ataxia and a headache (Arnold-Chiari type 1 malformation, tumor)

FAQ

- Q: What intoxications are most likely to cause ataxia?
- A: Benzodiazepines, the major anticonvulsants (except valproate), psychotropic medications, ethanol, tricyclics, and antihistamines
- Q: How long can postinfectious cerebellar ataxia last?
- A: Rarely, it may last for months, but usually improves during that time.
- Q: What is the role of physical therapy for cerebellar ataxia?
- A: Repetitive exercise balance and coordination may improve ataxia. Vestibular compensation exercise may improve vertigo in patients with vestibular ataxia.

ATELECTASIS

Richard M. Kravitz

BASICS

DESCRIPTION

- State of collapsed and airless alveoli
- May be subsegmental, segmental, or lobar, or may involve the entire lung
- A radiographic sign of an underlying disease and not a diagnosis unto itself

EPIDEMIOLOGY

- Depends on the underlying disease causing atelectasis
- Resorption atelectasis the most common form

RISK FACTORS

Genetics

Depends on the underlying disease causing atelectasis (i.e., cystic fibrosis; primary ciliary dyskinesia)

GENERAL PREVENTION

- Maintaining adequate cough
- Good airway clearance techniques in patients at risk for atelectasis

PATHOPHYSIOLOGY

- Reduced lung compliance
- Loss of alveoli (if extensive) may lead to hypoxia.
- Intrapulmonary shunting develops from hypoxia-induced pulmonary arterial vasoconstriction, which may lead to areas of ventilation/perfusion (V/Q) mismatch and further hypoxia.
- If atelectasis is extensive and long-term, pulmonary hypertension may develop.
- Atelectatic areas are prone to bacterial overgrowth and possible secondary infection.

ETIOLOGY

- Airway obstruction (resorption atelectasis):
 - Most common cause of atelectasis in children
 - Obstructed communication between alveoli and trachea
- Large airway obstruction:
 - Intrinsic: Foreign-body aspiration, mucus plug, tumor, plastic bronchitis
 - Extrinsic: Hilar adenopathy, mediastinal mass, congenital lung malformations

- Small airway obstruction
 - Acute infection: Bronchiolitis, pneumonia (respiratory infections are the most common cause of acute atelectasis)
 - Altered mucociliary clearance: CNS depression, smoke inhalation, pain
- Mechanical compression of the pulmonary parenchyma or pleural space (compressive atelectasis):
 - Intrathoracic compression: Pneumothorax, pleural effusion, lobar emphysema, intrathoracic tumors, cardiomegaly, diaphragmatic hernias
- Abdominal distention: Large intra-abdominal tumors, hepatosplenomegaly, massive ascites, morbid obesity
- Decreased surface tension in the small airways and alveoli (adhesive atelectasis):
 - Stems from surfactant deficiency
 - Diffuse surfactant deficiency (e.g., hyaline membrane disease, acute respiratory distress syndrome, smoke inhalation)
 - Localized surfactant deficiency (e.g., acute radiation pneumonitis, pulmonary embolism)
- Neuromuscular weakness (hypoventilation):
 - Inherent weakness (e.g., Duchenne muscular dystrophy, spinal muscular atrophy, paralysis)
 - Acquired weakness (e.g., postanesthesia hypoventilation)

DIAGNOSIS

HISTORY

- Dependent on the underlying disease process
- May be asymptomatic
- Cough and/or wheeze can be present
- Dyspnea
- Chest pain
- Special questions:
 - Is the atelectasis acute, recurrent, or chronic in terms of its duration?
 - Is there a history of asthma, chronic lung disease, or exposure to smoke or toxic fumes that would increase the risk for atelectasis?

PHYSICAL EXAM

- May be normal
- Tachypnea
- Rales or rhonchi
- The most specific sign is localized decrease or loss of breath sounds.
- Dullness to percussion if large area involved
- Tracheal deviation and shift of heart sounds toward atelectatic side
- Localized wheezes in cases of partial obstruction
- Cyanosis (seen when extensive atelectasis is present, causing impairment of oxygenation and areas of ventilation/perfusion mismatch)

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Appropriate test is dependent on the underlying etiology:

- Asthma:
 - Spirometry
 - Sweat test (if cystic fibrosis suspected)
- Infection:
 - Cultures (sputum, blood, bronchoalveolar lavage fluid)
 - Nasal washing (especially for viruses)
 - PPD (when tuberculosis is suspected)
- Foreign-body aspiration:
 - Bronchoscopy (to remove the obstructing agent. Rigid bronchoscopy is indicated if the obstructing agent is a foreign body; flexible can be used for mucus plugs, plastic bronchitis, or infectious etiology)
- Immunodeficiency:
 - CBC with differential
 - Immunoglobulins (IgG, IgA, IgM)
 - HIV testing
- Congenital malformations:
 - CT scan of the chest (for lung malformation)
 - Bronchoscopy (for H-type tracheoesophageal fistula [TEF] or bronchial stenosis)

Imaging

- Chest radiograph:
 - Most important diagnostic tool
 - Radiographic signs of atelectasis:
 - Loss of lung volume from the affected lobe
 - Compensatory hyperexpansion of the remaining lobes on the affected side
 - Shift of interlobar fissures
 - Elevation of diaphragm
 - Mediastinal shift toward the affected side
 - Approximation of ribs on the affected side
- CT of chest:
 - Confluence of bronchi and blood vessels converge toward the affected side
 - Provides information with regard to precise location and extent of any obstructing process

DIFFERENTIAL DIAGNOSIS

- Pneumonia:
 - Viral pneumonia versus subsegmental atelectasis
 - Bacterial pneumonia versus segmental or lobar atelectasis
- Thymus (may often be mistaken for atelectasis in an upper lobe)
- Congenital malformations (e.g., sequestration, bronchogenic cyst)
- Pleural effusion

**TREATMENT****ADDITIONAL TREATMENT****General Measures**

- Treat underlying disease (i.e., removal of aspirated foreign body; clearance of mucus plugs; treatment of any underlying infection)
- Chest physical therapy with bronchodilators (usually for at least 1 month).
- If no improvement with conservative therapy, a bronchoscopy with lavage to remove possible mucus plug is indicated (lavage may be with saline or, in select cases, with recombinant human DNase or N-acetylcysteine).
- Consider surgery to remove the affected region:
 - Chronic or recurrent atelectasis
 - Unresponsive to therapy
 - Focal bronchiectasis has developed.
 - Significant morbidity is seen.

- Prevention of recurrent or future atelectasis: Directed toward underlying cause, when applicable
- Airway clearance is important in clearing areas of atelectasis.
- Various techniques are available including:
 - Manuel chest physiotherapy
 - Mechanical chest physiotherapy (ThAIRapy vest)
 - Incentive spirometry
 - Acapella or Flutter devices
 - Intermittent positive pressure breathing (IPPB) or intrapulmonary percussive ventilator (IPV)
 - Mechanical insufflator-exsufflator (Cough Assist):
 - For patients with weakened cough (i.e., neuromuscular weakness)

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

Expect improvement: 1–3 months in typical, uncomplicated cases

PROGNOSIS

- Dependent on the underlying disease process
- In otherwise healthy individuals: Excellent

COMPLICATIONS

- Recurrent infections
- Bronchiectasis
- Hemoptysis
- Abscess formation
- Fibrosis of the pulmonary parenchyma

**CODES****ICD9**

- 518.0 Pulmonary collapse

ICD10

- J98.11 Atelectasis
- P28.10 Unspecified atelectasis of newborn

FAQ

- Q: When is the optimal time for bronchoscopy?
- A: There are no established criteria for when a bronchoscopy should be performed. A bronchoscopy should be done early in the course of illness when:
 - There is a high suspicion of a foreign body.
 - Significant respiratory distress is present.
 - Cases of acute chest syndrome in patients with sickle cell disease
 - If the atelectasis is extensive and conservative treatment is ineffective
 - Bronchoscopy is infrequently performed in patients with cystic fibrosis secondary to its recurrent nature.

ATOPIC DERMATITIS

Albert C. Yan

BASICS

DESCRIPTION

Atopic dermatitis or eczema is a chronic, recurrent, pruritic skin eruption seen in individuals with associated personal or family history of atopy (e.g., asthma, allergies, hay fever, or rhinitis). The disease is characterized by intermittent acute flares. It most commonly begins in infancy or early childhood.

EPIDEMIOLOGY

Incidence

- Atopic dermatitis is a common disease, occurring in nearly 1 in 5 children.
- ~60% of patients with atopic dermatitis will develop it in the 1st year of life, and 30% between the ages of 1 and 5 years.

Prevalence

- A family history of atopy (e.g., allergies, asthma, eczema, or hay fever) is present in 30–70% of patients.
- Atopic dermatitis is usually worse in the winter, but can flare at any time of year.

RISK FACTORS

Genetics

- There is a genetic trait seen in atopic dermatitis, with 30–70% of family members having atopy (allergies, asthma, eczema, or hay fever).
- The exact mode of inheritance is not well defined and appears to be multifactorial. However, in a subset of patients, studies indicate a strong link to filaggrin mutations among patients suffering from atopic dermatitis, asthma, and ichthyosis vulgaris.

PATHOPHYSIOLOGY

- Histologic findings are dependent on the stage of atopic dermatitis (i.e., acute or chronic).
- Lymphocytes can be seen infiltrating the epidermis.
- The acute form shows spongiosis and intercellular edema that can lead to vesicle formation.
- The chronic form is characterized by epidermal psoriasiform hyperplasia and hyperkeratosis.

ETIOLOGY

- Etiology of atopic dermatitis is multifactorial, with genetic, environmental, physiologic, and immunologic factors.
- Increased viral (warts and molluscum) and dermatophyte infections seen in these patients appears to be related to cytokine-induced suppression of endogenous antimicrobial peptides.
- Patients often have elevated IgE levels and decreased chemotaxis of neutrophils.
- Up to 70% of patients have a family history, but the mode of inheritance is not well defined.

DIAGNOSIS

HISTORY

- Age of onset
- Location
- Prior treatment
- Bathing habits
- Family history of atopy (allergies)
- Asthma
- Eczema
- Hay fever
- Special questions:
 - Excessive dryness exacerbates this disease; therefore, inquiry about bathing habits, frequency, and emollients is helpful.

PHYSICAL EXAM

- Acute flares reveal weeping and crusted erythema.
- Chronic disease is characterized by hyperpigmentation or hypopigmentation, lichenification, and scaling.
- The distribution of the disease is dependent on age.
 - During infancy to ~2 years of age, the disease is widespread and includes cheeks, forehead, scalp, and extensor surfaces.
 - In children from ~3–11 years of age, the disease involves the more characteristic flexural sites with lichenification.
 - The hands and face can also be involved.
 - From adolescence to adulthood, the flexures, neck, hands, and feet are frequently involved, with the face and neck flaring occasionally.
- When the disease is severe, it can present as exfoliative erythroderma with diffuse scaling and erythema.
- Other associated findings include: Dennie-Morgan folds (infraorbital folds), pityriasis alba (dry white patches), hyperlinear palms, facial pallor, infraorbital darkening, follicular accentuation, keratosis pilaris (dry, rough hair follicles on extensor surfaces of upper arms and thighs), and ichthyosis.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- No tests by themselves are diagnostic of atopic dermatitis.
- Biopsy can be helpful to rule out papulosquamous disease, such as psoriasis.
- IgE levels are often elevated. When extremely high, evaluation for associated comorbidities such as HyperIgE syndrome should be considered
- Bacterial cultures can help identify superinfection during acute flares. Rapid fluorescent antibody studies, polymerase chain reaction studies, or viral cultures, and Tzanck smear can identify complications of eczema herpeticum.
- Patch testing can help differentiate atopic dermatitis from contact dermatitis.

DIFFERENTIAL DIAGNOSIS

- Diagnostic criteria have been established for atopic dermatitis:
 - Severe seborrheic dermatitis
 - Contact dermatitis
 - Allergic or irritant, psoriasis
 - Wiskott-Aldrich syndrome
 - Langerhans cell histiocytosis
 - Acrodermatitis enteropathica
 - Scabies
 - Xerosis
 - Hyper-IgE syndrome (including recently described mutations in STAT3, DOCK8, and tyk2)
- Metabolic deficiencies:
 - Carboxylase deficiencies
 - Prolidase deficiencies

TREATMENT

MEDICATION (DRUGS)

- Antihistamines, such as hydroxyzine or diphenhydramine, may help to decrease itching in selected patients.
- Topical steroids control inflammation and mid- to high-potency steroids can be used during acute flares, with tapering of steroids to milder potency when control is achieved. Once cleared, topical steroids can be held and substituted with emollients. Long-term use of steroids can lead to atrophy, telangiectasias, tachyphylaxis, and occasionally, stunting of growth.
- Oral antibiotics are indicated when there is superinfection of lesions. Dilute bleach baths (about 1/4 cup per full tub of water or about 1 tsp per gallon of water) can be used as a once or twice weekly 10-minute soak to help reduce bacterial colonization and risk for recurrent skin infection.
- Antivirals are needed for cases of eczema herpeticum. During acute flares with oozing and crusting and when there is superinfection with bacteria or herpes simplex virus, compresses can be helpful.
- Tacrolimus ointment and pimecrolimus cream are topical therapies recently approved for use in children 2 years of age and older. These are calcineurin phosphatase inhibitors that act to suppress T-cell function. Because these agents are not steroids, they are not atrophogenic and do not appear to alter hypothalamic-pituitary axis function. However, less is known regarding its long-term effects in children. Children who receive this medication should receive instructions for diligent sun protection and sunscreen use to minimize potentiation for sun damage.

- Systemic steroids are generally not used because of the chronicity of atopic dermatitis, and are reserved for when control of the eruption is very difficult, and then use should be of short duration.
- Phototherapy with UVB can be used in patients with extensive disease that is resistant to other therapy.
- The use of topical barrier repair agents cleared by the US Food and Drug Administration include N-palmitoylethanolamine cream, MAS063DP cream, and various ceramide formulations and may be useful adjuncts to therapy.

ADDITIONAL TREATMENT

General Measures

- There is no cure for atopic dermatitis.
- Parents must understand that this is a chronic disease with intermittent flares and that control is the aim of treatment.
- Good skin care is critical to maintenance and includes use of mild soaps, frequent use of emollients, and avoidance of excessive bathing.
- Avoidance of irritants from the environment, such as wool sweaters or blankets, is recommended. Protective clothing at night to avoid scratching while sleeping is also helpful, as is trimming the nails.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

It should be emphasized to parents that atopic dermatitis is a chronic disease and that good skin care is necessary to control disease activity. Up to 40–50% of children will outgrow their atopic dermatitis after the age of 5 years.

COMPLICATIONS

- Decreased cell-mediated immunity, decreased chemotaxis, and decreased production of endogenous antimicrobial peptides can result in increased infection (e.g., viral, dermatophyte, bacterial). Patients with atopic dermatitis have a high density of *Staphylococcus aureus* on their skin, and given the fissures and open excoriations, there is a risk of superinfection of these lesions.
- The decreased integrity of the skin can result in widely spread cutaneous infections such as herpes simplex infection, known as Kaposi varicelliform eruption or eczema herpeticum. Similar problems can also be seen with coxsackievirus or molluscum contagiosum and used to occur with Vaccinia.

- Cataracts can be found in patients with atopic dermatitis.
- Overuse of potent topical steroids can result in hypopigmentation, telangiectasias, atrophy, and striae, as well as excess systemic absorption leading to hypothalamic–pituitary axis suppression and growth retardation.
- Early growth delay is not uncommon among children with atopic dermatitis, although later catch-up growth is generally seen. This may be related to various mechanisms including impaired growth-hormone release. This growth delay can occur independent of topical steroid exposure.
- Pigmentary changes may result from overuse of topical medications; however, the lesions of atopic dermatitis may themselves cause postinflammatory skin color changes independent of topical therapy.

CODES

ICD9

691.8 Other atopic dermatitis and related conditions

ICD10

- L20.83 Infantile (acute) (chronic) eczema
- L20.89 Other atopic dermatitis
- L20.9 Atopic dermatitis, unspecified

FAQ

- Q: Will the child outgrow this?
- A: Up to 40–50% of children will outgrow their atopic dermatitis after age 5 years. In some patients, however, the disease will persist to variable extents throughout adulthood.
- Q: When atopic dermatitis is controlled, is any treatment necessary?
- A: Excessive dryness can exacerbate or flare disease. Therefore, less frequent use of soaps and frequent use of emollients are recommended.
- Q: Do food hypersensitivities play a role in atopic dermatitis?
- A: This is a debated issue. In general, the majority of patients are probably not adversely affected by foods. However, some individuals, particularly those who are unresponsive to routine therapy, may benefit from screening for food hypersensitivity and a trial of avoidance to any foods that test positive. The most common foods associated with exacerbation when an association can be made are eggs, milk, wheat, soy, peanuts, and fish.

ATRIAL SEPTAL DEFECT

Jonathan Fleenor

BASICS

DESCRIPTION

- An opening in the atrial septum, other than a patent foramen ovale (PFO)
- 4 major types of atrial septal defects (ASDs):
 - Secundum atrial septal defect
 - Primum atrial septal defect
 - Sinus venosus atrial septal defect
 - Coronary sinus atrial septal defect
- A patent foramen ovale usually does not cause a significant intracardiac shunt. A probe patent foramen ovale can be found in up to 15–25% of normal hearts at pathologic exam.
- Secundum defects make up 60–70% of all atrial septal defects. Usually there is a shunt from the left atrium to the right atrium.
- Primum defects occur in ~30% of all atrial septal defects. They are usually associated with a cleft mitral valve. This defect is the result of an abnormality of the endocardial cushions, and therefore is also referred to as an incomplete AV canal defect.
- Sinus venosus defects can be of the superior or inferior vena caval type and occur in ~5–10% of all atrial septal defects. In atrial septal defects of the superior vena caval type, the right pulmonary veins (usually right upper lobe) may drain anomalously to the superior vena cava or right atrium.
- Coronary sinus atrial septal defects are rare and occur in <1% of all atrial septal defects. They are often associated with absence of the coronary sinus and a persistent left superior vena cava that joins the roof of the left atrium (also known as an “unroofed coronary sinus”).

EPIDEMIOLOGY

Females > males (2:1)

Incidence

- Difficult to determine
- Occurs in 6–10% of all cardiac anomalies encountered

PATHOPHYSIOLOGY

- A left-to-right shunt occurs through the atrial septal defect. For large defects, this results in right atrial and right ventricular (RV) volume overload.
- There is usually increased pulmonary blood flow.
- The left-to-right shunt generally increases with time as pulmonary resistance drops and right ventricular compliance normalizes.
- Moderate and large defects are associated with a Qp/Qs ratio of >2:1.
- The direction of atrial shunting is determined by the relative compliance of the right and left ventricles.

ETIOLOGY

- Atrial septal defects may be associated with partial or total anomalous pulmonary venous drainage, mitral valve anomalies, transposition of the great arteries, or tricuspid atresia.
- Although usually isolated, atrial septal defects may occur as part of a syndrome (Holt-Oram [autosomal dominant]).

DIAGNOSIS

HISTORY

- Most infants are asymptomatic.
- Older children with moderate left-to-right shunts are often asymptomatic, but may have mild fatigue or dyspnea, especially with exercise.
- Children with large left-to-right shunts may complain of fatigue and dyspnea, which may become noticeable as the child gets older.
- Growth failure is uncommon.
- Older patients with large atrial shunts may develop atrial arrhythmias.

PHYSICAL EXAM

- Inspection and palpation of the precordium are usually normal, although older children with a large atrial septal defect may have a hyperdynamic precordium, right ventricular heave, or precordial bulge.

- Auscultation reveals 3 important features:
 - Wide and “fixed” splitting of S₂. Splitting of S₂ (A₂ and P₂ components) is caused by a delay in emptying of a volume-loaded right ventricle.
 - A systolic ejection murmur at the upper left sternal border. This murmur is caused by an increase in blood flow across a normal pulmonary valve. It may be differentiated from the murmur of pulmonary stenosis because there is no click.
 - A diastolic murmur at the lower sternal border, indicating a Qp/Qs ratio of at least 2:1. This murmur is caused by increased flow across the tricuspid valve.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- ECG:
 - Usually normal sinus rhythm with an rSR' (incomplete right bundle branch block pattern) in lead V₁, V₃R, and V₄R, indicating right ventricular volume overload. For larger shunts, ECG may show evidence of right atrial enlargement as well as 1st-degree AV block. A late finding suggestive of pulmonary hypertension is right ventricular hypertrophy.
- Chest radiograph:
 - Cardiomegaly (right atrium and right ventricle), increased pulmonary vascular markings, and a dilated pulmonary trunk are seen in patients with significant left-to-right shunts.
- Echocardiogram:
 - A 2-D echo study is diagnostic; it reveals the location, size, and associated defects, if any. It may demonstrate dilated right-heart structures. Color Doppler generally permits visualization of the direction of shunt flow. Older children and adolescents may require transesophageal echo to best define the atrial septal defect.
- Cardiac catheterization:
 - Generally unnecessary. It is indicated when pulmonary vascular disease is suspected (determination of pulmonary vascular resistance) or for associated cardiac defects.

DIFFERENTIAL DIAGNOSIS

- Ventricular septal defect
- Patent ductus arteriosus
- AV canal defect
- Valvular pulmonary stenosis

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Infants with congestive heart failure should be treated with diuretics.
- Elective closure is indicated for atrial septal defects associated with large left-to-right shunts, cardiomegaly, or symptoms.
 - The timing of closure is usually deferred until 3–5 years of age.
 - For most secundum-type atrial septal defects, device closure of the defect can be performed in the cardiac catheterization laboratory, thus avoiding surgery.
- Prevention of paradoxical emboli and cerebrovascular accidents is an uncommon but possible indication for closure of atrial septal defects or patent foramen ovale.
- Irreversible pulmonary hypertension from a long-term left-to-right shunt usually does not occur until adolescence or young adulthood.
- Sinus venosus, primum, and coronary sinus–type atrial septal defects require surgical closure. The mortality of surgical repair for an uncomplicated ASD approaches 0%.
- There is some anecdotal evidence suggesting that PFOs are a cause of migraine headaches in certain populations. Prospective adult studies are currently ongoing to further investigate this question.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Children with typical auscultation, chest radiograph, and ECG findings should undergo an echocardiographic evaluation to determine the location and size of the atrial septal defect.
- Children with atrial septal defects should have regular follow-up to assess for signs of congestive heart failure or right ventricular volume overload. Restriction of activity is unnecessary. SBE prophylaxis is not indicated for an isolated secundum atrial septal defect. Residual atrial septal defect after surgery is rare.
- SBE prophylaxis is indicated for the 1st 6 months (assuming no residual defect) after closure of a secundum defect.
- Complications related to surgery include:
 - Sinus node dysfunction
 - Venous obstruction (facial or pulmonary edema) may occur after a sinus venosus atrial septal defect repair.
 - Postpericardiotomy syndrome, which manifests with nausea, vomiting, abdominal pain, or fever, may occur a few weeks after surgical repair. Although a friction rub may not be present, the chest radiograph may show cardiomegaly and the echocardiogram may reveal a pericardial effusion.

PROGNOSIS

- The prognosis for small atrial septal defects seems excellent without specific therapy.
- Spontaneous closure of small secundum atrial septal defects can occur in up to 80% of infants in the 1st year of life. Isolated secundum atrial septal defects of moderate and large size do not typically cause symptoms in most infants and children.
- Pulmonary hypertension is rare in childhood.
- Atrial flutter and fibrillation occur in up to 13% of unoperated patients older than 40 years.
- Bacterial endocarditis is rare in children with isolated atrial septal defect.
- Paradoxical emboli may occur, and should be considered in patients with cerebral or systemic emboli.

CODES

ICD9

- 429.71 Acquired atrial septal defect
- 745.4 Ventricular septal defect
- 745.5 Atrial septal (ostium secundum type)

ICD10

- Q21.1 Atrial septal defect
- Q21.2 Atrioventricular septal defect

FAQ

- Q: When should a moderate secundum atrial septal defect be closed?
- A: This can generally be electively performed in children prior to their starting grade school.
- Q: What is the significance of a patient having GI complaints (nausea and vomiting) 2–3 weeks after surgical closure of an atrial septal defect?
- A: This may represent a pericardial effusion (postpericardiotomy syndrome).

ATTENTION-DEFICIT/HYPERACTIVITY DISORDER (ADHD)

William G. McNett

BASICS

DESCRIPTION

- Attention-deficit hyperactivity disorder (ADHD) is a syndrome characterized by persistent and developmentally inappropriate levels of inattention and/or hyperactivity and impulsivity. It can be classified into 3 subtypes:
 - Hyperactive/impulsive
 - Inattentive
 - Combined
- DSM-IV criteria for diagnosis:
 - At least 6 of 9 behaviors in inattention and/or hyperactivity/impulsivity
 - Persisting for at least 6 months that is maladaptive and inconsistent with developmental level
 - Some symptoms present before age 7 years
 - Impairment from symptoms present in 2 or more settings
 - Clear evidence of clinically significant impairment in social, academic, or occupational functioning

Prevalence

- 3–7% of school-age children
- 3–4 times more common in males than females
- Females more likely to have inattentive type

RISK FACTORS

Genetics

- Risk of ADHD in first-degree relatives is ~25%.
- Concordance in monozygotic twins: 59–81%; dizygotic twins: 33%

COMMONLY ASSOCIATED CONDITIONS

- Learning disorders
- School failure
- Tic disorder
- Oppositional defiant disorder and conduct disorder
- Mood disorders: anxiety and depression
- Poor peer relations

DIAGNOSIS

- Typically, patients are brought to medical attention during the early school years because their behavior falls out of normal range in their ability to pay attention in class, to avoid class disruption, and/or to control impulsive behavior.
- Many patients with ADHD can be diagnosed and treated in the pediatrician's office.
- A large percentage of patients with ADHD may have associated conditions and will need multidisciplinary pediatric teams of developmental pediatrics, psychologists, neurologists, and/or psychiatrists for assessment and treatment.

SIGNS AND SYMPTOMS HISTORY

- A detailed history of the child's behavior at home, school, and with peers is needed.
- Onset and duration of noted behaviors
- Ability to make and keep friends
- Academic progress
- Birth history with details about prematurity, *in utero* drug exposure, and perinatal asphyxia
- Developmental history, specifically language acquisition and fine motor skills
- Sleep history
- Family history of ADHD and/or learning disorders
- Family history of cardiac disease including arrhythmias, hypertrophic cardiomyopathy or sudden cardiac death in children or young adults
- Social history: those who live with patient, recent family discord, separation, recent death in the family, recent change in schools
- Past medical history and medication history

PHYSICAL EXAM

- Hearing and vision testing to rule out vision disturbances or hearing impairment, respectively, as a cause of inattention
- Weight and height measurements for baseline before starting medication and to help rule out thyroid dysfunction as underlying cause
- Vital signs including BP and pulse are important for baseline measurements.
- Examination of neck to ensure no obvious thyroid enlargement or change in thyroid gland
- Skin exam to rule out neurocutaneous syndromes
- Thorough cardiac exam
- Thorough neurological exam to rule out an intracranial process that may cause similar symptoms

DIAGNOSTIC TESTS & INTERPRETATION

- Rating scales:
 - Multiple scales available including Connor Rating Scales-Revised, Vanderbilt ADHD Rating Scales, Child Behavior Checklist
 - Both parent and teacher ratings are routine components of the assessment.
 - Some assess only ADHD (Connor); others include assessment of possible co-morbidities (Vanderbilt and Child Behavior Checklists).
 - Most scales may be used by clinicians for follow-up to assess effectiveness of treatment.
 - All 3 scales have similar reliability and validity; most clinicians choose a single tool and gain familiarity with it.
- IQ and achievement testing:
 - Necessary to rule out mental retardation and learning disorder that may mimic ADHD or be a comorbidity of ADHD
 - An evaluation for an Individual Educational Plan (IEP) should be obtained following parental request of the child's school. Note: Federal law mandates that all school-age children have an IEP based upon written request by the parent. Who administers the IEP depends on whether the school is public or private, and on the school district.

Lab

Based on history and/or physical exam, consider:

- Thyroid function tests: If growth curves show unexpected acceleration or deceleration of growth
- Blood lead level to rule out lead toxicity
- CBC to rule out anemia
- EKG prior to starting stimulant medication if family history is significant

DIFFERENTIAL DIAGNOSIS

- Medical:
 - Seizures
 - Sleep disorder
 - Sensory impairment (vision, hearing)
 - Thyroid disorder
 - Medication side effects
 - Toxins (lead)
 - Iron deficiency anemia
 - Postconcussion syndrome
- Developmental:
 - Mental retardation
 - Autism spectrum disorder
 - Language or speech disorder
- Educational:
 - Learning disabilities
 - Inappropriate school environment
- Psychiatric:
 - Depression
 - Mania
 - Anxiety disorders
 - Obsessive-compulsive disorder
 - Oppositional defiant disorder
 - Conduct disorder
- Social:
 - Disorganized/chaotic family environment
 - Physical abuse/neglect
 - Sexual abuse
 - Psychosocial stressors

TREATMENT

GENERAL MEASURES

- 3 treatment modalities in combination:
 - Educational support
 - Behavior modification/psychological counseling
 - Medication (usually stimulant)
- Although all 3 modalities may not be necessary, they all should be discussed with the patient and parents.

NON-PHARMACOLOGIC

- Educational:
 - Request a 504 Plan through patient's school to evaluate for possible accommodations (different than an IEP)
 - Proper educational placement
 - Small teacher-to-student ratio in classroom
 - Good communication between school and home
 - Homework log monitored by teacher and parent
- Psychological support may be helpful for:
 - Patient who has poor peer relations
 - Patient with a comorbidity
 - Families that are having difficulty with parenting issues
 - Families that are unstructured and may contribute to patient's symptoms

MEDICATION (DRUGS)**First Line**

- **Stimulant:** Methylphenidate (Ritalin, Methylin, Metadate, Focalin, Concerta, Daytrana Patch), dextroamphetamine-amphetamine (Dexedrine, Dextrostat, Adderall)
- **Efficacy:** 80% of children with ADHD show significant improvement with use of stimulant medication soon after proper dosing is achieved.
- **Pharmacokinetics:** Individual response is highly variable. Onset is within 20–30 minutes. Stimulants have different duration of action: Short-acting stimulants last 3–6 hours (Methylphenidate, Ritalin, Methylin, Focalin, Dexedrine, Dextrostat, Adderall) with dosing 2–3 times/d; Long-acting stimulants last 3–8 hours (Methylphenidate SR, Ritalin SR, Methylin ER, Metadate ER, Dexadrine Spanules); and extended-release stimulants last 8–12 hours (Ritalin LA, Metadate CD, Concerta, Focalin XR, Daytrana, Vyvanse, Adderall XR) needing once-a-day dosing.
- **Dose:** Weight-based dosing is not effective because of differences in metabolism. Start with smallest dose and titrate up for effect. Start with short-acting medication. For some younger children, this may provide a sufficient duration of therapy for school. If a second dose is needed, converting to a longer-acting medication is reasonable. Start medication when the parents are available to watch for side effects and duration of action (typically over a weekend). Follow closely with the parents; ask them to get feedback from school on a weekly basis until dose is properly adjusted. This process may take 1–2 months to be completed.
- **Side effects:** Decreased appetite, abdominal pain, weight loss, tics, headache, difficulty falling asleep, and jitteriness. Most stimulant-related side effects are short-lived and are responsive to dose or timing adjustments. Severe movement disorders, obsessive–compulsive ruminations, or psychotic symptoms are very rare and disappear when medication is stopped.
- **Contraindications:** Glaucoma, symptomatic cardiovascular disease, hyperthyroidism, hypertension

Second Line

- Atomoxetine (Strattera): Selective norepinephrine uptake inhibitor. once-a-day dosing, same side-effect profile as stimulants, not as efficacious as a stimulant but may be a viable alternative for patients who do not tolerate stimulant medication or if a patient's family is hesitant to use stimulants. Effects of medication may not be seen for several weeks after starting.
- Others: α -Adrenergic (clonidine, Guanfacine), tricyclic antidepressants (imipramine, nortriptyline, desipramine), atypical antidepressants (Wellbutrin, Effexor). Usually prescribed by specialists, including psychiatrists and behavioral specialists.

ISSUES FOR REFERRAL

- When comorbidities are suspected
- If patient is not responding to increasing dose of medication
- If the patient is having difficulty tolerating different stimulants
- Onset of symptoms beyond grade school

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS**

- Initially, follow-up should be every 1–2 weeks until proper dosing is achieved. Can be done by telephone or e-mail communication.
- After initial stabilization, patients should be seen every 3–6 months.
- Monitor weight, height, BP, and heart rate.
- Assess for change in growth velocity.
- Assess family and peer relationships.
- Assess school performance.
- Check for medication side effects. If onset of sleep is disturbed, consider melatonin for sleep initiation.
- Assess for ongoing need for medication.

FAQ

- Q: Does complementary and alternative medical (CAM) therapies, including diet, play a role in treating ADHD?
- A: Although in the past it has been thought that certain foods and additives caused ADHD, there are no scientific studies that show changes in diet to be of benefit. Frequently, families will want to explore the use of CAM therapies either in conjunction with or instead of treatment with stimulant medication. In addition to not showing benefit, there may be safety issues associated with certain CAM therapies. If safety can be assured, it may be reasonable for patients to try for a finite period of time if it ultimately helps the patient. If CAM therapy fails, the parents may be more willing to try stimulant medication.
- Q: Is medication needed every day?
- A: This depends on the needs of the patient. Some patients need medication daily in order to function successfully with peers or in structured environments, like team sports or weekend schools. Other patients who need help mainly with focusing attention do well with medication only during learning periods (school days). Many patients will not need medication during the summer holiday or during school breaks.
- Q: How long will my child be on medication?
- A: A large percentage of children with ADHD will continue to have symptoms as adults. Although every patient is different, some patients may need to continue medication through formal learning (high school and college). During this time, they should be able to learn coping strategies to minimize the effects of their symptoms. If treatment goals are being met, it is reasonable to have a trial off medications to see if performance off medications can be sustained (sometimes called a drug holiday).
- Q: Are there support groups available?
- A: An organization that is widely recognized as an advocacy and support group for families is Children and Adults with Attention Deficit/hyperactivity Disorder (www.chadd.org). This organization provides links to local groups that meet regularly, and provides a forum for parents to discuss having a child with ADHD. One should use discretion when using online resources; there are many online websites that are sponsored by pharmaceutical companies and others that encourage alternatives to medication and actively discourage use of currently recommended treatments.

ATYPICAL MYCOBACTERIAL INFECTIONS

Richard M. Rutstein

BASICS

DESCRIPTION

Atypical mycobacterial (ATM) infection refers to disease caused by *Mycobacterium* other than tuberculosis, bovis, and leprae, and usually involves *Mycobacterium avium intracellulare*, *M. scrofulaceum*, *M. kansasii*, *M. fortuitum*, and *M. chelonae*. These diseases are also referred to as nontuberculous mycobacterial infections, environmental mycobacterial infections, and mycobacteria other than tuberculosis (MOTT) infections.

EPIDEMIOLOGY

- 80–90% of cases of adenitis caused by ATM infection occur in preschool-aged children (ages 1–5 years).
- In children with chronic illness, especially cystic fibrosis, lung disease from ATM may be a factor in progressive lung disease.
- In adults in the US, the prevalence of ATM pulmonary disease is now higher than that caused by *Mycobacterium tuberculosis*.
- Early in the HIV epidemic, the incidence rate of disseminated disease in HIV-infected adults was ~40%; in HIV-infected children, 10–20%. This rate has decreased markedly in recent years through the routine use of prophylaxis and because of the improved immunologic function in HIV-infected individuals on newer antiretroviral agents.
- A rare genetic defect, leading to intraleukin-12 receptor deficiency, has been associated with increased risk of ATM-related disease. Treatment with tumor necrosis factor-alpha-modifying agents (such as infliximab and etanercept) also increases the risk.

PATHOPHYSIOLOGY

- Organisms are ubiquitous in the environment (soil, fresh water, ocean water, home and hospital water, dust, and food [eggs, dairy products, meat]).
- It is spread by aerosol inhalation or ingestion of contaminated food, dust, or water.
- Person-to-person spread has never been documented and is not a concern.

ETIOLOGY

- The most common associated illness is unilateral chronic cervical adenopathy/adenitis in preschool-aged children.
- In adults, ATM infection may cause a chronic single pulmonary nodule or more extensive chronic lung disease.
- In children and adults infected with HIV, disseminated disease is common, yet it is not common in other acquired or congenital immunodeficiencies that affect T-cell function.
- Rarely, it may cause otitis/mastoiditis as well as pulmonary disease in immunocompetent children.
- Chronic skin, bone, or soft tissue infections may develop after trauma/surgery, acupuncture, or application of tattoos, usually with *M. chelonae* or *M. fortuitum* as the etiologic agents.
- Infections of indwelling central venous catheters appear to be on the increase, especially among children on chemotherapy.
- Colonization with this mycobacterium is common among older patients with cystic fibrosis. Whether these organisms play a pathogenic role in ongoing lung damage in this population is an area of intense study.

DIAGNOSIS

HISTORY

- Region of residence
- Recent travel
- Length of time of adenopathy, associated systemic symptoms
- Contact with cats (for differential of cat-scratch disease or toxoplasmosis)
- Systemic symptoms, such as fever and weight loss, make neoplastic disease more likely.
- Chronic cough would suggest *M. tuberculosis*.
- Recent upper respiratory symptoms/fever suggest viral or bacterial cause.

PHYSICAL EXAM

- Most common: Single or regional cervical adenopathy, 90% of the time, is unilateral, firm, not fixed, and not especially tender or warm; occasionally, there is spontaneous drainage.
- Generalized adenopathy makes ATM disease unlikely.
- Systemic signs of infection are absent.
- Hepatosplenomegaly indicates other diagnosis, especially neoplastic disease or HIV-related illness.
- Normal nutritional status
- In disseminated disease, chronic high fevers, abdominal pain, and wasting are common.
- Occasionally may cause SQ nodules that frequently ulcerate.

DIAGNOSTIC TESTS & INTERPRETATION

Pitfalls: Use of incision and drainage/aspiration for treatment of adenitis, which can lead to chronically draining node. Aspiration may be needed to make the original diagnosis, but total excision results in almost 100% cure rates.

Lab

- Specific PPD tests are not readily available at this time. Many children with ATM adenitis will have 5–10-mm reactions to standard PPD: in one study, 27% of those with culture proven NTM adenitis had a PPD > 10 mm.
- Definitive diagnosis is made by isolation and identification of organism. The most frequently identified strains are: *M. avium intracellulare*, *M. kansasii*, *M. chelonae*, *M. fortuitum*, and *M. scrofulaceum*.
- Normal chest radiograph
- In disseminated disease, cultures are positive from blood and bone marrow aspirates.
- Diagnosis using PCR assays under development. May be helpful on staining of biopsied material.

DIFFERENTIAL DIAGNOSIS

- For unilateral adenopathy/adenitis:
- Viral/bacterial adenitis—affected nodes are tender, warm, and erythematous; usually associated with upper respiratory symptoms and/or fever.
- Cat-scratch disease (contact with cat, usually kitten). Frequently, child will have scratch/puncture mark on arm. There are rarely any systemic signs/symptoms.
- Neoplastic disease

TREATMENT

MEDICATION (DRUGS)

For disseminated or pulmonary disease, or when complete surgical excision of an infected node is not possible, 3- or 4-drug treatment regimens based on sensitivity. Combinations generally include several of the following antibiotics: Rifabutin, clarithromycin or azithromycin, ethambutol, ciprofloxacin, and amikacin. Newer antibiotics, such as mefloquine and moxifloxacin, may also have significant activity against atypical mycobacterial strains.

SURGERY/OTHER PROCEDURES

Complete surgical excision for isolated adenopathy secondary to ATM; chemotherapy unnecessary in most cases

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Routine follow-up should be done for 1 year after excision to monitor for possible local/contralateral recurrence.

PATIENT EDUCATION

Prevention: For HIV-infected children with severe immunodeficiency, prophylaxis with once-weekly azithromycin decreases the risk of development of disseminated disease.

PROGNOSIS

- For localized adenopathy: Excellent
- For disseminated disease: Generally treatable in the rare immunocompetent individual
- In patients with AIDS: Generally treatable in terms of symptom relief which required lifelong therapy, but with newer anti-HIV therapies, NTM chemotherapy may be stopped after 1–2 years.

COMPLICATIONS

- Chronic draining of infected cervical nodes
- Rarely, pulmonary disease or dissemination
- Chronic skin/bone infections
- Disseminated disease

CODES

ICD9

- 031.0 Pulmonary diseases due to other mycobacteria
- 031.1 Cutaneous diseases due to other mycobacteria
- 031.9 Unspecified diseases due to mycobacteria

ICD10

- A31.0 Pulmonary mycobacterial infection
- A31.8 Other mycobacterial infections
- A31.9 Mycobacterial infection, unspecified

FAQ

- Q: Should all cases of cervical adenitis be tested for ATM?
- A: The typical case of cervical adenitis, presenting with the usual prodrome, responds rapidly to appropriate oral or parenteral antibiotics, which would not be the case if ATM were the culprit. Certainly, a PPD test should be done on all children with cervical adenitis. If the node is aspirated, in addition to routine bacterial cultures, fluid should be sent for mycobacterial culture. Additionally, testing for cat-scratch disease should be part of the evaluation of all cases of cervical adenitis.
- Q: Should patients with disease secondary to ATM undergo a chest radiograph?
- A: Yes. Although uncommon, ATM-related pulmonary disease can be seen in children.
- Q: If the node is excised, should oral therapy be instituted?
- A: Most studies suggest that oral therapy is unnecessary following total excision.

AUTISM/PERVASIVE DEVELOPMENTAL DISORDER (PDD) SPECTRUM

Alisson Richards

David C. Rettew

Jeanne Greenblatt (5th edition)

BASICS

DESCRIPTION

- Neurodevelopmental syndrome characterized by:
 - Delays/impairments in development of social, communication, play, and behavioral skills
 - Onset usually in 1st years of life
- Spectrum of related disorders:
 - Autistic disorder: Symptoms prior to age 3 years, impairments in social relatedness, communication, and play, and restricted interests/activities
 - Asperger disorder: Social deficits, restricted range of interests, relatively preserved language development, average to above-average cognitive abilities
 - Pervasive developmental disorder not otherwise specified: Subthreshold autism
 - Childhood disintegrative disorder: Developmental deterioration after 24 months of age
 - Note: DSM5 proposal is to combine all diagnoses above into 1 diagnosis, autism spectrum disorder

EPIDEMIOLOGY

Prevalence

- ~1% or 1 child in every 110, with rate possibly increasing
- 4–5 times more common in males than females

RISK FACTORS

Genetics

- Strong genetic influence
- Risk in 1st-degree relatives 2–8%
- Immunizations: Initial association with vaccines not established (multiple studies)

COMMONLY ASSOCIATED CONDITIONS

- Mental retardation
- Gastrointestinal problems
- Seizure disorders
- Sleep disorders
- Attention problems, anxiety, depression, mood disturbances
- Aggression and self-injury

DIAGNOSIS

Typically pediatricians are the 1st point of contact and play an important role in early recognition, which is then followed by screening tools and referral for early intervention through a developmental pediatrician, psychologist, child psychiatrist, or neurologist where assessment and treatment plans can be coordinated with the schools.

HISTORY

- A detailed prenatal, neonatal, developmental, medical, family, and social history essential
- Delays/impairments in communication:
 - Rare cases present with “acquired epileptic aphasia” (paroxysmal electroencephalogram in sleep)
 - Marked inability to initiate and sustain conversation (when speech is present)
 - Cognitive delays
- Delays/impairments in reciprocal social interactions:
 - Impairment in eye contact, facial expression, nonverbal social behaviors
 - Impaired social interactions
 - Lack of imaginary play appropriate to developmental level
 - Lack of pointing
 - Doesn’t include others in play
- Stereotyped behaviors and restricted interests:
 - Stereotypies (e.g., rocking, hand flapping)
 - Restricted range of interests/activities
 - Attachment to unusual objects, fascination with parts of objects
 - Behavioral rigidity, distress with changes in routine
 - Unusual sensory interests in objects or persons (smelling, touching, sensitivity to clothing)

PHYSICAL EXAM

- Evaluate for growth disturbance
- 20–30% have macrocephaly: Neurocutaneous disorder, storage disease, hydrocephalus, or no identifiable cause
- Signs of self-injurious behavior
- Stereotypical behavior, involuntary movements, motor coordination abnormalities, mirror/overflow movements
- Ophthalmologic/audiologic evaluations to rule out visual or hearing deficits
- Long, thin face, prominent ears: Fragile X (macroorchidism may not be present until after puberty)
- Pigmented lesions: Neurocutaneous syndromes, hypopigmented macules/fibromas suggest tuberous sclerosis
- Microcephaly: Toxoplasmosis, other viruses, rubella, cytomegalovirus, herpes virus (TORCH) infection, Angelman syndrome, Rett disorder
- Look for spasticity, visual loss, ataxia: Leukodystrophy

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Head MRI/CT: If intellectual or focal neurologic deficit is present, suspect neurocutaneous disease:
 - Electroencephalogram if epilepsy is suspected (~25%)
 - Chromosome studies: If child is intellectually disabled
 - Genetic tests/microarrays: if child is intellectually disabled
 - Toxoplasma, other viruses, rubella, cytomegalovirus, herpesvirus titers: Setting of microcephaly
 - CBC: Evaluation of growth delay and/or pica
 - Blood lead level: R/O lead intoxication
 - Thyroid function tests: R/O hyper-/hypothyroidism
 - Audiogram/brainstem auditory evoked response: For children with speech and language delay and to rule out hearing deficits
 - Ophthalmologic evaluations to rule out visual deficits

Diagnostic Procedures/Other

Screening tools:

- Modified Checklist for Autism in Toddlers (M-CHAT) downloadable at <http://www.firstsigns.org/downloads/m-chat.PDF>
- Social Responsiveness Scale (SRS)
- Autism Diagnostic Observation Schedule (ADOS) and Autism Diagnostic Interview (ADI-R) are structured interviews and assessments usually performed by a psychologist, developmental pediatrician, psychiatrist, or neurologist: Considered the gold standard

DIFFERENTIAL DIAGNOSIS

- Intellectual impairment: MAY not have pervasive developmental disorder/autism IF communication, behavior, play, and social skills appropriate to developmental age
- Rett syndrome: Females; hand-washing/-wringing movements, head-growth deceleration before 48 months of age
- Deafness: Delayed/absent oral language acquisition; behavioral/social difficulties may relate to language delays.
- Mixed receptive-expressive language disorder: No deficits in social interactions or restricted range of interests
- Selective mutism
- Anxiety, obsessive-compulsive disorder, or PTSD

TREATMENT

MEDICATION (DRUGS)

- Pharmacotherapy treats associated symptoms of autism:
- Symptoms/medications to consider:
 - Self-injurious behavior: Atypical/typical antipsychotics, guanfacine, clonidine
 - Sleep disturbances: Melatonin, clonidine, trazodone
 - Seizures: Newer anticonvulsants, carbamazepine, phenytoin, valproate, barbiturates (may worsen hyperactivity/irritability)
 - Hyperactivity/attention difficulties: Psychostimulants, atomoxetine, bupropion, clonidine, guanfacine
 - Obsessive-compulsive disorder symptoms/perseveration: SSRIs, clomipramine
 - Tic disorders: Guanfacine, clonidine, atypical/typical antipsychotics
 - Depression: SSRIs, bupropion, venlafaxine
 - Anxiety: SSRIs, buspirone, venlafaxine, benzodiazepines (rarely as may increase disorganization and agitation)
 - Aggression: atypical antipsychotics, SSRIs, anticonvulsants, guanfacine
- FDA-approved medications include aripiprazole ages 6–17 and risperidone ages 5–16
 - Important to monitor baseline glucose and lipids as atypical antipsychotics are associated with metabolic syndrome
 - Used for associated aggression and irritability

ALERT

- Autism and the pervasive developmental disorder spectrum disorders vary greatly in symptom presentation. Discordancy among clinicians' diagnoses and under- and overdiagnoses of these disorders are common.
- Symptom presentation differs at different stages of development.
- Medication often not helpful for core autistic features and patients often develop side effects
- Subclinical seizure types may be detected only on electroencephalogram

ADDITIONAL TREATMENT

**General Measures
Nonpharmacologic**

- Psychoeducational assessment: Support cognitive, developmental, adaptive, functional, communication, and social needs:
 - Intensive educational/behavioral interventions should target acquisition of communicative, social, cognitive skills.
- Early sustained structured behavioral intervention using applied behavior analysis (ABA) and behavior modification highly beneficial in many children
- Vocational training important for some adolescents and adults

- Social skills training especially for higher-functioning patients is essential.
- Education and support for parents and siblings integral to treatment
- Conventional psychotherapy not indicated to address core features of autism and pervasive developmental disorder

COMPLEMENTARY & ALTERNATIVE THERAPIES

- Almost 1/3 of children with ASD have received some form of complementary and alternative medicine (CAM).
- Important to ask and understand what is being used

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Prognosis linked to cognitive ability and acquisition of social/communication skills
- Early intervention and provision of services can improve prognosis.
- If no language by 5 years of age, substantial language development unlikely
- Children with autism/pervasive developmental disorder often require lifelong treatment and support.
- Physician should remain active in long-term treatment planning and individual and family support

DIET

Little systematic evidence to support that gluten-free diets are helpful, but there are many claims of their effectiveness

CODES

ICD9

- 299.00 Autistic disorder, current or active state
- 299.91 Unspecified pervasive developmental disorder, residual state

ICD10

- F84.0 Autistic disorder
- F84.9 Pervasive developmental disorder, unspecified

FAQ

- Q: What are the chances of having a 2nd child with autism?
- A: In families with 1 child with autism, the recurrence risk for subsequent children is 3–7%. This is in contrast to the risk in the general population, which is 0.1–0.2%.
- Q: What is the value of brain imaging in autism?
- A: MRI may help diagnose a heritable syndrome with genetic counseling implications (e.g., leukodystrophy, tuberous sclerosis), but is usually unhelpful in high-functioning cases without severe intellectual impairment and focal neurologic findings.
- Q: Does the MMR vaccine cause autism?
- A: There is no causal association between the MMR vaccine and autism.

AUTOIMMUNE HEMOLYTIC ANEMIA

Michele P. Lambert

BASICS

DESCRIPTION

Autoimmune hemolytic anemia is characterized by shortened red cell survival that is caused by autoantibodies directed against RBCs, with or without the participation of complement on the red cell membrane.

EPIDEMIOLOGY

Incidence

- ~1–3:100,000 persons/year
- Peak incidence in childhood is in first 4 years of life with warm autoimmune hemolytic anemia.

Prevalence

- Less common in children and adolescents than in adults
- No apparent racial or sexual predisposition (in childhood)

PATHOPHYSIOLOGY

- Warm autoantibodies (~80% cases):
 - Maximal activity of *in vitro* antibody RBC binding at 37°C
 - IgG-class antibody usually
 - IgG-coated RBCs cleared, predominantly in the spleen, by macrophages
- Cold autoantibodies (cold agglutinins) (7–25%):
 - Maximal activity of *in vitro* RBC binding at temperatures between 0°C and 30°C
 - Almost always caused by IgM antibody with specificity for antigens of the *i*/I system on RBCs
 - Anti-I antibodies characteristic of *Mycoplasma pneumoniae*-associated hemolysis
 - Anti-i antibodies are usually found in infectious mononucleosis.
 - Hemolysis is complement dependent.
- Paroxysmal cold hemoglobinuria:
 - IgG autoantibody binds RBC at cooler areas of the body (i.e., extremities), causing irreversible binding of complement components (C3 and C4). When coated RBCs enter warmer areas of the body, IgG falls off and complement causes hemolysis (Donath–Landsteiner biphasic hemolysis).
 - Unusual IgG antibody with anti-P specificity
 - Most frequently found in children with viral infections (30%)

ETIOLOGY

- Idiopathic
- Passive transfer of maternal antibodies
- Secondary to an underlying disorder
 - Infection: Viral (e.g., *Mycoplasma*, Epstein–Barr virus, cytomegalovirus, hepatitis, HIV) or bacterial (e.g., *Streptococcus*, typhoid fever, *Escherichia coli* septicemia)
 - Drugs: Antimalarials, antipyretics, sulfonamides, penicillin, rifampin
 - Hematologic disorders: Leukemia, lymphoma
 - Immunopathic/autoimmune disorders: Lupus, mixed connective tissue disorders, Wiskott–Aldrich syndrome, ulcerative colitis, rheumatoid arthritis, common variable immunodeficiency, scleroderma, Evans syndrome/ALPS (autoimmune lymphoproliferative syndrome)
 - Tumors: Ovarian, carcinomas, thymomas, dermoid cysts

DIAGNOSIS

Natural History:

- Acute disease:
 - Onset with rapid fall in hemoglobin level over hours to days
 - Usual course: Complete resolution of disease within 3–6 months
 - Resolution more likely in children who present between 2 and 12 years of age
- Chronic disease:
 - Slower onset of anemia over weeks to months, with some having persistence of hemolysis or intermittent relapses
 - More likely to be associated with underlying chronic illness
 - More common in adults and children <2 years or >12 years of age

HISTORY

- Pallor
- Jaundice
- Dark urine
- Fever
- Weakness
- Dizziness
- Syncope
- Exercise intolerance

PHYSICAL EXAM

- Pallor
- Jaundice
- Splenomegaly
- Hepatomegaly
- Tachycardia, systolic flow murmur, S3 gallop
- Orthostasis in acute onset

DIAGNOSTIC TESTS & INTERPRETATION

Lab

CBC:

- Hemoglobin level decreased (occasionally, thrombocytopenia seen in Evans syndrome)
- Mean corpuscular volume may be normal.
- Reticulocyte count increased (although may also be decreased if reticulocytes bear the target antigen)
- Peripheral smear: Spherocytes, polychromasia, macrocytes, agglutination
- Direct antiglobulin test (Coombs)—positive (usually):
 - Single most important test
 - Warm autoimmune hemolytic anemia will have IgG ± C3 positive.
 - Cold autoimmune hemolytic anemia and paroxysmal cold hemoglobinuria will have C3 positive.
- Haptoglobin level decreased
- Indirect hyperbilirubinemia
- Elevated lactate dehydrogenase
- Urinalysis: Hemoglobinuria, increased urobilinogen

- Bone marrow aspiration: Erythroid hyperplasia (to rule out leukemia or lymphoma associated with autoimmune hemolytic anemia)
- Cold agglutinin titer: Positive (usually >1:64)
- Donath–Landsteiner test should be performed in cases of suspected paroxysmal cold hemoglobinuria.

ALERT

- A negative Coombs test can occur when small numbers of IgG or C3 molecules are present on the red cell membrane or if most of the coated red cells are cleared from circulation (i.e., in cases of less severe hemolysis, low-affinity antibodies, or in cases of very severe, rapid clearance).
- Radiolabeled Coombs test or enzyme immunoassays are more sensitive diagnostic tests in these circumstances.
- Reticulocytopenia may occur in most severe cases where the antibody coats and removes reticulocytes.

DIFFERENTIAL DIAGNOSIS

- Defects intrinsic to RBC:
 - Membrane defects such as hereditary spherocytosis
 - Enzyme defects including hemolytic episode due to G6PD deficiency
 - Hemoglobin defects
 - Congenital dyserythropoietic anemias
 - Paroxysmal nocturnal hemoglobinuria
- Defects extrinsic to RBC:
 - Immune mediated:
 - Isoimmune: Hemolytic disease of the newborn, blood group incompatibility
 - Autoimmune (see “Etiology”)
 - Drug-dependent RBC antibodies
 - Hemolytic transfusion reaction
 - Nonimmune-mediated:
 - Idiopathic
 - Secondary to an underlying disorder (i.e., hemolytic uremic syndrome, thrombotic thrombocytopenic purpura)
 - Mechanical: March hemoglobinuria, heart valves

TREATMENT

MEDICATION (DRUGS)

First Line

Corticosteroids:

- Indication:
 - In IgG-mediated disease, steroids have been shown to interfere with macrophage Fc and C3b receptors responsible for RBC destruction. In addition, they have been shown to elute IgG Ab from the RBC surface (improving survival).
 - In chronic, warm, autoimmune hemolytic anemia, pulsed high-dose dexamethasone has been shown to be effective in some cases.
- Complications:
 - Both short- and long-term side effects
 - Generally not effective in cold agglutinin disease

- Dose:
 - Start prednisone PO/methylprednisolone IV at 2 mg/kg/d in divided doses.
 - Tapering of steroids should begin after a therapeutic response is achieved (may take several days to weeks).
- Goal:
 - Initially, to return to normal hemoglobin level with tolerable doses of steroid, or off steroids entirely
 - In some patients, goal may be achieving decreased hemolysis and a clinically asymptomatic state with minimal steroid side effects.
 - Alternative treatments should be considered for patients unresponsive to steroids or who require high doses for maintenance of hemoglobin level.

Second Line

- IV immunoglobulin:
 - Indication:
 - May be useful in selected cases of immune hemolytic anemia unresponsive to steroids
 - Mechanism of action is not entirely clear
 - Effect is usually temporary; retreatment may be required every 3–4 weeks
 - Complications:
 - Red cell antibodies in IVIG preparations may be a confounder
 - Aseptic meningitis.
 - Theoretical risk of transfusion transmitted viral infection
 - Expensive
 - Dose: Up to 1 g/kg/d for 5 days has been required to achieve a beneficial effect.
- Plasmapheresis/exchange transfusion:
 - Indication:
 - Will slow the rate of hemolysis in severe disease, especially if IgM mediated
 - Indicated if thrombotic thrombocytopenic purpura cannot be excluded
 - Complications:
 - Only of short-term benefit
 - Expensive
- Rituximab: monoclonal anti CD20 antibody likely works through depletion of B cells
 - Indicated in refractory AIHA (375 mg/m² weekly for 2–4 weeks)
 - Response 40–100%
 - Particularly useful in Warm AIHA
 - Adverse effects: fever, chills, rigors, hypertension, bronchospasm; rare risk of viral infections
- Immunosuppressive agents (antimetabolites and alkylating agents):
 - Indication:
 - When there is a clinically unacceptable degree of hemolysis that is refractory to steroids and splenectomy
 - Some have been effective in cold agglutinin disease.

- Complications:
 - There are varying side effects dependent on the agent used. Therefore, clinical indications must be strong and exposure to drug should be limited.
- Dose:
 - Adjusted to maintain WBC >2,000, absolute neutrophil count (ANC) > 1,000, and platelet count at 50,000–100,000 cells/mm³
- Alemtuzumab (anti CD52): may be effective very refractory AIHA particularly secondary to B-CLL

ADDITIONAL TREATMENT

General Measures

Blood transfusion:

- Indication: Physiologic compromise from the anemia (usually only in severe acute onset)
- Complications:
 - The blood bank may be unable to find compatible blood. In IgG-mediated disease, autoantibody is usually pan reactive; therefore, you must use the least incompatible unit of blood.
 - In cold agglutinin disease, use a blood warmer for all infusions to decrease IgM binding and monitor for acute hemolysis during transfusion.

SURGERY/OTHER PROCEDURES

Splenectomy:

- Indication:
 - Patients unresponsive to medical management, who require moderate- to high-maintenance doses of steroids or who develop steroid intolerance may be candidates.
- Not effective in cold agglutinin disease
- Response rate is 50–70%, with many partial remissions.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Hemoglobin level q4h to q12h (depending on severity) until stable
- Reticulocyte count: Daily
- Spleen size: Daily
- Hemoglobinuria: Daily

COOMBS TEST: WEEKLY PROGNOSIS

- Dependent on age, underlying disorder (if any), and response to therapy. See also “Diagnosis” section (“Natural History”).
- Mortality in pediatric series ranged from 9% to 19%.

COMPLICATIONS

- May be increased risk of venous thrombosis in patients with AIHA
- May also predispose to lymphoproliferative disorders
- Gallstones related to chronic hemolysis

CODES

ICD9

283.0 Autoimmune hemolytic anemias

ICD10

- D59.0 Drug-induced autoimmune hemolytic anemia
- D59.1 Other autoimmune hemolytic anemias

FAQ

- Q: Will the anemia go away?
- A: Children with cold autoantibodies tend to have short-lived illness, whereas children with warm antibodies often have a chronic clinical course characterized by periods of remissions and relapses.
- Q: Is this contagious?
- A: No. Another child may acquire the same viral illness; however, the body’s response to produce an autoantibody is dependent on the individual patient.

AVASCULAR (ASEPTIC) NECROSIS OF THE FEMORAL HEAD (HIP)

Ali Al-Omari

Wudbhav N. Sankar

John Dormans

BASICS

DESCRIPTION

- Avascular (aseptic) necrosis results from the interruption of the blood supply to bone (either traumatic or nontraumatic occlusion).
- The femoral head is the most common site.
- A particular type of avascular necrosis of the hip that occurs in children is known as Perthes disease (see "Perthes Disease").

RISK FACTORS

Genetics

Variable, depending on cause.

PATHOPHYSIOLOGY

- Death and necrosis of bone with gradual return of blood supply
- Necrotic bone gradually resorbed and replaced by new bone

ETIOLOGY

- Traumatic:
 - Hip fracture
 - Hip dislocation
 - Slipped capital femoral epiphysis
 - Complication of casting, bracing, surgery
- Nontraumatic:
 - Idiopathic (older, after physeal closure); similar to adult avascular necrosis
 - Idiopathic (younger, before physeal closure, Perthes disease)
 - Caisson disease
 - Sickle cell disease
 - Septic arthritis
 - Steroids or chemotherapy
 - Malignancy (Leukemia)
 - Gaucher disease
 - Viral infection (HIV, CMV)
 - Radiation therapy
 - Hypercoagulable states

DIAGNOSIS

HISTORY

- Onset (gradual or after traumatic event)
- Association with:
 - Trauma
 - Medications (steroids or chemotherapy)
 - Casting, splinting, surgery (iatrogenic)
 - Pain, limping
 - Stiffness (decreased range of motion)

PHYSICAL EXAM

- Gait:
 - Limping
 - Antalgic gait (decreased)
 - Trendelenburg gait
- Note range of motion:
 - Flexion and extension
 - Abduction and adduction
 - Internal and external rotation
- Hip joint irritability (short arc rotation)
- Signs of other disease process (e.g., sickle cell disease)
- Physical examination trick: Loss of internal rotation is usually the first and most affected loss of motion seen.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Initial lab tests

- Laboratory examinations should be normal in most forms of avascular necrosis of the femoral head.
- Exceptions:
 - Sickle cell disease
 - Septic arthritis
 - Chemotherapy

Imaging

- Radiographic findings:
 - Sclerosis
 - Subchondral fracture
 - Collapse
 - Reossification
 - Repair
- Other potential findings:
 - Cysts
 - Physeal growth arrest (young)
 - Early osteoarthritis
 - Subluxation

DIFFERENTIAL DIAGNOSIS

- Trauma:
 - Osteochondral fracture
 - Impaction fracture
 - Epiphyseal/physeal fracture
- Infection:
 - Osteomyelitis
 - Septic arthritis
- Neoplastic process: Epiphyseal tumors (chondroblastoma, Trevor disease, etc.)
- Rheumatologic processes

TREATMENT

MEDICATION (DRUGS)

- NSAIDs may be effective in decreasing associated inflammation.
- If associated with steroid use, discontinuation or elimination if appropriate

ADDITIONAL TREATMENT

General Measures

- Maintain range of motion (physical therapy, traction, continuous passive motion).
- Contain the femoral head in the acetabulum (see “Perthes Disease” treatment principles).
- Duration of therapy variable, depending on cause

SURGERY/OTHER PROCEDURES

Redirectional osteotomy:

- Femoral or acetabular reorientation
- Core decompression to stimulate new blood supply (older patient)

ONGOING CARE

DIET

- Thought not to alter disease process
- Recommend general balanced diet

PROGNOSIS

- Overall, good if mild involvement and patient is young
- See “General Prevention.”
- When to expect improvement: Variable, depending on cause
- Moderate to severe cases may end up requiring a total hip replacement

COMPLICATIONS

- Decreased range of motion, pain, limping
- Osteoarthritis
- Physeal arrest with growth disturbance

ALERT

Signs to watch for:

- Subluxation
- Early osteoarthritis
- Growth arrest

CODES

ICD9

- 732.1 Juvenile osteochondrosis of hip and pelvis
- 733.42 Aseptic necrosis of head and neck of femur

ICD10

- M87.059 Idiopathic aseptic necrosis of unspecified femur
- M91.80 Other juvenile osteochondrosis of hip and pelvis, unspecified leg

FAQ

- Q: What type of medication is most often associated with avascular necrosis of the hip?
- A: Steroids
- Q: For avascular necrosis in children (Perthes disease of the hip, for example), is younger or older age associated with a better prognosis?
- A: Younger age

BABESIOSIS

Oluwakemi B. Badaki-Makun

Frances M. Nadel

BASICS

DESCRIPTION

- Human babesiosis is a tick-borne malarial like illness characterized by fever, malaise, and hemolytic anemia
- Most infected individuals are asymptomatic

EPIDEMIOLOGY

- The 1st human case in the US was reported from California in 1966
- Transmission usually occurs in the summer and early fall
- In the US, most cases have been reported from the Northeast, Midwest, and Pacific Coast
 - Endemic areas include Rhode Island, Massachusetts, and New York
 - Cases have been reported in New Jersey, Maryland, Virginia, Georgia, Wisconsin, and Minnesota

Incidence

There were >450 confirmed cases of human babesiosis diagnosed in the US between 1968 and 1993.

Prevalence

- Difficult to ascertain because asymptomatic infection appears to be common in endemic areas
- It has been reported, for instance, that seroprevalence is as high as 9% in some endemic areas of Rhode Island

RISK FACTORS

- Asplenia (functional or anatomic)
- Malignancy
- HIV/AIDS
- Immunosuppressive medications
- Primary immunodeficiency syndrome
- Extremes of age, especially age >50 years

Genetics

There is no known genetic predisposition.

GENERAL PREVENTION

- Prevention begins with avoidance of tick bites (especially important for high-risk individuals; see “Risk Factors” below)
- Simple measures include wearing long-sleeved shirts and long pants, with pants tucked into the socks in tick-infested areas
- Avoid endemic regions during the peak months of May to September
- Light clothing will make ticks easier to see
- Use DEET-containing insect repellents during outdoor activities
- Spraying one’s clothing with a permethrin tick repellent may also be helpful
- Children and dogs should be inspected daily for ticks after being outside
- Currently, there is no universal laboratory screening of blood products
- Prophylaxis is not recommended after a tick bite
- Currently, there is no vaccine available

PATHOPHYSIOLOGY

- A bite from an infected tick transmits the protozoa
- Incubation period:
 - Usually 1–4 weeks
 - Can be as long as 9 weeks
- Infection of the erythrocyte causes membrane damage and lysis, which promotes adherence to the endothelium and microvascular stasis
- The spleen plays an important role in decreasing the protozoal load, through antibody production and filtering abnormally shaped infected red blood cells

ETIOLOGY

- Human babesiosis is caused by the intraerythrocytic parasite of the *Babesia* genus
- In the northeast US, *Babesia microti* is the most commonly isolated agent
- *Babesia divergens* is the responsible agent in Europe
- WA-1 and MO-1 cause babesiosis in western US and Missouri, respectively
- *Ixodes dammini* (*Ixodes scapularis*), the same tick responsible for Lyme disease, is the invertebrate vector for *B. divergens*
- Rarely, the disease has been acquired through transplacental/perinatal transmission or through transfusion of contaminated blood products
 - Babesiosis is the most common tick-borne disease transmitted by contaminated blood transfusions

COMMONLY ASSOCIATED CONDITIONS

It is estimated that 11–23% of patients have concurrent Lyme disease.

DIAGNOSIS

HISTORY

- Few patients recall a tick bite
- Patients live in or have recently traveled to an endemic region
- Initial symptoms begin 1–4 weeks after the tick bite and are vague. They may include progressive fatigue, malaise, headaches, and anorexia, accompanied by intermittent fevers as high as 40°C
- Chills, myalgias, and arthralgias may follow these symptoms
- Less common complaints include cough, sore throat, abdominal pain, and emotional lability

PHYSICAL EXAM

- Fever is often the only finding
- Mild conjunctival injection and pharyngeal erythema
- Some may have mild hepatomegaly and/or splenomegaly
- Jaundice or hematuria may also be seen
- Petechiae and ecchymosis occur in rare cases, most often in the presence of severe illness with associated shock and/or DIC

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Giemsa- or Wright-stained thick and thin blood smears may demonstrate the intraerythrocytic ring form:
 - This is often confused with the ring form of *Plasmodium falciparum*, the etiologic agent of malaria
 - Rarely, the pathognomonic “Maltese Cross” form of the *Babesia* parasite may also be seen on the blood smear
 - Multiple smears should be performed as initial smears may be falsely negative
- Indirect immunofluorescent assay:
 - Antigen-specific for *B. microti*
 - In endemic areas, the test has a sensitivity of 91% and a specificity of 99%
 - Can be used when blood smears are negative
 - In general, a titer = 1:64 indicates exposure
 - Titer = 1:256 suggests acute infection
 - There is little correlation between titer levels and severity of disease
 - Immunoglobulin levels decline rapidly within months of recovery
- Polymerase chain reaction is highly sensitive and specific
- Isolation of the parasite can be done by intraperitoneal injection of a patient’s blood into a golden hamster, but results take weeks
- Other tests: Most of the abnormal routine test results are the result of hemolysis
- Urinalysis:
 - Proteinuria
 - Hemoglobinuria
- CBC:
 - Normal leukocyte count/leukopenia
 - Normocytic/normochromic anemia
 - Thrombocytopenia
 - Atypical lymphocytosis
 - Reticulocytosis
- Possible positive Coombs test
- Elevated ESR
- Liver function tests: Elevated bilirubin, lactate dehydrogenase, and liver transaminases
- In asymptomatic patients, these tests are often normal

ALERT

False negatives:

- The blood smears may not demonstrate the protozoan at low levels of parasitemia
- Serologic false positives for *B. microti* include cross-reactivity with other *Babesia* sp. or malarial organisms
- Theoretical serologic false positives for WA1:
 - Rheumatoid factor
 - Antinuclear antibody
 - Antibody to *Toxoplasma gondii*

DIFFERENTIAL DIAGNOSIS

- Nonspecific viral syndrome
- Malaria
- Influenza
- Lyme disease
- Ehrlichiosis

TREATMENT

MEDICATION (DRUGS)

Regardless of regimen, treatment is generally for 7–10 days.

First Line

- Asplenic, immunodeficient, or severely symptomatic patients should be treated with clindamycin and quinine IV
- The pediatric dose of clindamycin is 20–40 mg/kg/day IV/PO divided q6–8h (max 600 mg/dose). The adult dose is 600 mg PO q8h or 300–600 mg IV q6h
- Quinine is dosed 10–25 mg/kg/day PO divided into 3 doses. Adult dose is 650 mg PO q8h

Second Line

- Combination of atovaquone and azithromycin:
 - Has similar treatment effectiveness with fewer side effects (such as vertigo, tinnitus and GI upset) than clindamycin and quinine in adults
 - Use of atovaquone and azithromycin has not been studied in the pediatric population; clindamycin and quinine are the recommended treatment choice for symptomatic children
 - Pediatric dosing: Atovaquone 20 mg/kg (max 750 mg) q12h; azithromycin 10 mg/kg (max 500 mg) PO on day 1 and 5 mg/kg (max 250 mg) daily thereafter
 - Adult dosing: Atovaquone 750 mg q12h; azithromycin 500–1000 mg PO on day 1 and 250–1000 mg PO daily thereafter
- In areas endemic for Lyme disease and Ehrlichiosis, consider adding doxycycline until lab confirmation of absence of either disease in the patient with babesiosis

ADDITIONAL TREATMENT

General Measures

Those with mild clinical disease usually recover without treatment.

Additional Therapies

- For life-threatening infections, exchange transfusion has been successful. Consider in patients with severe parasitemia ($\geq 10\%$), severe hemolysis or renal/hepatic/pulmonary compromise
- Progressive respiratory distress may require mechanical ventilation

ALERT

- Signs to watch for:
 - Respiratory distress, especially after treatment has begun
 - Pancytopenia and lymphadenopathy: May indicate the development of hemophagocytic syndrome
- Pitfalls:
 - Children who are from endemic areas and have an acute febrile illness may be misdiagnosed with a nonspecific viral illness
 - One should be suspicious for a coinfection with Lyme disease or ehrlichiosis (human anaplasmosis) in those who are not responding to standard therapy
 - Delayed recognition of this uncommon disease may be life threatening in the immunocompromised patient
 - In endemic areas, babesiosis should be considered in a post-transfusion febrile illness in at-risk populations

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

When to expect improvement:

- Some improvement of symptoms should be noted within 24–48 hours of onset of therapy
- Those who are only mildly affected usually have resolution of their symptoms over a few weeks
- For severely affected and immunodeficient patients, the convalescent period may be as long as 18 months
- In untreated asymptomatic individuals, parasitemia may persist for months to years
- Long-term complications are rare
- Recrudescence has been reported

COMPLICATIONS

- Rarely fatal in the US
- Pancytopenia and overwhelming secondary bacterial sepsis may occur
- Serious and fulminant complications have been described:
 - Pulmonary edema and adult respiratory distress syndrome, often happening after treatment has begun
 - CHF
 - Renal failure
 - Hemophagocytic syndrome/disseminated intravascular coagulation
 - Seizures/coma
- Those co-infected with Lyme disease are susceptible to more severe disease and complications

FAQ

- Q: How long does a tick have to be attached for infection to occur?
- A: In general, successful transmission requires at least 24 hours of attachment.
- Q: How should a tick be removed?
- A: The tick should be grasped with forceps as close to its head as possible and pulled straight up. If possible, it should be saved for identification.
- Q: Does infection confer lifetime immunity?
- A: Reinfection is possible.

BACK PAIN

Heather McKeag

Thomas H. Chun (5th edition)

BASICS

DEFINITION

Any condition causing pain of the thoracic, lumbar, or sacral spine

EPIDEMIOLOGY

- Recurrent/chronic back pain: 8% of adolescents
- 12–50% lifetime prevalence

RISK FACTORS

- Increased risk with repetitive activity and age
- Role of obesity yet to be determined
- Inheritance patterns for some congenital (scoliosis, Scheuermann kyphosis), inflammatory/rheumatologic causes, and sickle cell disease have been described.

ETIOLOGY

- Back pain can result from a variety of causes involving the bony or muscular structures of the back, intervertebral discs, spinal cord, or peripheral nerves.
- Specific etiology identified ~50% of the time

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- **Mechanical/trauma**
 - Disc herniation
 - Musculotendinous strain
 - Apophyseal ring fracture
- **Developmental**
 - Pars defects: Children usually > 10 years
 - Spondylolysis (stress fracture of posterior vertebral elements/pars interarticularis, repetitive-stress injury)
 - Spondylolisthesis (anterior displacement/“slip” of vertebral body, evolution of bilateral spondylolysis)
 - Scheuermann kyphosis: Deformity of thoracic spine associated with vertebral body wedging

- **Inflammatory**
 - Juvenile idiopathic arthritis
 - Ankylosing spondylitis
 - Inflammatory diskitis
- **Neoplastic**
- **Infectious**
 - Diskitis
 - Epidural abscess
- **Other**
 - Sickle cell, abdominal disease (pancreatitis, pyelonephritis), psychogenic
- **Age differentiation:**
 - < 10 years: Diskitis, tumor, epidural
 - > 10 years: Pars defects, inflammatory disorders

ALERT

Warning signs of potentially serious causes of back pain in children include:

- Young age: < 4 years old
- Duration of pain: > 3 weeks
- Chronic interference with normal activity (e.g., school, sports, play)
- Associated fever, weight loss, or other systemic symptoms
- Postural shift of trunk
- Neurologic abnormality
- Limitation of spinal motion (e.g., bending forward, straight leg raise)

HISTORY

- History to include:
 - Onset of symptoms
 - Characteristics of pain
 - History of trauma
 - Pain with activity
 - Inflammatory symptoms
 - Systemic symptoms
 - Neurologic symptoms
- **Question:** Focal pain, neurologic symptoms, interference with activity?
- **Significance:** Increased concern for pathology
- **Question:** Symptoms improved with rest?
- **Significance:** Spondylolysis, Scheuermann kyphosis, muscular strain, overuse
- **Question:** Stable pain or worse at night?
- **Significance:** Tumor, infection, inflammatory

PHYSICAL EXAM

- **Finding:** Inspection—sacral dimples, hair tufts, vascular anomalies, café-au-lait spots, or discrepancies in limb length?
- **Significance:** Occult abnormalities
- **Finding:** Palpation—point or focal tenderness along spine?
- **Significance:** If bony, consider fracture; if paraspinal, consider muscle strain
- **Finding:** Range of motion—forward flexion → increases strain on anterior elements of spine (vertebral bodies and disk spaces)?
- **Significance:** Pain—herniated disk, diskitis, vertebral osteo, vertebral body tumor
- **Finding:** Range of motion—extension → increases strain on posterior elements of spine (facet joints, pars interarticularis, pedicles)?
- **Significance:** Pain—fracture, spondylolysis, osteoid osteoma, tumor

Also perform:

- FABER test (flexion, abduction, external rotation with foot on opposite knee) → pressure on bent knee and opposite hip strains SI joint.
- Neurologic exam: Reflexes, Babinski, gait, sensation, strength, tone
- Abdominal/pelvic exams

DIAGNOSTIC TESTS & INTERPRETATION

- **Test:** CBC, ESR, CRP, blood culture
- **Significance:** Infection
- **Test:** ANA, RF, HLA B27
- **Significance:** Inflammatory

Imaging

- Plain x-rays (AP and lateral; oblique and flexion/extension if warranted) of the spine:
 - Scottie Dog's Collar: Spondylolysis (stress fracture of the pars interarticularis)
 - If negative, pursue further imaging
- Bone scan: Occult/subtle bony lesions
- CT spine: Spondylolysis/spondylolisthesis
- MRI: Tumor, infection, disk injuries

**TREATMENT****ADDITIONAL TREATMENT****General Measures**

- If warning signs are absent, conservative management with NSAIDs, physical therapy, and close follow-up are appropriate.
- Abnormal exam/history warrants imaging.
- Spondylolysis/spondylolisthesis:
 - <50% slip: Conservative medical treatment
 - >50% slip/persistent back pain: Surgical treatment
- Diskitis: Anti-staphylococcal coverage
- Bed rest/activity limitation: Adult data do not support this strategy.
- General Prevention
 - Back muscle strengthening and hamstring stretching exercises may be helpful.
 - Maximum backpack load: 10–15% body weight

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS**

- Patients managed conservatively should be re-evaluated within 2 weeks.
- All patients should follow up immediately for any worsening symptoms, especially pain or neurologic symptoms.
- Referral to primary care sports medicine or orthopedic colleagues when necessary

PROGNOSIS

- Dependent on the underlying cause
- The majority, when properly diagnosed and treated, do well, without significant sequelae.
- Not possible to predict future course of spondylolysis, spondylolisthesis, or Scheuermann kyphosis.

COMPLICATIONS

Paralysis, other permanent neuromuscular injury, chronic back pain

**CODES****ICD9**

- 724.1 Pain in thoracic spine
- 724.2 Lumbago
- 724.5 Backache (postural)

ICD10

- M54.5 Low back pain
- M54.89 Other dorsalgia
- M54.9 Dorsalgia, unspecified

FAQ

- Q: Which children should have activity restrictions?
- A: High-risk children (i.e., those with spinal or bony abnormalities of familial histories of spondylolysis) should avoid hyperextension and contact sports.
- Q: When can/should the child resume activities?
- A: Low-risk children with a normal neurologic exam can resume activity or sports when they are pain free.

BAROTITIS

Judith Brylinski Larkin

BASICS

DESCRIPTION

- Barotrauma of the middle or inner ear, most commonly caused by flying in an airplane or scuba diving but also caused by elevators and high altitudes
- May also be seen in those who have used a hyperbaric oxygen chamber and in people involved in explosions—blast injuries
- Referred to as “middle ear squeeze” by scuba divers

EPIDEMIOLOGY

- Severe disease uncommon in commercial aircraft because of pressurization
- Significant disease is more common in scuba divers, in those who fly military aircraft, and during use of hyperbaric oxygen chambers.

Incidence

- There is wide variation, with studies reporting an incidence of 8–55% for children after a single flight.
- Most studies agree that the incidence is ~20% in adults after a single flight.
- 40% incidence in scuba diving

RISK FACTORS

- Age: Infants or toddlers are at higher risk because of small eustachian tubes.
- Disease states that impede normal eustachian tube function: Otitis media, upper respiratory tract infection (URI), allergic rhinitis
- Smoking
- Vigorous use of Valsalva maneuver

GENERAL PREVENTION

- Gradual descent during scuba diving—never rapid
- When ascending, divers should avoid rising more quickly than their air bubbles.
- Yawning, swallowing, chewing, or doing Valsalva maneuver during takeoff and landing in planes, and during ascent and descent when scuba diving
- Gentle Valsalva—never vigorous
- Avoid flying or diving when you have a URI or allergic rhinitis.
- Avoid sleeping on plane during takeoff and landing.
- Break seal of wet suit hood to allow water to fill external canal before descent.
- Avoid use of ear plugs.

PATHOPHYSIOLOGY

- Boyle’s Law states that as pressure of a gas decreases, volume increases, and as pressure of a gas increases, volume decreases.
- Ambient pressure decreases during airplane/scuba diving ascent and increases during descent.
- During ascent, the tympanic membrane bulges outward and the eustachian tube vents the excess middle ear pressure. Pressure is easily equalized.
- During descent, the TM bulges inward and the eustachian tube resists inward flow of air. Pressure equalization is difficult.
- At a pressure differential of 60 mm Hg (greater ambient to middle ear pressure), subjective discomfort is reported.
- At a pressure differential of 90 mm Hg, the eustachian tube collapses and becomes obstructed. Autoinflation is unsuccessful.
- Tympanic membrane can rupture at pressure differentials >100–400 mm Hg.
- Barotitis is sometimes classified using Teed’s classification of disease severity (see “Physical Exam”).

ETIOLOGY

Differences in the atmospheric pressure between the inner ear, middle ear, and environment result in injury to the middle and/or inner ear.

DIAGNOSIS

HISTORY

- Ear pain, pressure sensation, diminished hearing
- Symptoms of inner ear damage may include vestibular and/or auditory complaints including tinnitus, vertigo, nausea, and vomiting.
- History of recent airplane flying, scuba diving, or hyperbaric oxygen chamber use

PHYSICAL EXAM

- Nystagmus
- Hearing loss
- Teed’s classification to describe appearance of the tympanic membrane:
 - Grade 0: Symptoms without physical signs
 - Grade 1: Diffuse redness and retraction of TM
 - Grade 2: Grade 1 plus slight hemorrhage into TM
 - Grade 3: Grade 1 plus gross hemorrhage into TM
 - Grade 4: Bulging TM with air-fluid level, blood in TM
 - Grade 5: Free hemorrhage into TM and ear canal with perforation of TM

DIAGNOSTIC TESTS & INTERPRETATION

Imaging

CT of the inner ear may be indicated in patients with vestibular symptoms or hearing loss to rule out inner ear damage.

Diagnostic Procedures/Other

Hearing tests should be performed on all patients who have signs of barotrauma and on patients with normal physical exams but who are symptomatic.

DIFFERENTIAL DIAGNOSIS

- Otitis media with effusion
- Acute otitis media
- Otitis externa
- Blunt trauma to the tympanic membrane
- Exposure to extremely loud noise

TREATMENT

MEDICATION (DRUGS)

- Nasal decongestant sprays (oxymetazoline [Afrin]):
 - Have been reported by some to be helpful but a randomized clinical trial showed no advantage over placebo
 - Theory: By constricting mucosal arterioles, eustachian tube function is enhanced.
 - Topical decongestants are used 1 hour prior to plane travel/diving and 1/2 hour prior to plane descent.
 - 2 drops/sprays per nostril
 - Use in children over 6 years of age.
- Oral decongestants:
 - 2 randomized controlled trials suggest that oral decongestants may be effective, though a trial in children did not show a beneficial effect.
 - May be helpful through the same physiologic pathway as topical agents
 - Should be initiated 1–2 days prior to the expected pressure change
- Antihistamines:
 - May also be helpful by reducing mucosal edema and enhancing the eustachian tube orifice
 - Can be used on the day of the expected pressure change
- Nasal surfactants may be useful but ongoing studies are needed.
- Pain relievers such as acetaminophen, ibuprofen, and naproxen may be useful for severe pain.

ADDITIONAL TREATMENT**General Measures**

- Valsalva maneuver (blowing the nose while pinching the nostrils closed) may be helpful when diving or descending and will force air into the middle ear via the eustachian tube, thereby equalizing the pressure between the middle ear and the environment. This should be done gently.
- Swallowing, yawning, and chewing can help to release pressure through the eustachian tube when descending in an airplane or when returning to the water surface while scuba diving.
- Politzer bag: Instrument used for clearing pressure disequilibrium that has not improved with Valsalva maneuvers and a trial of decongestants.
- Otovent: Another instrument that may be used for treatment or prevention; usage can be taught to children as young as 2–6 years of age.
- Myringotomy with or without tubes may be required to relieve pressure in severe disease. It may also be used as a preventative measure in those with a history of barotitis.
- Myringotomy is effective for the patient with excruciating pain or unrelenting eustachian tube dysfunction; this is best performed by an otolaryngologist.

SURGERY/OTHER PROCEDURES

Rarely, myringotomy with or without tube insertion is required to relieve pressure and pain, as well as prevent complications. Myringotomy is a surgical procedure where a small incision is made in the tympanic membrane. This opens the middle ear space and equalizes the pressure on both sides of the tympanic membrane. Myringotomy without tube insertion will relieve pressure, but the opening may close very quickly and may not allow time for the barotrauma to heal; on occasion, myringotomy with tube insertion is necessary. Tympanostomy tubes are not appropriate for scuba divers.

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

Most patients with barotitis can be managed conservatively. Those with complications noted above require specialist referral.

PROGNOSIS

- Complete spontaneous resolution in mild cases
- Middle ear barotrauma is usually self-limited and correctable with the techniques described in the “General Measures” section. In rare instances, where there is severe pain or eustachian tube dysfunction, myringotomy with or without tube insertion will relieve the pressure differential.

- Pressure differential without damage to the middle or inner ear usually resolves within a few days of returning to normal atmospheric pressure.
- Barotitis that results in injury to the middle or inner ear has a variable rate of improvement; some damage may be permanent (e.g., that to the organ of Corti), while other injury is reversible (e.g., that involving the tympanic membrane).
- Variable outcome for auditory and vestibular symptoms and injuries to the inner ear

COMPLICATIONS

- Vertigo
- Tinnitus
- Hearing loss
- Tympanic membrane rupture
- Oval or round window rupture
- Hemorrhage

- 993.0 Otitic barotrauma

ICD10

T70.0XXA Otitic barotrauma, initial encounter

FAQ

- Q: Is the Valsalva maneuver also effective on plane ascent?
- A: Yes, creating even greater pressure in the middle ear by performing the Valsalva maneuver can overcome a resistant eustachian tube and result in sudden venting of increased middle ear pressure.
- Q: Can children with otitis media travel in airplanes?
- A: Yes, Weiss and Frost (1987) have shown that commercial air travel did not result in worsening of symptoms and, in fact, the presence of otitis media with effusion seemed to be protective against barotitis.
- Q: How can I minimize my child's ear pain when traveling in an airplane?
- A: For infants: Have them nurse, take a bottle, or suck on a pacifier during ascent and descent. Older children may eat or chew gum or suck on hard candies. This will result in pharyngeal movements that will repeatedly open the eustachian tube and equalize middle ear pressure to environmental pressure. Children can also be taught the Valsalva maneuver. If the child is currently experiencing an upper respiratory infection, use of decongestants prior to flight may be helpful.

BELL PALSY

Stephen J. Falchek

BASICS

DESCRIPTION

- This paralysis may involve all of the modalities affected by the 7th cranial nerve:
 - Mimetic facial movement
 - Taste
 - Cutaneous sensation
 - Hearing acuity
 - Lacrimation
 - Salivation

The most important feature in diagnosis and management of Bell palsy is the distinction between a peripheral and a central 7th nerve palsy.

EPIDEMIOLOGY

Incidence

- Annually, incidence ranges from 3/100,000 in patients <10 years to 25/100,000 in adults.
- Only 1% of cases have bilateral involvement.

PATHOPHYSIOLOGY

Nearly all cases of true Bell palsy are believed to arise from a viral infection of the facial nerve and, in particular, the geniculate ganglion.

ETIOLOGY

- Idiopathic: pregnancy related
- Infectious:
 - Herpes simplex virus 1
 - Human herpes virus 6
 - Herpes zoster (without Ramsay–Hunt syndrome)

COMMONLY ASSOCIATED CONDITIONS

Associated illnesses can cause or predispose to an isolated facial nerve palsy, but are important to distinguish from a classic Bell palsy.

- Rubella
- Lyme disease (*Borrelia burgdorferi*): In Lyme neuropathy, early reports indicated a preponderance of tic bite histories involving the ipsilateral face, implying a retrograde migration of the spirochetes into the nerve and resultant nerve root/arachnoid irritation in at least some cases, as opposed to hematogenous dissemination and CNS penetration.
- Epstein–Barr virus (EBV)
- Cytomegalovirus (CMV)
- Mumps
- HIV
- *Mycoplasma pneumoniae*
- Sarcoidosis

DIAGNOSIS

SIGNS AND SYMPTOMS

HISTORY

- Mastoid or retroauricular pain ipsilateral to the side of developing symptoms (40–50% of patients)
- 50% of patients will have no clear sensory prodrome.
- Bell palsy often follows some identifiable infectious illness, such as viral upper respiratory tract infection (URI) symptoms, *Mycoplasma pneumoniae* infection, Lyme disease or infectious mononucleosis. However, an identified antecedent illness is not requisite for the diagnosis.

- The onset is almost always rapid, with progression to a fairly constant state of unilateral paresis or paralysis within hours to 2–3 days.
- As the weakness progresses, the patient (and family members) may note:
 - Difficulty with oral motor tasks (e.g., eating and drinking) due to inability to maintain mouth closure
 - Inability to completely close the eye on the affected side (sometimes leading untrained observers to note an eyelid “droop” on the normal side, due to the contrast with normal eyelid closure and movements)
 - Decreased lacrimation, and eye itching and burning
 - Hyperacusis
 - Ipsilateral facial numbness (less commonly)
 - Distortion of the taste of foods (dysgeusia)
- Bilateral symptoms (<1%) are distinctly rare and suggest an alternative diagnosis, such as Guillain–Barré syndrome or other infectious, inflammatory, or metabolic disease.

PHYSICAL EXAM

- Weakness of all muscles of mimetic facial movement is noted on the affected side.
- A classic feature of peripheral facial nerve palsies is symmetric weakness or paralysis of the upper (frontalis), middle (orbicularis oculi), and lower (orbicularis oris) muscles on voluntary and involuntary mimetic movements. Having the patient wrinkle his or her forehead/raise his or her eyebrows, close his or her eyes tightly, and bare his or her teeth or smile, respectively, tests these.
- Occasionally, slow or absent spontaneous blinking on the affected side.
- The corneal reflex should be decreased or absent on the affected side, but the consensual response on the unaffected side should be preserved.
- The sensory division of the 7th cranial nerve is tested by examining taste perception on the anterior tongue:
 - This is done by applying, ipsilaterally, swabs soaked in a sugar solution and a salt solution to the anterolateral aspect of the tongue, without allowing for mouth closure and dispersion of the substances to the other side. Taste sensation should be ipsilaterally decreased.
 - Despite complaints of retro-auricular pain and unilateral facial “numbness,” abnormalities of cutaneous sensation typically are not verifiable by sensory testing in pure 7th-nerve palsies. The presence of true diminution of sensation should raise the question of other cranial nerve involvement (e.g., 5th cranial nerve).
- Examination of the external auditory canal on both sides is crucial.
 - Vesicular lesions of the tympanic membrane indicate a zoster-associated palsy (i.e., Ramsay–Hunt syndrome).
 - Purulent acute otitis media or evidence of trauma mandate aggressive antibiotic treatment and possibly urgent surgical subspecialty evaluation and imaging of the temporal bone.

DIAGNOSTIC TESTS & INTERPRETATION

Imaging

- The decision to defer medical imaging in the evaluation of a typical Bell palsy should be based on a sound clinical history and physical examination. Unusual features should provoke thoughtful review and broader investigation where indicated.
- MRI of the head with gadolinium enhancement: recommended in cases of unusual presentation or progression (e.g., bilateral involvement, slow progression (over >1 week), or other cranial nerve findings). Several small series have proposed that gadolinium enhancement of the involved 7th nerve predicts a slower or less optimal recovery.

DIFFERENTIAL DIAGNOSIS

- Trauma:
 - Birth (especially forceps pressure to lateral face)
 - Congenital facial palsies should not be regarded as Bell palsy, but rather symptomatic of some other cause.
 - Temporal bone/petrous bone fractures
 - Deep lacerations or trauma to parotid region
- Infection:
 - Purulent acute otitis media/mastoiditis
 - Basilar meningitis
 - Petrositis (Gradenigo syndrome)
 - Varicella zoster virus (VZV; Ramsay–Hunt syndrome)
 - Syphilis
 - Trichinosis
 - Tuberculosis
 - Leprosy
- Inflammatory:
 - Sarcoidosis
 - Behçet disease
 - Giant cell arteritis
 - Polyarteritis nodosa
 - Guillain–Barré syndrome
 - Melkersson–Rosenthal syndrome: rare neurologic disorder characterized by recurring facial paralysis, swelling of the face and lips (usually the upper lip), and the development of folds and furrows in the tongue
- Tumors:
 - Cerebellopontine angle tumors, osteosarcomas, cholesteatomas, neurofibromas, lymphoma
 - Hyperostosis cranialis interna, osteopetrosis
- Metabolic:
 - Diabetes (nerve ischemia)
 - Hyperparathyroidism
 - Hypothyroidism
 - Porphyria
- Congenital/Genetic:
 - Congenital absence or hypoplasia of depressor anguli oris muscle
 - Möbius syndrome
 - Chiari malformation
 - Syringobulbia

TREATMENT

Identifying treatable causes of 7th-nerve palsy (e.g., Lyme borreliosis and Ramsay–Hunt syndrome) is crucial for optimizing outcome and preventing comorbidities of these illnesses.

GENERAL MEASURES

- Eye protection and lubrication: A significant risk for corneal injury is best managed by applying artificial tear solutions at least 3–4 times daily and lubricating gels (e.g., Lacri-Lube) at night. Patching and protective eyewear, during active play and sleep, is usually prescribed on the basis of the degree of remaining eyelid closure.
- Corticosteroids: Prednisone, considered only within the first 72 hours of symptoms. Recommended dose: 1 mg/kg/d (maximum 80 mg) for 5 days, with a taper over the following 5 days.
- Acyclovir: Most clearly indicated for the treatment of Ramsay–Hunt syndrome. It is also used empirically by some practitioners in standard Bell palsy management, although evidence for its supplementary use to corticosteroids is relatively weak; see discussion below. Recommended dose: 20 mg/kg/d, divided into 5 times a day, for 10 days; maximum 400 mg 5 times daily. Generally, any evidence of vesicular eruption in the ear canal or face should be treated promptly with acyclovir, as outcomes from VZV-associated palsies are reported to be worse in general.

Physical Therapy

The benefits of facial muscle physical therapy remain controversial. Despite an increasing number of studies, some with controls, and subsequent meta-analyses, the results are conflicting. At present, there is no incontrovertible evidence for benefit due to facial physical therapy. There is no evidence that facial physiotherapy is harmful. The decision to pursue physical therapy after Bell palsy is a matter of personal preference for the practitioner and family.

MEDICATION (DRUGS)

- Corticosteroids: Recent large series and meta-analyses indicate that treatment with corticosteroids is effective in reducing the risk of incomplete recovery; however, this treatment seems to be only effective if initiated within the first 48 hours of symptoms. Furthermore, statistical significance in treatment versus placebo seems to be most evident only in patients older than 40 years. However, the occurrence of synkinesias does seem to be less in patients treated with steroids within 48 hours across all age groups.
- Antivirals: These same series suggest that there is little or no benefit to therapy with either acyclovir or valacyclovir alone, and that there is at best a non-statistically significant improvement when used in combination with corticosteroids.
- Antibiotics: In areas where Lyme disease is endemic, many practitioners will begin treatment with oral antibiotics presumptively, while awaiting serologies (recall that the IgM titer is the most useful in the acute setting). (See “Lyme Disease” chapter):

First Line

- Prednisone, 60–80 mg/day for 5 days, with a subsequent taper over 5 days; total treatment course 10 days; must be initiated in the first 48 hours for significant results.
- Amoxicillin, 50 mg/kg/d divided in 3 doses for 21–28 days, when Lyme disease suspected

Second Line

For presumed Lyme disease:

- Patients >8 years: doxycycline, 100 mg b.i.d. for 21–28 days
- Patients of all ages: cefuroxime, 30 mg/kg/d in 2 divided doses for 21–28 days

SURGERY/OTHER PROCEDURES

Surgical decompression: Previously, surgical decompression of the 7th nerve had been proposed as a possible treatment in cases where recovery was delayed or the clinical course more severe. No clinical evidence to support the benefit of this strategy has emerged. Surgical decompression is best reserved for “other” cases of facial nerve palsy in which there is a definable syndrome of nerve compression due to extrinsic factors, such as exostoses, tumor, etc.

ISSUES FOR REFERRAL

Subspecialty consultation: In general, patients are referred if their recovery time is prolonged or if there is a relapsing pattern or other deviations from the expected course. However, the presence of other questionable cranial nerve involvement, recent trauma, meningeal symptoms, or neurologic findings (e.g., eye movement abnormalities, acute hemiparesis, etc.) should be viewed with great concern and evaluated in an urgent-care setting.

ONGOING CARE

DIET

There are no dietary restrictions that affect the outcome of Bell palsy.

PATIENT EDUCATION

Minimizing risk for injury to the cornea ipsilateral to the facial palsy may require either restricting some activities where debris or contusions to the eye are likely, or wearing protective eyewear during such activities. Examples include beach activities and competitive sports. These restrictions only need to be in effect so long as there is inadequate closure of the eyelid on the affected side.

PROGNOSIS

- 60–70% full-recovery rate from isolated 7th-nerve palsy
- Signs of recovering function (generally improving control of mimetic movement) are typically apparent by the 3rd week after onset.
- Prognosis for recovery seems to be worse with either a secondary deterioration in function after 2–4 days, no signs of recovery after three weeks, or demonstrated gadolinium enhancement of the affected facial nerve on MR imaging.
- Of patients with less than total recovery, many will experience at least partial return to normal function; cosmetic results vary in this group.
- Outcome of idiopathic facial palsy as a pregnancy complication seems to be less favorable (~55% full recovery).
- Up to 7% of patients may experience a 2nd occurrence at some point in the future.

COMPLICATIONS

- Corneal injury, due to decreased lacrimation and poor eye closure
- Several sequelae, generally related to aberrant reinnervation of affected end organs, are observed after an episode of Bell palsy.
 - Various synkinesias (abnormal involuntary movements that accompany a normally executed voluntary movement), including the Marin–Amat phenomenon (spontaneous eye closure with mouth opening, or its converse)
 - Blepharospasm, hemifacial spasm, facial contractures
 - The “crocodile tears” phenomenon (eating provokes ipsilateral tearing) results from crossed reinnervation between lacrimal and salivary parasympathetic fibers.

FAQ

- Q: How does one differentiate between peripheral facial nerve palsy and a CNS lesion?
- A: A critical step in diagnosis is the differentiation of peripheral from central (upper motor neuron) lesions. With upper motor neuron lesions (above the level of the 7th-nerve nucleus), there is preferential weakness of lower facial musculature and, sometimes, differential paresis of voluntary versus spontaneous emotional mimetic movements. Brainstem lesions, on the other hand, may produce a peripheral-appearing lesion, but almost always have involvement of other pathways and cranial nerve nuclei, e.g., ipsilateral lateral rectus palsy and contralateral somatic hemiplegia (Millard–Gubler syndrome).

BEZOARS

Andrew B. Grossman

BASICS

DESCRIPTION

- Accumulation of foreign material in the GI tract
- Commonly divided into 3 categories based on the substances from which they are derived:
 - Phytobezoar (vegetables/fruits)
 - Trichobezoar (hair)
 - Lactobezoar (milk/formula)
- Documented over 2 millennia and has medical value in some cultures

EPIDEMIOLOGY

- Phytobezoars occur almost exclusively in adults.
- 90% of trichobezoars occur in female patients younger than 20 years.
- Lactobezoars occur mostly in premature, low-birth-weight infants.

PATHOPHYSIOLOGY

- Trichobezoars:
 - Associated with mental retardation, pica, trichotillomania, and trichophagia; may ingest own hair but also rugs and animal or doll hair
 - History of trichophagia is obtained in only 50% of cases.
 - Retention and accumulation of hair strands in the gastric folds
 - Bezoars may become large and form a cast in the stomach leading to abdominal mass.
 - Bezoar may extend through the pylorus into the small bowel. This “tail” may obstruct the ampulla of Vater, leading to jaundice and pancreatitis.
 - Most cases of trichophagia do not result in bezoar formation.

- Phytobezoars:
 - Most common form among adults, rare in children
 - Associated with gastric dysmotility and poor gastric emptying (either primary or following gastric surgery) and hypochlorhydria
 - Composed primarily of cellulose, hemicellulose, lignins, and tannins
- Lactobezoars (milk):
 - Most often reported in premature, low-birth-weight infants being fed high-calorie premature formula (although there are reports in full-term infants and exclusively breast-fed infants)
 - Factors contributing to lactobezoar formation include:
 - Formulas with high casein content
 - Early and rapid feeding advancement in small infants
 - High-caloric-density formulas
 - Formulas with high calcium/phosphate content
 - Continuous tube feedings
 - Altered gastric motility in low-birth-weight infants

ETIOLOGY

Classification of bezoars is dependent on the most prominent substance from which they are formed, including:

- Trichobezoars: Hair, carpet
- Phytobezoars: Indigestible fruit and vegetable matter
- Lactobezoars: Milk

- Less common materials include foreign bodies, gallstones, and medicines, including vitamins, antacids, psyllium, sucralfate, cimetidine, and nifedipine; can occur in CF patients after lung transplantation
- Colonic and rectal bezoars due to indigestible sunflower seeds, popcorn, and gum have been reported in children and adults. These usually present with obstruction, although encopresis and colitis-type symptoms have been described.

DIAGNOSIS

HISTORY

- Signs and symptoms of bezoar formation include:
 - Pain
 - Halitosis
 - Nausea
 - Vomiting
 - Diarrhea
 - Gastric ulceration
 - Upper GI bleeding and perforation
 - Left upper quadrant mass
- Trichobezoars:
 - Unusual patterns of balding
 - Palpable left upper quadrant mass in the abdomen is often detected
 - Hair found in the stool
- Phytobezoars:
 - Abdominal mass is palpable in <50% of patients.
- Lactobezoars:
 - Abdominal distention, diarrhea, emesis, increased gastric residuals

DIAGNOSTIC TESTS & INTERPRETATION**Lab**

- Iron-deficiency anemia
- Presence of steatorrhea or protein-losing enteropathy

Imaging

- Plain abdominal x-ray: Heterogenous intragastric mass that could be mistaken for food-filled stomach
- Upper GI barium studies may identify and outline the mass.
- Ultrasound and CT can also be helpful

Diagnostic Procedures/Other

Endoscopy allows for direct visualization, elucidation of composition of bezoar

DIFFERENTIAL DIAGNOSIS

Any gastric foreign body can mimic a gastric mass and may present on palpation.

**TREATMENT****ADDITIONAL TREATMENT****General Measures**

- Trichobezoars:
 - Difficult to remove endoscopically, attempts to fragment may result in migration and small bowel obstruction
 - Solution is surgical removal: They are normally large, and hair is not dissolvable.

- Phytobezoars:
 - Medications such as prokinetic agents to stimulate gastric motility
 - Enzyme therapy to help dissolve the material
 - N-acetylcysteine treatment via nasogastric tube has been documented in one case report
 - Endoscopic fragmentation or extraction
 - Surgical extraction
 - Diet alteration
- Lactobezoars:
 - Withholding feedings for 48 hours while the patient is sustained on IV fluids will resolve most lactobezoars.
 - Gentle gastric lavage may be helpful.

- T18.4XXA Foreign body in colon, initial encounter

FAQ

- Q: What are some commonly used medications that can lead to bezoar formation?
- A: Vitamins, antacids, psyllium, sucralfate, cimetidine, and nifedipine
- Q: What may place an infant at risk for formation of a bezoar?
- A: The literature suggests that formulas with high casein content may be linked with lactobezoar formation. Other possible contributing factors include early and rapid feeding advancement in small infants, high-density formulas, formulas with a high calcium/phosphate content, continuous tube feedings, and altered gastric motility in low-birth-weight infants.

BILIARY ATRESIA

Kathleen M. Loomes

BASICS

DESCRIPTION

Biliary atresia is a progressive obliteration of the extrahepatic and intrahepatic biliary ducts of the liver.

EPIDEMIOLOGY

- Extrahepatic biliary atresia accounts for 25–30% of cases of neonatal cholestasis.
- Occurs with a frequency of 1 per 8,000–15,000 live births
- Most common cause of neonatal jaundice for which surgery is indicated

RISK FACTORS

Genetics

- No clear genetic inheritance can be demonstrated.
- Rarely reported to recur in families
- Human genes that determine laterality and genes that affect bile duct development may be important in pathogenesis of some cases.

PATHOPHYSIOLOGY

- Extrahepatic biliary atresia can affect all or part of the extrahepatic biliary tree.
- When only the distal common bile duct, cystic duct, or gallbladder is affected, biliary drainage may be established (<10% of patients).
- Coexisting anomalies are found in ~20% of patients; associations include:
 - Absence of the inferior vena cava with azygous continuation
 - Preduodenal portal vein and symmetric liver
 - Malrotation
 - Situs inversus
 - Bronchial anomalies
 - Multiple spleens (polysplenia)
 - Other anomalies within the spectrum of heterotaxy, including structural congenital heart defects in a minority
- Histology:
 - Extrahepatic biliary obstruction begins near the time of birth and progresses.
 - For approximately the 1st year, liver biopsy shows cholestasis, interlobular bile duct proliferation, and a mononuclear infiltrate invading the periductal tissue:
 - Bile plugs may be present within ducts.
 - Portal tracts are expanded by fibrosis.
 - Some patients may already have well-established cirrhosis.
 - Later biopsies show degeneration and loss of bile ducts.
 - If the biopsy is performed at <4 weeks of age, the pathology may be confused with other causes of neonatal cholestasis, such as giant cell hepatitis.

ETIOLOGY

Etiology is unclear; each of the following has been suggested but has never been substantiated:

- Environmental factors
- Viral infection (Reovirus 3, rotavirus, cytomegalovirus)
- Vascular insufficiency
- Genetic factors: No clear genetic inheritance; likely genetic predisposition
- Immune dysregulation in neonate affecting hepatobiliary system
- Pancreatic reflux
- Defective morphogenesis:
 - Ductal plate malformations have been noted in some biliary atresia liver biopsies.
 - Laterality or developmental genes may play a role in some cases.
- Multifactorial (e.g., in a genetically susceptible host, a viral infection soon after birth could trigger an immune reaction that progressively destroys the biliary tree)

DIAGNOSIS

HISTORY

- Typically, the patient is an otherwise healthy infant who develops jaundice within the 1st 90 days of life.
- Stools usually pale, but may have normal color

PHYSICAL EXAM

- Jaundice is best visualized by examination of the hard palate, buccal mucosa, or sclerae.
- Jaundice may not be present until the bilirubin exceeds 5–7 mg/dL in the newborn period and 2 mg/dL in the older child.
- Acholic stools, hepatomegaly, and abnormal liver consistency need not be present to establish the diagnosis.

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other

- Conjugated hyperbilirubinemia is defined as a conjugated fraction >2 mg/dL or a conjugated bilirubin >15% of the total.
- Any infant with a conjugated hyperbilirubinemia should be referred for workup:
 - Fractionated bilirubin
 - Aspartate aminotransferase, alanine aminotransferase, alkaline phosphatase, γ -glutamyl transferase, total protein, albumin:
 - CBC, PT/PTT
 - Bacterial cultures (blood, urine, stool)

- Further diagnostic testing should be done as clinically indicated, with early referral to a pediatric gastroenterologist.
 - Viral studies (hepatitis B, hepatitis C, Epstein-Barr virus, TORCH, HIV, adenovirus, enterovirus)
 - α_1 -Antitrypsin level with Pi typing
 - Urine and plasma amino acids
 - Urine organic acids and succinylacetone
 - Urine bile acid analysis
 - Urine for reducing substances while the child is ingesting lactose; if positive, assay of galactose-1-phosphate uridylyl transferase activity
 - X-ray studies to exclude evidence of congenital infections and Alagille syndrome (i.e., calcifications of brain and butterfly vertebrae), as indicated
 - Eye exam for congenital infections and eye anomalies associated with Alagille syndrome (posterior embryotoxon)
 - Sweat chloride measurement
 - Thyroid function tests
- Other studies:
 - Abdominal ultrasound to rule out biliary anomalies such as choledochal cyst; also may identify laterality defects, such as polysplenia; although ultrasound findings are not diagnostic, identification of the “triangular cord” sign may be significant.
 - Hepatobiliary scintigraphy
 - Liver biopsy
 - Operative cholangiogram, if liver biopsy is suggestive of biliary obstruction

DIFFERENTIAL DIAGNOSIS

The differential diagnosis includes all causes of neonatal cholestasis:

- Extrahepatic causes of neonatal cholestasis:
 - Biliary atresia
 - Choledochal cyst
 - Neonatal sclerosing cholangitis
 - Bile duct stenosis
 - Anomalies of the choledochopancreaticoduodenal junction
 - Spontaneous perforation of the common bile duct
 - Obstructing neoplasia or stone
 - Inspissated bile or mucous plug
- Infection
 - Sepsis
 - UTI
 - TORCH infections (*Toxoplasma*, rubella, cytomegalovirus, herpes simplex virus)
 - Coxsackie B virus, echovirus, adenovirus, enterovirus
 - Viral hepatitis
 - HIV

- Epstein-Barr virus
- Metabolic abnormalities:
 - α_1 -Antitrypsin deficiency
 - Cystic fibrosis
 - Galactosemia
 - Inborn errors of bile acid metabolism
 - Hereditary fructose intolerance
 - Zellweger syndrome
 - Tyrosinemia
 - Neonatal iron storage disease (likely to present with liver failure)
 - Citrin deficiency
 - Respiratory chain disorders
- Genetic disorders:
 - Alagille syndrome (syndromic bile duct paucity)
 - Trisomy 17, 18, and 21 and Turner syndrome
 - Progressive familial intrahepatic cholestasis:
 - FIC1 deficiency (Byler syndrome)
 - BSEP deficiency (PFIC2)
 - MDR3 deficiency
 - Benign recurrent intrahepatic cholestasis
 - Dubin-Johnson syndrome
 - Rotor syndrome
- Drugs/toxins:
 - Medications
 - Total parenteral nutrition
- Systemic disease:
 - Postshock
 - Postasphyxia
 - CHF
 - Panhypopituitarism
- Other:
 - Idiopathic neonatal giant cell hepatitis
 - Nonsyndromic paucity of interlobular bile ducts

TREATMENT

ADDITIONAL TREATMENT

General Measures

- After the diagnosis of extrahepatic biliary atresia is established, Kasai portoenterostomy is performed.
- Subsequent management is directed at providing nutrition and monitoring for common problems.
- Recent studies show that average 2-year survival post-Kasai with native liver is ~50%.

SURGERY/OTHER PROCEDURES

- Kasai hepatopartoenterostomy (Kasai procedure) is performed to establish biliary drainage. Corticosteroids are used postoperatively in many centers to improve biliary drainage, but well-controlled studies have not been completed to date.
- Indications for transplantation include persistent cholestasis, life-threatening hemorrhage from portal hypertension, failure to thrive, intractable pruritus, recurrent cholangitis, ascites, and liver failure.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- In 1 recent study, the best prognostic factor was a total bilirubin <2 mg/dL at the 3-month follow-up post-Kasai.
- Outcomes are less favorable overall in patients with BA splenic malformation syndrome.
- Development of ascites was associated with a poor outcome (early liver transplantation).
- Common long-term problems:
 - Poor growth
 - Fat-soluble vitamin deficiency
 - Recurrent cholangitis
 - Portal hypertension
 - Pruritus
 - Ascites
 - Progression of liver damage despite a surgical drainage procedure
- The clinician should:
 - Monitor growth parameters and fat-soluble vitamins.
 - Monitor liver span, liver texture, and spleen size to follow progress of disease.
 - Follow liver function tests and CBC.
 - Watch closely for cholangitis: Suggestive findings include fever, elevated transaminases, and γ -glutamyl transferase levels.

ALERT

- Age at the time of surgical intervention is the most important determinant of outcome—delay in diagnosis can be tragic.
- Without surgical intervention, 50–80% of children will die from biliary cirrhosis by age 1 year, and 90–100% by age 3 years.

DIET

- Malabsorption is common and leads to fat-soluble vitamin deficiency and malnutrition; patients receive routine supplementation with vitamins A, D, E, and K.
- Diet should be enriched with medium-chain triglycerides, which do not require bile flow for absorption.
- Nasogastric tube feedings should be implemented if growth is inadequate.

COMPLICATIONS

- Prevention of cholangitis: During the 1st year of life, most children are maintained on daily oral antibiotics to prevent infections from ascending into the liver.
- Pruritus is common and develops when there is increased serum bile acid concentration. Approaches to treatment (with limited success) include ursodeoxycholic acid, antihistamines, cholestyramine, improved nutrition, rifampin, phenobarbital, and naloxone.
- Hyperlipidemia/xanthomas: Hyperlipidemia can be treated with choleric agents, bile acid-binding resins, and improved nutrition.

- Ascites: Spironolactone, chlorothiazide, and furosemide are commonly used diuretics. Acute changes in fluid balance or a rapid diuresis can be achieved using furosemide with albumin replacement.

CODES

ICD9

751.61 Biliary atresia

ICD10

- Q44.2 Atresia of bile ducts
- Q44.7 Other congenital malformations of liver

FAQ

- Q: When should a patient with neonatal jaundice have a fractionated bilirubin test?
- A: If hyperbilirubinemia has not resolved by 2 weeks of age. This allows ample time for evaluation of neonatal cholestasis and the possible need for surgical intervention.
- Q: What are the most important factors in success of the Kasai portoenterostomy?
- A: The age at referral of the patient for evaluation and the experience of the center performing the procedure.
- Q: Can the physician prioritize the diagnostic evaluation?
- A: The diagnostic workup for neonatal cholestasis is usually prioritized to investigate the most treatable and dangerous etiologies, taking into account the history, physical exam, and laboratory findings. Since outcomes in biliary atresia depend on age at surgery, the diagnosis must be made early. The full workup should be complete within a few days to 2 weeks, depending on the age of the child.

BLASTOMYCOSIS

Leonel Toledo

Theoklis Zaoutis (5th edition)

BASICS

DESCRIPTION

- Systemic infection caused by the dimorphic soil fungus *Blastomyces dermatitidis*
- Dimorphism is characterized by a mold phase (mycelial form) that grows at room temperature and a yeast form that grows at body temperature.
- Incubation period estimated at 30–45 days

EPIDEMIOLOGY

- Similar to other dimorphic fungi, *B. dermatitidis* is a soil saprophyte (mycelial form).
- No person-to-person transmission has been documented.
- Congenital infections occur rarely.

Prevalence

- Infection is endemic in the US in the southeast and central states and in the towns bordering the Great Lakes, with the highest incidence in Arkansas, Kentucky, Louisiana, Mississippi, North Carolina, Tennessee, and Wisconsin.
- Other reported areas of infection include parts of Canada (Ontario, Manitoba), Africa, India, and South America.
- Disease may be more severe and chronic in children with T-cell defects (especially HIV infection).
- Children account for 3–11% of cases of blastomycosis.

GENERAL PREVENTION

- No special precautions for hospitalized patients are indicated.
- The natural reservoir is undetermined.

PATHOPHYSIOLOGY

- Inhalation of the fungus into the lung is followed by an inflammatory response with neutrophils and macrophages.
- Blastomycosis most commonly presents as a subacute pulmonary disease, but the clinical spectrum of the disease extends from asymptomatic to disseminated disease that involves the skin, bones, and genitourinary system.
- As many as 50% of infections are asymptomatic.

ETIOLOGY

- Infection is most commonly caused by inhalation of spores from *B. dermatitidis*.
- Less common modes of acquiring the infection include accidental inoculation, dog bites, conjugal transmission, and intrauterine transmission.
- Point-source outbreaks have been associated with occupational and recreational activities that occur in areas with moist soil and decaying vegetation, such as along streams and rivers.
- Natural infection occurs only in 2 mammalian species, humans and dogs.

COMMONLY ASSOCIATED CONDITIONS

- Pulmonary blastomycosis:
 - Most common form of infection by *Blastomyces* in children
 - Can be acute, subacute, or chronic
 - Illness severity can vary greatly, from asymptomatic to presentations of upper respiratory tract infection, bronchitis, pleuritis, pneumonia, or severe respiratory distress.
- Cutaneous blastomycosis:
 - Skin manifestations are variable and include nodules, verrucous lesions, subcutaneous abscesses, or ulcerations.
 - Cutaneous disease occurs following pulmonary inoculation in most cases, but can also occur after direct inoculation into the skin.
- Disseminated blastomycosis:
 - Usually begins as pulmonary infection, with subsequent spread to involve skin (most commonly), bone, genitourinary tract, and CNS.
 - Can disseminate to virtually any organ system.

DIAGNOSIS

HISTORY

- For children with acute pulmonary blastomycosis, the most common presenting symptoms are:
 - Cough (may be productive)
 - Fever
 - Chest pain
 - Malaise
- Children with chronic pulmonary disease present with:
 - Chronic (>2 weeks) nonproductive cough
 - Pleuritic chest pain
 - Poor appetite
 - May also be a history of fever, chills, weight loss, fatigue, night sweats, or, rarely, hemoptysis
- History of residence or travel to an endemic area

PHYSICAL EXAM

- Initial pulmonary infection may present with physical exam findings similar to those of bacterial pneumonia.
- Respiratory signs and symptoms often have resolved by the time cutaneous manifestations are apparent.
- Skin involvement appears as nodules, nodules with ulceration, and, finally, granulomatous lesions with advancing borders.
- Sites in disseminated disease include lung, skin, bone, genitourinary tract, CNS, and, infrequently, liver and spleen, lymph nodes, thyroid, heart, adrenals, omentum, GI tract, muscles, and pancreas.

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other

- Definitive diagnosis requires the growth of *B. dermatitidis* from a clinical specimen.
- Direct visualization of the yeast form may be performed on samples of sputum, urine, cerebrospinal fluid, bronchoalveolar lavage sample, or tissue biopsy.

- Culture of the organism from samples can be performed and a DNA probe used to identify *B. dermatitidis*.
- Serologic tests lack sensitivity and specificity and are generally not helpful in establishing blastomycosis.
- A negative serologic test does not rule out infection, and a positive test should not be used as an indication to start treatment with *Blastomyces*.
- The most accurate serologic test is the enzyme immunoassay.
- An assay to detect *Blastomyces* antigen in urine is available, but cross-reactivity occurs in 70–100% of patients with histoplasmosis, paracoccidioidomycosis, and *Penicillium marneffei* infections.
- Chest radiography commonly reveals lobar consolidation. Cavitation, fibronodular patterns, and mass effect may also be seen.

DIFFERENTIAL DIAGNOSIS

- Acute bacterial infection
- Neoplasm
- Tuberculosis
- Sarcoidosis
- Other fungal infections causing pneumonia

TREATMENT

MEDICATION (DRUGS)

- Though acute pulmonary infections may resolve without treatment, the high rate of progression to extrapulmonary disease leads many experts to recommend treatment for all cases of blastomycosis.
- Mild or moderate pulmonary or extrapulmonary disease:
 - Oral itraconazole
 - Alternative agents include ketoconazole or fluconazole.
- Severe pulmonary disease, other severe infection, or immunosuppression:
 - IV amphotericin B
 - Therapy may be switched to oral itraconazole after clinical stabilization with amphotericin B.

- CNS blastomycosis:
 - Lipid amphotericin B over 4–6 weeks, followed by an oral azole
- During pregnancy:
 - IV amphotericin B
 - Azoles should be avoided owing to potential teratogenicity.
- Length of therapy is site dependent:
 - ≥ 6 months or longer for pulmonary disease
 - ≥ 12 months or longer for bone or CNS disease
- Lifelong suppressive therapy with oral itraconazole may be required for immunosuppressed patients and in patients who experience relapse despite appropriate therapy.
- Voriconazole, a new azole agent, has in vitro activity against *B. dermatitidis* and penetrates the CSF better than itraconazole. Anecdotal reports support its use as an option for step-down therapy for CNS infection.

SURGERY/OTHER PROCEDURES

Occasionally drainage of abscesses and debridement of bone are necessary.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- All azoles can cause hepatitis.
- Hepatic enzymes should be measured before starting therapy, 2–4 weeks after therapy has begun, and every 3 months during therapy.
- All azoles inhibit P-450 enzymes. Consider drug–drug interactions when the patient is taking other medications.

PROGNOSIS

- Before antifungal medications were available, the mortality associated with blastomycosis was up to 90%.
- Appropriate treatment with antifungal medications results in excellent cure rates and mortality rates of <10%.
- The prognosis for chronic cutaneous disease is better than that for systemic disease.

COMPLICATIONS

- Dissemination is the main complication of the infection, occurring in up to 80% of children with blastomycosis.
- Systemic infection may be well advanced before symptoms are noted, making eradication more difficult. Long-term therapy and follow-up may be necessary.

BLEPHARITIS

Lee R. Atkinson-McEvoy

BASICS

DESCRIPTION

- Inflammation or infection of the margins of the eyelid
- Hallmark clinical features include redness, itching or burning, and crusting or scaling of the lid margins
- Classified according to location:
 - Anterior blepharitis involves the eyelashes and follicles of the eyelid. It is usually caused by seborrhea and/or infection—bacterial (e.g., *Staphylococcus* infection), viral (e.g., molluscum contagiosum), and parasitic (phthiriasis).
 - Posterior blepharitis involves the meibomian gland openings. This occurs in meibomian gland dysfunction.
- Anterior blepharitis:
 - Seborrheic blepharitis:
 - Notable for easy-to-remove, yellow, greasy scales along the eyelashes
 - Occurs in conjunction with similar seborrheic scales of the eyebrow, scalp, and external ears
 - Staphylococcal blepharitis:
 - Acute, localized infection of the eyelid margin caused by *Staphylococcus aureus* or *S. epidermidis*.
 - Hallmark features of staphylococcal-induced blepharitis are fibrinous, difficult-to-remove scales at the eyelash bases with concomitant inflammation of the lid margin, and occasionally loss of eyelashes
 - Mixed blepharitis: Presence of a staphylococcal infection complicating seborrhea of the eyelids

GENERAL PREVENTION

- Treat seborrheic dermatitis of scalp early.
- Discourage eye rubbing in patients.
- Encourage frequent hand washing for children.
- For children with allergic symptoms, oral antihistamines may decrease eye rubbing.

EPIDEMIOLOGY

Atopic or allergic contact dermatitis as a cause of blepharitis occurs in up to 65% of patients.

Incidence

- No studies that give an exact incidence but is a commonly seen diagnosis
- Up to 30% of patients with trisomy 21 (Down syndrome) have blepharitis

RISK FACTORS

- Presence of atopic, allergic, or seborrheic dermatitis
- Contact lens wearers
- Presence of dry eye

PATHOPHYSIOLOGY

- There are several glands—meibomian glands, pilosebaceous glands of Zeis, and the apocrine glands of Moll—that exit along the eyelid margin. These glands produce the lipid component of tears.
- When these glands become infected or dysfunctional, the clinical features notable for blepharitis may occur.
- Spread of bacteria to the glands of Zeis or the meibomian glands can lead to development of a hordeolum, or sty.
- Staphylococcal exotoxins can lead to conjunctivitis or keratitis.

ETIOLOGY

COMMONLY ASSOCIATED CONDITIONS

- Seborrheic dermatitis
- Allergic or contact dermatitis
- Down syndrome (trisomy 21)
- Ocular rosacea
- Dry eye (keratoconjunctivitis sicca) is associated with staphylococcal blepharitis.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Complaints of irritation (burning, pain, or itching sensation) that are worse in the morning
- Eye discharge or crust, particularly along lashes
- Erythema of eyelid margins
- Eyelid sticking
- Eyelash loss

HISTORY

Ask about:

- History of previous inflammation of eyelid margins, or presence of symptoms for a prolonged period of time
- Pruritus
- Use of any medications or products (e.g., contact lenses, soaps, or makeup) used on or around the eye
- Environmental irritants (e.g., smoke, allergens)
- Frequent rubbing of the eye or contact with eyelids by hands
- Hand-washing practices
- Cleansing of eyelids
- Past medical and family histories of atopy
- Seasonal variation of symptoms (suggests allergic etiology)
- History of lice

PHYSICAL EXAM

- Evaluate eyelid margins and eyelashes for crust, erythema, loss of hair, and ulceration.
- With chronic infection, you may see thickening of the eyelid margin.
- With herpes simplex viral infection, you may see grouped vesicles along the eyelid.
- Evaluate remainder of eye, particularly the conjunctiva and sclera, for evidence of inflammation or infection. A slit-lamp exam is indicated if there seems to be any evidence of involvement of the conjunctiva or sclera.
- Examine the scalp and skin of the head for evidence of seborrhea, atopic dermatitis, contact dermatitis, louse infestation, or rosacea.

DIAGNOSTIC TESTS & INTERPRETATION**Lab**

- Laboratory testing is indicated only in cases that do not respond to treatment.
- Bacterial or viral culture of the lid margins can be helpful in cases when the diagnosis is unclear, or in severe cases of blepharitis with ulceration.
- Giemsa staining of conjunctival scrapings may show the presence of neutrophils, which is useful in cases where cultures do not conclusively show signs of infection.

DIFFERENTIAL DIAGNOSIS

- Atopic or contact dermatitis
- Psoriasis
- Rosacea (usually accompanied by dilated telangiectasia of the blood vessels in the lid margins, cheeks, nose, and chin)
- Dacryostenosis
- Acute conjunctivitis (bacteria, viral, or allergic)

**TREATMENT****GENERAL MEASURES**

- Eyelid margin cleansing twice daily is considered 1st-line therapy:
 - A warm compress should be placed over closed eyelids for 5–10 minutes to loosen debris.
 - Next, the eyelid margins should be cleansed with a dilute mixture of baby shampoo (brands that do not irritate the eyes) and water.
 - Commercial eyelid cleansers are also available.
 - A cotton swab dipped in the cleansing solution can be used to help release the crust.
- Contact lens use should be avoided until resolution of symptoms.
- Prolonged viewing of television, computer screens, or hand-held games results in decreased blinking and drying of the eye; these should be avoided during symptoms of blepharitis. Excessive use of these should be evaluated in children with recurrent episodes of blepharitis.

MEDICATION (DRUGS)**First Line**

- Lid hygiene with dilute baby shampoo or commercial eyelid cleanser
- Topical antibiotic such as bacitracin or erythromycin applied to eyelids 1 or more times per day or at bedtime for at least 1 week

Second Line

- In cases associated with seborrhea, treatment of the accompanying scalp and eyebrow involvement should be initiated with selenium sulfide shampoo once to twice a week, with manual removal of the crusting in those areas with a fine-toothed comb or soft-bristle brush.
- More resistant cases, blepharitis associated with rosacea, or those that fail to improve may be treated with an oral antibiotic such as erythromycin in younger children or doxycycline in older adolescents for 2–4 weeks.
- Any evidence of involvement of the sclera or conjunctiva especially if herpes is suspected should be referred to an ophthalmologist.

**ONGOING CARE**

- Once symptoms have resolved, there is no need for routine follow-up of blepharitis.
- If symptoms begin to recur, encourage early initiation of eyelid hygiene with the soap-and-water wash.

**CODES****ICD9**

- 041.10 Staphylococcus infection in conditions classified elsewhere and of unspecified site, staphylococcus, unspecified
- 373.00 Blepharitis, unspecified

ICD10

- B95.8 Unspecified staphylococcus as the cause of diseases classified elsewhere
- H01.009 Unspecified blepharitis unspecified eye, unspecified eyelid
- H01.019 Ulcerative blepharitis unspecified eye, unspecified eyelid

FAQ

- Q: Is blepharitis contagious?
- A: Blepharitis is not spread to other family members. However, the bacteria that can cause the infection may be transmitted by hand contact; thus, frequent hand washing is recommended.
- Q: Does blepharitis recur?
- A: Blepharitis may recur. In cases of children with seborrhea and atopic dermatitis, treatment of these conditions may limit the frequency of flare-ups. Early eyelid hygiene may limit the severity of future recurrences.

BONE MARROW AND STEM CELL TRANSPLANT

Valerie I. Brown

BASICS

DESCRIPTION

Reconstitution of damaged, defective, or infiltrated bone marrow with IV infusion of hematopoietic progenitor (stem) cells from:

- The patient (autologous)
- An identical twin (syngeneic)
- A histocompatible donor (allogeneic)

TREATMENT

TREATMENT INDICATIONS

- Accepted indications if a human leukocyte antigen (HLA)-identical related donor is available:
 - Acute lymphoblastic leukemia in 2nd complete remission and in certain very high-risk subtypes
 - Acute myelogenous leukemia in 2nd complete remission and in 1st complete remission in certain high-risk subtypes.
 - Chédiak-Higashi and other severe neutrophil defects
 - Chronic myelogenous leukemia when in the chronic phase and within a year from time of diagnosis.
 - Congenital bone marrow failure syndromes:
 - Diamond-Blackfan anemia
 - Shwachman-Diamond syndrome
 - Fanconi anemia
 - Hemophagocytic lymphohistiocytosis (HLH)
 - Inborn errors of metabolism
 - Juvenile myelomonocytic leukemia
 - Lymphoma in 2nd complete remission
 - Myelodysplastic syndromes
 - Myelofibrosis
 - Osteopetrosis
 - Severe aplastic anemia
 - Sickle cell anemia
 - Systemic lupus erythematosus, especially if unresponsive or intolerant to conventional medical therapy
 - Severe combined immunodeficiency and other congenital immunodeficiencies
 - Thalassemia major
 - Wiskott-Aldrich syndrome
- In certain cases, if an HLA-identical related donor is unavailable, then an HLA-identical unrelated donor is used as an alternative.
- Autologous transplantation is an accepted treatment for lymphoma in 2nd complete remission and for high-risk or stage IV solid tumors in complete remission or very good partial response (neuroblastoma) or in 2nd complete remission (germ cell tumor, Wilms tumor, Ewing sarcoma—experimental).

DONOR SELECTION (IN ORDER OF PREFERENCE)

- Identical twin: The increased risk of relapse of leukemia is offset by decreased treatment-related mortality.
- Human leukocyte antigen-identical sibling:
 - <30% of stem cell transplant candidates have an HLA-identical sibling.
- Other family members:
 - Rarely (i.e., in 5% of families), a nonsibling relative who is phenotypically mismatched for 1 antigen will be found.
- Haploidentical transplantations (2 or 3 human leukocyte antigen-antigen mismatches) have been performed but require depletion of T cells from the graft to avoid fatal graft-versus-host disease.
- Unrelated donors: The National Marrow Donor Program (NMDP) has > 2 million volunteers registered and maintains a cooperative search agreement with European registries. >60% of preliminary searches yield at least 1 potential donor.
- Autologous (either peripheral stem cells or bone marrow)

PRETRANSPLANT REGIMENS (CONDITIONING)

- The purpose of conditioning (either chemoradiotherapy or chemotherapy alone) is 3-fold:
 - To provide immune suppression to avoid destruction of the allograft by residual immunologically active cells in the host
 - To destroy any residual cancer cells and load antigen-presenting cells with tumor antigens
 - To provide space for the new bone marrow to grow
- Agents used primarily for immunosuppression:
 - Cyclophosphamide
 - Fludarabine
 - Antithymocyte globulin
 - Alemtuzumab (Campath)
- Agents used primarily for antineoplastic effects or bone marrow ablation:
 - Busulfan
 - Cytarabine (ARA-C)
 - Etoposide (VP-16)
 - Carmustine (BCNU)
 - Carboplatin
 - Melphalan
- Agents used for both purposes:
 - Total-body irradiation
 - Thiotepa
- Nonmyeloablative (reduced intensity):
 - Uses less cytotoxic preparative regimens
 - Requires profound immunosuppression of host and a generous infusion of hematopoietic stem cells for donor engraftment to occur
 - Can lead to sustainable mixed chimerism but can also result in complete loss of donor over time
 - Being pursued to reduce risk of organ toxicity and therefore can be offered to patients with nonhematologic malignancies or with malignancies that have been heavily pretreated who would ordinarily not meet the criteria for a myeloablative transplant

STEM CELL COLLECTION METHODS

- Conventional bone marrow
- Peripheral blood stem cells collected via apheresis
- Umbilical cord blood

ONGOING CARE

TOXICITIES/COMPLICATIONS

- Chemoradiotherapy:
 - Universal: Nausea/vomiting/diarrhea, alopecia, pancytopenia, mucositis
 - Possible and agent specific:
 - Total-body irradiation: Skin erythema, parotitis
 - Cyclophosphamide: Hemorrhagic cystitis, syndrome of inappropriate secretion of antidiuretic hormone, cardiomyopathy
 - ATG: Allergy, serum sickness
 - Busulfan: Seizures, pulmonary fibrosis, bronzing of the skin
 - ARA-C: Fever, neurologic symptoms, acute respiratory distress syndrome (ARDS)
 - Etoposide/Etopophos: Allergic reactions
 - BCNU: Pulmonary fibrosis
- Graft failure:
 - Usually due to destruction of the graft by the immunologically active cells in the host or insufficient absolute number of donor stem cells infused
 - Predisposing factors:
 - Previous blood transfusions
 - Use of reduced-intensity preparative regimens
 - Use of methotrexate to prevent graft-versus-host disease
 - T-cell depletion of donor cells
 - Can occur early (failure to engraft) or even after successful engraftment
 - Rare in human leukocyte antigen-identical sibling transplantations
 - Risk increases with unrelated donors (6%) or T-cell depletion (14% but depends on the degree of T-cell depletion, and the use of ATG seems to decrease incidence of graft rejection significantly)
 - Usually fatal unless patient receives 2nd transplant emergently
- Graft-versus-host disease: See topic
- Infection:
 - The major cause of nonrelapse mortality
 - Immune dysfunction is caused by a period of severe myelosuppression immediately following stem cell transplant, lack of sustained transfer of clinically significant donor-derived B-cell and T-cell immunity, a recapitulation of normal lymphoid ontogeny, and the effects of graft-versus-host disease and its treatment.
 - In the 1st month posttransplantation, bacterial and fungal infections predominate. Use of prophylactic broad-spectrum antibiotics and antifungal agents during the time of severe myelosuppression has helped considerably.
 - In the 2nd and 3rd months, viral infections predominate, which include cytomegalovirus, adenovirus, herpesvirus (HSV, HHV6), varicella virus, and polyomavirus (BK) as well as *Pneumocystis carinii* pneumonia.
 - After 3 months: Herpes zoster and bacterial infections in patients with chronic graft-versus-host disease

- Acyclovir prophylactically is used in patients who are herpes zoster virus or varicella zoster virus positive. Foscarnet is started prophylactically in cytomegalovirus seropositive recipients receiving a seronegative allograft; use of ganciclovir is avoided for the 1st 100 days posttransplant because of drug-related neutropenia.
 - Note: After T-depleted transplantations, the risk of fatal Epstein-Barr virus infection is increased.
- Hemorrhagic cystitis
 - Occurs weeks to months posttransplant
 - Caused by cyclophosphamide, viruses, and GvHD
 - Therapy: IV hydration, antiviral therapy (cidofovir), urology intervention (bladder irrigation, Alum, Formalin)
- Hepatic veno-occlusive disease (sinusoidal obstruction syndrome):
 - Usually occurs within 3 weeks posttransplant
 - Clinical criteria met when 2 of the following are present:
 - Hepatomegaly and/or right upper quadrant pain
 - Hyperbilirubinemia (>2 mg/dL)
 - 5% weight gain and/or ascites
 - Incidence of 25% (range, 5–60%) and mortality of 38% (range, 3–67%) have been reported.
 - Progressive hepatic failure with multiorgan failure (renal insufficiency/failure, respiratory embarrassment, and/or encephalopathy) often develops in severely affected patients.
 - Therapy is largely supportive. Currently, there is no definitive therapy. Use of defibrotide is experimental.
- Interstitial pneumonitis:
 - Typically appears 40–80 days post–bone marrow transplant as rapid-onset tachypnea, fever, and hypoxia associated with bilateral interstitial infiltrates
 - Mortality rate >60%
 - Common causes include:
 - Cytomegalovirus
 - *Pneumocystis carinii*
 - Idiopathic: When no bacterial, viral, fungal, or protozoan cause is identified. Radiation to the lungs probably plays a role in the development of “idiopathic” pneumonitis.

POTENTIAL LONG-TERM SEQUELAE

- Endocrine:
 - Hypothyroidism: Seen in ~20% of patients after total-body irradiation
 - Growth hormone deficiency: Seen in over 1/2 of patients receiving total-body irradiation
 - Primary gonadal failure and absence of development of secondary sexual characteristics are common, especially if the recipient was prepubertal at the time of transplantation or received total-body irradiation.
 - Metabolic syndrome: incidence of insulin resistance is as high as 50%.

- Infertility: Sterility is expected after total-body irradiation; fertility may be preserved after cyclophosphamide alone; if possible, cryopreservation of sperm or oocytes is strongly encouraged prior to transplantation.
- Ophthalmologic: Cataracts are seen in 40% of patients after total-body irradiation and in 20% after chemotherapy alone. A higher incidence is seen in those who also receive steroids.
- Dental: Poor calcification of teeth and root blunting have been seen. The defects are more severe in children younger than age 7 at transplantation.
- Pulmonary: Bronchiolitis obliterans (BO) or bronchiolitis obliterans organizing pneumonia (BOOP)
- Neuropsychological:
 - Intellectual function: Few prospective studies published
 - Long-term depression and anxiety: Have been reported
- Renal:
 - Radiation nephritis
 - Hemolytic uremic syndrome and thrombocytopenic purpura occur, especially during treatment with cyclosporine.
 - Hypertension: Incidence is twice as high than in general population.
- Secondary malignancies: 15-year cumulative incidence rates are 20% and 6% after regimens with and without total-body irradiation, respectively.
- Recurrent leukemia: Current treatment options include donor leukocyte infusions to induce graft versus leukemia effect, nonmyeloablative (reduced intensity) transplants, or full allogeneic bone marrow transplant.

IMMUNIZATIONS POSTTRANSPLANT

- If patients are free of chronic graft-versus-host disease and off all immunosuppression medications for at least 6 months:
 - At 1 year posttransplant, patients should begin primary immunization schedule with DPaT, iPV, Hib, hepatitis A, hepatitis B, Menactra (if > 11 years old), Pneumovax, and Pevnar.
 - At 2 years posttransplant, patients should receive measles, mumps, rubella, HPV (females 9–26 years old), and varicella vaccines.
- If patients have chronic graft-versus-host disease:
 - Hold immunizations until patient no longer has graft-versus-host disease and has been off immunosuppression for >6 months except for influenza, Pneumovax, and Pevnar vaccines, which should be given 1 year posttransplantation.
- All patients should receive influenza vaccine after 4 months posttransplant and then annually.

FAQ

- Q: When can a patient return to school after transplantation?
- A: Typically, patients receiving autologous transplants and those receiving allogeneic transplants can return to school 6 months and 9 months posttransplantation, respectively, depending on the patient’s immune reconstitution and function and the season; avoid returning to school during flu season; may need to adjust schedule because of fatigue.
- Q: If my patient relapses after bone marrow transplant, can a 2nd bone marrow transplant be done?
- A: Previously, there were few therapeutic options for patients who relapsed <1 year post–bone marrow transplant. Remissions after an infusion of buffy coat (containing T cells) from the patient’s donor, called *donor leukocyte infusion*, have been achieved. Although most successful infusions have been in patients with chronic myelogenous leukemia, success has also been seen in acute leukemia. Chronic graft-versus-host disease will often result.

BOTULISM

Sheila M. Nolan

BASICS

DESCRIPTION

- An illness produced by neurotoxins elaborated by *Clostridium botulinum*, which causes an acute, descending, flaccid paralysis
- The neurotoxin may be ingested or absorbed from infected wounds, or ingested spores germinate, producing toxin.
- There are 3 primary types of illness:
 - In infant botulism, ingested spores germinate and colonize the infant's colon and elaborate toxin.
 - In adults, the patient ingests preformed toxin while eating improperly prepared or stored foodstuffs.
 - In wound botulism, spores germinate in an infected wound and toxin is absorbed.

EPIDEMIOLOGY

- Infants are usually white, breast-fed, and from middle-class families.
- There often is a history of a recent change in feeding practice (addition of formula or solids or changing from breast to bottle feeding).
- Honey seems to be a particularly contaminated food and has been implicated in California. Corn syrup has also been reported to contain botulinum spores but much less frequently than honey and has been associated with significantly fewer cases of infant botulism.
- Breastfed infants get ill at an older age than do bottle-fed infants; all cases of sudden infant death syndrome (SIDS) associated with infant botulism have been in bottle-fed infants.
- Food-borne cases are usually associated with the use of home-processed foods—especially vegetables, fruits, and condiments.

Incidence

- Infant botulism occurs in the 1st year of life, with >95% of cases reported in the 1st 6 months.
- Intestinal botulism is the most common form of human botulism in the US, with >100 cases reported annually.
- Wound botulism is very rare.

Prevalence

- Cases are seen more frequently in rural and suburban areas.
- Most cases have been reported in California, Utah, and Pennsylvania.

RISK FACTORS

Infants who have <1 bowel movement per day may be at increased risk.

GENERAL PREVENTION

- Botulinum toxin is heat labile; 5 minutes of boiling will destroy the toxin.
- Home-canned foods should be boiled for ≥ 10 minutes before serving.
- Spores are more resistant to heat. Home canners must use temperatures well above boiling to destroy spores effectively (120°C for 30 minutes). Pressure cookers are needed to achieve these conditions.

PATHOPHYSIOLOGY

- Neurotoxin is taken up by nerve endings and irreversibly blocks acetylcholine release in peripheral cholinergic synapses.
- Cranial nerves are usually affected first and most severely, leading to difficulty swallowing and loss of airway-protective reflexes. Respiratory failure develops.
- Botulinum toxin does not cross the blood–brain barrier; therefore, the sensorium remains clear.
- Recovery occurs with the regeneration of terminal motor neurons and the formation of new motor end plates.
- Infants are particularly prone to colonic colonization with *C. botulinum*. When foods other than breast milk are introduced in breast-fed infants, changes in flora may be especially important.

ETIOLOGY

C. botulinum, the etiologic agent, is a gram-positive, spore-forming, obligate anaerobic bacteria that is found in soil throughout the world.

DIAGNOSIS

HISTORY

- Usually constipation, with a progressive course of lethargy, weakness, and poor feeding
- Occasionally, progression may be quite rapid, and the abrupt onset of lethargy and weakness may suggest the diagnosis of bacterial sepsis or meningitis.
- Food-borne cases result in complaints of emesis in ~50% of patients.
- There may initially be complaints of diarrhea followed by constipation.
- The incubation period from ingestion to the onset of symptoms is usually 18–36 hours (range, a few hours to several days).
- Patients complain of weakness and dry mouth.
- Visual complaints include blurry vision, loss of accommodation, and diplopia.
- Patients may complain of dysphagia or dysarthria.
- Patients may have urinary retention.
- Fever is absent.
- Within 3 days, there is the onset of the characteristic descending, symmetrical paralysis. The cranial nerves are usually affected 1st.
- Mentation is clear, except for understandable anxiety and agitation.
- Wound botulism:
 - Has an incubation period of 4–14 days
 - Fever may or may not be present.
 - Patients often report constipation, but rarely nausea or vomiting.
 - They may complain of unilateral sensory changes and of purulent discharge from the wound.

PHYSICAL EXAM

- Older children and adults:
 - Often appear alert and are afebrile
 - Ptosis, extraocular palsies, and fixed and dilated pupils are often the 1st signs of descending paralysis.
 - Loss of airway-protective reflexes and respiratory muscle weakness leads to respiratory failure.
 - The triad of bulbar palsies, a lucid sensorium, and the absence of fever should prompt one to consider strongly a diagnosis of botulism.
- Infant botulism:
 - Presents in a similar way
 - Patients are usually afebrile.
 - They are usually weak, with decreased spontaneous activity at presentation.
 - They have an expressionless (masklike) face, ptosis, a weak cry, poor head control, and generalized weakness and hypotonia.
 - Pupils:
 - Often midposition initially and may be at least weakly reactive
 - Pupillary response is fatigable.
 - In many cases, pupils become fixed and dilated for a period.
 - Except for the symmetric, descending paralysis, the remainder of the physical examination is normal.
- Signs of autonomic instability include unexpected fluctuations in skin color, BP, and heart rate.
- Physical examination trick:
 - In infants, early in the course of the disease, pupillary and corneal reflexes may fatigue easily.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Tests for the presence of toxin or the organism can be conducted on patient samples (serum, gastric aspirates, feces, or wound exudate) or suspected foodstuffs.
- Anaerobic cultures of a wound or the GI tract may yield the organism.

Imaging

EEG, MRI, and CT are nonspecific and usually normal in the absence of any complications.

Diagnostic Procedures/Other

Requirements for testing:

- Most tests for toxin and cultures are conducted by state health departments.
- The most common test performed is an assay for botulinum toxin in stool.
- Specimens must be shipped in sealed, break-proof, and leak-proof containers. Even small amounts of toxin, if inhaled or ingested, can lead to disease.
- Suspect foods should be shipped refrigerated and in their original containers if possible.
- Electromyography (EMG) shows a characteristic pattern of brief-duration, sharp-amplitude, overly abundant motor unit action potentials (brief short-acting potentials).

DIFFERENTIAL DIAGNOSIS

- Infections:
 - In noninfants, bacterial sepsis, meningitis, poliomyelitis, tick paralysis, and diphtheric polyneuritis
 - In infants, sepsis and meningitis may present in a similar way.
 - Absence of fever and a clear sensorium make sepsis and meningitis less likely.
- Neurologic:
 - Myasthenia gravis usually spares the pupillary response, whereas it is fatigable in botulism, if not absent.
 - In Werdnig-Hoffman disease (type I spinal muscle atrophy), facial muscles are spared.
- Toxins: Drug ingestions may lead to weakness and lethargy.

TREATMENT

MEDICATION (DRUGS)

- Antibiotics are not helpful in infant botulism:
 - In suspected infant botulism, aminoglycoside antibiotics (e.g., gentamicin) should be avoided, as they may produce an abrupt worsening of the weakness and ensuing respiratory failure.
- Prompt recognition of infant botulism and early treatment with human IV botulism immunoglobulin (BabyBIG®) has been shown to decrease time to recovery and hospital discharge. BabyBIG® is available through the California Department of Public Health’s Infant Botulism Treatment and Prevention Program.
- Equine antitoxin is not recommended for infant botulism.
- Antibiotics are indicated only for documented complications such as pneumonia.
- Cathartics are not beneficial, and enemas may cause colonic distention and increased toxin absorption.
- Cases of botulism resulting from ingested toxin or wound infection:
 - Should be treated with heptavalent botulinum antitoxin (HBAT), available from the CDC
 - Antitoxin should not be administered to asymptomatic individuals who have only eaten suspect foods.
- Wound botulism should be treated with IV penicillin G 250,000 U/kg/d.

ADDITIONAL TREATMENT

General Measures

- All patients with suspected botulism should be admitted to the hospital and have continuous monitoring of their heart rate, respiratory rate, and oxygenation, as well as frequent assessment of their respiratory effort and airway-protective reflexes.
- The mainstay of therapy is meticulous supportive care. Particular attention is paid to respiratory and nutritional needs.
- Endotracheal intubation may be necessary both for patients with frank respiratory failure and when airway-protective reflexes are lost.
- Wounds should be explored and débrided, and anaerobic cultures should be obtained.

- Cases of suspected toxin ingestion should be treated early with induced emesis and/or gastric lavage in an attempt to decrease toxin exposure.
- All cases should be reported to the state health department and the Centers for Disease Control (CDC), Atlanta, Georgia.
- Supportive care should be continued until the patient is able to be weaned from respiratory support and begin PO feedings.

IN-PATIENT CONSIDERATIONS

Initial Stabilization

Good supportive care with emphasis on respiratory support, including intubation and mechanical ventilation when needed, is the most important consideration in emergency therapy.

ONGOING CARE

PROGNOSIS

- Food-borne botulism carries a mortality rate of 20–25%. This rate is lower in patients <20 years old (10%).
- Patients with a shorter incubation period usually have more severe involvement and a worse prognosis, probably related to an increased amount of toxin ingested.
- If recognized early and treated aggressively, botulism carries a good prognosis, and complete recovery can be expected. Fatigability may persist for up to 1 year.
- Infant botulism has an estimated mortality rate of <5% in hospitalized patients. Complete recovery can be expected when disease is recognized early and treated appropriately.

COMPLICATIONS

- The most serious and fatal complication is respiratory failure due to paralysis of the respiratory muscles.
- Bulbar dysfunction in infant botulism may lead to dehydration before presentation.
- The loss of airway-protective reflexes can lead to aspiration and pneumonia.
- Constipation and urinary retention may precede the onset of paralysis and may complicate later management as well. Cases of severe *Clostridium difficile* enterocolitis with hypovolemia, hypotension, and prolonged ICU stays have been reported in infants with botulism.
- The earliest symptoms in adults and older children may be visual changes, including blurred vision, loss of accommodation, and diplopia.
- Syndrome of inappropriate secretion of diuretic hormone and urinary tract infections have been reported in infants with infant botulism.

FAQ

- Q: Can infant botulism recur?
- A: True recurrence in infant botulism has not been documented.
- Q: Should antitoxin be given to persons who have ingested food that they think might be contaminated with botulinum toxin?
- A: Because the antitoxin carries a significant risk of serum sickness, it should be given only to persons with neurologic symptoms.
- Q: Where is antitoxin obtained?
- A: Antitoxin may be obtained from the Centers for Disease Control and Prevention, Atlanta, Georgia; 770-488-7100.
- Q: Where is human IV botulism immunoglobulin obtained?
- A: Human IV botulism immunoglobulin, which is produced from pooled human plasma from screened individuals, may be obtained from the California Department of Health Services Infant Botulism Treatment and Prevention Program; 510-231-7600.

BRAIN ABSCESS

Catherine Zorc
Jeffrey P. Louie (5th edition)

BASICS

DESCRIPTION

- Suppurative infection involving the brain parenchyma
- May be a single or multiple lesion

EPIDEMIOLOGY

- Males are affected more than females (2:1 male-to-female predominance).
- Average age of presentation is ~7 years of age.

Incidence

~1,500–2,500 cases (adults and pediatric combined) occur per year.

Prevalence

2–4% of children with cyanotic congenital heart disease will develop a brain abscess (tetralogy of Fallot being the most common).

RISK FACTORS

- Cyanotic congenital heart disease
- Otorhinolaryngologic infections such as sinusitis, mastoiditis, and chronic otitis media
- Meningitis (especially with neonates)
- Penetrating head trauma
- Surgical manipulation of the brain (ventriculoperitoneal shunts, tumor removal)
- Esophageal manipulation (sclerotherapy or dilation)
- Cystic fibrosis
- Dental infections
- Lung infections
- Any site of infection (osteomyelitis, orbital, cellulitis, urinary tract infections)
- Patients who have traveled to endemic areas with neurocysticercosis (Latin America, parts of Africa, Asia, and the Indian subcontinent).
- Congenital or acquired immunocompromised patients
- No definitive etiology occurs in 30% of patients

GENERAL PREVENTION

- During recreational activities, wearing helmets may prevent penetrating head trauma.
- Preventive medicine: Dentistry and otorhinolaryngology

PATHOPHYSIOLOGY

- Microorganisms enter the brain parenchyma through contiguous or hematogenous (metastasis) pathways.
- Location of brain abscesses:
 - Cyanotic congenital heart disease patients tend to have abscesses within the middle meningeal artery distribution: Frontal, parietal, and temporal lobes.
 - Frontal abscesses are commonly seen with sinus and dental infections.
 - Temporal, parietal, or cerebellar abscesses tend to occur with mastoiditis or otitis media.
 - Brain abscesses can occur anywhere in the brain parenchyma, regardless of a predisposing risk factor, secondary to hematogenous metastasis.

ETIOLOGY

- Bacteria are the most common causes.
- *Streptococcus* sp. and *Staphylococcus* sp. are the most commonly cultured microorganisms.
- Neonates may develop abscesses after a Gram-negative meningitis (*Proteus*, *Citrobacter*, and *Enterobacter*).
- A single organism is found in ~70% of patients.
- Anaerobic organisms are being found with increasing incidence with improved laboratory and culture techniques. Common pathogens are *Bacteroides*, *Peptostreptococcus*, *Fusobacterium*, *Propionibacterium*, *Actinomyces*, *Veillonella*, and *Prevotella*.
- No growth of a pathogen occurs in 30% of specimens.
- Parasitic infections are often caused by *Taenia solium* (neurocysticercosis).
- Fungi and protozoa are commonly found in immunocompromised patients.

DIAGNOSIS

HISTORY

The location of the brain abscess or abscesses will often influence the history of presentation and physical exam.

- Fever, headache, and vomiting each occur in ~60–70% of cases.
- Classic triad of fever, headache, and focal neurologic findings occurs in <30% of cases.
- Headache is the most common complaint.
- Average duration of symptoms prior to diagnosis is ~4 weeks.
- Vomiting and mental-status changes can often be the presenting chief complaints.
- Neonates will often have a history of meningitis before developing a brain abscess.
- Questions should focus on acute or chronic otolaryngologic infections such as sinusitis, chronic otitis media, and mastoiditis, as well as a history of cholesteatomas.
- Cyanotic congenital heart disease should be determined, as well as partially repaired cyanotic congenital heart disease.

PHYSICAL EXAM

- Neonates may present with a full fontanel, increasing head circumference, seizures, or vomiting.
- Older children may have signs of a focal neurologic deficit, hemiparesis, or even papilledema.
- Meningeal symptoms occur in ~30% of patients.
- Ataxia may be found with cerebellar lesions.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Routine lab tests are not helpful and cannot rule out the diagnosis.
- <10% of blood cultures are positive.
- CBC may be mildly elevated, and <10% will show a left shift.
- ESR is a poor indicator of brain abscesses.
- Electrolytes may show low sodium, indicating syndrome of inappropriate secretion of diuretic hormone.

- A lumbar puncture is contraindicated if any intracranial mass lesion is suspected, but if CSF is obtained:
 - It may show a mild-to-moderate pleocytosis (20% of patients may have normal values).
 - Opening pressure is always elevated.
 - Glucose may be decreased in 30% of patients.
 - Protein is elevated in 70% of cases.
 - CSF cultures are often sterile, unless the abscess ruptures into the ventricles.

Imaging

- CT with contrast and MRI scans are the studies of choice in diagnosing brain abscesses.
- Cranial ultrasound may be useful in premature neonatal cases.

ALERT

- Not all patients with brain abscesses have fevers.
- Pitfalls:
 - Failing to consider a brain abscess in a child with altered mental status, fevers, and meningismus
 - Performing a lumbar puncture
 - Failing to use contrast with the CT scan

DIFFERENTIAL DIAGNOSIS

- **Infectious**
 - Meningitis
 - Encephalitis
 - Subdural empyema
 - Epidural abscess
- **Vascular**
 - Venous sinus thrombosis
 - Migraine
 - Cerebral infarct
 - Cerebral hemorrhage
- **Miscellaneous**
 - Primary or secondary tumor
 - Pseudotumor cerebri
 - Hydrocephalus

TREATMENT

MEDICATION (DRUGS)

- Broad-spectrum antibiotics should be started at the time of diagnosis, until identification of the microorganism is determined. At that time, the antibiotics can be tailored to the offending microorganism.
- Most brain abscesses are removed surgically. A few may require CT-guided aspiration.
- MRI or CT-guided stereotactic aspiration is encouraged.

- When multiple abscesses are found on CT scan, 1 lesion should be aspirated to identify the microorganism.
- Some patients are managed successfully with antibiotics alone, which may be appropriate in carefully selected patients, especially if there is a single abscess <2 cm. Antiparasitic medications are controversial in the treatment of neurocysticercosis.
- Antifungals should be considered for immunocompromised patients.
- The use of steroids is controversial.
- Antiepileptic therapy may be indicated, but there are no studies that guide use in patients with brain abscess.
- If a patient is manifesting signs and symptoms of increased intracranial pressure (Cushing triad: Bradycardia, hypertension, and abnormal respirations) or if the patient is comatose and is unable to protect his or her airway, the patient should be intubated, hyperventilated, and given mannitol.
- Patients with unknown predisposing factors should be evaluated by cardiology, dental, and otorhinolaryngology. Immunology should be considered in children with significant medical histories of chronic infections.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- A high index of suspicion is required to diagnose a brain abscess. A delay in diagnosis or performing a lumbar puncture for suspected meningitis increases mortality and morbidity.
- With the advent of CT and MRI scans, the mortality rate has dropped from ~30% to <14%.
- Multiple abscesses, coma on presentation, <2 years of age, performance of a lumbar puncture, and rupture of abscess into the ventricle carry a higher mortality rate. 30–40% of patients have some morbidity. This ranges from seizures, hemiparesis, focal neurologic deficits, or hydrocephalus to cognitive/behavioral problems.

PATIENT MONITORING

- Neonates and older patients may be discharged with home physical therapy and home nursing for IV antibiotics.
- Patients will need IV antibiotics for a total of 3–4 weeks. Some may require longer courses of antibiotics.
- Some children will need follow-up CT or MRI scans.
- Follow-up with neurosurgical, rehabilitation, and neurology clinics is usually required.

COMPLICATIONS

- Arise from the location, size, and number of intracranial abscesses
- Can vary from syndrome of inappropriate secretion of diuretic hormone or seizures to focal neurologic deficits

FAQ

- Q: Do all brain abscesses require surgery?
- A: No. Select cases will regress with antibiotics and follow-up with MRI.
- Q: What is the best way to diagnose brain abscess?
- A: MRI

BRAIN INJURY, TRAUMATIC

Jerry Larrabee

Karen LeComte (5th edition)

BASICS

DESCRIPTION

Traumatic brain injury (TBI): Damage to the brain from accidental or nonaccidental trauma:

- Children >1 year: GCS <14, amnesia >15 minutes for event, penetrating head injury
- Children <1 year: Any LOC, protracted emesis, suspected abuse
- Severe brain injury: Usually initial GCS <9

EPIDEMIOLOGY

- Trauma, number 1 cause of death of children >1 year. Head injury most common contributor to morbidity and mortality.
- Between 29,000 and 50,000 children in the US <19 suffer permanent disability from TBI each year.
- Age-dependent mechanism of injury and pathophysiology
- <2 years old: Nonaccidental trauma is principle cause of TBI.
- >2 years old: Falls (~37%) are most common cause of trauma.
- For severe TBI, nonaccidental trauma remains principal cause in young children.
- Motor vehicle accidents in older children, although penetrating injuries becoming more common

PATHOPHYSIOLOGY

- Primary:
 - Focally applied forces: Lacerations, penetration injuries, skull fractures
 - Contusions, intracerebral hematomas uncommon. Epidurals, classic subdurals <10% in children
 - Acceleration-deceleration/shearing forces: Cervical spine injuries, diffuse axonal injury (DAI), non-aneurysmal subarachnoid hemorrhage, subdural hematoma (SDH) from shear forces
- Secondary:
 - Extension of injury to viable tissue/entire brain
 - Dysautoregulation of cerebral blood flow, neuroexcitotoxicity and inflammatory mediators. CT or MRI signs of edema may progress over 3–5 days (see “Treatment”).
- Age-specific pathophysiology
 - Infants/toddler:
 - Shear forces on the brain due to acceleration/deceleration avulse axons from their cell bodies (DAI); often compounded by tearing and bleeding of dural veins.
 - Unmyelinated infant brain absorbs rather than transfers impact. Immature, distensible skull renders brain less likely to contuse or herniated, but more likely to sustain diffuse secondary injuries, with swelling.
 - Subgaleal hematoma, cephalohematoma (below the periosteum), and caput succedaneum (confined to the superficial scalp) at birth do not predict brain injury.

- More severe birth trauma can result in SDH.
- Bilateral interhemispheric SDH suggests nonaccidental trauma.
- Diffuse injuries secondary to shaken impact syndrome can lead to cerebral swelling with secondary infarction and/or decreased central respiratory control, leading to apnea, hypoxia, and cerebral edema.
- Children <3 at risk of growing skull fracture when leptomeningeal cyst protrudes through a dural tear (late effect).
- Suspect nonaccidental trauma with growing skull fracture, if >1 cranial bone involved, or if other injuries are present.
- Older children/adolescents:
 - Still more subject to DAI than adults due to incomplete myelination
 - Projectile injuries in adolescent population
 - Can result from nonaccidental trauma (usually with other stigmata of assault)

DIAGNOSIS

HISTORY

- Eyewitness accounts are invaluable.
- Details of who was caring for the child
- Falls: Did loss of consciousness precede fall? Height of fall, surface of impact
- History of epilepsy, cardiac problems
- History of previous concussions (consider “second impact syndrome”) or trauma
- Intoxication (of child, caregiver, others in the environment)
- Prior physical abuse/neglect?
- Restrained motor vehicle passenger? Angle of impact
- How did patient act or change over time? Unresponsive? Confused? Headache? Visual changes? Vomiting? Seizure?

PHYSICAL EXAM

Rapid neurologic exam in trauma:

- Can derive some of these by observation. Note presence of neuromuscular blockers/sedation
 - Level of arousal: Awake, lethargic, stuporous, unresponsive
 - Resting posture: Spontaneous, restless, still normal, flexor, extensor
 - Respiration: In context of arousal and posture, hyperpnea or Cheyne-Stokes respiration
 - Response to stimulation: Voice, pain (of earlobe to avoid spinal withdrawal response); note localization, withdrawal, posturing
 - Pupils: Equal, anisocoria >1 mm, unequal/sluggish pupil, unequal/wide/fixed pupil
 - Extraocular movements: Disconjugate gaze nonlocalizing with drugs/trauma, 3rd nerve palsy uncal herniation sign, 4th nerve palsy common in head injuries, 6th nerve palsy from trauma or increased ICP

- Brainstem reflexes: Corneals (V & VII), oculocephalic if patient unable to cooperate with eye exam and cervical spine cleared. Avoid gag—raises ICP
- Muscle reflexes/motor exam: Lateralizing signs may indicate contralateral hemispheric lesion, with ipsilateral dilated pupil may indicate uncal herniation
- Sensory: Brief for 4 limbs/spinal level if indicated
- This exam should be repeated often according to the patient’s level of acuity. A more detailed exam tailored to degree of arousal can be done as the patient is stabilized.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

In all patients with suspected TBI, consider:

- CBC (infants can have a large amount of intracranial blood loss)
- PT/PTT (to evaluate a possible bleeding disorder as a possible preoperative laboratory test)
- Electrolytes
- Toxin screen

Imaging

- Unenhanced CT scan of the brain is the imaging study of choice for initial evaluation of a patient with suspected TBI.
- Abnormal CT: Lesion density, midline shift, compression of cisterns, bone fragments
- MRI: Useful for DAI (with a negative head CT) as well as showing small lesions (e.g., punctate contusions)
- In suspected cervical spine injury where patient is unresponsive, MRI of the spine to rule out noncontiguous unstable ligamentous injury
- Long-bone films if degree of injury is not consistent with history or history of fall from unclear height
- With CT scan showing normal brain/ventricular spaces: Consider EEG and lumbar puncture if a nontraumatic etiology for altered mental status is suspected.

DIFFERENTIAL DIAGNOSIS

Neurologic presentation varies in severity from a normal examination through coma similar to hypoxic-ischemic brain injuries (e.g., near-drowning), other causes of stupor/coma, seizure activity (postictal encephalopathy).

- Distinction between simple concussion, DAI, and hypoxic-ischemic injury may be difficult at initial presentation, becoming clear as clinical picture/neuroimaging evolves.

TREATMENT

- Airway, breathing, circulation
- Prehospital stabilization: Avoid hypoxemia and hypotension (strong, possibly modifiable, independent predictors of outcome in TBI)

ADDITIONAL TREATMENT

General Measures

- Maintenance of CPP >50 positively influences outcome in TBI (MAP – ICP = CPP), especially in first 48 hours.
- A rapid neurologic exam repeated over time is instrumental in directing the patient's care.
- Secondary survey: External evidence of head injury/deformities, ecchymoses (periorbital-orbital roof fracture; mastoid-petrous temporal fracture), lacerations, penetrations. CSF leak nasal/otic.
- Seizures: Ativan 0.1–0.2 mg/kg IV at 2 mg/min or rectal Diastat 0.3–0.5 mg/kg if no IV access. Then load fosphenytoin 15–20 mg/kg IV. Important to treat to avoid increased ICP, neurotoxicity, hypoxia.
- No evidence that seizure prophylaxis > 1 week post-trauma prevents late seizures
- No evidence that steroids improve outcome
- Hypothermia may be protective, no difference in long-term outcome.
- No evidence for prophylactic use of mannitol, though it is effective for control of increased ICP. Bolus doses 0.25 g/kg of body weight to 1 g/kg of body weight to goal ICP <20 mm Hg
- Hypertonic saline for increased ICP as above under fluid resuscitation
- The postresuscitation GCS score should be recorded in all trauma patients.
- Involvement of neurosurgery with moderate GCS <13 injury, even if patient initially stable
- Survival for children with severe TBI is greater when treated in pediatric ICU.
- Decompressive craniectomy may be considered given the following conditions:
 - Diffuse cerebral swelling on cranial CT imaging
 - Within 48 hours of injury
 - No episodes of sustained ICP >40 mm Hg before surgery
 - GCS >3 at some point subsequent to injury
 - Secondary clinical deterioration
 - Evolving cerebral herniation syndrome
- AAP guidelines set conditions for return to play depending on severity of concussion:
 - Grade I—mild; no LOC, amnesia, or confusion; return to play after 20 minutes
 - Grade II—moderate; no LOC, some confusion and amnesia > 15 minutes; return to play after 1 week
 - Grade III—severe; LOC; return to play after 1 month; assume cervical spine injury/stabilize no return to play unless symptoms resolved, including exertional symptoms
 - An AAP concussion statement outlines graded return activities barring symptoms and suggests (a) no same-day return; (b) and consider removal from season play for 3 concussions in one season or postconcussive symptoms >3 months

IN-PATIENT CONSIDERATIONS

Initial Stabilization

- Cervical spine stabilization and clearance; in severe TBI, entire spine is stabilized:
 - If necessary, orotracheal intubation with rapid sequence induction; avoid hypotension
 - Hyperventilation may induce regional cerebral ischemia in children, especially in first 24 hours.
 - Increased ICP managed by bed elevation of 30 degrees, hypertonic fluids, sedation
- Hemodynamic stabilization (normal high systolic BP ~135) predictor of better outcome in TBI (Median systolic BP = 90 mm Hg + [2 × age in years])
 - Hemodynamic instability indicative of systemic hemorrhage (abdomen, long-bone fractures). Pericardial tamponade (narrow pulse pressure). Neurogenic shock.
 - Hypotension late sign. Early: ↑HR, ↓capillary refill, ↓urine output
 - Fluid resuscitation: Consider hypertonic saline. Mounting evidence of improved outcomes especially with hemorrhagic shock and TBI (titrate continuous 3% saline infusion 0.1–1 mL/kg/h).
 - Fluid bolus may worsen intracranial hypertension (ICP).
 - Consider monitoring ICP to maintain <20 mm Hg for abnormal admission CT scan, and GCS 3–8 after CPR, or normal CT and GCS 3–8, and posturing, or hypotension, or if serial neurologic exams precluded by sedation.

ONGOING CARE

PROGNOSIS

- Presence of both hypoxemia and hypotension on arrival to ER bode poorly.
- 24-hour GCS better predictor of outcome than postresuscitation; PRISM score also helpful
- GCS <3 poor prognosis unless secondary to epidural hematoma; rapid evacuation can minimize permanent deficits
- Diffuse white matter, subcortical gray or brainstem lesions on MRI portend long periods of coma and poorer outcome
- Somatosensory evoked potentials (VEPs or BAEPs) are less sensitive but have high specificity in predicting neurologic outcome.
- Degree of injury on head CT can be predictive.
- Patients who have sustained moderate-to-severe head injury (GCS = 13) often have academic difficulties, memory abnormalities, and disinhibition.
- Monitoring for cognitive difficulties, hyperactivity, seizures, hydrocephalus, movement disorders, paralysis, visual/hearing disturbance, headache; psychologists, neurologists, neurosurgeons, ophthalmologists, audiologists, and physical therapists may be helpful.
- Leptomenigeal cyst (especially in children <3 years old) almost always develops within 6 months of injury.
- Refer any patient with known skull fracture who manifests a new swelling in area of old fracture to neurosurgery for 3D CT imaging of the head.
- ~10% of patients with severe head injury will develop epilepsy.

BRAIN TUMOR

Michael J. Fisher

BASICS

DESCRIPTION

A primary neoplasm arising in the CNS

EPIDEMIOLOGY

Incidence

- Most common solid neoplasm of childhood (2nd to leukemia in overall incidence)
- Incidence rising (> 3,000 new cases/year)
- 4.5 cases/100,000 children/year
- Peak incidence in children ≤ 7 years of age

Prevalence

- Slight male predominance
- Majority arise infratentorially (within cerebellum or brainstem) in children 1–11 years of age
- Majority arise supratentorially in children < 1 year of age

RISK FACTORS

Genetics

- Not a heritable condition
- Primary CNS tumors are associated with several familial syndromes:
 - Neurofibromatosis with optic pathway gliomas (NF1) and meningiomas (NF2)
 - Tuberous sclerosis with gliomas and rarely ependymomas
 - Li–Fraumeni syndrome with astrocytomas
 - Von Hippel–Lindau with cerebellar hemangioblastoma
 - Turcot syndrome with primitive neuroectodermal tumor

PATHOPHYSIOLOGY

The majority of tumors are classified based on their histology. The most common are:

- Glioma:
 - Arises from astrocytes (supportive tissue)
 - > 50% of childhood CNS tumors
 - Ranges from low grade (often in the cerebellum or optic pathway) to high grade (grade III to IV; in the cerebrum or brainstem)
 - Locally recurrent and invasive when high grade
- Primitive neuroectodermal tumor/medulloblastoma:
 - Malignant embryonal tumor arising from unknown cell type
 - Comprises ~20% of childhood CNS tumors
 - Most common malignant brain tumor in children
 - Majority arise in the midline of the cerebellum (referred to as medulloblastoma)
 - Predisposition for leptomeningeal dissemination
- Ependymoma:
 - Arises from ependymal cells that line the ventricular system
 - 8–10% of childhood CNS tumors
 - Most commonly occurs in the 4th ventricle; may arise in the spinal cord
 - Locally recurrent and invasive; spinal metastases rare at initial diagnosis

- Germ cell tumor:
 - Derived from totipotent germ cells
 - 3–5% of childhood CNS tumors
 - Majority are located in the pineal or suprasellar region
- Atypical teratoid/rhabdoid tumor:
 - Rare embryonal tumor arising from unknown cell type; often misdiagnosed as primitive neuroectodermal tumor
 - < 3% of childhood CNS tumors
 - Majority arise in children < 5 years of age
 - Propensity to arise in the posterior fossa with frequent leptomeningeal dissemination; reported in association with malignant rhabdoid tumors of the kidney
- Craniopharyngioma: 6–9% of childhood CNS tumors
- Tumors of the choroid plexus
- Ganglioglioma
- Meningioma and hemangioblastoma, rare in children

ETIOLOGY

- No specific causative agents are known, but there is an association with radiation, chemical exposure, other malignancies, familial/heritable diseases, immunosuppression (lymphoma)
- Molecular markers and variants of individual tumor types are being identified.

DIAGNOSIS

Tumor location dictates symptoms and signs.

HISTORY

- Headache and vomiting (particularly in the morning), irritability, and lethargy are associated with increased intracranial pressure.
- Difficulty swallowing, slurred speech, and diplopia may indicate brainstem tumor.
- Visual-field deficits (bumps into things) could indicate optic tract lesion.
- Focal weakness hints at pyramidal tract lesion.
- Ataxia may be a sign of cerebellar lesion.
- Changes in behavior or school performance, new-onset seizures, and weakness could be signs of supratentorial lesion.
- Polyuria/polydipsia may indicate hypothalamic/pituitary lesion.
- Failure to thrive, emaciation, euphoria, and increased appetite in an infant may indicate hypothalamic lesion (diencephalic syndrome).
- Back pain, extremity weakness, and bowel/bladder dysfunction could signify spinal cord metastases (often seen with primitive neuroectodermal tumor/medulloblastoma and germ cell tumors).

PHYSICAL EXAM

- Papilledema, impaired upgaze and/or lateral gaze, macrocephaly (infants), and bulging fontanelle are signs of increased intracranial pressure.
- Focal deficit on neurologic exam helps localize the mass lesion:
 - Isolated cranial nerve VI and VII palsies may indicate brainstem tumor.
 - Ataxia and dysmetria could indicate cerebellar mass.
 - Decreased visual acuity, visual-field deficit, absent pupillary light response, and strabismus may all be signs of optic tract tumor.
 - Changes in cognitive function, mood, and affect could indicate supratentorial lesion.
 - Impaired upgaze, convergence nystagmus, and pupils respond to accommodation but poorly to light are signs of pineal lesion (Parinaud syndrome).
- Signs of neurocutaneous disease (e.g., café-au-lait spots, Lisch nodules) may indicate a syndrome such as neurofibromatosis type 1.

DIAGNOSTIC TESTS & INTERPRETATION

Imaging

- MRI with and without gadolinium enhancement is the “gold standard” for identification, localization, and characterization of tumors.
- CT can be used as an initial study, but if negative and a high index of suspicion, follow with MRI. Useful to evaluate for hydrocephalus and hemorrhage.

Diagnostic Procedures/Other

Staging of tumor:

- Postoperative head MRI within 24–48 hours to determine residual disease before postoperative inflammatory changes are prominent
- Spine MRI and CSF cytology required for neuraxis staging of tumors with high risk of leptomeningeal dissemination
- Elevated α -fetoprotein and quantitative β -human chorionic gonadotropin in CSF and serum are markers for germ cell tumors.

DIFFERENTIAL DIAGNOSIS

- Infection: Cerebral abscess
- Tumors: Metastatic tumor to brain, uncommon with childhood solid tumors
- Trauma: Hemorrhage unlikely to be confused with tumor
- Congenital:
 - Arteriovenous malformation
 - Hamartoma
 - Dysplastic brain

- Psychosocial: Some patients with nausea, vomiting, or behavior changes are first diagnosed with psychiatric disorders, GI disorders, failure to thrive, or anorexia nervosa prior to discovery of a brain tumor.

ALERT

New onset of psychoses should prompt imaging to rule out tumor.

**TREATMENT****SURGERY/OTHER PROCEDURES**

- Both for histology and to attempt maximal tumor debulking; should be performed by experienced pediatric neurosurgeon
- Rarely indicated in intrinsic pontine (brainstem) glioma
- Ventriculoperitoneal shunt when needed for obstructive hydrocephalus (risk of peritoneal seeding minimal)

ALERT

Patient should be referred to a pediatric brain tumor/oncology center at diagnosis (preoperatively).

Radiotherapy

- Volume and dose vary depending on histology.
- Radiation therapy to the tumor bed is used for most patients with brain tumors.
- Medulloblastoma/primitive neuroectodermal tumor patients need craniospinal radiation therapy. The one exception is infants and young children (<3 years of age), in whom cognitive deficits from radiation therapy can be devastating.
- Duration of radiation therapy: Usually 6 weeks
- Newer approaches to limit exposure of normal brain include intensity modulated and proton radiotherapy.

MEDICATION (DRUGS)

- Dexamethasone to control increased intracranial pressure (0.5 mg/kg divided q6h)
- Chemotherapy:
 - Drugs are most often used in combination:
 - Carboplatin, vincristine, or 6-thioguanine, procarbazine, CCNU, vincristine for low-grade glioma
 - Cisplatin, CCNU, vincristine, etoposide, and cyclophosphamide are active agents for primitive neuroectodermal tumor/medulloblastoma.
 - Temozolomide for high-grade glioma
 - New protocols currently being evaluated:
 - High-dose chemotherapy with stem cell rescue for high-risk primitive neuroectodermal tumor/medulloblastoma
 - Targeted therapies, angiogenesis inhibitors
 - Duration of chemotherapy: 6 months to 2 years

ALERT

Possible conflict with other treatments: Chemotherapy can alter anticonvulsant levels.

**ONGOING CARE**

- Neurologic deficits can take months to improve or stabilize with permanent deficit.
- Any worsening or relapse of symptoms must be evaluated for tumor recurrence.
- MRI every 3 months the 1st year, every 6 months for the next 2 years, and annually thereafter. Benefit of routine surveillance imaging is controversial.

PROGNOSIS

- Dependent on histology of tumor, location, and extent of initial resection
- Glioma:
 - Low grade: ≥90% 5-year progression-free survival (PFS) following gross total resection; 45–65% for subtotal resection
 - High grade: Median survival 8–31 months; depends on grade and extent of resection
 - Intrinsic pontine: Median overall survival of 9–13 months from diagnosis
- Medulloblastoma:
 - 79–83% PFS at 5 years if localized, gross total resection achieved, and >3 years old at diagnosis
 - <50% PFS if disseminated
- Ependymoma:
 - 50–83% survival at 5 years with total resection
 - <30% survival with subtotal resection
- Infants overall have a worse prognosis, possibly due to the limitations of therapy and/or the aggressiveness of the tumor.

ALERT

Even benign tumors may be life-threatening if their location precludes resection.

COMPLICATIONS

- Secondary to disease:
 - Increased intracranial pressure:
 - Obstruction of CSF flow
 - Requires immediate neurosurgical evaluation
- Secondary to radiotherapy:
 - Neurocognitive sequelae (age and dose related)
 - Endocrinopathy (growth hormone deficiency, hypothyroidism, gonadal dysfunction)
 - Risk of second malignancies (meningioma, glioma, sarcoma)
- Secondary to chemotherapy:
 - Risks associated with bone marrow suppression (infection, bleeding, anemia)
 - Hearing loss
 - Risk of secondary leukemia

**CODES****ICD9**

- 191.9 Malignant neoplasm of brain, unspecified
- 225.9 Benign neoplasm of nervous system, part unspecified
- 239.6 Neoplasm of unspecified nature of brain

ICD10

- C71.9 Malignant neoplasm of brain, unspecified
- D33.9 Benign neoplasm of central nervous system, unspecified
- D43.9 Neoplasm of uncertain behavior of CNS, unsp

FAQ

- Q: Are my other children at risk for getting a brain tumor?
- A: No (except in rare cases of certain familial syndromes).
- Q: Did something I do cause this?
- A: No. In addition, the claims made about high-power lines and cellular phones causing brain tumors or cancer are unproven.

BRANCHIAL CLEFT MALFORMATIONS

Anita Bhandari
Raezelle Zinman

BASICS

DESCRIPTION

- The fetal branchial apparatus is a foregut derivative and develops in the 2nd fetal week.
- 5 paired pharyngeal arches are separated by 4 endodermal pouches internally and 4 ectodermal clefts externally.
- Overgrowth of the 2nd through 4th cleft creates the cervical sinus and occurs during weeks 4 and 5.
- Persistence of the cervical sinus produces a spectrum of cysts, sinus tracts, and fistulas.
- **Classification:**
 - 1st branchial cleft anomalies:
 - Site: anywhere from external auditory canal to angle of mandible, usually superior to or within parotid
 - Fistula tract: External auditory canal
 - 2nd branchial cleft anomalies
 - Site: Ventral to anterior border of sternocleidomastoid muscle, lateral to carotid sheath, and dorsal to submandibular gland
 - Fistula tract: Palatine tonsil
 - 3rd branchial cleft anomalies:
 - Site: Posterior triangle in middle to lower left side of the neck near level of upper thyroid lobe
 - Fistula: Upper lateral piriform sinus wall to lower lateral neck posterior to sternocleidomastoid muscle
 - 4th branchial cleft anomalies:
 - Site: Close association to thyroid gland associated with clinical thyroiditis if cyst infected
 - Fistula: Apex of piriform sinus to base of neck anterior to sternocleidomastoid muscle

EPIDEMIOLOGY

- Overwhelming majority of cysts in newborns and infants are developmental, whereas in children and adults they are inflammatory or neoplastic.
- Midline malformations are most often thyroglossal duct cysts or dermoids.
- Cysts occurring in the laterocervical region are usually branchial cleft malformations, the most common of these are derivatives of the 2nd cleft, followed by those of the 1st cleft, of the 4th pouch and thymic cysts.
- 3rd and 4th branchial cleft anomalies are rare, with most presenting as sinus tracts rather than cysts.
- Suspect congenital anomaly in the clinical setting of recurrent infection.

RISK FACTORS

Genetics

Familial history of branchial defects occasionally noted

DIAGNOSIS

HISTORY

- Present since birth
- Recurrent neck infections
- Intermittent discharge from neck
- Fever
- Tenderness

PHYSICAL EXAM

- Mass usually mobile
- Usually a single lesion
- Nonpulsatile
- Lesion usually nontender (unless actively infected)
- Assess for sites of drainage:
 - At the anterior or posterior border of the sternocleidomastoid muscle
 - In the posterior pharynx at the tonsillar fossa or piriform sinus

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC with differential: Increased WBC with left shift seen with infection
- Tuberculin test to rule out tuberculosis
- Microbiology: oral cavity flora in neck abscess suspicious for branchial pouch anomaly

Imaging

- Chest radiography to assess for hilar adenopathy, suggesting a systemic process (such as tuberculosis or malignancy)
- Lateral neck radiography to assess for airway compromise (not usually seen)
- Ultrasound to help differentiate solid masses from cystic masses
- Fistulogram to inject contrast into the fistula to delineate its course
- CT scan of neck for superior spatial delineation and definition of anatomic compartment of the lesion
- MRI for more detailed soft tissue characterization and recognition of solid components within cystic masses

DIFFERENTIAL DIAGNOSIS

- Congenital:
 - Anterior triangle of neck:
 - Thymic cyst
 - Midline and anterior triangle of neck:
 - Ranula
 - Laryngocele
 - Sialocele
 - Thyroglossal cyst
 - Dermoid/teratomatous cyst:
 - Bronchogenic cyst
 - Posterior triangle of neck:
 - Lymphangioma
 - Hemangioma

- Inflammatory:
 - Adenitis
 - Granulomatous disease (sarcoidosis, tuberculosis)
 - Lymphoepithelial cysts (HIV)
 - Otorrhea
 - Parotiditis
 - Retropharyngeal abscess
 - Thyroiditis
- Tumors:
 - Lymphoma
 - Rhabdomyosarcoma
 - Cystic schwannoma (anterior triangle of neck)
 - Pilomatrixoma

TREATMENT

MEDICATION (DRUGS)

Antibiotics are indicated if the lesion is infected.

SURGERY/OTHER PROCEDURES

- Excision of the entire lesion is the standard approach.
- Novel endoscopic and marsupialization approaches have recently been reported.
- Surgery should be delayed if infection present.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Postoperative follow-up as outpatient for wound inspection
- Observation for recurrence or reinfection

ALERT

- Lesion may recur if not completely excised.
- High incidence of reinfection if not properly treated.

PROGNOSIS

If lesion completely excised: Excellent. Many patients require multiple procedures.

COMPLICATIONS

- Cysts, sinus tracts, and fistulae can become recurrently infected (especially with abscess formation).
- Surgery is more difficult if there have been previous infections or previous surgery.
- Damage to facial, hypoglossal, and glossopharyngeal nerves or carotid artery can occur during surgical repair.
- Recurrence of the lesion seen if not fully removed.
- Thyroiditis
- Parotiditis (more common in first branchial arch malformation)

CODES

ICD9

744.41 Branchial cleft sinus or fistula

ICD10

- Q18.0 Sinus, fistula and cyst of branchial cleft
- Q18.2 Other branchial cleft malformations

FAQ

- Q: Can the cyst, fistula, or sinus recur?
- A: Only a 3% recurrence rate is seen if the lesion is completely excised. A higher rate of recurrence is seen in cases of incomplete excision or with previous surgeries.
- Q: Should the lesion be removed as soon as it is discovered?
- A: The lesion should not be removed if there is an active infection present; treat the infection first and then schedule elective surgery.

BREAST ABSCESS

Charles A. Pohl

BASICS

DESCRIPTION

- Breast abscess: Infection of the breast bud or tissue associated with localized pus and inflammation
- Mastitis: Infection of the breast tissue observed primarily during lactation

EPIDEMIOLOGY

Incidence

5–11% of women with breastfeeding mastitis develop a breast abscess.

Prevalence

- Affects primarily infants (peak age 1–6 weeks) and adolescents
- Bilateral abscesses, seen among neonates, are rare.
- Male-to-female ratio is 1:2 in neonates.

RISK FACTORS

- In lactating teens, primiparity
- Gestational age >40 weeks
- Mastitis

GENERAL PREVENTION

- Avoid breast manipulation (including piercing).
- In lactating teens, establish good breastfeeding techniques.
- Recognize and treat mastitis early.

PATHOPHYSIOLOGY

- Newborns:
 - Trauma, breast hypertrophy from maternal estrogen, or compromised host defenses enable spread of bacteria that are often colonized in the nasopharynx and umbilicus.
 - The bacteria and/or its toxin, in turn, cause(s) subcutaneous destruction and loculated pus formation.
- Adolescents/adults: Trauma (e.g., sexual manipulation, nipple rings, tight-fitting bras, incorrect latching during breastfeeding), contiguous spread of a local infection (e.g., mastitis, acne), or underlying structural abnormalities (e.g., mammary duct ectasia, epidermal cysts) cause breast tissue edema and destruction by bacteria and/or its toxin.
- When mastitis is associated with breastfeeding, the inflammation inhibits milk release. The stasis of milk, in turn, may allow for bacterial proliferation.

ETIOLOGY

- Newborn infection: *Staphylococcus aureus* (most common), group A or B streptococcus, and Gram-negative enteric bacteria, including *Escherichia coli*, *Pseudomonas aeruginosa*, *Proteus mirabilis*, salmonella species
- Adolescent/adult infection: *S. aureus* (most common) with up to 19% being methicillin-resistant; *E. coli*, *P. aeruginosa*, *Mycobacterium tuberculosis*, *Neisseria gonorrhoeae*, and *Treponema pallidum* are infrequent pathogens.

DIAGNOSIS

HISTORY

- Ask about history of breast trauma or manipulation, concomitant illness or infections, and patient's immunologic status.
- Constitutional symptoms including irritability and lethargy usually are absent unless the infection involves deeper tissue or the bloodstream (1/3 of cases).
- Low-grade fever
- Salmonella infections generally present with GI symptoms.

PHYSICAL EXAM

- Firm, tender breast mass with overlying erythema and warmth. Fluctuant mass may be present.
- Regional adenopathy
- Purulent nipple discharge (rare)
- Necrotizing fasciitis is distinguished from breast abscess by pain out of proportion to the cutaneous signs, crepitus, or presence of straw-colored bullae.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Gram stain and culture of nipple discharge, needle aspirate, and/or surgical incision and drainage help(s) guide therapeutic decisions if a fluctuant mass or discharge is present.
- Blood culture:
 - Useful in neonates
 - Consider full sepsis work-up if patient is febrile and toxic-appearing.
- CBC: Leukocytosis (>15,000 cells/mm³) is present in 1/2–2/3 of patients.
- Surveillance cultures of nasopharynx and umbilicus should be considered in neonates to rule out colonization with *S. aureus*.

Imaging

Ultrasound may be useful if fluctuant mass is suspected or if poor response to antimicrobial therapy.

Diagnostic Procedures/Other

If fluctuant, needle biopsy may be diagnostic and therapeutic.

DIFFERENTIAL DIAGNOSIS

- Physiologic conditions:
 - Breast engorgement (usually bilateral; absence of fever and erythema)
 - Mastodynia (painful breast engorgement; associated with ovulatory cycles; cyclic pattern)
- Infectious: Cellulitis including mastitis (absence of a loculated breast mass)
- Tumors (rare):
 - Fibroadenomas
 - Rhabdomyosarcoma
 - Non-Hodgkin lymphoma
 - Fibrocystic disease
 - Intraductal papilloma
 - Cystosarcoma phyllodes
 - Hemangioma
- Trauma:
 - Contusion (firm, tender, poorly defined mass)
 - Hematoma (sharply defined mass with ecchymosis)
 - Fat necrosis (firm, nontender, circumscribed, mobile mass)
- Miscellaneous: Mondor disease (thrombophlebitis of the subcutaneous veins in the breast)
 - Typically seen in adults
 - Presents with tenderness and pain
 - Associated with trauma
 - Spontaneously resolves
- Vascular malformation

ALERT

- Neonatal infections require prompt recognition, intervention, and identification of other involved sites to avoid widespread infection and poor outcome.
- Unrecognized fluctuant mass and its subsequent drainage will delay therapeutic response.
- Incidence of community-acquired methicillin-resistant *Staphylococcus aureus* (CA-MRSA) is increasing in many regions of the country.

TREATMENT

MEDICATION (DRUGS)

- Neonatal infection:
 - Parenteral β -lactamase-resistant antistaphylococcal antibiotics (e.g., Nafcillin 100 mg/kg/24 h) or ceftriaxone 50–75 mg/kg/24 h)
 - Aminoglycosides (e.g., gentamicin 2.5 mg/kg/dose q8–12h) should be included if the infant appears ill or if the Gram stain reveals Gram-negative bacilli.
 - Consider vancomycin (40 mg/kg/24 h) if MRSA suspected in neonate over 1 month of age.
- Adolescent infection:
 - Parenteral antistaphylococcal antibiotics (e.g., nafcillin 50–100 mg/kg/24 h; maximum 12 g/24 h)
 - Consider amoxicillin–clavulanic acid (45 mg/kg/24 h) or clindamycin (450–1,800 mg/24 h orally with max dose 1.8 g/24 h; 1,200–1,800 mg/24 h parenterally with max dose 4.8 g/24 h) in patients with penicillin allergies and those who are well appearing and without systemic symptoms.
 - Consider adding aminoglycosides in situations as described above.
- Duration:
 - Usually for 10–14 days
 - Length of parenteral treatment is based on isolate and the clinical response. Oral agents may be used after a few days if a good clinical response occurs.

ADDITIONAL TREATMENT

General Measures

- Warm compresses
- Nonsteroidal anti-inflammatory agents (NSAIDs) help control the inflammation and pain in older children.
- Continuation of breastmilk expression helps prevent engorgement and further milk stasis.

ISSUES FOR REFERRAL

Consider referral to an infectious disease specialist if recurrent.

SURGERY/OTHER PROCEDURES

- Incision and drainage if a fluctuant mass is present
- Surgical exploration is necessary if necrotizing fasciitis is suspected.

IN-PATIENT CONSIDERATIONS

Admission Criteria

- Ill appearance
- Neonates
- Inability to tolerate oral medications
- Concern for medication nonadherence

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Clinical improvement should be evident after 48 hours of parenteral antibiotics.

ALERT

Signs to watch for:

- A poor or delayed clinical response to antibiotic therapy suggests a resistant organism, an unusual pathogen, or a different diagnosis.
- An evolving fluctuant mass warrants surgical intervention.
- Reaccumulation of fluctuant mass
- Toxic appearance, prolonged fever, purulent discharge, or progressive erythema postoperatively
- Crepitus associated with excessive pain and/or straw-colored bullae suggests necrotizing fasciitis.

PATIENT EDUCATION

- Continue breastfeeding.
- Establish good breastfeeding techniques.

PROGNOSIS

- Most children recover without any sequelae.
- Neonates are more likely to have bilateral abscesses (<5% cases).
- Neonates have higher morbidity and complications.

COMPLICATIONS

- Cellulitis (most common; 5–10%)
- Abscess rupture with disseminated infection (e.g., bacteremia, pneumonia)
- Septicemia
- Toxin syndromes (e.g., toxic shock syndrome)
- Necrotizing fasciitis
- Scar formation from mammary gland destruction (associated with a reduced breast size after puberty)

CODES

ICD9

- 611.0 Inflammatory disease of breast
- 675.11 Abscess of breast associated with childbirth, delivered, with or without mention of antepartum condition
- 675.12 Abscess of breast associated with childbirth, delivered, with mention of postpartum complication

ICD10

- N61 Inflammatory disorders of breast
- O91.119 Abscess of breast associated with pregnancy, unsp trimester
- O91.12 Abscess of breast associated with the puerperium

FAQ

- Q: How can you differentiate a breast abscess from mastitis?
- A: Although both illnesses involve signs of inflammation (i.e., warmth, erythema, swelling, tenderness), a breast abscess is distinguished from mastitis in that the former presents as a firm, well-defined mass (with or without fluctuant material).
- Q: Should a mother discontinue breastfeeding if she has a breast abscess?
- A: To avoid milk stasis, breastfeeding should be continued unless impeded by a surgical incision site or the overall clinical condition of the mother.
- Q: What is the role of homeopathic remedies (e.g., belladonna, *Phytolacca*) in the treatment of mastitis and breast abscess?
- A: Currently, there is insufficient scientific evidence to support their routine use.
- Q: Are anaerobic organisms common pathogens for breast abscesses?
- A: No. Although anaerobic pathogens are isolated in up to 40% of infections, their role is controversial, and therapy directed at them is unnecessary.

BREASTFEEDING

Amy E. Renwick

BASICS

DESCRIPTION

Breast milk is recognized by the American Academy of Pediatrics (AAP), the World Health Organization (WHO), and many other groups as the optimal nutrition for human infants.

- Physiology:
 - Milk secretion becomes possible near the middle of pregnancy. After delivery, production increases, starting with colostrum. Transitional milk “comes in” with a rapid increase in volume within ~2–5 days of delivery.
 - Prolactin produced in response to nipple stimulation (i.e., suckling, pumping, etc.) causes the continuous secretion of milk into the lumen of breast alveoli.
 - The volume of milk produced appears to be a function of frequency of removal rather than serum levels of prolactin. Inhibitory factors in the milk provide negative feedback to decrease milk production when the breast is not drained. Mechanical pressure from engorgement may also decrease production.
 - Oxytocin released from the posterior pituitary gland causes ejection of milk into the ducts and sinuses of the breast (let-down), making the milk available for removal.
 - Let-down can be triggered by physical stimulation of the breast or by mental stimulation such as hearing a baby’s cry or looking at a picture of an infant.
- Composition:
 - Largely independent of maternal diet, with the exception of fatty acids and water-soluble vitamins.
 - Colostrum is particularly high in proteins, including secretory immunoglobulin A.
 - Hindmilk, expressed as the breast is nearing emptying, has a significantly higher fat content than foremilk from the beginning of the feeding.
- Benefits of breastfeeding:
 - For child:
 - Decreases risk of postneonatal death; reduces incidence and severity of gastroenteritis, respiratory infections, acute otitis media, bacterial meningitis, obesity, sudden infant death syndrome (SIDS), asthma, leukemia and UTIs
 - May decrease risk of high cholesterol, diabetes, hypertension, lymphoma, and celiac disease
 - For mother: Decreases risk of ovarian and breast cancer, hastens return to prepregnancy weight, decreases postpartum bleeding
 - For family: Cost savings over buying formula, fewer workdays lost to care for ill child, assists with optimal child spacing (via lactational amenorrhea)
 - For society: Improved public health, lower health expenditures, decreased environmental impact

EPIDEMIOLOGY

Prevalence

- 75% of infants in the US begin breastfeeding (according to Centers for Disease Control and Prevention [CDC] data from 2007)
- At 3 months, 33% breastfeed exclusively
- At 6 months, 43% breastfeed, 13% exclusively
- Only 22% of infants breastfeed at 12 months of age
- Racial disparities in breastfeeding exist, with lower rates of initiation found among blacks when compared to whites.

RISK FACTORS

- Contraindications to breastfeeding:
 - Infant with classic galactosemia
 - Maternal conditions:
 - HIV (in developed countries)
 - Illicit drug use
 - Active, untreated tuberculosis
 - Herpes simplex virus lesions on breast (may use other breast if unaffected)
 - HTLV-I or -II positive
 - Exposure to radioactive material, while there is radioactivity in the milk
 - Use of some medications, such as cytotoxic drugs
- Maternal risk factors for not initiating or not continuing breastfeeding:
 - Not planning to breastfeed prior to delivery
 - Young age (<25 years)
 - Low education (less than high school education)
 - Being single
 - Cigarette smoking
 - Participation in WIC (Special Supplemental Nutrition Program for Women, Infants and Children)
- Infant conditions that may interfere with breastfeeding:
 - Prematurity
 - Low birth weight
 - Hyperbilirubinemia, if infant is treated with phototherapy, or if mother is asked to stop breastfeeding by health care professional
 - Hypotonia
 - Cleft lip or palate
 - Ankyloglossia (tongue-tie)
- Maternal conditions that may interfere with breastfeeding:
 - History of breast surgery
 - Abnormal breast shape
 - Inverted nipples
 - Use of medications that inhibit lactation (e.g., antihistamines, oral contraceptives)
 - Severe or chronic illness
- Common reasons cited for breastfeeding cessation:
 - Inadequate milk production, or infant not seeming satisfied with breast milk
 - Infant having difficulty feeding
 - Sore nipples
 - Returning to work or school

DIAGNOSIS

HISTORY

- Maternal breastfeeding experience with previous children?
- Frequency and duration of feedings:
 - Should feed at least 8–12 times a day in the 1st weeks of life, with no more than 4 hours between feedings
 - Time needed to empty the breast varies from ~5–20 minutes.
- Signs that infant is satisfied afterward: Is the infant calm, not rooting or sucking, sleepy?
- Does mother feel sensation of let-down (by ~2 weeks postpartum)?
- Do breasts feel full prior to a feeding, and less full afterward?
- Any sustained pain during feeding? Initial discomfort should resolve within about a minute. Continued pain may indicate an improper latch, injured nipple, candidal infection of the nipple, or mastitis.
- Number of wet diapers and bowel movements each day? By 3–5 days, infants should have 3–5 wet diapers and bowel movements each day. By 5–7 days, expect about 6 wet diapers and 3–6 bowel movements. It is important to note that this stooling pattern may change for breastfed babies, who may only stool once every 4–5 days by ~4 weeks of life.
- Family support? Support from partners, other family members, and friends may increase the likelihood of breastfeeding success.

PHYSICAL EXAM

- Direct observation of a feeding:
 - Is mother alert to infant’s cues? Alertness, restlessness, rooting, lip smacking, and sucking are early signs of hunger; crying is a late sign.
 - Are mother and infant positioned comfortably? Mother should not have to bend down. Infant should be well supported, with head, shoulders, and hips aligned.
 - For an effective latch, lips should be everted and mouth wide open, with lips approaching a 180° angle. As much as possible of the areola, especially the lower portion, should be in the infant’s mouth.
 - Signs of a good suck and milk transfer include deep, rhythmic movement of the jaw; frequent sounds of swallowing; and milk visible in the infant’s mouth.
- Weight:
 - Newborns should lose no more than 7–10% of their birth weight in the few days following delivery, and should return to birth weight within 2 weeks.
 - Expect initial weight gain of ~20–30 g/d in the 1st 2 months of life.
 - Be aware that standard CDC growth charts are not based predominantly on breastfed infants, who may weigh less than formula-fed infants from 3–12 months of age. The CDC and the AAP now recommend using WHO growth charts rather than the CDC growth charts for all children 0–2 years.

- Oropharynx, for thrush or anatomic abnormalities
- Jaundice
- Hydration status
- Mother's nipples:
 - Inversion
 - Cracking or bleeding may result from improper latch, removal of infant from nipple without breaking suction, or prolonged exposure to moisture.
 - Erythema: Seen with candidal infection; often accompanied by a burning sensation

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Bilirubin level, if clinically indicated
- Sodium level in infant, if there is concern for dehydration
- Sodium level in breast milk, if infant is hypernatremic

TREATMENT

MEDICATION (DRUGS)

- Vitamin D, 400 IU/d, beginning as early as the 1st few days of life and by 2 months. Continue even if supplementing with formula, unless getting at least 1 L of formula daily. May be given in the form of a daily multi- or tri-vitamin, or as vitamin D drops.
- Fluoride, beginning at 6 months, when indicated.
- Iron, 1 mg/kg/d, from age 4 months until taking iron-rich complementary foods, has been recommended for term infants who are exclusively or primarily breastfed; 2 mg/kg/day starting by age 1 month is recommended for preterm infants.
- Thrush or candidal infection of the nipples requires simultaneous treatment of both mother and infant with a topical antifungal agent, such as Lotrimin cream in the mother and oral nystatin solution in the baby, in addition to washing of any objects that have contact with the infant's mouth.

ADDITIONAL TREATMENT

General Measures

- Cracked nipples may be treated by applying breast milk and allowing nipples to air dry, or by applying purified lanolin. Nipples should be kept dry. If the infant must be removed from the breast while sucking, the mother should slide a clean finger into the mouth to break the suction 1st.
- Engorgement can be relieved by frequent feeding or pumping, or by the application of cool compresses. If engorgement causes difficulty with latching, some milk can be pumped or expressed manually prior to putting the child to the breast.
- Clogged milk ducts may be addressed with warm compresses, frequent emptying of the breast, massaging the area, and varying feeding positions.
- Pumping or breast shells may help with inverted nipples.

COMPLEMENTARY & ALTERNATIVE THERAPIES

- Herbs traditionally used to try to increase milk supply (galactagogues) include:
 - Fenugreek (*Trigonella foenum-graecum*): Usually taken as tea or capsules. May be effective (limited evidence); thought to be safe. Maternal side effects may include asthma symptoms, diarrhea, allergic reaction, decreased blood sugar, and maple syrup odor.
 - Milk thistle (*Silybum marianum*): Usually taken as a tea. Not studied
 - Goat's rue (*Galega officinalis*): Usually taken as a tea. Not studied

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- 2–3 days after newborn hospitalization: Weight check, physical exam, and observation of feeding
- At age 2–3 weeks: Weight check and breastfeeding support

DIET

- For the infant:
 - No food or fluid other than breast milk is needed for the 1st 6 months of life.
 - After 6 months, iron-rich foods should be part of the diet, and other complementary foods may be introduced.
- For the mother:
 - ~500 kcal/d are used for breastfeeding.
 - Women should avoid breastfeeding for at least 2 hours after alcohol consumption; the level in milk correlates with the level in blood. Ethanol also inhibits let-down.
 - If infant has G6PD deficiency, mother should avoid fava beans and certain medications.

COMPLICATIONS

- Infant:
 - Hyperbilirubinemia
 - Dehydration
 - Hypernatremia
 - Failure to thrive
- Mother:
 - Engorgement
 - Clogged milk duct
 - Mastitis
 - Candidal nipple infection
 - Cracked nipples

FAQ

- Q: How do I know if my baby is getting enough milk?
- A: Look for signs of effective feeding as described above. Your baby should suck deeply and rhythmically during a feeding, seem satisfied after a feeding, make at least 6 wet diapers a day after the 1st week, and gain weight.
- Q: How can I increase my milk supply?
- A: Increase the frequency of feeding or pumping. Offer the 2nd breast after your baby finishes with the 1st. Alternate the side that is offered 1st. Pump after nursing sessions. If pumping often, use a hospital-grade double pump. Get plenty of sleep and fluids, and try to reduce stress.
- Q: How long can expressed breast milk be stored safely?
- A: At room temperature (up to 77°F) for 3–8 hours. In a refrigerator, for 3–8 days. In a freezer, for 6–12 months. Thawed breast milk should be refrigerated and used within 24 hours of thawing.
- Q: How long should breastfeeding be continued?
- A: The AAP recommends breastfeeding at least until 12 months of age, and as long afterward as is mutually desired. The WHO recommends breastfeeding for at least 2 years. Exclusive breastfeeding is nutritionally adequate for the 1st 6 months.
- Q: Can adoptive mothers breastfeed?
- A: Induced lactation is possible. Lactation experts should be consulted.

BREASTFEEDING JAUNDICE AND BREAST MILK JAUNDICE

John I. Takayama

BASICS

DESCRIPTION

Early-onset breastfeeding jaundice (BFJ) and late-onset breast milk jaundice (BMJ) are the 2 major overlapping causes of jaundice in otherwise healthy breastfed infants:

- BFJ: Associated with inadequate breastfeeding; exaggerated early onset (3–5 days), unconjugated hyperbilirubinemia (>12 mg/dL)
- BMJ: Associated with being fed breast milk; late onset (1–6 weeks), unconjugated hyperbilirubinemia (>10 mg/dL)

EPIDEMIOLOGY

Incidence

BMJ affects 10–30% of breastfed newborns during the 2nd to 6th weeks of life.

RISK FACTORS

For Jaundice

- Blood group incompatibility with positive direct antiglobulin test
- Other known hemolytic disease (e.g., glucose-6-phosphate dehydrogenase [G6PD] deficiency)
- Gestational age
- Previous sibling received phototherapy
- Exclusive breastfeeding
- Race (e.g., East Asian)

Genetics

- BFJ: Subsequent siblings of infants with jaundice are more likely to develop jaundice.
- BMJ: Mutations in the bilirubin uridine diphosphate-glucuronosyltransferase gene (*UGT1A1*) have been identified in a Japanese population and were felt to be associated with BMJ.

PATHOPHYSIOLOGY

- Bilirubin is a breakdown product of hemoglobin and other heme-containing proteins. In newborns, shorter lifespan of a larger number of erythrocytes, immaturity of the bilirubin uptake and conjugation system in the liver, and increased enterohepatic circulation (initiated by a more rapid hydrolysis of conjugated bilirubin to the unconjugated form) contribute to hyperbilirubinemia and jaundice.
- BFJ: Inadequate intake of milk and calories with or without relative dehydration, leading to increased intestinal bilirubin absorption and enterohepatic circulation
- BMJ: Several hypotheses proposed, but remain unproven. Factors found in the milk of some mothers of infants with BMJ include:
 - Pregnenediol isomer: Steroid metabolite of progesterone, competitive inhibitor of hepatic glucuronyl transferase
 - Increased concentrations of nonesterified (free) fatty acids that inhibit hepatic glucuronyl transferase
 - Factors that increase enterohepatic circulation of bilirubin (e.g., β -glucuronidase)
- Defects in bilirubin *UGT1A1* may be associated with BMJ.

ETIOLOGY

BFJ is likely to be the predominant cause of early-onset jaundice; however, it is often difficult to distinguish from jaundice related to other causes because of considerable overlap.

DIAGNOSIS

HISTORY

Ask the following questions:

- How is the infant feeding?
 - Infrequent and difficult breastfeeding are predictors of BFJ.
 - Many BFJ infants have increased enterohepatic circulation and dehydration, reflected by delayed passage of meconium and significant weight loss.
 - Poor intake also delays stooling, which contributes to increased enterohepatic circulation of bilirubin.
- Is there a family history of jaundice in a sibling?
 - Prior history may indicate similar risk factors and genetic propensities for developing jaundice.
 - Severe neonatal jaundice suggests familial or inherited hemolytic disease.
- Are there relatives with a history of anemia, gallbladder disease, or splenectomy? Hemolytic anemias constitute an inheritable cause of severe and prolonged jaundice.
- Are there maternal risk factors?
 - Maternal illness (e.g., diabetes) and medication use (e.g., oxytocin) are associated with jaundice.
 - Infants born to mothers positive for group B streptococcus are at increased risk for neonatal sepsis.
 - Recent epidemiologic studies indicate a positive relationship between maternal age and hyperbilirubinemia.
- Are there birth-related risk factors?
 - Sepsis should be included in the differential diagnosis. Assess for presence of fever, prolonged rupture of amniotic membranes, or cloudy or malodorous amniotic fluid.
 - Traumatic delivery, including the use of instruments, such as forceps or vacuum, may result in jaundice because of associated bruising and cephalohematomas.
- When did jaundice become noticeable?
 - Jaundice before 24 hours of age suggests a hemolytic process or infection.
 - Early jaundice beyond 24 hours is associated with BFJ.
 - Prolonged jaundice beyond 1–2 weeks suggests BMJ.
- How is the infant doing? Infants with BMJ are in good health, vigorous, eating well, and gaining weight.

PHYSICAL EXAM

Jaundice generally progresses from the face to the lower extremities in proportion to rising serum bilirubin concentrations. Look for the following:

- Cephalohematoma, facial bruising: May contribute to hyperbilirubinemia
- Increased respirations, cyanosis, grunting, nasal flaring, intercostal retractions: May suggest infection

- Hepatosplenomegaly: Suggests infectious, metabolic, or severe hemolytic causes of hyperbilirubinemia
- Abdominal distention: Suggests intestinal obstruction
- Dry mucous membranes and skin tenting: Consistent with dehydration which may contribute to BFJ
- Well-appearing older infant who is gaining weight: Consistent with BMJ

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Generally, minimal laboratory evaluation is necessary in a healthy breastfed infant with mild to moderate jaundice in the absence of risk factors for other causes of jaundice. However, BFJ and BMJ are diagnoses of exclusion. The following tests should be considered, depending on the clinical presentation:

- Total serum bilirubin (or transcutaneous bilirubin), with level interpreted by age:
 - May assist in diagnosis and choice of therapy
 - Must be measured in all infants with very early jaundice <24 hours of age
 - Recommended in all infants with persistent jaundice
- Conjugated or direct serum bilirubin: Elevated level (>1 mg/dL or 10% of total serum bilirubin) may indicate infection, biliary obstructive disease, cholestasis, metabolic disease, or severe hemolysis.
- Maternal blood type and Rh status in all cases; infant blood type, Coombs test, and/or Rh test on cord blood if indicated (mother's blood type is O and/or Rh is negative): Identifies risk for hemolytic anemia from blood type and/or Rh incompatibility, with considerations for treatment at lower levels of total serum bilirubin
- CBC and smear:
 - Abnormal hematocrit assists in diagnosis of polycythemia or anemia; the smear is helpful to look for signs of hemolysis.
 - Decreases in hematocrit over time may reflect ongoing hemorrhage or hemolysis.
 - Abnormal white cell count may indicate infection.
- G6PD quantitative test:
 - G6PD deficiency is common worldwide, and a rapid increase in bilirubin may occur later than in other types of hemolytic disease.
 - Risk of kernicterus seems to be higher in infants with G6PD deficiency, indicating consideration of treatment at lower levels of total serum bilirubin.

DIFFERENTIAL DIAGNOSIS

- Infection: Sepsis (jaundice is usually not the sole presenting sign)
- Hematologic:
 - ABO or Rh isoimmunization
 - Erythrocyte enzyme defects (e.g., G6PD deficiency)
 - Erythrocyte membrane defects (e.g., hereditary spherocytosis)
 - Polycythemia

- GI: Intestinal obstruction (e.g., meconium ileus, Hirschsprung disease, pyloric stenosis)
- Congenital: Transient familial neonatal hyperbilirubinemia
- Metabolic:
 - Hypothyroidism
 - Galactosemia
 - Gilbert syndrome
 - Crigler-Najjar syndrome
- Miscellaneous:
 - Dehydration
 - Cephalohematoma
 - Maternal oxytocin use

TREATMENT

ADDITIONAL TREATMENT

General Measures

- BFJ:
 - Increase frequency of breastfeeding to 10–12 times during the 1st 3 days of life.
 - Supplement with formula if significant feeding problems or poor milk production
 - Phototherapy if serum bilirubin levels exceed the American Academy of Pediatrics (AAP) recommended threshold levels for phototherapy for full-term healthy infants based on infant’s age in hours, gestational age, and neurotoxicity risk factors (i.e., implement phototherapy for infants 25–48 hours old if total serum bilirubin ≥ 12 –15 mg/dL; 49–72 hours old if bilirubin ≥ 15 –18 mg/dL; > 72 hours old if bilirubin ≥ 18 –20 mg/dL)
 - Phototherapy may contribute to dehydration; therefore, it is essential to monitor hydration status.
 - Consider partial exchange blood transfusion for full-term healthy infants 25–48 hours old with total serum bilirubin > 19 –22 mg/dL and for infants ≥ 48 hours old with total serum bilirubin > 22 –25 mg/dL. Exchange transfusion should be considered in conjunction with phototherapy.
 - Home phototherapy poses less of an obstruction to effective breastfeeding than does hospitalization, and may be an option in certain circumstances (e.g., bilirubin levels close to the threshold for hospital phototherapy according to AAP practice guidelines).
- BMJ:
 - Continue observation.
 - Refrain from complete or partial interruption of nursing and the feeding of formula.
 - If bilirubin > 20 mg/dL consider supplementation with formula or interruption of breastfeeding temporarily and substitute with formula and/or administration of phototherapy.
- Supportive therapy:
 - BFJ and BMJ: Monitor serum bilirubin levels closely.
 - BFJ: Lactation consultation
 - BMJ: Close observation
- BFJ and BMJ: Continue treatment until serum bilirubin levels are consistently within acceptable levels.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Pitfalls:
 - Visual assessment of jaundice may be inaccurate.
 - Thresholds for starting phototherapy are lower for infants with hemolytic diseases, including G6PD deficiency and Rh incompatibility, and for premature infants and infants who are ill because kernicterus occurs at lower levels of bilirubin than in newborns without these risk factors.
 - Discharge follow-up at 72–120 hours of age, especially for breastfed infants, is important to identify significant hyperbilirubinemia, given decreasing duration of postpartum hospital stay.
 - Follow-up assessment should include infant weight, oral intake, pattern of voiding and stooling, and jaundice.

Patient Monitoring

When to expect improvement:

- BFJ: If phototherapy is instituted, expect significant improvement in jaundice within 24 hours.
- BMJ: After temporary interruption of breastfeeding for 24–48 hours, though interruption of breastfeeding is rarely necessary

PROGNOSIS

- BFJ and BMJ: Generally excellent if hyperbilirubinemia is identified and treated appropriately; however, both evaluation and treatment may contribute to disruption of breastfeeding and increased parental anxiety, resulting in breastfeeding cessation.
- Bilirubin encephalopathy (kernicterus) is extremely rare if serum bilirubin ≤ 30 mg/dL in infants who are otherwise well.
- Increased risk for hyperbilirubinemia in subsequent siblings

COMPLICATIONS

- BFJ and BMJ: Kernicterus (bilirubin encephalopathy; extremely rare), characterized acutely by lethargy, hypotonia, opisthotonus, and seizures, and on a more chronic basis by hearing loss, upward gaze palsy, and cerebral palsy
- Cessation of breastfeeding
- Parental and health care provider anxiety

CODES

ICD9

774.39 Breast milk jaundice

ICD10

P59.3 Neonatal jaundice from breast milk inhibitor

FAQ

- Q: Will my baby have developmental or neurologic problems afterward?
- A: Not from jaundice, if hyperbilirubinemia is appropriately monitored and treated
- Q: Will exposure to sunlight decrease the level of jaundice?
- A: Yes; however, avoid prolonged exposure and direct sunlight to prevent sunburn. Periodic indirect sunlight (e.g., exposure in a warm sunlit room) is sufficient.
- Q: Should I stop breastfeeding?
- A: The frequency of breastfeeding should be increased and appropriate lactation consultation obtained for BFJ. Early, frequent breastfeeding may decrease the risk. For BMJ, temporary cessation of breastfeeding will lower the total serum bilirubin; however, this recommendation should only be considered along with supplementation with formula and phototherapy if total serum bilirubin is ≥ 20 mg/dL.

BREATH-HOLDING SPELLS

Neera Goyal
Paul S. Matz

BASICS

DESCRIPTION

- Breath-holding spells (BHS) are benign, non-epileptic events in young children. May be associated with color change, loss of consciousness, and tonic and/or clonic movements.
- Can be frightening for parents and caregivers
- Classified into two main types: cyanotic and pallid.
 - Cyanotic BHS: Involuntary and reflexive expiratory apnea resulting in cerebral anoxia.
 - Pallid BHS: Vagal-mediated bradycardia or asystole resulting in cerebral anoxia (breath holding only a minor component).
- True epileptic events, called anoxic-epileptic seizures, may be triggered by either type.

GENERAL PREVENTION

- Toddlers may learn that intense crying can lead to a cyanotic BHS, followed by secondary gain of an action or object. Caregivers should minimize giving in to what the child wants so as not to reinforce the BHS.
- Main injury risk associated with BHS is head trauma. Children should be lowered to the floor and away from sharp or hard surfaces.

EPIDEMIOLOGY

- 50–60% of children with BHS have the cyanotic type; 20–30% have the pallid type; and 20% are mixed or unclassifiable
- Occur primarily between ages 1 and 5 years and resolve by school age. Rare before 6 months of age.
- Boys and girls affected equally, although boys may peak earlier (13–18 months) than girls (19–24 months).
- Most children with BHS have multiple episodes per week. Frequency of spells may range from multiple episodes daily to once yearly.

Incidence

BHS are relatively common among young children, with an estimated prevalence of 5%.

RISK FACTORS

Genetics

- There is a familial tendency for BHS.
- Approximately one third of children have a family member with a history of BHS in childhood.
- Within families, multiple children may have different types of BHS.
- Some data indicate autosomal dominant inheritance with reduced penetrance; however, no gene has been identified.

ETIOLOGY

- Cyanotic:
 - Usually triggered by violent crying
 - Breath holding is reflexive and occurs on expiration.
 - Trigger leads to hypocapnic cerebral ischemia and reflexive Valsalva, causing increased intrathoracic pressure, expiratory apnea, and hypoxemia.
- Pallid:
 - The trigger is usually a sudden, unexpected stimulus, frequently a mild head injury.
 - Excessive vagal response, resulting in severe bradycardia or asystole and cerebral anoxia.
- Anoxic–epileptic seizures:
 - Occasionally both types may lead to anoxic-epileptic seizures with/without status epilepticus
 - In contrast to idiopathic epilepsy, these occur secondary to cerebral anoxia.

COMMONLY ASSOCIATED CONDITIONS

- Iron deficiency anemia has been associated with BHS. However, the precise mechanism for this association is unclear.
- Sleep-disordered breathing may have an association with cyanotic BHS.

DIAGNOSIS

SIGNS AND SYMPTOMS HISTORY

- Clinical history is the key to diagnosis and will distinguish BHS from epileptic seizures:
 - BHS are provoked by a situation or event.
 - BHS seizures are brief and recovery is rapid.
 - Changes in skin color and loss of consciousness occur before seizure activity
- Cyanotic type:
 - Intense crying followed by forced expiration and apnea.
 - Rapid onset of cyanosis followed by loss of consciousness, generalized clonic jerks, opisthotonus, and/or bradycardia.
- Pallid type:
 - Triggered by a startle or minor trauma
 - Crying is not prominent, but pallor is common.
 - Followed by loss of consciousness, loss of muscle tone, and a fall to the ground.
 - Bradycardia with periods of asystole longer than 2 seconds may be observed.
- A family history of sudden death should prompt further cardiac investigation.

PHYSICAL EXAM

Physical examination, including neurologic and cardiovascular exam, should be normal.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Evaluation for iron deficiency anemia, including CBC, MCV, and TIBC may be helpful.
- Low serum ferritin may be an early indicator of iron deficiency.
- No other laboratory studies, including serum electrolytes, are routinely indicated.

Imaging

- Neuroimaging is not routinely indicated.

Diagnostic Procedures/Other

- 12-lead ECG to evaluate for long QT syndrome and other abnormalities should be strongly considered, particularly for pallid BHS.
- EEG should be considered for children with prolonged loss of consciousness, suspected epileptic activity, or significant post-ictal symptoms
- If EEG is requested, ocular compression with ECG may provide additional useful information in confirming the diagnosis of BHS.

DIFFERENTIAL DIAGNOSIS

- Behavioral:
 - Voluntary breath holding (characterized by prolonged inspiratory phase)
 - Psychogenic seizures
- Neurologic:
 - Epilepsy
- Cardiac:
 - Long QT syndrome
 - Wolff–Parkinson–White syndrome
 - Complete heart block
 - Supraventricular tachycardia
 - Hypertrophic cardiomyopathy
 - Vasovagal syncope

TREATMENT

INITIAL STABILIZATION

- Children should be lowered to the floor and away from sharp or hard surfaces.
- Airway clearance and cardiopulmonary resuscitation may be necessary for prolonged events.
- Most events are self-limited.

MEDICATION (DRUGS)

First Line

- Iron therapy may be beneficial, particularly for those with concomitant iron deficiency anemia
 - Ferrous sulfate, 5–6 mg/kg/day. Recommended course of treatment is ~8 weeks.

Second Line

- Anticholinergic therapy has been used for severe, frequent pallid BHS to reduce vagal activity:
 - Oral atropine sulfate or atropine methonitrate
 - Transdermal scopolamine patches
- Piracetam, a derivative of the inhibitory neurotransmitter GABA, has been demonstrated to be effective in preventing BHS. The mechanism of action for this drug remains unclear.
- Antiepileptic medication may be used to prevent anoxic-epileptic seizures associated with BHS.

SURGERY/OTHER PROCEDURES

In rare cases of severe BHS with significant bradycardia or asystole, pacemaker implantation may successfully prevent recurrent events. However, the vast majority of patients can be managed without surgery.

ISSUES FOR REFERRAL

- Prolonged seizure activity or significant post-ictal symptoms may require further neurologic investigation and intervention.
- Prolonged loss of consciousness with hypotension or family history of sudden death may suggest life-threatening cardiac dysrhythmias and require further cardiac investigation.
- Children with severe cyanotic BHS and anatomic or functional airway abnormalities may be at risk for life-threatening events; referral for tracheostomy or ventilator assistance may be necessary.

IN-PATIENT CONSIDERATIONS**Admission Criteria**

Children with bradycardia, asystole, or epileptic activity requiring cardiopulmonary resuscitation should be admitted for stabilization and further evaluation.

Discharge Criteria

Discharge from the hospital is appropriate once other causes, including neurologic and cardiovascular abnormalities, have been ruled out.

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS**

Only routine follow-up is indicated for uncomplicated BHS.

PATIENT EDUCATION

- An important part of managing children with BHS is counseling parents with regard to the expected benign course for these events.

DIET

An iron-rich diet may prevent iron deficiency anemia, which has been associated with BHS.

Activity

- No specific precautions for activity
- Parents should not avoid regular discipline in an attempt to prevent BHS.

Prevention

- Most events triggered by a minor injury or crying cannot be prevented.
- Special treatment or attention should be avoided to minimize secondary gain.
- Children having a BHS should be lowered to the floor and away from sharp or hard surfaces.
- Cardiopulmonary resuscitation should generally be avoided.
- Prolonged unconsciousness (> 1 minute) warrants more complete medical evaluation.

PROGNOSIS

Prognosis is excellent. BHS generally occur in otherwise healthy children and spontaneously resolve by 4–7 years of age.

COMPLICATIONS

- Not associated with significant long-term complications
- Approximately 20% of children with a history of BHS may experience syncope in later childhood
- Reports of death consequent to BHS are exceedingly rare.

FAQ

- Q: Are children with BHS at risk for any permanent neurologic or developmental problems?
- A: Children with BHS are not at increased risk for developing epilepsy. Normal cognitive development is expected.
- Q: Should all patients with BHS have an ECG and EEG?
- A: ECG should be strongly considered for children with BHS, particularly those with pallid type, to evaluate for long QT syndrome and other cardiac abnormalities that could be potentially fatal. Routine EEG is not warranted for these patients unless the history or exam is not consistent with a diagnosis of BHS.
- Q: How often should a child with BHS be evaluated by a physician?
- A: Once an initial evaluation has been completed and the diagnosis of BHS has been confirmed, only routine follow-up is necessary.

BRONCHIOLITIS (SEE ALSO: RESPIRATORY SYNCYTIAL VIRUS)

Howard B. Panitch

BASICS

DESCRIPTION

Acute lower respiratory tract infection causing obstruction of the small to medium conducting airways of the lung

EPIDEMIOLOGY

- In the US, occurs from late fall through the winter and early spring. The respiratory syncytial virus (RSV) epidemic season begins earlier in the southeastern US, and in some areas (e.g. Florida, Hawaii) can occur throughout the year. Parainfluenza 3 occurs throughout the year, as does adenovirus. Influenza virus epidemics usually begin in late fall, peak in January/February, and wane by April. Human metapneumovirus peaks slightly later in the year (March) than does RSV (January).
- RSV infects most children within the 1st 2 years of life; 57% of those hospitalized are <6 months.
- RSV reinfection occurs in 50–75% of children followed, and reinfection within the same RSV season is possible.
- ~1/2 of all children experience an infection with parainfluenza 3 before 1 year of age.
- Mortality associated with primary RSV infection in otherwise healthy children has been estimated to be 3.1 deaths per 100,000 person-years in infants <1 year of age, and is ~1–3% among children with underlying conditions. It is the most common viral cause of death in infants <1 year old.
- Up to 50% of infants with bronchiolitis develop subsequent wheezing.
- Patient groups at high risk of severe RSV disease:
 - Premature infants (<36 weeks' gestation)
 - Infants ≤10 weeks of age at time of RSV infection
 - Congenital heart disease
 - Chronic lung disease (including bronchopulmonary dysplasia [BPD])
 - Low birth weight
 - Cystic fibrosis
 - Compromised immune function (from chemotherapy, transplant, congenital or acquired immunodeficiencies)
 - Neuromuscular diseases
 - Trisomy 21

DIAGNOSIS

HISTORY

- Rhinorrhea with clear to white copious nasal secretions
- Initial hoarse cough for 3–5 days; progresses to deep, wet cough of increased frequency
- Poor feeding is an early sign of respiratory fatigue; may lead to dehydration
- Low-grade fever is characteristic but not a reliable marker of severity of disease; contributes to increased insensible fluid loss
- Restlessness or lethargy may indicate impending respiratory failure (hypoxemia and/or CO₂ retention).
- Apnea can be sole presenting sign in younger infants.
- Cyanosis/color change or increased work of breathing may suggest impending respiratory failure.

PHYSICAL EXAM

- General appearance:
 - Interactive versus ill appearing
 - Paroxysmal cough (most common sign), not associated with a “whoop”
- HEENT exam
 - Nasal flaring
 - Nasal congestion with copious secretions
- Pulmonary exam
 - Pattern of breathing: Apnea or periodic breathing
 - Tachypnea: >70/min is associated with severe illness
 - Intercostal retractions (increased resistance, decreased compliance); subcostal retractions (hyperinflation)
 - Thoracoabdominal asynchrony
 - Hyperresonance to percussion
 - Diffuse, high-pitched heterophonic wheezing
 - Prolonged expiratory phase
 - Fine inspiratory crackles (may be heard in both bronchiolitis and pneumonia)
 - Diffuse rhonchi
- Other findings:
 - Signs of dehydration
 - Low-grade fever
 - Tachycardia
 - Bradycardia associated with apnea
 - Possible cyanosis of nail beds and oral mucosa
 - Liver and spleen typically caudally displaced by hyperinflated lungs

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Pulse oximetry: To assess oxygenation
- Arterial blood gas:
 - Degree of hypoxemia (determine A-a gradient)
 - Evidence of respiratory failure and respiratory acidosis with CO₂ retention (late finding)
- Serum electrolytes: Sickest patients may have syndrome of inappropriate antidiuretic hormone release and hyponatremia.
- RSV serology (acute and convalescent serum samples): No practical application for clinical use
- Rapid viral identification:
 - Best samples for testing:
 - Nasopharyngeal aspirate
 - Nasopharyngeal wash
 - Adequate samples for testing:
 - Nasal swab
 - Tracheal aspirate
 - BAL fluid
- Rapid tests:
 - Immunofluorescence assay (direct or indirect):
 - >85% sensitivity and specificity
 - Results in 45 minutes
 - Negative predictive value >87%
 - Enzyme immunoassay (EIA):
 - 60–90% sensitivity
 - 70–95% specificity
 - Negative predictive value 75–98%
 - Results in 15–30 minutes
 - Does not require the presence of viable virus
 - Reverse transcriptase polymerase chain reaction (RT-PCR):
 - 93.5–100% sensitivity
 - 63.9–100% specificity
 - Results in <1 hour

- Viral culture:
 - Culture of nasopharynx
 - Considered “gold standard.” May take up to 14 days for results
 - Sensitivity and specificity highly dependent on quality of sample, handling of specimen, and time to delivery to virology laboratory

Imaging

Chest radiography findings include:

- Hyperinflation, flattened diaphragms
- Peribronchial thickening
- Patchy or more extensive atelectasis
- Possible collapse of a segment or a lobe
- Diffusely increased interstitial markings commonly seen

DIFFERENTIAL DIAGNOSIS

- Pneumonia (viral or bacterial)
- Asthma
- Gastroesophageal reflux (GER)
- Foreign body aspiration
- Exposure to noxious agents (chemicals, fumes, toxins)
- CHF
- Cystic fibrosis

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Most cases are mild and may be treated at home.
- Adequate fluid intake
- Maintenance of nasal airway patency:
 - Short-term nasal decongestant
 - Suction secretions with suction bulb.

Additional Therapies

- Careful fluid hydration; deficit plus ~2/3 maintenance fluids
- Supplemental oxygen:
 - Given to any patient with hypoxemia
 - Preferably warmed and humidified by nasal cannula, head box, or tent
- Management to overcome airway obstruction:
 - Bronchodilators:
 - Some (but not all) infants with bronchiolitis will improve clinically with bronchodilator administration. A trial of an aerosolized β -adrenergic agent with critical assessment to see if there is any relief of symptoms is reasonable.
 - Infants with a prior history of wheezing or familial history of asthma or atopy are more likely to respond to bronchodilators.
 - Theophylline is not usually useful as a bronchodilator in bronchiolitis, and may potentially worsen GER, if present.
 - Nebulized epinephrine:
 - Potentially beneficial in infants with moderate to severe bronchiolitis. It is both an α - and β -receptor agonist.
 - Both racemic epinephrine (0.1 mL/kg of 2.25% solution) and L-epinephrine have been studied separately and showed beneficial results compared with β -agonists.

- Anticholinergic agents: Ipratropium bromide has not been shown to be effective in the treatment of bronchiolitis.
- Corticosteroids:
 - In previously healthy infants, corticosteroids are not routinely recommended. Use of systemic (oral or parenteral) steroids may confer a small benefit in shortening duration of hospital stay or symptoms (<1/2 day).
 - The combination of inhaled epinephrine with oral dexamethasone in children cared for in an emergency room may decrease the need for hospitalization.
 - Use of inhaled corticosteroids does not decrease duration of symptoms or recurrence of cough and wheezing after acute bronchiolitis resolves.
- Leukotriene modifiers:
 - Infants who develop wheezing with RSV infection have high concentrations of cysteinyl leukotrienes and histamine in respiratory secretions.
 - The role of montelukast in acute bronchiolitis remains unclear.
 - Use of montelukast to prevent postbronchiolitis wheezing does not appear to be effective.
- Mucolytics:
 - Recombinant human DNase and *N*-acetylcysteine are not effective in shortening the duration of symptoms in infants with bronchiolitis.
 - Hypertonic saline (3%) aerosolized in combination with epinephrine shortens length of hospitalization compared to use of epinephrine alone.
 - Hypertonic saline can be used safely without pretreatment with a bronchodilator.
- Surfactant:
 - Shown to prevent progression of deterioration in lung mechanics in a small number of infants with respiratory failure requiring mechanical ventilation secondary to RSV bronchiolitis
- Heliox:
 - Helium–oxygen mixtures used in place of nitrogen–oxygen (air) have been shown to improve clinical score and shorten ICU stays in small series of infants with severe bronchiolitis.
 - The gas does not alter the course of the underlying illness, but because helium is less dense than nitrogen, resistance in areas of turbulent flow is decreased.
 - This in turn can decrease breathing effort, respiratory rate, and heart rate.
- Antibiotics:
 - Not usually indicated
 - Other than otitis media or urinary tract infection, the incidence of concurrent serious bacterial infection (pneumonia, meningitis, sepsis) is <7% in healthy infants with no underlying disease who have RSV bronchiolitis.
- Antiviral agents (ribavirin): See Respiratory Syncytial Virus
- Immunoprophylaxis: See Respiratory Syncytial Virus

IN-PATIENT CONSIDERATIONS**Admission Criteria**

- Historical risk factors for severe disease:
 - <2 months of age
 - Gestational age <36 weeks
 - Underlying cardiopulmonary disease (e.g., hemodynamically significant heart disease, BPD)
 - Immunodeficiency or other high-risk group for developing severe disease
 - Presence of apnea, tachypnea (respiratory rate >70/min), retractions, poor feeding, pallor, lethargy, or agitation (signs of impending respiratory failure)
 - Pulse oximetry <95% in room air
 - Atelectasis on chest radiograph

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

- Most infants with no underlying disease improve within 3–5 days. In some, nasal congestion and cough may continue for 1–3 weeks. Premature infants and those with underlying cardiopulmonary disease typically experience a protracted illness.
- Those who need mechanical ventilation may have difficulties with extubation owing to excessive secretions and atelectasis.
- As many as 50% of infants will have recurrent wheezing through the 1st decade of life.

PROGNOSIS

- For most previously healthy infants, the prognosis is good.
- Premature infants of 32–35 weeks' gestation hospitalized for bronchiolitis have been shown to have an increased number of subsequent hospitalizations for respiratory problems, a greater number of outpatient visits, and an increased risk of sudden death compared with those who were not hospitalized for bronchiolitis.
- Mortality associated with primary RSV infection in otherwise healthy infants is 0.005–0.02%.
- Up to 50% of infants with bronchiolitis develop subsequent episodes of recurrent wheezing until 11 years of age.
- Bronchiolitis obliterans may be a sequela in patients infected with adenovirus or *Mycoplasma pneumoniae*.

COMPLICATIONS

- Impending respiratory failure (increased breathing effort, retractions, hypoxemia, CO₂ retention, lethargy)
- Sudden deterioration suggesting atelectasis due to mucous plugging
- Fatigue may occur in infants who have prolonged and extensive disease.
- Fatigue will manifest with increased pCO₂ and worsening hypoxemia.

ALERT

- Hypoxemia is common, so always monitor oxygen saturation.
- Be aware of apnea.
- In cases of clinical bronchiolitis, causes of false-negative ELISA tests:
 - Poor quality of sample
 - Sample contamination
 - Insufficient sample
 - Non-RSV bronchiolitis

ADDITIONAL READING

**CODES**

- ICD9
- 079.6 Respiratory syncytial virus (RSV)
- 786.07 Wheezing

ICD10

- J20.5 Acute bronchitis due to respiratory syncytial virus
- J21.9 Acute bronchiolitis, unspecified

FAQ

- Q: How did my child get bronchiolitis?
- A: RSV bronchiolitis is a common, seasonal, lower respiratory tract infection that is easily transmissible.
- Q: Can my child become reinfected?
- A: Children can become reinfected with RSV bronchiolitis, and infection can occur more than once during the same respiratory season.
- Q: Do patients with bronchiolitis need to be isolated?
- A: RSV-positive patients need to be isolated with other RSV-positive patients and from uninfected patients.
- Q: Will my child develop asthma?
- A: Recurrent wheezing has been described in up to 50% of infants with RSV bronchiolitis. However, most data are retrospective and observational. Whether RSV per se can contribute to the development of asthma and allergic sensitization remains unclear.

BRONCHOPULMONARY DYSPLASIA (CHRONIC LUNG DISEASE OF PREMATURITY)

John M. Good

BASICS

DESCRIPTION

A chronic lung disease, seen mainly in premature infants, characterized by inflammation and scarring in the lungs.

GENERAL PREVENTION

- Prevention of prematurity
- Antenatal steroids
- Early use of surfactant Limited use of high pressure ventilation

EPIDEMIOLOGY

Prevalence

BPD is one of the most common chronic lung diseases in children.

RISK FACTORS

- Birth weight of <1250 g
- Infants who were born at >30 weeks' gestation.

PATHOPHYSIOLOGY

- Remains complex and poorly understood
- Lung damage caused by a variety of toxic factors which interferes with alveolarization (septation), leading to alveolar simplification with a reduction in the overall surface area for gas exchange as well as damage to the developing pulmonary vasculature.

DIAGNOSIS

SIGNS AND SYMPTOMS

HISTORY

- Maternal use of antenatal steroids
- Gestational age, birth weight, APGAR score
- Initial resuscitative efforts, need for intubation, use of surfactant, duration in intubation, type of ventilation, duration of supplemental oxygen therapy, and other factors: These may have influenced the type and degree of lung injury.
- Familial history of asthma, atopy, or other children with bronchopulmonary dysplasia
- Social support structure
- Any potentially exacerbating factors, such as exposure to smoking
- Feeding and sleeping history

PHYSICAL EXAM

- Review of systems, including careful assessment of work of breathing both at rest and during activity
- A review of growth charts
- Vitals including respiratory rate and pulse oximetry both at rest and with activity
- Signs of pulmonary hypertension, including peripheral edema, hepatomegaly, and venous distention

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Electrocardiogram: Often followed serially to assess for right ventricular hypertrophy
- Echocardiogram: Often, a useful adjunct to follow patients with right ventricular hypertrophy
- Cardiac catheterization: Reserved for patients with evidence of pulmonary hypertension and cardiac dysfunction
- Pulmonary function testing: Often used to follow patients and evaluate responsiveness to interventions
- Blood gases: Useful in acute and chronic management of bronchopulmonary dysplasia to follow the degree of hypoxia and hypercapnia

Imaging

Changes on chest radiography include hyperinflation, emphysema, cyst formation, pulmonary edema, fibrosis, and cardiovascular changes. Severity of these changes may help predict the severity of the disease.

Diagnostic Procedures/Other

Bronchoscopy, barium swallow, pH probe, and sleep studies may reveal underlying conditions contributing to pulmonary dysfunction.

DIFFERENTIAL DIAGNOSIS

- Asthma
- Atelectasis
- Bronchiolitis obliterans
- Congenital heart disease
- Cystic adenomatoid malformation
- Cystic fibrosis
- Idiopathic pulmonary fibrosis
- Infections
- Meconium aspiration syndrome
- Patent ductus arteriosus
- Pneumonia
- Recurrent aspiration
- Subglottic stenosis
- Tracheomalacia <http://www.emedicine.com/ped/topic158.htm>

TREATMENT

GENERAL MEASURES

Diet

- Infants with bronchopulmonary dysplasia may have increased caloric needs as much as 150 kcal/kg/d.
- Premature and critically ill infants may be deficient in antioxidants. Supplementation has not yet been shown to affect outcomes.

MEDICATION (DRUGS)

- Diuretics:
 - Used for treating pulmonary edema, often improving lung mechanics and gas exchange
 - Furosemide may have other benefits, including effects on prostaglandin synthesis, direct vasodilatation, and improved surfactant production.
 - Side effects from long-term furosemide therapy include azotemia, ototoxicity, electrolyte abnormalities, excessive urinary calcium loss, osteopenia, and nephrocalcinosis.
 - Thiazide diuretics, usually used with a potassium-sparing diuretic such as spironolactone, are not as effective as furosemide.
 - Routine monitoring of electrolytes is recommended for patients on long-term diuretic therapy.
 - Electrolyte supplementation is often required with long-term diuretic usage.
- Bronchodilators:
 - Inhaled β -agonists are effective treatment for reversible bronchospasm, although safety and efficacy of long-term use has yet to be established.
 - Albuterol is often the drug of choice, although longer-acting agents are often used as well.
 - Muscarinic antagonists may be useful adjuncts, especially in patients who are not significantly responsive to albuterol. Believed to work on large- and medium-sized airways
 - Cromolyn, though not a bronchodilator, is often used for its anti-inflammatory effects and has a low side-effect profile.
 - Methylxanthines are often used in the treatment of apnea, have a mild diuretic effect, and help improve diaphragmatic contractility, making them potentially useful in bronchopulmonary dysplasia.
- Pulmonary vasodilators:
 - Supplemental oxygen is an effective vasodilator and remains a mainstay of treatment for infants with hypoxia.

- Steroids:
 - Steroid usage is controversial.
 - Increased risk for sepsis has probably been overstated.
 - Often used successfully in short regimens to wean ventilatory support and hasten extubation
 - No long-term benefits of steroid therapy have been demonstrated.
 - Inhaled steroids may provide anti-inflammatory effects without systemic side effects, making them attractive as both prevention and treatment.
 - Routine use in premature infants is an active area of investigation.
 - Linear growth retardation has been a concern.
 - Newer agents that can be nebulized are now available, improving drug delivery in small infants.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- A multidisciplinary approach is recommended for all patients with moderate and severe disease.
- Team may include primary care physician, pediatric pulmonologist, pediatric cardiologist, nutritionist, and speech, respiratory, occupational, and physical therapists.
- Monitor growth and nutritional status.
- Monitor neurodevelopmental status, including NICU “high-risk” follow-up.

ALERT

- Ensure adequate calcium and phosphorus intake in patients at risk for hyperparathyroidism and rickets.
- Patients <2 years of age are candidates for respiratory syncytial virus immune globulin injections (palivizumab; Synagis), if not contraindicated.
- Patients >6 months are candidates for influenza vaccine, if not contraindicated.
- Chest physiotherapy may cause pathologic fractures in patients with osteopenia.

PROGNOSIS

- Most survivors demonstrate slow, steady improvement.
- High death rate (17–47%) for patients with severe disease requiring prolonged mechanical ventilation
- No treatment modality has shown significant impact on the long-term outcome of chronic bronchopulmonary dysplasia.
- Survivors often have long-term pulmonary sequelae including hyperinflation, reactive airways, and exercise intolerance.
- Even older children and young adults who were thought to be asymptomatic can have abnormal responsiveness to exercise.
- Newer technologies, in particular high-frequency ventilation and exogenous surfactant, have improved survival rates for premature infants; however, reduction in the incidence and severity of bronchopulmonary dysplasia has been difficult to demonstrate.

COMPLICATIONS

- Prolonged intubation may cause subglottic stenosis and tracheomalacia.
- Pulmonary hypertension may occur as a result of vasculature damage and subsequent intimal proliferation, which may, in turn, produce right ventricular hypertrophy and, if severe enough, cor pulmonale.
- Pulmonary edema often occurs secondary to increased pulmonary capillary permeability and increased pulmonary pressures.
- Reactive airways, bronchospasm, and altered pulmonary mechanics owing to a poorly compliant lung may result in abnormal pulmonary function testing and increased work of breathing.
- Malnutrition and growth failure may occur as a result of increased work of breathing and a subsequently high caloric expenditure.
- Impaired lung defenses result in an increased susceptibility to infection, especially respiratory syncytial virus.

ICD-9 CODES

ICD9
770.7 Bronchopulmonary dysplasia

ICD10
P27.1 Bronchopulmonary dysplasia origin in the perinatal period

FAQ

- Q: Will antibiotics help my child?
- A: Some evidence indicates that infection with ureaplasma may be important in the pathogenesis of bronchopulmonary dysplasia. It remains to be seen whether treatment affects outcome. Overuse of antibiotics increases occurrence of antibiotic resistance.

- Q: Which babies should get respiratory syncytial virus immunoglobulin injections (palivizumab; Synagis)?
- A: The AAP Committee on Infectious Diseases recommends immunoprophylaxis for infants with bronchopulmonary dysplasia who are <2 years of age at the onset of respiratory syncytial virus season. Other premature infants may be candidates as well, with or without bronchopulmonary dysplasia:
- Infants born at ≤28 weeks at the onset of respiratory syncytial virus season and who are ≤12 months should receive immunoprophylaxis monthly for the entire season.
- Infants born at 29–32 weeks’ gestation and who are ≤6 months at the beginning of respiratory syncytial virus season should also receive immunoprophylaxis.
- Infants born between 32 and 35 weeks may or may not be candidates for palivizumab (Synagis) depending on the presence or absence of other risk factors, such as day-care attendance, school-aged siblings, exposure to environmental air pollutants, congenital abnormalities of the airways, or severe neuromuscular disease.
- Q: Will anti-respiratory syncytial virus immunoprophylaxis (palivizumab; Synagis) prevent my baby from getting respiratory syncytial virus?
- A: It will not prevent respiratory syncytial virus infection, but it will help your child’s own immune system attack the virus.
- Q: Will my child have asthma when he grows up?
- A: Asthma occurs in >50% of older children who survived bronchopulmonary dysplasia.
- Q: What types of additional therapies can help my child?
- A: Such therapies include the following:
 - Chest physiotherapy may help to mobilize secretions and to prevent atelectasis.
 - Speech and occupational therapy may help infants who have had prolonged intubation or other interventions that interfere with oral functioning (and, therefore, may have some degree of oral-motor dysfunction and oral aversion).
 - Other infants simply with increased work of breathing may have disorganized suck and swallow, making oral feedings difficult.
 - Physical therapy may help infants with gross and fine motor delays, poor tone, and abnormal posture.
 - Parents can learn many of the therapies to incorporate therapeutic exercises and positioning into their daily routines.

BRUISING

Julie W. Stern

BASICS

DEFINITION

Bruises are the result of extravasation of blood into the skin. Conventional usage often groups petechiae and bruises (or ecchymoses) together as purpura and defines them as follows:

- Petechiae: Flat, red, or reddish purple, 1–3 mm, nonblanching
- Ecchymoses: Larger than petechiae, local extravasation, nonpulsatile, sometimes palpable, color depends on age of lesion

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- **Congenital/anatomic**
 - Coagulation factor abnormality: Hemophilia, von Willebrand disease
 - Platelet defect: Bernard–Soulier syndrome, Glanzmann thrombasthenia, and storage pool defects
 - Congenital alloimmune or isoimmune thrombocytopenia
 - Neonatal extramedullary hematopoiesis
 - Hereditary hemorrhagic telangiectasia
- **Infectious**
 - Meningococemia
 - Viral infections (coxsackievirus, echovirus)
 - Rocky Mountain spotted fever
 - Syphilis
 - Pertussis—secondary to severe cough
 - Septic or fat emboli
 - Disseminated intravascular coagulation—acquired factor deficiency
- **Toxic, environmental, drugs**
 - Warfarin—acquired factor deficiency
 - Corticosteroids—striae caused by increased capillary fragility
 - Aspirin and ibuprofen—cause a qualitative platelet abnormality
 - Sulfonamides
 - Bismuth
 - Chloramphenicol
- **Trauma**
 - Normal activity
 - Child abuse
 - Valsalva, crying, forceful coughing
 - Cupping or coin rubbing
 - Tight garments
- **Tumor (quantitative platelet abnormality): Bone marrow replacement**—leukemia, myelofibrosis, or (rarely) metastatic solid tumors
- **Genetic/metabolic**
 - Uremia
 - Vitamin C deficiency
 - Vitamin K deficiency—owing to antibiotics, biliary atresia, malabsorption (acquired factor deficiency)

- **Allergic/inflammatory/vasculitic**
 - Henoch–Schönlein purpura
 - Bone marrow failure: Aplastic anemia (including Fanconi, paroxysmal nocturnal hemoglobinuria)
 - Increased destruction: Idiopathic thrombocytopenic purpura, Evans syndrome, lupus
 - Nephrotic syndrome
 - Collagen vascular disease
 - Ehlers–Danlos syndrome
 - Snake bite (copperhead)
- **Miscellaneous (disorders that simulate bruises)**
 - Ataxia telangiectasia
 - Cherry angiomas
 - Kaposi sarcoma

DIAGNOSIS TO THE PATIENT

General goal is to determine if the cause of the bruising is thrombocytopenia, a coagulation disorder, or an extrinsic factor (such as trauma, infection).

- **Phase 1:** Determine if the history of bruising and/or petechiae is acute or chronic in onset and if there is known trauma vs. spontaneous lesions (see Table 1)

Table 1. How to estimate the age of bruises

1. New	Purple, dark red
2. 1–4 days	Dark blue to brown
3. 5–7 days	Greenish to yellow
4. >7 days	Yellow

- Acute onset of diffuse subcutaneous bleeding with bruises of different ages may indicate severe thrombocytopenia.
- Generally, children will not bruise or develop petechiae spontaneously until the platelet count is $<20,000/\text{mm}^3$.
- Idiopathic thrombocytopenic purpura, leukemia, aplastic anemia, and so forth, can cause this bleeding.
- A hematologist should be consulted because of the risk of potentially life-threatening bleeding.
- Chronic history of recurrent bleeding may indicate an inherited coagulation defect such as von Willebrand disease or hemophilia. Familial history may be positive, although von Willebrand disease often goes undiagnosed into adulthood if there has been no challenge such as surgery.
- **Phase 2:** Perform screening tests for bleeding disorders to categorize the abnormality
 - Platelet count to assess level of thrombocytopenia
 - PT/PTT: Prolongation of either one or both of these may aid in diagnosis of von Willebrand disease, coagulation factor deficiencies, liver disease, and vitamin K deficiency.
 - Bleeding time: Prolongation may indicate a platelet aggregation disorder or von Willebrand disease. Use as a screening test is controversial and rarely used routinely in pediatrics.
 - PFA-100: Value as screening test for bleeding disorders controversial

HISTORY

- **Question:** Significant bruising in the neonatal period?
- **Significance:** May indicate neonatal thrombocytopenia, congenital infections, and sepsis with disseminated intravascular coagulation
- **Question:** Bleeding in the neonatal period?
- **Significance:** Hemophilia. Other inherited disorders of coagulation may not be diagnosed until a child is older; tend to be mild, may be uncovered with preoperative testing or postoperative bleeding complications. Idiopathic thrombocytopenic purpura may occur at any age.
- **Question:** Pattern of bruising?
- **Significance:** In a younger child, may indicate normal toddler activity, child abuse, or religious practices such as coining (common among Southeast Asians).
- **Question:** Use of aspirin, ibuprofen, cough syrups with guaifenesin, and/or antihistamines?
- **Significance:** Platelet dysfunction; use of these drugs may also unmask an otherwise mild inherited bleeding disorder.
- **Question:** Ecchymosis or petechiae?
- **Significance:** Infections such as meningococemia or viruses and collagen vascular diseases may present with these.
- **Question:** Familial history?
- **Significance:** Positive familial history of inherited disorders of coagulation factors or platelet aggregation may aid in directing the workup. Negative familial history does not rule out any of these disorders.

PHYSICAL EXAM

- **Finding:** Good appearance, with a history of an antecedent viral illness?
- **Significance:** Those with idiopathic thrombocytopenic purpura often appear well, though often with a history of an antecedent viral illness.
- **Finding:** Ill appearance?
- **Significance:** It should raise concerns about malignancy, infection (especially meningococemia), or other acquired coagulation factor deficiencies such as those seen with liver failure.
- **Finding:** Bruising in unusual locations (back, genitalia, thorax)?
- **Significance:** Should raise suspicions of child abuse, especially if lesions are in different stages of healing or suggest the pattern of a hand or belt.
- **Finding:** Purpura confined mostly to the legs?
- **Significance:** Typical of Henoch–Schönlein purpura
- **Finding:** Multiple ecchymoses in the pretibial regions?
- **Significance:** Most toddlers will have that occur with normal activity.

- **Finding:** Petechiae entirely above the nipple line?
- **Significance:** Consistent with Valsalva maneuver, severe cough, and viral infections
- **Finding:** Deeper bleeding in muscles and joints?
- **Significance:** Hemophilia
- **Finding:** Bleeding in mucous membranes?
- **Significance:** Severe thrombocytopenia, streptococcal pharyngitis, varicella, measles, and other viral infections can cause this.
- **Finding:** Gingival and/or mucous membrane bleeding?
- **Significance:** Von Willebrand disease can present with this.
- **Finding:** Involvement of the reticuloendothelial system?
- **Significance:** Can be found with malignancies such as leukemia or with viral or bacterial infections, indicated by hepatosplenomegaly or lymphadenopathy.
- **Finding:** Upper extremity limb malformations and bruising?
- **Significance:** May present with syndromes such as Fanconi anemia and thrombocytopenia absent radii (TAR)

ALERT

Factors that make this an emergency include:

- Severe thrombocytopenia below 10,000–20,000/mm³ carries a higher risk of spontaneous internal bleeding including intracranial bleeding.
- Bleeding or bruising accompanied by evidence of leukemia or other malignancy
- Evidence of sepsis (disseminated intravascular coagulation) or meningococemia

DIAGNOSTIC TESTS & INTERPRETATION

- **Test:** CBC
- **Significance:** Platelet count is the most important; abnormalities of WBC or Hgb may aid in diagnosis of bone marrow infiltration or failure.
- **Test:** PT
- **Significance:** Elevation may indicate warfarin ingestion or factor VII deficiency or vitamin K deficiency.
- **Test:** aPTT
- **Significance:** Prolongation is seen with hemophilia and may be seen in von Willebrand disease.
- **Test:** Both PT and PTT
- **Significance:** Both are prolonged in disseminated intravascular coagulation, liver failure, and severe vitamin K deficiency.
- **Test:** Bleeding time
- **Significance:** Lengthened in platelet aggregation disorders and with drug effects
- **Test:** Fibrinogen
- **Significance:** Decreased in liver failure, disseminated intravascular coagulation
- **Test:** Urinalysis
- **Significance:** Hematuria and/or proteinuria may indicate Henoch–Schönlein purpura, nephrotic syndrome, or other vasculitis.

**TREATMENT****General Measures**

Thrombocytopenia precautions for platelets <20,000–50,000—toddlers may need a helmet until platelet count recovers; patients with hemophilia may need restricted activity, generally not needed for patients with von Willebrand disease. Depends on underlying cause:

- Factor replacement for hemophilia
- Platelet transfusion for thrombocytopenia due to decreased production
- IVIG/steroids/Rh immune globulin for ITP

ISSUES FOR REFERRAL

- Outpatient evaluation for bruising without significant thrombocytopenia, family history of bleeding disorder
- Suspected child abuse

Admission Criteria

Severe thrombocytopenia, suspected child abuse, significant bleeding, significant head trauma

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS****Patient-Monitoring**

Recurrent and chronic ITP possible

COMPLICATIONS

Significant bleeding with a bleeding disorder, thrombocytopenia

**CODES****ICD9**

- 287.2 Other nonthrombocytopenic purpuras
- 459.89 Other specified disorders of circulatory system
- 782.7 Spontaneous ecchymoses

ICD10

- D69.2 Other nonthrombocytopenic purpura
- R23.3 Spontaneous ecchymoses
- R58 Hemorrhage, not elsewhere classified

CLINICAL PEARLS

- The amount of bruising may not correlate with the amount of internal bleeding that has occurred. Hemophiliacs can significantly drop their hemoglobin during a thigh or psoas bleed without having much in the way of ecchymosis.
- A child presenting with idiopathic thrombocytopenic purpura may have bruises and petechiae from head to toe without changing the hemoglobin much at all.

FAQ

- Q: Is hemophilia always diagnosed in the newborn period?
- A: No. A familial history may provide clues, but a significant number of patients represent a spontaneous mutation. Additionally, not all boys with hemophilia will bleed with circumcision, and the diagnosis may not be made until the infants become more active.
- Q: What is a common cause of bruising among girls?
- A: Girls may first come to attention at menarche and be diagnosed at that time with von Willebrand disease. Rarely, girls whose fathers have hemophilia may be unfavorably lyonized and, therefore, have decreased factor levels consistent with mild hemophilia.
- Q: Can boys with a family history of von Willebrand disease be circumcised?
- A: Yes, but only within the first few days of life and testing does not need to be completed prior to procedure. If procedure is not completed in the neonatal period, testing may need to be delayed until 6 months of life or later.

BRUXISM

Howard M. Rosenberg
Rochelle G. Lindemeyer
Zuhair Sayany (5th edition)

BASICS

DESCRIPTION

- Nonfunctional grinding of the teeth
- Poorly understood phenomenon with many suggested etiologies
- Usually a subconscious activity that may occur during the day or night
- Clenching is a related condition which is also considered to be a nonfunctional habit.
- Nonfunctional (or “parafunctional”) habits include mandibular movements not involved with normal chewing, swallowing, or speaking, e.g., chewing pencils, nails, or cheek, or biting lip.
- If made aware of their tooth grinding while awake, children can often stop. However, bruxism while asleep is more difficult to modify and has become classified with restless leg syndrome and sleep walking.

EPIDEMIOLOGY

- May occur throughout life, but frequency tends to peak up to the ages of 7–10 years, then decreases with age
- Infants have been known to grind their teeth with the eruption of the first primary tooth.
- May sometimes be temporarily or intermittently present, making diagnosis difficult
- Girls may be affected more frequently, but there are not adequate studies on the role of gender.
- More common in children with developmental disabilities, principally severe mental retardation, Down syndrome, and some autism spectrum disorders
- Recent literature implicates genetics in bruxism, but no genetic mechanism has been explained.

Prevalence

In children, prevalence has been reported to be from 7% to 88% (with most reports indicating an average of 15–30%).

ETIOLOGY

The exact cause is not known, but several factors have been implicated and most feel that it is multifactorial:

- Dental (local) factors (current evidence is that they play only a small role, about 10%):
 - Occlusal interferences, including malocclusions, in which teeth do not interdigitate smoothly
 - High dental restorations (e.g., fillings or crowns)
 - Intraoral irritation (e.g., sharp tooth cusp)
 - Teething

- Psychological factors:
 - Nervous tension (related to stress, anger, and aggression)
 - Personality disorders
 - Mental retardation
 - Post-traumatic stress disorder
- Common systemic factors:
 - Moving between levels of sleep
 - Neuromuscular disorders (e.g., cerebral palsy)
 - Brain injury
 - Burn injuries
 - Hyperactivity
- Uncommon or rare systemic factors:
 - Asthma
 - Obstructed breathing (as with large tonsils and adenoids)
 - Genetics
 - Allergies
 - Nutritional and vitamin deficiencies
 - Intestinal parasites
 - Endocrine disorders
 - Restricted mobility of the cervical spine
 - Posture of the head
 - Mouth breathing
 - Medications (amphetamines, antidepressants—particularly serotonin reuptake inhibitors)

DIAGNOSIS

- Teeth:
 - Wear facets, abraded areas
 - Extreme wear of primary teeth is occasionally observed, but it is extremely rare that pulp becomes exposed or nerve damage occurs.
 - Broken dental restorations
 - Loosening
 - Exacerbation of pre-existing periodontal disturbances (gingival inflammation and recession, alveolar bone loss)
 - Pain or sensitivity
- Muscular symptoms in any of the head and neck muscles most often seen in the lateral pterygoids followed by the medial pterygoids and masseters:
 - Pain
 - Trismus
 - Spasm

- Headache especially in the morning
- Temporomandibular joint (TMJ) disorders:
 - Pain in the TMJ area
 - Symptoms (pain, trismus, spasm) in the masticatory muscles
 - Limited mandibular range of motion
- Grinding sounds, nocturnal (at night) and/or diurnal (during the day), which may be extremely distressing to parents and caregivers

DIFFERENTIAL DIAGNOSIS

- Dental problems
- Seizures
- Drug reaction
- Stress

TREATMENT

MEDICATION (DRUGS)

Rarely used:

- Analgesic for symptoms
- Anti-inflammatory (e.g., ibuprofen) for symptoms
- Muscle relaxants for symptoms
- Mild tranquilizers if anxiety plays an etiologic role

ADDITIONAL TREATMENT

General Measures

- Patient and family education: Ensure that the bruxism itself does not become an issue generating stress for the child.
- Behavior (habit) therapy
- Stress counseling:
 - Identify and address sources of stress
 - Biofeedback exercises
- Counseling/psychotherapy
 - Hypnosis

Additional Therapies

- Uncommonly used:
 - Plastic or vinyl bite guard (must not interfere with normal dental growth and development)
 - Occlusal adjustment (selective tooth grinding to balance the bite): There is no evidence-based support.
 - Dental restorations: Treat and restore carious lesions. Stainless steel crowns may be used for extreme wear in primary teeth to stop tooth sensitivity and/or prevent pulpal exposure.
- Rarely used:
 - Orthodontics
 - Tonsillectomy and adenoidectomy

COMPLEMENTARY & ALTERNATIVE THERAPIES

Rarely used:

- Warm compresses for muscle or TMJ symptoms
- Limit affected muscle activity (e.g., “do not open wide,” “take very small bites,” “do not chew gum”)
- Ultrasound
- Transcutaneous electrical nerve stimulation (TENS)
- Acupressure and/or acupuncture
- Correct cervical spine dysfunction (particularly head position) or posture

IN-PATIENT CONSIDERATIONS

Initial Stabilization

- Treatment for bruxism is rarely indicated in children.
- Therapy is justified if damage to the permanent dentition or periodontal structures is observed (occasionally in adolescents).
- Limit treatment to the most simple and reversible measures. There are inadequate data to support the efficacy of irreversible treatment (e.g., selective tooth grinding, orthodontics) in children.
- For comatose patients with self-injurious issues, various mouth guards or mouth props have been protective; intraoral botulinum-A injections have relieved the spasticity.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Continue to monitor for significant associated problems; intercede if damage to permanent dentition and/or periodontal structures is observed.

PROGNOSIS

- Although associated problems are well documented, there are no data that establish cause-and-effect relationships for bruxism in childhood continuing into adulthood.
- Preschool children:
 - Typically ceases without therapeutic intervention
 - Associated problems are rare.
- School-aged children:
 - Typically ceases without therapeutic intervention
 - Monitor for associated conditions without treatment
- Adolescents:
 - More commonly benefit from therapeutic intervention
 - Associated problems may also require therapy (e.g., abrasion of teeth; muscular, TMJ symptoms).

- Special-needs children:
 - Long-term prognosis is poor.
 - Acute situations in children who are comatose or those who have suffered traumatic brain injuries or severe burns may be managed by the use of prefabricated bite blocks, or in rare cases, by the fabrication of custom-fitted mouth guards. These appliances are used primarily to prevent self-injurious soft-tissue damage from parafunctional reactions such as lip, cheek, and tongue biting.

CODES

ICD9

- 306.8 Other specified psychophysiological malfunction
- 327.53 Sleep related bruxism

ICD10

- F45.8 Other somatoform disorders
- G47.63 Sleep related bruxism

FAQ

- Q: How should bruxism in a preschool child be treated?
- A: The great majority of bruxism in children stops without any therapy. Considering the controversial nature of treatment modalities, it is prudent to advise no treatment for childhood bruxism and to advise the parents that the condition is common and is usually outgrown.
- Q: What about treating bruxism in adolescence?
- A: Because damage to the permanent teeth or periodontal structures may have long-term consequences, bruxism in adolescence may be a concern. Still, treatment should be limited to the most simple and reversible approaches. Careful dental evaluation would be an important first step.
- Q: Does damage to the primary teeth result in problems with the permanent teeth or with the TMJ?
- A: There is no evidence that bruxism in children leads to problems during adolescence or later.
- Q: Should custom-fitted mouth guards be fabricated for children with traumatic brain or burn injuries who engage in lip or tongue biting?
- A: The long-term prognosis is often poor in these patients. For patients with transitory soft-tissue injuries, conservative measures such as prefabricated bite blocks to get through the acute stage should be tried first. Patients who exhibit chronic chewing may require the fabrication of custom-fitted mouth guards, which may require the use of deep sedation or general anesthetic procedures to construct the appliance. The risk of these procedures would need to be weighed against the benefit of the bite guard.

BULIMIA

Nadja Peter

BASICS

DESCRIPTION

Bulimia nervosa is an eating disorder characterized by:

- Recurrent episodes of binge eating characterized by rapid consumption of large amounts of food in discrete periods of time, usually <2 hours
- Compensatory behavior such as self-induced vomiting, laxative or diuretic use, strict dieting, or vigorous exercise to induce weight loss
- Minimum average of 2 binge-eating episodes per week for at least 3 months
- Feeling of lack of control over eating behavior during eating binges
- Frenzied quality, often occurring alone and secretively
- Associated feelings of guilt, anxiety, low self-esteem, and depression
- Persistent overconcern with body shape and weight
- Symptoms and psychopathology may overlap with anorexia nervosa and eating disorder not otherwise specified, but does not occur exclusively during episodes of anorexia nervosa.

EPIDEMIOLOGY

- Onset in late adolescence to early adulthood (range: 13–28 years of age)
- Age of onset has been decreasing in recent generations.
- Females account for 85–90% of cases.
- 83% of patients have lifetime history of an anxiety disorder, 63% have a lifetime history of depression.

Prevalence

- Affects 1–3% of young females in Western countries
- Affects 4–10% of adolescent and college-aged females
- 10× more common than anorexia nervosa

RISK FACTORS

Genetics

Recent studies, including twin studies, suggest that bulimia nervosa and binge eating may be familial.

GENERAL PREVENTION

- Emphasize healthy self-esteem and body image during visits with preadolescents and adolescents
- There is some evidence that regular family dinners may have some protective effect.

ETIOLOGY

- Personality traits of low self-esteem, self-regulatory difficulties, frustration, intolerance, and impaired ability to recognize and express feelings directly have been described in patients with bulimia nervosa.
- There appears to be a small positive association between childhood sexual abuse, traumatic events, PTSD, and the development of an eating disorder, but the size and nature of this association is as yet unknown.
- May be 2 subtypes:
 - Multi-impulsive: Patient relies on bingeing and purging as a way of regulating intolerable states of tension, anger, and fragmentation.
 - Postdieting: Binge eating is precipitated by dietary restraint with compensatory behaviors maintained by reduction of guilty feelings associated with fears of weight gain.

- Neuroendocrine abnormalities may also play a role: Abnormalities in serotonergic and vagal function have been demonstrated in patients with bulimia nervosa.
- Cholecystokinin response to a meal is decreased in patients with bulimia nervosa, which may also indicate abnormal satiety signaling.
- May be abnormalities in other hormones or neurotransmitters, such as leptin, dopamine, and endorphins, but unclear if these are cause or effect

DIAGNOSIS

HISTORY

- Eating-disorder specific:
 - Eating habits
 - Rituals, behaviors
 - Body image
 - Actual and desired weights, minimum and maximum weights
 - Use of laxatives, diuretics, diet pills, emetics
 - Presence of binge or purge behavior
 - Menstrual history
 - History of exercise
 - Unease with other people watching them eat
 - Preoccupation with food/eating
 - Preoccupation with body weight/shape
 - Fear of loss of control over one's body
- General:
 - Weakness or fatigue, or hyperactivity
 - Thirst, frequent urination
 - Headaches
 - Abdominal pain, fullness, or bloating; nausea
 - Constipation or diarrhea
- Psychiatric:
 - Mood disorder
 - Substance abuse
 - Anxiety
 - Personality disorders
 - Suicidal tendencies
 - Low self-esteem
 - Feelings of ineffectiveness
- Family:
 - Medical and psychiatric histories

PHYSICAL EXAM

- Vital signs: Check for hypotension
- Weight: May be normal, overweight, or underweight
- Edema of hands and feet: Evidence of low albumin or compensatory renal sodium and water retention
- Calluses on knuckles or hands: Russell sign secondary to inducing vomiting
- Erosion of dental enamel: Exposure to gastric juices secondary to frequent vomiting
- Muscle cramps or weakness: Hypokalemia
- Special questions:
 - How much do you want to weigh?
 - How do you control your weight?
 - How do you feel about yourself?
 - How often do you vomit, use diuretics or laxatives?

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Perform a laboratory evaluation as part of the diagnostic workup. Laboratory evaluation is most useful for assessing complications; there is no diagnostic or confirmatory laboratory test for bulimia nervosa. Many patients have normal laboratory studies.
- CBC: Iron-deficiency anemia
- Electrolytes, including calcium, magnesium, and phosphate: Abnormalities may occur as a result of prolonged vomiting or use of laxatives.
- BUN and creatinine: Renal function usually normal, but BUN may be elevated secondary to dehydration or low secondary to protein loss
- Glucose: Patient may be hypoglycemic.
- Cholesterol, lipids: May be elevated in starvation states
- Amylase: Pancreatitis
- Total protein, albumin, prealbumin: Usually normal, but may be low as evidence of malnutrition
- Liver function tests: Transaminases may be mildly elevated (up to twice normal).
- ESR: Almost invariably normal; if elevated, consider occult organic process
- Total carbon dioxide: Metabolic alkalosis from vomiting or metabolic acidosis if using laxatives
- Urine toxicology screen (optional): May be positive, as this disorder often is associated with substance abuse

Imaging

- Electrocardiogram with rhythm strip: May reveal U waves associated with hypokalemia
- Consider upper GI series with small-bowel follow-through
- Consider dual-energy x-ray absorptiometry (DEXA) scan if prolonged amenorrhea, to evaluate bone density

Diagnostic Procedures/Other

Eating disorder questionnaires: Questionnaire assessments appear to be equivalent to diagnostic interview in diagnosing bulimia nervosa.

DIFFERENTIAL DIAGNOSIS

- Psychogenic vomiting
- Drug abuse
- GI obstruction
- Hiatal hernia

TREATMENT

MEDICATION (DRUGS)

- Antidepressants:
 - Decrease the binge-purge behavior
 - Improve attitudes about eating
 - Lessen preoccupation with food and weight
 - Fluoxetine (Prozac), sertraline (Zoloft), desipramine, citalopram, and fluvoxamine (Luvox) have been used with good results in patients with bulimia nervosa.
 - Effect of antidepressant may diminish over time, and patient may relapse when drug is stopped.
 - Psychotherapy combined with antidepressant therapy appears to have the best outcome.

- Response rate to alternative treatments after cognitive behavioral therapy and antidepressant first-line therapy is generally low.
- Few studies either of medication or psychotherapy have included patients under 18 years of age, so preferred therapy in these patients is still uncertain.
- Stool softeners: Often of little use for constipation; consider nonstimulating osmotic laxatives if severe
- Ondansetron: Shown in 1 study to decrease vomiting frequency; may help normalize the physiologic mechanism controlling satiation

ADDITIONAL TREATMENT

General Measures

- Outpatient psychotherapy
- Cognitive behavioral therapy (CBT):
 - More effective than interpersonal psychotherapy or behavioral therapy alone. The psychotherapy with the best evidence of efficacy
 - Helps patients determine other ways to cope with the feelings that precipitate purging and to try to correct maladaptive beliefs about body image
 - May also be done in a self-help format, which may be effective as well. Self-help manual format also showing promise
 - 1 study of CBT in adolescents showed considerable promise.
- Individual interpersonal psychotherapy also helpful in longer term
- Family treatment (to help with dysfunctional family dynamics)
- Group therapy
- During treatment, patients and their families may cause “splitting” of the hospital staff. To avoid this, always be supportive and maintain consistency in stating goals.

Additional Therapies

Physical activity was shown in 1 study to reduce the pursuit of thinness and to decrease bingeing/purging behavior. Both physical activity and yoga have shown promise as adjunct treatments.

IN-PATIENT CONSIDERATIONS

Initial Stabilization

Hospitalize in cases of:

- Hypovolemia
- Severe electrolyte disturbances
- Intractable vomiting
- Acute psychiatric emergencies (e.g., suicidal ideation, acute psychosis)
- Medical complication of malnutrition (e.g., aspiration pneumonia, cardiac failure, pancreatitis, Mallory–Weiss syndrome)
- Comorbid diagnosis that interferes with the treatment of the eating disorder (e.g., severe depression, obsessive-compulsive disorder, severe family dysfunction)
- Failure of outpatient therapy

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Reduction in binge and purge episodes may take months or years.
- Behavioral and thought disorders associated with bulimia nervosa may be of long duration.

Patient Monitoring

Signs to watch for:

- Weight loss or major weight fluctuations
- Electrolyte abnormalities
- Muscle cramps
- Fatigue
- Depression or mood disturbance
- Willful behavior or acting out

PROGNOSIS

- Very low mortality: 0.3% (but may be underestimated secondary to poor follow-up in studies)
- Most patients have episodic course with trend toward improvement.
- No studies of long-term prognosis in adolescents
- Adult studies: 5–10-year follow-up:
 - 50% made full recovery
 - 30% relapsed
 - 20% still met full criteria for bulimia nervosa
- Poor prognostic indicators:
 - Concomitant depression, personality disorder, or substance abuse
 - Frequent vomiting
 - History of substance abuse
- Good prognostic indicators:
 - High motivation for treatment
 - No concurrent disruptive psychopathology
 - Good self-esteem

COMPLICATIONS

- Pulmonary:
 - Aspiration pneumonia
 - Pneumomediastinum
- GI:
 - Pancreatitis
 - Parotid or salivary gland enlargement
 - Gastric and esophageal irritation and gastroesophageal reflux
 - Mallory–Weiss tears
 - Paralytic ileus (due to laxative abuse and hypokalemia)
 - Severe constipation (due to laxative abuse and subsequent dependence)
- Metabolic:
 - Hypokalemia (due to laxative abuse or vomiting)
 - Secondary cardiac dysrhythmias, myopathy, ileus
 - Electrolyte imbalances, including hypomagnesemia; acid–base disturbances
 - Fluid imbalances
 - Hyperamylasemia
 - Edema (secondary to hypoproteinemia or renal sodium and water retention secondary to hypovolemia and secondary hyperaldosteronism)
 - Bone loss (if amenorrhea; significantly more common in anorexia nervosa)
- Dental:
 - Enamel erosion
 - Caries and periodontal disease

CODES

ICD9
307.51 Bulimia nervosa

ICD10
• F50.2 Bulimia nervosa
• F50.9 Eating disorder, unspecified

FAQ

- Q: How do I determine if a patient has anorexia with vomiting or bulimia?
- A: The key feature of bulimia nervosa is the binge episode, which distinguishes it from anorexia nervosa. If there are not at least 2 binge eating episodes per week for at least 3 months, the diagnosis is not bulimia.
- Q: What laboratory abnormalities should I look for in my patients with bulimia?
- A: Electrolyte abnormalities, particularly hypokalemia. Patients may develop a hypochloremic metabolic alkalosis. If electrolytes are significantly abnormal, the patient should be hospitalized until they have normalized.

C1 ESTERASE INHIBITOR DEFICIENCY

Judith Kelsen

BASICS

DESCRIPTION

- A hereditary and acquired form of recurrent angioedema. The attacks are usually without urticaria.
- Has been classified into a number of types, including:
 - Hereditary angioedema (HAE) type I (transmitted as autosomal dominant)
 - HAE type II (transmitted as autosomal dominant)
 - Acquired angioedema (AAE) type I, II, III, IV
 - AAE type II
- HAE type I accounts for ~85% of the C1 esterase deficiencies and is a genetic alteration that leads to impairment of mRNA transcription or translation and, therefore, decreased enzyme synthesis. Often thought of as quantitative deficiency.
- HAE type II is a genetic alteration that leads to production of an inactive protein. May be thought of as a qualitative deficiency.
- HAE type III is an estrogen-dependent form; typical clinical features of type I with normal C1 INH level and function and normal C4. These cases are all female and have dominant mode of inheritance.
- In acquired deficiency of C1 esterase inhibitor, (C1-INH) there appears to be a normal ability to synthesize the enzyme; however, the enzyme is metabolized at an increased rate. This syndrome may be seen in patients with autoimmune diseases or malignancy and usually occurs after the 4th decade of life.
- AAE type I is a very rare syndrome usually associated with lymphoproliferative (usually B-cell) carcinomas, autoimmune diseases, and paraproteinemias. Because of the other disease processes, complement-activating factors and idiotype–anti-idiotype complexes act to increase consumption of C1-INH.

- AAE type II develops when an autoantibody is produced against the C1-INH protein. When these antibodies adhere to the C1 esterase molecule, conformational change occurs, leading to decreased function or enhanced metabolism. This type is often associated with autoimmune disorders.
- AAE type III: Associated with sex hormones (specifically in pregnancy).
- AAE type IV: Drug-induced AAE, particular associated with ACE inhibitors or angiotensin receptor blockers.
- AAE forms may be differentiated from HAE by genetic studies and serologically by significantly decreased C1q, C1r, and C1s levels, and decreased functional activity of the enzyme in AAE

EPIDEMIOLOGY

Incidence

1:50,000

Genetics

HAE type I and II are transmitted as autosomal dominant.

PATHOPHYSIOLOGY

- C1-INH is a single-chain polypeptide with a molecular weight of 108 kd. The gene has been identified on chromosome 11 (11q12–q13.1). It is involved in the control of vascular permeability.
- C1-INH is a member of the serpin family of serine protease inhibitors, produced in the liver.
- This protein inhibits the classic complement pathway by inhibiting activation of C2 and C4. In the fibrinolytic system, C1-INH inhibits formation of plasmin, the activation of C1r and C1s, and the formation of bradykinin from kininogen.
- Deficiency of this enzyme results in activation of the classic complement system along with fibrinolysis and kinin formation, which is felt to participate in the production of angioedema.
- Kinin is known to cause similar histologic lesions to histamine, but without pruritus.
- The complement activation leads to production of C2b, a product that also has kininlike activity, and bradykinin, a vasoactive peptide that may also participate in the formation of angioedema.

DIAGNOSIS

HISTORY

- Presentation: Patients with HAE usually present in the 2nd decade of life with angioedema involving the subcutaneous tissues (mostly involving the extremities).
- Attacks can be precipitated by trauma, infection, or pregnancy.
- Classically the edema develops gradually over several hours and increases slowly over 12–36 hours.
- However, patients may experience abdominal attacks with sudden and very severe onset without visible edema.
- GI effects: Predominant symptom in 25% of patients: Angioedema involving the GI tract may lead to severe pain, vomiting, and diarrhea as well as ascites. Secondary to transient edema of small bowel resulting in intestinal obstruction, ascites and hemoconcentration.
- Respiratory complications: 2 of 3 patients will have orofacial or laryngeal swelling.
- Hives: The edema usually occurs without evidence of inflammation; rash resembles urticaria (however, episodes of urticaria have also been documented).
- The variability of clinical manifestations, even among individuals with the same genetic mutation, is striking, implicating nongenetic factors or other genes as possible mediators of clinical presentation.
- Emesis
- Diarrhea
- Hypotension from extravasation of plasma into the skin
- Hemoconcentration
- Azotemia
- CNS complaints, including headache, hemiparesis, and seizures, may be triggered by trauma or stress.
- AAE presents similarly, in the same way but usually in the 4th decade of life; not associated with a familial history.

PHYSICAL EXAM

Depending on the clinical features, angioedema causes pale, well-demarcated, tense, brawny, nonpruritic, and nonpitting single or multiple localized swellings. These may involve the periorbital tissues, genitalia, face, tongue, lips, larynx, extremities, and GI tract.

DIAGNOSTIC TESTS & INTERPRETATION**Lab**

- C1-INH concentration
- C1-INH activity
- C4 concentration: Low serum level
- C4D: Cleavage product of C4, low even when C4 is normal
- C1q concentration (usually lower in patients with AAE)

DIFFERENTIAL DIAGNOSIS

- IgE mediated:
 - Episodic angioedema
 - Allergic reactions to food and drugs
 - Physically induced angioedema
- Hypocomplementemic HAE
- Idiosyncratic:
 - NSAIDs
 - Other drugs
- Lupus erythematosus
- Idiopathic

**TREATMENT****ADDITIONAL TREATMENT****General Measures**

- During an acute episode, management focuses on adequate respiratory and fluid resuscitation and the treatment of pain.
- In HAE, acute attacks are treated with replacement of the C1-INH with IV concentrates. Fresh frozen plasma may also be used.
- A recent study has demonstrated that the time to onset of symptom relief is an appropriate end point for assessing the efficacy of C1-INH therapy.
- For prophylaxis, androgens (such as danazol and stanozolol) are used in postpubertal patients with HAE of both types. These androgens stimulate the synthesis of C1 inhibitor, and although the level of activity is not normalized, it is increased sufficiently to be clinically efficacious.

- In prepubertal children, androgens are used only in those with severe attacks; purified C1-INH can be used if available. Antifibrinolytics should be used in prepubertal children over androgens.
- Patients should avoid estrogen OCP or use with caution.
- For patients who do not tolerate androgens, tranexamic acid and ϵ -aminocaproic acid (antifibrinolytic inhibitors or plasmin activity) may be used, although they carry the risk of significant side effects.
- AAE type I patients may respond to epinephrine for reversal of airway compromise.
- AAE type I requires an intensive search for malignancy, although this form of AAE occasionally appears before the development of clinical signs of the malignancy.
- Androgens are also effective in preventing attacks in individuals with this syndrome.
- AAE type II requires immunosuppression to decrease formation of the autoantibody.
- These patients may respond to C1-INH concentrate.
- Androgen treatment has not led to good clinical response.
- Prophylaxis prior to dental procedures or surgery: High-dose danazol
- Potential treatment: Plasma kallikrein antagonists
Bradykinin antagonists
Serine protease inhibitors
- Genetic counseling: Given autosomal dominant inheritance, family counseling is important.

IN-PATIENT CONSIDERATIONS**Initial Stabilization**

Therapy is divided into management of the acute attack, maintenance therapy for HAE, and more specific interventions for those with AAE.

**CODES****ICD9**

- 277.6 Other deficiencies of circulating enzymes
- 279.8 Other specified disorders involving the immune mechanism

ICD10

- D84.1 Defects in the complement system

FAQ

- Q: What are other causes of angioedema?
- A:
 - Classic allergic reactions to food and drugs
 - Physically induced angioedema
 - IgE-mediated episodic angioedema
 - Idiosyncratic reactions to nonsteroidal anti-inflammatory and other drugs
 - Lupus erythematosus
 - Idiopathic causes
- Q: What are the usual precipitating factors in causing reactions?
- A: Recurrent episodes of angioedema, abdominal pain, nausea, and vomiting that occur spontaneously or after local trauma, especially to the upper respiratory tract:
 - Vigorous exercise
 - Emotional stress
 - Menstruation

CAMPYLOBACTER INFECTIONS

Matthew P. Kronman

Eric J. Haas (5th edition)

Louis M. Bell, Jr. (5th edition)

BASICS

DESCRIPTION

- *Campylobacter* is a motile, curved, microaerophilic, non-lactose-fermenting, oxidase-positive Gram-negative rod that requires oxygen and carbon dioxide for optimal growth.
- Three main *Campylobacter* species involved in human infections include *C. jejuni* and *C. coli* (which cause enteritis) and *C. fetus* (implicated in systemic illness). Rarer human pathogens include *C. concisus*, *C. curvus*, *C. hyointestinalis*, *C. lari*, *C. rectus*, *C. sputorum*, and *C. upsaliensis*.

EPIDEMIOLOGY

- *Campylobacter* infections are among the most common causes of enteritis worldwide, with the highest attack rates observed in children <4 years.
- More than 2 million cases of *Campylobacter* infection are estimated to occur in the U.S. annually.
- Estimated rates of *Campylobacter* infection vary widely worldwide. In the U.S., the estimated annual rate is 12.7/100,000, and the highest rate is in New Zealand at 396/100,000.
- 30–100% of chickens, turkeys, and water fowl are infected asymptotically. Other reservoirs of infection include swine, cattle, sheep, horses, rodents, household pets (especially young pets), and contaminated water and milk.
- Transmission of disease is by the fecal-oral route from contaminated food and water or by direct contact with fecal material from animals or persons infected with the organism.
- 40% of *Campylobacter* enteritis is estimated to be attributable to chicken consumption; other risk factors for *Campylobacter* enteritis include use of acid-suppressive medications and consumption of chicken prepared outside the home.
- Frequent exposure to *Campylobacter* (e.g., among food handlers and abattoir workers), may protect against disease.
- Person-to-person transmission of *C. jejuni* has been reported when the index cases were young children who were incontinent of feces; vertical transmission from mother to neonate has also been reported.
- Asymptomatic hospital personnel or food handlers have not been implicated as sources.
- The peak rate of isolation occurs in the warmer months of the year (late summer, early fall).
- *Campylobacter* is the most common cause of travelers' diarrhea in Southeast Asia, accounting for a third of all infections.

- Compared with 1996–1998, foodborne illnesses caused by *Campylobacter* in the U.S. decreased 30% in 2009.
- Resistance to fluoroquinolones and macrolides is becoming increasingly common—both ranging from ~20–40% in the U.S. and as high as >80% in some parts of the world—and thought to be related to both human and agricultural use of antibiotics.

GENERAL PREVENTION

- Hand washing after contact with animals or animal products, cleaning cooking utensils and cutting boards after contact with raw poultry, proper cooling and storage of foods, pasteurization of milk, and chlorination of water supplies will decrease the overall risk for infection.
- Diapered infants with symptomatic infection should be excluded from child care until resolution of diarrhea.
- In the hospital setting, contact precautions are recommended for infected infants and children who are incontinent of stool and should be maintained until the patient receives at least 48 hours of antibiotic treatment.
- Certain *C. jejuni* strains with decreased risk of secondary Guillain-Barré syndrome (GBS) are being considered as candidates for vaccine development.

PATHOPHYSIOLOGY

- *Campylobacter* spp. possess 1 or 2 flagella that provide the organism's motility and facilitate intestinal colonization.
- *C. jejuni* adheres to epithelial cells and mucus, secretes cytotoxins (which play a role in the development of watery diarrhea), can invade intestinal epithelial cells, and induces an inflammatory ileocolitis.
- As few as 500 organisms may be required to produce infection.
- Bacteremia, although uncommon, can occur, especially in the neonate and immunocompromised host; *C. fetus* is the species most likely to be isolated. *C. fetus* can also cause neonatal meningitis.
- *C. upsaliensis*, *C. lari*, and *C. hyointestinalis* have been identified in immunocompromised individuals and are usually associated with a self-limiting enteritis but can occasionally cause systemic illness.

DIAGNOSIS

HISTORY

- Fever, abdominal pain, bloody diarrhea? Illness is characterized by fever, abdominal pain, and bloody diarrhea. Symptoms can last for 24 hours and be indistinguishable from a viral gastroenteritis, or can be relapsing, thus mimicking inflammatory bowel disease.
- Abdominal pain, diarrhea, malaise, and fever: Signs and symptoms of *C. jejuni* infection.
- Duration of symptoms? Incubation period is 1–7 days and is usually self-limited by 5–7 days.
- Inflammatory ileocolitis? The most common manifestation in children.
- If the infection establishes a chronic phase (20% of infected patients), symptoms may mimic inflammatory bowel disease and other immunoreactive complications may occur.

Exposures:

- Inadequately cooked poultry or poultry prepared outside the home? Chickens are asymptomatic carriers.
- Exposure to unpasteurized milk products? Unpasteurized milk is a source of *Campylobacter* infection.
- Well water used? Contaminated water serves as a reservoir.
- New pets or young pets? Young animals (dogs and cats) may be reservoirs of infection.

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other

- Examination of fecal specimen for darting motility of *C. jejuni* by darkfield or phase-contrast microscopy, if examined within 2 hours of passage, can permit presumptive diagnosis.
- Stool culture: Can be used, but selective media (Skirrow, Butzler, or campy-BAP), microaerophilic conditions, and an incubation temperature of 42°C must be used to isolate *Campylobacter* species.
- DNA-based testing: Development of this diagnostic tool will improve the ability to detect and differentiate *Campylobacter* spp. much faster than the current gold standard of stool culture.

ALERT

Not all bacterial colitis presents with blood or mucus in the stool. Therefore, increased suspicion for bacterial colitis should exist if the diarrhea is prolonged or the patient has significant environmental exposures.

DIFFERENTIAL DIAGNOSIS

- *Campylobacter* infection should be considered in all patients with a diarrheal illness, especially those with a history of bloody or mucous stools, recurrent gastritis, or in immunocompromised hosts.
- Other important intestinal and foodborne bacterial pathogens include *Aeromonas*, *C. difficile*, *E. coli*, *Listeria*, *Plesiomonas*, *Salmonella*, *Shigella*, *Vibrio* species, and *Yersinia*.
- Viral and parasitic pathogens to consider include Rotavirus, Norovirus, Adenovirus types 40 and 41, *Giardia*, *Cyclospora*, and *Cryptosporidium*.

TREATMENT

MEDICATION (DRUGS)

- Immunocompetent children with diarrhea usually improve with rehydration alone.
- Select patient populations (HIV and other immunocompromised individuals, pregnant women) may benefit from early therapy.
- If treated early in the course of enteritis (<4 days), erythromycin or azithromycin appear to be effective in eradicating the organism from the stool within 2–3 days.
- Ciprofloxacin, tetracycline, aminoglycosides, and imipenem are alternative antimicrobials if resistant or bacteremic strains are present, although fluoroquinolone resistance in particular is rising.
- Treatment duration for enteritis is 5–7 days.
- Appropriate treatment of bacteremia should be based on antimicrobial susceptibility testing.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- When treated, symptoms should improve in 2–3 days.
- In the untreated patient, the median excretion of organism is to 2–3 weeks, but can be as long as 3 months. Asymptomatic carriage is uncommon in humans.

PROGNOSIS

For patients with enteritis, the prognosis is very good, regardless of whether antibiotic treatment is given.

COMPLICATIONS

- Postinfectious immunologic complications include reactive arthritis, GBS, Miller-Fisher syndrome (a GBS variant predominantly affecting eye movement), Reiter syndrome, and erythema nodosum.
- GBS is estimated to affect 1 in 1000 patients with *Campylobacter* infection.

- *C. jejuni* is the most frequently identified cause of GBS with serotypes O:19 and O:41, and is responsible for up to 40% of GBS cases.
- HLA-B27 antigen is associated with reactive arthropathy. The estimated incidence of reactive arthritis after *Campylobacter* infection ranges from 0% to 7%.
- Seizures may develop in young children with enteritis and high fevers.
- A typhoidlike syndrome and meningitis have also been reported in patients with *Campylobacter* infection.
- Spontaneous abortion and hemolytic-uremic syndrome have been described with *C. upsaliensis*.

CODES

ICD9

008.43 Intestinal infection due to campylobacter

ICD10

A04.5 Campylobacter enteritis

FAQ

- Q: Is treatment necessary if the child is asymptomatic by the time the *Campylobacter* is isolated as the pathogen causing the enteritis?
- A: No treatment is needed in this situation. Therapy for symptomatic patients, although it may be of benefit, has not been proven efficacious.
- Q: Are there any risks of *Campylobacter* infection to pregnant patients?
- A: Women infected symptomatically or asymptotically may experience recurrent abortions or preterm deliveries. Life-threatening infections to the fetus or newborn are also possible.
- Q: Can one develop immunity to *Campylobacter* infections?
- A: Immunity to *C. jejuni* is acquired after 1 or more infections. For children living in endemic areas, effective natural immunity is a result of significant repeated early exposure with a progressive decrease in the illness/infection ratio as age increases.
- Q: What is the relationship between GBS and *C. jejuni* infection?
- A: Many strains of *C. jejuni* have surface glycolipids that are similar to gangliosides, which are abundant in the central and peripheral nervous systems. Antibody formation from this infection binds to the gangliosides, causing the demyelinating process characteristic of GBS.

CANDIDIASIS

Michelle Dunn

Theoklis Zaoutis (5th edition)

BASICS

DESCRIPTION

A spectrum of diseases caused by *Candida* species (yeasts):

- In immunocompetent children, most candidiasis is manifested as superficial mucosal (oropharyngeal candidiasis or thrush) and cutaneous (diaper dermatitis) infection.
- In immunocompromised children, *Candida* may cause invasive and disseminated disease.

EPIDEMIOLOGY

Incidence

Incidence of nosocomial *Candida* infections has risen over the past 20 years, and *Candida* spp. are currently the 3rd most commonly recovered isolates in cases of nosocomial bloodstream infection in premature infants and older children.

RISK FACTORS

Surgery, central venous catheters, prematurity, neonates, total parenteral nutrition, transplant recipients, malignancy, neutropenia, corticosteroid use, antibiotic therapy, and burn patients

GENERAL PREVENTION

- Sterilize bottle nipples and toys to prevent reinoculation of oral candidiasis.
- Avoid unnecessarily long courses of broad-spectrum antibiotics.
- Maintain IV catheters and catheter–skin insertion sites appropriately.
- Some evidence exists for using prophylactic fluconazole in high-risk preterm infants

ETIOLOGY

- Neonatal colonization is acquired from infected vaginal mucosa during birth. Incidence of colonization increases with age of the infant. Transmission also occurs during nursing from the mother's breast or from imperfect sterilization of bottle nipples. Colonization is an important risk factor for invasive infection.
- *C. albicans* is the most common species isolated in children; the remaining infections are caused by other *Candida* spp., including *C. glabrata*, *C. parapsilosis*, and *C. tropicalis*.

COMMONLY ASSOCIATED CONDITIONS

Candida spp. may cause disease at any site.

- Mucosal candidiasis:
 - Oropharyngeal candidiasis (thrush) occurs in up to 40% of healthy newborns. Patches of white, curdlike material are visible on the buccal and gingival mucosa. It may cause mouth pain and poor nursing. In older children, it is associated with the use of antibiotics or immunosuppressive drugs, conditions of endocrine or immune dysfunction, and malignancy.

- Candidal glossitis occurs secondarily to antibiotic therapy. The tongue is smooth and erythematous, and patients complain of glossodynia (painful tongue). Perlèche (angular cheilosis) results from chronic licking of the corners of the mouth and is characterized by fissuring, erythema, and pain.
- Esophageal candidiasis occurs in HIV-infected patients and those on immunosuppressive therapy; 30% have associated thrush.
- Cutaneous candidiasis:
 - Diaper dermatitis is most common during infancy because of predisposing factors found with diaper use.
 - Intertriginous candidiasis is characterized by a confluent, erythematous, weeping rash with a scaling edge found at skin folds: Axillae, groin, gluteal folds, intramammary region, interdigital spaces, and umbilicus. Predisposing factors in healthy patients include chronic moisture, recent antibiotic use, and obesity.
- Vaginal candidiasis: Characterized by vaginal discharge (curdlike or mucoid), pruritus, vulvar burning, and dysuria. Oral contraceptives, antibiotics, pregnancy, corticosteroids, and immunodeficiency are predisposing conditions. Classified as uncomplicated or complicated:
 - Uncomplicated: 90% of patients; condition is mild to moderate; frequency is sporadic; organism is *C. albicans*; the host is immunocompetent.
 - Complicated: 10% of patients; presence of any one of the following factors defines a complicated infection: Severe, recurrent infection by non-*albicans Candida* spp.; or predisposing host factor
 - The reliability of self-diagnosis is poor (<50% correct); therefore, potassium hydroxide (KOH)/pH testing is suggested for diagnosis.
- Congenital candidiasis: Cutaneous infection acquired from contaminated amniotic fluid that is usually treated with topical antifungal agents and has an excellent prognosis
- Invasive candidiasis:
 - Defined as candidemia and disseminated candidiasis
 - Occurs in the immunocompromised host. Risk factors include prematurity, malignancy, immunodeficiency syndromes, diabetes mellitus, broad-spectrum antibiotic therapy, corticosteroids, chemotherapy, hyperalimentation, indwelling catheters, recent complex surgery, and stem cell or organ transplantation.
 - The most frequent sites of involvement are the GI tract, lungs, kidneys (pyelonephritis, mycetoma), liver, spleen, eyes, and brain (meningoencephalitis). Fungal sepsis may occur. Peritoneal, urinary tract, and cardiac valve candidal infections are most often related to instrumentation or catheterization in the immunocompromised host.

DIAGNOSIS

HISTORY

- Recurrent infection:
 - In oral thrush, reinfection may occur from nipples, pacifiers, or toys (see “General Prevention” and “Alert”).
 - In recurrent vaginitis, bacterial or non-*albicans Candida* spp. infections are possible.
- Recent antibiotic use: Oral thrush often occurs in infants, but may occur in normal older children after treatment with systemic antibiotics.
- Predisposing conditions: Systemic dissemination of infection is more likely with impaired immunity.
- Visual changes or discomfort: Features of endophthalmitis include eye pain, blurred vision, scotomata, and photophobia.

PHYSICAL EXAM

- Oral lesions: Buccal or lingual mucosa, gingiva, and tongue lesions have a characteristic white, friable pseudomembrane that when scraped away, reveals reddened, denuded, and sometimes ulcerated mucosa.
- Rash:
 - The rash of monilial diaper dermatitis is initially scattered.
 - Erythematous papules progress and coalesce into a deeply erythematous, weeping, confluent rash with a scaling border and satellite lesions.
 - In neonates with congenital candidiasis, skin findings include vesicles, pustules, or a diffuse macular rash.
 - Patients with invasive candidiasis may also present with a diffuse, erythematous rash.

DIAGNOSTIC TESTS & INTERPRETATION

Dilated retinal examination (by an ophthalmologist): Endophthalmitis, a sight-threatening complication, should be excluded in all patients with candidemia.

Lab

- Direct light microscopic examination of specimen:
 - Clinical diagnosis of mucosal, cutaneous, and vaginal candidiasis can be confirmed by microscopic examination of material scraped gently from lesions.
 - KOH preparation (10% or 20% potassium hydroxide) allows visualization of the long, branching, hyphae of *C. albicans*.
 - Vaginal pH remains normal (<4.5) with vaginal candidiasis.

- Fungal culture:
 - *Candida* spp. can be isolated from culture of mucosal or cutaneous scrapings, blood, urine, CSF, bone marrow, tissue biopsy, abscess aspirate, and bronchoalveolar lavage fluid.
 - However, the sensitivity of blood culture is only 50–60% in patients with invasive candidiasis.

Imaging

CT scan, ultrasound, and echocardiogram: Important to identify deep organ lesions (liver, spleen, brain, kidney, or heart) associated with disseminated infection

DIFFERENTIAL DIAGNOSIS

- Oral lesions:
 - Aphthous stomatitis
 - Acute necrotizing gingivitis
 - Herpes gingivostomatitis
 - Other viral causes of stomatitis (e.g., coxsackievirus)
- Diaper dermatitis: Atopic, seborrheic, bacterial, or occlusional
- Intertriginous infections: Seborrheic and atopic dermatitis
- Vaginitis
- Congenital candidiasis:
 - Viral infections (especially herpes viruses)
 - Bacterial infections
 - Benign neonatal skin conditions
- Invasive candidiasis: Bacterial infection or other fungal infection
- Chronic mucocutaneous candidiasis: HIV

TREATMENT

MEDICATION (DRUGS)

- Oral candidiasis: Nystatin suspension until 2 days after lesions have cleared. In older patients, nystatin as a swish-swallow suspension or in oral tablet form for >7 days is effective. Clotrimazole lozenges are also effective; 10 mg dissolved in mouth 5 times daily for 7 days.
 - Fluconazole and ketoconazole are effective for infections that are persistent or occur in immunocompromised hosts. Azole-resistant *C. albicans* has been described in HIV-infected individuals with recurrent infection.
- Esophageal candidiasis:
 - A therapeutic trial with fluconazole for patients with presumed esophageal candidiasis is a cost-effective alternative to endoscopy;
 - Symptoms should resolve within 7 days after the start of therapy.
 - A 14–21-day course is recommended. Itraconazole solution and IV amphotericin B are acceptable alternatives.
- Cutaneous or intertriginous candidiasis and candidal diaper dermatitis:
 - Both are treated by keeping the area dry and using nystatin (100,000 U/g q.i.d.) until the rash has cleared.
 - Topical regimens of clotrimazole 1%, miconazole 2%, ketoconazole 2%, and econazole 1% are also effective.
- Uncomplicated vaginal candidiasis:
 - Topical agents are highly effective in uncomplicated infections (cure rates >80%): clotrimazole, miconazole, butoconazole, and terconazole (dose varies with 1-, 3-, or 7-day treatment).
 - Oral agents are also effective: Fluconazole (10 mg/kg up to 150 mg as a single dose), ketoconazole (400 mg daily for 5 days), and itraconazole (200 mg b.i.d. for 1 day or 200 mg daily for 3 days)
- Complicated vaginal candidiasis:
 - Extend antimycotic therapy to 7–14 days
 - Non-*albicans* species of *Candida* usually respond to topical boric acid (600 mg/d for 14 days). Azole-resistant *C. albicans* infections are extremely rare in the immunocompetent host.
- Recurrent vaginitis (more than 4 episodes of proven infection during a 12-month period):
 - Usually caused by azole-susceptible *C. albicans*
 - Induction therapy with 2 weeks of a topical or oral azole is followed by a maintenance regimen for 6 months.
 - Suitable maintenance regimens include fluconazole (150 mg weekly), ketoconazole (100 mg daily), itraconazole (100 mg every other day), or daily therapy with a topical azole.
- Systemic or disseminated candidiasis:
 - Begin treatment in hospital because of severity of illness, underlying disease process, and need for the IV route of drug administration.
 - Address predisposing factors (e.g., removal of indwelling catheters).
 - Antifungal agents commonly used in children include amphotericin B, fluconazole, or the combination of fluconazole plus amphotericin B (with the amphotericin B administered for the 1st 5 or 6 days only).
- Fluconazole may be used in those infected with a *Candida* sp. known to be fluconazole susceptible. Many *C. glabrata* and *C. krusei* are resistant.
- Flucytosine could be considered in combination with amphotericin B for more severe infections. It should not be used alone because resistance quickly develops.
- Lipid-based amphotericin B: 3–6 mg/kg/d IV. Appropriate for patients who are refractory to, intolerant of, or at high risk of being intolerant of conventional amphotericin B preparations
- Intolerance to conventional amphotericin B is usually defined as initial renal insufficiency (creatinine clearance <25 mL/min), significant rise in creatinine during therapy (to 2.5 mg/dL in adults or 1.5 mg/dL in children), or severe acute administration-related toxicity. The toxicity of amphotericin (rigors, anemia, thrombocytopenia, and renal failure) requires close monitoring and may limit its use.

- Caspofungin, only available IV, is approved for candidal esophagitis, candidemia, and other invasive candidal infections.
- Duration of therapy is longer for candidal meningitis (4 weeks), endophthalmitis (6–12 weeks), endocarditis (>6 weeks following surgical therapy), and osteomyelitis (6–12 months).

ALERT

Pitfalls:

- Failure to eliminate source of reinfection. Recurrent thrush in a breast-fed infant may indicate *C. albicans* colonization of the mother's nipples; this can be eliminated by treatment of the nipples with nystatin cream.
- Failure to consider that symptoms of persistent vaginitis may be caused by non-*albicans Candida* spp. or by bacteria (see "Vaginitis")
- Failure to maintain a high index of suspicion for invasive candidiasis in an immunocompromised patient. Persistent fevers despite antibiotic therapy, diffuse rash, and visual complaints are important clues.

CODES

ICD9

- 112.0 Candidiasis of mouth
- 112.89 Other candidiasis of other specified sites
- 771.7 Neonatal *Candida* infection

ICD10

- B37.0 Candidal stomatitis
- P37.5 Neonatal candidiasis
- B37.9 Candidiasis, unspecified

FAQ

- Q: When should an older child with thrush be worked up for possible immunodeficiency?
- A: Thrush in the older child is usually caused by recent antibiotic or steroid treatment. If no apparent cause is found, an immunologic evaluation that includes HIV testing should be considered.

CARBON MONOXIDE POISONING

Kevin Osterhoudt

BASICS

DESCRIPTION

- Carbon monoxide (CO) is an odorless gas produced via incomplete combustion of carbonaceous fuels.
- CO poisoning occurs when carboxyhemoglobin and CO accumulation leads to impaired physiologic function.

EPIDEMIOLOGY

CO poisoning is the leading cause of death by poisoning within the US.

Incidence

- More than 136,000 CO exposures were reported to the American Association of Poison Control Centers in 2009, with ~1/3 of such exposures occurring in children.
- Seasonal cold weather leads to increases in incidence of exposure.

GENERAL PREVENTION

- Furnaces should receive regular maintenance by skilled technicians.
- Automobiles, gas-powered machinery, and nonelectrical space heaters should only be used with proper ventilation.
- CO detectors should be installed within living spaces.

PATHOPHYSIOLOGY

- On inhalation, some CO binds to hemoglobin to form carboxyhemoglobin.
- Carboxyhemoglobin does not carry oxygen.
- Carboxyhemoglobin produces an allosteric leftward shift of the oxyhemoglobin dissociation curve.
- Carboxyhemoglobin elimination half-life:
 - ~4 hours in room air
 - 1–2 hours in 100% oxygen
 - 20 minutes in 100% oxygen at 3 atmospheres
- CO interacts with cellular proteins, leading to impaired mitochondrial function.
- CO is a source of oxidative stress and poisoning may begin a cascade of inflammatory vasculitis within the CNS.

ETIOLOGY

- Common sources of CO exposure include:
 - Automobile or boat exhaust
 - Smoke inhalation from house fires
 - Oil, gas, or kerosene space heaters or cooking stoves
 - Portable electricity generators and construction equipment
 - Faulty home furnaces
- The solvent methylene chloride is metabolized to CO by the liver after ingestion, inhalation, or dermal absorption.

COMMONLY ASSOCIATED CONDITIONS

Victims of house fires may suffer from thermal injury and/or cyanide poisoning.

DIAGNOSIS

Many emergency medical services crews carry CO detectors.

HISTORY

- Health of family members?
 - CO is an environmental gas that often sickens multiple household members.
- Use of furnace or space heaters?
 - May suggest source of exposure
- Time of exposure?
 - Carboxyhemoglobin levels must be interpreted with consideration to their timing.
- Duration of exposure?
 - Toxicity is related to both magnitude and duration of exposure.
- Loss of consciousness?
 - Syncope appears to be the best clinical predictor of delayed neurologic sequelae.
- Signs and symptoms:
 - Mild CO intoxication:
 - Malaise
 - Nausea
 - Light-headedness
 - Headache
 - Vomiting
 - Moderate to severe CO intoxication:
 - Confusion
 - Syncope
 - Weakness
 - Angina

PHYSICAL EXAM

- Soot on nasal mucosa: Suggests possibility of thermal pulmonary injury
- Hypotension: Suggests severe CO poisoning
- Cherry red skin: This classic sign is mostly a postmortem finding.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Co-oximetry: Allows quantitation of carboxyhemoglobin
- Arterial blood gas: Allows accurate assessment of oxygenation
- Hemoglobin quantitation: The percent carboxyhemoglobin concentration must be considered in relation to the total hemoglobin.
- Serum bicarbonate: A wide anion gap metabolic acidosis suggests the accumulation of lactate, which may result from severe CO poisoning or concomitant cyanide poisoning.
- Creatine kinase: CO poisoning victims are susceptible to rhabdomyolysis.
- Troponin: CO poisoning may lead to myocardial injury.
- ECG: Hypoxemia and metabolic poisoning may lead to cardiac ischemia.

Imaging

- Neuroimaging:
 - Not routinely helpful in acute management
- Globus pallidus and subcortical white matter changes may be seen after severe or chronic CO poisoning.

ALERT

Pitfalls:

- Pulse oximetry frequently overestimates the percentage of oxyhemoglobin.
- Smokers may have carboxyhemoglobin levels up to 10%.
- Hemolysis, or the presence of fetal hemoglobin, may lead to mild elevation of carboxyhemoglobin.
- In-hospital carboxyhemoglobin levels are not good at predicting risk of delayed neurologic sequelae.

DIFFERENTIAL DIAGNOSIS

- Influenza
- Gastroenteritis
- Vasomotor syncope
- Asphyxia
- Stroke

TREATMENT

General Measures

- Recognize CO exposure.
- Remove patient from source of CO.

ADDITIONAL TREATMENT

- Consider hyperbaric oxygen treatment referral to prevent delayed neurologic sequelae.
- Relative indications:
 - Loss of consciousness
 - Seizures
 - Pregnancy
 - Persistent neurologic symptoms
 - CO concentration >25%
- Contraindications:
 - Concurrent illness or injury requiring ongoing acute care
 - Unvented pneumothorax
 - Lack of accessible hyperbaric oxygen chamber
- Complications:
 - Barotitis media
 - Tympanic membrane rupture
 - Claustrophobic anxiety
 - Seizure
 - Pneumothorax

ALERT

Pitfalls:

- Failure to differentiate CO poisoning from winter viral illness
- Syncope may be hard to discern in young infants
- Undue delay in hyperbaric oxygen therapy, which is most effective in 1st 6 hours after exposure

ISSUES FOR REFERRAL

- Neuropsychological testing may benefit individuals with perceived neurocognitive deficits.
- Cardiac evaluation for those with myocardial ischemia

IN-PATIENT CONSIDERATIONS

Initial Stabilization

Administer 100% oxygen at least until patient is asymptomatic and carboxyhemoglobin level is <5–10%.

Admission Criteria

- Perceived merit of hyperbaric oxygen therapy
- Persistent neurologic symptoms
- Evidence of myocardial ischemia
- Associated injuries that merit hospitalization

Discharge Criteria

- Conclusion of hyperbaric therapy
- Stable cardiovascular and neurologic systems after elimination of excess carboxyhemoglobin

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Delayed neurologic sequelae may develop 2–40 days after exposure.

PROGNOSIS

- Acute mortality appears to be caused by carboxymyoglobin formation and ischemic ventricular dysrhythmia.
- Patients stable on presentation to medical care have a good prognosis for recovery.
- Delayed neurologic sequelae may manifest in as many as 10–40% of patients after a CO-mediated syncope episode.

COMPLICATIONS

- Death
- Delayed neurologic sequelae, e.g.:
 - Neurocognitive deficits
 - Personality changes
 - Parkinsonism

CODES

ICD9

986 Inhalation of carbon monoxide

ICD10

- T58.94XA Toxic effect of carbon monoxide from unspecified source, undetermined, initial encounter
- T58.94XD Toxic effect of carbon monoxide from unspecified source, undetermined, subsequent encounter
- T58.94XS Toxic effect of carbon monoxide from unspecified source, undetermined, sequela

FAQ

- Q: At what carboxyhemoglobin level should hyperbaric oxygen therapy be recommended?
- A: In practice, most dissociation of carboxyhemoglobin occurs with administration of normal-pressure oxygen before hyperbaric therapy can be administered.
- The advocated value of hyperbaric oxygen is to limit cerebral ischemic reperfusion injury in an effort to ameliorate delayed neurologic sequelae.
- Carboxyhemoglobin levels may not directly correlate in this risk stratification, and the occurrence of syncope or seizure may be used as a surrogate marker.
- Currently, patients with CO concentrations >25% may be considered as potential candidates for hyperbaric oxygen.
- Q: In a household, which family member is at greatest risk of CO poisoning?
- A: Smaller and younger children have greater minute ventilation rates and may attain higher carboxyhemoglobin concentrations at a given exposure level.
- It is unclear whether it is possible that developing brain tissue is more susceptible to the deleterious effects of CO poisoning.

CARDIOMYOPATHY

Nelangi Pinto

BASICS

DESCRIPTION

Cardiomyopathy (CM) is defined as a disease of the heart muscle which results in impaired function (systolic, diastolic, or both). It is classified based on structural and functional abnormalities:

- Dilated cardiomyopathy (DCM): The key finding in DCM is impairment of ventricular systolic function with cardiac dilation. Predominantly involves the left ventricle (LV), and manifests as CHF.
- Hypertrophic cardiomyopathy (HCM): Excessive thickening of the LV that is not secondary to load conditions such as aortic stenosis or hypertension. Up to 20–25% of the patients exhibit LV outflow tract obstruction.
- Restrictive cardiomyopathy (RCM): A myocardial disease in which there is impairment of ventricular diastolic function (or relaxation) from an increased stiffness of the ventricle. This results in decreased ventricular filling while systolic function is generally preserved.
- Left ventricular noncompaction (LVNC): A disease where the myocardium of the LV has not completely compacted resulting in persistence of trabeculations and myocardial dysfunction.

EPIDEMIOLOGY

Incidence

- Overall incidence of cardiomyopathy is 1–2 cases per 100,000 people. There is a peak incidence during the 1st year of life and a 2nd peak in adolescence.
- DCM: Studies have reported the incidence to range from 0.3–2.6 cases per 100,000 people.
- HCM: Reported incidence is 0.3–0.5 cases per 100,000 people.

Prevalence

- DCM: 36 cases per 100,000 people
- HCM: Estimated to be 10–20 cases per 100,000 people
- RCM: Least common form of CM (<5%)
- LVNC: ~9% of CM cases

RISK FACTORS

Genetics

- DCM: Familial DCM accounts for ~20% of cases.
 - Autosomal dominant inheritance remains the most common pattern. Although no specific gene has been identified as the cause of familial DCM, 6 genes have been localized in different family cohorts.
 - DCM has also been seen in association with diseases of X-linked inheritance, such as Duchenne and Becker muscular dystrophy, and Barth syndrome.
 - May also be inherited via mitochondrial DNA, with differing penetrance.
- HCM: ~60% of reported cases are thought to be inherited. Traditionally, HCM is inherited in an autosomal dominant pattern with incomplete penetrance.
- RCM: Idiopathic cases may have a familial occurrence and may be associated with a skeletal myopathy. An autosomal dominant form of the disease with variable penetrance has been associated with Noonan syndrome.
- LVNC: Familial in 20–30%. May be X-linked, mitochondrial, autosomal recessive or dominant

ETIOLOGY

- DCM: There are many etiologies for DCM. Etiology is identified only ~30% of the time:
 - Of known causes, the most common is myocarditis (coxsackievirus B, echovirus, adenovirus). DCM can also occur from toxin exposure (anthracyclines), ischemic coronary artery disease (anomalous left coronary artery from the pulmonary artery, coronary aneurysms), and chronic tachyarrhythmias
 - Can occur as a finding associated with another disease or syndrome. These include X-linked muscular dystrophies, inborn errors of fatty-acid oxidation, disorders of mitochondrial oxidative phosphorylation, nutritional deficiencies, primary and secondary carnitine deficiency.
 - It may be familial and genetically inherited.
 - DCM is most commonly idiopathic.
- HCM: Etiology is known about 25% of the time. Often genetically inherited. Caused by myocyte hypertrophy with fibrillin disarray.
- RCM: Most commonly idiopathic, although known causes include:
 - Systemic disease such as lupus erythematosus, sarcoidosis, amyloidosis, infiltrative diseases (Gaucher disease, Hurler syndrome), storage diseases (Fabry disease), carcinoid syndrome, and radiation-induced fibrosis
 - Familial forms of RCM

DIAGNOSIS

In the early stages of all 3 forms of cardiomyopathy, the symptoms are nonspecific and can mimic other disease processes. The cardiac examination can be completely normal. Therefore, those patients who raise suspicion for this disease either by family history or clinical presentation should be carefully evaluated.

HISTORY

- DCM: Symptoms usually develop slowly although they may also be of sudden onset:
 - Irritability
 - Respiratory distress
 - Dyspnea with exertion
 - Anorexia, abdominal pain, nausea
 - Failure to thrive
 - Exercise intolerance
 - Syncope
 - Palpitations
- HCM: Children are often asymptomatic and are first referred for evaluation based on family history or for murmur evaluation. Of those with symptoms, the following may be present:
 - Chest pain with exertion
 - Dizziness
 - Syncope
 - Palpitations
- RCM: Symptoms are usually due to systemic and pulmonary congestion from high atrial pressures. They are usually more evident late in the disease:
 - Dyspnea with exertion
 - Abdominal pain
 - Chest pain
 - Palpitations

PHYSICAL EXAM

- Cardiac:

- DCM: Tachycardia, cardiomegaly, hepatomegaly, S3 or S4 gallop; evidence of congestive heart failure, and decreased cardiac output
- HCM: Can be normal or have systolic murmur owing to mitral regurgitation and/or LV outflow tract obstruction. The presence of outflow tract obstruction produces a systolic ejection murmur of variable intensity related to the degree of obstruction; the murmur increases in intensity with Valsalva and decreases in magnitude with squatting. A parasternal or carotid thrill may be present, as may an S4 gallop.
- RCM: Jugular venous pulse either fails to fall or rises during inspiration (Kussmaul sign): The presence of S3 or S4. Advanced cases may exhibit weak peripheral pulses as evidence of low cardiac output.
- Respiratory (DCM and RCM): Tachypnea, rales, wheezing
- Abdominal (DMC and RCM): Hepatomegaly, ascites, tenderness to palpation

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Initial lab tests

DCM: In addition to routine inflammatory markers, specific tests should be obtained to establish the cause:

- Metabolic: Carnitine level, serum organic acids, and urine organic and amino acids, pyruvate, lactate, thyroid function tests
- Genetic: Chromosomal analysis, mutations of the dystrophin gene
- Infectious: Enterovirus, coxsackievirus A/B, hepatitis, cytomegalovirus, Epstein-Barr virus, adenovirus, parvovirus, herpes simplex virus, and human immunodeficiency virus
- Brain natriuretic peptide (BNP) is often used to follow heart failure in patients with CM.

Imaging

Echocardiogram:

- Allows for assessment of systolic function, ventricular dimensions, outflow tract obstruction, and diastolic filling properties
- DCM: Significant dilation of left (and right) ventricle with decreased systolic function
- HCM: Gold standard for diagnosis: LV hypertrophy, intraventricular pressure gradient, and systolic anterior motion of the mitral valve
- RCM: Disproportionately dilated atria with impaired diastolic filling by Doppler. LV function is normal until late stages.
- LVNC: Deep trabeculations and intertrabecular recesses in the LV, ventricular hypertrophy and systolic dysfunction

Diagnostic Procedures/Other

- Nonspecific tests:
 - Chest radiograph: Cardiomegaly, pulmonary venous congestion, pulmonary edema, and pleural effusions; segmental atelectasis from compression of the bronchioles

- EKG: Supraventricular or ventricular arrhythmia may be seen.
 - DCM: Sinus tachycardia, nonspecific ST segment and T-wave changes;
 - HCM: Hypertrophy, deep Q waves;
 - RCM: Atrial enlargement, nonspecific ST and T-wave changes;
 - LVNC: Marked ventricular hypertrophy, T-wave inversion.
- Cardiac catheterization:
 - DCM: Rarely used as the primary diagnostic tool in this disease; the procedure is used to delineate coronary anatomy and to perform endomyocardial biopsies.
 - HCM: Determination of the presence or absence of LV outflow tract obstruction, evaluation of diastolic dysfunction, classic spike and dome arterial pulse tracing, Brockenhough phenomenon (a beat following a premature ventricular contraction exhibits an arterial pulse pressure less than that of a control beat).
 - RCM: Atrial pressures are elevated from increased LV and RV end-diastolic pressures. Ventricular pressures exhibit a rapid and deep early decline at the onset of diastole followed by a rapid rise to a plateau in early diastole (dip and plateau or square-root sign).

DIFFERENTIAL DIAGNOSIS

- DCM: Children and young adults often present with symptoms that mimic other disease states:
 - For example, abdominal distention, right upper quadrant pain, nausea, and anorexia indicate right heart failure, but could be mistaken for hepatic or gallbladder disease.
 - Wheezing, tachypnea, and dyspnea on exertion may be diagnosed as bronchitis or asthma.
 - Cardiomegaly on chest radiograph may be mistaken for a large pericardial effusion.
- HCM: This disease must be differentiated from the LV hypertrophy that is seen in a well-trained athlete.
- RCM: Should be distinguished from constrictive pericarditis because the latter is usually a remediable process. A history of tuberculosis, trauma, or cardiac surgery may suggest constrictive pericarditis.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- DCM:
 - At the time of diagnosis, a trial of IV γ -globulin and/or other immunomodulators (prednisone, azathioprine) to treat possible myocarditis though impact on outcomes is unclear.
 - Diuretics
 - Afterload reduction (enalapril, captopril)
 - Inotropic agents (milrinone, dobutamine, digoxin)
 - Aldactone (improves New York Heart Association [NYHA] functional class)
 - Anticoagulation to avoid embolic complications
 - Antiarrhythmics as needed, β -adrenergic blockers (metoprolol, carvedilol)
 - Ventricular assist devices have been used in those with end-stage heart failure either as a bridge to recovery or to transplantation.
- HCM: β -adrenergic blockers remain 1st-line medical therapy. Calcium channel blockers or disopyramide may also be used. Antiarrhythmics may also be part of the medical regimen. There is no evidence that prophylactic medical treatment will reduce the risk of sudden death.

- If medical therapy is not effective, other options may include septal myectomy (for severe outflow obstruction) and atrioventricular sequential pacing.
- The placement of an implantable cardioverter defibrillator (ICD) may be indicated.
- RCM: The mainstay of medical therapy is symptomatic treatment:
 - Diuretics can be used with caution to treat venous congestion without reducing the ventricular filling pressure.
 - Antiarrhythmics are used to treat the high incidence of atrial arrhythmias.
 - ICDs have also been used to treat life-threatening ventricular arrhythmias.
 - Anticoagulation is used owing to the high risk of thrombus formation and embolic complications from hemostasis in the dilated atrium.
 - Because of the natural history of this disease, most patients eventually require a cardiac transplant.
- Patients with cardiomyopathies are generally restricted from strenuous exercise due to increased risk of sudden cardiac death.

SURGERY/OTHER PROCEDURES

- DCM or RCM: Heart or heart–lung transplantation (if the pulmonary vascular resistance is elevated); transplantation may be necessary if all therapeutic endeavors prove to be futile.
- HCM: Septal myectomy if indicated

IN-PATIENT CONSIDERATIONS

Initial Stabilization

Patients with DCM may present critically ill requiring intubation and inotropic support.

ONGOING CARE

PROGNOSIS

- DCM: The rate of death or transplant is ~30% at 1-year and 46% at 5-year follow-up. Age (>6 years), ventricular function, and symptoms of congestive heart failure at diagnosis are risk factors for a worse outcome.
- HCM: Overall incidence of sudden death is 4–6% in children and adolescents, and as low as 1% in adults. Between the ages of 12 and 35 years and in young athletes, HCM is the most common cause of sudden death. Obstruction may slowly develop or progress. Heart failure symptoms usually do not occur until adulthood. Survival is poorer (82%) for those diagnosed at <1 year of age.
- RCM: The reported median survival in RCM is 1.4 years in children with <20% freedom from death or transplant at 5 years.
- LVNC: 5-year survival free of death or transplantation is 75%.

COMPLICATIONS

- CHF can occur in all forms of cardiomyopathy.
- Arrhythmias may be seen and are frequently ventricular in origin.
- Thrombus formation can be seen owing to the stasis of blood in dilated cardiac chambers and the hypocontractile ventricle. Therefore, systemic or pulmonary emboli are possible.

ICD9

425.4 Other primary cardiomyopathies

ICD10

- I42.0 Dilated cardiomyopathy
- I42.8 Other cardiomyopathies
- I42.9 Cardiomyopathy, unspecified

FAQ

- Q: Should family members be evaluated once a cardiomyopathy is diagnosed in a 1st-degree relative?
- A: Yes. In some forms of cardiomyopathy, there is a strong genetic component and family members should be evaluated. If the cardiomyopathy is known to be acquired, evaluation of relatives is not required.
- Q: Does the cardiomyopathy of infants of diabetic mothers carry the same clinical course and outcome as that of patients with HCM?
- A: No. The pathophysiology is initially similar in that asymmetric hypertrophy of the ventricular septum is often seen with or without LV outflow obstruction. However, the clinical course of the cardiomyopathy in these infants is usually benign and resolves within the 1st 6 months of life.
- Q: What are the differentiating features of HCM and the benign physiologic hypertrophy of an athlete's heart?
- A: Several criteria are used to make this distinction. For example, a familial history of HCM raises the suspicion of this entity. Studies have suggested specific echocardiographic LV dimensions to differentiate benign hypertrophy and HCM (i.e., a wall thickness of ≥ 15 mm or LV cavity dimension <45 mm are more consistent with HCM). Also, evidence of abnormal mitral valve inflow is suggestive of HCM.

CATARACT

Gil Binenbaum

Anne K. Jensen

William Anninger

Brian J. Forbes (5th edition)

BASICS

DESCRIPTION

Any opacification of the normally clear crystalline lens of the eye. While many cataracts are small and nonprogressive and do not cause visual symptoms, visually significant cataracts represent a major challenge and require prompt diagnosis and management for optimal visual outcome.

EPIDEMIOLOGY

- Accounts for between 10% and 40% of childhood blindness worldwide.
- Ranges from 1 to 15 per 10,000 children worldwide, and 1 to 3 per 10,000 children in developed countries.

GENERAL PREVENTION

There is currently no known way to prevent congenital cataracts other than correcting any underlying metabolic abnormality if present. It is essential, however, that all newborns (and all children) receive screening eye examinations by healthcare providers. In much of the world, early diagnosis and referral is still the limiting factor for a child's ultimate visual prognosis.

PATHOPHYSIOLOGY

- Derangement of the normal developmental growth of the crystalline fibers of the central lens nucleus or peripheral lens cortex. The location of the opacity often suggests the gestational age at which it occurred.
- Frequently classified according to morphology or etiology.
- Dense central opacities of ≥ 3 mm are visually significant and may produce visual disability

ETIOLOGY

- Congenital: About 1/3 are inherited, 1/3 are associated with systemic disorders, and 1/3 are idiopathic.
- Familial: May be inherited as autosomal dominant, autosomal recessive, or X-linked recessive traits. Autosomal dominant cataracts are most commonly bilateral nuclear opacities but marked variability can be present even within the same pedigree. Multiple contributing genetic loci have been identified.
- Acquired:
 - Toxic: May result from chronic steroid use or radiation exposure
 - Traumatic: May result from either blunt or penetrating ocular trauma. Often stellate or rosette shaped
 - Inflammatory: From chronic uveitis
- Ocular Abnormalities: May be associated with other primary ocular abnormalities, including aniridia and various anterior chamber dysgenesis syndromes
- Systemic Conditions: See below.

COMMONLY ASSOCIATED CONDITIONS

- Prenatal factors: Intrauterine infection (toxoplasmosis, syphilis, rubella, cytomegalovirus, or herpes simplex, collectively known as TORCH infection), fetal alcohol syndrome
- Metabolic and endocrine: Galactosemia, neonatal hypoglycemia, hypoparathyroidism, diabetes mellitus
- Chromosomal: Trisomy 21 (Down syndrome), 13 or 15; Turner syndrome
- Dermatologic: Congenital ichthyosis, hereditary ectodermal dysplasia, infantile poikiloderma
- Renal: Lowe and Alport syndromes
- Skeletal: Marfan and Conradi syndromes
- Rheumatologic: Juvenile idiopathic arthritis, other uveitis (psoriatic, HLA-B27, etc.)
- Other: Craniofacial and mandibulofacial syndromes, neurofibromatosis, myotonic dystrophy, Fabry disease

DIAGNOSIS

HISTORY

- Decreased visual responses? Cataracts may decrease vision.
- Sun sensitivity or squinting in bright light? Cataracts may cause glare and light sensitivity.
- Strabismus (ocular misalignment)? May indicate loss of vision in one eye
- White pupil? Cataracts may appear as a white object in or under the pupil.
- Asymmetric or abnormal pupillary reflections (red eyes) with flash photography? Cataract may block the normal red reflex.
- Nystagmus? May be an ominous sign for the degree of vision loss
- Ocular trauma? Can cause traumatic cataract
- Delayed development? Especially with significant bilateral congenital cataracts, patients may fail to attain developmental milestones.
- Careful family and prenatal history? Up to 1/3 of congenital cataracts are inherited. Also assess for history of intrauterine infection or alcohol exposure.
- Positive family history or known history of an associated systemic condition? See "Associated Conditions."

PHYSICAL EXAM

- Decreased visual acuity: In preverbal child, assess via fix and follow. In verbal child, assess with Snellen chart.
- Strabismus: May indicate loss of vision
- Leukocoria: White pupil
- Absent, asymmetric or irregular red reflex: Use direct ophthalmoscope. Most sensitive method to detect cataract
- Nystagmus: Very poor prognostic sign
- Laterality of disease: Bilateral cataracts are more likely due to systemic disease.
- Globe (eyeball) size: Microphthalmia (small eye) suggests congenital cataracts..
- Complete physical exam: To assess for associated conditions

DIAGNOSTIC TESTS & INTERPRETATION

Lab

For cases with a definitive etiology, laboratory evaluation is typically not necessary. For bilateral cataracts without a clear cause, a selective workup to rule out associated conditions may be indicated.

- Serologies: Titers to rule out TORCH infections and syphilis; blood glucose, calcium, and phosphate to exclude metabolic disorders such as diabetes and hypoparathyroidism
- Urine tests: Reducing substances to rule out galactosemia; protein, amino acids, and pH to rule out Lowe syndrome
- Red blood cell enzyme levels: Galactokinase and gal-1-uridylyltransferase as part of galactosemia workup
- Karyotype: In conjunction with genetic consultation and ocular examination of parents and siblings

Imaging

Ocular ultrasonography if unable to visualize structures posterior to the opacity.

Diagnostic Procedures/Other

- Complete, timely ophthalmic evaluation by a pediatric ophthalmologist, including slit-lamp biomicroscopy and dilated fundus examination.
- Electrophysiologic testing of the visual system may be helpful to evaluate visual potential.

DIFFERENTIAL DIAGNOSIS

- The differential diagnosis of childhood cataracts is more concerned with the underlying cause of leukocoria (white pupil) rather than the presence of some other entity, as the cataract itself is readily identified on examination.
- Leukorrhea or poor red reflex DDX: Retinoblastoma, retinopathy of prematurity, persistent fetal vasculature, uveitis, retinal detachment, Coats disease, others
- Cataracts may also be an expression of an underlying systemic disease, which must be diagnosed for the child's overall benefit.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Importance of timely referral:
 - Congenital cataracts may require surgical removal by 4–6 weeks of age to prevent irreversible deprivation amblyopia, so quick referral is critical.
 - Acquired pediatric cataracts may also cause amblyopia, typically prior to 7 years of age.
- Conservative management:
 - Partial cataracts with good visual acuity that do not block the visual axis may be managed conservatively with observation, pharmacologic pupillary dilatation, and/or amblyopia treatment as needed (occlusion of the contralateral eye). Glasses may or may not be of additional help.
 - Small cataracts may progress, so nonsurgical cases require close follow-up.

SURGERY/OTHER PROCEDURES

- Visually significant cataracts must be removed surgically, followed by optical correction for aphakia (lacking a lens), pseudophakia (artificial lens), and/or inability to accommodate (focus in), and amblyopia treatment.
- Successful treatment may be extremely difficult, and intervention must occur very early in life in the case of congenital cataracts or as soon as possible in later-onset cataracts.
- To prevent deprivation amblyopia in bilateral cases, both cataracts are typically removed within 1 or 2 weeks of each other, if not simultaneously.
- Postoperative care:
 - Overview: Removing the lens leaves the child aphakic (without a lens). Postoperative optical correction with contact lens, glasses, and/or intraocular lens (pseudophakic) and amblyopia treatment are essential for optimal visual prognosis.
 - Contact lens: In children <1 year, optical correction of bilateral aphakia is most frequently accomplished with contact lenses or spectacles. In unilateral cases, a contact lens is best if tolerated.
 - Intraocular lens (IOL): In children >1 year, IOLs are frequently placed. Timing and willingness to place IOLs varies depending on surgeon and family preference.
 - Amblyopia therapy: In unilateral cataract cases, successful visual rehabilitation usually requires aggressive occlusion therapy to the normal eye, possibly for years. Even when treatment is successful, normal binocular vision with preserved depth perception is unlikely.
 - Contact VS IOL: The Infant Aphakia Treatment Study Group recently reported no difference in visual grating acuity at 1 year for 114 infants aged 1–6 months with unilateral cataract randomized to IOL placement or aphakia with contact lens. However, an increased rate of additional procedures was reported for the IOL group (63% vs. 12%).

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS

- Without treatment, visually significant cataracts result in progressive visual loss. When an opacity that is present at birth or very early in life is not promptly addressed, the visual loss quickly becomes irreversible.
- Once surgical removal is performed and optical correction is started, the child, parents, and ophthalmologist enter into an intensive and long rehabilitation period, lasting until visual maturity and stability are reached (usually 7–10 years of age). Afterward, yearly eye examinations are a minimum requirement.
- Parental and educational support services, as well as special local, state, and federal services for the visually handicapped and blind may be required, as not all children with successful surgical results will have good vision.

ALERT

PITFALLS include (i) lack of early diagnosis, referral, and treatment, (ii) lack of understanding of irreversible deprivation amblyopia, and (iii) lack of compliance with postoperative optical correction and occlusion therapy.

PROGNOSIS

- Before 1980, most children treated for monocular cataracts had a best corrected vision <20/200, and children with bilateral cataracts had 20/80–20/200 acuities.
- Earlier surgery, better surgical techniques, and rapid postsurgical optical correction now frequently result in best-corrected visual acuities of 20/40–20/200 for monocular cataracts and 20/40 or better for bilateral cataracts.
- Useful vision can be restored or obtained in newborns with unilateral cataracts if the surgery is completed within the first 6 weeks of life. After this time, visual restoration becomes progressively more difficult, because of irreversible deprivation amblyopia.
- The prognosis for visual rehabilitation in children with bilateral congenital cataracts is slightly better, providing surgical removal and optical correction are accomplished early, preferably prior to 8 weeks of age.
- Although later-onset cataracts have a better prognosis because the visual system has developed to some degree, these children still require immediate evaluation and treatment.
- In all cases, the onset or presence of nystagmus before the cataract is removed is an ominous sign of poor outcome and adds further urgency to the need for surgical removal.
- Family compliance with both postsurgical optical correction and amblyopia treatment is critical and directly affects the child's ultimate visual outcome later in life.

COMPLICATIONS

- Lack of removal of a visually significant cataract at the appropriate time leads to irreversible deprivation amblyopia, in which case no amount of surgery, optical correction, or amblyopia therapy is of benefit.
- Cataract removal in children leaves the eye without a lens (aphakic), with an IOL (pseudophakic), and/or unable to focus without some type of optical correction (spectacles or contact lenses). Unless rapid restoration of optical correction occurs, irreversible refractive amblyopia may still occur after the cataract is removed, particularly if the cataract is unilateral.
- Short- and long-term postoperative complications also include visual axis reopacification, glaucoma (elevated intraocular pressure with optic nerve damage), retinal detachment, and very rarely endophthalmitis (intraocular infection). These complications may lead to vision loss or loss of the eye, and long-term ophthalmology follow-up is required.

ICD9 CODES

- 366.04 Nuclear cataract
- 366.9 Unspecified cataract
- 743.30 Congenital cataract, unspecified

ICD10

- H25.10 Age-related nuclear cataract, unspecified eye
- H26.9 Unspecified cataract
- Q12.0 Congenital cataract

FAQ

- Q: Is surgical removal of the cataract a visual cure?
- A: No. Surgery is only the beginning of treatment, which also includes optical correction and amblyopia therapy.
- Q: Once the cataract is removed, will intensive, extensive follow-up be needed?
- A: Yes. The visual prognosis is directly related to postsurgical treatment compliance.
- Q: Is the cataract easier to treat when the child is older?
- A: No. Irreversible deprivation amblyopia develops as the child grows, precluding any chance for normal vision. In newborns, cataracts must typically be removed at 4–6 weeks of age.

CAT-SCRATCH DISEASE

Laura K. Brennan
Louis M. Bell (5th edition)

BASICS

DESCRIPTION

Cat-scratch disease (CSD) is a subacute, regional lymphadenitis syndrome that occurs following cutaneous *Bartonella henselae* inoculation, usually from a cat scratch or bite.

EPIDEMIOLOGY

Incidence

- There are ~24,000 cases and 2,000 hospital admissions each year; CSD likely represents the most common cause of chronic benign regional adenopathy.
- CSD occurs in patients of all ages, with the majority of cases being in those <21 years old.
- CSD is more common when one is scratched by a cat <12 months of age and/or a cat with fleas.

GENERAL PREVENTION

- Preventive measures should be directed toward minimizing contact between infected cats and people.
- Keeping kittens and older cats indoors and avoiding rough play may decrease the likelihood of infection.
- Avoidance of stray animals and good local care of any sustained bite or scratch are essential.
- Care of cats should involve effective flea control.

PATHOPHYSIOLOGY

- Following infection, the primary inoculation site shows acellular areas of necrosis in the dermis, surrounded by multiple layers of histiocytes and epithelioid cells; a zone of lymphocytes surrounds the histiocytes and some giant cells may be present.
- Involved nodes initially develop generalized lymphoid hyperplasia, followed by the development of stellate granulomas; the centers are acellular and necrotic, and may be surrounded by histiocytes and peripheral lymphocytes.
- Progression leads to microabscesses, which may become confluent and lead to pus-filled sinuses within the infected nodes.

ETIOLOGY

The etiologic agent is now referred to as *Bartonella henselae* (previously, *Rochalimaea henselae*), a fastidious, slow-growing, pleomorphic gram-negative bacillus.

DIAGNOSIS

HISTORY

- Cat contact:
 - >90% of patients have an antecedent cat contact.
- A skin rash:
 - A papule generally appears on the skin at the site of inoculation 3–12 days after the initial cat scratch.
 - This papule then often progresses through a vesicular and crusty stage.

- Appearance of large lymph nodes:
 - Within 1–2 weeks after appearance of a skin lesion, lymphadenopathy in the region of drainage (generally immediately proximal to the skin lesion) may be noted.
- Other symptoms:
 - Fever and mild systemic symptoms (such as generalized achiness, malaise, and anorexia) may also be present in up to 30% of patients.

PHYSICAL EXAM

- ≥ 1 red papule at the inoculation site may be detectable.
- The true sign of CSD (present in ~90% of cases) is chronic or subacute lymphadenitis involving the 1st or 2nd set of nodes draining the inoculation site:
 - The groups affected, in decreasing order of frequency, are the axillary, cervical, submandibular, periauricular, epitrochlear, femoral, and inguinal lymph nodes.
 - Affected nodes are usually tender, with overlying erythema, warmth, and induration.
 - ~10–30% spontaneously suppurate or form a sinus tract to the skin.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Indirect fluorescence antibody (IFA) testing:
 - For detection of serum antibodies to *B. henselae*
 - Available at many commercial laboratories, state public health laboratories, and the Centers for Disease Control and Prevention
 - Should be used to confirm a CSD diagnosis
 - In general, IFA IgG titers <1:64 suggest no current infection; titers between 1:64 and 1:256 represent possible early or old infection (and should be rechecked in 1–2 weeks); titers >1:256 strongly suggest active or recent infection.
 - There is less sensitivity with IgM titers, which may not always be positive at diagnosis, even in acute disease.
 - A single IgG titer of $\geq 1:512$, a 4-fold rise in titer, or seroconversion is necessary for serologic diagnosis of CSD.
- Enzyme immunoassay (EIA) testing:
 - Also for detection of serum antibodies to *B. henselae*
 - Similar sensitivity and specificity to IFA
- Blood cultures:
 - Using lysed or centrifuged blood may at times yield *B. henselae* growth from infected individuals in whom bacteremia is suspected.
 - Growth typically is obtained on blood agar after 12–15 days, but may require incubation period of up to 45 days.
- Polymerase chain reaction (PCR):
 - Available in some commercial and research laboratories
 - Sensitive and specific method for diagnosis of *Bartonella* infection in tissue specimens (e.g., needle aspiration of lymph node)
 - PCR+ serum samples have been reported in several patients, but serum PCR is likely less sensitive than IFA serology.

- Warthin-Starry silver stain:
 - May demonstrate *B. henselae* bacilli in chains, clumps, or filaments within necrosed areas of lymph node or within primary inoculation site of the skin.
 - Not specific for *B. henselae* and not definitively diagnostic of CSD, but is strongly suggestive in conjunction with compatible clinical findings

DIFFERENTIAL DIAGNOSIS

Most known causes of lymphadenopathy (see “Neck Masses”). Location of the abnormal lymph nodes may supply a strong clue.

TREATMENT

MEDICATION (DRUGS)

- Antibiotics shown to be effective against *B. henselae* include:
 - Trimethoprim-sulfamethoxazole (TMP-SMX), the macrolides, rifampin, doxycycline, ciprofloxacin, and gentamicin.
 - A recommended regimen for uncomplicated CSD would include azithromycin 500 mg initially then 250 mg daily for a total of 5 days in patients >45.5 kg and 10 mg/kg on the 1st day and 5 mg/kg for the subsequent 4 days.
 - Alternatively, trimethoprim-sulfamethoxazole (TMP-SMX) 6–8 mg/kg of TMP 2 or 3 times daily for 7 days in children may be used.
- For immunocompromised patients and those with severe or systemic disease (including encephalitis), azithromycin, erythromycin, or doxycycline should be administered; gentamicin sulfate 5 mg/kg/d divided q8h IM or IV for at least 2 weeks should also be administered in cases of endocarditis. Optimal duration of treatment is unclear, but may need to be up to several months in immunocompromised patients to prevent relapse.

ADDITIONAL TREATMENT

General Measures

Antibiotic therapy for CSD in immunocompetent hosts is somewhat controversial as the disease is self-limited and most reports suggest little or no overall improvement with antibiotics. Many experts suggest conservative, symptomatic treatment only, except in severe or systemic disease or in immunocompromised patients.

ISSUES FOR REFERRAL

- Consider infectious disease consult to aid in evaluation and diagnosis.
- Consider general surgery consult for needle aspiration if needed.

SURGERY/OTHER PROCEDURES

- Percutaneous needle aspiration of painful, fluctuant nodes can be performed for relief of pain.
- Incision and drainage should be avoided to reduce the risk of sinus tract formation, and surgical excision is generally not necessary.

IN-PATIENT CONSIDERATIONS

Admission Criteria

- Severe pain refractory to oral analgesics
- Workup to rule out serious other causes of lymphadenopathy or symptomatology
- Severe or unusual complications of CSD

Discharge Criteria

- Pain under adequate control
- No concern for serious or life-threatening complications or other disorders requiring further evaluation or treatment

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Most patients will have a benign course and may expect resolution of systemic symptoms in <2 weeks.
- Slow resolution of enlarged or painful lymph nodes will occur over weeks to months (usually ≤4 months).
- ~10–30% of affected lymph nodes will spontaneously suppurate.
- 5–15% of patients will have disseminated disease; the course for patients with severe complications, including encephalitis, will be more prolonged, but without lasting sequelae.

PROGNOSIS

- Most patients have a benign course with complete recovery.
- Patients with significant complications, such as encephalopathy, thrombocytopenic purpura, or bone lesions, usually have a more prolonged course but still have a good long-term prognosis.

COMPLICATIONS

- Regional lymphadenitis
- Fever of unknown origin
- Osteolytic bone lesions
- Parinaud oculoglandular syndrome:
 - Occurs when the site of primary inoculation is the conjunctiva or eyelid
 - A mild to moderate conjunctivitis develops along with ipsilateral preauricular lymphadenopathy.

- Encephalopathy/encephalitis:
 - May occur suddenly 2–6 weeks after the initial symptoms of CSD, and seizures may be the heralding symptom
 - Patients may become delirious and then comatose for several days before recovering.
 - Spinal fluid is typically normal or shows minimal WBC and protein elevation.
 - Recovery is generally complete.
- Neuroretinitis:
 - Acute (usually unilateral) vision loss from optic nerve edema
 - Associated with stellate macular exudates
- Visceral organ involvement:
 - Occasionally hepatosplenic involvement with multiple hypoechoic lesions will be found on abdominal ultrasound exam.
- Erythema nodosum:
 - Likely represents a delayed hypersensitivity reaction to the infection
 - Most often involves the subcutaneous fat of the legs and, at times, dorsum of arms, hands, and feet
- Osteolytic bone lesions occur as a rare complication.
- Other, rare complications:
 - Thrombotic thrombocytopenic purpura
 - Henoch-Schönlein purpura
 - Erythema marginatum
 - Mesenteric lymphadenitis
 - Pneumonia
 - Arthralgias
 - Osteomyelitis
 - Hypercalcemia
 - Guillain-Barré Syndrome
 - Transverse myelitis
- Endocarditis

FAQ

- Q: Can a sibling develop CSD from an infected patient?
- A: No; person-to-person transmission is not reported.
- Q: Should the parents of a child with CSD get rid of the cat?
- A: In general, this is not recommended. These animals are not ill; the capacity to transmit disease appears to be transient, and recurrent disease is rare.

CAVERNOUS SINUS SYNDROME

Sabrina E. Smith

Dennis J. Dlugos

BASICS

DESCRIPTION

- Cavernous sinus syndrome comprises disease processes that localize to the cavernous sinus—a venous plexus that drains the face, mouth, tonsils, pharynx, nasal cavity, paranasal sinuses, orbit, middle ear, and parts of the cerebral cortex.
- Small lesions in this region may produce dramatic neurologic signs.

EPIDEMIOLOGY

Incidence

Cavernous sinus syndrome is a rare but serious condition.

PATHOPHYSIOLOGY

- The cavernous sinus is located lateral to the pituitary gland and sella turcica, superior to the sphenoid sinus, and inferior to the optic chiasm.
- Within the cavernous sinus are the carotid artery, the pericarotid sympathetic fibers, and the abducens nerve (VI); within its lateral wall are the oculomotor nerve (III), the trochlear nerve (IV), and the ophthalmic and maxillary divisions of the trigeminal nerve (V1, V2).
- Cavernous sinus syndrome is typically caused by septic or aseptic sinus thrombosis, neoplasm, or trauma. Acute obstruction by mass or thrombosis may progress rapidly if not diagnosed and treated quickly.

ETIOLOGY

- Infectious agents include *Staphylococcus aureus*, *Streptococcus pneumoniae*, Gram-negative rods, and anaerobes; *Mucormycosis* and *Aspergillus* in immunocompromised patients.
- Aseptic venous thrombosis has been associated with sickle cell anemia, trauma, dehydration, vasculitis, pregnancy, oral contraceptive use, congenital heart disease, inflammatory bowel disease, and hypercoagulable states.
- Neoplasms involving the cavernous sinus include pituitary adenomas, meningiomas, trigeminal schwannomas, craniopharyngiomas, lymphomas, neuromas, chordomas, chondrosarcomas, nasopharyngeal carcinomas, and very rarely teratomas. Neoplasms may present with diplopia, visual-field deficits, headache, or isolated cranial nerve deficits.
- The lateral extension of pituitary neoplasms into the cavernous sinus usually affects the 3rd cranial nerve, with the 4th and 6th nerves less commonly involved. Rupture of a cystic craniopharyngioma may present as acute cavernous sinus syndrome.
- Carotid-cavernous fistulas, often with a more chronic course, are direct high-flow shunts between the internal carotid artery and the cavernous sinus. Most often sequelae of trauma, they may present with a history of ocular motility deficits, arterialization of conjunctival vessels, and a bruit usually heard best over the orbit. Less commonly, rupture of a carotid cavernous aneurysm may lead to fistula formation.

- Nonspecific and idiopathic inflammation of the cavernous sinus, also called idiopathic cavernous sinusitis or Tolosa–Hunt syndrome, has been reported in patients as young as 3 1/2 years. This is a diagnosis of exclusion. However, MRI may show enlargement of the affected cavernous sinus with an adjacent soft-tissue mass that resolves after treatment with steroids.

DIAGNOSIS

HISTORY

- Recent facial furuncle or cellulitis, sinusitis, dental infection, otitis, or orbital cellulitis may predispose to cavernous sinus syndrome.
- Fever, headache, eye pain, diplopia, and facial paresthesias may be present.

PHYSICAL EXAM

- Conjunctival injection with lid swelling and proptosis indicates cavernous sinus venous congestion.
- Ptosis, anisocoria, ophthalmoparesis, and facial sensory changes are signs of cranial nerve involvement.
- Horner syndrome: Sympathetic nerve fibers traveling with V1 may be affected. Usually occurs in conjunction with an abducens nerve (CN VI) palsy with an inability to abduct the eye.
- Signs and symptoms begin unilaterally, but may rapidly spread bilaterally.
- The optic nerve and visual acuity are spared early in cavernous sinus syndrome, but can be affected as it progresses.
- Funduscopic findings include venous dilatation and hemorrhages.
- Ocular bruit may be heard in any acute cavernous sinus syndrome, but especially in carotid-cavernous fistula.
- Signs of meningitis and systemic toxicity rapidly evolve if infections are untreated.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC, ESR, PT/PTT, blood culture: Basic studies in any child with suspected acute cavernous sinus syndrome. Blood cultures are positive in 70% of cases of septic venous sinus thrombosis.
 - Lumbar puncture should be performed if there is no contraindication and infection is suspected.
 - ~35% of patients with septic cavernous sinus thrombosis have CSF findings consistent with bacterial meningitis—excess neutrophils, increased protein, and/or decreased glucose.
- Evaluation for a prothrombotic state should be considered in patients with cavernous sinus thrombosis, especially in the absence of infection or trauma. Specific labs include protein C activity, protein S functional, antithrombin III activity, Factor V Leiden gene mutation, prothrombin gene mutation, anticardiolipin antibodies, β -2-glycoprotein antibodies, dilute Russell viper venom time, homocysteine, lipoprotein(a), and Factor VIII activity.

- Antinuclear antibody panel, angiotensin-converting enzyme level, and HIV test should be obtained before diagnosis of Tolosa–Hunt syndrome (diagnosis of exclusion).

Imaging

Any child with proptosis, cranial nerve findings, or an ocular bruit should have an urgent MRI or CT.

- MRI, with and without gadolinium, with special attention to the cavernous sinus and parasellar region, is the imaging study of choice.
- Magnetic resonance venography may be helpful.
- CT angiography may be the preferred study to evaluate for carotid-cavernous fistula.

Diagnostic Procedures/Other

- Diagnosis of carotid-cavernous fistulas requires angiography.
- Nasopharyngeal biopsy and culture if *Mucormycosis* or *Aspergillus* is suspected

DIFFERENTIAL DIAGNOSIS

Other disorders that may resemble cavernous sinus syndrome include:

- Orbital cellulitis
- Sphenoid sinusitis
- Thyroid eye disease
- Cavernous carotid aneurysm
- Orbital apex tumor
- Orbital pseudotumor
- Ocular migraine
- Ocular trauma
- Burkitt lymphoma

ALERT

- Ophthalmoplegic migraine or cluster headache must be distinguished from cavernous sinus syndrome by neuroimaging studies and history.
 - Proptosis does not occur in migraine or cluster headache.
 - Ophthalmoplegic migraine is a diagnosis of exclusion, especially on first presentation.
- Acute infection and hemorrhage of the pituitary gland—pituitary apoplexy—may present with acute bilateral ophthalmoplegia and signs of acute pituitary insufficiency; most commonly occurs with pituitary neoplasms, but may also occur in pregnant women at the time of delivery.
- Chronic granulomatous disorders such as sarcoid and tuberculosis may underlie cavernous sinus syndrome.

TREATMENT

First priority is to rule out septic cavernous sinus thrombosis, life-threatening infections of the face, sinuses, middle ear, teeth, and orbit.

MEDICATION (DRUGS)

First Line

- For septic cavernous sinus thrombosis, broad-spectrum antibiotics (including coverage of penicillinase-resistant staphylococci and anaerobes) are begun immediately. Duration of therapy is usually 2–4 weeks beyond the resolution of symptoms.
- Amphotericin B if *Mucormycosis* or *Aspergillus* is suspected.
- Idiopathic cavernous sinusitis, a diagnosis of exclusion, responds to corticosteroids. Treatment should not be started until neoplasm and infection have been ruled out.

Second Line

Anticoagulation is controversial, but 1 study in adults found that heparin reduced morbidity from septic cavernous sinus thrombosis.

SURGERY/OTHER PROCEDURES

- Surgical drainage of the primary infection (i.e., sinusitis) may be indicated (avoiding surgical manipulation of the cavernous sinus itself).
- Post-traumatic carotid-cavernous fistulas rarely close spontaneously and have been treated with endoarterial balloon embolization.

ONGOING CARE

- Septic cavernous sinus thrombosis may relapse or embolic abscesses may develop 2–6 weeks after therapy has been stopped.
- Repeat MRI with gadolinium should be considered, especially if symptoms recur or new symptoms develop.
- Mortality remains 13–30%, and <40% of patients recover fully from cranial nerve deficits.
- Patients with carotid-cavernous fistulas frequently have persistent cranial nerve deficits even after embolization.

- Idiopathic cavernous sinusitis responds to steroids, but relapses can be problematic. Clinical follow-up and serial MRI scans are indicated to rule out a low-grade neoplasm or fungal infection.
- Consultation with a neuro-oncologist and a neurosurgeon is important for suspected neoplasms or surgical lesions.

PROGNOSIS

- Prognosis depends on the underlying cause.
- Bacterial infections usually respond if diagnosed and treated promptly.

COMPLICATIONS

- Vary with the cause of cavernous sinus syndrome. Septic cavernous sinus syndrome thrombosis and fungal infections may rapidly evolve to bilateral thrombosis, life-threatening sepsis, and meningitis.
- Visual impairment and cranial nerve palsies may persist.
- Mucormycosis, usually seen in patients with diabetic ketoacidosis, is especially dangerous.
- Carotid arteritis with resulting stenosis, occlusion, or embolism may occur, resulting in focal neurologic deficits.
- Aseptic cavernous sinus syndrome thrombosis may evolve to more extensive intracranial venous sinus thrombosis.
- Local spread of neoplasms will continue if not treated appropriately.

CODES

ICD9

- 325 Phlebitis and thrombophlebitis of intracranial venous sinuses
- 437.6 Nonpyogenic thrombosis of intracranial venous sinus
- 671.50 Other phlebitis and thrombosis complicating pregnancy and the puerperium, unspecified as to episode of care or not applicable

ICD10

- O22.50 Cerebral venous thrombosis in pregnancy, unsp trimester
- I67.6 Nonpyogenic thrombosis of intracranial venous system
- G08 Intracranial and intraspinal phlebitis and thrombophlebitis

FAQ

- Q: Will my child's eye movements return to normal?
- A: In most cases, oculomotor nerves regain function as other signs improve, although they may take the longest to recover.
- Q: Can more pain medicine be given?
- A: There is often an attempt to balance side effects of sedation and hypoventilation against the need for pain control, especially when intracranial pressure is a concern.

CAVERNOUS TRANSFORMATION AND PORTAL VEIN OBSTRUCTION

Vani V. Gopalareddy

John Y. Tung

BASICS

DESCRIPTION

- Major cause of prehepatic portal hypertension
- Cavernous transformation: The collection of collaterals that develop around an obstructed vessel
- Portal vein obstruction:
 - In pediatrics, obstruction is most typically of the portal vein.
 - Main portal vein or splenic vein is obstructed anywhere along its course, between the hilum of the spleen and the porta hepatis.
 - In cirrhosis and hepatic malignancies, the thromboses usually begin intrahepatically and spread to the extrahepatic portal vein. In most other etiologies, the thromboses usually start at the site of origin of the portal vein. Occasionally, thrombosis of the splenic vein propagates to the portal vein, most often resulting from an adjacent inflammatory process such as chronic pancreatitis.

EPIDEMIOLOGY

- Most children with portal vein thrombosis present between birth and 15 years of age.
- Acute presentation is rare.
- Chronic cases present with complications of portal hypertension.
- Bleeding is more typical in patients presenting <7 years of age.
- Splenomegaly in the absence of symptoms is more typical for patients ages 5–15.

RISK FACTORS

Genetics

A genetic basis of this problem has not been identified, although congenital abnormalities of the heart, major blood vessels, biliary tree, and renal system are often found.

PATHOPHYSIOLOGY

Asymptomatic splenomegaly or upper gastrointestinal hemorrhage, resulting from extrahepatic portal hypertension. Less commonly, the patient presents with ascites or failure to thrive.

ETIOLOGY

50% of portal vein obstructions are idiopathic. Identified causes include:

- Congenital vascular anomaly:
 - Portal vein malformation
 - Webs or diaphragms within the portal vein
- Clot resulting from a hypercoagulable state
- Clot from other causes:
 - Omphalitis
 - Umbilical-vein catheterization
 - Portal pyelophlebitis
 - Intra-abdominal sepsis
 - Surgery near the porta hepatis
 - Sepsis
 - Cholangitis
 - Dehydration
 - Trauma
- Other causes for portal vein obstruction in older children:
 - Ascending pyelophlebitis from perforated appendicitis
 - Primary peritonitis, cholangitis, and pancreatitis causing a splenic vein thrombosis
 - Inflammatory bowel disease

DIAGNOSIS

HISTORY

- Other causes of splenomegaly (see “Splenomegaly” topic for complete differential):
 - Exposure to infectious mononucleosis
 - Metabolic storage disease (e.g., Gaucher disease)
 - Malignancy (e.g., chronic myelogenous leukemia)
- History of prematurity and admission to NICU should alert the clinician to previous umbilical catheterization and increased risk of portal vein thrombosis.

SIGNS AND SYMPTOMS

- Clinical history and examination should concentrate on identifying possible causes predisposing to portal vein obstruction.
- Portal vein obstruction does not affect liver function unless the patient has an underlying liver disease such as cirrhosis. This is partially due to a compensatory increased flow of the hepatic artery maintaining the total hepatic blood flow.

PHYSICAL EXAM

Splenomegaly and possible hemorrhoids: Spleen is measured from the left anterior axillary line at the costal margin diagonally toward the umbilicus and inferiorly toward the iliac crest.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC: Leukopenia and thrombocytopenia will be present if there is hypersplenism.
- Aspartate aminotransferase/alanine aminotransferase/ γ -glutamyl transferase: Should be normal
- PT/PTT: May be abnormal if malabsorption is present
- Additional testing associated with hypercoagulable states (as clinically indicated):
 - Protein C
 - Protein S
 - Anti-thrombin III levels
 - Factor V Leiden mutation
 - Activated protein C resistance
 - Lupus anticoagulation evaluation
 - Anticardiolipin antibodies (IgA, IgG, IgM)
 - Antinuclear antibody
 - Blood homocysteine
 - Prothrombin 20-21-0 mutation
 - Methylene tetrahydrofolate reductase mutation evaluation
 - Factor VIII coagulant
 - Reptilase time
 - Heparin cofactor II
 - Tissue plasminogen activator
 - Plasminogen activator inhibitor-1
 - Sticky platelet evaluation
 - Paroxysmal nocturnal hemoglobinuria (genetics or flow cytometry evaluation)

Imaging

- Ultrasound with Doppler:
 - To examine portal vein flow and to identify collateral veins if there is cavernous transformation of the portal vein
 - Liver may be slightly small, but may be normal in texture.
 - Remains the most useful imaging study
- CT or MRA can give additional information if needed.

Diagnostic Procedures/Other

- Liver biopsy:
 - Exclude other etiologies
 - Not done as a routine
- Upper endoscopy and sigmoidoscopy: To define extent of varices

Pathological Findings

- Portal hypertension: Spider nevi, prominence of abdominal veins, splenomegaly
- Bruising: Prominent especially when there is a coexistent consumption of clotting factors
- Normal liver palpation and percussion
- Ascites rarely present

DIFFERENTIAL DIAGNOSIS

The differential diagnosis must exclude other causes of splenomegaly and portal hypertension.

**TREATMENT****ADDITIONAL TREATMENT****General Measures**

Therapy is designed to manage variceal hemorrhage and to identify an underlying cause to determine if the patient is at risk for additional venous thrombosis or malignancy.

Therapy for GI hemorrhage:

- Prophylactic variceal banding for large varices
- β -Blocker therapy in older children
- Rex shunt (mesenterico–left intrahepatic portal vein shunt):
 - Created using the internal jugular vein, internal iliac vein, or dilated coronary vein, which is used to connect the superior mesenteric vein and the umbilical portion of the left portal vein (in the liver)
 - Restores the physiologic intrahepatic portal vein perfusion
 - Avoids the consequences of long-term portosystemic shunting, especially hepatic encephalopathy
- Portosystemic shunts: Divert portal blood into the low-pressure systemic venous circulation. Classified into:
 - Nonselective shunts: These communicate the entire portal venous system to a systemic venous circulation such as the mesocaval shunt, proximal splenorenal shunt, and portacaval shunts. Nonselective shunts divert more blood into the systemic venous system, and patients are more likely to have encephalopathy.
 - Selective shunts: These divert the gastrosplenic portion of the portal venous flow into the left renal vein or the inferior vena cava. The most common selective shunt is the distal splenorenal shunt (also known as the Warren shunt).

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS**

Focus on growth parameters, early detection of malabsorption, presence of GI hemorrhage, and nutritional intervention.

Patient Monitoring

Pitfalls:

- Patient should be advised about activity restrictions owing to splenomegaly. Spleen guards are recommended.
- Patient should be told to avoid medicines that interfere with platelet function.
- Medications that increase BP that are sometimes found in over-the-counter cold medications (e.g., phenylephrine) can increase splanchnic pressures and may provoke variceal bleeds.
- Aggressive contact sports are actively discouraged in children with hepatosplenomegaly.

PROGNOSIS

Long-term prognosis is good:

- Upper GI hemorrhage becomes less problematic as the child becomes older.
- Rex shunt restores normal physiology and decreases portal pressure. It is the 1st-line therapy in experienced centers.
- Most patients receive β -blockers or undergo prophylactic banding. If the liver function remains normal as in most cases, it is rare for encephalopathy to develop unless a large portosystemic shunt is created.

COMPLICATIONS

- Variceal hemorrhage from the upper tract or from the perianal varices
- Splenomegaly with hypersplenism: Thrombocytopenia, consumption coagulopathy, leukopenia
- Steatorrhea and protein-losing enteropathy occur secondary to venous congestion of the intestinal mucosa.

- Degree of portal hypertension is variable and depends on the formation of spontaneous shunts that may decompress the portal hypertension. These autoshunts may predispose to the development of complications such as hepatic encephalopathy or hepatopulmonary syndrome.
- Spleen can undergo autoinfarction, resulting in intermittent episodes of pain.
- A large spleen is susceptible to traumatic rupture, and spontaneous rupture may occur with infectious mononucleosis.

- I82.890 Acute embolism and thrombosis of other specified veins
- I82.891 Chronic embolism and thrombosis of other specified veins

FAQ

- Q: Should I restrict my child's activities?
- A: Contact sports should be limited or a spleen guard used. NSAIDs, including aspirin, should be avoided because of the risk of hemorrhage.

CELIAC DISEASE

Alycia A. Leiby
Vani V. Gopaloreddy

BASICS

DESCRIPTION

Celiac disease (CD) can be defined as a lifetime sensitivity to the gliadin fraction of the wheat protein gluten, (gluten consists of 4 gliadin fractions), and related alcohol-soluble proteins (called *prolamines*) found in rye and barley. CD occurs in genetically susceptible individuals who ingest these proteins, leading to chronic intestinal inflammation, epithelial damage, villous atrophy, and decreased absorptive surface. The mucosal lesions and symptoms resolve upon withdrawal of gluten-containing foods.

- Other names: Celiac sprue, nontropical sprue, and gluten-sensitive enteropathy
- The presentations of CD can be divided into the following categories:
 - Classic GI form: Typical presentation is younger than the age of 2 years, within a few months after the introduction of gluten-containing foods in the diet. The child presents with diarrhea, failure to thrive, anemia, fat malabsorption, wasting of muscles, bloated abdomen, fractious and unhappy behavior. The stools are explosive and foul, and half of the young children may have vomiting.
 - Celiac crisis: A rare presentation with explosive watery diarrhea, marked abdominal distention, dehydration, hypotension, lethargy, and electrolyte abnormalities
 - Late-onset GI form: Presentations in children older than 2 years include recurrent abdominal pain, bloating, constipation, mild or intermittent diarrhea, weight loss, and (rarely) nausea and vomiting.
- Extraintestinal form
- Strong to moderate evidence:
 - Dental enamel defects: Caries of permanent dentition in all 4 quadrants (30%), hypoplasia of permanent teeth
 - Skin: Dermatitis herpetiformis in 5% of patients > 15 years of age. The lesions are severely pruritic with erythematous blisters distributed symmetrically over the external surface of the extremities and on the trunk. Urticaria (hives) and psoriasis are also described.
 - Osteopenia/Osteoporosis
 - Short stature: 8–10% of children with short stature have CD.
 - Reproductive system: Delayed puberty, infertility, and spontaneous abortion, low-birth-weight infants
 - Hematological system: Anemia (iron-deficiency anemia unresponsive to treatment with oral iron)
 - Arthritis

- Evidence less strong:
 - Hepatic system: Cryptogenic hepatitis, autoimmune hepatitis, and chronic hypertransaminasemia, hepatic failure
 - CNS: Epilepsy, depression, dementia, schizophrenia, ataxia (“gluten-associated ataxia” due to cerebellar degeneration), migraine headaches. Behavioral changes such as irritability
 - Silent/Asymptomatic: Patients lack any GI or extraintestinal signs and symptoms. They are usually identified by population serologic screening or have the family history of CD. The small intestinal biopsy reveals mucosal damage in this group of individuals.
 - Potential/Latent CD: These patients have positive serology for the disease; however, the small intestine reveals normal histology. Over time, with further ingestion of gluten, it is believed that some of these individuals will develop CD.

EPIDEMIOLOGY

Incidence

- CD can present at any age after the introduction of gluten containing cereals.
- Women are more affected than men

Prevalence

- The prevalence of CD in children is between 3 and 13 per 1000 patients.
- Prevalence varies with the population studied; in the U.S. it is ~1 in 130.

RISK FACTORS

Risk increased by:

- Syndromes: Down (17-fold) Turner, and Williams
- Selective IgA deficiency (31-fold)
- 1st-degree relatives of patients with CD (18-fold)
- Diabetes Type 1: (4-fold)
- Repeat testing may be needed for at-risk patients who have negative initial serology and are HLA DQ2 and/or DQ8 positive.
- Breastfeeding, especially through the introduction of gluten may decrease the risk of celiac disease.

Genetics

- There is a 5–15% prevalence in 1st-degree relatives with CD. The concordance in monozygotic twins is supportive of a genetic role.
- 86–90% of patients have the HLA-DQ2, and ~5% carry the HLA-DQ8 allele.
 - 30% of general population in North America is HLA-DQ2 positive
 - Absence of DQ2 and DQ8 tests have a high negative predictive value.

COMMONLY ASSOCIATED CONDITIONS

- Autoimmune thyroiditis
- Type 1 diabetes mellitus
- Sjögren syndrome
- Selective IgA deficiency
- Williams syndrome
- Down syndrome
- Turner syndrome

DIAGNOSIS

Failure to thrive, weight loss, abdominal pain, vomiting, diarrhea, constipation, abdominal distention

HISTORY

- Diet? Determine the relationship between initiation of gluten and the manifestation of symptoms.
- Description of stools? Stools tend to be explosive and foul smelling.
- Description of behavior? Young children tend to be irritable, older children may complain of fatigue, joint pains.

PHYSICAL EXAM

- Growth pattern: Some may have short stature and failure to thrive.
- Classic presentation is a large abdomen with wasted buttocks. Most patients do not have that appearance.
- Signs of anemia, dental enamel defects, dermatitis herpetiformis.

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other

- Specific tests:
 - Serology, including tissue transglutaminase antibody IgA (tTG IgA), antiendomysial antibody (AEA), antigliadin antibody IgA/IgG (AGA IgA/IgG)
 - IgA quantification: 0.2–0.4% of the general population and 2–7% of patients with CD are IgA deficient; therefore, it is recommended to check serum IgA concurrently with the serology tests. If patients are IgA-deficient, then the IgA-type CD tests are unreliable.
 - Antigliadin antibody (AGA) IgA and IgG: 50–90% with active CD are positive. Unfortunately, many normal individuals without CD will have an elevated AGA IgG causing much confusion. This test is not recommended in population screening because of low specificity.
 - Deamidated antigliadin antibody IgA and IgG (D-AGA): Newer serologic test with 85% sensitivity and 95% specificity
 - tTG IgA: The autoantigen responsible for the endomysial pattern is tTG (90–100% sensitive and specific). The tTG assay correlates well with antiendomysial antibody (AEA) and biopsy. It is less expensive, rapid, and not a subjective test as opposed to the AEA assay.

- Nonspecific tests:
 - Laboratory tests for vitamin and mineral deficiency states, tests of absorption (fecal fat, D-xylose uptake), bone densitometry, class II HLA genotyping (DQ2 and DQ8), CBC, iron panel
- It is recommended to obtain multiple small bowel biopsies during endoscopy due to the patchy distribution of lesions.
 - Before the biopsy is done, check all the celiac antibodies as a screening test.
 - Separate biopsy from the duodenal bulb should also be taken
 - Biopsy should be done on an unrestricted diet.
 - The current recommendation is to obtain a small bowel biopsy on a gluten-containing diet. Symptoms should resolve on a glutenfree diet (GFD) with normalization of serology tests and the restoration of small bowel histology. Routine repeat biopsy is not necessary in children.

Pathological Findings

Features that characterize CD are:

- Partial, subtotal, or total villous atrophy
- Increased intraepithelial lymphocytes (>30%)
- Crypt hyperplasia
- Increased crypt cell mitosis
- Infiltration of lamina propria with excess lymphocytes (CD4 T cells mainly) and plasma cells

DIFFERENTIAL DIAGNOSIS

- Presumed infectious causes:
 - Giardiasis
 - Rotavirus, parasites
 - Chronic gastroenteritis
 - Postenteritis enteropathy
 - Intractable diarrhea of infancy
 - Tropical sprue
 - Intestinal bacterial overgrowth
 - Immunodeficiency syndromes (HIV)
- Presumed noninfectious:
 - Milk or soy protein intolerance
 - Protein-calorie malnutrition
 - Eosinophilic gastroenteritis
 - Autoimmune enteropathy
 - Graft-versus-host disease
 - Collagenous sprue
 - Peptic duodenitis
 - Immunodeficiency syndromes
 - Crohn disease
 - Congenital enteropathies (microvillus inclusion disease, tufting enteropathy)
 - Bowel ischemia
 - Radiation
 - Chemotherapy

TREATMENT

MEDICATION (DRUGS)

- Lactase enzyme replacement at the beginning of GFD
- Calcium and vitamin D for osteopenia
- Iron for iron deficiency anemia

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

tTG and AGA titers are useful monitoring for recovery. A decrease in these antibodies is expected with a GFD, accompanied by improvement of presenting symptoms.

- It is suggested to recheck tTG after 6 months of GFD, then yearly in asymptomatic patients.

DIET

- GFD with resolution of GI symptoms within weeks:
 - Within 2 weeks of commencing a GFD, 70% of patients will note symptomatic improvement.
 - May need to restrict lactose initially due to secondary lactase deficiency
- GFD:
 - Avoidance of all wheat, rye, barley
 - Consider avoiding oats, secondary to cross-contamination with wheat proteins

PROGNOSIS

In patients on a strict GFD, there is very little risk of malignant lymphoma and other malignancies. In patients with CD, it is strongly recommended to remain on a GFD for life.

COMPLICATIONS

- Intestinal lymphoma has been reported in 10–15% of adult patients (>40 years of age) with CD who were noncompliant with GFD.
- Other complications (described mostly in adults) include other GI malignancies including carcinoma as well as strictures, ulcerative jejunoileitis, splenic atrophy, and skeletal disorders.
- Refractory CD
- Note: This has not been reported in childhood.
 - A diagnosis of exclusion defined by persistent symptoms of malabsorption despite a strict GFD for at least 6 months with continued villous atrophy on duodenal biopsy
 - This should provoke a workup for other causes of villous atrophy.
 - Affects up to 5% of adult patients with CD

- 75% of these patients harbor an abnormal clonal intraepithelial T-lymphocyte population, which is associated with a condition currently classified as “cryptogenic enteropathy-associated T-cell lymphoma.”
- Complications of refractory sprue: Enteropathy-associated T-cell lymphoma, ulcerative jejunoileitis, and collagenous sprue.
- Treatment: Immunosuppressives including corticosteroids, azathioprine, cyclosporin, total parenteral nutrition, in addition to GFD

FAQ

- Q: Are oats included in the gluten-containing cereal group?
- A: Strictly speaking, wheat, rye, and barley are more closely related in their development from the primitive grains than are oat, rice, corn, sorghum, and millets, which do not activate CD. Gluten free means a diet devoid of all wheat, rye, and barley. Several studies have shown that ingestion of oats did not cause histologic or clinical deterioration. However, it is important to use a brand of oats that has been tested and shown not have any gluten contaminants.

CELLULITIS

Nicholas Tsarouhas

BASICS

DESCRIPTION

- Cellulitis is an acute, spreading pyogenic inflammation of the dermis and subcutaneous tissue, often complicating a wound or other skin condition.
- Cellulitis may be further classified by the unique area of the body it affects (e.g., periorbital or orbital cellulitis, peritonsillar cellulitis, etc.).

EPIDEMIOLOGY

- The most common cause of cellulitis in children is *Staphylococcus aureus* or *Streptococcus pyogenes* infection, which develops secondary to local trauma of the integument.
- Community-acquired methicillin-resistant *S. aureus* (CA-MRSA) infections continue to rise but are not seen as commonly with cellulitis as they are with purulent abscesses.
- The prevalence of CA-MRSA among purulent skin and soft tissue infections is >60% in some communities.
- Clinical failures with penicillin-resistant *S. pneumoniae* have not yet become a significant problem in cases of uncomplicated cellulitis.
- Bacteremic disease is uncommon owing to the tremendous efficacy of vaccines against both *Haemophilus influenzae* type b (HIB) and *Streptococcus pneumoniae*.

GENERAL PREVENTION

- Good wound care can prevent most cases.
- All wounds should be cleaned with soap and water, then covered with a clean, dry cloth.
- Topical antibiotic ointment is optional.

PATHOPHYSIOLOGY

- Cellulitis usually occurs after local trauma that breaches the integument (abrasions, lacerations, bite wounds, excoriated dermatitis, varicella, etc.).
- May develop secondary to local invasion or infection (e.g., sinusitis leading to orbital cellulitis)
- Hematogenous dissemination (rarely)

ETIOLOGY

- S. aureus*: MSSA (methicillin-susceptible *S. aureus*) and MRSA
- Group A β -hemolytic streptococci (GABHS, or *S. pyogenes*)
- S. pneumoniae* (uncommon)
- Group B streptococci (GBS), gram-negative rods (GNRs): In neonates
- HiB (rare)
- Pseudomonas aeruginosa*, anaerobic bacteria: In immunocompromised children
- Pasteurella* species: From cat and dog bites
- Eikenella corrodens*: From human bites

COMMONLY ASSOCIATED CONDITIONS

- Periorbital:
 - Usually from local trauma (scratch, impetigo, eczema, excoriated varicella, etc.)
 - Hematogenous spread is very uncommon.
 - Rarely associated with infectious conjunctivitis
- Orbital:
 - Commonly associated with severe sinusitis
 - Less commonly: Dental abscess, trauma, hematogenous spread
- Buccal: Usually from local trauma; hematogenous seeding also very rare.
- Peritonsillar:
 - Commonly secondary to GABHS pharyngitis
 - Cellulitis may progress to a peritonsillar abscess.
- Extremity: Usually secondary to local trauma
- Breast: Usually with mastitis (neonates)
- Perianal:
 - Seen in infants and young children
 - Etiology: GABHS
 - Perianal pain, pruritus, and erythema; sometimes associated with bloody stools
- Cellulitis–adenitis syndrome:
 - Uncommon infection of neonates and infants
 - Etiology: GBS, *S. aureus*, GNRs
 - Bacteremia/Meningitis commonly associated

DIAGNOSIS

HISTORY

- An expanding, red, painful area of swelling is the most common presentation.
- Mild constitutional symptoms (with or without fever) are commonly associated with cellulitis.
- A history of local trauma to the integument is the clue to the portal of bacterial entry.
- Visual changes, proptosis, or painful or limited eye movements are classic findings in orbital cellulitis.
- Painful swallowing, pain with opening the mouth (trismus), and muffled (“hot potato”) voice are classic presenting symptoms of peritonsillar cellulitis/abscess.

PHYSICAL EXAM

- Erythema, edema, tenderness, and warmth: Usual clinical findings of cellulitis
- Distinct demarcation of raised erythema: Classic description of erysipelas, a superficial cellulitis usually associated with *S. pyogenes*
- A red streak extending proximally from the extremity: Lymphangitis, which usually implies more serious involvement
- Regional adenopathy: Commonly associated with minor cellulitis; occasionally complicated by lymphadenitis

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- WBC: Normal or elevated
- Blood culture: Rarely positive. Ill-appearing children and children with extensive areas of cellulitis may warrant a blood culture.
- Wound culture: As resistance continues to rise (especially MRSA), wound cultures are useful.

Imaging

- Radiographs: Sometimes helpful to rule out complications such as osteomyelitis. Also useful in cases of suspected foreign bodies
- Ultrasound: Often useful to distinguish cellulitis from abscess, which might need incision and drainage (I & D).
- Head CT scan: Important in cases when clinical distinction between periorbital and orbital cellulitis is difficult. Useful in orbital cellulitis to delineate extent of disease

Diagnostic Procedures/Other

In some cases, a cutaneous biopsy, examined by an experienced pathologist, may be needed to identify the correct diagnosis.

DIFFERENTIAL DIAGNOSIS

- Allergic angioedema* can be excluded by its lack of tenderness and the absence of fever.
- Allergic reactions to *insect stings* are usually pruritic and may present with mild-to-severe local erythema; a bite history should be sought.
- Red giant *urticarial* lesions, similarly, may masquerade as cellulitis.
- Contact dermatitis* is distinguished by its painlessness, pruritus, and the Koebner phenomenon (appearance of isomorphic lesions in the lines of scratching).
- A *traumatic contusion* may be mistaken for cellulitis, but the history should be confirmatory.
- Severe *conjunctivitis* presents with conjunctival injection, chemosis, and discharge.
- “*Popsicle panniculitis*,” a cold-induced fat injury to the cheeks of infants, mimics buccal cellulitis; a history of cold weather exposure, eating ice, or popsicle sucking should be sought.
- Erythema nodosum*, a panniculitis, consists of raised, tender lesions that are frequently over the shins; it may present as a single erythematous lesion. It is associated with systemic disorders, including inflammatory bowel disease.
- Superficial thrombophlebitis* is distinguished by a tender cord palpable along the course of the affected superficial vein.
- An *eye malignancy* (retinoblastoma), invasive *tumor* (rhabdomyosarcoma), or *metastatic disease* (neuroblastoma, leukemia, lymphoma) may simulate periorbital or orbital cellulitis.

TREATMENT

MEDICATION (DRUGS)

- Most cases of uncomplicated, superficial cellulitis may still be treated with β -lactam oral antibiotics active against *Staphylococcus* and *Streptococcus* (e.g., amoxicillin—clavulanate or cephalexin).
- Cephalexin may be the most cost-effective option in the routine outpatient management of uncomplicated cellulitis, especially in areas where MRSA prevalence is low (<10%).
- Alternatively, in areas where the local prevalence of community-associated MRSA is very high, empiric therapy for skin and soft tissue infections might include an antibiotic with MRSA coverage, such as clindamycin or trimethoprim-sulfamethoxazole.
- Abscesses, in which *S. aureus* is a likely pathogen, should be treated with clindamycin or trimethoprim-sulfamethoxazole; importantly, however, the mainstay of therapy is I & D.
- Trimethoprim-sulfamethoxazole, importantly, does not cover GABHS, a known important pathogen in some skin and soft tissue infections.
- Erythromycin may be used in patients allergic to penicillin.
- Isolates resistant to erythromycin may be cross-resistant to clindamycin as well.
- Tetracycline, doxycycline, and minocycline are additional alternatives, especially in the penicillin-allergic patients.
- Ill-appearing children or those with extensive cellulitic lesions require IV antibiotics.
- As MRSA infections continue to rise, many experts now recommend clindamycin as initial parenteral therapy.
- Oxacillin, nafcillin, cefazolin, and ampicillin-sulbactam are reasonable alternatives when MRSA is not strongly suspected.
- Vancomycin is used as empiric therapy in ill-appearing children or with severe or rapidly progressive infections.
- Linezolid, a newer antibiotic that can be given IV or PO, is very effective against MRSA, but it is expensive and should mostly be reserved for multiresistant organisms.
- If hematogenous dissemination is a strong possibility, an agent active against HiB also should be added (e.g., ceftriaxone, cefotaxime).
- The duration of antibiotics (IV and PO) should generally be 7–10 days.
- Bite wounds should have tetanus and rabies prophylaxis issues addressed.

ALERT

- Remember to consider the possibility of MRSA in all deep, invasive, or persistent infections (i.e., consider clindamycin).
- Penicillin and amoxicillin are never good empiric choices for cellulitis owing to their poor *S. aureus* coverage.

ADDITIONAL TREATMENT

General Measures

Local care of cellulitis involves elevation and immobilization of the limb to reduce swelling and cool sterile saline dressings to remove purulence from open lesions.

SURGERY/OTHER PROCEDURES

Abscesses should always be drained.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Steady improvement should be expected.
- If daily improvement is not noted, consider:
 - Inappropriate antimicrobial coverage
 - A deeper infection or abscess that needs drainage
 - Foreign body

PROGNOSIS

The prognosis for complete recovery is good as long as appropriate antimicrobials are administered in a timely fashion.

COMPLICATIONS

- Local or distant spread of infection is possible.
- Suppuration and abscess formation may occur (e.g., peritonsillar abscess).
- Extremity cellulitis may extend into the deep tissues to produce an arthritis or osteomyelitis, or it may extend proximally as a lymphangitis.
- Orbital cellulitis may be complicated by visual loss and/or cavernous sinus thrombosis.
- Prior to widespread immunization against HiB, the bacteremia associated with facial cellulitis was associated with pneumonia, meningitis, pericarditis, epiglottitis, arthritis, and osteomyelitis.

CODES

ICD9

- 041.00 *Streptococcus* infection in conditions classified elsewhere and of unspecified site, streptococcus, unspecified
- 682.9 Cellulitis and abscess, unspecified site

ICD10

- B95.5 Unspecified streptococcus as the cause of diseases classified elsewhere
- L03.90 Cellulitis, unspecified

FAQ

- Q: Should MRSA be considered only in patients with risk factors such as recent hospitalization, chronic illness, health care worker contact, and recent antibiotic use?
- A: No. MRSA is commonly isolated now from patients with no identified risk factors.
- Q: Is ophthalmology consultation necessary in all cases of periorbital cellulitis?
- A: Ophthalmology consultation is not necessary in simple, uncomplicated cases of periorbital cellulitis that clearly have no associated proptosis, limitation in extraocular eye movement, or visual impairment that would suggest a more serious orbital cellulitis.

CEREBRAL PALSY

Stephen Contompasis

BASICS

DESCRIPTION

Cerebral palsy (CP) describes a group of disorders of movement and posture, limiting activity, attributed to nonprogressive underlying brain pathology. The motor disorders of CP are often accompanied by disturbances of sensation, cognition, communication, perception, and/or behavior, or by a seizure disorder:

- Spastic (pyramidal; 75%): Increased deep tendon reflexes, sustained clonus, hypertonia, and the clasp-knife response:
 - Spastic diplegia: Lower extremity involvement
 - Spastic hemiplegia: 1 side of the body involved
 - Spastic quadriplegia: Total body involvement; usually associated with dystonia
- Dyskinetic (10%): Fluctuating tone, rigid total body involvement by definition. Persistent primitive reflex patterns (asymmetric tonic neck reflex, labyrinthine)
 - Athetoid: Slow writhing movements (or chorea; rapid, random, jerky movements)
 - Dystonic: Posturing of the head, trunk, and extremities
- Ataxic (<10%): Characterized by cerebellar signs (ataxia, dysmetria, past pointing, tremor, nystagmus) and abnormalities of voluntary movement
- Mixed (10%): 2 or more types codominant, most often spastic and dyskinetic
- Other (10%): Criteria for CP met, but specific subtype cannot be defined
- Extrapyrarnidal: Sometimes applied to nonspastic types of CP as a group

EPIDEMIOLOGY

- ~50% of cases are associated with prematurity.
- Increased concordance among monozygotic versus dizygotic twins in some studies (not in others)
- Intrauterine growth retardation (IUGR) more common in CP than controls, especially for full-term infants in whom CP develops
- Male > female (1.3:1)
- Inconsistent relationship to maternal age, socioeconomic status, and parity
- Prenatal factors are more strongly associated with subsequent CP than are perinatal or postnatal factors; however, individual risk factors are poorly predictive of subsequent CP in the individual child.
- Perinatal asphyxia accounts for only ~9% of CP; diagnosis requires evidence of hypoxic-ischemic insult, severe encephalopathy (e.g., neonatal seizures, severe hypotonia), and consistent laboratory/radiologic findings.
- Increased with multiple gestation (10% were twins in 1 study)
- Prevalence ~2/1,000

ETIOLOGY

- Not apparent in most cases. A more recently recognized perinatal factor is the presence of chorioamnionitis; mild or even subclinical infection may have increased association with CP.
- Epidemiologic studies indicate 2 types of vulnerability to CP:
 - Prematurity: Vulnerability of the periventricular white matter between 28 and 32 weeks of gestation results in periventricular leukomalacia.
 - IUGR: Fetal growth retardation associated with CNS dysgenesis, non-CNS malformation, teratogens, growth retardation, evidence of hypoxic-ischemic encephalopathy

COMMONLY ASSOCIATED CONDITIONS

- Sensory:
 - Sensorineural and conductive hearing loss
 - Impaired visual acuity
 - Oculomotor dysfunction
 - Strabismus
 - Cortical visual impairment
 - Somatosensory impairments
- Cognitive/developmental:
 - Intellectual disability in ~50%, especially in spastic quadriplegia
 - Autism, ADHD
 - Language and learning disabilities
 - Dysarthria
 - Sleep and behavioral disturbances
- Neurologic:
 - Seizures
 - Hydrocephalus
- Musculoskeletal:
 - Contractures
 - Hip subluxation/dislocation
 - Scoliosis
- Cardiorespiratory:
 - Upper airway obstruction
 - Aspiration pneumonia
 - Restrictive lung disease/thoracic deformity
 - Reactive airway disease
- GI/nutritional:
 - Poor growth
 - Gastroesophageal reflux
 - Constipation
 - Oral motor dysfunction/dysphagia
- Urinary: Neurogenic bladder
- Skin: Decubitus ulcers
- Dental:
 - Malocclusions
 - Caries
 - Gingival hyperplasia
 - Abnormalities of enamel (congenital)

DIAGNOSIS

HISTORY

- Prenatal:
 - Exposure to toxins/drugs
 - Infections or fever
 - HIV/STD risk
 - Vaginal bleeding
 - Abnormal fetal movement
 - Preeclampsia (especially proteinuria)
 - Breech position
 - Poor maternal weight gain
 - Premature labor
 - Fetal distress
 - IUGR
 - Prenatal testing
 - Placental disorders
- Perinatal:
 - Premature delivery
 - Neonatal resuscitation
 - Low Apgar scores (<5 at 5 minutes)
 - Birth trauma
 - Evidence of neonatal encephalopathy (seizures, lethargy, hypotonia)
 - Complicated neonatal course (intraventricular hemorrhage, prolonged respiratory support, meningitis, sepsis, hyperbilirubinemia)
- Postnatal:
 - Hospitalization for severe infection or trauma
 - Periodic or persistent deterioration in function (suggests neurodegenerative/metabolic disease)
- Development:
 - Significant delay in motor milestones/motor quotient (age of typical skill attainment/age of attainment <0.5) (e.g., not rolling at 10 months, not sitting at 12 months, not walking at 24 months)
 - Associated with persistent primitive reflexes (e.g., prominent tonic neck and labyrinthine responses at 1 year of age) and delayed or absent development of protective reactions (e.g., lateral prop at 7 months, parachute at 13 months)
 - Associated delays in language, play, social, and adaptive behavior

PHYSICAL EXAM

- General observation: Evidence of dysmorphism/pigmentary skin changes and growth abnormalities (clues to etiology)
- Head circumference: To evaluate for microcephaly/macrocephaly/hydrocephaly; growth velocity points to timing of brain pathology.
- Strabismus/cataracts/iris or retinal abnormalities: Eye exam: Cranial nerve damage, muscle imbalance, metabolic disease, or congenital infection
- Musculoskeletal:
 - Decreased range with contractures
 - Leg-length discrepancy: Hip dislocation
 - Spinal curvature/scoliosis

- Neurologic:
 - Documentation of best level of visual motor/manipulative skills (transfer, hold a cup): To follow course of motor impairment
 - Cranial nerves: Strabismus, speech and swallowing, vision and hearing
 - Tone: Spasticity versus rigidity versus hypotonia
 - Strength: Often decreased
 - Hyperactive deep tendon reflexes and clonus in spasticity; Babinski reflex (extensor response to plantar stimulation)
 - Persistent primitive reflexes
 - Protective reactions: Head and trunk righting, prop reactions, parachute; cerebellar signs
 - Balance, stability

ALERT**Pitfalls:**

- Overdiagnosis of CP in premature infants with spastic hypertonia; normalization of tone/function may take up to 2 years.
- False or premature assumption of cognitive deficit in children with severe dysarthria. May take years of augmentative communication supports to determine true potential
- Slowly progressive neurodegenerative disease and pediatric neurotransmitter disorders may masquerade as CP.
- Cervical cord lesions may masquerade as quadriparetic spastic CP.
- Determination of ideal body weight/caloric requirements may be complex in CP; skinfold measuring <10th percentile best indicator of poor nutrition
- Pain is a common problem, with more than half of adults and children with CP reporting pain as an ongoing health concern.

DIAGNOSTIC TESTS & INTERPRETATION**Lab**

- Genetic and metabolic studies: If history or physical suggests a progressive or hereditary disorder
- Blood chemistries, liver function studies, cell counts: Evaluate nutritional/metabolic status, anticonvulsant levels

Imaging

- Brain imaging: Perform when hydrocephalus is suspected; can help determine etiology
- Radiography: Should be done routinely in spastic diparesis for hip dislocation; consider scoliosis films.
- Radionuclide studies to evaluate gastroesophageal reflux, gastric emptying, aspiration

Diagnostic Procedures/Other

- Hearing and vision: All in 1st year, with regular follow-up exams
- Audiologic evaluation required per guidelines
- Urodynamic studies: Spastic bladder in those with recurrent UTIs or voiding dysfunction
- Sleep study: May disclose treatable obstructive sleep apnea in those with somnolence or abnormal sleep-wake cycles

- Pulmonary function studies: Document progressive restrictive pulmonary dysfunction (e.g., in severe scoliosis)
- Consider bone density: Liability to fractures
- Brain wave (EEG): If seizure suspected

DIFFERENTIAL DIAGNOSIS

- Motor syndromes related to spinal cord, lower motor neuron, peripheral nerve, primary muscular disease, or progressive disorders of the basal ganglia (dopa-responsive dystonia)
- Connective tissue disorders (primary and secondary) resulting in musculoskeletal abnormalities (e.g., arthrogyrosis multiplex, skeletal dysplasias)
- Inborn errors of metabolism and CP: Protean manifestations, dyskinesia, ataxia, postnatal growth failure, neurologic deterioration, recurrent vomiting

**TREATMENT****ADDITIONAL TREATMENT****General Measures**

- Family-centered care is directed toward optimizing activity and participation.
- Interdisciplinary clinics: Services (medical, surgical, therapy) coordinated with primary physician
- More frequent health maintenance visits and coordination meetings from a medical home practice may assist in managing multiple chronic associated health conditions.
- Spasticity reduction with IM injections of botulinum toxin and oral or intrathecal Baclofen used increasingly, though consensus on functional improvement long term is variable
- Orthopedic management with directed procedures to reduce contractures and improve posture has more evidence on improving functional outcomes long term.
- Education services: Recent emphasis on inclusion/mainstreaming; for many, special education services are still required.
- Augmentative communication supports especially for nonverbal/dysarthric children
- Physical, occupational, speech/language therapy, other allied health professionals: Therapy provided in home, school, and hospital settings; directed primarily at improved mobility, self-care, and communication; orthodontists for braces
- Counseling support for children coping with chronic disability
- Social services: Provided in a variety of contexts to aid in the coordination of care
- Vocational counseling and employment options, assistance with transition to adulthood, self-advocacy, self-determination
- Transition to adult health care system

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS**

- Requirements for follow-up vary greatly with the degree of disability and impairment. An interdisciplinary clinic setting may be more appropriate for a child with severe CP.
- Early referral to a pediatric orthopedist is indicated, especially for monitoring of the hip.
- Early referral for developmental assessment: Need for early intervention, to optimize development and promote family coping

DIET

Nutritional assessment and support for those with dysphagia or poor growth (especially calcium, vitamin D intake)

- G80.3 Athetoid cerebral palsy
- G80.9 Cerebral palsy, unspecified

FAQ

- Q: Is severe clumsiness a form of CP?
- A: Mild spastic diplegia or hemiplegia may present this way, but tone abnormalities and significant functional impairments distinguish CP from milder developmental coordination disorders.
- Q: Do all children with CP also have intellectual disability?
- A: Only ~50% have intellectual disability.

CERVICITIS

Sarah E. Winters
Elizabeth M. Wallis
Jane Lavelle (5th edition)

BASICS

DESCRIPTION

Infection of the endocervix resulting in inflammation, leading to mucopurulent cervical discharge, edema, erythema, bleeding, and friability of the cervix and endocervical canal

EPIDEMIOLOGY

- The true incidence of cervicitis is unknown, but the primary causes (gonorrhea/chlamydia) are more common in adolescents and young adults than any other age group.
- Because many patients are asymptomatic and the interpretation and presence of the clinical signs is quite variable, many cases go undiagnosed.

RISK FACTORS

- Early age of coitarche
- Multiple sexual partners
- Absent/Inconsistent condom use

ETIOLOGY

In most cases of cervicitis, no pathogen is isolated. Common causes include:

- *Chlamydia trachomatis*
- *Neisseria gonorrhoeae*
- *Herpesvirus hominis*
- *Trichomonas vaginalis*
- *Mycoplasma genitalium*

COMMONLY ASSOCIATED CONDITIONS

The presence of other sexually transmitted infections (STIs) must be considered, including:

- Syphilis
- Hepatitis B
- HIV
- Bacterial vaginosis

DIAGNOSIS

HISTORY

- Often asymptomatic
- If symptomatic: Symptoms consistent with but not diagnostic of cervicitis:
 - Abnormal vaginal bleeding and/or discharge? Inflamed cervix may bleed spontaneously or following sexual intercourse
 - Dysuria? May indicate urethritis or bladder infection
 - Vulvar itching? May be associated discharge from cervical inflammation or a coexisting vaginal infection
 - Dyspareunia? Common complaint owing to the sensitive cervix

- Past medical history—important to evaluate risk factors related to sexual health, but not diagnostic of cervicitis:
 - Previous STI? Identifies patients at increased risk for reinfection
 - Last menstrual period? Symptomatic infection often occurs within 7 days of the last menstrual period because of loss of the protective endocervical mucous plug.
 - Birth control method? Condoms are protective.
 - Exposure to infected partner? Identifies patient at increased risk
 - Gravity?
 - Parity?

PHYSICAL EXAM

- Abdominal: No tenderness on palpation of the abdomen—infection is limited to the cervix.
- Vaginal: Signs of vaginal/external lesions consistent with herpes simplex virus (HSV)
- Pelvic:
 - Mucopurulent discharge from the cervical os or yellow exudative discharge present on a cotton-tipped swab from the endocervical canal: Clinical evidence of cervical infection
 - No cervical motion or adnexal tenderness or masses: Pathology has not extended beyond the cervix to the upper genital tract.
 - Friability of the exocervix: Easily induced bleeding from the cervical canal, not to be confused with normal cervical ectopy (area of columnar epithelium around the cervical os presenting as a discrete, nonfriable, reddish circle)

ALERT

Pitfalls:

- Failure to recognize the importance of evaluating the internal pelvic organs by physical examination with the presenting symptoms of dysuria, vaginal discharge, or abnormal menstrual bleeding in the postpubertal female.
- Imperative not to confuse normal cervical ectropion in an adolescent with cervicitis.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Nucleic acid amplification tests done on the patient's urine offers the least invasive method to detect chlamydia and/or gonococcal infection. Cervical or vaginal swabs may also be used for nucleic acid amplification tests provided that there is no bleeding:
 - Cervical swabs, vaginal swabs obtained by the health care provider, and urine have similar sensitivity and specificity.
 - Cervical cultures for chlamydia and gonorrhea will also identify the pathogen, but require a speculum examination.
 - Identifies the pathogen, which is important for patient and partner treatment and disease surveillance

- HSV culture if vesicular rash or ulcers are present: Important to identify the cause of the ulcers for treatment and patient counseling
- Wet preparation, culture or antigen testing for *T. vaginalis*: Often coexisting infection when other STIs are identified.

DIFFERENTIAL DIAGNOSIS

- It is helpful to consider cervicitis/vaginitis as a single disease in the evaluation process because the symptoms of these two entities are the same.
- Inflammation of the vulva, urethra, and/or bladder, and vagina
- In patients presenting with abnormal menstrual bleeding, these infectious causes are common.
- Pregnancy is a frequent cause of abnormal vaginal bleeding.
- Foreign body can be associated with both discharge and bleeding.
- PCOS, thyroid dysfunction, and hyperprolactinemia can all present with abnormal vaginal bleeding.

TREATMENT

MEDICATION (DRUGS)

- Gonorrhea:
 - Ceftriaxone 250 mg IM or, if not available, cefixime 400 mg PO in a single dose PLUS azithromycin 1 g PO, single dose or doxycycline 100 mg PO b.i.d. for 7 days
 - Recently noticed patterns of resistance to fluoroquinolones have caused the CDC to no longer recommend this class as 1st line of treatment of gonococcal cervicitis in the U.S. If fluoroquinolones are used, a test of cure is necessary.
- *C. trachomatis*:
 - Azithromycin 1 g PO, single dose
 - Doxycycline 100 mg PO b.i.d. for 7 days
 - Erythromycin base 500 mg PO q.i.d. for 7 days
- *T. vaginalis*:
 - Metronidazole 2 g PO, single dose
 - Metronidazole 500 mg PO b.i.d. for 7 days
 - Tinidazole 2 g PO in a single dose
- *H. hominis*:
 - Acyclovir 400 mg PO t.i.d. for 7–10 days or until resolution
 - Acyclovir 200 mg PO 5 times daily for 7–10 days or until resolution
 - Famciclovir 250 mg PO t.i.d. for 7–10 days or until resolution
 - Valacyclovir 1 g PO b.i.d. for 7–10 days or until resolution

IN-PATIENT CONSIDERATIONS**Initial Stabilization**

Patients meeting the criteria for the clinical diagnosis of cervicitis or those who have a high likelihood of infection should receive presumptive therapy for *N. gonorrhoeae* and *C. trachomatis*. Treat other pathogens if clinically indicated or if documented by laboratory studies.

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS**

- The recommended treatment regimens have an excellent cure rate.
- The patient should have resolution of symptoms 3–5 days after starting therapy.
- Routine follow-up cultures are not necessary unless the patient remains symptomatic or in the case of pregnancy.
- Nucleic acid amplification tests done <6 weeks following treatment may yield false-positive results because of persistence of dead organisms.
- Detection of an STI at follow-up is most likely the result of re-exposure and reinfection.

Patient Monitoring

- Partners should be referred for evaluation and treatment if laboratory diagnosis of GC/Chlamydia or *Trichomonas* is made
- GC/Chlamydia are reportable STIs

PROGNOSIS

If treated appropriately, patients are cured and have no sequelae from the infection.

COMPLICATIONS

The patient with endocervical infection is at risk for:

- Reinfection
- Other STIs
- Pregnancy

- Symptomatic or asymptomatic upper genital tract disease, (pelvic inflammatory disease), with all its sequelae:
 - Tubo-ovarian abscess
 - Infertility
 - Ectopic pregnancy
 - Chronic pelvic pain

**CODES****ICD9**

- 098.15 Gonococcal cervicitis (acute)
- 099.53 Other venereal diseases due to chlamydia trachomatis, lower genitourinary sites
- 616.0 Cervicitis and endocervicitis

ICD10

- A54.03 Gonococcal cervicitis, unspecified
- A56.01 Chlamydial cystitis and urethritis
- N72 Inflammatory disease of cervix uteri

FAQ

- Q: How much cervical motion tenderness is present in patients with cervicitis?
- A: None. Patients with cervicitis have inflammation and infection of the cervix only. They do not have any evidence of peritoneal inflammation on physical examination; therefore, patients with tenderness should be treated with the protocols recommended by the Centers for Disease Control and Prevention for pelvic inflammatory disease. This does not include the use of a single dose of azithromycin.
- Q: Which partners should be referred for treatment?
- A: Sex partners from the preceding 60 days should be referred for evaluation and treatment. Treatment is based on documented or presumptive etiologies.
- Q: What is the appropriate treatment for *M. genitalium*?
- A: *M. genitalium* has clearly been implicated in the development of urethritis in males and is thought to play some role in the development of cervicitis in females (although that role is not entirely clear). Data suggests that azithromycin may be the best treatment for this infection.
- Q: How often should asymptomatic sexually active adolescents be screened for STIs?
- A: Sexually active men and women under 25 should be screened annually for STIs.

CHANCROID

Heather McKeag

Christine S. Cho (5th edition)

BASICS

DESCRIPTION

Infection with the gram-negative coccobacillus *Haemophilus ducreyi*, resulting in necrotizing, purulent, painful genital ulcers that may be associated with regional lymphadenitis.

EPIDEMIOLOGY

- Probably underrecognized and underreported
- In underdeveloped countries, it is a major cause of genital ulcer syndrome.
- Major cofactor in the transmission of HIV
- Seen more commonly in males; females are more likely to be asymptomatic.
- Occurs in discrete outbreaks; endemic in some areas of the U.S.
- Sexual contact is the only known route of transmission.
- If diagnosed in children, sexual abuse should be considered.

Incidence

Cases in the U.S. steadily declined until 2000, since then the incidence has fluctuated. In 2009, there were 28 reported cases.

RISK FACTORS

Increased association with individuals involved in drug use and prostitution

GENERAL PREVENTION

- Condom use
- Treatment of partners whether or not they have symptoms
- Evaluation for the presence of other sexually transmitted diseases

PATHOPHYSIOLOGY

- Trauma and abrasion allow the organism to penetrate the epidermis.
- 3–10 days later, an erythematous, tender papule develops and progresses to a pustule.
- The pustule ruptures after 2–3 days, leaving a shallow ulcer with a painful, necrotic base with undermined edges.
- Single or multiple ulcers may be present.

ETIOLOGY

The most common causes of genital ulcer syndrome include syphilis, HSV, and chancroid.

COMMONLY ASSOCIATED CONDITIONS

- Associated with HIV transmission and infection
- Coinfection with syphilis and human herpesvirus may occur (10%).

DIAGNOSIS

Diagnosis of chancroid routinely based on clinical findings after the exclusion of other causes of genital ulcer disease.

HISTORY

- Males usually present with symptoms referable to an acute painful genital ulcer.
- Females may be asymptomatic or present with nonspecific symptoms (dysuria, vaginal discharge, pain with stooling or sexual intercourse, rectal pain, or bleeding).

PHYSICAL EXAM

Classic findings:

- Extremely painful ulcer with an irregular, undermined border and a gray, necrotic center:
 - In males: Found on prepuce or coronal sulcus
 - In females: Found on the vulva, cervix, or perianal area
- Painful, unilateral, inguinal lymphadenopathy in 50%: May spontaneously drain (bubo)
- Extragenital sites are rare and include the inner thigh area, breasts, fingers, mouth.

DIAGNOSTIC TESTS & INTERPRETATION

Diagnosis is made by clinical findings and exclusion of other causes of genital ulcers.

Lab

- Gram stain from the base of the ulcer: May show short gram-negative coccobacilli in parallel “school of fish” arrangement. This finding does not compare favorably with culture-proven or clinically diagnosed cases, so routine use is not helpful.
- Cultures from the ulcer:
 - *H. ducreyi* is a fastidious organism and requires specialized media and technique for successful isolation.
 - Compared with newer amplification techniques, it has been proven to be 75% sensitive
 - Currently the only method routinely available for the definite diagnosis of chancroid
- DNA amplification:
 - A genital ulcer multiplex polymerase chain reaction (GUM) test has been developed for simultaneous amplification of DNA targets from *H. ducreyi*, *T. pallidum*, and HSV types 1 and 2; offers improved sensitivity when compared with culture
 - This technology is not routinely available

- Monoclonal antibody:
 - Monoclonal antibody against the outer membrane protein of *H. ducreyi* using immunofluorescent antibody has also proven to be more sensitive than culture.
 - Could provide easy, rapid, inexpensive, sensitive testing, but not available currently
- Additional testing:
 - Culture and PCR for HSV 1 & 2, RPR: Evaluation for the common causes of genital ulcer syndrome should be done routinely.
 - HIV test: Genital ulcers are a significant cofactor for HIV infection.

DIFFERENTIAL DIAGNOSIS

- Chancroid must be distinguished from the other causes of genital ulcers, including syphilis, herpes simplex virus (HSV), lymphogranuloma venereum, and granuloma inguinale. More than one of these pathogens may be present in individual cases.
- Uncommon etiologies include:
 - Trauma
 - Fixed drug eruptions
 - Lymphogranuloma venereum
 - Inflammatory bowel disease
 - Behçet syndrome

TREATMENT

MEDICATION (DRUGS)

- Azithromycin 1 g PO, once
- Ceftriaxone 250 mg IM, once
- Ciprofloxacin 500 mg b.i.d. for 3 days (patients > 18 years)
- Erythromycin 500 mg q.i.d. for 7 days
- One-time directly observed dosing with azithromycin or ceftriaxone recommended.

SURGERY/OTHER PROCEDURES

Persistent inguinal fluctuant adenitis may be treated with either needle aspiration or incision and drainage.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Symptoms improve within 3–7 days.
- Ulcers heal between 1 and 4 weeks.
- Lymphadenopathy may take longer to regress; may progress to fluctuance in spite of adequate therapy.
- Patients should be followed weekly until symptoms resolve.
- For patients who do not follow the typical course, consider other causes of genital ulcers; noncompliance; presence of a coexisting sexually transmitted disease, especially HIV infection; and, rarely, presence of a resistant organism.
- Recent sexual partners (within the preceding 10 days) should be treated.
- If initial HIV and syphilis test results are negative, they should be repeated in 3 months following diagnosis of chancroid.

PATIENT EDUCATION

Prevention: Condom use with all sexual activity

COMPLICATIONS

- Draining bubo
- Coinfection with syphilis and HSV
- HIV infection

CHEST PAIN

Steven M. Selbst

BASICS

DEFINITION

Chest pain is a common pain syndrome in childhood. It is less common than abdominal pain and headache. Commonly Associated Conditions

COMMONLY ASSOCIATED CONDITIONS

- Asthma
- Cystic fibrosis
- Diabetes mellitus (long-standing)
- Hypertrophic cardiomyopathy
- Kawasaki disease
- Marfan syndrome
- Sickle cell disease
- Systemic lupus erythematosus

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- **Musculoskeletal disorders**
 - Chest wall strain
 - Costochondritis
 - Direct chest trauma
 - Slipping rib syndrome
- **Cardiac pathology**
 - Arrhythmia (supraventricular tachycardia, premature ventricular contractions)
 - Coronary artery anomalies
 - Coronary artery aneurysms (Kawasaki disease)
 - Infections (myocarditis, pericarditis)
 - Myocardial infarction/ischemia
 - Structural abnormalities: Aortic stenosis, hypertrophic cardiomyopathy, pulmonic stenosis, mitral valve prolapse, severe coarctation of the aorta
- **GI disorders**
 - Caustic ingestions
 - Esophageal foreign bodies
 - Esophagitis (sometimes tetracycline, “pill,” induced)
- **Psychogenic causes**
 - Anxiety
 - Hyperventilation
- **Respiratory disorders**
 - Asthma
 - Cough (prolonged)
 - Pleural effusion
 - Pneumonia
 - Pneumothorax: Spontaneous, trauma related, drug related (cocaine)
 - Pneumomediastinum
 - Pulmonary embolism
- **Miscellaneous**
 - Breast mass
 - Cigarette smoke
 - Pleurodynia
 - Precordial catch syndrome
 - Shingles
 - Sickle cell crises
 - Thoracic tumor

APPROACH TO THE PATIENT

Identify the rare child with a serious cause for chest pain (see table in “Physical Exam”—[Important Physical Findings on General Examination of Child with Chest Pain])

- **Phase 1:** Is the patient in acute distress? If so, begin emergency management and proceed rapidly to find the cause of pain.
- **Phase 2:** For most stable children with chest pain, determine whether laboratory tests are needed to help identify the cause.
- **Phase 3:** Treat specific conditions as appropriate. Begin analgesics, reassure the family, and arrange for follow-up care.

Hints for Screening Problems

Take a thorough history and perform a careful physical exam. Examine the chest last—do not focus only on this area. Use laboratory tests sparingly, only to confirm clinical suspicions.

HISTORY

- **Question:** How severe, how often is the pain?
- **Significance:** Constant, frequent severe pain is more likely to be distressing, interruptive of daily activity. Serious etiology is not well correlated with frequency, severity of pain.
- **Question:** What is the type of pain? Its location?
- **Significance:** Burning pain is associated with esophagitis. Sharp, stabbing pain relieved by sitting up or leaning forward is typical of pericarditis. Young children do not describe or localize chest pain well.
- **Question:** When was the onset of pain?
- **Significance:** Acute pain (<48 hours) is more likely to have an organic cause. Chronic pain (>6 months) is more likely to be psychogenic, idiopathic. In an older child with sudden onset of pain, consider an arrhythmia, pneumothorax, or musculoskeletal injury. In a young child with sudden onset of pain, consider a foreign body (coin) in the esophagus, or injury.
- **Question:** Is the pain induced by exercise?
- **Significance:** Exercise-induced chest pain may be related to serious cardiac disease or asthma.
- **Question:** Recent trauma, rough play, or muscle overuse?
- **Significance:** Musculoskeletal (chest wall) pain
- **Question:** Eaten spicy foods? Taken tetracycline or other pills?
- **Significance:** Esophagitis. Teens often take pills with little water and then lie down. The undissolved pill may lodge in the esophagus and cause pain.
- **Question:** Recent use of cocaine?
- **Significance:** Hypertension, tachycardia, myocardial ischemia, or pneumothorax
- **Question:** Use of oral contraceptives or recent leg trauma?
- **Significance:** Pulmonary embolism. This is rare in the pediatric age group.

- **Question:** Recent significant stress (e.g., move, death of loved one, serious illness)?
- **Significance:** Psychogenic pain. We know children have headaches and abdominal pain related to stress. Chest pain may also relate to unusual stress.
- **Question:** Associated complaints?
- **Significance:** Fever may imply pneumonia, myocarditis, and pericarditis. Syncope, palpitations may imply cardiac arrhythmias or severe anemia. Joint pain, rash may relate chest pain to collagen vascular disease. Pain that resolves with parental attention may indicate an emotional cause.
- **Question:** Positive familial history?
- **Significance:** Hypertrophic cardiomyopathy is often familial. Those with this disorder may have familial history positive for sudden death. When there is a positive familial history of heart disease or chest pain, the parents may be unusually concerned about the symptom in a child. The child often has a nonorganic cause.
- **Question:** Past medical history?
- **Significance:** Previous Kawasaki disease, long-standing insulin-dependent diabetes mellitus, and sickle cell disease may have serious cardiac or pulmonary complications leading to chest pain. Marfan syndrome has increased risk for aortic dissection, pneumothorax. Asthma has increased risk for pneumonia, pneumothorax. Collagen vascular disease has increased risk for pleural effusion, pericarditis. Most underlying structural cardiac lesions rarely produce chest pain.

PHYSICAL EXAM

- **Important physical findings on general examination of child with chest pain**
 - Severe distress
 - Chronically ill appearance
 - Fever
 - Skin rash or bruising
 - Abdominal pathology
 - Arthritis present
 - Anxiety apparent
- **Finding:** Child is in significant distress?
- **Significance:** Requires emergency care; stabilization. Consider pneumothorax, arrhythmia.
- **Finding:** Child appears chronically ill?
- **Significance:** Chest pain may be found in serious illnesses such as malignancy (Hodgkin lymphoma) or systemic lupus erythematosus.
- **Finding:** Fever?
- **Significance:** Consider pneumonia, myocarditis, pericarditis
- **Finding:** Skin bruising present?
- **Significance:** Chest pain may be related to unrecognized trauma. Osteomyelitis of the rib is a rare cause.
- **Finding:** Abdominal pathology?
- **Significance:** Pain may be referred to the chest.
- **Finding:** Arthritis present?
- **Significance:** Collagen vascular disease may manifest as pleural effusion, chest pain.
- **Finding:** Unusually anxious child?
- **Significance:** Underlying stress may lead to pain.

- **Important physical findings on chest examination of child with chest pain**
 - Breast abnormality
 - Subcutaneous emphysema
 - Heart murmur, rub, arrhythmia
 - Chest wall tenderness
- **Finding:** Breast enlargement, asymmetry, tenderness?
- **Significance:** Physiologic breast changes in young teens may be painful. Consider pregnancy in teenage girls.
- **Finding:** Decreased breath sounds, wheezing?
- **Significance:** May suggest pneumonia, asthma with overuse of chest wall muscles.
- **Finding:** Subcutaneous emphysema palpable on chest or neck?
- **Significance:** Pneumothorax, pneumomediastinum
- **Finding:** Heart murmur, rub, arrhythmia?
- **Significance:** Congenital heart disease, cardiac infections such as myocarditis, pericarditis, supraventricular tachycardia, ventricular tachycardia
- **Finding:** Tenderness of chest wall, costochondral junctions?
- **Significance:** Musculoskeletal pain

ALERT

Factors that make this an emergency include:

- Pneumothorax: May present with severe sudden chest pain, respiratory distress, cyanosis, hypotension
- Cardiac arrhythmia: Ventricular tachycardia or supraventricular tachycardia in an older child may progress to heart failure or a lethal rhythm.
- Cocaine intoxication: May present with pneumothorax, cardiac arrhythmia, hypertension
- Direct chest trauma: May lead to cardiac contusion and arrhythmia
- Caustic ingestions or esophageal foreign bodies require prompt attention.

DIAGNOSTIC TESTS & INTERPRETATION

- **Test:** EKG
- **Significance:**
 - Obtain if history suggests cardiac pathology (e.g., acute onset of pain, pain on exertion, pain associated with syncope, dizziness, palpitations, history of congenital heart disease, serious associated medical problems [Kawasaki disease, diabetes mellitus], use of cocaine)
 - Obtain also if physical exam is abnormal. For instance, respiratory distress, cardiac abnormality, fever, significant trauma
- **Test:** Holter monitor
- **Significance:** Arrange for this study if cardiac arrhythmia suspected. Electrocardiogram may fail to detect intermittent arrhythmia.
- **Test:** Exercise stress test, pulmonary function tests
- **Significance:** Obtain if pain induced by exertion
- **Test:** Drug screen
- **Significance:** Obtain if cocaine use suspected

Imaging

Chest radiograph:

- Same as for EKG
- Obtain also if history suggests cardiac or pulmonary pathology, tumor, Marfan syndrome, or foreign body (coin ingestion)
- Obtain also if physical exam suggests decreased breath sounds or palpation of subcutaneous air

**TREATMENT****ADDITIONAL TREATMENT****General Measures**

Chest pain in children is rarely related to cardiac pathology: Not all children with chest pain have a benign etiology; pain associated with exertion, syncope, dizziness is concerning for heart disease; if the child is febrile, consider pneumonia or viral myocarditis. Treat specific cause when found. OTC analgesics (acetaminophen, ibuprofen) suffice for most pain. Antacids may be diagnostic and therapeutic for esophagitis pain. Rest, heat, relaxation techniques may be useful. Avoid expensive, invasive laboratory studies with chronic pain and normal physical exam, benign history.

ISSUES FOR REFERRAL

- Acute distress
- Significant trauma
- History of heart disease or related serious medical problem
- Pain with exercise, syncope, palpitations, dizziness
- Serious emotional disturbance
- Esophageal foreign body, caustic ingestion
- Pneumothorax, pleural effusion

**ONGOING CARE****PROGNOSIS**

40% will have continued chest pain for 6–24 months. Most have an excellent prognosis.

**CODES****ICD9**

- 277.00 Cystic fibrosis without mention of meconium ileus
- 493.90 Asthma, unspecified type, unspecified
- 786.50 Chest pain, unspecified

ICD10

- E84.9 Cystic fibrosis, unspecified
- J45.909 Unspecified asthma, uncomplicated
- R07.9 Chest pain, unspecified

FAQ

- Q: How common is chest pain in children?
- A: Chest pain is a common pain syndrome reported in 6/1,000 children who present to an urban emergency department. The complaint is less common than abdominal pain or headache. Although children of all ages may complain of chest pain, the mean age is about 12 years.
- Q: Is follow-up important?
- A: Yes. Serious pathology is unlikely to be found if not diagnosed initially. However, watch for signs of exercise-induced asthma or for emotional problems that were not obvious initially. Ensure that the child returns to normal activity when appropriate.
- Q: What is the prognosis for most children with chest pain?
- A: Most children with chest pain have an excellent prognosis. ~40% of children with chest pain will have continued symptoms for 6–24 months.

CHICKENPOX (VARICELLA, HERPES ZOSTER)

Genevieve L. Buser

Barbara M. Watson (5th edition)

BASICS

DESCRIPTION

Varicella-zoster virus (VZV) is a highly contagious neurotropic herpesvirus.

EPIDEMIOLOGY

- Person-to-person transmission occurs by droplet and airborne transmission of infectious respiratory secretions or direct contact with vesicles and respiratory secretions.
- Incubation 10–21 days (usually 14–16 days) after exposure; cases most contagious 2 days before the rash appears until 5 days after new lesions stop appearing.
 - Immunocompromised patients may have longer or shorter incubation.
 - Post-IVIG, incubation may be up to 28 days.
- Neonates born to mothers with active VZV develop rash 9–15 days (range 1–16) later.
- Immunity from natural disease is usually lifelong; but symptomatic and asymptomatic re-infections do occur, boosting antibody levels.
- Cell-mediated immunity (especially NK cells) is more important than humoral immunity in limiting primary and zoster forms of VZV.
- Disease is more severe in immune-compromised persons, infants >3 months, adolescents, adults, persons with pulmonary disorders (asthma), persons with chronic skin disorders (eczema), and persons on oral and/or IV steroids or long-term aspirin therapy.
- Congenital varicella embryopathy: Risk is 1–2% when maternal primary VZV infection occurs before the 20th week of gestation.
- Since wild-type VZV decreased by 85% from 1995 to 2004, breakthrough VZV or reinfection now represents 62% of all reported VZV cases.

GENERAL PREVENTION

- Since 1995, varicella has been a vaccine-preventable disease and it has been incorporated in the harmonized immunization schedule recommended by the American Academy of Pediatrics (AAP) and American Committee on Immunization Practices (ACIP). Please refer to www.cdc.gov for most up-to-date information.
- Active immunization:
 - Live-attenuated Oka strain vaccine.
 - The vaccine is recommended for routine immunization of all healthy susceptible children, adolescents, and adults.
- Immunogenicity: ~85% of immunized children developed protective levels of humoral and cellular immunity after 1 dose; ~100% with 2 doses. 3 × less likely to have breakthrough disease when 2 doses of vaccine were administered.
- Effectiveness: 70–90% effective against all VZV disease; 100% effective against severe disease (e.g., median number of vesicles was 50 in vaccinated children and 250 in unvaccinated children).
- Duration of immunity > 10 years.

- Contraindications:
 - Anaphylaxis to vaccine components (e.g., neomycin, gelatin)
 - Pregnant, immunocompromised, or <12 months of age.
 - HIV is an exception: It is recommended to vaccinate HIV-positive children if CD4+ T-cell counts are ≥15%. Give doses 3 months apart.
 - High-dose corticosteroid doses of >2 mg/kg/d or >20 mg/d of prednisone, or its equivalent, for ≥14 days are considered immunosuppressive doses: VZV vaccine should not be given until corticosteroid therapy has been discontinued for at least 1 month.
 - This does not apply to topical, inhaled, nasal or physiologic replacement corticosteroids.
- Postexposure prophylaxis:
 - If no contraindication to VZV vaccine: Administer VZV vaccine to susceptible hosts (1st or 2nd dose) within 72 hours (up to 120 hours) of exposure.
 - See “General Measures” for isolation.
 - If contraindications to VZV vaccine: Consider passive immunization.
- Passive immunization if:
 - (i) No evidence of immunity in exposed person, and (ii) probability that exposure will result in infection, and (iii) likelihood of complications of VZV in the exposed person due to risk factors.
 - Administer varicella immunoglobulin (VariZIG) or intravenous immunoglobulin (IVIG) as per protocol within 96 hours of exposure.
 - If VariZIG or IVIG is unavailable, or >96 h have passed, some experts recommend post-exposure prophylaxis with oral acyclovir (20 mg/kg q6h, for 7 days), beginning 7–10 days after exposure.
 - See “General Measures” for isolation.

DIAGNOSIS

HISTORY

- Chickenpox:
 - Fever concurrent with rash.
 - Rash: Pruritic maculopapular to vesicles “dew drop on a rose petal”; appear in crops, begin on trunk/back, then to extremities, face. Vesicles break and crust over 3–5 days. Lesions in all stages on same child.
 - Headache, malaise, decreased appetite.
- Zoster:
 - Prodrome of pain, pruritus, paresthesias, allodynia in 1–3 dermatomes 1–3 days prior to appearance of vesicles. Scab in 5–10 days.
 - No systemic symptoms unless dissemination outside of dermatome (e.g., viremia)

PHYSICAL EXAM

- Chickenpox:
 - Pathognomonic rash: May be scant or atypical in immunocompromised hosts
 - Vesicles may appear in the mouth, conjunctiva, vagina, and urethra.
 - Assess for complications: Interstitial pneumonia, encephalitis, secondary bacterial infection (especially group A streptococcus).

- Zoster:
 - Chest > ophthalmic branch of trigeminal (V1)
 - Ramsey-Hunt: Zoster oticus and ipsilateral lower motor neuron palsy (7th, geniculate).
 - Hutchinson sign: Zoster on medial side of nose and herpes zoster ophthalmicus
 - Assess for extra-dermatomal lesions to suggest dissemination, and infection.

DIAGNOSTIC TESTS & INTERPRETATION Lab

- Immunofluorescence: Vesicular fluid, bronchoalveolar lavage (BAL)
- PCR: Vesicular fluid, blood, CSF, BAL
- Culture: Vesicular fluid, blood, CSF, BAL
- Serology:
 - Acute and convalescent sera: Enzyme immunoassay (EIA), immunofluorescence assay (IFA), latex agglutination (LA), fluorescent antibody to membrane antigen (FAMA), and enzyme-linked immunosorbent assay (ELISA).
 - The complement-fixation test is not reliable in determining immunity and has been abandoned.

DIFFERENTIAL DIAGNOSIS

The differential diagnosis includes other causes of vesicular rash:

- Coxsackie virus infection (hand, foot, mouth)
- Eczema herpeticum
- Herpes zoster with dissemination
- Impetigo
- Insect bites
- Monkeypox
- Mycoplasma (erythema multiforme)
- Pseudomonas (ecthyma gangrenosum)
- Rickettsial pox
- Scabies
- Toxic epidermal necrosis, Stevens-Johnson, and various noninfectious vesicular conditions of the skin.

TREATMENT

MEDICATION (DRUGS)

- Acyclovir, valacyclovir, famciclovir, foscarnet, and vidarabine have been shown in clinical trials to be effective against VZV.
- Acyclovir is the drug of choice in children.
- Any child who is ill enough to warrant hospitalization and whose rash demonstrates new vesicle formation should be treated with IV acyclovir, including immunocompromised hosts:
 - <1 year: 10–20 mg/kg q8h
 - ≥1 year: 500 mg/m² q8h, or 10–20 mg/kg q8h
 - ≥12 years: 10 mg/kg q8h
- Because of poor oral bioavailability, use IV route in immunocompromised hosts.
- Treat for 7–10 days, or until no new lesions for 48 hours.
- Chickenpox or zoster in outpatient immunocompetent patient requiring treatment because of risk factors:
 - Acyclovir (PO): (>2 years old): 20 mg/kg q6h, to max of 800 mg q6h, for 5 days.
 - Valacyclovir (PO): (≥12 years old) 1000 mg q8h, for 5 days. Better bioavailability.

- Children with VZV should not receive salicylates because of the association with Reye syndrome. Use acetaminophen to control fever.
 - Consider treatment in immunocompetent patients if there is an increased risk of complications: ≥12 years old, secondary household case, chronic cutaneous or pulmonary disease, newborn infants, or persons on short or intermittent or inhaled corticosteroids, or long-term salicylate therapy.
- In the era of a preventable disease, acyclovir should be considered before complications of varicella warrant hospitalization.

ADDITIONAL TREATMENT

General Measures

- Isolation of hospitalized patients with chickenpox:
 - Contact and Airborne Precautions of the index case for the duration of vesicular eruption and all vesicles crusted (usually 5 days, longer in immunocompromised patients)
 - Use negative-pressure rooms, if possible.
 - Exposed susceptible persons should be in Contact and Airborne precautions from day 8 to 21 after the onset of rash in the index patient.
 - Neonates born to mother with VZV: Contact and Airborne precautions until day 28.
 - Embryopathy does not require precautions if there are no active lesions.
 - Persons who received VariZIG or IVIG should be kept in Contact and Airborne precautions for 28 days after exposure.
- Isolation of hospitalized patients with zoster:
 - Immunocompromised patients who have zoster (localized or generalized) and immunocompetent patients with disseminated zoster should remain in Contact and Airborne Precautions for the duration of the illness, as above.
 - Immunocompetent patients with localized zoster: Contact Precautions until all lesions crusted.
- Isolation of outpatients with chickenpox:
 - Child should remain at home, away from susceptible and high-risk persons, until no new eruptions and all vesicles have crusted.
- Isolation of outpatients with zoster:
 - For immunocompetent patients with localized zoster, Contact Precautions are recommended until all lesions are crusted. If lesions can remain completely covered, child may return to school; however, active lesions are infectious.
 - Antivirals such as acyclovir, valacyclovir, or famciclovir may shorten the duration of outpatient VZV disease and shedding to others.

 **ONGOING CARE**

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

For normal healthy individuals, follow-up is not necessary.

PROGNOSIS

- For most children, this childhood exanthema is a benign disease that lasts 6–8 days.
- Postherpetic neuralgia can cause significant morbidity following zoster.

COMPLICATIONS

Complications are associated with significant morbidity and may occur regardless of the use of acyclovir:

- Secondary bacterial infection—especially group A streptococcal infections and *Staphylococcus aureus*
- CNS (1 in 4000): Transverse myelitis, myelopathy, encephalitis (60 cases/yr prevaccine), meningo-encephalitis, acute cerebellar ataxia, necrotizing retinitis
- Varicella interstitial pneumonitis (more common in adults and infants)
- GI: Pancreatitis, appendicitis, and hepatitis
- Heme: Idiopathic thrombocytopenia, disseminated intravascular coagulation (hemorrhagic VZV)
- Nephritis
- Vasculopathy of small and large cerebral vessels causing strokes
- Zoster sine herpete: Radicular pain without rash, but virologic confirmation of reactivation. Can be dermatomal or CNS.
- Individuals with AIDS may have chronic VZV, including progressive myelopathy.
- Congenital varicella syndrome: Characterized by limb atrophy and scarring of the extremity (cicatrices), CNS, and eye manifestations.
- Postherpetic neuralgia: neuropathic pain more common in zoster patients >60 years.
- Death: 1–2 deaths per week in the US; between 1990 and 1994, varicella was the most common vaccine-preventable cause of death in individuals <20 years. However, the universal immunization program has reduced this to 4 deaths in the year 2001.

FAQ

- Q: What do you do for a patient on corticosteroids who has not had VZV and is exposed to VZV?
- A: The patient is considered immunosuppressed if he is receiving >2 mg/kg/d or >20 mg/d of prednisone or its equivalent. If the child is susceptible, had sufficient exposure, and is at risk for serious disease, he is a candidate for passive immunization with VariZIG or IVIG, or acyclovir post-exposure prophylaxis, because a vaccine is contraindicated now. Also, he should be on Contact and Airborne precautions (if inpatient) from day 8 to 28 from the exposure.
- Q: What about asthmatic patients on inhaled steroids? Can they be immunized safely, and are they at risk of more severe varicella if not immunized?
- A: Yes, asthmatics on inhaled steroids can be safely immunized because the dose of inhaled steroid is not immunosuppressive. Recent data show that asthmatic children who are unimmunized get more severe wild-type varicella disease.
- Q: Is there any patient who should not receive VZV vaccine?
- A: Yes. Immunosuppressed individuals, pregnant patients, and infants <1 year old should not receive the VZV vaccine. HIV patients can get VZV vaccine if CD4+ T-cell counts are ≥15%.
- Q: How contagious is breakthrough (reinfection) varicella disease?
- A: Surveillance studies have demonstrated that the secondary attack rate from breakthrough (re-infection) varicella is 30% in individuals with >50 lesions. Hence, when such individuals can expose high-risk susceptible patients in health care settings, infection control precautions should be observed. Public health investigation of outbreaks has demonstrated transmission of varicella from vaccinated individuals to high-risk, susceptible individuals (e.g., acute lymphocytic leukemia, transplant recipients, or HIV).
- Q: If a child gets zoster, with wild-type or vaccine strain, should she or he be treated with antiviral drugs?
- A: Maybe, surveillance studies have demonstrated that adolescents and children who develop herpes zoster after wild-type varicella infection have more pain and hospitalizations due to secondary infection than those with vaccine-strain varicella. Treatment of herpes zoster in children (as has been demonstrated in adults) shortens the course of illness and, more importantly, in school-aged children, decreases shedding. Since active surveillance has demonstrated that herpes zoster cases can be index cases in outbreaks, it is a public health option to treat herpes zoster in children who are going back to school.
- Q: I carry both the varicella-zoster and the zoster vaccine in my office, as I see both children and adults. Can I use the zoster vaccine in a child, instead of the varicella-zoster vaccine?
- A: No. The zoster vaccine is formulated very differently than the varicella-zoster vaccine, and should only be given to in adults >60 years old, as indicated.

CHILD ABUSE, PHYSICAL

Sarah M. Frioux

Cindy W. Christian

BASICS

DESCRIPTION

Injuries or illnesses that occur to children as a result of family dysfunction. In practice, child abuse is considered nonaccidental injury of children at the hands of their caregivers. Physical abuse is legally defined by state laws.

EPIDEMIOLOGY

- Abuse may occur in families from any socioeconomic class, ethnicity, or community.
- The recognition of child physical abuse begins with the clinician's acknowledgement that child abuse occurs commonly.
- Parents who were abused as children are at much greater risk for abusing their own children. It is estimated that 30% of abused children go on to be abusive parents.

Incidence

- In 2008, there were 3.3 million referrals to child welfare agencies in the US for child abuse and neglect. ~702,000 children were determined to be victims of child maltreatment.
- The child abuse victimization rate was 9.3 per 1,000 children in the national population.
- Almost 1,800 abusive deaths per year, by conservative estimates

Prevalence

Domestic violence and child abuse have a 50% concurrence.

GENERAL PREVENTION

- Much of what is considered prevention is actually early intervention in high-risk families.
- Primary prevention would include universal parenting education and home visitation for all families. Currently, families thought to be at risk for abuse are identified and offered services.
- Home visitation by nurses for low-income, 1st-time mothers has been shown to decrease the risk for child abuse.
- Screening families for domestic violence can be the 1st clue to child victimization.

ALERT

Pitfalls:

- Failing to consider abuse in the differential diagnosis of all pediatric trauma
- Failing to consider abuse in the differential diagnosis of all infants and toddlers with mental status changes (especially apparent life-threatening events [ALTEs]), even in the absence of bruising
- Failing to consider alternative medical diagnoses in children for whom you suspect abuse
- Acute (<10 days) rib fractures are easily missed on radiographs.

ETIOLOGY

Multifactorial:

- Includes societal, familial, and individual factors
- Associated with poverty, family stress, family isolation

COMMONLY ASSOCIATED CONDITIONS

- Domestic violence
- Sexual abuse
- Neglect
- Emotional abuse
- Juvenile delinquency
- Poverty
- Parental substance abuse, including alcohol

DIAGNOSIS

HISTORY

- A detailed history of injury is essential for comparing the mechanism provided by the historian with the injuries identified.
- The following historical features should raise the question of child physical abuse:
 - History provided does not correlate with findings.
 - Child's development is not compatible with mechanism described.
 - History of events changes with time.
 - Unexpected delay in seeking care
 - No history of trauma is provided. In such cases, ask when the child was last well, and who was caring for the child at that time. This may be helpful in identifying when the child was injured and by whom.
 - Search for indications of family stress, isolation, substance abuse, and violence, including domestic violence.

PHYSICAL EXAM

- Always perform a complete exam in a well-lit room.
- Assess for:
 - Growth failure
 - Bruises: Any inflicted injury that lasts >24 hours constitutes significant injury.
 - Burns
 - Oral injuries
 - Palpable rib fractures
 - Abdominal injuries
 - Genital injuries
 - Retinal hemorrhages: Children with suspected abusive head trauma should have a dilated eye exam by an ophthalmologist.
- Are the findings explained by any medical condition? Examples would include multiple bruises in a patient with a bleeding disorder or long bone fractures in a patient with a metabolic bone disease (such as rickets).

DIAGNOSTIC TESTS & INTERPRETATION

Lab

For children with bruising and/or bleeding:

- CBC, including a platelet count: Evaluate for anemia and thrombocytopenia.
- Prothrombin time/partial thromboplastin time, INR: Evaluate for hemophilia and other bleeding disorders.
- Platelet function evaluation (PFA-100): Evaluate for von Willebrand disease.
- Liver function tests: Evaluate for liver injury.
- Amylase, lipase: Evaluate for pancreatic injury.
- Urinalysis: Screen for genitourinary injury, abdominal trauma, or myoglobinuria.
- Creatine kinase (if muscle injury or extensive soft tissue injury): Evaluate for muscle injury, possible myoglobinuria.
- Lumbar puncture: Evaluate for meningitis; identify bloody CSF.
- Toxicology screen: For unexplained altered mental status or if it is suspected that the child may have been poisoned

Imaging

- Skeletal survey: Recommended for all children <2 years old and for occasional children 2–5 years old with suspected abusive injuries. Repeat skeletal surveys 2–3 weeks after initial presentation often reveal additional fractures that were not visible at the time of acute injury.
 - Not generally used for children >5 years
 - Bony injuries highly suggestive of physical abuse include posterior rib, metaphyseal (also known as bucket-handle or corner fractures), scapular, sternal, and spinous process fractures.
- Other radiography: Clavicle, long bone shaft, and linear skull fractures are common accidental fractures that have low specificity for physical abuse.
- Radionuclide bone scan: Serves as an adjunct to skeletal survey
- CT and MRI:
 - For suspected head, thoracic, or abdominal trauma
 - MRI or head CT should be considered in all children <1 year with other concerning/suspicious injuries, such as unexplained bruises or fractures.
 - Subdural hemorrhage is a hallmark of abusive head trauma. Subdural hemorrhages associated with abuse can be located anywhere around the brain, but are often found in the posterior interhemispheric fissure.

Pathological Findings

In cases of child death due to suspected physical abuse, a full autopsy must be completed by a qualified examiner.

DIFFERENTIAL DIAGNOSIS

- Varies depending on injury sustained
- Bruises:
 - Accidental injury
 - Dermatologic disorders: Mongolian spots, erythema multiforme, phytophotodermatitis
 - Hematologic disorders: Idiopathic thrombocytopenic purpura (ITP), leukemia, hemophilia, vitamin K deficiency, disseminated intravascular coagulopathy (DIC), platelet disorders, hemophilia
 - Cultural practices: Cao gio (coining; practice of rubbing the skin with a coin to alleviate various symptoms of illness); quat sha (spoon rubbing)
 - Infection: Sepsis, purpura fulminans (e.g., with meningococemia)
 - Genetic diseases: Ehlers-Danlos, familial dysautonomia (with congenital indifference to pain)
 - Vasculitis: Henoch-Schönlein purpura
- Burns:
 - Accidental burns
 - Infection: Staphylococcal scalded skin syndrome, impetigo
 - Dermatologic: Phytophotodermatitis, Stevens-Johnson syndrome, fixed drug eruption, epidermolysis bullosa, severe diaper dermatitis
 - Cultural practices: Cupping (process by which a small amount of alcohol is heated in a cup and inverted over the skin). As the heated air cools, a vacuum is produced causing ecchymotic lesions. It is believed that this suction from the cup will draw out illness. Moxibustion (Chinese folk remedy in which cones or balls of the moxa herb are burned on the skin at therapeutic points)
- Fractures:
 - Accidental injury
 - Birth trauma
 - Metabolic bone disease: Osteogenesis imperfecta, copper deficiency, rickets
 - Infection: Congenital syphilis, osteomyelitis
- Head trauma:
 - Accidental head injury
 - Hematologic disorders: Vitamin K deficiency (hemorrhagic disease of the newborn), hemophilia, DIC
 - Intracranial vascular abnormalities
 - Infection
 - Metabolic diseases: Glutaric aciduria type I

**TREATMENT****ADDITIONAL TREATMENT****General Measures**

- Report all suspected abuse to local child welfare agency.
- Report abuse to law enforcement when injuries warrant police investigation.
- Consult social worker.

IN-PATIENT CONSIDERATIONS**Admission Criteria**

- Hospitalization is primarily for the treatment of the identified injuries.
- Admission to the hospital to ensure the protection of the child during initial investigation by child welfare is sometimes necessary.

Discharge Criteria

Discharge disposition is generally dependent on determinations from child welfare agencies regarding the safety and welfare of the child victim.

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

- Cases will be investigated by child welfare agents and/or the police.
- Need for foster care placement and/or ongoing supervision decided by child welfare investigators
- Improvement of individual injuries varies according to the injury.
- Family functioning may improve with intervention for some families, but may never improve for others. Changes in family functioning often require intensive, long-term intervention.
- Noncompliance with medical follow-up or additional injuries to child may indicate ongoing abuse or parental substance abuse.

PROGNOSIS

Varies greatly depending on injuries sustained, family problems, available support systems

COMPLICATIONS

- Death
- Mental retardation
- Cerebral palsy
- Seizures
- Learning disabilities, school failure
- Emotional problems

FAQ

- Q: What are the signs of abusive head trauma?
- A: Abusive head trauma is a clinical diagnosis based on history, physical exam findings, and radiologic data. The hallmark of abusive head trauma is subdural hemorrhage, which is often a marker for diffuse, deceleration brain injury. Most victims (80%) have retinal hemorrhages, which tend to be bilateral, multilayered, and sometimes severe. Some, but not all, children have old and/or new skeletal or skin injuries, although these are not always identified. The symptoms of head trauma in young children are nonspecific and include mental status changes, apparent life-threatening events, vomiting, lethargy, irritability, and seizures. Abusive head injury in infants is often missed by physicians who fail to consider the diagnosis in babies with the above-mentioned symptoms, leading to further injury or death of abused infants.
- Q: Are retinal hemorrhages pathognomonic for physical abuse?
- A: No. Retinal hemorrhages may be seen in a variety of diseases and in many newborn infants. They occur in ~30% of newborns delivered vaginally. In these children they usually resolve in a few days, but may rarely last for 5–6 weeks. Outside of the newborn period, severe inflicted injury is the leading cause of retinal hemorrhages in children. Retinal hemorrhages may also result from increased intracranial pressure, severe hypertension, carbon monoxide poisoning, meningitis, vasculitis, endocarditis, and coagulopathy. Severe, bilateral hemorrhages are often related to abuse.
- Q: When is a child abuse report filed?
- A: Whenever there is a suspicion, based on the history, physical exam, laboratory data, and/or psychosocial assessment, that a child's injuries or illnesses were a result of abuse or neglect. Certainty regarding the diagnosis is not needed.
- Q: Can I be held liable for reports that are made that are not substantiated?
- A: No. Health care workers who report suspected abuse in good faith are protected by state laws that mandate physicians to report suspected abuse.

CHLAMYDIAL INFECTIONS

Marleine Ishak
Sumit Bhargava

BASICS

DESCRIPTION

Chlamydiae are obligate intracellular bacteria responsible for pulmonary infections, ocular trachoma, STDs, and infections of the genital tract in the pediatric and adult population.

- The genus *Chlamydomphila* has 3 species known to affect humans:
 - *C. trachomatis*
 - *C. psittaci*
 - *C. pneumoniae*
- All 3 species can produce the clinical picture of the so-called atypical or interstitial pneumonia.
- *C. trachomatis* can cause afebrile pneumonia in 10–20% of infants born to infected mothers. Infected infants usually present prior to 2 months of age. Up to 50% of patients have a history of inclusion conjunctivitis.
- *C. psittaci* is mainly pathogenic for birds and occasionally affects humans, typically causing interstitial pneumonitis with associated fever, headache, malaise, and nausea.
- *C. pneumoniae* causes pneumonia, pharyngitis, sinusitis, and bronchitis in humans. Along with *Mycoplasma pneumoniae*, *C. pneumoniae* probably accounts for most of the community-acquired pneumonias (CAP) in school-age children and adolescents.

ALERT

- *C. trachomatis*:
 - Infection can occur in infants delivered by cesarean section, even without rupture of amniotic membranes.
 - Ocular prophylaxis at birth does not reliably prevent conjunctivitis or extraocular infection, even if erythromycin ointment is used. Topical treatment alone is not recommended because it does not eradicate the nasopharyngeal colonization.
- *C. pneumoniae*:
 - Lack of a commercially reliable test for diagnosis. Microimmunofluorescence (MIF) is proven diagnostic in >50% of infected children. An increase in antibody titer may be delayed for several weeks after onset of symptoms. Early antimicrobial therapy may interfere with the development of detectable antibodies.
 - Sometimes, it is difficult to differentiate between infection and carrier state, and between recent and past infection.
 - Recurrent infections are common. Prolonged nasopharyngeal shedding can occur for months after acute disease.
- Isolation: Standard precautions for both *C. pneumoniae* and *C. trachomatis*
- Control measures: In infants infected with *C. trachomatis*, the mother and her sexual partner should be treated. None for *C. pneumoniae*

GENERAL PREVENTION

Adequate surveillance and treatment of *C. trachomatis* colonizing the genital tract of pregnant women is the best way of preventing disease in the infant.

EPIDEMIOLOGY

- *C. trachomatis*:
 - There are at least 18 serologically distinct variants (serovars A through K).
 - *C. trachomatis* is the most frequent cause of epididymitis in sexually active young men.
 - Incubation period: 5–14 days after delivery for conjunctivitis
 - The possibility of sexual abuse should be considered in older infants and children with vaginal, urethral, or rectal *C. trachomatis*.
- *C. psittaci* (psittacosis/ornithosis):
 - Both healthy and sick birds can transmit the bacteria via the airborne route by their excrement or secretions.
 - Important sources of human disease are parakeets, parrots, macaws, pigeons, and turkeys.
 - Workers in poultry slaughter plants, poultry farms, pet shops, laboratory workers, and pet owners are at high risk.
 - Although usually rare in children, it should be considered in any child with environmental exposure who develops an atypical pneumonia. The incubation period is 7–14 days.
- *C. pneumoniae*: Antigenically, morphologically, and genetically distinct from other chlamydiae
 - It is assumed to be transmitted from person to person through aerosolized respiratory secretions.
 - *C. pneumoniae* has recently been associated with atherosclerotic cardiovascular disease. Limited evidence associates *C. pneumoniae* with asthma and bronchospasm, Alzheimer disease, multiple sclerosis, Kawasaki disease, HIV and other immune disorders, malignancy, otitis media, and episodes of acute chest syndrome in patients with sickle cell disease.
 - Coinfection with other respiratory pathogens, especially *M. pneumoniae* and *Streptococcus pneumoniae*, is frequent.
 - Incubation period: ~21 days

Incidence

- *C. trachomatis*:
 - This is the most common reportable sexually transmitted infection in the USA. The number of new infections exceeds 4 million annually.
 - *C. trachomatis* is responsible for neonatal conjunctivitis, trachoma, pneumonia in young infants, genital tract infection, and lymphogranuloma venereum (LGV).
 - Rates of infection in adolescent girls are 15–20%.
 - 23–55% of all cases of nongonococcal urethritis in men are caused by *C. trachomatis*. Up to 50% of men with gonorrhea may be coinfecting with *C. trachomatis*.
 - *C. trachomatis* pneumonia usually develops in infected infants <2 months of age (2 weeks to 5 months). The contagiousness of pulmonary disease is unknown, but is considered low.
 - Half of the neonates born to infected mothers via vaginal delivery will acquire *C. trachomatis*. Conjunctivitis may develop in 30–50%.
 - Pneumonia may develop in up to 30% of infants with nasopharyngeal infection.

- Ocular trachoma caused by serovars A, B, Ba, and C is the most common cause of preventable blindness in the world, but is rare in the USA.

Prevalence

C. pneumoniae:

- Increased prevalence rates of *C. pneumoniae* specific antibody have been documented in school-age children, reaching 30–45% in adolescents.
- Studies of CAPs in children have found *C. pneumoniae* in 6–19% of cases. Evidence of lower respiratory tract infection has been found in 0–18% of the pediatric population.
- Most infections are mild or asymptomatic. Acute infection does not appear to vary by season. A carriage state has been detected in 2–5% of patients. Recurrent infection is common, especially in adults.

DIAGNOSIS

HISTORY

- *C. trachomatis*:
 - Presents between 4 and 12 weeks of age
 - Insidious onset
 - Afebrile illness
 - Rhinorrhea
 - Repetitive cough: Staccato type in >50% of infants; sometimes, pertussis-like coughing spells
 - Conjunctivitis in up to 50% of infants
 - Mild-to-moderate respiratory distress
- *C. pneumoniae*:
 - Often insidious onset
 - May manifest as pharyngitis, sinusitis, bronchitis, or pneumonia
 - Fever
 - Hoarseness
 - Prolonged cough; can be productive
 - Biphasic course

PHYSICAL EXAM

- *C. trachomatis*:
 - Afebrile
 - 50% of patients will have conjunctivitis with discharge (can be seen up to several weeks after birth).
 - Rhinitis with mucoid discharge or nasal stuffiness, sometimes causing significant airway obstruction
 - Hypoxia is frequently present
 - Apneic episodes may be seen in preterm infants
 - Moderate tachypnea (50–60 breaths/min)
 - Staccato cough
 - Scattered rales on chest auscultation
 - Wheezing is an uncommon finding.
- *C. pneumoniae*:
 - Patients may be asymptomatic or mildly to moderately ill.
 - Prolonged cough (2–6 weeks)
 - Cervical lymphadenopathy
 - Postnasal discharge
 - Nonexudative pharyngitis: Wheezing, frequently without rales, on chest auscultation
- *C. psittaci*:
 - Abrupt onset of fever.
 - Nonproductive cough
 - Malaise

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- *C. trachomatis*:
 - Definitive diagnosis is by isolation of the organism in tissue culture. Confirmation is by microscopy of the characteristic inclusions by fluorescent antibody staining. Specimens are obtained from the nasopharynx, conjunctiva, vagina, or rectum. Dacron polyester-tipped swabs should be used for collection.
 - FDA-approved nucleic acid amplification methods such as polymerase chain reaction (PCR), strand displacement amplification (SDA), and transcription-mediated amplification (TMA) are more sensitive (98%) than cell culture and more specific and sensitive than DNA probe, direct fluorescent antibody (DFA), or enzyme immunoassay (EIA). In addition, these have been approved for urine studies in both men and women, making them useful noninvasive tests for adolescents.
 - DNA probe, DFA, and EIA are the most common nonculture direct antigen-detection tests approved by the FDA. These are most sensitive (90%) and specific (95%) in conjunctival specimens. These methods can have false-positive results when used for vaginal or rectal specimens.
 - Serum antibody detection is difficult to perform, and tests are not widely available.
 - Eosinophilia of 300–400/mm³, hyperinflation, bilateral diffuse infiltrates on chest radiograph, and elevation of IgM (> 110 mg/dL) and IgG (> 500 mg/dL) are indirect evidence that indicate *C. trachomatis* pneumonia.
 - Only culture should be used for sexual abuse or other forensic purposes.
 - Annual Chlamydia screening for all sexually active women younger than age 25 and for all pregnant women in the first trimester of pregnancy is recommended.
- *C. pneumoniae*:
 - No reliable test is available commercially. Serologic testing is the primary laboratory means of diagnosis.
 - The nasopharynx is the optimal site for recovery of *C. pneumoniae*. It is also isolated from sputum and pleural fluid.
 - Serologic diagnosis by MIF is the most sensitive and specific test. Evidence of acute infection: 4-fold elevation of IgG titers, specific IgM titer of ≥ 1:16, specific IgG titer of ≥ 1:512, WBC count is usually normal.
- *C. psittaci*:
 - 4-fold increase in acute and convalescent serum antibodies concentrations.

Imaging

Chest radiography:

- *C. trachomatis*: Hyperinflation with bilateral diffuse infiltrates
- *C. pneumoniae*: Focal to bilateral infiltrates; pleural effusions

DIFFERENTIAL DIAGNOSIS

- *C. trachomatis*:
 - Viral respiratory pathogens: Respiratory syncytial virus (RSV), adenovirus, influenza A and B, parainfluenza
 - Other agents that can cause pneumonitis: cytomegalovirus, *Pneumocystis carinii*, *Ureaplasma urealyticum*, *Bordetella pertussis*

- *C. pneumoniae*:
 - *M. pneumoniae*
 - Influenza A and B
 - Parainfluenza
 - Adenovirus
 - Respiratory syncytial virus
 - Can resemble typical bacterial pneumonia
 - Less frequently: *C. psittaci*, *Coxiella burnetii*, or *Legionella pneumophila*

TREATMENT

MEDICATION (DRUGS)

- *C. trachomatis*:
 - Erythromycin, 50 mg/kg/d divided q.i.d. for 14 days (therapy is effective in 80–90% of cases). Additional topical therapy is unnecessary. An association between oral erythromycin and infantile hypertrophic pyloric stenosis (IHPS) has been reported in infants <6 weeks of age. Parents should be informed of the possible risk of IHPS and its signs.
 - If the patient does not tolerate erythromycin, oral sulfonamides may be used after the immediate neonatal period. Children >8 years can be treated with tetracycline, 25–50 mg/kg/d divided q.i.d. for 7 days
 - A single 1-g oral dose of azithromycin may be used in children ≥45 kg or ≥8 years of age.
 - In adults and adolescents, a single 1-g dose of azithromycin or doxycycline 100 mg b.i.d. orally for 7 days is first-line treatment.
- *C. pneumoniae*:
 - Erythromycin suspension: 50 mg/kg/d divided q.i.d. for 14 days. For adolescent patients, erythromycin 500 mg q.i.d. for 14 days or 250 mg q.i.d. for 21 days. An alternative for children >9 years is doxycycline 100 mg b.i.d. for 14 days.
 - Clarithromycin: 15 mg/kg/d divided b.i.d. for 10 days is as effective as erythromycin.
 - Azithromycin: 10 mg/kg on day 1 (maximum, 500 mg) followed by 5 mg/kg days 2–5 (maximum, 250 mg) is as effective as erythromycin in pediatric studies.
 - Adolescents can be treated with doxycycline 100 mg b.i.d. for 14–21 days, tetracycline 250 mg q.i.d. for 14–21 days, azithromycin 1.5 g for 5 days, levofloxacin 500 mg/d PO or IV for 7–14 days, or moxifloxacin 400 mg/d PO for 10 days.
 - Antibiotic treatment failure rate is ~20%. A second course of therapy is sometimes needed. Follow-up should be recommended.

ONGOING CARE

PROGNOSIS

- In general, good
- Infection with *C. trachomatis* has been associated with long-term respiratory sequelae, such as an increased incidence of reactive airway disease and abnormal pulmonary function tests.
- Slow recovery
- Cough and malaise may persist for several weeks.

COMPLICATIONS

- In very young infants, chlamydial pneumonia can lead to apnea or respiratory failure. If untreated, infection can persist for weeks to months and can lead to persistent hypoxemia

- Complications of psittacosis include myocarditis, hepatitis, pancreatitis, and secondary bacterial pneumonia.
- 40% of women whose chlamydial infection is untreated develop pelvic inflammatory disease. 20% of these women may become infertile.
- Role of Chlamydia in pathogenesis of asthma and atherosclerosis is under investigation.

CODES

ICD9

- 077.98 Unspecified diseases of conjunctiva due to chlamydiae
- 079.98 Unspecified chlamydial infection
- 483.1 Pneumonia due to chlamydia

ICD10

- A74.0 Chlamydial conjunctivitis
- A74.9 Chlamydial infection, unspecified
- J16.0 Chlamydial pneumonia

FAQ

- Q: If the mother has an untreated genital infection, should we treat the asymptomatic newborn?
- A: Yes. The child should receive oral erythromycin for 14 days.
- Q: Do we need to pursue the diagnosis of other STDs?
- A: Yes. Gonorrhea, syphilis, hepatitis B, and human immunodeficiency virus infection need to be ruled out. If conjunctivitis is present, an ocular swab to exclude *Neisseria gonorrhoeae* infection must be included.
- Q: When do we need to suspect *C. trachomatis* pneumonia?
- A: In any infant <4 months of age who presents with cough, tachypnea, and rales on examination, when the chest radiograph shows bilateral infiltrates with hyperinflation.

CHOLELITHIASIS

Michelle T. Rook
Vera de Matos (5th edition)

BASICS

DESCRIPTION

Cholelithiasis is defined by the presence of cholesterol and/or pigment stones in the gallbladder. Rare in infancy and childhood, it is usually found incidentally on an ultrasound. Risk factors in children include obesity, hemolytic disease, cystic fibrosis (CF), Crohn disease, and long-term total parenteral nutrition (TPN).

EPIDEMIOLOGY

- Cholelithiasis is relatively uncommon in childhood and adolescence; however, the incidence is increasing.
- Gallstones occurring in utero and in infancy have been described.
- Obesity accounts for up to 1/3 of the gallstones observed in all children and the majority of children with no underlying medical conditions. Obesity is estimated to increase the risk of gallstones in children by over 4-fold.
- Canadian Eskimos and Native Africans have the lowest risk of cholelithiasis.
- Native Americans, Swedes, Scandinavians, and Czechs have the highest risk.
- Pigment stones are more prevalent in prepubertal children, whereas cholesterol stones are predominant in adolescence and adulthood.

Incidence

- Prior to puberty the incidence of gallstones is equal in males and females. After puberty the incidence increases in females.
- In females, the incidence of cholelithiasis is 0.27% between the ages of 6 and 19 years, increasing to 2.7% between the ages of 18 and 29 years.
- There is an increased incidence in sickle cell disease, with up to 50% having gallstones by 22 years of age.

Prevalence

- The prevalence of cholelithiasis in children and adolescents reported in the literature is ~0.1–0.6%.
- In obese children, the prevalence is 2%.
- In children with sickle cell disease, the prevalence is 17–29%.
- The prevalence of gallstones in North American and European adults is 10–20%.

RISK FACTORS

- Acute renal failure
- Anatomic abnormalities (biliary stricture, duodenal diverticulum)
- CF
- Chronic hemolysis (sickle cell disease, thalassemia, spherocytosis, malaria)
- Chronic overnutrition with carbohydrate and triglyceride-rich, low-fiber diet
- Down syndrome
- Family history
- Female gender
- Hepatobiliary disease/cirrhosis

- Ineffective erythropoiesis (vitamin B₁₂ and folate deficiencies)
- Medications (estrogens, octreotide, clofibrate, furosemide, cyclosporine, ceftriaxone, oral contraceptives)
- Necrotizing enterocolitis
- Obesity
- Pregnancy/Parity
- Prematurity
- Prolonged fasting/low-calorie diets/rapid weight loss
- Severe Crohn disease of the ileum and/or ileal resection
- TPN
- Trauma/Abdominal surgery

Genetics

- Mutations have been identified in genes encoding the ABC transporters for phosphatidylcholine (adenosine triphosphate-binding cassette, subfamily B), for bile salts (*ABCB11*), or for cholesterol 7 α -hydroxylase (*CYP7A1*), the CCK-A receptor (*CCKAR*) and the CF gene (*CFTR*).
- *ABCB4* is also known as *MDR3* (multidrug-resistant 3 glycoprotein). *MDR3* is a phospholipid translocator in the hepatocyte membrane, involved in biliary phosphatidylcholine excretion. *MDR3* deficiency can cause severe neonatal liver disease, but mutations in *MDR3* have also been associated with cholelithiasis, cholestasis of pregnancy, and biliary cirrhosis.
- Variants of *ABCG8* and *UGT1A1*, associated with bile acid metabolism and Gilbert syndrome, are risk factors for cholelithiasis
- Other gene polymorphisms are currently under investigation in humans.

GENERAL PREVENTION

Exercise and dietary modifications can decrease gallstone formation.

PATHOPHYSIOLOGY

- Bile is an aqueous solution of lipids, with bile salts, phospholipids, and cholesterol. Changes in the proportion of bile constituents, nucleation (aggregation of cholesterol crystals), changes in gallbladder motility, or infection can lead to stone formation.
- Stones are of 3 types: pigment (5–50% in pediatric patients), cholesterol stones, and mixed.
- Black pigment stones are associated with increased unconjugated bilirubin:
 - Hemolytic diseases
 - Abnormal erythropoiesis
 - Enterohepatic circulation of unconjugated bilirubin:
 - Ileal resection, Crohn disease
 - CF
- Brown pigment stones are associated with infection.
- The solubility of cholesterol in bile depends on bile salts and phospholipid concentrations. Cholesterol stones are associated with:
 - A decrease in bile salt pool
 - Decreased bile acid synthesis
 - Hypersecretion of cholesterol into the bile
 - Gallbladder stasis (weight loss, pregnancy, long-term TPN)
 - Increased biliary mucus secretion
 - Medications: furosemide, ceftriaxone, cyclosporine

DIAGNOSIS

HISTORY

- Gallstones in children are most commonly incidental findings on abdominal ultrasound.
- Biliary colic, pancreatitis, obstructive jaundice, cholangitis, or other complications should be excluded.
- Intolerance to fatty food rarely exists in children.
- The history should always include questions concerning:
 - Previous episodes of right upper quadrant (RUQ) abdominal pain
 - Any risk factors for hemolysis
 - History of prematurity and necrotizing enterocolitis
 - Nutritional history
 - Medication use
 - Surgical history
 - Associated medical conditions (e.g., short gut syndrome, ileal disease)

PHYSICAL EXAM

- The physical exam may be completely normal or may uncover the acute abdomen of pancreatitis.
- Murphy sign (tenderness on palpation of the RUQ of the abdomen associated with inspiration) may be elicited in adolescents.
- Silent gallstones present coincidentally in infants and young children.
- Classic symptoms of RUQ pain (Murphy sign) and vomiting are more common in older children and adolescents.
- Younger children present with nonspecific symptoms, including obstructive jaundice, and mild elevation in transaminases.
- Fever is unusual in all age groups and often indicates the development of rare complications in children:
 - Cholecystitis
 - Choledocholithiasis
 - Cholangitis
 - Gallbladder perforation:
 - Pancreatitis develops in 8% of patients with gallstones and is the most common complication.
 - Pancreatitis is more common in obese adolescents who have undergone rapid weight reduction, as reported in the adult population.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Laboratory tests should include a complete blood count, urinalysis, amylase, lipase, fractionated bilirubin, alkaline phosphatase, γ -glutamyltransferase (GGT), and transaminase levels.
- Results should typically be within normal ranges.
- Abnormal results may suggest infection, obstruction, or another disease process.

Imaging

- Ultrasound is the diagnostic procedure of choice: Noninvasive with high sensitivity and specificity
- Plain radiography may not be useful, as the majority of gallstones in children are not radio-opaque.
- Magnetic resonance cholangiopancreatography (MRCP) is useful to define anatomy in hepatobiliary disease and identify choledocholithiasis.

Diagnostic Procedures/Other

- Endoscopic retrograde cholangiopancreatography (ERCP) is diagnostic for evaluation of choledocholithiasis and therapeutic for removal of stones, stenting, or decompression of the biliary tree.
- Surgery should be considered for symptomatic patients.

Pathological Findings

Pigment stones may be black or brown. Black stones are associated with hemolysis or cirrhosis. Brown stones are associated with biliary tract infection.

DIFFERENTIAL DIAGNOSIS

- Acalculous gallbladder disease
- Biliary dyskinesia
- Cholecystitis
- Common bile duct stones
- Congenital biliary anomalies
- Hydrops of the gallbladder (may be associated with Kawasaki disease)

TREATMENT

MEDICATION (DRUGS)

- Spontaneous resolution in asymptomatic children is common, without the need for frequent medication use.
- Ursodeoxycholic acid (UDCA) suppresses hepatic cholesterol synthesis and secretion and can improve gallbladder muscle contractility by decreasing muscle cell cholesterol content in the plasma membranes.

ADDITIONAL TREATMENT

General Measures

- Primary prevention: High fiber intake, diet low in saturated fatty acid and nuts, and moderate physical activity. Children with asymptomatic gallstones should only be observed. During infancy, there is a chance for spontaneous stone dissolution, especially if cholelithiasis is linked to TPN.
- In children who are dependent on TPN and in patients with short bowel syndrome, pseudo-obstruction, inflammatory bowel disease, and with a hemoglobinopathy, gallstones should be removed.
- Laparoscopic cholecystectomy is the procedure of choice in symptomatic children.

- Prevention of gallstone formation is done by treating underlying risk factors (small enteral feeds in addition to TPN, early pancreatic enzyme supplements in patients with CF, using alternative forms of contraception in high-risk populations, and weight control in obese infants and children with known hemolytic disease).
- Pigment stone formation increases with age. Sickle cell patients should have the gallbladder removed when stones are identified. This will decrease the risk of cholecystitis and other complications and will also help to differentiate between biliary colic and sickle cell crisis.
- Patients with a history of cholecystitis are at increased risk for further episodes (69% will have biliary colic within 2 years, and 6% will require cholecystectomy).

SURGERY/OTHER PROCEDURES

- Indicated in symptomatic gallstones
- Laparoscopic cholecystectomy is the procedure of choice.

ALERT

Lithotripsy using shock waves has not been approved for use in children.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Asymptomatic patients: Monitor for onset of symptoms; no utility for repeat imaging or labs unless symptomatic
- Symptomatic patients: Consider cholecystectomy.

CODES

ICD9

- 574.20 Calculus of gallbladder without mention of cholecystitis, without mention of obstruction
- 574.21 Calculus of gallbladder without mention of cholecystitis, with obstruction

ICD10

- K80.20 Calculus of gallbladder without cholecystitis without obstruction
- K80.21 Calculus of gallbladder without cholecystitis with obstruction

FAQ

- Q: Does my child with CF have a greater problem with gallstones?
- A: Yes. Children with CF may have more frequent development of gallstones than will normal children. Reports of gallstones while on UDCA therapy have also been noted.
- Q: Why does my child with sickle cell disease have gallstones?
- A: Because the hemolytic process involves breakdown of hemoglobin, which produces bilirubin. This process may accelerate the formation of pigmented gallstones.
- Q: If my child has repeated attacks of abdominal pain and there are gallstones in the gallbladder, should he have surgery? What kind?
- A: Yes. Laparoscopic cholecystectomy is typically recommended.

CHOLERA

Matthew P. Kronman

BASICS

DESCRIPTION

- *Vibrio cholerae* is a curved, motile gram-negative rod. Many serogroups exist, but only serogroups O1 and O139 cause epidemic clinical cholera.
- *V. cholerae* serogroup O1 is divided into 2 biotypes: Classical and El Tor. The classical biotype was formerly predominant, but currently the El Tor biotype is more commonly observed, having achieved worldwide spread since the 1960s.
- *V. cholerae* serogroup O139 was 1st identified in 1992 and resembles the O1 El Tor biotype, but possesses a distinct lipopolysaccharide and capsule.
- Humans are the only known host for *V. cholerae*, but organisms can also exist freely in water, thereby potentially contaminating fish and shellfish.

EPIDEMIOLOGY

- Diarrheal disease, including cholera, is the 2nd leading cause of mortality in children <5 years worldwide.
- Reporting systems for cholera are not robust, in part owing to national fears concerning travel and trade restrictions. Accurate incidence rates are therefore not available, but the World Health Organization (WHO) estimates 3–5 million cases of cholera occur annually, resulting in as many as 100,000 deaths.
- The 1st 6 recorded cholera pandemics occurred prior to 1923, but the current 7th pandemic began in 1961.
- Most cholera occurs in Asia and Africa, but *V. cholerae* is now endemic in many countries secondary to the 7th pandemic and increasing globalization. Regions previously free of cholera have become susceptible to severe outbreaks, as occurred in Haiti in 2010.
- In the US, most cases result from travel, but the Gulf Coast of Louisiana and Texas have an endemic focus of cholera, resulting in disease related to undercooked shellfish consumption.

- Inadequate drinking water and sanitation create an environment for increased transmission; peri-urban slums, refugee camps, areas of recent disaster, etc., are high-risk areas for cholera epidemics.
- The typical incubation period is usually 2–3 days but ranges from ~12 hours to 5 days.
- People with low gastric acidity (which decreases killing of ingested organisms) and those with blood group O are at increased risk of cholera.
- Young children are at increased risk of severe cholera.
- 75% are infected asymptomatically; of those with symptoms, the range of illness can be moderate to severe.
- Case fatality rates are ~1% when timely treatment is available, but can rise as high as 50% in severe cases in extremely resource-limited settings.
- Secondary transmission can occur in households with affected members if strict handwashing and hygiene is not followed.
- *V. cholerae* isolates resistant to tetracyclines, fluoroquinolones, sulfonamides, and β -lactams are increasingly reported worldwide.

GENERAL PREVENTION

- Transmission:
 - Handwashing after defecation and before food preparation is essential. Boiling or disinfection of water also prevents infection.
 - Thorough cooking of shellfish (which can be naturally contaminated) prevents infection.
 - During travel to endemic areas, avoidance of swimming or bathing in fresh water is recommended.
 - In the hospital setting, contact precautions are recommended for infected infants and children who are incontinent of stool for the duration of illness.
 - Confirmed cases of cholera must be reported to the local department of health.
 - Prophylaxis of contacts of confirmed cases is not currently recommended by the WHO, but hygiene teaching and anticipatory guidance are crucial.
- Vaccines:
 - No cholera vaccines are available in the US.
 - Two whole cell killed oral cholera vaccines have ~50% efficacy in preventing cholera over the subsequent 2-year period.
 - Whole cell killed injectable cholera vaccines provide a similar efficacy to oral vaccines but are generally not recommended owing to increased side effects.

PATHOPHYSIOLOGY

- Infection follows ingestion of large numbers of organisms from contaminated water or food (particularly raw or undercooked shellfish and fish, but also room temperature damp vegetables).
- The infectious dose for severe cholera is ~ 10^8 organisms, but can be as little as 10^4 organisms in young children or those with decreased gastric acidity, such as those on acid suppression or after certain meals.
- The key virulence factor responsible for the profuse watery diarrhea seen in cholera is cholera toxin.
- Cholera toxin is made up of 1 A and 5 B subunits. The B subunits facilitate attachment of toxin to intestinal cells, and the A subunit activates adenylate cyclase, increasing intracellular levels of cyclic adenosine monophosphate (cAMP), which causes chloride and sodium to be secreted into the gut lumen. Water follows via osmosis.
- Those with severe illness can progress rapidly to severe dehydration, circulatory collapse, and death.
- Symptomatic patients may shed as many as 10^{10} to 10^{12} organisms per liter of stool and will shed organisms for 1–2 weeks.

DIAGNOSIS

HISTORY

- Fever, vomiting, profuse watery diarrhea? Severe illness is characterized by voluminous watery diarrhea (at times up to 1 liter per hour) flecked with mucus (“rice-water stools”).
- Sick contacts with similar symptoms? Cholera epidemics can spread rapidly.
- Exposures:
 - Return from travel within the last 5 days? Cholera is endemic in many parts of the world, and the incubation period is typically 2–3 days.
 - What is the patient’s water source? Contaminated water serves as a reservoir.
 - Inadequately cooked shellfish? Shellfish such as oysters and crabs can harbor the organism.

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other

- Selective media (thiosulfate citrate bile salts sucrose agar) must be used to isolate *V. cholerae*. This selective media is not typically used for routine stool culture, so clinicians must alert the microbiology laboratory if culture testing for *V. cholerae* is desired.
- Serologic testing on acute and convalescent sera is also available through the Centers for Disease Control and Prevention (CDC).
- Stool culture may not always be positive in suspected cases of cholera, and rapid dipstick methods to identify cholera toxin and lipopolysaccharide, direct fluorescent antibody assays, and polymerase chain reaction (PCR)-based diagnostic methods also exist.

DIFFERENTIAL DIAGNOSIS

- Other *Vibrio* species can cause gastroenteritis (commonly caused by *V. parahaemolyticus* but also by *V. fluvialis*, *V. hollisae*, and *V. mimicus*) or wound infections and sepsis (*V. vulnificus*). Of these, only *V. parahaemolyticus* and *V. vulnificus* cause outbreaks.
- Additional important intestinal bacterial pathogens include *Aeromonas*, *Campylobacter*, *Clostridium difficile*, *Escherichia coli*, *Listeria*, *Plesiomonas*, *Salmonella*, *Shigella*, *Vibrio* species, and *Yersinia*.
- Viral and parasitic pathogens to consider include rotavirus, norovirus, adenovirus types 40 and 41, *Giardia*, *Cyclospora*, and *Cryptosporidium*.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- The mainstay of treatment for cholera is rapid institution of rehydration.
- Patients with moderate disease may require only oral rehydration solutions, but those with more severe disease (volume loss > 10%) require intravenous fluids.
- Oral rehydration solutions should be administered in frequent small sips to those with vomiting, and should contain at minimum 75 mEq/L of sodium to replete the significant sodium losses associated with cholera.

- Antibiotics are recommended for those with severe cholera; debate exists as to whether those with moderate cholera ought to receive antibiotics.
- Sensitive strains of *V. cholerae* are susceptible to doxycycline, ciprofloxacin, azithromycin, and trimethoprim-sulfamethoxazole, though there are increasing reports of resistance worldwide.
- Single-dose azithromycin can reduce the duration of symptoms by 50% and may reduce excretion of the organism to 1–2 days.
- During outbreaks, rapid institution of improved sanitation and safe water availability are critical to decrease the extent of the outbreak.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

In the untreated patient, the typical period of *V. cholerae* shedding is 1–2 weeks. Asymptomatic carriage is uncommon.

PROGNOSIS

For patients with prompt rehydration, the prognosis is very good, regardless of whether antibiotic treatment is given.

COMPLICATIONS

- The main complications of cholera are those of severe dehydration, such as renal failure, thrombosis, and cardiovascular collapse.
- There are no significant long-term complications of cholera.

CODES

- ICD9**
001.9 Cholera, unspecified
- ICD10**
A00.9 Cholera, unspecified

FAQ

- Q: What foods should I avoid while traveling to cholera-endemic regions?
- A: Foods that incur a risk of cholera transmission include untreated or unboiled water and ice, undercooked fish and shellfish, raw vegetables, food and beverages from street vendors, and cooked food stored at ambient temperature.
- Q: Does cholera pose a risk to pregnant patients?
- A: Given the severe fluid losses, cholera can be a life-threatening infection to the fetus, with fetal loss occurring in as many as 50% of women in their 3rd trimester despite aggressive fluid resuscitation.
- Q: What is the risk of developing cholera among household contacts of those with disease?
- A: Up to 50% of household contacts may develop diarrheal symptoms, typically within 2 days of exposure to the index case.

CHRONIC DIARRHEA

Edisio Semeao

BASICS

DESCRIPTION

- Diarrhea lasting >2–4 weeks, whereas acute diarrhea, generally caused by enteric pathogens, is self-limiting and duration of symptoms <1 week
- Stool output >200 g/d in children and adults or 10 g/kg/d in infants is considered diarrhea.
- The initial focus is to establish the pattern of stool output with regard to:
 - Volume
 - Frequency
 - Consistency
 - Gross appearance

EPIDEMIOLOGY

- Chronic diarrhea seen in the tropics and developing countries is more likely infectious in nature than in the US.
- Gender and genetic factors do not play a significant role in most cases of chronic diarrhea.

PATHOPHYSIOLOGY

The major categories are osmotic and secretory. Inflammatory and motility disorders are smaller but important subcategories to consider.

- Osmotic diarrhea occurs when unabsorbable solute accumulates in the lumen of the small intestine and colon:
 - This increases the intraluminal osmotic pressure and results in excessive fluid and electrolyte losses in stool.
 - Osmotic diarrhea will improve with fasting.
 - Osmotic diarrhea is usually related to malabsorption of dietary products or to the presence of congenital or acquired disaccharidase deficiency or glucose-galactose defects.
- Secretory diarrhea occurs when the net secretion of fluid and electrolyte is in excess of absorption in the intestine:
 - The intestinal mucosa is normally very active in both of these processes.
 - The diarrhea occurs independently of the osmotic load in the intestinal lumen and does not improve with fasting.
 - The mechanisms for secretory diarrhea include the activation of intracellular mediators such as cAMP, cGMP, and calcium-dependent channels.
 - These mediators stimulate active chloride secretion from the crypt cells and inhibit the neutral coupled sodium chloride absorption.
- Inflammation in the intestine can cause an alteration in mucosal integrity resulting in exudative loss of mucus, blood, and/or protein. Increased permeability and altered mucosal surface area may affect absorption and result in diarrhea owing to a malabsorptive process.
- Motility disorders will affect the intestinal transit time. Hypomotility states such as stasis from bacterial overgrowth can lead to diarrhea.

DIAGNOSIS

HISTORY

- Evaluation of the stool pattern, including consistency, frequency, and appearance:
 - The history of blood and mucus in stool is strongly suggestive of inflammation.
 - Large-volume stools (>750 mL/d) imply small bowel disease and/or a secretory process.
 - Watery stools tend to be more associated with carbohydrate malabsorption, small bowel processes, medications, and functional processes.
 - Steatorrhea (fatty stools) can be greasy, oily, foul smelling, and bulky and are usually associated with pancreatic disease, bacterial overgrowth, and short bowel syndrome.
- Dietary intake including the types of food and the occurrence of diarrhea in close relationship to specific foods (e.g., dairy products) may be diagnostic. The amount and type of liquid ingested may also be helpful in diagnosis.
- Nutritional status and growth parameters need to be assessed. The presence of growth failure or malnutrition has considerable implications compared with a child with normal growth and no history of weight loss.
- Onset of diarrhea such as abrupt or gradual is important to determine. Overall duration of the diarrhea and pattern of intermittent versus continuous may also help in determining the underlying process.
- Other symptoms associated with the diarrhea are important to assess and include abdominal pain, fever, bloating, tenesmus, soiling, rashes, and joint complaints.
- Exposure to medications (antibiotics, laxatives, chemotherapeutic agents) or herbal therapies
- History of abdominal surgery
- Inquire about travel history.
- Family history of certain disorders may raise the level of suspicion in the patient. These include celiac disease, inflammatory bowel disease, cystic fibrosis, and other pancreatic processes.

PHYSICAL EXAM

- Nutritional status: Compare height, weight, and head circumference with normal standards and previous exam measurements.
- Anthropometric measurements are important in assessing loss of body fat and muscle mass.
- Peripheral edema, ascites, rash, dystrophic nails, alopecia, chronic chest findings, and pallor may all be indicative of nutritional deficiencies secondary to chronic diarrhea.
- A rectal exam may reveal stool impaction with overflow diarrhea:
 - Is there blood in the stool?
 - Perianal disease (fistula, skin tags, abscess)
- Evidence of infection should be considered with symptoms such as fever, bloody diarrhea, and vital sign instability.
- Aphthous lesions, arthritis, and clubbing
- The abdominal exam in most patients is generally nonspecific.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Stool samples:
 - Stool should be tested for occult blood and for the presence of fecal leukocytes.
 - Stool pH and reducing substances: If stool is positive for reducing substances and/or the pH is <5.5, carbohydrate malabsorption with or without proximal small bowel injury is likely. (Note: Sucrose is not a reducing substance. If sucrose malabsorption is suspected, stool sample has to be hydrolyzed with hydrochloric acid and heat before analysis.)
 - A positive Sudan stain of the stool is indicative of fat malabsorption. However, a 72-hour fecal fat collection remains the gold standard to diagnose fat malabsorption.
 - Stool for fecal elastase to assess fat malabsorption
 - Stool should be cultured for bacteria, ova and parasites, and viral organisms. *Clostridium difficile* toxins A and B are heat labile, and stool must be kept cool during transport. Collect stool in the correct containers to ensure accurate and reliable analysis.
 - Stool may be collected for electrolyte and osmolality measurements. Osmotic gap >100 mOsm/kg is indicative of an osmotic diarrhea.
 - Spot or 24-hour collection for fecal α_1 -antitrypsin to assess protein loss
 - Stool collection for fecal calprotectin to assess for IBD—protein found in neutrophils that enter the bowel during an inflammatory process
- Blood samples:
 - Hemoglobin and RBC
 - Prealbumin and albumin are good parameters of protein and overall nutritional status.
 - Electrolytes
 - Erythrocyte sedimentation rate and C-reactive protein (CRP) can serve as markers for inflammatory conditions.
 - Hormonal studies to assess for secretory tumors (vasoactive intestinal peptide [VIP], gastrin, secretin, urine assay for 5-HT)
 - In the evaluation for celiac disease, serum antitissue transglutaminase antibody and antiendomysial antibodies as long as the total serum IgA is normal
 - Hepatic panel, coagulation profile, and fat-soluble vitamin levels (25 OH vitamin D; vitamins E, A, K) may be helpful to assess fat malabsorption.
 - Viral serologies such as HIV and cytomegalovirus need to be considered in the immunocompromised host with diarrhea.
 - Thyroid studies in patients with large-volume watery diarrhea
- Specialized studies:
 - A D-xylose absorption test is helpful in screening for small bowel injury. Timed serum D-xylose following oral ingestion is significantly lower in diseases causing diffuse mucosal damage to the small bowel (i.e., postviral enteropathy, celiac disease).
 - A hydrogen breath test may be helpful in evaluating for the possibility of small bowel bacterial overgrowth.
- Sweat chloride if cystic fibrosis is suspected

Imaging

- Plain radiograph studies usually not helpful
- Upper GI series with small bowel follow-through may show partial small bowel obstruction, strictures, or evidence of inflammatory bowel disease.
- Abdominal CT scan may help in assessing the pancreas for calcifications and inflammation.

Diagnostic Procedures/Other

- Endoscopy with small bowel biopsy and small bowel aspirate for culture to help diagnose certain congenital, immunologic, or infectious causes of diarrhea:
 - Small bowel disaccharidase studies will help detect carbohydrate malabsorption.
- Colonoscopy will diagnose colitis related to inflammatory bowel disease or infection.
- Video capsule endoscopy may also be used to further evaluate the small bowel for evidence of inflammation.

DIFFERENTIAL DIAGNOSIS

- Infants (<1 year of age):
 - Cow’s milk and/or soy protein intolerance
 - Intractable diarrhea of infancy is associated with diffuse mucosal injury beginning at <6 months of age resulting in malabsorption and malnutrition.
 - Infectious/protracted postinfectious diarrhea
 - Microvillus inclusions disease
 - Autoimmune enteropathy
 - Hirschsprung disease with enterocolitis
 - Transport defects (e.g., congenital chloridorrhea)
 - Nutrient malabsorption (e.g., congenital glucose-galactose malabsorption and congenital lactase deficiency, sucrase-isomaltase deficiency)
 - Cystic fibrosis
 - AIDS enteropathy
 - Primary immune defects
 - Munchausen syndrome by proxy (factitious)
 - Drug, toxin induced
- Children (1–5 years of age):
 - Chronic nonspecific diarrhea of infancy (toddler’s diarrhea)
 - Infectious/postinfectious enteritis
 - Giardiasis
 - Eosinophilic gastroenteritis
 - Sucrase-isomaltase deficiency
 - Tumors (neuroblastoma, VIPoma with secretory diarrhea)
 - Inflammatory bowel disease
 - Celiac disease
 - Cystic fibrosis
 - Small bowel bacterial overgrowth
 - AIDS enteropathy
 - Constipation with (overflow) encopresis
 - Acquired short bowel syndrome
 - Shwachman syndrome
 - Factitious
- Children (>5 years of age):
 - Similar to above
 - Acquired lactose deficiency (early adolescent)
 - Inflammatory bowel disease
 - Celiac disease
 - Constipation with (overflow) encopresis
 - Irritable bowel syndrome (adolescent)
 - Laxative abuse (adolescents)
 - Infection

- Bacterial (*Aeromonas*, *Plesiomonas*, *Campylobacter*, *Salmonella*, *Mycobacterium tuberculosis*, *Yersinia*, recurrent *C. difficile*)
- Viral (rotavirus, adenovirus, Norwalk virus, Noro virus)
- Parasites (amoeba, trichuris, cryptosporidium, *Giardia*, *Schistosoma*, *Cyclospora*)
- Small bowel bacterial overgrowth
- Tumors (neuroblastoma, VIPoma with secretory diarrhea)
- Primary bowel tumors (rare, adolescent)
- Complex congenital heart disease with protein-losing enteropathy
- Pancreatic insufficiency/chronic pancreatitis
- Hyperthyroidism
- Diabetes

TREATMENT

MEDICATION (DRUGS)

- The use of antimotility agents such as loperamide and Lomotil, and antisecretory agents, such as octreotide, may have a role in noninfectious causes of diarrhea. However, identification and treatment of the underlying cause of diarrhea is always preferable.
- Pancreatic enzymes may be used in specific patients.
- Luminal (nonabsorbed) antibiotics for small bowel bacterial overgrowth

ALERT

- In certain cases in which the diet is altered as a therapeutic intervention, the physician must ensure that the patient is still absorbing adequate calories and micronutrients so that the nutritional status of the patient is not further compromised.
- Avoid the reinstitution of a regular diet too quickly following a severe and/or protracted insult to the gut since this may further exacerbate the diarrhea.
- The use of antimotility and antisecretory agents should be judicious and as an adjunct to other therapy, but not as the mainstay in the treatment regimen.
- In patients with cow’s milk and/or soy allergy, rechallenge after 12 months of age in a controlled environment in case anaphylaxis occurs.
- Children with the following symptoms should see a health care provider:
 - Signs of dehydration
 - Diarrhea for more than 24–48 hours
 - A fever of 102°F or higher
 - Stools containing blood or pus
 - Stools that are black and tarry

ADDITIONAL TREATMENT

- The 1st goal is to ensure adequate hydration status, nutritional intake and to permit normal growth and development.
- Antibiotics when infection is suspected
- Many causes of congenital diarrhea do not have specific therapy available, and treatment is supportive.

- Diet: If infection is severe or protracted, a predigested formula may be necessary early in the recovery phase. If oral nutrition appears inadequate, the formula can be given in a slow, continuous fashion via a nasogastric/jejunal tube. Remove offending agent (e.g., cow’s milk protein, soy protein, lactose, or gluten). In cases in which there is increased motility and thus rapid transit time, such as in chronic nonspecific diarrhea, alterations in the diet can be very helpful. Elimination of sorbitol-containing juices, which increases the osmotic load, and low-carbohydrate diet will help to lower the osmotic load delivered to the intestine. Furthermore, a high-fat diet will slow the intestinal transit time and increase the time available to absorb fluid, electrolytes, and nutrients from the intestinal tract.

FAQ

- Q: If my infant has cow’s milk allergy, when can he have cow’s milk?
- A: In patients with cow’s milk and/or soy allergy, rechallenge should be after 12 months of age and should be in a controlled environment in case anaphylaxis occurs. If the testing is negative, ingestion of cow’s milk can be recommended.
- Q: What are the best markers for success in management of chronic diarrhea?
- A: If weight and height normalize, the chances of continued malabsorption are unlikely.

CHRONIC GRANULOMATOUS DISEASE

Mathew Fogg

BASICS

DESCRIPTION

Rare inherited defect involving phagocytes. The defective phagocytes (neutrophils and monocytes) have a decreased or absent ability to generate reactive oxygen intermediates, leaving the host susceptible to recurrent bacterial and fungal infections.

EPIDEMIOLOGY

Prevalence

~1 in 500,000 individuals

RISK FACTORS

Genetics

- Gene mutations may occur spontaneously and are inherited as an X-linked variant or autosomal recessive variant.
- Mutations may occur in any 1 of the 4 subunits of the neutrophil NADPH oxidase complex.

PATHOPHYSIOLOGY

- Associated defects involve the NADPH oxidase complex of the neutrophil.
- Neutrophils in chronic granulomatous disease (CGD) have an impaired ability to combat infection via an impaired respiratory burst.
- The NADPH oxidase complex is composed of 4 subunits, any of which may be defective in CGD:
 - 60% of patients with CGD have a defect in the gp91-phox subunit, which is inherited in an X-linked manner.
 - 33% of patients have a defect in the p47-phox subunit, which is inherited in an autosomal recessive manner.
 - Defects occur less frequently in the p22-phox and p67-phox subunits.

ETIOLOGY

CGD is not acquired; it is inherited as an X-linked variant or as an autosomal variant.

DIAGNOSIS

HISTORY

- Usually present <2 years of age with marked lymphadenopathy, hepatosplenomegaly, draining lymph nodes, and pneumonias
- Tend to develop infections with unusual organisms, such as *Staphylococcus aureus*, *S. epidermidis*, *Serratia marcescens*, *Pseudomonas*, *Escherichia coli*, *Candida*, *Aspergillus*, *Nocardia*, and *Salmonella*
- Disease is inherited in an X-linked and autosomal recessive pattern. Therefore, there may be other affected family members.
- Mother with lupus: There is a higher incidence of lupus in females who are carriers for CGD.

SIGNS AND SYMPTOMS

- General goal: Decide whether the patient's type of infections (osteomyelitis, perirectal abscess) and infecting organisms are consistent with the diagnosis of CGD.
- Order a DCF or DHR assay.
- If abnormal, initiate sulfamethoxazole/trimethoprim prophylaxis.

PHYSICAL EXAM

- Skin abscess or boils: Patients develop frequent skin infections.
- Mucous membrane and perirectal infections: Patients commonly develop infections at mucous membrane and epidermal junctions, especially in the perirectal area.
- Lymphadenopathy: Patients commonly develop lymphadenopathy and draining lymph nodes.
- Hepatosplenomegaly: Common finding in patients with CGD
- Abnormal lung examination: Pulmonary disease common in patients with CGD

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Nitroblue tetrazolium test:
 - Older test for CGD, no longer widely used by immunologists
 - Neutrophils from normal individuals can reduce the dye, resulting in a color change. Neutrophils from patients with CGD cannot reduce the dye, and it remains colorless.
 - Neutrophils and monocytes from patients with CGD have an impaired hexose monophosphate shunt. Therefore, they have a decreased conversion of NADP to NADPH and a decreased oxidative burst, which results in an inability to reduce the nitroblue tetrazolium in this study.
 - Results may be inaccurate if not performed by experienced technician.
- DCF or DHR assay:
 - Can directly measure the production of hydrogen peroxide using a fluorescent label and flow cytometry
 - Patients with CGD have decreased hydrogen peroxide production.
 - DHR and DCF are very similar tests.
- Immunoblotting: Can be used to quantify the amount of each NADPH subunit present

DIFFERENTIAL DIAGNOSIS

- Infectious: Infections are related to the immunodeficiency.
- Genetic/Metabolic:
 - Leukocyte glucose-6-phosphate dehydrogenase deficiency
 - Myeloperoxidase deficiency
 - Humoral immunodeficiencies
 - Complement deficiencies

TREATMENT

MEDICATION (DRUGS)

- Antibiotic prophylaxis: Trimethoprim-sulfamethoxazole is the antibiotic of choice, because both components are concentrated in the neutrophil and for its bacterial spectrum.
- Recombinant interferon- γ :
 - Reserved for patients with severe disease
 - May decrease the incidence of infection

- Acute infections:
 - Broad-spectrum IV antibiotics: Should be a low threshold to start this therapy. Severe infections should be treated with broad-spectrum IV antibiotics until an organism is identified. Good initial antibiotics include IV penicillins, aminoglycosides, and antipseudomonal antibiotics.
 - Amphotericin B: Should not be withheld if a fungal infection is suspected or if the patient's clinical status is deteriorating despite broad-spectrum antibiotics.
 - Leukocyte transfusions: Reserved for severe infections; efficacy is controversial.

ISSUES FOR REFERRAL

Factors that may help alert you to make a referral:

- New diagnosis of CGD:
 - Immunologists can assist with antibiotic prophylaxis and with parameters for when to seek medical attention.
 - Can help identify which genetic variant is responsible for the patient's disease
- Pregnant carrier for CGD:
 - Immunologists can help with prenatal diagnosis.
 - Some centers may consider in utero bone marrow transplantation for an affected fetus.
- Fever or suspected infection: Patients with CGD tend to develop infections in unusual sites with unusual organisms. An immunologist can help with the evaluation and appropriate antibiotic coverage.

COMPLEMENTARY & ALTERNATIVE THERAPIES

Bone marrow transplant: CGD has been cured in patients with matched transplants.

 **ONGOING CARE**

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- CGD is a lifelong disease.
- Patients tend to develop chronic lung disease; therefore, pulmonary function studies should be followed at least annually.
- Liver disease is also common; therefore, liver function studies should also be followed at least annually.
- Female carriers should be observed for signs of lupus erythematosus.

PROGNOSIS

- Survival beyond the 4th decade is common.
- Bone marrow transplantation is curative.

COMPLICATIONS

These patients have an increased susceptibility to bacterial and fungal infections that usually are not pathogenic in normal hosts:

- Recurrent skin infections
- Sepsis
- Chronic lung disease (secondary to recurrent infections)
- Chronic liver disease (secondary to recurrent infections)
- Chronic osteomyelitis of large and small bones
- Malabsorption
- Systemic and discoid lupus erythematosus: Increased incidence in female carriers
- The diagnosis of CGD should be considered in patients with:
 - Recurrent lymphadenitis
 - Staphylococcal hepatic abscess
 - *Aspergillus* or *Nocardia* pneumonia
 - *Serratia marcescens* osteomyelitis
 - Infections with *Pseudomonas cepacia*
 - *Salmonella* sepsis
 - Perirectal abscesses
 - Brain abscesses

ICD10

D71 Functional disorders of polymorphonuclear neutrophils

FAQ

- Q: What do the infecting organisms have in common?
- A: Patients with CGD are most susceptible to catalase-positive organisms.
- Q: Are all CGD patients with fever admitted automatically?
- A: No. It is true that these patients are more prone to invasive and systemic infections, but these patients are not admitted with every febrile episode (especially if there is evidence of a minor bacterial or viral infection). However, subtle signs of an invasive infection must be taken very seriously, and these patients are certainly admitted.
- Q: Can a prenatal diagnosis be made?
- A: Yes. However, currently this can be done only in a limited number of research laboratories, and the testing is not commercially available. Testing involves chorionic villus sampling, and it can be done only on families in which the specific mutation has been mapped.

CHRONIC HEPATITIS

John Y. Tung MB

Vani V. Gopalareddy

BASICS

DESCRIPTION

- Chronic hepatitis is a continuing inflammation of the liver that may lead to cirrhosis.
- Features include inflammation not caused by acute self-limiting infection or past drug exposure with raised transaminases and histologic evidence of hepatitis.

EPIDEMIOLOGY

Depends on the cause of the underlying disease:

- Nonalcoholic steatohepatitis (NASH) is a leading cause of elevated AST/ALT.
- Hepatitis B: Common in immigrant children from Asia and Eastern Europe
- Hepatitis C: Common in those who had blood transfusions and blood products before screening became available, users of IV drugs, nasal cocaine users
- Wilson disease presents mainly in older children (>2 years) and adults.
- Autoimmune liver disease is more common in females and older children. (suspect in >6 months age)
- Autoimmune hepatitis (AIH) may be associated with other autoimmune conditions such as diabetes, ulcerative colitis, autoimmune thyroiditis, and celiac disease.
- Cystic fibrosis and α_1 -antitrypsin deficiency: Predominantly white patients but may occur in other ethnic groups.

PATHOPHYSIOLOGY

Pathology has been traditionally classified as chronic persistent hepatitis, chronic aggressive hepatitis, and chronic lobular hepatitis. The hepatocytes are damaged, with inflammatory cellular infiltration accompanied by liver regeneration.

- Chronic persistent hepatitis:
 - Minimal portal tract fibrosis
 - Slightly widened portal tracts
 - Limiting plate is intact and inflammation does not extend beyond this.
 - No bridging fibrosis between portal tracts
- Chronic aggressive hepatitis:
 - Perilobular hepatitis, with inflammatory cells extending from portal tracts into parenchyma with fibrosis
 - Piecemeal necrosis: Necrotic hepatocytes surrounded by lymphocytes and fibroblasts
 - In advanced disease, fibrosis bridges the portal tracts (bridging fibrosis).
 - Cirrhosis occurs when there is loss of architecture owing to fibrosis.
- Chronic lobular hepatitis:
 - Liver architecture is preserved with scattered changes of acute hepatitis with hepatocyte necrosis in the lobules (perivenular regions).
- These changes are most often associated with hepatitis B and non-A, non-B hepatitis.

ETIOLOGY

- Autoimmune liver disease
- Viral hepatitis
- Obesity (NASH)
- Progressive familial intrahepatic cholestasis syndromes (PFIC)
- Congenital hepatic fibrosis
- Cystic fibrosis
- Metabolic disease:
 - Mitochondrial disease
 - Lysosomal storage disorders
 - Peroxisomal disease
 - Lipid storage disease
 - Glycogen storage disease
 - Wilson disease and others
- Drug hepatotoxicity:
 - Methotrexate
 - Isoniazid
 - Thioguanine
 - 6-Mercaptopurine
 - Valproate
- Liver disease associated with other chronic diseases:
 - Cardiac disease
 - Autosomal recessive polycystic kidney disease
 - Diabetes mellitus
 - Langerhans cell histiocytosis
 - Immunodeficiency
 - Total parenteral nutrition cholestasis

DIAGNOSIS

HISTORY

- Preceding clinical signs and symptoms for at least 6 months and complete medical history:
 - History of blood transfusions
 - Surgery
 - Medications
 - Foreign travel
 - Social circumstances that predispose to liver diseases
- Symptoms of chronic illness can be nonspecific:
 - Poor growth
 - Intermittent jaundice
 - Abdominal pain
 - Bleeding
 - Malabsorption
 - Fever
 - Amenorrhea
 - Poor school achievement
 - Itching
- Variceal bleeding may be a presenting syndrome in patients with portal hypertension.
- A history of jaundice in infancy, family history of liver disease or autoimmune liver disease, blood transfusions, IV drug use, or multiple sexual partners can suggest an etiology of hepatitis.

PHYSICAL EXAM

Stigmata of chronic liver disease are:

- Spider nevi
- Cutaneous shunts
- Palmar erythema
- Cyanosis (hepatopulmonary syndrome)
- Jaundice
- Itching
- Enlarged liver or small, shrunken liver
- Splenomegaly
- Ascites
- Rickets
- Mental changes
- Fetor associated with high ammonia
- Obesity

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Albumin, creatinine, γ -glutamyl transferase, aspartate aminotransferase, alanine aminotransferase, bilirubin, PT, CBC, blood group, Coombs test
- Other testing as indicated by the specific clinical presentation:
 - Viral serologies: Hepatitis B, hepatitis C, hepatitis D
 - Autoantibodies: Type 1: Smooth muscle (also called antiactin), antinuclear, antisoluble liver antigen, Type 2: Liver kidney microsomal, primary sclerosing cholangitis: pericytoplasmic antineutrophil (p-ANCA)
 - Immunoglobulins: IgG elevated in autoimmune liver disease
 - Fasting glucose, insulin levels, CRP, lipid profile (suspected NASH)
 - α 1-Antitrypsin level and phenotype
 - Serum ceruloplasmin, serum copper, 24-hour urine copper (+/?penicillamine challenge), quantitative liver copper (Wilson disease)
 - Cholesterol, triglycerides elevated in cholestatic syndromes, glycogen storage, Alagille syndrome, certain lysosomal disease, steatohepatitis
 - Metabolic workup as indicate
 - CPK level to rule out muscle source of elevated ALT/AS
 - Urinary succinylacetone: Tyrosinemia
 - Urinary bile acids: Bile acid synthetic defects and some progressive intrahepatic cholestatic syndrome
 - Sweat test and cystic fibrosis genotyping
 - Alpha-1-fetoprotein
 - Fibrosis markers (FibroSURE; FibroTest; ActiTest) are not validated for children but may be useful in older patients.

Diagnostic Procedures/Other

- Ultrasound: Focus on liver, spleen with Doppler flow studies. This may also demonstrate steatosis.
- Other testing as indicated by specific clinical presentation:
 - MRI can demonstrate percentage steatosis
 - Fibroscan can measure liver stiffness/fibrosis.
 - Liver biopsy

- Percutaneous transhepatic cholangiography, endoscopic retrograde cholangiopancreatography or magnetic retrograde cholangiopancreatography may be useful if primary sclerosing cholangitis is suspected
- Colonoscopy: Sclerosing cholangitis, inflammatory bowel disease
- Bone marrow aspirate to exclude Niemann-Pick type C or other storage disorders
- Enzyme from white cells or cultured fibroblasts (skin biopsy) to exclude lysosomal storage disease, glycogen storage disease
- Angiography: Congenital or acquired venous or arterial malformations, assessment of portosystemic shunt
- Cardiac catheterization to assess pulmonary hypertension and cardiac status
- Macroaggregated albumin scan to assess hepatopulmonary syndrome and hepatic encephalopathy
- Muscle biopsy to assay respiratory chain enzymes in mitochondrial disorders
- Genotyping: Wilson disease, cystic fibrosis, and others

DIFFERENTIAL DIAGNOSIS

Nonhepatic etiologies of lab or physical exam abnormalities:

- Hepatomegaly: Elevated right-sided cardiac pressures, such as patients with Fontan operations, right-sided heart failure; respiratory diseases with lung hyperexpansion
- Splenomegaly:
 - Blood malignancies
 - Storage diseases
 - Hematologic disease with hemolysis
 - Infection
 - Vascular
- Jaundice: Often confused with hypercarotenemia
- Elevated transaminases: Consider nonhepatic sources such as skeletal muscles in myopathies. With jaundice, consider hypopituitarism in infancy.
- Alkaline phosphatase: May be elevated in growing children and in rickets; may not indicate biliary obstruction.
- γ -Glutamyl transferase:
 - Produced in choroid plexus, renal tubules, pancreatic and biliary ducts
 - Often elevated in patients on antiepileptic drugs and in alcoholics
- Abnormal coagulation: Anticoagulant medications, bacterial overgrowth with malabsorption, inherited disorders of coagulation, sepsis

TREATMENT

ADDITIONAL TREATMENT

General Measures

The management of patients is dictated by the underlying diagnosis.

- General management:
 - Maintaining growth and development is paramount.
 - Fat-soluble vitamins (A, D, E, K) given orally are poorly absorbed in cholestasis, and levels must be monitored.
 - Anthropometric parameters must be recorded, including skinfold thickness.
 - Body mass index
 - Medium-chain triglyceride-rich formulas can reduce fat malabsorption.
 - Branched-chain amino acids may be useful in patients with hepatic encephalopathy.
 - Ursodeoxycholic acid: Choleric
 - Encourage bolus feedings; minimizing continuous feeding and total parenteral nutrition may reduce gallbladder sludge.
 - Proactive involvement of clinical psychologist, play therapist can help alleviate problems such as depression and fear.
 - Aggressive weight management in patients with obesity/hypermetabolic syndrome with steatohepatitis. Curbing passive activities such as television, computer games.
 - Chronic debilitating pruritus: Indication for liver transplantation after failure of medical therapy. Treatment for pruritus includes:
 - Antihistamines
 - Cholestyramine
 - Naltrexone
 - Rifampicin
 - Ursodeoxycholic acid
 - Monitoring portal hypertension: Assessment of portal flow on ultrasound and splenic size may provide some indication of disease progression.
 - Treatment of recurrent cholangitis may decelerate the progression of liver disease.
 - Aggressive treatment for spontaneous bacterial peritonitis in patients with ascites
 - Early referral to a liver transplant center
 - Complete immunization schedule including hepatitis A
- Specific management depends on the underlying liver disease.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Look for hepatocellular carcinoma developing in patients with chronic liver disease, an ultrasound scan of liver and AFP every 6 months is a reasonable schedule.
- Advise patients with enlarged spleens to wear a spleen guard and avoid activities that can cause splenic rupture.

PROGNOSIS

Some diseases are treatable while others are progressive and not amenable to treatment. A subset of patients will progress to end-stage liver disease and regular liver transplantation.

CODES

ICD9

- 571.40 Chronic hepatitis, unspecified
- 571.41 Chronic persistent hepatitis
- 571.42 Autoimmune hepatitis

ICD10

- K73.0 Chronic persistent hepatitis, not elsewhere classified
- K73.9 Chronic hepatitis, unspecified
- K75.4 Autoimmune hepatitis

FAQ

- Q: What are the risks of providing very young patients with a liver transplant?
- A: Although transplant in the very young is more difficult, with the increased use of split liver techniques, outcomes of orthotopic liver transplantation in infants have improved.
- Q: Why should we be aggressive with vitamin supplementation?
- A: There is significant malabsorption of vitamins A, D, E, and K. Vitamins D and E deficiencies are the most significant, causing rickets and neuropathy.
- Q: Oral supplements of vitamins are sometimes very difficult to administer in the very young. How can I overcome this problem?
- A: It is common practice in some centers to give vitamins D and E as an intramuscular injection on a monthly basis, with levels done in between.
- Q: Why do jaundiced children scratch?
- A: The accumulation of bile salts causes pruritus.
- Q: Are the stigmata of chronic liver disease also seen in children?
- A: Spider nevi, liver palms, splenomegaly, cutaneous shunts, and clubbing are very common.

CHRONIC KIDNEY DISEASE

Rebecca Ruebner
Lawrence Copelovitch

BASICS

DESCRIPTION

- Chronic kidney disease (CKD), previously referred to as chronic renal failure: The Kidney Disease Outcomes Quality Initiative (K/DOQI) of the National Kidney Foundation (NKF) defines CKD as either kidney damage or a decreased glomerular filtration rate (GFR) for 3 or more months
- Kidney damage is defined as pathological abnormalities or markers of kidney injury, including abnormalities in the composition of the blood or urine, or abnormalities in imaging tests.
- CKD is stratified from stages 1–5:
 - Stage 1: normal GFR (>90) but some evidence of kidney damage
 - Stage 2: GFR 60–89
 - Stage 3: GFR 30–59
 - Stage 4: GFR 15–29
 - Stage 5: GFR <15 or dialysis/transplant (end-stage)

EPIDEMIOLOGY

Incidence

~3–8 new cases of end-stage renal failure are reported per 1 million children per year.

Prevalence

- Among children in the US with CKD entered into the North American Pediatric Renal Transplant Cooperative Study, 65.9% are boys and 63.9% are white.
- Prevalence of CKD has been reported to be 32.4 per 1 million children in western Europe, with 6% <3 years of age, 30% between 3 and 9 years of age, and 64% between 9 and 15 years of age.

RISK FACTORS

Genetics

Several hereditary diseases can cause CKD, including:

- Alport disease (partially X-linked dominant)
- Polycystic kidney disease (autosomal recessive or dominant)
- Familial juvenile nephronophthisis (autosomal recessive)
- Cystinosis (autosomal recessive)
- Hyperoxaluria (autosomal recessive)
- Congenital nephrotic syndrome (autosomal recessive)
- Nail patella syndrome (autosomal dominant)
- Sickle cell disease (autosomal recessive)

PATHOPHYSIOLOGY

- Infants <2 years of age develop CKD due to either obstructive uropathy or renal hypodysplasia.
- Children 2–5 years of age develop CKD secondary to neonatal vascular accidents and hemolytic-uremic syndrome, obstructive uropathy, or renal hypodysplasia.
- More common causes of CKD in older children and adolescents include various types of glomerulonephritis (e.g., focal segmental glomerulosclerosis, crescentic glomerulonephritis, lupus nephritis), reflux nephropathy, or hereditary causes (e.g., Alport syndrome).

ETIOLOGY

- Congenital:
 - Renal dysplasia/hypoplasia
 - Obstructive uropathy (posterior urethral valves, prune belly syndrome)
 - Polycystic kidney disease
- Acquired:
 - Nephrotic syndrome (FSGS)
 - Glomerulonephritis (lupus, vasculitis)
 - Chronic interstitial nephritis

DIAGNOSIS

HISTORY

- Past history:
 - Perinatal complications
 - Oligohydramnios
 - Single umbilical artery
 - Recurrent UTIs
 - Enuresis
- Familial history:
 - Renal disease
 - Hearing impairment

SIGNS AND SYMPTOMS

- Malaise
- Poor appetite
- Vomiting
- Bone pain
- Headache (if hypertensive)
- Polyuria
- Polydipsia

PHYSICAL EXAM

- General:
 - Short stature
 - Retarded weight gain
 - Dermatologic pallor
 - Fetid breath

- Head, ears, eyes, nose, and throat:
 - Retinal changes
 - Presence of preauricular sinus
 - Hearing deficit
- Chest:
 - Rales
- Heart:
 - Flow murmur
 - Gallop
 - Rub
- Abdomen:
 - Palpable kidneys
 - Suprapubic mass
- Extremities:
 - Rachitic changes
 - Edema
 - Absent patella
- Neurologic system:
 - Developmental delay
 - Altered mental status
 - Hypotonia
 - Irritability

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Serum chemistries: Azotemia, hyperkalemia (if advanced), acidemia, hypocalcemia, hyperphosphatemia, elevated alkaline phosphatase (Onset of these electrolyte abnormalities is CKD stage 4, GFR <30.)
- CBCs: Normocytic anemia with low reticulocyte count (CKD stage 3, GFR <60)
- Urinalysis: Isosthenuria, proteinuria
- Intact parathyroid hormone: Elevated
- 25-Vitamin D: often low
- 24-hour urine collection: GFR can be estimated with concomitant blood sampling by calculating the creatinine clearance: $U_{\text{creat}} \times (\text{volume voided}/1,440)/P_{\text{creat}} \times 1.73/\text{body surface area}$. The resultant value is expressed as mL/min/1.73 m². Normal range is 90–140 mL/min/1.73 m² above age 2
- A simpler and more commonly used method to estimate GFR in children >1 year of age with CKD is the CKiD bedside equation, an update to the traditional Schwartz formula. The calculation is already corrected for surface area and does not require a urine collection: $\text{Height (cm)} \times 0.413 \text{ correction factor}/P_{\text{creat}}$. Plotting the reciprocal of the serum creatinine versus time can approximate the rate of decline of renal function. This may be useful in determining when renal replacement therapy will be necessary.

Imaging

- Chest x-ray: Pulmonary edema, cardiomegaly
- Bone films: Delayed bone age, rickets, osteomalacia, osteitis fibrosa
- Renal ultrasound: Small echogenic kidneys, cystic kidneys, hydronephrosis
- EKG, in hyperkalemic patients: Peaked T waves

DIFFERENTIAL DIAGNOSIS

- Differentiate acute kidney injury from CKD
- Usually, CKD is insidious and associated with poor growth, delayed puberty, rickets, polyuria, and anemia. The kidneys may be smaller on renal ultrasound. A renal biopsy may be indicated to determine the cause of renal failure if genetic causes are suspected (for family counseling) or if treatment is being considered.

TREATMENT

MEDICATION (DRUGS)

- Phosphate binders (e.g., calcium carbonate, calcium acetate, sevelamer; avoid aluminum if possible)
- 1,25-dihydroxy vitamin D and/or 25-hydroxy vitamin D
- Alkali therapy (e.g., sodium bicarbonate/citrate)
- Antihypertensive therapy
- ACE inhibitors (renoprotection)
- Recombinant erythropoietin
- Ferrous sulfate (if iron deficient)
- Recombinant human growth hormone

ADDITIONAL TREATMENT

ISSUES FOR REFERRAL

Pediatric primary care physicians should observe patients with CKD in consultation and with assistance from a pediatric nephrologist.

COMPLEMENTARY & ALTERNATIVE THERAPIES

Dialysis: Indications similar to those for acute renal failure or when GFR <10 mL/min/1.73 m² and patient is experiencing fatigue, poor school performance, or weight loss due to severe dietary restrictions.

ALERT

During episodes of gastroenteritis, infants with CKD may be prone to dehydration because they have obligatory polyuria due to a concentrating defect. Do not use urine output level or specific gravity of urine as indices for hydration. If hospitalized, fluid levels considered “maintenance” may be insufficient due to polyuria.

SURGERY/OTHER PROCEDURES

- Transplantation: In some cases, a preemptive transplant may be offered instead of dialysis.
- Consider arteriovenous fistula or graft placement for patients who will require long-term hemodialysis.

ONGOING CARE

DIET

Restrictions mandated by condition:

- Protein (not less than RDA in children)
- Phosphate
- Potassium
- Sodium (indicated if patient swollen)
- Fluid (indicated in conditions related to oliguria)

PROGNOSIS

Depends on underlying cause, child’s age, degree of renal insufficiency, and need for dialysis or transplantation. There is a significantly increased risk of cardiovascular morbidity and mortality in young adults with CKD.

COMPLICATIONS

- Growth retardation is particularly severe when CKD develops in the 1st year of life. Growth failure may be secondary to poor nutrition, bone disease, acidosis, or a direct effect on the growth hormone-IGF-1 axis.
- Renal osteodystrophy may be seen early in association with CKD, taking the form of growth failure, bowing of the lower extremities, and slipped epiphysis. Vitamin D deficiency and secondary hyperparathyroidism are the major factors leading to bone disease.
- Anemia develops secondary to decreased erythropoietin secretion and decreased erythrocyte survival. The anemia is a normocytic variant associated with a low reticulocyte count.
- Cardiovascular disease including LVH, and coronary artery disease often develops in early adulthood. Uncontrolled hypertension, anemia, hyperlipidemia, and hyperparathyroidism all contribute to this leading cause of death in adults with CKD.
- Neurodevelopmental delay increases in children with CKD. This is probably due to uremic effects on the development of the brain.
- Hypertension may be seen in some patients with CKD, due either to hyperreninemia or hypervolemia.
- Platelet abnormalities, protein-calorie malnutrition, and immunologic disturbances are also seen in patients with uremia.

CODES

ICD9

- 585.1 Chronic kidney disease, Stage I
- 585.2 Chronic kidney disease, Stage II (mild)
- 585.9 Chronic kidney disease, unspecified

ICD10

- N18.1 Chronic kidney disease, stage 1
- N18.2 Chronic kidney disease, stage 2 (mild)
- N18.9 Chronic kidney disease, unspecified

FAQ

- Q: Which OTC medications should be avoided in children with CKD?
- A: NSAIDs, pseudoephedrine (if patient hypertensive), enemas containing phosphate, and antacids containing magnesium or aluminum should not be taken.
- Q: Can children with CKD receive immunizations?
- A: Children with CKD should especially receive all necessary immunizations, because some vaccines are contraindicated after transplantation. In some cases, booster immunizations are necessary because of an inadequate response to the initial series (e.g., hepatitis B virus, measles, mumps, rubella; varicella).
- Q: When is recombinant human erythropoietin indicated?
- A: Generally, this medication should be considered when the hematocrit level is <33% (hgb <11.0 g/dL).

CIRRHOSIS

Rose C. Graham

BASICS

DESCRIPTION

Cirrhosis is the end stage of progressive hepatic necrosis, fibrosis, and regenerative nodule formation that may occur as a result of many different liver diseases. It results in distortion of liver architecture and compression of hepatic vascular and biliary structures. In its advanced form, it is irreversible and often requires liver transplantation for survival of the patient.

EPIDEMIOLOGY

- On the basis of varying causes, no specific epidemiologic pattern can be identified.
- Cirrhosis due to chronic HCV infection is the most common indication for liver transplantation in adults.
- Biliary cirrhosis due to biliary atresia is the most common indication for liver transplantation in children.

Genetics

- Many distinct genetic disorders can cause cirrhosis, such as Wilson disease and hereditary hemochromatosis.
- Human leukocyte antigen (HLA) associations have been identified in several autoimmune disorders, including sclerosing cholangitis.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Compensated (latent) cirrhosis: Asymptomatic, with no signs or symptoms of liver disease. Discovered incidentally either during routine physical examinations with an enlarged liver and/or palpable spleen, or as a result of an investigation for an unrelated condition.
- Decompensated (active) cirrhosis: As cirrhosis progresses, overt signs and symptoms may occur including failure to thrive, muscle weakness, fatigue, fever, jaundice, pruritus, edema, abdominal pain, ascites, steatorrhea, spontaneous bleeding (i.e., epistaxis) or bruising, and deterioration in school performance or depression. In addition, this stage may present with acute, precipitous liver failure or a life-threatening complication such as an esophageal variceal hemorrhage.

HISTORY

Based on the varying etiologic agents, one should elicit pertinent historical features characteristic of each specific problem, as detailed:

- Exposure to infectious hepatitis, antecedent viral illnesses
- Exposure to hepatotoxins
- Family or personal history of genetic, metabolic, or autoimmune diseases
- Neurologic problems, deteriorating school performance, depression (Wilson disease)

PHYSICAL EXAM

- General: Poor growth, malnutrition, fever, cachexia, obesity [Nonalcoholic steatohepatitis (NASH)]
- Skin: Jaundice, flushing, pallor, cyanosis, palmar erythema, spider angiomas, fine telangiectasia (face and upper back), easy bruising
- Abdomen: Ascites (distention, fluid wave, shifting dullness), caput medusa (prominent periumbilical veins), splenomegaly, rectal varices, hepatomegaly, or a shrunken liver
- Extremities: Digital clubbing, hypertrophic osteoarthropathy, muscle wasting, peripheral edema
- Endocrine: Gynecomastia, testicular atrophy, delayed puberty
- Central nervous system: Asterixis, positive Babinski sign, mental status changes, hyperreflexia, muscle wasting
- Eyes: Kayser–Fleischer rings (Wilson disease)

DIAGNOSTIC TESTS & INTERPRETATION

Lab

These tests focus on determining the etiology and the severity of liver disease prior to a liver biopsy.

- Tests of liver cell injury: Alanine aminotransferase (ALT), aspartate aminotransferase (AST), lactic dehydrogenase (LDH)
- Tests of synthetic function: Albumin and other serum proteins, prothrombin time (PT), partial thromboplastin time (PTT), international normalized ratio (INR), ammonia, plasma and urine amino acids, serum lipids and lipoproteins, cholesterol and triglycerides
- Tests of cholestasis: Fractionated bilirubin, alkaline phosphatase, γ -glutamyltransferase, cholesterol, serum and urine bile acids
- Tests of fibrosis: Serum markers may be useful to evaluate hepatic fibrosis noninvasively; however, these are still being investigated for clinical utility. Possible markers include procollagen III peptide, tissue inhibitor of metalloproteinase, type IV collagen, laminin, hyaluronic acid, and prolyl-hydroxylase.
- Miscellaneous disease-specific serum tests:
 - Viral serologies: Toxoplasma, rubella, cytomegalovirus, herpesvirus, hepatitis B, hepatitis C, Epstein–Barr virus, other viruses
 - Wilson disease: Serum ceruloplasmin, 24-hour urine copper, and slit-lamp exam for Kayser–Fleischer rings
 - α_1 -Antitrypsin deficiency: α_1 -Antitrypsin serum level and protease inhibitor (Pi) phenotype
 - Autoimmune hepatitis: Sedimentation rate, autoantibodies (antinuclear, anti-smooth muscle, anti-liver kidney microsomal, anti-F-actin), serum immunoglobulins
 - Hemochromatosis: Serum iron, total iron binding capacity, ferritin
 - Metabolic/genetic: Fasting blood sugar, lactate, pyruvate, uric acid, sweat test, carnitine, creatine phosphokinase (CPK), porphyrins, serum amino acids, urine organic acids, urine reducing substances, urine succinylacetone, fatty acid degeneration products, α -fetoprotein

Imaging

- Ultrasound with Doppler images: Evaluates for anatomic variation or obstruction of the biliary tree, presence of ascites, portal hypertension, and vascular obstruction
- Hepatobiliary radioisotope scanning: Assess for biliary excretion in neonatal cholestasis.
- Cholangiography [magnetic resonance cholangiopancreatography (MRCP)]: Assess for intra- and extrahepatic biliary disease (stones, choledochal cyst, sclerosing cholangitis).
- Elastography by ultrasound or magnetic resonance imaging is a newer technique still being studied that may be useful in quantifying liver fibrosis noninvasively.

Diagnosis Procedures/Surgery

- Liver biopsy:
 - Percutaneous needle biopsy, intraoperative wedge biopsy, transjugular liver biopsy
 - Confirm the presence, type, and degree of activity of cirrhosis.
 - Various hepatic diseases that progress to cirrhosis have characteristic histologic findings. However, the process of cirrhosis may obscure the nature of the original insult, rendering morphologic and histologic classifications unhelpful.
- Cholangiography:
 - Intraoperative cholangiography: Assess for extrahepatic biliary atresia in neonates.
 - Endoscopic retrograde cholangiopancreatography (ERCP): Assess for extrahepatic biliary disease in older patients where MRCP is not helpful or therapeutic interventions possible (i.e., stent placement).

DIFFERENTIAL DIAGNOSIS

- Biliary:
 - Extrahepatic biliary atresia
 - Choledochal cyst
 - Tumors
 - Common bile duct and biliary lithiasis
 - Alagille syndrome
 - Biliary hypoplasia
 - Sclerosing cholangitis
 - Graft-versus-host disease
 - Vanishing bile duct syndrome due to drugs (e.g., trimethoprim–sulfamethoxazole)
 - Langerhans cell histiocytosis
- Hepatic:
 - Infectious hepatitis, including toxoplasma, rubella, cytomegalovirus, herpes virus (TORCH) infections, viral hepatitis B, C, D; Epstein–Barr virus, other viruses
 - Autoimmune hepatitis
 - NASH, associated with obesity
 - Drugs/toxins and alcohol

- Genetic/metabolic (examples for each category, not a complete list):
 - Cystic fibrosis
 - α_1 -Antitrypsin deficiency
 - Congenital hepatic fibrosis
 - Progressive familial intrahepatic cholestasis (PFIC)
 - Wilson disease
 - Hereditary hemochromatosis
 - Carbohydrate defects: Galactosemia, hereditary fructose intolerance, glycogen storage III and IV
 - Amino acid defects: Tyrosinemia
 - Lipid storage diseases: Gaucher disease, Niemann–Pick type C
 - Mitochondrial disorders: Fatty acid oxidation defects, respiratory chain defects
 - Peroxisomal disorders: Zellweger syndrome
 - Porphyrrias: Erythropoietic protoporphyria
- Vascular:
 - Budd–Chiari syndrome
 - Venocclusive disease
 - Congestive heart failure

TREATMENT

MEDICATION (DRUGS)

First Line

- Fat-soluble vitamin supplementation: Vitamins A, D, E, and K
- Diuretic therapy (furosemide, spironolactone, chlorothiazide) for patients with ascites
- Albumin infusions for patients with refractory ascites
- Beta-blockers have been shown to decrease portal pressure and reduce the risk of variceal bleeding in adults with portal hypertension.
- Antibiotics, if suspicious for spontaneous bacterial peritonitis (avoid nephrotoxic agents)
- Lactulose, lactitol, and neomycin are used for patients with hepatic encephalopathy.

SURGERY/OTHER PROCEDURES

- Endoscopic variceal band ligation or sclerotherapy for variceal GI bleeding
- Paracentesis for refractory ascites or diagnosis of spontaneous bacterial peritonitis
- Portosystemic shunt placement [surgical or radiologic transjugular intrahepatic portosystemic shunting (TIPS) procedure] for complications of uncontrolled portal hypertension
- Liver transplantation

ONGOING CARE

DIET

- Malnutrition is common in chronic liver diseases because of several metabolic derangements, fat malabsorption, anorexia, and increased energy requirements.
- Adequate caloric intake is critical and, often, will require supplemental nasogastric tube feedings.
- Some of the dietary fat should be provided as medium-chain triglycerides, which do not require bile for absorption.
- Fat-soluble vitamin levels should be monitored and supplemented, if necessary.
- Careful attention must also be paid to fluid and electrolyte balance; sodium restriction (<2 mEq/kg/d) may be necessary in the presence of ascites.

Activity

Spleen guard and avoidance of abdominal trauma if significant splenomegaly

PROGNOSIS

- The prognosis for cirrhosis leading to decompensation depends on the underlying cause.
- The underlying condition should be treated where possible (e.g., Wilson disease, autoimmune hepatitis)
- Poor prognostic features in children include prolonged INR unresponsive to vitamin K, ascites, malnutrition, low plasma cholesterol, elevated bilirubin level, and presence of hepatorenal syndrome.

COMPLICATIONS

- Malnutrition and growth failure
- Malabsorption (diarrhea, steatorrhea, fat-soluble vitamin deficiencies)
- Portal hypertension and variceal bleeding
- Chronic gastritis, peptic ulcer disease, gastroesophageal reflux
- Ascites
- Encephalopathy
- Hypersplenism (associated with anemia, thrombocytopenia, and neutropenia)
- Anemia
- Coagulopathy
- Hepatopulmonary syndrome (hypoxemia, cyanosis, dyspnea, digital clubbing)
- Hepatorenal syndrome (rapidly progressive renal failure in patients with cirrhosis)
- Bacterial infections, spontaneous bacterial peritonitis
- Hepatocellular carcinoma

CODES

ICD9

- 571.5 Cirrhosis of liver without mention of alcohol
- 571.6 Biliary cirrhosis

ICD10

- K74.5 Biliary cirrhosis, unspecified
- K74.60 Unspecified cirrhosis of liver

FAQ

- Q: Will my child with cystic fibrosis develop cirrhosis?
- A: The medical literature cites a 5–10% incidence of cirrhosis in children with cystic fibrosis. Children with cystic fibrosis liver disease who develop cirrhosis are at risk for complications of portal hypertension.
- Q: Will every child with cirrhosis need a liver transplant?
- A: Most children who develop cirrhosis from causes such as biliary atresia or metabolic disease will ultimately require a liver transplant.

CLEFT LIP AND PALATE

Oksana A. Jackson

Jesse A. Taylor

Christine A. Carman (5th edition)

David W. Low (5th edition)

BASICS

DESCRIPTION

- Cleft lip:
 - Deformity of the upper lip that may include a discontinuity of vermilion, skin, muscle, and mucosa, as well as the underlying gingiva and bone
 - May be unilateral or bilateral
 - A complete cleft extends into the nose. An incomplete cleft has a bridge of intact tissue between the oral and nasal cavities.
- Cleft palate:
 - May involve the gingiva, hard palate, and/or soft palate
 - Represents a visible separation between the 2 halves of the roof of the mouth, involving mucosa, muscle, and often the bones of the hard palate
 - A submucous cleft palate has intact mucosa, but the underlying muscle and bone are at least partially divided.

EPIDEMIOLOGY

Incidence

- Incidence of cleft lip with or without cleft palate is 1 in 700 births
- Incidence of cleft lip with or without cleft palate increases with parental (especially paternal) age >30 years. Some association with low socioeconomic class may be nutrition related.

Prevalence

- Racial heterogeneity noted in cleft lip and cleft palate (Asians, 2.1 in 1,000 births; whites, 1 in 1,000; blacks, 0.41 in 1,000)
- Isolated cleft palate is present in 1 in 2,000 births across races.

Genetics

- 1/3 of patients with cleft lip and/or cleft palate have a positive family history; positive family history is noted twice as often in cleft lip with or without cleft palate as in cleft palate alone.
- Some recognized patterns of malformation that include cleft lip and/or cleft palate may be caused by exposure to teratogens, but there is little evidence linking isolated clefts to exposure to any single teratogenic agent.
 - A notable exception is phenytoin; use during pregnancy has been associated with a 10-fold increase in the incidence of cleft lip.
- Incidence of cleft lip in infants born to mothers who smoke during pregnancy is twice that in those born to nonsmoking mothers.

PATHOPHYSIOLOGY

- Muscle fibers are atrophic and disorganized in the region of the cleft.
- Mitochondrial abnormalities are noted at the cleft margins by histochemical and electromyographic studies.

ETIOLOGY

- Cleft lip may result from failure of the medial nasal and maxillary processes to join *in utero*, or possibly from lack of adequate mesenchymal reinforcement, leading to subsequent breakdown and separation.
- Cleft palate results from failure of the palatal shelves to fuse.
- Prenatal dietary supplementation with folic acid and vitamin B₆ has led to lower-than-expected incidence of cleft lip and cleft palate and to a decreased incidence of neural tube defects.
- Bilateral cleft lip is associated with cleft palate in 86% of cases. Unilateral cleft lip is associated with cleft palate in 68% of cases.
- Cleft lip/cleft palate is more common on the left, particularly in boys.

COMMONLY ASSOCIATED CONDITIONS

- Among patients with clefts of the secondary palate alone, syndromes associated with microdeletions of chromosome 22q11.2 are currently the most common syndromic diagnoses.
 - Collectively known as 22q11.2 deletion syndrome, includes velocardiofacial syndrome, DiGeorge syndrome, and conotruncal anomaly face syndrome
 - Inheritance is autosomal dominant with considerable variability in phenotypic expression, which may include facial dysmorphism, developmental delay, cardiovascular anomalies, immunologic abnormalities, cleft palate, and velopharyngeal dysfunction.
- Next most common syndrome associated with palatal clefts is Stickler syndrome:
 - Characterized by autosomal dominance, cleft palate, epicanthal folds, flat facies, joint hyperflexibility, severe myopia, retinal detachment, and glaucoma
 - Caused by a mutation of the gene for type 2 collagen (chromosome 12q)
- Most common syndrome associated with clefts of the lip and/or palate is Van der Woude (autosomal dominant, lower lip pits, 1q32)
- Other genetic syndromes associated with cleft lip and/or palate:
 - CHARGE syndrome (pattern of malformation with majority of patients having CHD7 mutation)
- Smith–Lemli–Opitz (defect in cholesterol synthesis, 7q34) Pierre Robin Sequence is a condition usually associated with a wide U-shaped cleft palate.
 - Characterized by a small mandible, retropositioned tongue, and subsequent upper airway obstruction
 - May occur in infants with or without genetic syndromes (Stickler most common)
 - Most clefts are nonsyndromic and may be either multifactorial in origin or the result of changes at a major single-gene locus

DIAGNOSIS

HISTORY

- Prenatal exposure to alcohol, cigarettes, phenytoin, and isotretinoin
- Family history of cleft lip or cleft palate
- Speech problems in first-degree relative

PHYSICAL EXAM

- Incomplete or complete cleft of lip, alveolus, hard and soft palate, or uvula. Soft palate and uvula clefts are always midline, whereas lip, alveolar, and hard palatal clefts can be unilateral or bilateral.
- A bifid uvula or a notch in the bone at the posterior hard palate may indicate a submucous cleft.
- A small mandible and retropositioned tongue may indicate a risk for airway obstruction (Pierre Robin sequence).
- Look for associated anomalies of the face, heart, and extremities that may indicate a clefting syndrome.
- Tricks:
 - Examine the palate from the top of the patient, with the head in your lap, using a tongue depressor and flashlight.
 - Palpate the posterior hard palate for a possible notch in the bone.
 - Palpate the gums and maxilla for a possible notch in the floor of the nose.

DIAGNOSTIC TESTS & INTERPRETATION

- Complete ophthalmologic examination to check for myopia, glaucoma, and retinal detachment
- Pulse oximetry to check for desaturation while feeding or while supine
- Polysomnography to distinguish central from obstructive apnea
- Hearing evaluation
- Increased serum 7-dehydrocholesterol and decreased serum cholesterol to rule out Smith–Lemli–Opitz syndrome
- Karyotype to rule out specific genetic abnormalities
- Fluorescence *in situ* hybridization to rule out a chromosome 22q11.2 deletion
- Echocardiography, renal ultrasound, and endocrine laboratory studies if indicated

Imaging

Prenatal diagnosis of cleft lip is reliable by ultrasound; prenatal diagnosis of cleft palate remains unreliable by ultrasound. 3D ultrasound has improved the reliability of prenatal diagnosis. Fetal MRI provides excellent soft tissue definition and can be used when the diagnosis is uncertain on ultrasound or to better delineate the severity of the cleft. After birth, no additional radiologic imaging is indicated in patients with isolated cleft lip and/or palate.

TREATMENT

ADDITIONAL TREATMENT

General Measures
Airway management

- Prone positioning if the tongue is causing airway obstruction
- Plastic surgery and ENT consultation if airway obstruction persists

ORTHODONTICS

Preoperative orthodontics may include: Obturators to facilitate feeding and speech, nasolabial molding and palatal reposition before lip and palate repair, palatal expansion prior to bone grafting, conventional orthodontics, including braces, maxillary appliances, prosthetic teeth, bridgework, maxillary and/or mandibular distraction to advance the mid- or lower face

SURGERY/OTHER PROCEDURES

- Significant airway obstruction and desaturation in the neonatal period refractory to prone positioning may indicate the need for a tongue-lip adhesion, release of the floor of the mouth musculature, mandibular distraction, or tracheostomy.
- Wide clefts of the lip may benefit from preliminary lip adhesion at 2–3 months of age. Timing of definitive lip repair varies from 2 to 6 months of age.
- Palate repair is generally done at < 1 year of age to decrease speech and language difficulties.
- Otitis media is more common with cleft palate, and bilateral myringotomy tubes can be inserted at the time of cleft repair.
- Correction of secondary deformities may include:
 - Lip scar revision
 - Cleft nasal deformity correction (infancy to adulthood)
 - Alveolar bone grafts (usually when permanent canines are erupting)
 - Pharyngoplasty for soft palate–velopharyngeal incompetence
 - Closure of palatal fistulas
 - Orthognathic surgery for severe jaw deformities

Admission Criteria

Airway obstruction or severe feeding difficulties in the neonate

Discharge Criteria

- Stable airway
- Tolerating feedings

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Multidisciplinary team:

- Pediatrician
- Plastic surgeon
- Speech pathologist
- Orthodontist
- Pediatric dentist
- Psychologist
- Social worker
- Nurse practitioner
- Anthropologist (facial growth specialist)
- Geneticist
- Support groups

DIET

Cleft patients may have significant feeding problems because of an inability to generate negative intraoral pressure necessary to feed efficiently.

- Premie nipples with enlarged or cross-cut openings, or soft plastic squeezable bottles, can facilitate milk flow.
- Poor weight gain may necessitate nasogastric tube feedings.

PROGNOSIS

Good. Most patients undergo normal growth and development. Long-term follow-up by a multidisciplinary team and parental support are critical to optimization of outcomes.

COMPLICATIONS

- Airway obstruction and feeding disorders, particularly with Pierre Robin sequence
- Chronic otitis media
- Speech problems, including hypernasality and articulation errors
- Associated malformations:
 - ~1/3 of patients with cleft palate has associated anomalies, with isolated cleft palates having the highest. CNS, cardiac, urinary tract malformations, and clubfoot are commonly associated with clefting.
- Potential problems:
 - Hypernasal resonance and nasal air emission during speech may indicate velopharyngeal incompetence or palatal fistula. Up to 30% of patients may require additional palatal or pharyngeal surgery following initial palate repair.
 - Multiple ear infections may require prolonged use of myringotomy tubes to prevent hearing impairment. Audiograms should be obtained regularly.
 - Delays in speech and language development may require detailed evaluation, early intervention programs, and speech therapy.
 - Poor dentition, occlusal problems (crossbite), gingivitis, and crowding
 - Behavior disorders and psychosocial adjustment disorders
 - ~25% of affected individuals will manifest maxillary hypoplasia that requires jaw surgery to correct occlusal abnormalities.

ALERT

- Failure to diagnose airway obstruction in infants with Pierre Robin sequence may lead to failure to thrive or, in severe cases, death.
- Failure to diagnose associated anomalies may lead to missed syndromes and inaccurate genetic counseling.
- A submucous cleft palate can be easily missed until hypernasal speech is noted later in life.

CODES

ICD9

- 749.11 Cleft lip, unilateral, complete
- 749.12 Cleft lip, unilateral, incomplete
- 749.13 Cleft lip, bilateral, complete

ICD10

- Q36.0 Cleft lip, bilateral
- Q36.1 Cleft lip, median
- Q36.9 Cleft lip, unilateral

FAQ

- Q: will there be a scar
- A: All cleft lip repairs will leave some type of permanent scar, with potential asymmetry that may benefit from later additional lip scar revision.
- Q: What is the goal of surgery
- A: Goal is to create a lip that does not attract undue attention.
- Q: What is the most difficult part of surgery
- A: The nose is often the most difficult to correct, because of asymmetry in cartilage and skin contour.
- Q: Will my child be able to speak clearly?
- A: Most children will achieve velopharyngeal competence and normal speech, but may require additional speech therapy to achieve this goal.
- Q: Is cleft palate inherited?
- A: For nonsyndromic cleft lip with or without cleft palate:
 - Risk of having a second child with a cleft, if neither parent has a cleft: 4%
 - Child’s risk of later having a child with a cleft: 4%
 - Risk of having a third child with a cleft, if parents have 2 affected children but neither parent is affected: 9%
 - Risk of having a second child with a cleft, if 1 parent also has a cleft: 17%
- For nonsyndromic isolated cleft palate:
 - Risk of having a second child with a cleft, if neither parent has a cleft: 2%
 - Child’s risk of later having a child with a cleft: 3%
 - Risk of having a third child with a cleft, if parents have 2 affected children but neither parent is affected: 1%
 - Risk of having a second child with a cleft, if 1 parent also has a cleft: 15%

CLUBFOOT

Richard S. Davidson

BASICS

DESCRIPTION

Clubfoot is a congenital or neuromuscular deformity in which the hindfoot is fixed in equinus and varus and the forefoot is fixed in varus, equinus, and often cavus.

EPIDEMIOLOGY

- The risk of deformity increases by 20–30 times when there is an affected 1st-degree relative.
- Male > female (2:1)

Incidence

Incidence is 1–1.4/1,000 live births, but can vary among different ethnic groups.

PATHOPHYSIOLOGY

- Many anatomic abnormalities have been postulated as causing clubfoot:
 - Anomalous or deficient muscles, myoblasts, mast cells, abnormal primary bone formation, joint and muscle contractures, vascular anomalies (absent dorsalis pedis artery), nerve anomalies
 - Abnormalities of the fibrous connective tissue
- Interruption of the development of the embryonic foot has also been suggested.

ETIOLOGY

- Most cases are idiopathic (multifactorial inheritance pattern with significant environmental influence).
- Infrequently, neuromuscular imbalance may underlie the deformity (cerebral palsy, myelomeningocele, lipomas of the cord, caudal or sacral agenesis, polio, arthrogryposis, fetal alcohol syndrome).
- Rapid recurrence should prompt a thorough examination for possible underlying etiologies.

DIAGNOSIS

HISTORY

- Family history of clubfoot (3%)
- Onset of deformity (congenital or developmental)

PHYSICAL EXAM

- Careful examination of:
 - The neuromuscular system for neuromuscular etiologies such as lumbosacral sinuses, dimples, and lipomas as well as spasticity, asymmetry, and muscle imbalance
 - The hips for hip dysplasia
 - The neck for torticollis
- Physical exam trick:
 - Push the foot into a corrected position. Is the deformity fully correctable? Overcorrectable?

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- The diagnosis is clinical.
- Radiographs (after 3 months of age) may confirm bone position but cannot make the diagnosis.
- At 3–6 months of age, anteroposterior (AP) and lateral radiograph films in dorsiflexion (maximal correction) may help in defining residual deformity. The beam should be focused on the hindfoot for both the anteroposterior and lateral radiographs, as the measured angles will be hindfoot angles.
- Decreased talocalcaneal angle on the anteroposterior and lateral views ($\leq 25^\circ$) confirm persistent deformity.
- Medial displacement of the cuboid on the calcaneus and persistent plantar flexion of the forefoot on the hindfoot (talar to 1st metatarsal angle) indicate more complex deformities.

DIFFERENTIAL DIAGNOSIS

Distinguish other deformities of the foot:

- Metatarsus adductus or varus (heel is in neutral position, no fixed equinus)
- Calcaneovalgus (foot is in valgus, no fixed heel equinus)
- Vertical talus (foot is in valgus, heel in equinovalgus)
- Many children with clubfoot also have tibial torsion, which is a normal variant in our society that rarely requires treatment.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Ponseti method and its variations have become the standard of initial treatment.
- Initial treatment:
 - Care can begin in the 1st week after birth though later treatment is generally successful as well.
- Initial treatment is serial (weekly) manipulation and casting with long leg casts 1st correcting abduction, then rotation, then dorsiflexion. The talar head is stabilized with the casting physician's thumb while the contralateral hand manipulates the foot.
- Taping may be useful for treatment of the infant requiring ICU care; access to the feet should be maintained for blood tests.
- Failure to correct the deformity completely by manipulation within 8–12 weeks of casting should lead to surgical intervention.
- Long leg serial casting by the Ponseti technique improves results so that in most clubfeet little more than heel cord lengthening and possibly posterior ankle release is required. The operated foot is stabilized for healing for 1 month in a Ponseti-type cast.
- Following surgery, bracing with bars and shoes for 3 months full time and then 3 years nights and naps is an integral part of the Ponseti method.
- With the Ponseti method, 30–45% of patients may have various forms of recurrence requiring repeated casting and/or surgical release through maturity.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Realignment of the deformity is the goal and should be achieved with casting and surgery.
- Most surgeons cast the feet for 1 month postoperatively.
- With the Ponseti method, bars and shoes are recommended full time for 3 months and nights for 3 years to maintain the correction.
- Remember, the cause of the deformity is not corrected. Only the alignment of the bones and lengthening of the soft tissues are corrected.
- Depending on the severity of the deformity, all corrected clubfeet can be expected to demonstrate varying amounts of calf narrowing and weakness, ankle and subtalar stiffness, a difference between the feet of 1–2 shoe sizes, and even a leg-length discrepancy, usually <2 cm.
- There also will be decreased ankle and subtalar motion as compared to normal.
- Adolescent children with clubfeet often will get leg cramps and will tire easily while doing sports.
 - Recurrence of heel cord tightness is common, especially during periods of rapid growth. Additional heel cord stretching and casting and, infrequently, additional surgery may be needed.
- All true recurrences should lead to further evaluation for neuromuscular or syndromic causes that might have been missed in the infant.

FAQ

- Q: How can a rigid clubfoot be distinguished from a positional clubfoot?
- A: During initial evaluation of the child, it is important to assess the amount of flexibility in a clubfoot. This can be most easily done by flexing the hip to 90°, flexing the knee to 90°, and then gently trying to turn the forefoot into a straight position lined up with the thigh. If the foot easily spins around into a normal position, it can be assumed that this is a flexible or positional clubfoot. If deformity persists, this is a rigid deformity. If possible, the examining physician should palpate the heel to see if the os calcis comes out of its equinus position filling the heel pad. In some children, particularly with a rocker bottom sole, the heel pad looks as if it is in the correct position, but the os calcis remains in equinus with the posterior aspect of the os calcis proximal to the heel pad.
- Q: What percentage of clubfeet is successfully treated by casting?
- A: To some extent, the amount of success depends on how much correction is desired. Occasionally, cast correction will provide a partial correction. Some feet, after casting, can be held in the corrected position, only to spin back to the clubfoot deformity when released. Positional clubfeet are likely to improve with casting in perhaps 98% of cases. Rigid clubfeet are much less likely to be corrected by casting. The success rate with casting alone in the rigid feet is likely to be ~10%. It is important to remember that casting and surgery cannot make the clubfoot normal.

- Q: What will be the permanent disability of a congenital clubfoot deformity?
- A: Although casting and surgical correction of a congenital clubfoot can realign the bones, the surgery does little to correct the underlying neuromuscular problems. As a result, all children with rigid clubfeet are likely to have a leg-length inequality (usually <1.5 inches), a smaller foot (usually 1–2 sizes), calf narrowing that cannot be significantly improved with exercise, and joint stiffness (ankle, subtalar, and midfoot). Even children with optimal realignment of the deformity will notice their inability to perform gymnastic activities or running activities requiring normal range of motion of the ankle and foot. Many will complain of the inability to keep up with their peer group during adolescent and young adult sports activities.
- Q: How soon should an infant with congenital clubfoot be referred to an orthopedic surgeon?
- A: Casting begins within the 1st to 2nd week of life. Clearly, medical and life-threatening conditions will take precedence over the treatment of the clubfoot. Access to the feet for IV or blood studies will interfere with a casting regimen. Casting should begin as soon as is practical. It may even be possible to begin taping of the foot as an alternative to casting, which will still allow IV access to the feet. Referral to an orthopedic surgeon should, therefore, follow as soon as is practical. Studies have shown that excellent results can be obtained from the Ponseti method even when initiated after the 1st year of life.

COARCTATION OF AORTA

Luz Natal-Hernandez

Geoffrey L. Bird (5th edition)

BASICS

DESCRIPTION

- Discrete stenosis of the upper thoracic aorta, usually just opposite the site of insertion of the ductus arteriosus (juxtaductal). A segment of tubular hypoplasia and/or a remnant of ductal tissue gives rise to a prominent posterior infolding (“the posterior shelf”).
- The hemodynamic lesion is most often discrete, but may be long segment or tortuous in nature. It is usually juxtaductal but may occur in other sites (i.e., the abdominal aorta). The prevalence of other associations (bicuspid aortic valve) and long-term complications (hypertension) indicate the possibility that this lesion is part of a broader spectrum arteriopathy and/or endothelial disorder.

EPIDEMIOLOGY

Prevalence

- ~6–8% of patients with congenital heart disease have coarctation.
- Male > Female (1.5–4.0:1)

RISK FACTORS

Genetics

- Multifactorial: Occurs in 35% of patients with Turner syndrome (XO)
- Has been described in cases of monozygotic twins
- Many studies document the prevalence of a microdeletion at 22q11 in patients with arch anomalies and ventricular septal defects.

PATHOPHYSIOLOGY

- Decreased systemic blood flow to lower extremities after ductal closure
- Increased resistance to left ventricular (LV) outflow causes LV hypertrophy. Relative underperfusion of the renal vessels, baroreceptors, and multiple other mechanisms combine to induce a compensatory systolic hypertension.
- If the coarctation is severe, LV dysfunction and CHF result, with low cardiac output and increased LV end diastolic pressure.
- Decreased myocardial perfusion may be present in cases of very low output.

DIAGNOSIS

HISTORY

There are 2 typical patterns for the clinical presentation of coarctation:

- An infant with CHF or shock—a small, pale, irritable child in respiratory distress. Typically precipitated by ductal closure, this presentation is more common in infants with coarctation and other intracardiac malformations (20–30%):
 - Poor feeding
 - Dyspnea
 - Diaphoresis
 - Poor weight gain
 - Oliguria
- An otherwise asymptomatic child or adolescent with systolic hypertension and/or a heart murmur (70–80%):
 - Lower-extremity claudication
 - Headaches

PHYSICAL EXAM

- Tachypnea and tachycardia
- Discrepant arterial pulses and systolic blood pressure in the upper and lower extremities
- Weak, “thready” pulses
- Grades 2–3/6 systolic ejection murmur
- Gallop rhythm in an infant with CHF
- Ejection click of a bicuspid aortic valve
- The most important finding is decreased or absent lower extremity pulses. Are pulses present? Is there a delay between the brachial and femoral pulses?
- Heart murmur: Best heard at the upper left sternal border, at the base and radiating to the left interscapular area posteriorly
- An infant with severe coarctation and a patent ductus arteriosus (PDA) may have “differential cyanosis.” The lower part of the body appears cyanotic because the descending aortic flow is provided by the right ventricle (RV) through the PDA (check postductal saturation).

ALERT

- The most reliable clinical findings to diagnose native, residual, or recurrent coarctation are the presence of pressure differences in the upper and lower extremities and decreased or absent femoral pulses. Palpable pulses do not exclude coarctation. What one palpates is pulse pressure, not absolute systolic pressure.
- 4-extremity BP measurement is very important in assessing infants and children with possible congenital heart disease. Proper cuff size must be used.
- Bowel ischemia can be present in the ill patient, and emesis or poor feeding are hallmark signs.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- EKG: RV hypertrophy is usually present in symptomatic infants. EKG is often normal in children. LV hypertrophy is apparent with more severe coarctation or coarctation of longer standing, particularly in older children.
- Blood tests: In the patient presenting in extremis, management, initial therapy, and timing of surgery can be aided or guided by arterial blood gas analyses and markers of end organ dysfunction.

Imaging

- Chest x-ray: In the infant, moderate to severe cardiomegaly with increased pulmonary vascular markings (PVMs). In an asymptomatic child, the heart size is often normal, with normal PVMs. Rib notching may be seen in older children secondary to dilated intercostal collateral vessels.
- Echocardiography: Localization, degree of coarctation, and associated findings (PDA, arch hypoplasia, ventricular septal defect). Assessment of associated left-sided obstruction: Mitral valve abnormality, LV outflow obstruction, and aortic stenosis (bicuspid aortic valve)
- MRI: Clearly defines the location and severity of coarctation. Useful for serial follow-up postoperatively (especially aortic aneurysms)

Diagnostic Procedures/Other

Cardiac catheterization and angiography: Usually not indicated unless there are further questions to be answered and/or a planned intervention

DIFFERENTIAL DIAGNOSIS

- Other left-sided heart obstructive lesions
- Hypoplastic left heart syndrome
- Cardiomyopathy and/or myocarditis
- Critical aortic stenosis (aortic obstruction to a degree that adequate systemic perfusion depends upon patency of the ductus arteriosus)
- Shock from sepsis, metabolic disease, or other entities

TREATMENT

ADDITIONAL TREATMENT

General Measures

- For the sick neonate who presents with severe congestive heart failure or shock (possible ductal-dependent obstruction to systemic blood flow):
 - Prostaglandin infusion: 0.1 mcg/kg/min (anticipating adverse effects including apnea)
 - Inotropic support: 3–5 mcg/kg/min dopamine
 - Diuretics for pulmonary venous hypertension or pulmonary edema
 - Surgical intervention should follow as soon as possible.

- For the asymptomatic child, elective repair and assessment of hypertension are appropriate; however, aggressive antihypertensive pharmacotherapy is not indicated prior to surgical intervention.
- Other:
 - Interventional cardiology:
 - Percutaneous balloon angioplasty of native coarctation in infants and children is pursued in some centers. Others have concern about rates of recurrent stenosis, hypertension, aneurysm formation, and iliofemoral arterial injury.
 - Use of vascular stents to relieve the area of stenosis, particularly in older children and adolescents, have provided an alternative to surgical intervention. May increase the need for reintervention in the future when compared to the surgical approach.

SURGERY/OTHER PROCEDURES

- Infancy:
 - Surgical repair of severe coarctation and coarctation associated with intracardiac anomalies
 - The surgical mortality rate for infants with coarctation and a large ventricular septal defect ranges from 5–15% and is higher for children with more complex intracardiac anomalies.
- Childhood:
 - Elective coarctation repair between ages 18 months and 3 years in asymptomatic children without severe upper extremity hypertension. Later repair is associated with an increased risk of sustained hypertension and other late complications.
- Types of surgical repair: End-to-end anastomosis, subclavian flap aortoplasty, prosthetic patch aortoplasty, bypass graft

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Re-examine every 12 months with 4-extremity pulse and BP assessment.
- Residual or recurrent coarctation occurs most commonly in those patients requiring repair in early infancy and can depend on the method of intervention (e.g., higher incidence with patch aortoplasty and coarctation ridge resection); some centers delay percutaneous balloon angioplasty of residual or recurrent lesions until 2 months postoperatively.
- Persistent systemic hypertension: Most common in patients whose coarctation repair is delayed beyond late childhood
- Aortic aneurysm formation
- Intracranial aneurysms and/or cerebrovascular accidents
- Antibiotic prophylaxis to prevent endocarditis or endarteritis
- May have hypertension with exercise, even if normotensive at rest
- Exercise-induced hypertension without anatomic stenosis may respond to beta-blocker therapy.

PROGNOSIS

- Untreated coarctation has a poor natural history with the onset of CHF, especially in those patients with other intracardiac malformations. Claudication is common in older children with previously undiscovered coarctation. Generally, the short-term prognosis following successful intervention for isolated coarctation in infancy or childhood is excellent. Procedure-related mortality in every modern series is very near zero.
- Clinical conditions that may affect long-term prognosis after repair of coarctation include:
 - Residual or recurrent coarctation
 - Hypertension (rest and exercise)
 - Aortic aneurysm (associated with repair technique)
 - Associated intracardiac lesions
 - Intracranial aneurysms
 - Occurrence or progression of aortic valve disease
 - Premature coronary arterial and cerebrovascular disease
- Associated lesions:
 - Bicuspid aortic valve occurs in 85% of patients with coarctation.
 - PDA
 - Ventricular septal defect
 - Valvar or subvalvar aortic stenosis
 - Mitral stenosis: Often associated with structural mitral valve abnormalities (i.e., supralvalvar mitral ring, thickening of mitral leaflet, single papillary muscle with parachute deformity, or short dysplastic chordae tendineae)
 - Shone syndrome: Multiple left-sided obstructive lesions, including supralvalvar mitral ring, parachute mitral valve, subaortic obstruction, and coarctation
 - Berry aneurysm of the circle of Willis
 - Renal artery stenosis associated with abdominal coarctation
 - Congenital diaphragmatic hernia

COMPLICATIONS

- Shock, if severe untreated obstruction
- CHF, if severe untreated obstruction
- Systemic hypertension, before and after intervention
- Intracranial aneurysms
- Mesenteric ischemia
- Paraplegia
- Postoperative complications:
 - Bleeding
 - Postcoarctectomy syndrome/mesenteric ischemia
 - Paradoxical hypertension
 - Spinal cord ischemia (0.4%)
 - Residual coarctation
 - Chylothorax
 - Stridor
 - Diaphragm paralysis
 - Aortic aneurysm or dissection
 - Paralysis

CODES

ICD9

747.10 Coarctation of aorta (preductal) (postductal)

ICD10

Q25.1 Coarctation of aorta

FAQ

- Q: When is the most appropriate time to perform surgical repair of simple coarctation?
- A: Recommendations vary regarding the age at which asymptomatic children (without severe upper-extremity hypertension) should undergo intervention. Advances in technique no longer require patients to be “grown” to a threshold size or weight, and there is increasing evidence that severity and incidence of late complications correlate directly with older age at repair. While some authors mention 3–5 years of age, others recommend repair as early as 18 months to 2 years of age.
- Q: What is the incidence of systemic hypertension after surgical repair of coarctation?
- A: Greatly depends on age at repair, surgical method or technique, length of follow-up interval, and how one defines or measures hypertension. In no situation is the answer zero, and this important complication is one of several reasons patients require life-long detailed follow-up. 1 year after a technically perfect repair via resection with end-to-end anastomosis, the patient operated on in early childhood is unlikely to have hypertension at rest. However, 20 years further along, a patient of older age at repair is quite likely to have significant hypertension on exercise stress testing.

COCCIDIOIDOMYCOSIS

Leonel Toledo

Theoklis Zaoutis (5th edition)

Samir S. Shah (5th edition)

BASICS

DESCRIPTION

Coccidioidomycosis is an infection caused by the dimorphic fungi *Coccidioides immitis* and *Coccidioides posadasii*.

EPIDEMIOLOGY

- Primary infection is most commonly seen in the summer and fall months.
- The average incubation period is 10–16 days (range 1–4 weeks).
- There is no person-to-person spread.
- 60% of acute infections are subclinical (asymptomatic).
- Clusters of cases can involve dust storms, earthquakes, and occupational or recreational exposure.
- Congenital infection is rare.

Prevalence

C. immitis is found in the soil and is endemic in the southwestern US (western Texas, New Mexico, Arizona, California), northern Mexico, and parts of South and Central America. Up to 1/3 of the population in endemic areas has been infected.

RISK FACTORS

- Risk factors for disseminated coccidioidomycosis include immunosuppression, male gender, extremes of age (neonates and elderly), African or Filipino descent, and pregnancy.
- The course of illness is highly variable and dependent on host immune response and amount of exposure. HIV-infected patients and other patients with immunosuppression owing to T-lymphocyte dysfunction (lymphoma, organ transplantation, high-dose corticosteroids, receipt of immunomodulators) are particularly susceptible to severe forms of pulmonary and extrapulmonary coccidioidomycosis.

GENERAL PREVENTION

Infection control:

- No special isolation or precautions for the hospitalized patient
- Contaminated dressings from skin lesions should be handled and discarded with care.
- Inhalation of aerosolized spores from culture can be hazardous to laboratory personnel.
- Preventive efforts are aimed at dust control and trials to eliminate organisms from soil.
- Immunocompromised people should be counseled to avoid activities that may expose them to aerosolized spores in endemic areas.

PATHOPHYSIOLOGY

- In soil *Coccidioides* organisms exist in the hyphal phase. The hyphae produce spores called arthroconidia. Inhalation of arthroconidia from disturbed, arid soil is the major route of infection. In tissues arthroconidia enlarge to form spherules. Mature spherules release endospores that develop into new spherules and continue the tissue cycle.
- Most patients have infection limited to a localized area of lung and hilar nodes after mounting an intense inflammatory response with granuloma formation.
- Primary cutaneous coccidioidomycosis rarely occurs by direct inoculation of the skin (trauma). A relatively painless, indurated nodule with occasional central ulceration develops at the site of injury. Regional lymphadenopathy is often present.
- Extrapulmonary dissemination occurs via lymphatic or hematologic spread and usually involves the skin, bones and joints, and central nervous system, but can spread to virtually any organ system.

ETIOLOGY

- Osteomyelitis is subacute or chronic and frequently involves more than 1 bone (40%). Common sites are the hands, feet, ribs, and vertebrae.
- Meningitis develops within 6 months of initial infection. Hydrocephalus is a common complication. CNS vasculitis and intracerebral abscesses are rare.

DIAGNOSIS

HISTORY

- Travel or residence in an endemic area is typical. Risk factors for disseminated infection should be sought.
- Acute pneumonia:
 - Fever, dry or productive cough, and pleuritic chest pain
 - Systemic symptoms include headache, malaise, arthralgias, sore throat, and fatigue.
 - Also known as “valley fever”
- Hemoptysis, although rare in children, is reported in 15% of adults with symptomatic pulmonary infection.
- Trauma precedes primary cutaneous disease.
- Myalgias, arthralgias, chills, night sweats, and anorexia suggest systemic dissemination.
- Headache, vomiting, and altered mental status suggest meningitis.
- Most infections (60%) are asymptomatic.

PHYSICAL EXAM

- Signs of pneumonia and pleural effusions are often present with symptomatic pulmonary infection. Indurated nodules and regional lymphadenopathy are seen with primary cutaneous infection.
- Reactive rashes:
 - Contain no live organisms
 - Erythematous maculopapular rash is seen in 50% of symptomatic children.
 - Erythema nodosum and erythema multiforme occur later in the course of infection.
 - Erythema nodosum correlates with the development of cell-mediated immunity and is associated with a low incidence of dissemination.

- Hematogenous dissemination to the skin:
 - Lesions may consist of papules, nodules, abscesses, pustules, sinus tracts, and verrucous ulcers.
 - May be single or multiple
 - Can occur anywhere, but are most common on the nasolabial fold
- Chorioretinal lesions are present in $\leq 40\%$ of patients with disseminated disease.
- Stridor is present with infection of the subglottic tissues.
- Signs of increased intracranial pressure are seen with central nervous system infection. Classic signs of meningeal irritation are usually absent.

ALERT

- Clinicians in endemic areas should maintain a high level of clinical suspicion.
- Diagnosis in nonendemic areas may be missed owing to low clinical suspicion or missed travel history.
- False-negative serologic results may occur during the initial weeks of infection or in an immunocompromised host.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Direct examination and culture:
 - Cytologic examination of bronchoalveolar fluid is diagnostic in only about 1/3 of persons and is less sensitive than culture. Visualization of large spherules is possible in stained specimens of sputum, tracheal aspirates, urine, or tissue biopsy. They are rarely seen in CSF.
 - The organisms can be detected by culture in experienced laboratories. The yield is highest from purulent material. The yield from other sources, such as pleural fluid, blood, and gastric aspirates, is lower.
 - A DNA probe can identify *Coccidioides* species in cultures.
- Coccidioidin or spherulin skin intradermal testing has been used as an epidemiologic tool in the past but is no longer commercially available.
- Serologic studies:
 - *C. immitis*-specific IgM antibody is detectable in 75% of patients 1–3 weeks after symptom onset and usually is absent after 6 months. False-positive results are seen in 15% of patients with cystic fibrosis.
 - IgG is detected by the complement fixation (CF) assay from serum or CSF. It is positive in 50% of patients at 4 weeks and 83% at 3 months following symptomatic primary infection. In general, higher titers reflect more extensive infection and rising complement fixation antibody concentrations are associated with worsening disease.

- Enzyme immunoassay (EIA) for qualitative detection of IgM and IgG is sensitive but can yield false-positive results. It can be useful for screening, but a positive EIA should be confirmed with another test.
- Hematologic findings include elevated erythrocyte sedimentation rate, leukocytosis, and eosinophilia (in 10%).
- Other studies:
 - CSF findings in meningitis include hypoglycorrhachia and pleocytosis with mononuclear cell predominance.

Imaging

Radiologic studies:

- Chest radiograph may reveal well-circumscribed nodules, lobar or patchy pulmonary infiltrates, pleural effusions, cavitary lesions, and hilar adenopathy.
- Radiographs of involved bones may reveal lytic lesions. Scintigraphy or MRI of bone is more sensitive for the diagnosis of osteomyelitis.

DIFFERENTIAL DIAGNOSIS

- Other pulmonary mycoses (e.g., *Histoplasma capsulatum*, *Aspergillus fumigatus*, and *Blastomyces dermatitidis*)
- *Mycobacterium tuberculosis* (lung or CSF)
- *Mycoplasma pneumoniae*
- Influenza and other viral infections that present as bronchopneumonia
- Skin lesions may mimic other endemic mycoses, tuberculosis, actinomycetes, or syphilis.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Uncomplicated or minor disease is self-limited and should not be treated with antifungal therapy (>95% of cases).
- Treatment of uncomplicated respiratory infection is recommended for infants, pregnant women, and patients with continuous fever for > 1 month, > 10% weight loss, extensive or progressive pulmonary disease, or immunodeficiency (either from HIV or as a result of immunosuppressive medications). Use either oral fluconazole or itraconazole for 3–6 months.
- Diffuse pneumonia or immunocompromised host: Start therapy with amphotericin B and replace with oral fluconazole or itraconazole when clinical improvement is demonstrated. The total length of therapy should be at least 1 year, and for patients with severe immunodeficiency, oral azole therapy should be continued as secondary prophylaxis.
- Disseminated infection, nonmeningeal: Treat with oral fluconazole or itraconazole. Amphotericin B is alternative therapy, especially if lesions worsen or are at critical locations, such as the vertebral column. The duration of therapy may be longer than for those with pneumonia only.
- Meningitis: Oral fluconazole is preferred (800–1,000 mg/d). Itraconazole (400–600 mg/d) is also effective. Therapy should be continued indefinitely.
- Intrathecal amphotericin B may be useful in central nervous system infections.

- Voriconazole and posaconazole, new azole agents, have been shown to be effective in a few case reports.
- Surgical débridement is used for localized and persistent lesions in bone and lung.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Rising or unchanging CF titers while the patient is receiving treatment may indicate treatment failure, most often due to noncompliance or an occult focus that may require surgical drainage.
- All azoles inhibit P-450 enzymes. Consider drug–drug interactions when the patient is taking other medications.

PROGNOSIS

- Most infections are asymptomatic (60%) or mild (35%) and self-limited.
- Primary infection of the lungs is usually self-limited, with a course of illness lasting 1–3 weeks; complications (see above) may prolong the course.
- Fatigue can last for several months.
- Dissemination is infrequent (see above for risk factors). Morbidity and mortality have improved with use of antifungal therapy, but immunocompromised patients still have a poor prognosis after the development of disseminated infection. The mortality rate is 70% in HIV-infected patients with diffuse pulmonary coccidioidomycosis.
- Meningitis, untreated, is nearly always fatal within 2 years of diagnosis.

COMPLICATIONS

- Localized complications of primary pulmonary infection are infrequent and include pleural effusions and pericarditis.
- ~5% of lung infections result in residual pulmonary sequelae, usually nodules or abscess cavities. 1/3 of these cavities spontaneously resolve within 2 years. Hemoptysis and rupture of the abscess, with formation of an empyema, are potential complications in patients with unresolved cavities.
- Extrapulmonary dissemination usually develops within a year after the initial infection, but may appear much later if immunity is impaired (e.g., HIV infection, malignancy, immunosuppressive therapy).
- Hospital admission seems to be more common in patients with comorbid conditions and frequently necessitates surgical intervention.
- Hydrocephalus may occur with central nervous system involvement.

FAQ

- Q: Do all patients with symptomatic primary respiratory infection due to *C. immitis* require treatment?
- A: No. Since >95% of initial pulmonary infections are self-limited, treatment is not always required. Patients with concurrent risk factors (e.g., HIV, organ transplant, or high doses of corticosteroids) or evidence of unusually severe infections should always be treated. Factors suggesting increased severity of infection include weight loss of > 10%, night sweats, infiltrates involving more than half of 1 lung or portions of both lungs, and complement fixation antibody to *C. immitis* > 1:16.
- Q: How should pregnant women with coccidioidomycosis be managed?
- A: Diagnosis of primary infection during the 3rd trimester of pregnancy or immediately in the postpartum period should raise consideration for treatment. During pregnancy, amphotericin B is the treatment of choice because fluconazole and other azole antifungals are likely teratogenic.

COLIC

William B. Carey

BASICS

DESCRIPTION

- A poorly defined and incompletely understood state of prolonged or excessive crying in young infants who are otherwise well
- No standard definition of this phenomenon
- Best definition available: >3 hours a day of irritability, fussing, or crying on >3 days in any 1 week during the 1st 3–4 months of life in an infant who is otherwise healthy and well fed. Some add the criterion of a duration ≥ 3 weeks.
- Crying is not qualitatively different, but quantitatively. It is considerably more than the average.
- Lack of a firm, standard definition means that varying groups of subjects have been studied and limits our certainty as to incidence and causes of prolonged crying and as to effectiveness of management plans.

ALERT

Numerous pitfalls await the unprepared physician:

- Overdiagnosing the condition of the infant or caregiving inadequacies of parents
- Overtreatment of the infant with changes of feedings, medications, and various inappropriate procedures such as enemas and rectal manipulations. Despite the widely held, popular view that cow's milk allergy is a principal reason for excessive crying, no study of acceptable double-blind design has demonstrated its occurrence in infants who are free of respiratory, gastrointestinal (GI), or cutaneous manifestations of allergy.
- Unnecessary laboratory tests
- Colic is defined as a pattern of recurring episodes of crying. Other explanations should be carefully considered 1st for an acute bout of crying.
- The physician should be wary of enthusiastic reports in the popular press or the medical literature that "at last there is a cure for colic." Certainty is not easily achieved in an area where there is such a problem with definitions and with methodologic problems like achieving truly double-blind trials.

EPIDEMIOLOGY

Incidence and prevalence estimates difficult due to lack of standard definition. Incidence figures of 10–15% typically cited in texts.

RISK FACTORS

Genetics

No genetic influence has been discovered, but it has not been investigated. Temperamental traits are known to be largely inborn, however.

GENERAL PREVENTION

No study has yet demonstrated any certain way of preventing this prolonged or excessive crying. Methods that are likely to be helpful are:

- Education of all parents about infant crying and soothing.
- Informing them of the expected average number of hours per day.
- Most parents do not know that one of the common reasons for an infant to cry is fatigue, and that stimulation at these times is not helpful.
- Dealing with various pertinent parental anxieties when they occur should be undertaken.

PATHOPHYSIOLOGY

- No single cause is always found.
- Typically, the problem lies in the interaction between factors in the infant and the environment at a unique time of biological vulnerability:
 - In the infant there is a normal physiologic or temperamental predisposition to be more sensitive, irritable, intense, less rhythmical, or harder to soothe than average for the age.
 - Parents generally have not yet learned how to read the infant's individual needs correctly and respond appropriately. They may be manipulating the infant in ways that increase rather than decrease the amount of crying.
 - This interaction takes place at a time in the 1st 3–4 months when the immature central nervous system (CNS) makes the infant temporarily more vulnerable to the disorganizing effects of this poor fit.
- Colic generally occurs in the absence of any abnormality in the infant or the parents, but rather when the parents have not yet learned to interact harmoniously with the infant.
- There is no evidence that the bowel is at fault; flatulence is more likely to be the result of the crying than the cause.
- Psychosocial risk factors, such as poor support for the mother and various stressors, are probably more common than in noncolicky infants, but they are not necessary.
- When such external factors are present, they seem to exert their effects primarily by reducing the parent's ability to respond appropriately to the infant.
- Physical problems in the infant, such as milk allergy or gastric reflux, probably account for no >10% of all prolonged crying at this time, and would exclude an infant from this diagnosis of colic, which requires that the infant be physically well.

DIAGNOSIS

HISTORY

- Define symptoms: Intensity, duration, and frequency of crying. Some parents complain more than others about the crying.
- Colic typically begins shortly after a baby comes home from a newborn nursery.
- It can last until 3–4 months of age if not successfully managed.

ALERT

- If excessive crying lasts after 4 months, other diagnoses should be considered.
- Ask parents to describe a typical day:
 - Description of a typical day or keeping a crying diary is helpful.
 - This will give insights into the daily routine, feeding, rest, interpretive skills and responses of the parents.
- Ask parents to describe and demonstrate their soothing techniques.
- Information on the baby's temperament can be obtained by asking the parents to describe the baby's typical reaction patterns to stimuli.
- Medical history should include concerns about the pregnancy and the newborn period, anxieties related to parents' own experiences as children or with previous children, and the quality of family supports and other stressors.

PHYSICAL EXAM

- No findings are expected if the child has colic. However, examination should always be performed to reassure both parents and physician.
- Attempts at management over the telephone without a physical examination are likely to be unsuccessful.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

No tests are indicated unless specifically suggested by history or physical examination.

DIFFERENTIAL DIAGNOSIS

- Normal crying:
 - Average, normal infants cry about 2 hours a day at 2 weeks of age, just under 3 hours at 6 weeks, and then decrease to ~1 hour by 12 weeks.
 - Normal crying, like colic, tends to occur predominantly in the evening and can vary from day to day.

- Prolonged or excessive crying from physical causes:
 - Faulty feeding techniques: Overfeeding or underfeeding and inadequate burping or sucking
 - Physical problems in the infant: Acute disorders such as otitis media, intestinal cramping with diarrhea, corneal abrasion, and incarcerated hernia; or chronic ones such as gastroesophageal reflux
 - Cow's milk allergy, lactose intolerance, or transmission of irritating substances such as caffeine via breast milk

TREATMENT

MEDICATION (DRUGS)

- Drugs, such as phenobarbital or diphenhydramine, are seldom necessary.
- Some observers have reported beneficial effects when used for 1 or 2 weeks in conjunction with counseling, but these results have not as yet been subjected to double-blind studies.
- Simethicone has not been shown to be helpful. Herbal teas should not be recommended because of their varied and often unknown contents.

ADDITIONAL TREATMENT

General Measures

- The most effective form of treatment at present is counseling the parents about the interaction.
- Main points:
 - The infant is not sick.
 - Crying may be persistent, but there is no evidence of a physical problem.
 - There is no proof the infant is having pain, just distress. Avoid iatrogenic problems caused by suggesting that something is wrong with the infant.
 - The infant is probably overaroused and tired.
 - Education about infant crying.
 - Parents need to know how much normal infants cry and how they vary in sensitivity, irritability, and soothability.
 - The way parents react to their infants can affect the amount of crying.
 - Parents often do not understand that a common reason for infant crying is fatigue and a need to be left alone.
 - The excessive crying can be reduced.
 - Parents have to learn to tune in more sensitively to infants' needs and to be more appropriately and effectively responsive to them.
- Basic strategy:
 - Soothe more, as by a pacifier, repetitive sound, swaddling, swinging, or a hot water bottle, and stimulate less by decreasing the picking up, holding, and feeding the infant when it is not appropriate.
 - Contrary to popular opinion, there is no evidence that there is a better behavioral outcome at the present or later from the parents' always responding immediately to every cry.
 - A quiet environment, correction of any faulty feeding techniques, and a minimum of unnecessary handling without changing the composition of the feedings. Pertinent psychosocial issues should be dealt with.

- Expression of optimism by the pediatrician about the immediate outcome is justified and in itself improves chances of success. Simply saying that the colic will be gone by 3–4 months of age is not comforting and may be quite the opposite.
- Extra carrying does not help.
- Almost any procedure done with conviction is likely to be followed by a temporary reduction in crying because of the placebo effect.
- The normal trend toward diminished crying over time has given some forms of treatment an undeserved reputation of effectiveness.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- It is important to keep in close touch with parents of an excessively fussy baby. Telephone contact every 2–3 days is essential until improvement. Re-examination is rarely needed.
- Standard pediatric textbooks state that little can be done to change the pattern. However, several studies report that colic can be sharply reduced within 2–3 days if management such as that described above is used. Some infants take longer, but virtually all respond to suitable management.

DIET

Formulas changes are frequently attempted by physicians hoping for a simple solution, but they rarely are effective. Sometimes they seem to be helpful for a few days, only to cease being so soon after that.

PROGNOSIS

Without intervention, this prolonged crying usually diminishes somewhere around 3–4 months. Some recent studies have reported a variety of possible long-term outcomes such as continued aversive temperaments, more behavior problems, and diminished parental self-confidence. More investigations with attention to methodologic details are needed to clarify these matters. Particularly deserving attention is the possible pathogenic role of the physician in incorrectly informing the parents that there is something physically wrong with the infant.

COMPLICATIONS

- Excessive crying does not turn into any other condition, but the factors that caused it may contribute to sleep problems and other behavioral concerns in the infant after the colic has gone.
- Parents are usually exasperated by it.
- The most serious outcome is that, owing to parental exasperation, the infant may be physically abused.
- The infant is likely to be overfed.

CODES

ICD9

- 780.92 Excessive crying of infant (baby)
- 789.7 Colic

ICD10

- R10.83 Colic
- R68.11 Excessive crying of infant (baby)

FAQ

- Q: What is wrong with my baby? What can we do to relieve the pain? Why is he/she so gassy? How do you know that it is not due to an allergy? Shouldn't we strengthen the formula? You mean it's all my fault? Will this ever stop? What will he/she be like later?
- A: All the answers are to be found above.

COMA

Daniel Shumer

Amy R. Brooks-Kayal (5th edition)

Eric Marsh (5th edition)

BASICS

DEFINITION

Coma is defined as a state in which the patient appears to be asleep, shows no awareness of their surroundings, and cannot be aroused. Coma is a transient state, whereby patients recover, die, or progress to a permanent state of impairment. Often a medical emergency, immediate intervention may be required to preserve life and brain function (e.g., abnormalities in breathing, circulation, glucose, or electrolytes).

- Coma is at the far end of a spectrum of acute impaired consciousness, which also includes:
 - Lethargy or stupor: Patient arousable, but does not stay awake; impaired responses to commands
 - Delirium: A confused, agitated patient with fragmented attention, concentration, and memory
- Coma may progress to:
 - Persistent vegetative state: Chronic state of unconsciousness with no awareness or cognition, no voluntary responses, and no language abilities. Preserved autonomic functions and sleep/wake cycles.
 - Brain death: Coma, apnea, and no brainstem reflexes

ALERT

- Be aware of psychogenic coma and locked-in states (see “Differential Diagnosis”).
- Loss of protective airway reflexes signals impending respiratory failure.

EPIDEMIOLOGY

Traumatic and non-traumatic comas have similar annual incidences of about 30/100,000 children. Boys are more often victims of trauma and near drowning than are girls. Infants and young children are more likely to have a non-traumatic etiology; traumatic causes are more common in older childhood and adolescence.

PATHOPHYSIOLOGY

Dysfunction of the reticular activating system in the brainstem or bilateral cerebral dysfunction causes impaired arousal and consciousness.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- **Trauma**
 - Perform imaging for epidural/subdural or intracerebral bleeding, cerebral swelling, and/or diffuse axonal injury
- **Intoxication**
 - Household drug ingestion including barbiturates, opiates, psychotropics, and salicylates, street drugs, alcohol, smoke or carbon monoxide inhalation, ethylene glycol, lead and others

- **Hypoxia/diffuse ischemia**
 - Drowning, suffocation, myocardial infarction, heart failure, arrhythmia, hypotension
 - **Infection**
 - Bacterial or viral meningitis, encephalitis, postinfectious encephalomyelitis, toxic shock, subdural empyema, systemic shock/sepsis. The most common pathogen leading to coma is *Neisseria meningitidis*.
 - **Metabolic disorders**
 - Hypoglycemia (salicylate or ethanol intoxication, insulin overdose/hyperinsulinemia), diabetic ketoacidosis (DKA) (neurologic deterioration on initiation of insulin therapy), hyperglycemic nonketotic coma, Reye syndrome, electrolyte abnormalities (Na, K, Ca, Mg); hepatic/uremic encephalopathy; inborn errors of metabolism; endocrine abnormalities (hypothyroidism, Addisonian crisis); hypothermia/hyperthermia
 - **Tumor**
 - Can cause increased intracranial pressure and herniation
 - **Seizure**
 - Nonconvulsive status, spike and wave stupor
 - **Vascular**
 - Hemorrhage from arteriovenous malformation (AVM), aneurysm, coagulopathy, infarction, cerebral venous thrombosis, hypertensive encephalopathy
 - **Hydrocephalus**
 - Ventriculoperitoneal (VP) shunt obstruction, mass/bleed obstructing ventricular outflow
- Disorders mimicking coma:
- **Psychogenic coma**
 - Patient may resist passive eye opening, regard self in a mirror, and avoid passive arm fall over face and other noxious stimuli.
 - **Catatonia**
 - A form of psychogenic coma, patients may hold a posture, sit or stand.
 - **Locked-in state/complete paralysis**
 - Patient is paralyzed with intact cerebral function. May occur in severe neuromuscular disorders (acute polyneuropathy) or in ventral pontine lesions (hemorrhage, demyelination).

HISTORY

- **Question:** Evidence or history of head trauma, drowning, or other trauma?
- **Significance:** Are there concerns for nonaccidental trauma?
- **Question:** What medications are in the home? Has the patient been depressed or displayed suicidal behaviors?
- **Significance:** Ingestion/drugs/toxins
- **Question:** Recent fevers, viral or bacterial illnesses, mental status changes, sick contacts, immunosuppression, infectious risk factors?
- **Significance:** Infection

- **Question:** Medical history?
- **Significance:** Seizure disorder, diabetes, heart disease, neurologic disease including previous episodes of coma
- **Question:** Recent nausea, vomiting, mental status change?
- **Significance:** Increased intracranial pressure

PHYSICAL EXAM

- **Finding:** Vital sign changes?
- **Significance:** Hyperthermia suggests infection. Tachycardia suggests fever, pain, hypovolemia, arrhythmia, heart failure. Bradycardia suggests . . . etc.
- **Finding:** Signs of head trauma?
- **Significance:** Raccoon eyes (suggests fracture of frontal skull base), Battle’s sign (ecchymosis at mastoid suggests basilar skull fracture), retinal hemorrhages, bulging fontanelle, CSF leak from the nose or ear(s)
- **Finding:** Nuchal rigidity, Kernig and Brudzinski signs (often absent in infants with open fontanelles)?
- **Significance:** Signs of meningitis
- **Finding:** Papilledema?
- **Significance:** Suggests increased ICP
- **Finding:** Skin?
- **Significance:** Pallor (anemia), jaundice (liver failure), cyanosis (hypoxia), flushing (warm shock), bruising (trauma), rashes (infection)
- **Finding:** Neurologic—assess level of consciousness, verbal or motor response to voice, touch, and painful stimuli. Assess pupil size, symmetry and reflexes.
- **Significance:** Anisocoria suggests compression of oculomotor nerve or brainstem nucleus. Small reactive or large reactive pupils suggest intoxication. Fixed and dilated pupils suggest a brainstem injury or brain death. Assessment of eye movements can provide information about the function of cranial nerves. A persistent conjugate eye deviation suggests an injury to ipsilateral cerebrum or a contralateral seizure. Oculocephalic (doll’s eye), oculovestibular (caloric), pupillary, and gag reflex can assess cranial nerves and their brainstem nuclei. Assess muscle tone, motor responses to stimuli, and deep tendon reflexes. Abnormal motor responses: Decerebrate posturing (extension and internal rotation of the extremities), decorticate posturing (adduction and flexion at the elbows).
- Glasgow Coma Scale/Pediatric Glasgow Coma Scale—associated with prognosis in certain situations
 - Eye opening (score range 1–4)
 - Verbal response (score range 1–5)
 - Motor response (score range 1–6)

DIAGNOSTIC TESTS & INTERPRETATION

Initial blood studies obtained with placement of an IV line include:

- Glucose, electrolytes, blood urea nitrogen/creatinine, calcium, magnesium
- CBC and blood culture
- Arterial blood gas
- Toxicology screen
- Ammonia, liver transaminases

Other helpful studies based on the clinical picture may include:

- Metabolic labs (urine organic acids, serum amino acids), urinalysis, urine culture, thyroid function tests, cortisol, coagulation studies, carboxyhemoglobin (CO poisoning), LP with CSF protein, glucose, cell count and culture
- **Test:** LP
- **Significance:** To rule out infection, bleed; defer until after CT if focal exam or signs of increased ICP. If question of traumatic tap, spin out red cells promptly and examine fluid for xanthochromia.
- **Test:** EEG
- **Significance:** Helpful to rule out nonconvulsive status epilepticus
- **Test:** Electrophysiologic studies
- **Significance:** Somatosensory evoked, brainstem auditory evoked, and visual evoked potentials may be helpful for diagnosis and prognosis.

Imaging

- CT head: Quick noncontrast scan can detect hemorrhage, hydrocephalus, herniation, and masses. May be followed by contrasted images or MRI. Should be done prior to LP to rule out a mass (risk for herniation from LP).
- Cervical spine series (CT or lateral and anterior–posterior radiograph studies): Indicated if evidence of trauma by history or on physical exam. Spine must be stabilized until injury is ruled out.
- MRI brain: To look for causes if other workup is unrevealing.

**TREATMENT****SURGERY/OTHER PROCEDURES**

Neurosurgical intervention may be required in cases of head trauma, hemorrhage, mass lesion, or hydrocephalus. Neurology consultation is usually indicated.

IN-PATIENT CONSIDERATIONS**Initial Stabilization**

- First priority is stabilization of respiratory and hemodynamic status (airway, breathing and circulation management).
- If head trauma is suspected, stabilize the cervical spine with a collar while securing the airway.
- Endotracheal intubation: Often required for airway protection and adequate oxygenation
- Large-bore IV lines should be placed and isotonic fluids administered as needed to replace intravascular volume and maintain adequate blood pressure.

- Evidence of increased ICP:
 - Hyperventilate to decrease blood carbon dioxide to 30–35 torr
 - Give mannitol (0.5–1 g/kg IV). Can also give dexamethasone, 1–2 mg/kg IV
 - Fluids given should be isotonic and the volume limited to maintain adequate perfusion
 - Treat fever with antipyretics and environmental cooling methods
 - Elevate head to 30 degrees above horizontal, avoid head-turned posture to maximize cerebral venous drainage
 - Hospitalization in the intensive care unit for close monitoring of changes in respiratory status or signs of increased ICP
 - Neurosurgical consultation
- If finger-stick glucose determination is low, give 2–4 mL/kg of 25% dextrose (D25) IV (D10 if young infant).
- If opiate ingestion is suspected, administer naloxone (0.1 mg/kg IV for infants <5 years or <20 kg, 2 mg for older, larger children).
- Correct electrolyte and acid–base abnormalities
- Empiric treatment with IV antibiotics (ceftriaxone, vancomycin, and acyclovir, for example) should be given if bacterial or viral meningitis is suspected.

**ONGOING CARE****PROGNOSIS**

Prognosis depends on underlying etiology. Complete recovery is frequently seen after ingestions or metabolic comas. In contrast, patients with coma resulting from severe head trauma or hypoxic injury have lower survival rates and survivors often have significant neurologic sequelae and require long-term physical, occupational, and cognitive therapies. The Glasgow Coma Score has been shown to correlate with outcomes in some situations such as *traumatic brain injury* and viral encephalitis.

COMPLICATIONS

Acute coma:

- Brain injury
- Respiratory failure/aspiration
- Deep venous thrombosis
- Pneumonia (aspiration and infectious)

- 780.01 Coma

ICD10

- P91.5 Neonatal coma
- R40.20 Unspecified coma

FAQ

- Q: What is the value of the Pediatric Glasgow Coma Scale?
- A: The PGCS is helpful in predicting prognosis but not for diagnosing the cause of coma. However, the etiology of the coma can impact the usefulness of the scale. For example, PGCS has a better correlation with outcomes following traumatic brain injury than it does for cold-water drowning episodes.
- Q: When a bacterial infection is suspected as a potential etiology of coma, should antibiotic therapy be delayed until CSF has been obtained for testing?
- A: Starting antibiotic therapy prior to obtaining CSF may lead to a false-negative CSF culture. However, if there is any concern for increased ICP or mass effect from tumor or abscess causing coma, a CT should be obtained prior to an LP, and antibiotics should be started meanwhile. LP in the setting of mass effect can cause herniation. Therefore, if bacterial CSF infection is suspected, antibiotic therapy should not be delayed while stabilizing the patient and obtaining a head CT. Peripheral blood culture can be obtained at the time of IV placement.

COMMON VARIABLE IMMUNODEFICIENCY

Elena Elizabeth Perez

BASICS

DESCRIPTION

- A rare heterogeneous immunodeficiency syndrome characterized by:
 - Low IgG, A, and/or IgM
 - Recurrent infections
 - A wide spectrum of immunologic abnormalities including autoimmune disease, inflammatory conditions, and the development of lymphomas
- The most common clinically important primary immunodeficiency
- Other terminology for this disease include:
 - Acquired hypogammaglobulinemia
 - Adult-onset hypogammaglobulinemia
 - Dysgammaglobulinemia
 - Common variable hypogammaglobulinemia
- Diagnosis of exclusion, requiring variable reduction in 1 or more immunoglobulin classes (IgG, IgA, and/or IgM), impaired specific antibody responses, and in some cases reduction of B-cell number

EPIDEMIOLOGY

- Incidence is estimated to be 1 in 25,000 to 1 in 66,000 in the general population.
- Can present at any age
 - Most diagnosed between 20 and 40 years of age
 - Described in patients as young as 6 months
- Diagnosis is usually made several years after the onset of recurrent infections (pneumonia, sinusitis, otitis).
- A subgroup of children has been described in which the onset of disease was most often <5 years of age. This group was characterized by a relapsing and remitting course in which autoimmune disease predominated.
- About 20–25% of patients with common variable immunodeficiency have 1 or more autoimmune conditions at the time of diagnosis.
- Affects males and females equally.

RISK FACTORS

Genetics

- Complex genetics, likely multifactorial
- Rare recessive mutations described in:
 - T cell, inducible costimulatory (ICOS) 1 none kindred
 - CD19 in few unrelated families
 - B-cell activating factor (BAFF) in 2 siblings
 - CD20 and CD81 in 1 patient each
 - TAC1 (transmembrane activator and calcium-modulating cyclophilin ligand interactor (TNFRSF13B) in 8% of patients, associated with autoimmunity and lymphoid hyperplasia; heterozygous mutation more common than homozygous, significance not clear due to similar mutation found in healthy family members
- IgA deficiency more likely in offspring of parents with common variable immunodeficiency
- Incidence of IgA deficiency, autoimmune disease, malignancies increased in family members of patients with common variable immunodeficiency

PATHOPHYSIOLOGY

- Hypogammaglobulinemia is the main characteristic.
- Impaired immunoglobulin and specific antibody production despite normal B-lymphocyte numbers.
- An increased proportion of immature B cells is often present.
- Deficiency of class switched memory B cells associated with more complex disease (autoimmunity, granulomatous disease, hypersplenism, and lymphoid hyperplasia)
- Functional defects of both B and T lymphocytes are described.

ETIOLOGY

- The primary immunologic defect(s) leading to this syndrome is unknown: Multiple defects have been associated with common variable immunodeficiency including:
 - Lack of somatic mutation within variable region genes
 - Lack of memory B cells
- Some genetic defects have been described but do not account for the majority of cases. These include:
 - Inducible costimulatory receptor (ICOS) deficiency, <1% of patients
 - Mutations in TNF receptor family member transmembrane activator and calcium-modulator and cyclophilin ligand interactor (TAC1). TAC1 is involved in isotype switching of B cells. Only 1 TAC1 allele is mutated in majority of patients studied.
 - Mutation in TAC1 has also been observed in relatives of CVID patients who have IgA deficiency
 - B-cell defects include inability to secrete antibodies, and impaired upregulation of CD70 and CD86 (co-stimulatory molecules), and reduction of switched CD27+ B cells.
 - Impaired maturation, IL-12 secretion, and upregulation of costimulatory molecules by antigen presenting cells may impair T cells, which are important for providing help to B cells for antibody production.
 - Toll-like receptor 9 (TLR9) response and expression by B cells may also be impaired. TLR signaling pathways are being investigated for their potential role in pathogenesis of CVID.
 - Mutations in CD19, CD20, CD81 and BAFF are described in few cases

DIAGNOSIS

HISTORY

- Recurrent sinopulmonary infections, especially sinusitis and pneumonia, with encapsulated bacteria
- Autoimmune diseases such as autoimmune hemolytic anemia, idiopathic thrombocytopenic purpura, thyroid disease, and chronic active hepatitis
- Localized or systemic granulomatous disease that can be diagnosed years before low IgG is considered. Lungs, spleen, lymph nodes are most commonly affected. Can be misdiagnosed as sarcoidosis.
- Persistent diarrhea of infectious (e.g., *Giardia lamblia*) or noninfectious causes
- Inflammatory bowel disease-like disorder in 6–10% of patients
- Noninfectious, diffuse pulmonary complications described as granulomatous-lymphocytic interstitial lung disease (GLILD) exhibit granulomatous and lymphoproliferative histologic patterns (lymphocytic interstitial pneumonia [LIP], follicular bronchiolitis, and lymphoid hyperplasia).
- Severe or unusual viral infections with herpes simplex, cytomegalovirus, and varicella, such as pneumonitis, hepatitis, or encephalitis. Chronic meningoencephalitis can be seen with enteroviral infection.

PHYSICAL EXAM

- Evaluation should focus on the presence of infection.
- 30% of patients will have lymphadenopathy and/or splenomegaly.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- IgG, IgA, IgM below age-appropriate norms
- CBC with differential: Examine smear for evidence of hemolysis in autoimmune hemolytic anemia.
- Autoimmune antibody screen: Antinuclear antibody, autoantibody panel
- Stool culture for bacteria and ova/parasites to evaluate chronic diarrhea
- Isohemagglutinins as well as functional antibody titers to bacterial antigens such as tetanus, diphtheria, and pneumococcus are usually low to absent.
- Spirometry may be helpful in following chronic lung disease.
- Mitogen/Antigen stimulation studies will help assess lymphocyte function.
- T- and B-lymphocyte enumeration by flow cytometry
- B-cell phenotyping becoming more available
- Absent B lymphocytes suggests X-linked agammaglobulinemia rather than common variable immunodeficiency.
- Appropriate cultures based on site of infection

Imaging

Chest and sinus x-ray studies/CT scans may be warranted for evaluation of chronic disease.

Diagnostic Procedures/Other

- GI endoscopy with biopsies for cases of idiopathic persistent diarrhea
- Lymph node biopsy in suspected malignancy

DIFFERENTIAL DIAGNOSIS

- Other primary antibody-deficiency disorders: X-linked agammaglobulinemia and transient hypogammaglobulinemia of infancy
- Severe malabsorption with protein-losing enteropathy
- HIV infection
- Chronic lung disease: Cystic fibrosis, immotile cilia syndrome, and α_1 -antitrypsin deficiency
- Primary autoimmune diseases: Immune idiopathic thrombocytopenic purpura, autoimmune hemolytic anemia, systemic lupus erythematosus, thyroiditis

**TREATMENT****MEDICATION (DRUGS)****First Line**

Immunoglobulin replacement therapy

Second Line

Antibiotics as needed for infection, may also be used as adjunct to immunoglobulin replacement as prophylaxis.

ADDITIONAL TREATMENT**General Measures**

- Monthly IV immunoglobulin replacement:
 - Starting dose is usually 400–600 mg/kg/month IV or FDA-approved formulation(s) for SC administration, given weekly.
- Appropriate antibiotics for acute infections. Prophylactic antibiotics may be helpful in chronic/recurrent infections.
- Cautious use of corticosteroids may be necessary in the treatment of gastrointestinal (GI) and autoimmune manifestations.

ISSUES FOR REFERRAL

- Autoimmune manifestations
- GI: Chronic abdominal pain or signs of possible lymphoid hyperplasia

IN-PATIENT CONSIDERATIONS**Nursing**

- Supervision during IVIG administration
- Monitor for side effects of therapy
- Have anaphylaxis medications available

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS**

- Close and frequent follow-up is warranted for patients with severe, recurrent symptoms. It may be as frequent as monthly, depending on symptoms.
- Signs and symptoms suggesting malignancy (e.g., persistent adenopathy in absence of infection, significant weight loss, or abdominal mass) should be evaluated expeditiously. Abdominal pain may indicate infection or lymphoid hyperplasia.

Patient Monitoring

CBC with differential, ALT, Creatinine, IgG level

DIET

Normally no restriction

PATIENT EDUCATION

Several Web sites available to patients and families:

- Immune deficiency Foundation: <http://primaryimmune.org>
- International Patient Organization for Primary Immunodeficiencies: www.ipopi.org
- The Jeffrey Modell Foundation: www.jmfworld.org
- National Institute of Allergy and Immunology: www.niaid.nih.gov

PROGNOSIS

Immunoglobulin replacement therapy, prophylactic antibiotics when necessary, and close follow up by immunology have greatly improved the overall prognosis. The newer challenge with this disease is detection and management of autoimmune and other disease associated complications.

COMPLICATIONS

- Autoimmune disease in 20% of common variable immunodeficiency patients. Most common are autoimmune hemolytic anemia and idiopathic thrombocytopenia purpura.
- GI complications include chronic diarrhea, malabsorption, and weight loss. Inflammatory bowel disease and *Helicobacter pylori* infection have also been observed.
- Granulomatous infiltrations may mimic sarcoidosis.
- Lymphoproliferative disease: Overall risk is 8–10%. The most common are lymphomas, usually non-Hodgkin lymphoma, well differentiated, mostly Epstein-Barr virus negative.
- Chronic sinusitis and lung disease with abnormal pulmonary function tests
- Progressive decline in T-lymphocyte function

**CODES****ICD9**

- 279.00 Hypogammaglobulinemia, unspecified
- 279.06 Common variable immunodeficiency
- 279.10 Immunodeficiency with predominant T-cell defect, unspecified

ICD10

- D83.0 Common variable immunodeficiency with predominant abnormalities of B-cell numbers and function
- D83.2 Common variable immunodeficiency with autoantibodies to B- or T-cells
- D83.9 Common variable immunodeficiency, unspecified

FAQ

- Q: What is the life expectancy of patients with the diagnosis of common variable immunodeficiency?
- A: Because the clinical presentations and symptoms are variable, it is difficult to predict the life expectancy in individual patients. Intravenous immunoglobulin replacement, in addition to antibiotic therapy, has greatly improved the outlook for these patients. However, despite adequate therapy, a large percentage of patients with common variable immunodeficiency have a progressive decline in immune function. Major morbidity and mortality usually result from the associated complications of malignancy, chronic lung disease, and severe autoimmune disease. In one study, the mortality is estimated at 23–27% over a median follow-up of 7 years (0–25 years). The 20-year survival after diagnosis for males is 64% and for females 67% versus 92% and 94%, respectively, for the general population. Main causes of death include respiratory complications, granulomatous disease of organs, liver disease, malnutrition due to GI pathology, uncontrolled autoimmune manifestations and lymphoma.
- Q: Should patients with common variable immunodeficiency receive live viral vaccines?
- A: In general, patients receiving IVIG replacement therapy do not require any vaccinations. Live viral vaccines should be avoided in these patients, especially if they have deteriorating immune function.
- Q: Can common variable immunodeficiency be diagnosed prenatally?
- A: Because there are no clear genetic inheritance patterns, prenatal diagnosis is unavailable.

COMPLEMENT DEFICIENCY

Erin E. McGintee

BASICS

DESCRIPTION

- Complement consists of >30 plasma and cell membrane proteins that function as cofactors in defense against pathogenic microbes and in the generation of many immunopathogenic disorders.
- Biologic actions include:
 - Cytolysis: Destruction of cells by disrupting cell membrane
 - Opsonization of organisms, which facilitates phagocytosis
 - Inflammation by generation of peptides, which can upregulate chemotaxis and can cause vasodilatation
 - Clearance of immune complexes and apoptotic cells
 - Interaction and augmentation of adaptive immune response

EPIDEMIOLOGY

- Prevalence of known primary immunodeficiency is 1 per 100,000.
- Complement accounts for ~2% of all primary immunodeficiencies.

RISK FACTORS

Genetics

- Most complement deficiencies are autosomal recessive traits.
- Properdin deficiency is X-linked.
- C1 inhibitor deficiency is autosomal dominant.
- Heterozygotes are usually phenotypically normal.

PATHOPHYSIOLOGY

Table 1. Complement deficiency and related clinical problems

Deficiency	Clinical Manifestations
C1(qrs), C2, C4	Systemic lupus erythematosus, vasculitis, glomerulonephritis, pyogenic infections
C3	Glomerulonephritis, pyogenic infections, neisserial infections, immune complex disease
C1 inhibitor	Hereditary angioedema
Factor H, I	Hemolytic uremic syndrome, glomerulonephritis
Properdin	Neisserial infections
Factor B, D	Neisserial infections
MBL, MASP	Repeated infections, accelerated course of systemic lupus erythematosus, rheumatoid arthritis
C5, C6, C7, C8, C9	Disseminated neisserial infections
CD55, CD59	Paroxysmal nocturnal hemoglobinuria

ETIOLOGY

- 3 pathways (the classic, the alternative, and the mannose-binding lectin) converge on same terminal pathway—the membrane attack complex
- Classic pathway requires antibody for initiation, whereas alternative and mannose-binding lectin pathways can be activated without antibody.
- Complement deficiencies may be primary or secondary.
- Secondary deficiencies of complement are usually owing to a consumptive or decreased productive state:
 - Newborn state
 - Malnutrition, anorexia nervosa
 - Liver cirrhosis
 - Reye syndrome
 - Nephrotic syndrome

See the table “Complement Deficiency and Related Clinical Problems.”

DIAGNOSIS

HISTORY

Indications for evaluating complement system:

- Systemic lupus erythematosus, juvenile rheumatoid arthritis, or other immune complex disease
- Recurrent pyogenic infections
- 2nd episode of bacteremia at any age
- 2nd episode of meningococcal meningitis or gonococcal arthritis
- Recurrent angioedema without urticaria
- Pneumococcal bacteremia after infancy

PHYSICAL EXAM

Depends on suspected complement defect, but may see any of the following:

- Failure to thrive
- Scars from various infections
- Joint destruction
- Angioedema

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other

- CH50: To assess integrity of classical pathway:
 - The quantity of serum required to lyse 50% of an aliquot of antibody-sensitized sheep RBC
 - Specimen handling: Complement components are thermolabile; common cause of abnormal values is improper handling. Procedure may require use of dry ice.
- APH50: To assess integrity of alternate pathway
- C3, C4, and other individual components based on clinical history
- C1 esterase inhibitor level and function to evaluate for HAE.

DIFFERENTIAL DIAGNOSIS

- Humoral deficits such as immunoglobulin deficiency or dysfunction
- Consumptive process such as sepsis

ALERT

- Special care is required for the proper handling of blood test to prevent falsely low values.
- Sometimes the complement cascade can be activated and consume the complement factor, leading to the improper diagnosis of a complement deficiency.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Fresh-frozen plasma for acute severe infections
- Aggressive workup and management of infections
- Prophylactic antibiotics may be useful for recurrent infections.
- Immunization for pneumococci, *Haemophilus influenzae*, and *Neisseria meningitidis* for patient and household members
- Close monitoring for onset of autoimmune disease
- Study other family members for genetic counseling.
- Attenuated androgens and fibrinolysis inhibitor aminocaproic acid can be used as prophylaxis for HAE
- HAE can also be treated prophylactically or acutely with purified C1-INH concentrate, and acute attacks can also be treated with kallikrein antagonist given SC.

ONGOING CARE

COMPLICATIONS

Deficiencies can lead to:

- Recurrent infection
- Immune complex disease
- Autoimmunity

D84.1 Defects in the complement system

FAQ

- Q: How common are complement deficiencies?
- A: Very uncommon. They account for 2% of all immunodeficiencies.
- Q: When should I evaluate for a complement deficiency?
- A: Any child with recurrent sinopulmonary infections or > 1 episode of a neisserial infection.

CONCUSSION

Nicole Ryan

Daniel Licht

Nicholas S. Abend

BASICS

DESCRIPTION

- Concussion is a complex pathophysiological process affecting the brain, induced by traumatic biomechanical forces.
- There are a graded set of clinical symptoms that may or may not involve a loss of consciousness.
- Concussion may be caused by either a direct blow to the head, face, neck, or elsewhere on the body with an “impulsive” force transmitted to the head.
- Concussion typically results in the rapid onset of short-lived impairment of neurologic function that resolves spontaneously. In a small percentage of children, postconcussive symptoms may be prolonged.
- Concussion may result in pathological changes, but the acute clinical symptoms largely reflect a functional rather than structural injury and no abnormality is seen on standard neuroimaging studies.

EPIDEMIOLOGY

- A recent review estimated that up to 3.8 million recreation- and sport-related concussions occur annually in the U.S.
- Concussion is underreported.
- Most common sports include football, ice hockey, soccer, wrestling, lacrosse, basketball, baseball, softball, field hockey, and volleyball.
- Girls have higher rates of concussion than boys in similar sports.
- Risk of injury depends on game, position, and use of helmet.

GENERAL PREVENTION

Given that children may have a sense of invulnerability and desire to return to usual activities quickly, preparticipation medical visits should emphasize that reporting concussion immediately is essential and loss of consciousness is not the only manifestation of concussion. Helmet use is essential at reducing the severity of a blow to the head. Seatbelt use has dramatically reduced head trauma in motor vehicle accidents.

PATHOPHYSIOLOGY

- The brain is buoyed in the cranium by cerebrospinal fluid that acts as protective insulation. With acceleration–deceleration, the brain continues to experience momentum and strikes against bone. The temporal and frontal lobes are particularly prone to injury because of their location adjacent to irregular parts of the skull.
- Depressed level of consciousness is thought to be the result of rotational stretch injury to the reticular activating system in the dorsal aspect of the brain stem.

- Changes after concussion include changes in neuronal depolarization and neurotransmitter release, impaired axonal function, and altered brain autoregulation and glucose metabolism.
- Children may respond to brain trauma differently than adults due to developmental factors such as brain size, brain water content, myelination level, skull and suture geometry and elasticity, and differential skull to body proportions.

DIAGNOSIS

HISTORY

- Detailed symptom evaluation.
- Information regarding prior concussions.
- History of pre-existing cognitive or attention problems should be elicited to help guide interpretation of postinjury testing.

SIGNS AND SYMPTOMS

- Postconcussive symptoms may be divided into 4 domains:
 - Somatic: Headaches, fatigue, decreased energy, nausea, vision change, tinnitus dizziness, incoordination and balance difficulty.
 - Emotional/Behavioral: Irritability, increased emotionality, personality change, depression, or anxiety.
 - Cognitive: Slowed thinking and response time, impaired concentration, learning, memory, and problem solving ability.
 - Sleep disturbances are common.

PHYSICAL EXAM

- A detailed neurological examination should be performed to detect worrisome signs and to allow accurate observation over time.
- Mental status: Orientation (person, place, time), concentration (digit span), and memory (anterograde and retrograde).
- Cranial nerves: Pupil reactivity, eye movements (particularly smooth pursuit and saccadic movements), visual fields, face movement and sensation, tongue protrusion.
- Motor
- Sensory
- Cerebellar: Agility: Finger-to-nose-to-finger, rapid alternating movements (finger tapping, toe tapping), tandem gait (forwards and backwards, eyes open and closed).
- Exertion provocative tests: 5 push-ups, 5 sit-ups, 5 knee bends, 40-yard sprint; look for change in exam.

DIAGNOSTIC TESTS & INTERPRETATION

Imaging

- Computed tomography of the head (CT) is the test of choice to evaluate for intracranial hemorrhage or skull fracture 24–48 hours after injury. There is increased suspicion of intracranial injury in patients with severe headache, seizures, focal neurologic findings, repeated emesis, changes in alertness, slurred speech, poor orientation, neck pain, loss of consciousness >30 seconds, or significant irritability.
- Clear indications for CT have not been elucidated and children may have intracranial lesions with asymptomatic head injury, so a relatively low threshold for neuroimaging is appropriate.
- Children <1 year of age should be imaged because symptoms may be difficult to detect and nontraumatic etiologies must be considered.
- Children <2 years of age should be imaged unless there was a low-energy mechanism and no symptoms/signs for at least 2 hours.
- MRI is more appropriate if imaging is needed >48 hours after injury. Newer MRI modalities such as functional MRI, gradient echo, perfusion, and diffusion tensor imaging may be more informative but research to date is lacking. Susceptibility-weighted imaging (SWI) or echo gradient sequences can highlight small hemorrhages that are evidence of diffuse axonal injury (DAI). DAI is associated with more severe injury.

Diagnostic Procedures/Other

Neuropsychological testing:

- Computerized testing is now widely available and baseline testing is being performed by many school athletic departments. Research is still needed as to the optimum timing of this testing and whether it improves outcome.

TREATMENT

- Onsite acute evaluation should include the usual ABCs and evaluation for potential associated injuries such as cervical spinal injury.
- Standardized, validated instruments for mental status testing are available and can be administered quickly on the sideline (i.e., SCAT-2).

ADDITIONAL TREATMENT

General Measures

- Remove the child from the contest with no return to play if concussion is suspected.
- Monitor the athlete for several hours after the injury to evaluate for any deterioration.

- Consider referral to the emergency department if there is repeated vomiting, severe or worsening headache, seizure, unsteady gait, slurred speech, weakness or numbness in the extremities, unusual behavior, signs of a basilar skull fracture, or a GCS <15.
- Children <2 years of age may need more prolonged observation in an ED or inpatient setting.
- There is currently no evidence-based research on the use of any medication in the treatment of the concussed pediatric athlete.

ISSUES FOR REFERRAL

- Neuropsychological evaluation should be considered in children with multiple concussions or when recovery is not progressing as expected to document impairment, identify factors contributing to persisting difficulties, and guide school accommodations or formal intervention.
- If admitted for observation, consults by speech therapy, physical therapy, and psychiatry should be considered to evaluate subtle sequelae.

SURGERY/OTHER PROCEDURES

Neurosurgical evaluation or transfer to a trauma center should be considered for symptoms of prolonged unconsciousness, persistent mental status alterations, worsening postconcussive symptoms, abnormalities on neurologic examination, or abnormalities on neuroimaging.

IN-PATIENT CONSIDERATIONS

Admission Criteria

Consider admission if the child continues to have altered level of consciousness, if focal neurologic signs are present, or if patient remains severely symptomatic.

Nursing

If observation is required, nursing staff must be able to perform neurological assessments at regular intervals.

Discharge Criteria

- Planning must be individualized if intracranial lesions are present.
- The child and guardian should receive return to play guidelines focused on avoiding second impact syndrome, in which a second concussion occurs soon after a first concussion. Concussions have a cumulative effect and result in increased vulnerability to future injuries.

- No athlete should return to play while still symptomatic from a concussion. This includes physical, cognitive, or behavioral symptoms. There must be no symptoms or signs at rest or during exertion.
- Activities with a high cognitive demand should be limited while symptomatic, including television, computer, videogames, and texting. School accommodations may be needed.
- Before considering return to play, any medication to reduce symptoms must be stopped and the athlete must be symptom-free off medications.
- Return to play should occur in a gradual fashion because symptoms may be aggravated with exertion. Consider in sequence light aerobic activity, noncontact sport related activity, full practice, and then game play.
- Retirement should be considered for any athlete who has sustained 3 concussions in an individual season, has had postconcussive symptoms for more than 3 months, when recovery requires an increasing amount of time, or when concussions occur with less forceful injury.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

If the patient is discharged home for observation, the guardian should have detailed instruction regarding reasons to return to the ED. These include difficult to awaken or quickly falls back asleep, worsening headache or dizziness, emesis, seizures, blood or clear fluid from the ears or nose, major changes in behavior, any focal weakness/sensory/vision changes.

PROGNOSIS

- In general, the prognosis is excellent, but depends on the severity of the injury.
- The typical adult patient with a concussion will recover to baseline function in 6–12 weeks.
- Athletes and children usually recover in 48 hours. However, children with previous head injury, learning difficulties, or neurologic, psychiatric, or family problems may continue to show significant ongoing problems at 3 months.
- Chronic headaches, persistent difficulty with short- and long-term memory and episodic confusion are common sequelae of the cumulative damage that occurs with repeated concussive injuries.

COMPLICATIONS

- Postconcussion symptoms such as confusion, altered concentration, memory and problem solving, irritability, emotional changes, and headaches may take several months to resolve.
- Serious head injury may occur and requires immediate neurosurgical evaluation, neurocritical care, and often serial HCT imaging because intracranial lesions, such as contusion or hemorrhages (epidural, subdural, intraparenchymal), can expand. These may occur with or without skull fracture, and may occur without an initial loss of consciousness.

CONGENITAL HEPATIC FIBROSIS

Jessica Wen

J. Fernando del Rosairo (5th edition)

BASICS

DESCRIPTION

- Congenital hepatic fibrosis (CHF) is an inherited, noncirrhotic liver disease associated with cystic disease of the kidneys.
- Prominent clinical features include:
 - Portal hypertension
 - Increased risk of ascending cholangitis
- Liver biopsy shows the classic lesion of ductal plate malformation.
- Majority of patients with CHF have associated autosomal recessive polycystic kidney disease (ARPKD). However, several other genetic diseases also result in CHF.

EPIDEMIOLOGY

Incidence

The incidence of ARPKD is 1/20,000–1/40,000 live births.

RISK FACTORS

Genetics

- Inheritance is autosomal recessive in most families.
- PKHD1, the ARPKD/CHF disease gene, is located on chromosome 6p12. The gene is large, consisting of at least 86 exons extending over 469 kb of genomic DNA. It is expressed at high levels in fetal and adult kidneys and at lower levels in the liver and pancreas.
- Mutations of the PKHD1 gene include frameshift, nonsense, and out-of-frame splicing alterations that are consistent with a loss of function mechanism.
- The presence of 2 truncating mutations leads to the most severe phenotype, associated with death in the neonatal period.
- The PKHD1 gene product is a protein called polyductin or fibrocystin. It is a transmembrane protein located mostly on the primary cilia and apical surface of renal tubular cells and cholangiocytes. It complexes with polycystin 1 and polycystin 2, the mutated proteins in ADPKD. Together, the complex is thought to function as mechanotransducer, detecting the shear force from urine and bile flow. Further studies will be needed to identify the biologic function of polyductin and to determine how mutations of the protein cause disease.

PATHOPHYSIOLOGY

- Ductal plate malformation is a characteristic histologic lesion of the liver, implying a disturbance of the normal development of the bile ducts.
- Hallmarks on pathology include:
 - Dilated intrahepatic bile ducts, often described as staghorn shaped
 - Increased amounts of noninflammatory fibrosis in the portal tracts
 - Normal appearance of hepatocytes and lobular architecture
- The primary defect in ARPKD may be linked to ciliary dysfunction. The ciliary structure is abnormal in ARPKD renal tubule cells and cholangiocytes.
- Developmental abnormalities involve the liver and kidneys, and less commonly, the vasculature and the heart.
- Portal hypertension is thought to result from the fibrosis in the portal tracts, as well as, in some patients, from portal vein abnormalities.

COMMONLY ASSOCIATED CONDITIONS

- Hepatomegaly
- Hypersplenism
- Portal hypertension
- Conditions associated with the finding of ductal plate malformation:
 - CHF
 - ARPKD
 - Autosomal dominant polycystic kidney disease (ADPKD)
 - Caroli syndrome
 - CHF-nephronophthisis
 - Congenital disorder of glycosylation type 1b (phosphomannose isomerase deficiency)
 - Congenital malformation syndromes:
 - Meckel Gruber syndrome
 - Joubert syndrome
 - Jeune syndrome
 - Bardet-Biedl syndrome

DIAGNOSIS

HISTORY

- Severely affected patients are usually diagnosed in utero or shortly after birth, due to massively enlarged cystic kidneys. Prenatal renal dysfunction may result in pulmonary hypoplasia.
- Older patients may present with systemic hypertension or signs of portal hypertension and esophageal variceal bleeding
- Patients may present with fever and jaundice (cholangitis) or, rarely, with signs of liver failure.

PHYSICAL EXAM

- Firm, enlarged liver with a prominent left lobe
- Splenomegaly
- Kidneys may be palpable on abdominal exam.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Initial lab tests

- Thrombocytopenia and leukopenia are associated with hypersplenism.
- Liver enzymes and bilirubin are typically normal; transaminases may be mildly elevated in some patients.
- Usually hepatic synthetic function (albumin, prothrombin time) is normal.
- May see elevated blood urea nitrogen and creatinine with renal involvement
- Genetic testing is available.

Imaging

Ultrasound with Doppler:

- Increased hepatic echogenicity
- Splenomegaly
- Evidence of portal hypertension
- Cystic kidneys

Diagnostic Procedures/Other

Liver biopsy:

- Characteristic histology of ductal plate malformation
- If cholangitis is suspected clinically, send specimen for bacterial culture

DIFFERENTIAL DIAGNOSIS

Varies with presentation. Usually differential diagnosis is that of cirrhosis.

TREATMENT

MEDICATION (DRUGS)

Choleretic agents, including ursodeoxycholic acid, are used in bile stasis and refractory cholangitis.

ADDITIONAL TREATMENT

General Measures

- Suspected cholangitis should be managed with liver biopsy, culture, and appropriate antibiotics. Some patients with chronic cholangitis may require antibiotic prophylaxis.
- Endoscopic sclerotherapy and/or variceal banding provide relief from variceal hemorrhage in many cases.
- Activity:
 - No contact sports if splenomegaly is present.
 - Spleen guard may be used to protect against injury from abdominal trauma.

SURGERY/OTHER PROCEDURES

- Portosystemic shunting may be required.
- Liver transplant may be indicated for chronic cholangitis, recurrent bleeding, or progressive hepatic disease.
- Some children may require combined liver and renal transplantation.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Watch for recurrent upper GI tract bleeding.
- Morbidity occurs mainly from portal hypertension and cholangitis.
- There is an increased incidence of portal hypertension with age.
- Mortality may result from ascending cholangitis associated with sepsis and hepatic failure.
- Those presenting during childhood have better prognosis compared to those presenting within neonatal period

DIET

No restrictions are needed.

PROGNOSIS

- Good for older children who present with CHF.
- Ascending cholangitis with resultant sepsis and hepatic failure is a major cause of morbidity and mortality.

COMPLICATIONS

- Portal hypertension with hypersplenism and variceal bleeding
- Cholangitis
- Renal and/or hepatic failure
- Associated vascular anomalies in the liver and brain
- Increased risk of hepatocellular or cholangiocarcinoma
- Systemic hypertension owing to renal involvement

CODES

ICD9

777.8 Other specified perinatal disorders of digestive system

ICD10

P78.89 Other specified perinatal digestive system disorders

FAQ

- Q: Will other children of mine be affected?
- A: Maybe. The inheritance pattern is autosomal recessive, with the possibility of an affected sibling being 1:4.
- Q: Is my child at increased risk if he contracts viral hepatitis?
- A: Yes, the underlying liver disease places these patients at increased risk. They should be immunized against hepatitis A and B.
- Q: If my child has a fever, does she need to be seen by her doctor?
- A: Yes. Patients with CHF who have fever without an obvious source should be evaluated for possible cholangitis, at least by obtaining a blood culture and liver enzymes.

CONGENITAL HYPOTHYROIDISM

Adda Grimberg

BASICS

DESCRIPTION

Primary thyroid failure that is present at birth

EPIDEMIOLOGY

Incidence

- Increasing trend in the US of unclear etiology (definitional issues related to newborn screening vs. true increase from unidentified risk factors)
 - Had been 1 in 3,000–4,000 births, US and worldwide
 - In 2007, US incidence 1 in 2,370 births
- Male/female ratio is 1:2–1:3.
- 80% dysgenesis or agenesis; 20% dyshormonogenesis

Prevalence

- Racial differences: Prevalence in black infants ~1/3 that in whites
- Higher prevalence of congenital hypothyroidism in low-birth-weight (>2,000 g) and macrosomic (≥4,500 g) babies

RISK FACTORS

Genetics

- Dysgenesis is usually sporadic.
 - Familial occurrence in 2%
 - Mutations have been found in the TSH-receptor gene and in the transcription factors PAX-8, TTF-1, and TTF-2 (FOXE1).
- Dyshormonogenesis is inherited in an autosomal recessive pattern. Most commonly:
 - Chromosome 2p: Mutations in the thyroid peroxidase gene result in partial or complete loss of iodide organification.
 - Chromosome 19p: Mutations in the sodium-iodide symporter gene result in an inability to maintain the normal thyroid-to-plasma iodine concentration difference.
- Pendred syndrome (chromosome 7q): Mutations in PDS gene cause the most common syndromal form of deafness; a mild organification defect leads to goiter, usually in childhood.
- Down syndrome neonates have lower T₄ (left-shifted normal distribution) and mildly elevated TSH, suggesting a mild hypothyroid state.

ETIOLOGY

- Thyroid gland malformation:
 - Agenesis: Absent thyroid gland
 - Dysgenesis: Ectopic (e.g., sublingual) or incorrectly formed (e.g., hemigland) thyroid
- Dyshormonogenesis:
 - 15 known defects of thyroxine (T₄) synthesis, including those in iodide transport and iodide organification
- Transient hypothyroidism:
 - Maternal ingestion of antithyroid drugs
 - Transplacental transfer of maternal antithyroid antibodies (transient or permanent damage)
 - Exposure to high levels of iodine-povidone, Betadine in neonatal period

DIAGNOSIS

HISTORY

- Symptoms that may relate to hypothyroidism:
 - Prolonged jaundice
 - Poor feeding
 - Constipation
 - Sedate or placid child
 - Poor linear growth
- Family history of thyroid disorders:
 - Autoimmune thyroid disease
 - Vague histories of “mild hypothyroidism” not requiring treatment are often found in families with thyroid-binding globulin deficiency.
- Maternal medications
- Birth history
- Results of the newborn screen
- Signs and symptoms:
 - Most children are diagnosed by the neonatal screening program:
 - 5–10% false-negative rate
 - Neonatal screening protocols differ state to state (i.e., may screen T₄, TSH, or both).
 - In severely ill neonates who are transferred from 1 unit or hospital to another, be sure the state screen is not overlooked! If missed by the state screening procedure, the symptoms above are seen within the 1st 2 months of life.

PHYSICAL EXAM

- Signs that may relate to hypothyroidism:
 - Hypothermia
 - Large fontanelles (especially posterior) with wide cranial sutures
 - Coarse facial features, including macroglossia
 - Hoarse cry
 - Hypotonia
 - Delayed deep tendon reflex release
 - Distended abdomen
 - Umbilical hernia
- Examine for possible goiter; helpful tricks:
 - Inspect the base of tongue for ectopic gland.
 - While supporting the posterior neck and occiput, allow the infant’s head to hang back over a parent’s arm or exam table. This will extend the neck and allow better visualization of the anterior region.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Neonatal screening program (filter card):
 - Methods vary from state to state; screen for T₄ and then run TSH levels on the lowest 10th percentile of that day’s T₄ values or screen for TSH elevations.
 - Abnormal results on state screen should prompt *immediate* examination and confirmatory tests.
 - Because of delayed TSH elevations, very low-birth-weight babies and those with congenital cardiac anomalies may need rescreening for diagnosis.

- Confirmatory tests:
 - Serum T₄ and TSH are preferable to a repeated filter screen, which may result in delayed diagnosis and treatment.
 - If abnormalities in binding are suspected, also check thyroid-binding globulin level and free T₄ level or tri-iodothyronine (T₃) resin uptake.
 - Free T₄ level is the most sensitive indicator of secondary or tertiary hypothyroidism (hypopituitarism).
- Antenatal tests:
 - Fetal goiter can be detected by prenatal ultrasound.
- Reference ranges for 3rd trimester amniotic fluid concentrations of TSH and total and free T₄ are established for diagnosis of fetal hypothyroidism among those with goiters. Otherwise, cordocentesis is needed.

Imaging

- ¹²³I or technetium thyroid scan to define gland anatomy (agenesis, dysgenesis, ectopic gland)
- ¹²³I scan with perchlorate washout to help identify dyshormonogenesis
- ¹²³I scan must be obtained before beginning thyroxine replacement therapy. If this delays treatment, defer scanning until brain growth is complete (2 years of age), when a period off medication is safer.
- Ultrasonography can also evaluate thyroid anatomy (but not dyshormonogenesis) and does not require deferral of treatment.

DIFFERENTIAL DIAGNOSIS

- Developmental:
 - Transient hypothyroxinemia in the 1st weeks of life in premature babies
- Metabolic:
 - Sick euthyroid syndrome in severely ill neonates
- Secondary or tertiary:
 - Panhypopituitarism
 - Congenital isolated central hypothyroidism (a “hot spot” mutation in the TSH-β gene)
 - Central congenital hypothyroidism due to maternal Graves disease during pregnancy (estimated incidence 1:35,000; thought to indicate impaired maturation of the fetal hypothalamic–pituitary–thyroid system from a hyperthyroid fetal environment)
- Genetic:
 - Thyroid-binding globulin deficiency (X-linked recessive)
- Environmental:
 - Iodine exposure (e.g., delivery by cesarean section, surgery in the neonatal period)
 - Maternal iodine deficiency (American Thyroid Association has recommended that pregnant and lactating women take prenatal vitamins containing 150 mcg of iodine daily)
 - Maternal use of antithyroid drugs or lithium

- Immunologic:
 - Transfer of maternal antithyroid and TSH-receptor blocking antibodies

ALERT

False positives:

- X-linked thyroid-binding globulin deficiency: Low total T₄, normal TSH, and normal free T₄. Diagnose with low thyroid-binding globulin level or high T₃ resin uptake. No treatment is necessary!
- Panhypopituitarism: Low T₄ and low or low-normal TSH (i.e., loss of the negative feedback loop). Screen with free T₄. Treat with L-thyroxine as for primary hypothyroidism, and investigate for other pituitary hormone deficiencies.
- Blood specimens obtained before 48 hours of life may have “elevated” TSH as a result of the normal postnatal surge.

False negatives:

- Normal newborn screening can be falsely reassuring in babies with congenital central hypothyroidism.

TREATMENT

MEDICATION (DRUGS)

L-Thyroxine:

- 10–15 mcg/kg/d once a day. Titer dose to keep T₄ in the upper range of normal.
- TSH levels may not normalize for several weeks, even with good T₄ values.
- A minority of infants have variable pituitary–thyroid hormone resistance, with relatively elevated serum levels of TSH for their free T₄ that improves with age.
- Starting dose of 50 mcg daily (12–17 mcg/kg/d) may provide more rapid normalization (free T₄ by 3 days and TSH by 2 weeks).
- Duration: Lifelong:
 - If medication is started without imaging studies and diagnosis is not clear, can stop L-thyroxine after completion of brain growth (2–3 years of age). Re-evaluate need for supplementation after a 6-week trial off.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- When to expect improvement:
 - Most children are asymptomatic at diagnosis.
 - Parents may note an increase in activity, improvement in feeding, and increase in urination and bowel movements soon after starting treatment.
- Signs to watch for: Poor growth and low T₄ and elevated TSH values suggest poor compliance or undertreatment. Neuropsychologic sequelae:
 - IQ scores are predominantly in the normal range, but subtle impairments in language and motor skills and specific learning disabilities may occur despite early treatment. Neurocognitive evaluation and rehabilitation should be provided.
 - Maternal hypothyroxinemia during early gestation can lead to neurodevelopmental delays if not corrected during pregnancy.

DIET

- No restrictions
- Soybean flour (as in some formulas) can decrease gastrointestinal absorption of L-thyroxine.
- Pharmacies in recent years have been recommending that L-thyroxine be administered on an empty stomach. The Drugs and Therapeutics Committee of the Pediatric Endocrine Society recommended that consistency in administration, coupled with regular dose titration to thyroid function tests, is more important than improving absorption by restricting intake to only times of empty stomach.

PATIENT EDUCATION

- Whether the child will be retarded depends on when the diagnosis was made and how quickly treatment was started. There may be an increase in learning disabilities when compared with siblings, even in patients treated within the 1st 4 weeks of life.
- If a dose is forgotten, it should be given as soon as it is remembered. If it is the next day, 2 doses should be given.
- L-Thyroxine is available only in tablet form. The tablet should be crushed between 2 spoons and the powder dissolved in a small amount of formula or breast milk and offered to the baby at the start of a feeding to ensure complete ingestion.
- There are no side effects from the medication. The tablet contains only the hormone that the child’s thyroid is not making. It is synthetically produced, so there are no infectious risks.

PROGNOSIS

- Excellent, if treatment is started within the 1st 2 weeks of life
- Level of T₄ at birth is an important indicator of long-term sequelae.

COMPLICATIONS

- If untreated:
 - Severe mental retardation (cretinism)
 - Poor motor development
 - Poor growth
- Children with hypothyroidism as part of hypopituitarism do not seem to be as significantly affected by their low thyroid hormone levels as do those with primary hypothyroidism.

CODES

ICD9

- 243 Congenital hypothyroidism (disorder)
- 269.3 Mineral deficiency, not elsewhere classified
- 759.89 Other specified congenital anomalies

ICD10

- E03.0 Congenital hypothyroidism with diffuse goiter
- E03.1 Congenital hypothyroidism without goiter
- E00.9 Congenital iodine-deficiency syndrome, unspecified

FAQ

- Q: What are some of the reasons that a normal newborn will have an abnormal thyroid screen?
- A: Blood tests obtained prior to 48 hours of age may have an elevated TSH from newborn surge; some states (for quality control) will ask to have a certain percentage of tests repeated, even though they are normal.

CONGESTIVE HEART FAILURE

Jondavid Menteer

BASICS

DESCRIPTION

Heart failure (HF) is the pathophysiologic state in which the heart is unable to pump sufficient blood to meet the metabolic demands of the body.

- Right heart failure:
 - Hepatomegaly
 - Jugular venous distension
 - Edema
 - Right ventricular/parasternal heave
 - Ascites, pleural effusions
- Left Heart Failure:
 - Tachypnea, retractions, grunting
 - Pulmonary edema, rales
 - Orthopnea
 - Shock/depressed perfusion
 - Diffuse/displaced point of maximum impulse (PMI)
- Either left or right heart failure:
 - Exercise intolerance
 - Tachycardia
 - Sweating, especially when supine/sleeping
 - Poor perfusion/pulses
 - Poor feeding/GI symptoms
 - Growth failure (primarily weight)

RISK FACTORS

- In Utero
 - Arrhythmias: Supraventricular or ventricular tachycardia, complete heart block (CHB)
 - Volume overload: Atrioventricular (AV) valve regurgitation or arteriovenous malformation (AVM)
 - Primary myocardial disease: Cardiomyopathy (dilated, hypertrophic), myocarditis
 - Anemia: Rh isoimmune disease, thalassemia, and twin-twin transfusion
 - Premature closure of ductus arteriosus with isolated right ventricular failure
- In Neonates
 - Myocardial dysfunction: Asphyxia, acidosis, myocarditis, hypoglycemia, cardiomyopathy (dilated, hypertrophic, ventricular noncompaction), ischemia (anomalous left coronary artery from the pulmonary artery), metabolic defects, or pressure overload imposed by aortic stenosis, pulmonary hypertension, or coarctation of the aorta.
 - Volume overload: atrial septal defect (ASD) (large), ventricular septal defect (VSD) (large), patent ductus arteriosus (PDA) (moderate to large), truncus arteriosus, aortopulmonary window, anomalous pulmonary venous return, AVM in any location.
 - Arrhythmias: supraventricular or ventricular tachycardia, CHB.
 - Left heart inlet obstruction: Mitral stenosis, cor triatriatum, pulmonary venous obstruction.
 - Note: Certain cyanotic heart diseases such as hypoplastic left heart syndrome may present with elevated pulmonary blood flow or depressed systemic blood flow, and minimal desaturation. These patients may have HF in the first days of life due to increased pulmonary circulation or due to shock from ductal closure.
- In Infants
 - Myocardial dysfunction: Cardiomyopathy (dilated, hypertrophic, restrictive, ventricular noncompaction), endocardial fibroelastosis, metabolic/mitochondrial diseases, myocarditis, Kawasaki disease, anomalous left coronary artery

- from pulmonary artery, or chronic pressure overload due to coarctation of the aorta or aortic stenosis.
- Volume overload: ASD (large), VSD, PDA, common AV canal defect, partial anomalous pulmonary venous connections.
- Secondary causes: renal disease (volume overload, electrolyte disturbance), hypertension, hypothyroidism, sepsis.
- Arrhythmias: supraventricular or ventricular tachycardia, CHB.
- Pericardial effusion due to juvenile rheumatoid arthritis (JRA), systemic lupus erythematosus (SLE), other inflammatory diseases, or following repair of congenital heart disease (CHD).
- In Childhood and Adolescence
 - Unrepaired CHD with volume and/or pressure overload.
 - Repaired CHD with residual defects that result in volume and/or pressure overload.
 - Acquired heart disease: Pericarditis, myocarditis, endocarditis, acute rheumatic fever.
 - Cor pulmonale (pulmonary hypertension, Eisenmenger syndrome, chronic lung disease).
 - Cardiomyopathy due to primary myocardial disease (dilated, hypertrophic, restrictive, ventricular noncompaction), chemotherapy (anthracyclines), radiation therapy, sickle cell anemia, thalassemia, neuromuscular disease (e.g., Duchenne or Becker muscular dystrophy).

GENERAL PREVENTION

- Limited use of cardiac anthracycline drugs in cancer therapy
- Prompt treatment (within 1 week) of streptococcal pharyngitis to prevent rheumatic fever
- SBE prophylaxis to prevent infective endocarditis

ALERT

- In patients with HF due to large left-to-right shunts, long-term spontaneous clinical improvement of HF with decreased murmur may indicate the development of pulmonary vascular disease (Eisenmenger syndrome), leading to cyanosis eventually.
- Care must be used in the administration of oxygen to the undiagnosed infant with heart disease. A patient with single-ventricle physiology (e.g., hypoplastic left heart syndrome) can have manifestations of heart failure and mild desaturation (92–98%). Providing oxygen in this situation can result in shock due to excessive pulmonary blood flow and inadequate systemic blood flow.

ETIOLOGY

- Low cardiac output HF (e.g., all cardiomyopathy, severe atrioventricular valve regurgitation)
- High cardiac output HF
 - Left-to-right shunts (e.g., ASD, VSD, PDA)
 - AVM
 - Anemia and other non-cardiovascular causes

DIAGNOSIS

HISTORY

- Infants and Neonates
 - Prolonged feedings associated with tachypnea, retractions, or diaphoresis.

- Emesis, inadequate caloric intake, irritability with feeding, and failure to thrive.
- Frequent respiratory infections.
- Orthopnea – “spoiled baby” becomes distressed when supine.
- Family history of HF or sudden unexpected deaths.
- Childhood and Adolescence
 - Exercise intolerance with exertional dyspnea.
 - Palpitations or chest pain, especially during exercise.
 - Chronic cough, wheezing, orthopnea, fatigue, weakness, anorexia, nausea, and edema.
 - Gradual weight loss (anorexia, nausea, and increased metabolic demands).
 - Sudden weight gain (fluid retention).
 - Family history of HF or unexpected deaths at a young age.

PHYSICAL EXAM

- Infants And Neonates
 - Tachycardia
 - Gallop rhythm
 - Murmur of outflow obstruction, elevated flow, AV valve regurgitation, VSD, or semilunar valve incompetence.
 - Systolic click (semilunar valve abnormalities)
 - Abnormal second heart sound (fixed split, loud P2 component)
 - Tachypnea, wheezing, crackles, rales
 - Nasal flaring/grunting/retractions
 - Abdominal or cranial bruit
 - Hepatomegaly +/- splenomegaly
 - Edema (periorbital)
 - Cool and/or mottled extremities
 - Poor capillary refill or pulses
- Children And Adolescents
 - Tachycardia
 - Gallop rhythm
 - Murmur of outflow obstruction, elevated flow, AV valve regurgitation, VSD, or semilunar valve incompetence.
 - Loud second heart sound (P2 component)
 - Hyperactive precordium, displaced PMI
 - Tachypnea, retractions
 - Wheezing (“cardiac asthma”) or rales
 - Jugular venous distension
 - Hepatomegaly +/- splenomegaly
 - Edema (periorbital, peripheral)
 - Pulsus alternans, pulsus paradoxus
 - Cool extremities, poor pulses, poor capillary refill
 - Evaluation of mucus membranes, skin, and extremities for manifestations of Kawasaki disease, rheumatic fever, or endocarditis

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other

- Chest X-ray
- Cardiomegaly, increased pulmonary vascular markings, hyperinflation, pleural effusion, Kerley-B lines.
- Electrocardiography
 - Abnormal P-waves
 - ST-T wave changes (ischemia, strain, inflammation/myocarditis)
 - Heart block (1st, 2nd, 3rd degree) or tachyarrhythmia.
 - Characteristic ECG findings such as anomalous left coronary artery from the pulmonary artery (Q waves and/or inverted T waves in leads I and aVL, left ventricular hypertrophy, right ventricular hypertrophy, and/or lateral Q waves with or without active ischemic changes)

- Pericarditis pattern (diffuse ST elevation and/or low QRS voltage)
- Hypertrophy (cardiomyopathy, CHD, storage disease)
- Echocardiography
 - Rule out CHD, evaluate coronary origins
 - Assessment of cardiac systolic and diastolic function
- Cardiac Catheterization (for selected cases)
 - Assessment of cardiac hemodynamics and anatomy.
 - Endomyocardial biopsy may be helpful in the diagnosis of myocarditis, storage disease, or cardiomyopathy.
 - Electrophysiologic study to evaluate for the induction of arrhythmia.
 - Therapy (see later)
- Cardiac MRI or CT (for selected cases)
 - Delineation of complex anatomic abnormality
 - Right ventricular performance
- Other Laboratory Abnormalities
 - Blood gas: Metabolic acidosis with elevated lactate.
 - Chemistry: Hyponatremia (dilutional), pre-renal state
 - Blood counts: Anemia, leukocytosis, or leukopenia (e.g., viral myocarditis)
 - ESR elevation (e.g., acute rheumatic fever or Kawasaki disease)
 - B-type natriuretic peptide (BNP or NT-BNP) elevation
 - Urine: Proteinuria, high urine specific gravity, microscopic hematuria
 - Evaluation for metabolic causes of cardiomyopathy may include pyruvate, amino acid quantification, urine organic acids, carnitine, selenium, acylcarnitine profile, liver function tests
 - Viral evaluation (adenovirus, coxsackievirus, Epstein-Barr virus, cytomegalovirus, parvovirus, echovirus, etc.)

DIFFERENTIAL DIAGNOSIS

- Tachycardia:
 - Fever
 - Dehydration
 - Anemia
 - Supraventricular tachycardia or ventricular tachycardia without heart failure
 - Hyperthyroidism
 - Pericardial effusion
- Tachypnea:
 - Respiratory disease or infection
 - Pulmonary venous obstruction
 - Acidosis (metabolic disease, poisoning, etc)
 - Pneumothorax/pleural effusion
 - Carbon monoxide poisoning
- Edema:
 - Hypoalbuminemia
 - Systemic inflammatory conditions / allergies
 - Hypothyroidism
- Sepsis
 - Hepatomegaly:
 - Liver disease
 - Storage disease
 - Extramedullary hematopoiesis

 **TREATMENT**

ADDITIONAL TREATMENT

General Measures

Treatment of Underlying Cause

- Surgical palliation or correction of structural abnormality.

- Interventional cardiac catheterization (e.g., balloon dilation of aortic or pulmonary stenosis, coil embolization of patent ductus arteriosus, device closure of ASD, dilation, or stenting of coarctation of the aorta).
- Carnitine, Coenzyme Q10, riboflavin, antioxidant replacement for select cardiomyopathies.
- Targeted medical treatment of endocarditis, myocarditis, anemia, rheumatic fever, Kawasaki disease, or hypertension.
- Radiofrequency ablation of tachyarrhythmia.
- Medical therapy for patients, or mothers of fetuses with tachyarrhythmia.
- Pacing for bradyarrhythmias (e.g., heart block).
- Control of chronic inflammatory conditions, such as SLE or JRA.

COMPLEMENTARY & ALTERNATIVE THERAPIES

Management

- Assessment of degree of illness:
 - If perfusion is compromised or acidosis is present, ICU care is indicated.
 - Hospitalization may be necessary to initiate treatment or prepare for surgery in some cases (coronary abnormalities, aortic coarctation, myocarditis).
 - Many patients diagnosed as outpatients with CHD or cardiomyopathy may not require inpatient treatment. Immediate consultation with a pediatric cardiologist should be arranged.
- Immediate Management:
 - General measures: Activity restriction as indicated, oxygen as needed (not for patients with pulmonary overcirculation),
 - Sometimes: Tube feedings or parenteral nutrition if there is concern for splanchnic circulation or severe failure to thrive.
 - Drainage of pericardial effusion, if needed.
 - Inotropic agents (digoxin, milrinone, dobutamine in refractory cases, etc)
 - Intravenous immunoglobulin (IVIG) for myocarditis or Kawasaki disease
 - Loop diuretics (e.g., furosemide)
 - Nesiritide (synthetic BNP) for refractory fluid overload
 - Mechanical respiratory or circulatory support, if necessary (ventilator, extracorporeal membrane oxygenation, ventricular assist device)
- Chronic therapy:
 - Digoxin
 - Loop diuretics (e.g., furosemide) for fluid overload/edema
 - Afterload reduction [e.g. angiotensin-converting enzyme (ACE) inhibitors]
 - Antagonism of activated neurohormonal systems: ACE inhibitor or angiotensin receptor blocker, spironolactone, beta-blocker
 - Anticoagulation or anti-platelet therapy (especially in restrictive and severe dilated cardiomyopathy)
 - Biventricular pacing/resynchronization in some cases
 - Heart and heart/lung transplantation in select cases

 **ONGOING CARE**

FOLLOW-UP RECOMMENDATIONS

- Dependent on the etiology and degree of HF. Generally, initial follow-up of a patient with heart failure should be intensive, focussed on assessing response to therapy. Initial follow-up generally weekly, spreading to monthly or quarterly over time, under the supervision of a pediatric cardiologist.

- Depending on the etiology and degree of HF, echocardiography, ECG, blood chemistry, BNP levels, INR, Holter monitoring, and chest radiographs will be evaluated.

 **CODES**

ICD9

- 428.0 Congestive heart failure, unspecified
- 428.1 Left heart failure
- 428.9 Heart failure, unspecified

ICD10

- I50.1 Left ventricular failure
- I50.9 Heart failure, unspecified
- Q24.9 Congenital malformation of heart, unspecified

FAQ

- Q: My child has a large VSD and is prescribed digoxin and furosemide. Should I take salt out of his diet?
- A: No. Excessive salt restriction is seldom enforceable and is not necessary. A no-added-salt diet is generally sufficient.
- Q: What is the importance of tachycardia and bradycardia in heart failure?
- A: Tachycardia limits diastolic filling time and may result in a decreased output. However, bradycardia may be poorly tolerated in patients with heart failure and a relatively fixed stroke volume who are dependent on heart rate to maintain an appropriate output. Either may be problematic for a patient in chronic heart failure. Most HF patients do not have as much heart rate variation as healthy people.
- Q: What are the major causes of death to heart failure patients?
- A: Younger children tend to die of progressive heart failure. Ventricular arrhythmias are the most common cause of sudden death in older children and adults with HF. Other causes of mortality include infection and stroke.
- Q: My patient has a normal blood pressure, but the cardiologist says more ACE inhibition is necessary. Why?
- A: Blood pressure is the weight that the myocardial muscle must “lift” with every beat. By decreasing the blood pressure as much as possible (short of causing dizziness or syncope), the work done by the heart and myocardial oxygen consumption are reduced. Reduction of the systemic blood pressure also potentially reduces the amount of left-to-right shunting through a VSD, PDA, and AP window.

CONJUNCTIVITIS

Anne K. Jensen

Brian J. Forbes

William R. Katowitz (5th edition)

BASICS

DESCRIPTION

An inflammatory process of the conjunctiva, the membrane covering the eye and inside of the eyelids, manifested by redness and edema, frequently with associated discharge. It is critical to rule out *Gonococcus* infection because of the destructive nature of the eye disease and associated systemic infection.

EPIDEMIOLOGY

Incidence

- Children: Viral infection is the most common cause and is highly contagious.
- Neonates: Ophthalmia neonatorum, conjunctivitis in the 1st month of life, is the most common infection in neonates. Remains a significant cause of blindness in children worldwide. *Chlamydia trachomatis* is the most common infectious cause.

PATHOPHYSIOLOGY

- Results from bacterial, viral, allergic, or toxic activation of the inflammatory response that causes dilation and exudation from conjunctival blood vessels
- Pathology involves dilated conjunctival capillaries with leukocytic infiltration and edema of conjunctiva and substantia propria.

ETIOLOGY

- Ophthalmia neonatorum
 - In the 1st 24 hours of life, most likely due to irritation from silver nitrate or Betadine eyedrops.
 - *Gonococcus* conjunctivitis is treatable if recognized early but devastating if diagnosis is delayed or missed.
 - Chronic *Chlamydia* infection can lead to scarring and corneal opacity. *Chlamydial pneumonia* develops in 20% of patients with chlamydial conjunctivitis.
- Bacterial
 - Agents include staphylococci, streptococci, *Pseudomonas*, and *Haemophilus*, and serious complications of these are rare.
- Viral
 - Adenovirus is the most common agent.
 - Recurrent herpes simplex virus infection can lead to significant visual loss from corneal scarring, even with proper therapy.
 - Other viral etiologies usually follow a benign course, but may rarely lead to conjunctival scarring.
- Allergic
 - Histamine-mediated response

DIAGNOSIS

HISTORY

- Ophthalmia neonatorum
 - *Gonococcus*: Typically presents 2–4 days after birth with mucopurulent discharge.
 - *Chlamydia*: Typically presents 4–10 days after birth with mucopurulent discharge.
- Bacterial
 - Eye redness and mucopurulent discharge. Patient may complain of sticky eyelids upon waking. Mild photophobia and discomfort may be present but are typically not painful.
- Viral
 - HSV ocular infection may present as conjunctivitis. Often associated with corneal anesthesia, so painless. In neonates, occurs 1–2 weeks after birth as unilateral serous discharge and conjunctival injection.
 - Other viral causes often present with upper respiratory symptoms, fever, sore throat, eye redness, tearing, serous discharge, eyelid edema, and photophobia. Typically begins in one eye but spreads to the other within a few days. History of similar infection in siblings or contacts is common.
- Allergic
 - Bilateral itching and tearing. Classically, a complaint of itching or foreign body sensation in an older child with red eyes

PHYSICAL EXAM

- General
 - Cornea is clear.
 - Vision, pupils, and motility are normal.
 - Refer to an ophthalmologist for vesicular rash on eyelids or corneal changes, as the condition may be caused by herpes simplex virus and can be vision threatening.
- Bacterial
 - Mucopurulent discharge (opaque and thick)
 - Injected conjunctiva, episcleral vessels, palpebral conjunctival papillae
 - Preauricular lymphadenopathy less common
- Viral
 - HSV ocular infection may involve corneal ulceration or dendritic or disciform keratitis.
 - Serous discharge (clear and watery)
 - May involve pseudomembrane formation, pinpoint subconjunctival hemorrhages, and palpable preauricular lymph nodes
- Allergic
 - Bilateral conjunctival edema and chemosis

ALERT

- Failure to diagnose *Gonococcus* conjunctivitis may lead to corneal perforation.
- HSV ocular infection is associated with a significant risk of blindness. Have high suspicion for HSV with any recurrent unilateral eye redness, corneal changes, or vesicular rash on eyelids.
- Steroids can activate or accelerate unrecognized herpes simplex virus infection, and chronic use can lead to raised intraocular pressure or cataract formation.
- Chronic use of empiric broad-spectrum antibiotics for self-limited conjunctivitis can promote bacterial resistance though less so than for systemic antibiotic administration.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Gram stain
 - Note: Always for ophthalmia neonatorum
 - *Gonococcus*: Gram-negative intracellular diplococcus
 - *Chlamydia*: Intracytoplasmic, paranuclear inclusion bodies on Gram stain and conjunctival scraping with Giemsa stain for basophilic intracytoplasmic inclusion bodies
 - Viral or chemical: Polymorphonuclear leukocytes without bacteria.
- Culture
 - Viral: Cultures for HSV and adenovirus are not clinically useful.
 - Bacterial: Blood agar and chocolate agar
 - *Gonococcus*: Thayer-Martin media
 - *Chlamydia*: Culture techniques are not widely available. However, they remain the gold standard for diagnosis. Specimens should be obtained using an aluminum shafted Dacron-tipped swab and processed within 24 hours. A positive test is confirmed when the organism is identified using fluorescein-conjugated monoclonal antibody. Other equally effective methods involve polymerase chain reaction or direct fluorescent antibody.
- Conjunctival scrapings
 - Allergic: Mast cells and eosinophils
- Serum tests
 - Allergic: Immunoglobulin E may be elevated.
 - *Chlamydia*: The diagnosis of *Chlamydial pneumonia* can be made with a serum test, but is not reliable for *Chlamydial* conjunctivitis.

DIFFERENTIAL DIAGNOSIS

- Ophthalmia neonatorum
 - Chemical conjunctivitis: Noninfectious, mild, self-limited. Result of silver nitrate or povidone-iodine administration
 - Birth trauma: Unilateral, often with associated eyelid contusion, history of forceps use or difficult delivery
 - Congenital glaucoma: Mild redness, minimal discharge. Look for enlarged eye, cloudy cornea, tearing, and photophobia.
 - Nasolacrimal duct obstruction: Unilateral or bilateral discharge, may be clear to mucopurulent with reflux from nasolacrimal sac. Conjunctiva is usually white and nonerythematous.
- All conjunctivitis

- Preseptal cellulitis: Early eyelid edema/erythema. Looks like conjunctivitis, especially in young children with a difficult exam. Motility deficit, proptosis, decreased vision, and afferent pupillary defect are consistent with orbital cellulitis.
- Keratitis: Signifies corneal infection. May have associated conjunctivitis. Primary herpes keratitis is associated with vesicular eyelid rash and pain. Consult an ophthalmologist. Bacterial keratitis may be caused by staphylococci, streptococci, and *Pseudomonas*; Lyme spirochete; or vitamin A deficiency.
- Episcleritis: Inflammation of the thick loose connective tissue between the clear conjunctiva and the white-appearing stroma of the sclera. Rare disease in childhood. Can be associated with rheumatologic disease
- Scleritis: Presents as red eye. Severe disease involving inflammation of the sclera. Rare in childhood. Associated with systemic disease. Requires oral or IV steroids
- Iritis: Frequently unilateral, with or without a history of trauma. Photophobia, decreased vision, and constant pain (except if associated with juvenile rheumatoid arthritis). Contagious history is rare. Consult an ophthalmologist for full evaluation, including pupillary dilation.
- Systemic diseases with red eye
 - Varicella: Ocular involvement in rare cases. Treat with antiviral medications.
 - Stevens-Johnson syndrome: Secondary to viruses, mycoplasma, or adverse drug reaction. Mucous membrane involvement may lead to conjunctival bullae with risk of rupture and subsequent scarring.
 - Kawasaki disease: Acute vasculitis. Classic symptoms include (1) fever, (2) bilateral nonexudative conjunctivitis, (3) strawberry tongue, (4) oropharyngeal changes, (5) cervical adenopathy, (6) trunk rash, and (7) erythematous palms and soles with peeling around nail beds.

 **TREATMENT**

MEDICATION (DRUGS)

- Ophthalmia neonatorum
 - *Gonococcus*: Ceftriaxone, 30–50 mg/kg/d IV q8–12h and ocular irrigation followed by topical 0.5% erythromycin or 1.0% tetracycline ophthalmic ointments q.i.d. for 14 days. Also treat for *Chlamydia*.
 - *Chlamydia*: Oral erythromycin syrup, 12.5 mg/kg/d in 4 doses for 14 days. Topical 0.5% erythromycin or 1.0% tetracycline ophthalmic ointment q.i.d. both eyes for 14 days as above. (Povidone-iodine 1.25% ophthalmic drops q.i.d. can be used if other antibiotics are not readily available.)
- Bacterial
 - Empiric antibiotic treatment if bacterial infection is suspected, including erythromycin ointment, sulfacetamide 10%, polymyxin-trimethoprim, fluoroquinolone, or azithromycin drops
- Viral
 - Herpes simplex: Topical trifluorothymidine (Viroptic solution), 9 times a day for at least 14 days with or without systemic acyclovir
 - Other viral: Over-the-counter antihistamine or decongestant drops for comfort. Cidofovir has recently been considered as a potential antiadenoviral therapy, but its clinical use is limited by local toxicity to the skin, eyelids, and conjunctiva.
- Allergic

- A new class of topical mast cell stabilizers such as olopatadine b.i.d. is effective for more involved cases.

ADDITIONAL TREATMENT

General Measures

- Ophthalmia neonatorum
 - Cases of suspected gonococcal conjunctivitis should be hospitalized for IV antibiotics and workup for sepsis.
 - For suspected chlamydial infection topical and oral therapy is usually appropriate.
- Bacterial
 - Usually self-limited, but treatment may help shorten course and prevent spread of infection. Contact lens users should remove lenses until infection clears and consider use of fluoroquinolone.
- Viral
 - Suspected HSV warrants hospitalization for intravenous antiviral therapy.
 - For suspected adenovirus, children should stay home from school until no additional discharge. Cool compresses for comfort
- Allergic
 - Remove offending allergen if possible.
 - Mild symptoms can be treated with preservative-free artificial tears. Consider topical antiallergy medicine if symptoms persist
- Chemical
 - Close observation only. Self-limited

 **ONGOING CARE**

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Daily follow-up is necessary for *Gonococcus*, *Chlamydia*, and herpes simplex virus.
- For epidemic viral conjunctivitis, frequency is dictated by severity (daily to weekly).
- For allergic conjunctivitis, follow-up can be made after a few weeks of treatment.
- No office follow-up is recommended for routine conjunctivitis.
- Follow atypical conjunctivitis closely until a more serious disease can be excluded.
- A nonresponsive or worsening condition needs ophthalmic consultation.

COMPLICATIONS

- Significant complications are extremely rare for common bacterial, viral, or allergic conjunctivitis.
- Blindness may result from untreated neonatal conjunctivitis, or from recurrent HSV ocular infection.

 **CODES**

ICD9

- 077.99 Unspecified diseases of conjunctiva due to viruses
- 372.30 Conjunctivitis, unspecified
- 771.6 Neonatal conjunctivitis and dacryocystitis

ICD10

- B30.9 Viral conjunctivitis, unspecified
- H10.9 Unspecified conjunctivitis
- P39.1 Neonatal conjunctivitis and dacryocystitis

FAQ

- Q: Is conjunctivitis contagious?
- A: All infectious conjunctivitis is contagious, but to varying degrees. Viral or epidemic keratoconjunctivitis (EKC) is the most contagious. Careful handling of secretions, tissues, towels, and bed linens and strict handwashing usually prevent spread. Wipe surfaces with isopropyl alcohol or dilute bleach to prevent recontamination. *Gonococcus*, *Chlamydia*, and herpes simplex virus can be transmitted through infected discharge or secretions, but this is less common. The most common source is the infected birth canal.
- Q: Should the patient with “pink eye” (non-*Gonococcus*, non-*Chlamydia*, non-herpes simplex virus conjunctivitis) be treated with empiric antibiotics?
- A: Empiric treatment with topical antibiotics can cause harm in the case of sulfa-containing compounds. Antibiotic toxicity, including Stevens-Johnson reactions, can occur from sulfa antibiotics, and use of antibiotics long term promotes selection of resistant strains of bacteria. Empiric treatment also increases manipulation of the infected eye and thus increases the risk of spread.
- Q: How long is the patient with “pink eye” (non-*Gonococcus*, non-*Chlamydia*, non-herpes simplex virus conjunctivitis) contagious and when can the patient return to school?
- A: The organism can be recovered from the eye for up 2 weeks after onset of symptoms, demonstrating that patients are infectious during this time. Practically, children should probably be kept out of school for at least 1 week.

CONSTIPATION

Kristin N. Fiorino

Maria R. Mascarenhas

BASICS

DESCRIPTION

Delay or difficulty in defecation to <2–3 stools per week, which may result in pain, rectal bleeding, and encopresis or soiling. May also refer to a decrease in frequency of bowel movements compared with the patient's usual bowel pattern.

GENERAL PREVENTION

Dietary measures: High-fiber diet, plenty of fluids, fruits and vegetables, avoidance of excessive caffeine and milk (calcium) intake, plus regular physical activity.

PATHOPHYSIOLOGY

- Retention of stool allows water to move out of stool, increasing size and firmness.
- Decreased motility leads to a buildup of desiccated stool causing painful defecation that leads to ongoing stool retention. As the rectosigmoid enlarges, a child's ability to sense rectal fullness diminishes, and he or she may not appreciate the need to defecate. Often there is a family history of motility disturbances or constipation.

ETIOLOGY

- Most patients will have idiopathic or functional constipation with no identifiable cause: Usually an acute event followed by chronicity.
- Intentional or unintentional withholding of stool may result in hard stools, anal pain, and fissures that perpetuate and lead to constipation: Rectal dilatation, decreased sensation of the urge to defecate, shortening of the anal canal, decreased tone of the external anal sphincter, and encopresis can result.
- Precipitating events include:
 - Transition from breast milk to cow's milk
 - Excessive cow's milk intake
 - Insufficient water intake
 - Power struggle in toddlers
 - Refusal to use toilets outside the home
 - Zealous toilet training
 - Perianal streptococcal infection
 - Transient viral illness (diarrhea followed by constipation)
- Constipation also can be caused by anatomic anomalies in the lower GI tract, decreased propulsion, increased rectal sensitivity threshold, a functional outlet obstruction (muscular spastic levator ani or impaired relaxation of the puborectalis).
- Neurologic causes:
 - Abnormalities of the myenteric plexus
 - Intestinal pseudoobstruction
 - Congenital aganglionosis
 - Visceral neuropathies
 - Visceral myopathies
 - Familial dysautonomia

- Lesions of the spinal cord result in loss of rectal tone and sensation and reduced anal closure, affecting the sacral reflex center (e.g., meningocele, myelomeningocele, tethered cord).
- Anatomic disorders of anus and rectum (stricture, stenosis, mass, ectopic anus, imperforate anus, fistula)
- Endocrine abnormalities (hypothyroidism), drugs, electrolyte abnormalities

DIAGNOSIS

HISTORY

- Question: What is the timing of the passage of meconium?
 - If it is delayed for >48 hours, consider Hirschsprung disease.
- Is the child able to pass a bowel movement unaided by a suppository or enema?
 - If rectal stimulation is required for passage of a bowel movement, consider Hirschsprung disease or habituation to rectal stimulation.
- What are the size, frequency, and consistency of bowel movements?
 - 1–3 normal (in size and consistency) painless bowel movements may be passed every 1–3 days. The size of bowel movements reflects the caliber of the colon.
- Does the child experience frequent urination, bed-wetting, or urinary tract infections?
 - Frequently linked to chronic constipation.
- Is there soiling?
 - Soiling occurs with stool impaction or with nerve damage involving the anus.
- Is there the presence of rectal sensation?
 - Patients with long-standing constipation or withholding who develop a dilated rectum may lose the sensation of rectal distention.
- Is there a history of painful bowel movements or rectal fissure?
 - This could be the cause of withholding secondary to fear of painful bowel movements.
- Is the child experiencing any stressful events (i.e., new sibling, family death)?
 - Stress can precipitate stool withholding.
- Is there an unsteady gait?
 - This may suggest neuromuscular problems.
- Did the child experience difficult toilet training?
 - May be associated with encopresis.

PHYSICAL EXAM

- General: Look for evidence of systemic illness and alarm signals: Weight loss, anorexia, delayed growth, delayed passage of meconium, urinary incontinence, passage of bloody stools (in the absence of anal fissure), fever, vomiting, and diarrhea.
- Abdomen: Abdominal distention (indicative of the presence of stool or gas), presence of stool masses (size, location), distended bladder, and bowel sounds (may be decreased in intestinal pseudoobstruction)

- Rectal examination:
 - Perianal soiling
 - Size and position of anus (may suggest imperforate or ectopic anus)
 - Presence of skin tags and fissures
 - Perianal or anal erythema (streptococcal proctitis)
- Evidence of child abuse
- On digital examination, assess anal tone (decreased in functional constipation; long and tight anal canal in Hirschsprung); amount and consistency of stool; size of rectum (dilated rectum with chronic constipation; tight and empty anus with Hirschsprung disease); presence of blood
- Absence of anal wink or cremasteric reflex suggests neurologic abnormalities.
- Neurologic examination: Decreased reflexes in the lower extremities
- Back: Check for sacral dimple, tuft of hair (underlying sacral abnormality), flat buttocks, and patulous anus.

ALERT

- Grunting baby syndrome: Infants cry, scream, and draw up their legs during a bowel movement. They respond to rectal distention by contracting their pelvic floor. This is not constipation.
- Always rule out an organic cause.
- Always consider medications as a cause.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Water soluble contrast enema: An unprepped study is useful to diagnose Hirschsprung disease. A prepped study is useful to diagnose a stricture. Most patients with constipation will not require this test.

Imaging

Abdominal radiograph study: Look for evidence of bowel obstruction. Measurement of abdominal transit time with radio-opaque markers is useful for efficacy of cleanout and presence of a megarectum.

Diagnostic Procedures/Other

Anorectal manometry: Analyzes rectal sensation, resting and squeezing pressures, and pelvic floor dyssynergia (anismus)

DIFFERENTIAL DIAGNOSIS

- Hirschsprung disease: Congenital aganglionic megacolon
- Neuromuscular causes: Tethered spinal cord, spinal muscular atrophy
- Anal abnormalities: Anteriorly displaced anus (ectopic anus), imperforate anus, anal stenosis
- Endocrine abnormalities: Hypothyroidism, hyperparathyroidism, adrenal insufficiency
- Electrolyte imbalance: Hypokalemia, hyponatremia, hypomagnesemia, hypercalcemia
- Lead ingestion: Anemia, constipation, and abdominal pain
- Infant botulism: Constipation, aphonia, and weakness
- Infection: Chagas, tetanus
- Meconium ileus: Inspissated stool at birth in cystic fibrosis
- Inflammatory bowel disease (IBD)
- Celiac disease (gluten enteropathy)

- Abdominopelvic mass: Can cause constipation by pressure (i.e., distended bladder or pelvic tumor); pregnancy can also cause constipation.
- Chronic intestinal pseudoobstruction: Abdominal distention, diarrhea, and constipation
- Surgical conditions: Malrotation, congenital intestinal bands, intestinal stenoses, acquired colonic strictures resulting from IBD, necrotizing enterocolitis (NEC), pyloric stenosis
- Drugs: Calcium supplements, iron, barium, opiates, anticholinergic agents, antispasmodics

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Treatment of functional constipation:
 - Disimpaction: If patient is impacted, 3–5 hypertonic phosphate enemas may be required for initial disimpaction. Children >2–3 years of age require adult-size enemas, whereas younger children require pediatric-size enemas.
 - Evacuation: Following rectal disimpaction, evacuation can be achieved by using polyethylene glycol solution (Go-Lyately), orally or via nasogastric tube over 6–8 hours until the effluent is clear. Alternatively, MiraLAX can be used on a daily basis to achieve evacuation over 1–2 weeks. Doses are given in 4–8 oz of liquid once or twice daily. Maximum dose of MiraLAX or Go-Lyately 1.5 g/kg.
- Maintenance stool softeners:
 - Infants ≤6 months of age may be given sorbitol containing juices, lactulose, or Karo syrup. Children >6 months of age may be given lactulose (0.7–2 g/kg/d (1–3 mL/kg/d), max 40 g/d (60 mL/d)) or MiraLAX (0.5–1 g/kg, max 17 g/d).
 - Mineral oil or Kondremul (>1 year of age 1–3 mL/d, >6 years 10–25 mL/d) is added as an adjunctive lubricant to aid in the passage of stool but contraindicated in children <12–15 months as well as in children at risk for aspiration.
- Rescue stimulant laxatives: Bisacodyl or senna may be used as a stimulant laxative for short periods of time. Long-term use has been associated with colonic nerve damage in adults.
- Diet: A balanced diet of whole grains, fruits, and vegetables is recommended. A high-fiber diet is recommended (toddler 14 g/d; school-aged 17–25 g/d; adolescent 25–31 g/d). Fiber should be increased gradually to minimize side effects of flatulence. Caffeine and excessive milk-product intake (>16 oz/d of milk) may be constipating.
- Fluid intake: High fluid intake is important.
- Toilet sitting: Regular toilet sitting twice a day for 10 minutes, preferably 15–20 minutes after meals, is necessary to help retrain the bowel.
- Calendar: It is important to keep a record of stools, accidents, toilet sitting, and medications in order to identify causes of failure.
- Biofeedback can be helpful in patients who fail conventional therapy and who have the following abnormalities on anorectal manometry: Decreased sensory threshold to rectal distention, paradoxical contraction of the external anal sphincter and puborectalis muscle during simulated defecation (pelvic floor dyssynergia)

- Treatment of complications:
 - Encopresis (soiling or diarrhea): Abdominal radiographs with radio-opaque markers show large amounts of stool in the colon, including a dilated rectum and markers mainly in the rectosigmoid. Disimpaction or clean-out, followed by treatment of constipation, is recommended (see above).
 - Intestinal obstruction: Vomiting, abdominal pain, and constipation. Abdominal radiograph film shows intestinal obstruction. Make nil per os, (NPO) provide IV fluids, and rule out an acute abdomen. Then give enemas and clear out stool from below. Never give oral laxatives or a polyethylene glycol solution in a case of obstruction.
 - Sigmoid volvulus: Chronically constipated child with symptoms of acute abdomen, fever, tender abdomen, and palpable mass. Abdominal radiograph shows obstruction in the colon. Contrast enema may reveal and possibly reduce a volvulus.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Schedule regular visits to make certain therapy is maintained, decreasing the frequency of visits when patient is doing well.
- Parents should call when problems develop.
- Compliance and good follow-up are key to successful management of constipation.

PROGNOSIS

For functional constipation, the success rate is variable (45–90%). Presence of abdominal pain at the time of presentation, close follow-up, and use of mineral oil are good prognostic factors. Presence of soiling, use of stimulant laxatives, and lack of follow-up were associated with failure.

COMPLICATIONS

- Anal fissures: Infrequent hard stools can cause a tear of the anal mucosa, causing pain and withholding.
- Encopresis: Chronic constipation leads to progressive rectal dilatation and decreased rectal sensation. Fecal impaction results in secondary soiling or encopresis.
- Intestinal obstruction: Manifests as vomiting, abdominal pain, and constipation. Abdominal radiograph films show intestinal obstruction and presence of large amounts of stool.
- Sigmoid volvulus: A chronically constipated child may present with symptoms of acute abdomen, fever, tender abdomen, and palpable mass. Abdominal radiograph shows obstruction in the colon. Barium enema may be both diagnostic and therapeutic by achieving reduction.

CODES

ICD9

- 564.00 Constipation, unspecified
- 564.01 Slow transit constipation
- 564.09 Other constipation

ICD10

- K59.00 Constipation, unspecified
- K59.01 Slow transit constipation
- K59.09 Other constipation

FAQ

- Q: When is constipation an emergency?
- A: When intestinal obstruction, sigmoid volvulus, or Hirschsprung enterocolitis occurs.
- Q: Does MiraLAX have a taste?
- A: MiraLAX advantages include its lack of taste, smell, or odor and that it can be mixed in any liquid.

CONTACT DERMATITIS

Kara N. Shah

BASICS

DESCRIPTION

- An acute or chronic eczematous eruption that may result from either direct irritation to the skin (irritant contact dermatitis) or from a delayed-type (type IV) hypersensitivity reaction to a contact allergen (allergic contact dermatitis)
- Most cases of contact dermatitis are irritant contact dermatitis (>80%).

EPIDEMIOLOGY

Incidence

The incidence of contact dermatitis in children is not known.

Prevalence

- The prevalence of allergic contact dermatitis increases with age.
- Contact dermatitis can occur at any age but is relatively uncommon in infants.
- Infants are more likely to develop an irritant contact dermatitis.
- In children, the overall prevalence of allergic contact dermatitis is ~20%.

RISK FACTORS

- Susceptibility to certain contact allergens for delayed-type hypersensitivity is in part genetically determined.
- It is unclear whether atopic dermatitis is associated with an increased risk of developing contact dermatitis.
- Increased exposure to potential irritants and allergens and the chronic or intermittent development of an impaired skin barrier are predisposing factors.

GENERAL PREVENTION

Minimize contact exposure to known or potential irritants and allergens.

PATHOPHYSIOLOGY

- Allergic contact dermatitis requires initial exposure and sensitization to an allergen and only occurs in susceptible individuals. Repeated exposure to the allergen leads to the development of a T-cell-mediated delayed-type (type IV) hypersensitivity reaction.
- Irritant contact dermatitis does not involve an immunologic response and can occur in anyone, even after the 1st exposure to the irritant. It commonly results from frequent or chronic exposure to moisture and/or friction such as from water, saliva, or urine or to acidic or alkaline chemicals such as soaps and detergents.
- Both processes result in nonspecific findings of dermal and epidermal edema and inflammation and may be indistinguishable from other forms of eczematous dermatitis.

ETIOLOGY

- Irritant contact dermatitis:
 - Frequent handwashing or water immersion
 - Soaps and detergents
 - Saliva (lip licking)
 - Urine and feces (diaper dermatitis)
- Allergic contact dermatitis:
 - Nickel and other metals (cobalt, chromate)
 - Rubber/elastic (Thiuram)
 - Fragrances (e.g., Balsam of Peru)
 - Clothing dyes
 - Formaldehydes and formaldehyde-releasing products
 - Lanolin (wool alcohol)
 - Topical antibiotics (neomycin, bacitracin)
 - Rubber and rubber accelerators
 - Plants (*Toxicodendron* species, e.g., poison ivy, poison oak, and poison sumac, which contain the allergen urushiol)

DIAGNOSIS

HISTORY

- Patients may present with either the acute development of a pruritic inflammatory dermatitis or with the chronic persistence of a localized, mildly pruritic dermatitis.
- Many patients are unable to associate a specific allergen with the development of symptoms. With regard to acute allergic contact dermatitis, this is often due to the latency between the exposure and the development of symptoms (usually 48–72 hours but occasionally as long as several days).
- Patients with either an irritant contact dermatitis or a chronic contact dermatitis should be asked about all chemicals and other potential contact irritants or allergens to which they are intermittently or frequently exposed.

PHYSICAL EXAM

- Acute allergic contact dermatitis manifests as erythematous edematous papules and plaques, often with vesicles and crusting.
- Chronic allergic contact dermatitis manifests as erythematous and often hyperpigmented patches and plaques, usually with lichenification (accentuation of skin markings) as a result of chronic rubbing.
- Irritant contact dermatitis more commonly manifests as erythematous papules and patches with less prominent edema, vesiculation, and crusting.
- The morphology of contact dermatitis commonly consists of geometric, angulated, or asymmetric lesions that correlate with the pattern of allergen exposure.
- The distribution of the dermatitis may suggest particular allergens, such as the dorsum of the feet (shoe rubber) or earlobes and/or periumbilical area (nickel).
- In older children a perioral rash often signifies an irritant contact dermatitis from lip licking.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

In general, routine laboratory testing is not helpful in confirming the diagnosis of contact dermatitis.

Diagnostic Procedures/Other

Formal epicutaneous patch testing to evaluate suspected contact allergens may be performed by a dermatologist or allergist. The patch test involves the controlled exposure of multiple allergens to the skin. Positive reactions manifest with the development of erythema, edema, and vesicles at the site of exposure, usually within 48–96 hours. It may be performed using a standard panel of allergens (the T.R.U.E. Test) or by the application of selected allergens at the discretion of the specialist.

Pathological Findings

- Skin biopsy findings may not be specific and often overlap with other eczematous dermatoses.
- Acute contact dermatitis shows edema of the epidermis and dermis with a mixed inflammatory infiltrate. There may be intraepidermal vesicles and a prominence of eosinophils in the dermal inflammatory infiltrate.
- Chronic contact dermatitis usually shows prominent hyperkeratosis (thickening) of the stratum corneum and epidermal rete ridges with minimal edema. A sparse inflammatory infiltrate may be present.

DIFFERENTIAL DIAGNOSIS

- Infection:
 - Impetigo and cellulitis: Bacterial infections of the skin, usually caused by *Staphylococcus aureus* or group A *Streptococcus*, may manifest as erythematous, edematous crusted patches and plaques. Pustules and/or deep-seated inflammatory nodules may also be present. Infection is usually associated more with pain and tenderness than with pruritus.
 - Scabies: Intensely pruritic papules and nodules with a predilection for the hands and feet (especially the web spaces), the axillae, and the groin. There are often multiple affected family members.
- Neoplastic:
 - Langerhans cell histiocytosis: The skin manifestations may present as scaling red-brown papules and petechial macules that favor the scalp and the intertriginous areas, including the diaper area. Affected infants and children may also manifest gingival inflammation, hepatosplenomegaly, and adenopathy.
- Metabolic:
 - Acrodermatitis enteropathica: A genetic or acquired deficiency of zinc that usually presents with characteristic bullae and erosions involving the hands and feet and periorificial areas (perioral, periorcular, and perineal). These patients also develop failure to thrive, diarrhea, and alopecia.

- Immunologic:
 - Atopic dermatitis: Infantile atopic dermatitis usually begins within the 1st 6 months of life. It may favor the face and extremities or occur more diffusely with truncal involvement but usually spares the diaper area and the perinasal and periocular areas. It is associated with erythematous, excoriated, and crusted papules, patches, and plaques and with chronic pruritus, which is often worse at night. Atopic dermatitis is often accompanied by a personal or family history of atopy (reactive airways disease and/or allergic rhinitis).
 - Seborrheic dermatitis: Usually affects infants <1 year of age or adolescents. It manifests as erythema and greasy scaling patches that favor the scalp, face, ears, and intertriginous areas. It is usually asymptomatic.
 - Nummular eczema: A chronic, often intensely inflammatory and pruritic dermatitis that presents with multiple round, crusted, edematous, erythematous patches and plaques. Lesions often favor the extremities.
 - Psoriasis vulgaris: A chronic dermatitis that presents with recurrent well-defined erythematous plaques with silvery scale. Commonly affected areas include the scalp, elbows, knees, and genital regions.

TREATMENT

MEDICATION (DRUGS)

First Line

- Topical corticosteroids help with the pruritus and inflammation associated with both acute and chronic contact dermatitis. Use of a medium- to high-potency topical corticosteroid (class 2–4) for a short duration (1–2 weeks) is usually more effective than prolonged treatment with low-potency topical corticosteroids. The use of medium- to high-potency fluorinated topical corticosteroids should be avoided on the face, axillae, and groin. The skin of these areas is thinner and more susceptible to side effects. A low-potency topical corticosteroid such as hydrocortisone (class 6–7) should be used instead.
- Systemic antihistamines are generally not necessary for treating contact dermatitis, but can be considered if pruritus is extreme. The use of topical antihistamines is not recommended.
- In severe cases involving a large body surface area or associated with significant facial edema, a short course (14–21 days) of systemic corticosteroids may be appropriate, with tapering over 1–2 weeks to avoid a rebound of the dermatitis.

Second Line

The intermittent use of a topical calcineurin inhibitor such as tacrolimus ointment or pimecrolimus cream, which have anti-inflammatory and steroid-sparing properties, may be considered as adjunctive therapy in patients with chronic contact dermatitis.

ADDITIONAL TREATMENT

General Measures

- The most effective treatment involves identification and elimination of the offending allergens or exposures. This often requires extensive education of the patient and family regarding potential sources of exposure.
- Mild cases of acute contact dermatitis may not require treatment and will resolve within 1–2 weeks.
- Moderate to severe cases of acute contact dermatitis and most cases of chronic contact dermatitis often require treatment to reduce symptoms and hasten resolution.
- Prompt bathing with soap and water immediately after exposure to poison ivy, poison oak, or poison sumac may help to reduce exposure to the allergen in susceptible individuals. Zanol is an OTC cleanser that reportedly binds to and eliminates the urushiol allergen from the skin if used immediately after contact with poison ivy, poison oak, and poison sumac.
- Acute allergic contact dermatitis: Application of cool compresses and shake lotions with drying properties (i.e., Caladryl) can be helpful. Products containing colloidal oatmeal, such as Aveeno oatmeal bath and Aveeno lotion, may also be helpful in soothing inflamed skin.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Follow-up depends on the severity of the dermatitis and elimination of continued exposure to the allergen.
- Patients who do not improve after 1–2 weeks of therapy should be re-evaluated.

PATIENT EDUCATION

- Prevention:
 - Patients should be instructed on allergen avoidance, including the use of protective gloves and clothing where appropriate.
 - Ivy Block contains quaternium-18 bentonite (bentoquatam 5%), a barrier lotion that prevents exposure to the allergen in poison ivy if applied prior to anticipated exposure.

PROGNOSIS

Complete resolution can be expected after appropriate treatment and elimination of further exposure to the allergen.

COMPLICATIONS

Generally, there are no long-term complications, although secondary bacterial infections may occur.

CODES

ICD9

692.9 Contact dermatitis and other eczema (unspecified cause)

ICD10

- L23.9 Allergic contact dermatitis, unspecified cause
- L24.9 Irritant contact dermatitis, unspecified cause
- L25.9 Unspecified contact dermatitis, unspecified cause

FAQ

- Q: Can the fluid from blisters caused by poison ivy spread the rash to other parts of the body?
- A: The contents of the vesicles and bullae from rhus dermatitis are not contagious. After exposure to poison ivy is eliminated, new lesions appear because of the variable sensitivity of various areas of the body to the allergen.
- Q: After making lemonade at a picnic on the beach, my child developed a red, blistering rash on his face. What was the cause?
- A: A phototoxic form of contact dermatitis can result from exposure to plant compounds (psoralens) and ultraviolet light (sunlight). The condition is called phytophotodermatitis, and the plants that can cause this include lime and lemons, celery, dill, parsnip, and carrot juices.
- Q: Is it possible to avoid contact dermatitis using protective clothing or skin barrier creams?
- A: Yes. Proper-fitting protective gloves and clothing are a highly effective means of decreasing irritant exposure. However, gloves permeable to irritants such as organic solvents may increase the exposure to the irritant. Some contact allergens can also permeate rubber gloves, which therefore are of no benefit. Rubber gloves are contraindicated in individuals with immediate and delayed-type allergy to latex and rubber additives. With the exception of Ivy Block lotion, the use of barrier creams in the prevention of contact dermatitis is not effective.
- Q: How does saliva cause a perioral rash in some kids? Is there something unusual in the saliva that is causing this?
- A: “Lip-licker dermatitis” is an irritant dermatitis that results from chronic and/or excessive exposure to moisture. It is not caused by any specific substances in the saliva.

CONTRACEPTION

Molly J. Richards

Daniel H. Reirden

BASICS

DESCRIPTION

The prevention of conception or pregnancy. The “ideal” contraceptive is 100% effective, has no side effects, can easily be reversed, and can easily be used by adolescents.

Contraceptive types

- Abstinence: Refraining from intercourse
 - Most effective way to prevent transmission of HIV, viral hepatitis, human papilloma virus (HPV), herpes simplex virus (HSV), syphilis, *Neisseria gonorrhoeae*, and *Chlamydia trachomatis*
- Barrier methods to sperm entry (male and female condoms, diaphragm):
 - Male condoms: 85% effective with typical use. The female condom and diaphragm with spermicide are 79% and 84% effective, respectively.
 - Proper use of the male and female condoms can prevent transmission of HIV, HPV, HSV, syphilis, *N. gonorrhoeae*, and *C. trachomatis*.
- Spermicidal agents (foam, film, vaginal inserts):
 - Nonoxynal-9 is the active agent most widely used.
 - 73% effective in preventing pregnancy with typical use
 - Reduced transmission of *C. trachomatis* and *N. gonorrhoeae*
 - Spermicides used with condoms will increase overall efficacy to 93% with typical use.
- Hormonal agents (oral contraceptive pills, transdermal patch, vaginal ring, and emergency contraception [EC]):
 - Oral contraceptive pills: Include combination estrogen and progestin pills (COC) and the progestin-only pill (POP)
 - Monophasic COCs contain a fixed dose of estrogen and progestin, whereas phasic COCs may vary the doses of estrogen, progestin, or both.

- COC pills are 94.5–97% effective in preventing pregnancy with typical use (99.9% effective with perfect use) and have been shown to reduce the incidence of endometrial and ovarian cancers after as little as 3 months of use, protect against salpingitis (PID) and subsequent ectopic pregnancies, and decrease incidence of benign breast disease and dysmenorrhea. They are used effectively to treat problems including dysfunctional uterine bleeding and polycystic ovary syndrome.
- The POP contains progesterone only. It is sometimes referred to as the “mini-pill.” Effectiveness is highly dependent on perfect use.
- Transdermal patch: Contains ethinyl estradiol and norelgestromin. Each patch is left in place for 7 days and changed weekly, allowing 1 patch-free week per month to allow menses to occur; efficacy is comparable to that of oral contraceptive pills; convenient due to once-weekly change; may be less effective in women weighing >90 kg
- Vaginal ring: A soft, flexible, polymer ring containing ethinyl estradiol and etonogestrel that is inserted into the vagina for 3 weeks and then removed for 1 week to allow menses to occur; benefits include once-a-month insertion, avoidance of 1st-pass liver effects, and lower hormone doses.
- EC: Also called postcoital contraception; safe method of contraception that employs either COCs or POPs:
 - COC pills can reduce the risk of pregnancy by 75% after unprotected intercourse, if taken in correct doses within 72 hours.
 - The progesterone-only method may reduce the risk of pregnancy by 88%; although most effective when used within 72 hours of intercourse, some data suggest that treatment is effective up to 5 days after unprotected intercourse.

- Long-acting reversible contraceptive methods:
 - Depo-medroxyprogesterone acetate (Depo-Provera): Effective contraceptive administered IM once every 3 months
 - Etonogestrel implant: Single rod subdermal implant containing 68 mg of progestin etonogestrel providing contraception for up to 3 years. Benefits include long-term pregnancy prevention with little effort needed for compliance and high efficiency rates. May also decrease dysmenorrhea
 - Levonorgestrel-releasing intrauterine device (IUD): T-shaped polyethylene intrauterine device containing 52 mg of levonorgestrel. FDA approved for use for up to 5 years but may be effective up to 7 years. The annual failure rate is 0.1%. Has been shown to significantly reduce menstrual bleeding and dysmenorrhea
 - Copper T380 IUD: Contraceptive effect related to in utero oxidation with release of copper ions. The annual failure rate is reported to be as low as 0.8%. FDA approved for use up to 10 years but may be effective for up to 12 years

ALERT

- Advising teenagers to abstain from all forms of physical intimacy may be counterproductive in the context of their psychosocial development.
- Contraceptive use may lead to patients’ discontinuing use of condoms. Providers should emphasize at every visit that only condoms protect against sexually transmitted diseases.

GENERAL PREVENTION

- Encourage the consistent use of latex condoms.
- Patients using oral contraceptive pills must be strongly encouraged to cease tobacco use. Methods of treating nicotine dependence should be employed if indicated.

PATHOPHYSIOLOGY

- The spermicides nonoxynol-9 and octoxynol-9 act by destroying sperm cell membranes.
- Most spermicidal preparations contain an inert base (foam, cream, or jelly) to support the spermicidal agent and provide a barrier to sperm entry.
- Hormonal therapy suppresses ovulation by directly decreasing release of gonadotropin-releasing hormone (GnRH) from the hypothalamus and follicle-stimulating hormone (FSH) and luteinizing hormone (LH) from the pituitary gland.
- Progesterone causes thickening of the cervical mucus, thinning of the endometrium, and decreased tubal motility.
- Copper: Copper ions may inhibit transtubal sperm migration, thus preventing zygote formation.
- EC: Mechanisms of action include disruption of ovulation, impairment of the endometrium to prevent implantation, and possibly alteration of sperm or ova transport.

 **DIAGNOSIS**

HISTORY

General considerations in method selection include:

- What is the teen’s sexual history?
- Is sexual activity spontaneous or planned?
- Does the patient feel that she or he can be compliant with a daily pill or barrier methods?
- Does the patient require absolute confidentiality?
- Is the patient comfortable inserting a diaphragm or applying a condom?
- Does the patient have open communication with his or her partner?
- Does the patient desire pregnancy? Does his or her partner?
- Are there any other barriers to compliance with the chosen contraceptive method?

PHYSICAL EXAM

- Obtain baseline weight and BP.
- It is not necessary to perform a pelvic exam on young women initiating hormonal contraception. Biannual screening for STIs and regular Papanicolaou smears beginning at 21 years of age should be recommended.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Pregnancy test prior to initiating hormonal contraceptives

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Barrier methods: Trained personnel can teach the proper technique for application of the diaphragm and male and female condoms.
- Spermicides:
 - These must be inserted near the time of intercourse; some formulations require 10–15 minutes for activation, and most have an unpleasant taste.
 - Trained office personnel can teach the proper technique for insertion.
- Oral contraceptive pills:
 - Monthly packages of oral contraceptive pills contain 3 weeks of hormone, followed by 1 week of placebo or a pill-free interval.
 - Menstruation begins after 2–3 days of placebo.
 - Oral contraceptive pills are taken as a daily pill, preferably at the same time every day (to minimize nausea, some users find bedtime helpful).
 - The optimal time to start oral contraceptive pills is within 5 days after the start of the menstrual period. A “same-day” start method may be used to promote immediate use of pills provided the young woman is not pregnant at the visit.

- Oral contraceptive pills may not offer protection during the 1st cycle; therefore, a back-up barrier method should be used. Instructions for missed pills should be explained and given to all adolescents initiating oral contraceptive pills.
- Fertility returns, on average, 2–3 months after discontinuation. 1–2% of patients will experience a delay in fertility for up to 1 year.
- EC: 3 types of EC are available in the US: COCs (also known as the Yuzpe regimen), POPs, and the copper-releasing IUD:
 - The Yuzpe regimen is safe and well studied. It consists of two doses of COCs containing at least 100 mcg of estrogen with 0.5 mg of levonorgestrel each. The 2 doses should be taken 12 hours apart and within 72 hours of unprotected intercourse.
 - This dose of estrogen will often cause nausea and vomiting; therefore, pretreatment with an antiemetic, such as meclizine, is recommended.
 - POP methods: Only levonorgestrel has been studied as a nonestrogen-containing EC.
 - Plan B: Contains 0.75 mg of levonorgestrel per tablet and, although initially approved as 2 doses separated by 12 hours, subsequent studies have confirmed efficacy with both pills being taken at the same time (1.5 mg total dose). Additional studies have indicated efficacy up to 5 days after the unprotected coitus.
 - The FDA recently approved Plan B for over-the-counter status for women aged ≥17 years. Adolescents <17 years will still require a prescription.
- Long-acting reversible contraceptive methods:
 - Depo-Provera is given IM in the deltoid or gluteus maximus muscle:
 - Each injection has a 12-week duration and must be repeated every 12 weeks to ensure protection against pregnancy.
 - The initial injection is optimally given within 5 days after the start of the last menstrual period or when the provider can be reasonably assured that the patient is not pregnant.
 - Fertility (and ovulatory cycles) should return within 6 months of the last injection.

- Etonogestrel implant is inserted subdermally in the medial aspect of the nondominant arm 6–8 cm above the elbow. Training is required for insertion:
 - Implant provides contraception for up to 3 years.
 - Insertion should be scheduled when one can be as certain as possible that the adolescent is not pregnant.
 - Implant will offer contraceptive protection immediately if inserted at right time of cycle.
- Most adolescents (more than 90%) ovulate within 3–4 weeks of removal of implant.
- Levonorgestrel and Copper T380 IUDs are inserted into the uterus during an office pelvic exam by a trained provider:
 - Insertion should be scheduled when one can be as certain as possible that the adolescent is not pregnant; this is best achieved during the 5 days after the start of the last menstrual period or when switching from another effective hormonal contraceptive method.
 - Discomfort during IUD insertion is common, with 86% of adolescents reporting mild to severe pain with insertion.
 - Return to fertility is rapid following removal of either intrauterine device.

ALERT

Drug interactions:

- Drugs that activate the cytochrome P-450 enzyme will diminish the efficacy of hormonal contraceptives. This is of greatest concern with low-dose preparations and can be remedied by using higher doses.
- Drugs that diminish hormonal contraceptive effects include phenobarbital, carbamazepine, primidone, rifampin, griseofulvin, HIV protease inhibitors, and tetracyclines (including doxycycline). Hormonal contraceptives can increase levels of phenytoins, benzodiazepines, antidepressants, corticosteroids, β -blockers, theophylline, and alcohol. Hormonal contraceptives can decrease the efficacy of acetaminophen, oral anticoagulants, hypoglycemics, and methyldopa.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Patients using hormonal contraceptives should be seen within 6 weeks to 2 months of initiation, to evaluate compliance and side effects.
- BP should be monitored at every visit.

PROGNOSIS

- Within 3 months of oral contraceptive pill use, only 44–45% of patients remain compliant.
- After 1 year, only 33% are compliant.

COMPLICATIONS

- Barrier methods:
 - Latex allergy: Patients may use polyurethane rather than latex condoms.
 - Breakage or permeability: Oil-based lubricants and most intravaginal medications used with latex condoms will increase the risks of these complications. Animal skin condoms are permeable to viral pathogens.
 - Irritation, UTIs, and toxic shock syndrome (if the diaphragm is left in place longer than 24 hours) may be seen with diaphragm use.
- Spermicides:
 - Local irritation or allergic reaction
 - May increase the risk of HIV infection in adolescents with high-risk sexual partners
- Hormonal contraceptives:
 - Mortality from gynecologic and related causes was 7/100,000 in 15–19-year-old adolescents per year. If no fertility control measures were used, the mortality is 0.3/100,000 in nonsmoking oral contraceptive pill users and 2.2/100,000 in smoking oral contraceptive pill users.
 - Minor side effects of COC pills include menstrual spotting, nausea, breast changes, fluid retention, leukorrhea, minor headache, and depression.
 - Thromboembolic events and liver disease are extremely rare in nonsmoking adolescents using estrogen-containing oral contraceptive pills.
 - Contraindications to COC pills include history of thromboembolic event, structural heart disease, breast cancer, pregnancy, active liver disease, migraine headaches with an aura, prolonged immobilization, or severe hypertension. Caution should be taken when prescribing COC pills to adolescents with undiagnosed abnormal uterine bleeding, those <6 weeks postpartum, those who use medications that affect liver enzymes, and those with gallbladder disease.

- Minor side effects of POPs include weight gain, rapid hair turnover, and menstrual irregularities.
- Depo-medroxyprogesterone acetate has been shown to reduce bone mineral density in several studies. Because adolescence is the period of peak bone mass accretion, there is concern that its use during adolescence may increase the risk for osteopenia or osteoporosis later in life. Until more studies are available, it is probably advisable to avoid its use in those adolescents at high risk for osteoporosis, such as adolescents with anorexia nervosa or chronic renal failure.
- Nausea and/or vomiting occur in most patients using estrogen-based EC or “doubling up” on oral contraceptive pills.
- Most common side effect reported with etonogestrel implant is abnormal bleeding. A wide range of bleeding patterns may be experienced and it is not possible to predict the bleeding pattern for any individual.
- Overall, in the 90-day reference periods of clinical trial experience, 33.3% had infrequent bleeding, 21.4% had amenorrhea, 6.1% had frequent bleeding, and 16.9% had prolonged bleeding.
- The lower androgenic effect of etonogestrel may make side effects of acne and weight gain less frequent than with other progestins.
- Contraindications to IUD placement are those who are pregnant or suspected to be pregnant; have PID, either currently or in the past 3 months; have puerperal or postabortion sepsis (currently or in past 3 months); or have undiagnosed abnormal vaginal bleeding, malignancy of the genital tract, uterine abnormalities that distort the uterine cavity, an allergy to any component of IUDs, or Wilson disease (for the Copper T IUD only).

- Intrauterine devices have been associated with a slightly higher risk of PID within the 1st 20 days after insertion, especially if cervical infection is present. IUDs do not increase risk of PID above baseline after this time.
- Younger age may confer an increased risk of IUD failure from expulsion because of smaller uterus and higher incidence of nulliparity.
- The Copper T IUD has been associated with increased menstrual bleeding and spotting, especially in 1st 3–6 months after insertion. In addition, some women may experience menstrual pain and heavy bleeding throughout use.

CODES

ICD9

- V25.8 Other specified contraceptive management
- V25.09 Other general counseling and advice on contraceptive management
- V25.9 Unspecified contraceptive management

ICD10

- Z30.8 Encounter for other contraceptive management
- Z30.09 Encounter for other general counseling and advice on contraception
- Z30.9 Encounter for contraceptive management, unspecified

FAQ

- Q: My patient asks for confidentiality regarding contraception. Should I comply?
- A: Yes. Teenagers have the right to confidentiality regarding contraception and treatment of STDs. Every state has a law or provision for confidential access to contraceptive services. Importantly, it may be in the patient’s best interest to have a caring adult involved. Which adult and how he or she is involved should be negotiated with the adolescent.
- Q: One of my patients has asked me to prescribe EC in advance for her. Is this something that I should do?
- A: Studies done thus far have shown that use of EC is safe. In fact, there are no absolute contraindications to using progestin-only EC. Because unprotected sexual encounters often take place at a time when adolescents do not have access to their health care providers (e.g., evenings or weekends), advanced prescription is of benefit for many adolescents.
- Q: What should I tell my patient if she misses a dose of her oral contraceptive?
- A: If she has missed 1 pill, she should take it as soon as she remembers, then take the next pill at the regular time. If she has missed 2 doses, she should take 2 when she remembers, and then 2 the next day. She should use a back-up method during the cycle in which she had to “double up.” If she has missed 3 or more pills, she will probably menstruate. After discarding the last pack, she should start a new pack on the 1st Sunday after the start of her next period. She is not protected during the remainder of this cycle.

COR PULMONALE

Brian D. Hanna

Heather L. Meluskey

BASICS

DESCRIPTION

- Cor pulmonale is right ventricular (RV) failure secondary to an altered pulmonary process that results in a loss of functional capillary vascular bed and in excessive pulmonary artery pressure and pulmonary vascular resistance (PVR).
- Cor pulmonale is not the result of a primary congenital heart defect.

ALERT

- In newborns, the RV muscle mass is comparable to that of the left ventricle.
- RV failure from pulmonary hypertension (PH) occurs but is rare in newborns.
- RV failure in newborns is usually a consequence of hypoxemia, ischemia, metabolic acidosis (e.g., persistent fetal circulation), and/or premature restriction/closure of the intrauterine ductus arteriosus.

EPIDEMIOLOGY

- Cor pulmonale may be found at any age but is typically a result of a long-standing pulmonary process. However, severe bronchopulmonary dysplasia (BPD) is an increasingly common cause of neonatal PH.
- Primary pulmonary hypertension (PPHN) is most often diagnosed in the 2nd or 3rd decade of life with a female predominance, and it is often diagnosed during pregnancy.

Incidence

- PPHN has a yearly incidence of 2 per million.
- The incidence of cor pulmonale is dependent on the severity of the underlying lung pathology.

Prevalence

- Upwards of 2/1,000 neonatal intensive care unit patients will develop significant cor pulmonale.
- 2% of infants undergoing cardiac surgery will have PH, with an associated mortality of 10–20%.

RISK FACTORS

Genetics

- Pediatric patients with trisomy syndromes are at high risk for PH.
- Familial PH has been mapped to chromosome 2q32, but this is less frequently found in patients with secondary etiologies of PH.
- Region 2q32 point mutations encode for a defective bone morphogenetic receptor 2, a pulmonary vascular smooth muscle receptor that mediates proliferation.

PATHOPHYSIOLOGY

- Chronic hypoxia is the principal factor, resulting in a cascade of endothelial dysfunction with pulmonary vasoconstriction, followed by the development of PH.
- A variety of vasoactive mediators may be responsible for the effect on vasomotor tone.
- Alveolar hypoventilation, hypoxemia, hypercarbia, and/or acidemia all result in increased RV afterload and decreased RV systolic function.

ETIOLOGY

- Parenchymal lung disease (most common)
- Chronic obstructive pulmonary disease:
 - Cystic fibrosis
 - Asthma
- Restrictive lung disease:
 - Infectious
 - Pulmonary toxins
 - Pulmonary fibrosis
 - Bronchopulmonary dysplasia (combined)
- Upper airway diseases: Tonsillar/adenoidal hypertrophy
- Syndromes (Down, Treacher Collins)
- Neuromuscular disorders: Duchenne muscular dystrophy
- Chest wall deformities

COMMONLY ASSOCIATED CONDITIONS

- Pulmonary vascular abnormalities
- Collagen vascular diseases
- Pulmonary veno-occlusive disease
- Pulmonary thromboembolism
- PPHN

DIAGNOSIS

HISTORY

- Fatigue
- Failure to thrive/weight loss
- Dizziness
- Syncope
- Exercise intolerance
- Chest pain (secondary to RV ischemia)
- Palpitations
- Hemoptysis

ALERT

Hemoptysis is a life-threatening emergency and heralds a poor prognosis for any patient with PH.

PHYSICAL EXAM

- Tachycardia
- Parasternal RV impulse
- Cyanosis may be evident.
- Hepatomegaly, jugular venous distention, peripheral edema
- A loud, narrowly split or single 2nd heart sound (P₂), RV gallop, holosystolic murmur right of the sternum (tricuspid regurgitation), and/or diastolic murmur at the left upper sternal border (pulmonary insufficiency)

ALERT

In the newborn period to puberty, an abnormally increased RV impulse is best felt under the xiphoid sternum.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Brain-type natriuretic peptide is an excellent biomarker of RV diastolic dysfunction and is elevated with worsening cor pulmonale.
- Decreased PaO₂, increased PaCO₂, and a compensatory metabolic alkalosis
- Polycythemia may be consistent with chronic hypoxemia.

Imaging

- Chest radiograph: Cardiomegaly from RV dilation and main pulmonary artery enlargement
- Echo: RV dilation, RV hypertrophy, pulmonic insufficiency, and RV pressure estimate from tricuspid regurgitation and/or intraventricular septal position
- V/Q scan is beneficial to rule out thromboembolic disease.

Diagnostic Procedures/Other

- ECG: May show right atrial enlargement, RV hypertrophy, and T-wave inversion
- 6-minute walk: Measures functional capacity and limitations
- Cardiac catheterization, although invasive, remains the gold standard.
- Lung biopsy is usually contraindicated in the face of PH and significant lung disease.

Pathological Findings

- Vascular lesions (plexiform lesions)
- Parenchymal fibrotic lesions
- Concentric and eccentric remodeling

DIFFERENTIAL DIAGNOSIS

- Congenital heart disease with PH and right-to-left shunt (Eisenmenger syndrome)
- Obstruction of pulmonary venous return, both anatomic obstruction and left ventricular failure
- Pulmonary veno-occlusive disease
- Alveolar capillary dysplasia

**TREATMENT****MEDICATION (DRUGS)****First Line**

- Oxygen to keep saturations >90%
- Anticongestive medications (digoxin, diuretics)

Second Line

Vasodilator therapy with care not to worsen the intrapulmonary shunt

ADDITIONAL TREATMENT**General Measures**

- The primary goal is reduction of the abnormally elevated pulmonary artery pressure and the RV workload.
- If at all possible, address the primary etiology (i.e., tonsillectomy/adenoidectomy in a patient with obstructive upper airway disease).
- Fluid boluses are poorly tolerated and rarely augment systemic BP.
- Oxygen (nocturnal oxygen)
- Diuretics (if pulmonary congestion)
- Bronchodilators (theophylline)
- Digoxin (may improve RV contractility)
- Anticoagulants

- Pulmonary vasodilators:
 - Nitric oxide
 - Calcium channel blockers (only if > 1-year-old and cardiac output is not compromised)
 - Phosphodiesterase-5 inhibitors
 - Endothelin receptor antagonists
 - Prostanoid
- Atrial septostomy (in select cases, may improve cardiac output but at the expense of hypoxemia)
- Lung or heart–lung transplantation
- Usually self-limited activity
- No competitive sports
- Arginine, a nitric oxide donor, has been used; however, the increased amino acid concentrations are proliferative and may worsen the long-term prognosis.

SURGERY/OTHER PROCEDURES

Consider tracheostomy, Nissen fundoplication, and G-tube early

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

Home oxygen saturation monitoring is indicated when night O₂ is necessary to keep saturations >90%.

PROGNOSIS

- Patients with reversible lung disease usually have a better prognosis.
- Patients with cor pulmonale are at risk for sudden death because of the inability to augment cardiac output with exercise, growth, or febrile illnesses.
- Numerous medical therapies and lung transplantation may improve long-term survival.
- Long-term survival is variable and depends on the age at onset of pulmonary changes and the underlying conditions (e.g., Down syndrome) that may adversely affect survival.
- Death often occurs in the 2nd or 3rd decade of life.

COMPLICATIONS

Aside from the underlying lung process, the chronic hypoxia results in polycythemia, decreased systemic oxygen delivery, and RV failure secondary to the inability of the RV to handle the excessive afterload.

**CODES****ICD9**

- 415.0 Acute cor pulmonale
- 416.9 Chronic pulmonary heart disease, unspecified

ICD10

- I26.09 Other pulmonary embolism with acute cor pulmonale
- I27.81 Cor pulmonale (chronic)

FAQ

- Q: Is cardiac catheterization indicated in all patients with cor pulmonale?
- A: Yes. Although a great deal of information can be learned from echocardiogram, direct pulmonary artery pressure/resistance measurements require an invasive procedure. In addition, assessment of the reactivity of the pulmonary vascular bed to various agents (oxygen, prostacyclin, and calcium channel blockers) is best performed in the catheterization laboratory.
- Q: Is nocturnal oxygen therapy beneficial?
- A: Nocturnal oxygen has been speculated to delay the progression of cor pulmonale in some select patients with obstructive sleep hypoxemia.

COSTOCHONDRITIS

Richard M. Kravitz

BASICS

DESCRIPTION

Costochondritis is chest pain that emanates from a costal cartilage and is reproducible on compression of that cartilage.

ALERT

- Inflammatory costochondritis:
 - Important cause of school absence
 - Adolescents tend to limit physical activity unnecessarily for long periods.
 - Restriction of activities is usually not required.
 - Most adolescents still worry about cardiac problems, even after the diagnosis has been made.
- Infectious costochondritis:
 - Long-term IV antibiotics alone do not resolve the problem; surgical resection and repair also are required.
 - There is a tendency for the infection to spread to adjacent costal cartilages and across the sternum to the contralateral chest wall.
 - In general, avoid costochondral junctions when performing surgical procedures in the chest (i.e., chest-tube placement).

EPIDEMIOLOGY

Incidence

Incidence of sternal wound infections following median sternotomy is 0.1–1.6%.

Prevalence

- Costochondritis accounts for 10–31% of all pediatric chest pain.
- Peak age for chest pain in children is 12–14 years.

PATHOPHYSIOLOGY

- Inflammation of unknown etiology (histologic examination is usually normal)
- Infection:
 - Can present months to years after surgery (the costal cartilage is avascular, making it vulnerable to infection if it has been exposed, injured, or denuded of perichondrium)
 - Complication of median sternotomy
 - Occurs by spread from adjacent osteomyelitis or may arise de novo during surgery

ETIOLOGY

- Infectious:
 - Bacterial:
 - *Staphylococcus aureus* (especially after thoracic surgery)
 - *Salmonella* (in sickle cell disease)
 - *Escherichia coli*
 - *Pseudomonas* sp.
 - *Klebsiella* sp.
 - Fungal:
 - *Aspergillus flavus*
 - *Candida albicans*
- Posttraumatic injury

DIAGNOSIS

HISTORY

- Inflammatory costochondritis:
 - Pain usually preceded by exercise or an upper respiratory tract infection
 - Description of pain:
 - Usually sharp
 - Affects the anterior chest wall
 - Localized or radiates to the back or abdomen
 - Usually unilateral (left side greater than right side)
 - The 4th to 6th costochondral junction is the usual site of pain.
 - Motion of the arm and shoulder on the affected side elicits the pain.
 - Girls are affected more often than are boys.
- Tietze syndrome:
 - Onset is usually abrupt, but can be gradual.
 - Believed to be caused by a minor trauma, though etiology is unknown
 - Description of pain:
 - Radiates to arms or shoulder
 - May last up to several weeks
 - Swelling at the sternochondral junction may persist for several months to years
 - Usually affects the 2nd or 3rd costochondral joint
 - Pain is aggravated by sneezing, coughing, deep inspiration, or twisting motions of the chest
 - No differences in frequency between sexes
- Infectious costochondritis:
 - Slow, insidious course
 - Usually unimpressive clinical symptomatology

PHYSICAL EXAM

- Usually normal
- Inspect for evidence of trauma, scars, bruising, and swelling
- Palpation and percussion of the costochondral and costosternal junctions should reproduce and localize the pain.
- In Tietze syndrome, spindle-shaped swelling is visible at the sternochondral junction.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- WBC count not helpful (even when infection present)
- EKG (may be helpful if cardiac etiology is being considered)

Imaging

- Radiologic studies (chest x-ray, CT) usually not helpful
- Gallium scan:
 - May be useful in some cases of infectious origin
 - Not highly specific
 - May show increased radionuclide uptake
 - No evidence of osteomyelitis of the sternum in most cases
- Technetium bone scan:
 - Not highly specific

DIFFERENTIAL DIAGNOSIS

- Cardiovascular:
 - Myocardial infarction
 - Pericarditis
 - Pericardial effusion
 - Myocarditis
 - Endocarditis
 - Cardiomyopathy
 - Premature ventricular contractions
 - Supraventricular tachycardia
 - Dissecting aneurysm
- Pulmonary:
 - Asthma
 - Exercise-induced bronchospasm
 - Pneumonia
 - Pleural effusion
 - Pneumothorax
 - Pulmonary embolism

- GI:
 - Gastroesophageal reflux
 - Esophagitis
 - Gastritis
 - Achalasia
- Mechanical:
 - Muscle strain
 - Stress fractures
 - Precordial catch syndrome
 - Trauma
- Rheumatologic:
 - Rheumatoid arthritis
 - Ankylosing spondylitis
- Oncologic:
 - Rhabdomyosarcoma
 - Leukemia
 - Ewing sarcoma
- Miscellaneous:
 - Tietze syndrome
 - Psychogenic chest pain
 - Breast tissue pain (both sexes)

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Inflammatory costochondritis:
 - Anti-inflammatory and analgesic agents
 - Reassurance
 - If pain disturbs normal activities and sports, infiltration with local anesthetic may prove useful.
- Infectious costochondritis:
 - Prolonged course of IV antibiotics
 - Prompt surgical resection of all involved cartilage
 - Reconstructive surgery with muscular flaps should be done.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Inflammatory costochondritis:
 - Long-lasting condition
 - Follow-up once a year is recommended.
- Infectious costochondritis:
 - Long-term follow-up after surgery is mandatory.

PROGNOSIS

- Inflammatory costochondritis: Excellent
- Infectious costochondritis: Prognosis relates to:
 - Underlying clinical condition of the patient (i.e., immunocompromised, postradiation therapy for cancer, postcardiac surgery)
 - Extent of surgery required to reconstruct the area damaged by the infection

CODES

ICD9

- 733.6 Tietze's disease
- 786.50 Chest pain, unspecified
- 786.59 Other chest pain

ICD10

- M94.0 Chondrocostal junction syndrome [Tietze]
- R07.89 Other chest pain
- R07.9 Chest pain, unspecified

FAQ

- Q: Am I having or will I have a heart attack?
- A: Chest pain does not imply a heart problem. This pain arises from the chest wall; there is no risk of a myocardial infarction. A cardiac etiology to chest pain in an adolescent is usually uncommon.
- Q: Is costochondritis related to arthritis?
- A: There is no relation to any form of arthritis.

COUGH

Margaret McNamara

BASICS

DEFINITION

The result of a high-velocity expiration, which removes airway secretions, is generally reflexive, but may sometimes be voluntarily initiated or suppressed.

EPIDEMIOLOGY

Cough is the most common symptom presenting to primary care physicians in the US and worldwide, and chronic cough accounts for up to 9% of chief complaints to US pediatricians. In the US, billions of dollars are spent yearly on over-the-counter (OTC) cough and cold medications.

PATHOPHYSIOLOGY

Cough is a symptom of a variety of underlying conditions, which results from a complex reflex phenomenon initiated by cough receptors and mediated in the brainstem's cough center. These receptors are located throughout the large- to medium-sized airways (but not the lower airways), pharynx, paranasal sinuses, external auditory canal, and stomach, and are triggered by thermal, chemical, mechanical, or inflammatory stimuli. The resultant high-velocity expiration, which removes airway secretions, is generally reflexive, but may sometimes be voluntarily initiated or suppressed.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Infection and asthma are the most common causes of cough in all pediatric age groups and should always be considered.

- **Causes of acute (<2 weeks) or subacute/protracted (2–4 weeks) cough**
 - Infection
 - Reactive airway disease (RAD)
 - Sinusitis
 - Irritants
 - Allergy
 - Foreign body
- **Causes of chronic (>4 weeks) cough**
 - Infection
 - Asthma or asthmatic bronchitis
 - Sinusitis
 - Irritants (postinfectious, air pollution)
 - Allergy
 - Foreign body
 - Gastroesophageal reflux (GER)
 - Habitual or psychogenic
 - Anatomic abnormalities: Tracheoesophageal fistula, tracheobronchomalacia, laryngeal cleft, polyps, adductor vocal cord paralysis, pulmonary sequestration, bronchogenic cyst, cystic hygroma, vascular ring, tumor
 - Cystic fibrosis (CF)
 - Ciliary dyskinesia syndromes
 - Immunodeficiency states: HIV, immunoglobulin deficiencies (IgA, IgG), phagocytic defects, complement deficiency
 - Pulmonary hemosiderosis
 - Angiotensin-converting enzyme inhibitors
 - External auditory canal irritation

APPROACH TO THE PATIENT

Given the common nature of cough and the large differential diagnosis it generates, an extremely thorough history and physical exam (H&P) should direct a rational, stepwise approach. ACCP evidence-based clinical practice guidelines for evaluating chronic cough in pediatrics were published in 2006. In general, children with chronic cough should have a chest radiograph, and spirometry should be considered for children >3 years.

- Wright peak flow (WPF) rate; complete pulmonary function tests:
 - Easy to perform WPF in the primary care office with the proper flow meter
 - Helpful to get prebronchodilator and postbronchodilator rates if RAD suspected
 - Standardized tables available with values based on height and race
- Pulmonary function tests may be indicated for diagnosis as well as for assessment of severity or treatment of asthmatics.
- Mantoux test: Purified protein derivative (PPD) to rule out tuberculosis (TB).

HISTORY

- **Question:** Is the cough acute or chronic?
- **Significance:** Pediatric chronic cough is defined as daily cough that lasts for >4 weeks. Although there is significant overlap, differential diagnosis varies depending on the time course.
- **Question:** How is this problem different in children as compared with adults?
- **Significance:** Differential diagnosis varies considerably based on the patient's age.
- **Question:** Is there a recent history of upper respiratory infection (URI)?
- **Significance:** Serial URIs, the most common cause of chronic cough in children, can be diagnosed by a careful history that elucidates waxing and waning symptoms, and will avoid unnecessary tests. Children have an average of 6–8 URIs per year, with each lasting up to 2–3 weeks. Also consider postinfectious/irritative cough, or sinusitis (which complicates up to 5% of URIs). Overall, 8–12% of children with URIs develop complications.
- **Question:** What are the associated symptoms?
- **Significance:**
 - Fever, nasal discharge suggest infection.
 - Fever with chills or night sweats suggests TB; may also have weight loss with TB.
 - Sputum production indicates bronchiectasis or other lower airway pathology.
 - With rhinorrhea, halitosis, headache or facial edema, consider sinusitis.
 - With respiratory distress, suspect RAD, infection, or foreign body.
- **Question:** What is the quality of the cough?
- **Significance:**
 - Chronic wet cough suggests lower airway infection, CF, or bronchiectasis.
 - Dry cough suggests RAD, fungal infection.
 - Barking cough is usually associated with croup.
 - Honking cough is typical in psychogenic cough.
 - Brassy cough may be associated with tracheomalacia or habit cough.
 - Staccato cough suggests Chlamydia in infants.
 - Paroxysmal cough, with or without whoop, suggests pertussis, parapertussis.

- **Question:** What is the pattern of the cough?
- **Significance:**
 - Chronic nighttime cough suggests RAD.
 - With nighttime/early morning cough, consider sinusitis.
 - Seasonal cough suggests allergy.
- **Question:** Are there any known triggers of cough (e.g., smoke, cold air, dust, URI)?
- **Significance:** Consider irritant, allergy, or RAD
- **Question:** Is there any personal or familial history of atopy?
- **Significance:** Consider RAD
- **Question:** Is there a history of recurrent infections?
- **Significance:** Consider immunodeficiency, CF. Also consider pulmonary sequestration if patient has recurrent pneumonias in same location.
- **Question:** Is there any relation of cough to feedings?
- **Significance:** Consider aspiration, GER, and tracheoesophageal fistula in infants.
- **Question:** Is there a history of a choking episode?
- **Significance:** Consider retained foreign body, although there may not be a history of a choking episode in this case, and cough may be episodic as foreign body moves along respiratory tract.
- **Question:** Is there failure to thrive?
- **Significance:** Rule out TB, CF, immunodeficiency
- **Question:** What is the parental level of concern?
- **Significance:** Children's cough generates significant parental stress and concerns, and appreciation of parental worries is valuable when addressing this problem.

PHYSICAL EXAM

- Assess patient's general appearance
- **Finding:** Evidence of failure to thrive?
- **Significance:** Consider TB, CF, immunodeficiency
- **Finding:** Cyanosis or pallor?
- **Significance:** Rule out hypoxemia
- **Finding:** Signs of respiratory distress such as tachypnea, accessory muscle use?
- **Significance:** Most likely RAD or infection
- **Finding:** Barrel chest?
- **Significance:** Suggests air trapping due to chronic disease
- **Finding:** Clubbing?
- **Significance:** May be seen with bronchiectasis
- **Finding:** Nasal polyp?
- **Significance:** May be associated with allergic conditions or CF
- **Finding:** Tracheal deviation?
- **Significance:** Suggests mediastinal mass or foreign body aspiration
- **Finding:** Signs of atopic disease such as eczema, allergic shiners, transverse nasal crease, rhinitis, mucosal cobblestoning, injected conjunctivae?
- **Significance:** Suggest allergy, RAD.
- **Finding:** Rhinorrhea/purulent posterior pharyngeal drainage, sniffing, halitosis, periorbital edema, sinus tenderness?
- **Significance:** Suggest sinusitis
- **Finding:** Wheezing?
- **Significance:**
 - Polyphonic inspiratory or expiratory wheezes suggest RAD.
 - Monophonic or fixed wheezes should make one consider foreign body or mass/congenital lesion.

DIAGNOSTIC TESTS & INTERPRETATION

- Laboratory investigation should reflect a rational, stepwise approach based on likely etiologies after a thorough H&P.
- **Test:** Microbiology workup as indicated (e.g., polymerase chain reaction [PCR] for pertussis, direct fluorescent antibody [DFA] for viral panel, culture for *Chlamydia*).
- **Significance:** Aids in precise diagnosis and treatment as needed
- **Test:** Paranasal sinus CT scan
- **Significance:** Should be used judiciously to evaluate sinus disease.
- **Test:** CBC
- **Significance:** Eosinophilia suggests atopic disease or, rarely, parasitic infection; anemia should prompt one to consider chronic disease or, rarely, pulmonary hemosiderosis.
- **Test:** Sputum sample must contain alveolar macrophages to be adequate.
- **Significance:**
 - Eosinophils suggest asthmatic process or hypersensitivity reaction of lung.
 - Elevated polymorphonuclear cells suggest infection.
 - Predominance of macrophages suggests postinfectious hyper-responsive cough receptors.
 - Hemosiderin staining suggests pulmonary hemosiderosis.
 - Lipid-laden macrophages suggest recurrent aspiration.
 - Routine or special cultures based on likely pathogens
- **Test:** Serum IgE
- **Significance:** Significant elevation indicates allergy or, rarely, parasites.
- **Test:** CFTR mutation panel
- **Significance:** To diagnose CF. Alternatively, sweat chloride test, but need to be sure that laboratory has experience with this test.
- **Test:** Immune workup
- **Significance:** HIV; immunoglobulins
- **Test:** pH probe (or barium swallow)
- **Significance:** GER
- **Test:** Bronchoscopy
- **Significance:** To remove foreign body or obtain tissue samples
- **Test:** High-resolution CT scan of the thorax, video fluoroscopy, echocardiogram, sleep polysomnography, or nuclear medicine scans
- **Significance:** May be judiciously used and are generally reserved until after referral to a specialist

Imaging

Chest x-ray:

- Infiltrates may suggest pneumonia, bronchiolitis, pneumonitis, TB, CF, bronchiectasis, foreign body.
- Volume loss may be seen with foreign body aspiration; sometimes need to obtain lateral decubitus views in young children who cannot cooperate with inspiratory/expiratory views.
- Hyperinflation suggests RAD or CF.
- Mediastinal nodes may indicate infection (especially tuberculosis or fungal) or malignancy.

**TREATMENT****ADDITIONAL TREATMENT****General Measures**

- The goal is to treat the underlying cause of the cough, not the symptom.
- To avoid overuse of antibiotics, parents should be informed that viral URI can cause cough that commonly lasts up to 2–3 weeks.
- Educate parents about the beneficial function of cough to remove irritants and about the potential harm of suppressing a productive cough or cough secondary to RAD.
- Honey may be used in children over 1 year old. Acute cough from URI or chronic nonspecific cough (i.e., dry cough in the absence of asthma or other identifiable disease) may be safely, effectively, and inexpensively treated with honey.
- Specific pharmacologic interventions:
 - RAD: Bronchodilators ± inhaled anti-inflammatory agents, oral or inhaled steroids, removal of irritants
 - Infection: Appropriate antibiotics as indicated. May be considered in cases of chronic moist cough
 - Antihistamines (nonsedating) should be used only when cough coexists with rhinitis.
 - OTC cough medicines are widely prescribed and overused. Systematic reviews conclude that OTC preparations have not been shown to be efficacious in children <5 years of age, have been associated with significant toxicity in this age group, and should be avoided.
- Self-hypnosis is a safe, effective treatment for children with habitual cough.
- Children with “nonspecific cough” (i.e., without specific indicators by H&P as noted above) generally do not derive much benefit from medications and may undergo a period of “watchful waiting.” If medications are used, patients need to be reassessed in 2–3 weeks.

ISSUES FOR REFERRAL

- The vast majority of cases of cough, even when chronic, can be diagnosed and managed by the primary care physician.
- Factors in making a referral:
 - The cough is unresponsive to treatment.
 - The cause is likely to be an anatomic malformation or foreign body aspiration.
 - There appears to be involvement of other organ systems (e.g., failure to thrive, GER, congestive heart failure, immunodeficiency, unusual infection).
- Hemoptysis

Initial Stabilization

- Cough should be considered an emergency if there are associated signs or symptoms of respiratory distress.
- Routine emergency airway assessment should be undertaken on presentation and appropriate supportive measures started in cases in which there is concern.

- J40 Bronchitis, not specified as acute or chronic
- J45.909 Unspecified asthma, uncomplicated
- R05 Cough

FAQ

- Q: Is whooping cough still a problem despite routine childhood immunization?
- A: Yes. Pertussis often goes unrecognized as a cause of acute and chronic cough, particularly in infants who have not completed their immunization series and in older children, adolescents, and adults. Immunity from vaccination or natural infection may wane within 5 years, thus providing a constant reservoir of pertussis in the community.

CROHN DISEASE

Douglas Jacobstein

Robert Baldassano

Petar Mamula

BASICS

DESCRIPTION

Crohn disease (CD) is a chronic inflammatory bowel disease (IBD) that can affect any part of the GI tract.

EPIDEMIOLOGY

- ~20–25% of patients 1st present in childhood or adolescence.
- Family history is present in 30% of patients <30 years old.
- In adulthood, Male = Female; in childhood, Male > Female (1.6:1)

Incidence

- The incidence rate in children is 4.56/100,000 in North America.
- Highest incidence in the white population

RISK FACTORS

Genetics

- 1st-degree relatives have a 5–25% higher risk than the normal population.
- Family members of patients with CD have increased risk for both CD and ulcerative colitis.
- Offspring and siblings have an 8% risk of developing IBD.
- Concordance in monozygotic twins is 50%; in dizygotic twins, 38%.
- CD is complex genetic disease
- 71 CD susceptibility loci have been found on multiple chromosomes.
- CARD15 mutation is present in ~14–18% of patients. Homozygotes carry 2–4% lifetime risk of developing CD.
- Additional genetic links found to possibly predict responses to corticosteroids, anti-TNF agents

PATHOPHYSIOLOGY

- Interaction and combination of environmental factors, genetic susceptibility, host's intestinal flora, and a yet-undefined triggering factor (likely bacterial products) lead to a dysregulated immune response, causing chronic intestinal inflammation.
- Patients with the CARD15/NOD2 mutation have dysregulated response to bacterial products, which changes innate low-grade to a high-grade inflammatory response.
- There is highly significant association between CD and the IL23R gene on chromosome 1p31, which encodes a subunit of the receptor for the pro-inflammatory cytokine interleukin-23.
- Initially, the T-helper-1 lymphocyte pathway is activated, causing inflammatory cytokines to generate microscopic inflammation, which infiltrates all layers of intestine with cryptitis or crypt abscesses, and distortion of crypt architecture.
- Macroscopically, the intestinal wall is edematous, mesentery may be thickened, local lymph nodes enlarged, and fat extends from the mesentery and "creeps" over the serosal surface.
- Granulomas are found in 20–40% of biopsies and, if found, are pathognomonic.
- Normal bowel can exist in continuity with affected bowel (skip areas).

DIAGNOSIS

HISTORY

- Frequency of signs and symptoms:
 - Weight loss: 85%
 - Diarrhea: 80%
 - Abdominal pain: 85%
 - Fever: 40%
 - Rectal bleeding: 50%
 - Growth failure: 35%
 - Nausea and vomiting: 25%
 - Rectal disease: 25%
 - Extraintestinal signs: 25%
 - Perianal disease: 25%
- Symptoms depend on the intestinal site and the disease activity.
- Sites most often affected, in decreasing frequency, are terminal ileum, right colon, isolated colon, proximal small bowel, and upper GI tract (i.e., stomach, duodenum, esophagus).
- Chronic diarrhea
- Weight loss
- Growth failure (Careful charting of recent growth parameters, especially growth velocities from school or medical records, is essential.)
- Delayed puberty
- Recent travel (enteric infections)
- Antibiotic use (*Clostridium difficile*)
- Family history of IBD
- Extraintestinal disease:
 - Arthritis
 - Erythema nodosum
 - Pyoderma gangrenosum
 - Mouth ulcers
 - Episcleritis
 - Uveitis
 - Thromboembolic disease
 - Vasculitis
 - Renal stones
 - Amyloidosis
 - Sclerosing cholangitis
 - Pancreatitis

PHYSICAL EXAM

- Growth delay and weight loss, delayed puberty
- Abdominal examination:
 - Hyperactive bowel sounds
 - Right lower quadrant (RLQ) mass and tenderness
 - Palpable thickened loop of intestine
- Rectal and perianal examination: Skin tag, fissure, fistula, and abscess

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC; microcytic anemia due to iron deficiency, normocytic anemia due to chronic disease, macrocytosis suggesting nutrient deficiency: Iron, B₁₂, folate, zinc
- ESR, C-reactive protein, stool calprotectin (disease activity)
- Electrolytes (hydration, renal function)
- Transaminases, alkaline phosphatase, γ -glutamyl transpeptidase (hepatobiliary disease)

- Stool for occult blood and presence of white cells
- Stool cultures, *Clostridium difficile* toxin A and B
- Perinuclear antineutrophil cytoplasmic antibody (pANCA) and anti-*Saccharomyces cerevisiae* antibody (ASCA) may be helpful in differentiating among types of IBD.
- Genetic screening among healthy, asymptomatic patients is not recommended.

Imaging

- Consider plain abdominal x-ray in acute presentation to rule out obstruction or perforation.
- Barium upper GI and small bowel follow-through to evaluate extent of disease in small bowel not accessible to endoscopy
- Barium enema has been replaced by colonoscopy in acute colitis and is useful in evaluation of complications such as strictures and fistulas.
- CT scan and ultrasound are useful for evaluation of complications (abscess, phlegmon).
- MRI and abdominal ultrasound are increasingly being used for assessment of disease extent and activity.
- Colonoscopy and upper endoscopy with multiple biopsies are the gold standard tests for initial evaluation and diagnosis of CD.
- Video capsule endoscopy can be used to access small bowel not visualized at the time of endoscopy.

DIFFERENTIAL DIAGNOSIS

- Ulcerative colitis
- Appendicitis
- Infection:
 - *Mycobacterium tuberculosis*
 - *Salmonella*
 - *Shigella dysenteriae*
 - *Campylobacter jejuni*
 - *Aeromonas* spp.
 - *Yersinia enterocolitica*
 - *Clostridium difficile*
 - *Escherichia coli*
 - *Giardia lamblia*
 - *Cryptosporidium*
 - *Strongyloides*
- Hemolytic-uremic syndrome
- Henoch-Schönlein purpura
- Irritable bowel syndrome
- Peptic ulcer disease
- Autoimmune enteropathy, immunodeficiency
- Cow's milk protein allergy
- Small intestinal lymphoma

TREATMENT

MEDICATION (DRUGS)

- The goal of therapy is resolution of all symptoms, appropriate growth, and good quality of life. The therapy is used in a stepwise fashion.
- Several 5-aminosalicylic acid (5-ASA) preparations are being used according to their intestinal site of activation because of their anti-inflammatory properties:
 - Mesalamine (Asacol; terminal ileum, colon): 50–100 mg/kg/d (max 4.8 g/d for active disease and 3.2 g/d to maintain remission)
 - Mesalamine (Pentasa; duodenum, jejunum, ileum, colon): 50–100 mg/kg/d (max 4 g/d for active disease and 3 g/d to maintain remission)
 - Balsalazide (Colazal; 6.75 g/d; 110–170 mg/kg/d): Can be given to small children as liquid preparation
 - Mesalamine (Rowasa): 4-g enemas and 500-mg suppositories daily to b.i.d. PR
- Corticosteroids can control intestinal inflammation: 1–2 mg/kg/d oral prednisone (max 60 mg). Initially, patient is treated for several weeks and tapered off within several weeks. Topical hydrocortisone is useful in localized left-sided colonic disease and is available in liquid and foam enemas. Corticosteroid with controlled ileal release, budesonide (9 mg/d) is available.
- Nutritional therapy is frequently used in Europe and Canada as a 1st-line therapy:
 - Elemental and polymeric diet is reported to be effective in inducing remission in active disease.
 - To correct growth failure, an increase in caloric intake is recommended and can be given as overnight nasogastric feeding if oral supplements are not tolerated.
- Azathioprine, 2–3 mg/kg/d, and its metabolite 6-mercaptopurine, 1–1.5 mg/kg/d, are used for the immunomodulatory properties in patients who are unresponsive to corticosteroids or who are dependent on them, and for perianal disease. Adverse events include liver toxicity and leukopenia.
- Frequent laboratory follow-up is necessary, and WBC should be maintained $>3\text{--}4 \times 10^9/\text{L}$ and platelets $>100 \times 10^9/\text{L}$.
- Methotrexate, 15–25 mg IM or PO once a week
- Other immunomodulatory therapy used infrequently: Cyclosporine, tacrolimus (FK-506), thalidomide, etc.
- Antibiotics:
 - Metronidazole: 15 mg/kg/d
 - Ciprofloxacin: 20 mg/kg/d
- Infliximab, a biologic, chimeric anti-tumor necrosis factor- α antibody (5 mg/kg IV infusion, given every 2–3 months, after initial 3-dose induction therapy at 0, 2, and 6 weeks) for severe and fistulizing disease unresponsive to other therapy
- Other biologic therapies including anti-TNF- α antibodies adalimumab and certolizumab and the antiadhesion molecule natalizumab are available, but not yet approved for use in pediatric CD.
- Complementary therapy (probiotics, prebiotics)

SURGERY/OTHER PROCEDURES

- Surgery is used in patients with localized disease that is unresponsive to other therapy, intractable bleeding, stricturing disease, especially in case of proximal intestinal dilatation, and perforation. Several types of procedures are available: Strictureplasty, abscess drainage, and intestinal resection (side-to-side anastomosis is widely accepted).
- Most of these procedures are performed laparoscopically, which reduces recovery time.
- Surgery is not curative, and postoperative recurrence at the site of anastomosis is common.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- The morbidity of this disease is high. The majority of patients experience recurring disease.
- Most patients have good general health in between disease and go on to lead productive lives.
- Carcinoma surveillance is necessary on a regular basis.
- After 5 and 20 years of disease, the probability of survival is 98% and 89% of expected survival, respectively.
- Death is a rare complication (2.4% in a large series).

COMPLICATIONS

- Intestinal obstruction due to strictures, or adhesions
- Abscess or phlegmon formation
- Enterocenteric, enterovesical, enterovaginal, and enterocutaneous fistulas
- Perforation
- Gallstones, kidney stones
- Intestinal lymphoma, colon cancer
- Malabsorption resulting in deficiency (e.g., vitamin B₁₂ and bile salt deficiency, iron deficiency)
- Massive hemorrhage is rare (1%).
- Growth failure is frequent; final height is reduced and puberty is delayed in CD affecting prepubertal children.
- Osteopenia and osteoporosis secondary to inflammation, nutritional deficiency, and therapeutic side effects (corticosteroids)
- Toxic megacolon is a rare but serious complication.

CODES

ICD9

- 555.0 Regional enteritis of small intestine
- 555.1 Regional enteritis of large intestine
- 555.9 Regional enteritis of unspecified site

ICD10

- K50.019 Crohn's disease of small intestine with unspecified complications
- K50.119 Crohn's disease of large intestine with unspecified complications
- K50.919 Crohn's disease, unspecified, with unspecified complications

FAQ

- Q: Should the diet of patients with CD be restricted?
- A: Balanced nutrition is required to assure appropriate growth and development. The only foods not recommended are poorly digestible vegetables (if eaten raw), nuts, and popcorn, which can cause obstruction in the narrowed, inflamed intestine. Patients with secondary lactose intolerance should use lactase supplements or avoid milk products while ensuring adequate calories and calcium intake.
- Q: What is the cause of CD?
- A: Both genetic and environmental factors are important in the development of CD. Possible environmental factors include aseptic environment in the 1st few years of life, lack of breast-feeding, frequent use of antibiotics or aspirin, and diet.
- Q: Where can I learn more about CD?
- A: The Crohn and Colitis Foundation of America (CCFA, www.CCFA.org) is a nonprofit organization dedicated to the care of people with CD and ulcerative colitis.
- Q: What new therapies will be used in the near future?
- A: Biologic agents, which use our recently improved knowledge of the immune system either to downregulate inflammatory mediators or upregulate immunomodulatory mediators. It is hoped that this new class of therapies will greatly improve our care of people with CD.

CROUP

Daniel Walmsley

BASICS

DESCRIPTION

- Croup (laryngotracheobronchitis) is a common respiratory illness in children that presents with hoarseness, a characteristic barking cough, rhinorrhea, and fever.
- Spasmodic croup (subglottic allergic edema) refers to an illness characterized by sudden inspiratory stridor at night followed by sudden resolution. Mild cold symptoms may be present but are often absent. The child can have frequent attacks on the same night or for multiple, successive nights.

EPIDEMIOLOGY

- Accounts for 15% of the respiratory illnesses seen in children.
- Most commonly occurs in children between 6 and 36 months of age. Although cases can be seen up to 6 years of age, it is uncommon in children older than 6 years.
- Most prevalent in the fall to early winter
- More common in males
- ER visits for croup are most frequent between the hours of 10 pm and 4 am.

RISK FACTORS

- Age: mean age at presentation is 18 months.
- Season: fall or winter
- Anatomic narrowing of the airway (subglottic stenosis, Down syndrome)
- Prior history of croup
- Hyperactive airway (atopic children)
- Pre-existing airway swelling

ETIOLOGY

In children, the cricoid ring of the trachea, located in the immediate subglottic area, is the narrowest part of their upper airway. A small amount of edema in this region can lead to significant airway obstruction; which is what makes them especially susceptible to this illness.

Caused mainly by respiratory viruses including:

- Parainfluenza virus types 1–3, most commonly; accounting for 65% of cases
- Adenovirus
- RSV
- Influenza virus A,B
- Rhinoviruses
- Enteroviruses
- Metapneumovirus
- Enteric cytopathogenic human orphan virus (echovirus)
- Measles—in areas where measles is prevalent
- *Mycoplasma pneumoniae*
- Bacterial infection may occur secondarily by *Staph. aureus*, *S. pyogenes*, and *S. pneumoniae*

DIAGNOSIS

HISTORY

- Croup typically starts with rhinorrhea, cough, coryza, and congestion.
- After a short period (12–48 hours), upper airway obstruction occurs resulting in hoarseness, “barky cough”, and inspiratory stridor.
- Fever is often present.
- Symptoms persist for 3–7 days.

- The sudden development of inspiratory stridor without other upper respiratory tract infection (URI) symptoms or fever should prompt the consideration of a foreign body aspiration.
- Recurrent episodes of stridor should lead to the consideration of spasmodic croup, an anatomical abnormality, or an underlying condition such as atopy.
- In a child with truncal or multiple strawberry hemangiomas, a sudden episode of stridor without fever or URI symptoms should raise the concern for a hemangioma in the child’s airway.
- Bacterial tracheitis should be suspected in a child who develops marked worsening of symptoms with a high fever after having 5–7 days of mild croup symptoms.

PHYSICAL EXAM

- Examine in a comfortable position and every effort should be taken to minimize anxiety as this can often worsen the symptoms.
- Observe for stridor at rest, irritability, and fatigue. Assess respiratory status and level of consciousness.
- Vital signs: Fever and tachypnea may be present. A child with croup is usually not hypoxic because croup affects the upper airway. Hypoxia is seen only when complete airway obstruction is imminent.
- A child with croup will likely have a hoarse voice, coryza, inflamed pharynx, and varying degrees of respiratory distress.
- The degree of respiratory distress should be observed by assessing for tachypnea, nasal flaring, retractions, grunting, and use of accessory muscles.
- Children with significant upper airway obstruction may sit in a “sniffing” position with their neck mildly flexed and head mildly extended. This is in contrast to the “tripod” position noted in epiglottitis where the child is in a sitting position with the chin pushed forward and refusing to lie down.
- The presence of inspiratory stridor should be determined. Stridor may be present at rest or only with agitation and this difference will affect the patient’s management. Stridor at rest is a sign of significant upper airway obstruction and needs urgent treatment.
- The hydration status of the child should be assessed. Drooling should not be present with croup and, if present, may indicate a different diagnosis such as epiglottitis or peritonsillar abscess.
- The severity of croup can be determined by a clinical scoring system known as the modified Westley Croup Score (see Table 1). A score <3: mild disease; a score of 3–6: moderate disease; and a score >6: severe disease.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Croup is a clinical diagnosis and laboratory tests are not needed.
- The anxiety associated with blood draws may actually worsen the child’s condition.
- Rapid antigen tests to determine the viral agent responsible for the illness may be helpful if the child has an atypical presentation or for infection control if the child requires admission.

Imaging

- Radiographs may be helpful to rule out other causes of stridor; they should be considered in children with atypical courses, recurrent episodes, failure to

Table 1. Croup (laryngotracheobronchitis)—severity score for croup patients

Indicator of severity of illness	Score
<u>Inspiratory stridor</u>

Altered mental status	5

respond to treatment, or if a foreign body is suspected (although most are not radio-opaque).

- Classically, an anteroposterior view demonstrates the “steeple” sign; which is a narrowed air column in the subglottic area.

Diagnosis Procedures/Surgery

- Pulse oximetry
- Visual inspection of the airway via bronchoscopy and direct or fiberoptic laryngoscopy may be helpful in cases of recurrent croup to rule out an anatomical abnormality.

Pathological Findings

- Gross pathology: edema and erythema of the subglottic trachea; occasionally, pseudomembranes or exudate are noted.
- Microscopic: edema of airway lining with infiltration of neutrophils, histiocytes, plasma cells, and lymphocytes

DIFFERENTIAL DIAGNOSIS

- Mainly includes other causes of acute stridor with or without respiratory distress.
- Historically, distinguishing croup from epiglottitis was very significant in that the latter could lead to life-threatening airway obstruction. However, the introduction of the Hib vaccine in 1990 led to a marked decline in epiglottitis. Cases of epiglottitis still occur in unimmunized and underimmunized children; therefore, it is important to check the child’s immunization status.

Other important diseases to consider in the differential include:

- **Infectious:**
 - Acute epiglottitis
 - Bacterial tracheitis
 - Retropharyngeal abscess
 - Adenotonsillitis
 - Diphtheria

- Pneumonia
- Ulcerative laryngitis
- **Allergic/inflammatory:**
 - Asthma
 - Anaphylaxis (angioneurotic edema)
 - Microaspiration secondary to gastroesophageal reflux or hypotonia
- **Environmental:**
 - Foreign body aspiration
 - Caustic ingestion or burn
 - Smoke inhalation
 - Paraquat poisoning
- **Traumatic:**
 - Subglottic edema/stenosis postintubation
 - Laryngeal or subglottic hematoma
 - Laryngeal fracture
 - Papillomatosis
 - Hemangioma
 - Cystic hygroma
 - Lymphoma
 - Rhabdomyosarcoma
 - Thymoma
 - Teratoma
 - Thyroglossal duct cyst
 - Branchial cleft cyst
- **Congenital anomalies of the upper airway**
 - Tracheomalacia
 - Vascular ring
 - Laryngeal web
- **Genetic/metabolic:** Hypocalcemia

TREATMENT

INITIAL STABILIZATION

- Racemic epinephrine (see below)
- Corticosteroids
- Oxygen (if needed)
- Endotracheal intubation is very rarely required.

General Measures

- Children with mild symptoms can be treated with humidity, antipyretics, and oral hydration at home. However, RCTs have not shown benefit for the use of humidity.
- Short, acute episodes of stridor can be treated with cool mist, a bathroom filled with steam from a shower or cold night air. If the stridor persists, worsens or occurs at rest, the child should be seen in the emergency room.
- It is important to try to keep the child calm as agitation or anxiety can worsen symptoms and increase work of breathing.
- In the child with impending respiratory failure, prompt intubation and direct visualization of the airway in the operating room is imperative. Do not wait for X-rays to confirm a diagnosis.

MEDICATION (DRUGS)

- Corticosteroids and nebulized racemic epinephrine, the main treatments for croup, have resulted in a dramatic reduction in the number of admissions and length of hospital stays in patients with croup.
- Dexamethasone (PO or IM; half-life 36–54 hours) 0.15–0.6 mg/kg single dose has been shown to reduce symptoms in patients with moderate to severe croup. Oral dexamethasone is the most cost-effective steroid treatment available.
- Alternatively prednisolone 1–2 mg/kg for 1–3 daily doses can be given to a patient with croup, although there is no RCT evidence for this method. A recent double-blinded randomized trial demonstrated that a single dose of 1 mg/kg of prednisolone was NOT

as effective at keeping children from emergency medical care as 0.15 mg/kg of dexamethasone.

- Budesonide given via nebulizer at a dose of 2 mg administered q12h—shown in recent studies to be as effective as dexamethasone in reducing symptoms; less systemic absorption compared with dexamethasone, with maximum deposition of drug in the upper airway. Although widely accepted, budesonide is not as readily used as dexamethasone because it is not as cost-effective.
- Racemic epinephrine: A nebulized racemic epinephrine treatment offers immediate reduction in swelling of the laryngeal airway in children who present in extreme respiratory distress. Dose: 0.5 mL of 2.25% solution (D- and L-isomers) in 2.5 mL normal saline delivered via nebulizer as needed.
- L-epinephrine: If racemic epinephrine is not available, 5 mL of L-epinephrine 1:10,000 delivered via nebulizer is effective.

IN-PATIENT CONSIDERATIONS

Admission Criteria

- Severe respiratory distress on presentation (Croup score of >3)
- Persistent hypoxia despite treatment with steroids and racemic epinephrine
- Requirement of treatment of racemic epinephrine more than once over a 3- to 4-hour period
- Dehydration or risk for dehydration
- Admission should be strongly considered for children who present symptomatically to an ER more than once and have significant stridor on day 1 of illness as croup is usually worse on days 2–3.

Discharge Criteria

- Croup score of ≤3 over a 1- to 3-hour period of observation
- Does not require racemic epinephrine in the 3–4 hours prior to discharge
- Able to take adequate PO fluids

Issues for Referral

- The vast majority of children with croup do well. However, transfer to a facility where trained individuals can address pediatric airway problems should be considered if the patient is inadequately responding to treatment or has increasing respiratory distress.

PROGNOSIS

- The vast majority of patients do not require hospitalization.
- Almost all patients go on to complete recovery.

COMPLICATIONS

- Poor oral intake/dehydration
- Hypoxia
- Upper airway obstruction
- Respiratory failure (rare)

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- In most cases, the illness is self-limited, lasting 3–5 days
- A “rebound phenomenon” with worsening of stridor and respiratory distress after initial relief with the racemic epinephrine treatment may be seen up to 2 hours post treatment in some patients.
- Several studies have shown that children can be safely discharged 3–4 hours after racemic epinephrine treatment.

ALERT

Recurrent croup may signal an underlying anatomic problem and needs evaluation for other causes.

ICD10

J05.0 Acute obstructive laryngitis [croup]

FAQ

- Q: Is humidity currently recommended for a patient presenting with croup?
- A: In the previous year, the first randomized controlled trial of mist in the emergency department setting showed no improvement in symptoms in patients with moderate croup.
- Q: Should all children with croup receive steroids?
- A: Steroids are now the first-line treatment for croup. Meta-analysis review strongly supports the use of dexamethasone (PO or IM) or nebulized budesonide for children with moderate to severe croup scores. This analysis showed that steroids result in significant clinical improvement in the first 24 hours after treatment. Increasingly, studies of patients with mild croup are indicating these children may benefit from a single dose of dexamethasone.

CRYING

Mark F. Ditmar

BASICS

DEFINITION

- Crying is usually a normal physiologic response to stress, discomfort, unfulfilled needs such as hunger, pain, over- or under-stimulation, or temperature change.
- Crying is felt to be potentially pathologic if it is interpreted by caregivers as differing in quality and duration without apparent explanation and/or persists without consolability beyond a reasonable time (generally 1–2 hours).

ETIOLOGY

- The most likely cause of inconsolable crying in the first few months of life is, without question, infantile colic. Practitioners must be familiar with the clinical pattern of infantile colic, so that deviations are readily recognized.
- Patients' families often suggest teething as a cause of excessive crying (as well as fever, diarrhea, rashes, etc.). Objective data do not support a strong association.
- Be careful in ascribing symptoms and signs to teething.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- **Congenital/anatomic**
 - Intussusception
 - Gastroesophageal reflux/esophagitis
 - Volvulus
 - Gaseous distention (secondary to improper feeding or burping)
 - Incarcerated inguinal hernia
 - Peritonitis (acute abdomen)
 - Testicular/ovarian torsion
 - Constipation
 - Anal fissure
 - Meatal ulceration
 - Glaucoma
 - Urinary retention (secondary to posterior urethral valves)
 - Cardiac—anomalous coronary artery, hypoxia, congestive heart failure (CHF)
 - Increased intracranial pressure (hydrocephalus, tumor)
- **Infectious**
 - Otitis media/externa
 - Urinary tract infection (UTI)/pyelonephritis
 - Stomatitis/gingivitis
 - Meningitis/encephalitis
 - Discitis
 - Gastroenteritis
 - Mastitis
 - Arthritis, septic
 - Osteomyelitis
 - Perianal cellulitis
 - Balanitis
 - Dermatitis (especially pruritic as in scabies or painful as in staphylococcal scalded skin syndrome)

- **Toxic, environmental, drugs**
 - Neonatal drug withdrawal
 - Prenatal/perinatal cocaine exposure
 - Immunization reactions (especially DPT)
 - Isolated fructose intolerance
 - Drug reactions (especially antihistamines, pseudoephedrine, phenylpropanolamine), including maternal medications in breast milk
 - Vitamin A toxicity
 - Carbon monoxide exposure
 - Emotional/physical neglect
 - Foreign body ingestion (coin, pin)
 - Ear foreign body (e.g., cockroach)
- **Trauma**
 - Corneal abrasion
 - Foreign body (hypopharynx, eye, ear, nose)
 - Skull fracture/subdural hematoma
 - Intracranial hemorrhage
 - Retinal hemorrhage (e.g., shaken baby syndrome)
 - Other fractures (especially extremities)
 - Hair tourniquet syndrome (encircling finger, toe, penis, clitoris)
 - Open diaper pin
 - Bite (human, animal, insect)
- **Genetic/metabolic**
 - Sickle cell crisis
 - Phenylketonuria
 - Hypothyroidism
 - Electrolyte abnormalities (especially sodium)
 - Hypoglycemia
 - Hypocalcemia
 - Hypercalcemia
 - Inborn error of metabolism
- **Allergic/inflammatory**
 - Cow milk allergy
 - Celiac disease (gluten enteropathy)
 - Hemolytic-uremic syndrome
 - Henoch–Schönlein purpura
 - Kawasaki disease
- **Functional**
 - Parental expectations/responses
- **Miscellaneous**
 - Overstimulation
 - Persistent night awakening
 - Night terrors
 - Caffey disease (infantile cortical hyperostosis)
 - Dysrhythmia (especially supraventricular tachycardia)
 - IV infiltration
 - Autism
 - Teething
 - Headache/migraine
 - Temperament
 - Colic
 - Discomfort (cold, heat, itching, hunger)

ALERT

Factors that make this an emergency include:

- Suspicion of meningitis: Stiff neck, bulging fontanel, fever (especially infants <2–3 months)
- Suspicion of intestinal obstruction: Vomiting (especially bilious or projectile), mass on abdominal palpation, and/or bloody stools
- Suspicion of incarcerated hernia or testicular/ovarian torsion
- Evidence of cardiac compromise (CHF, supraventricular tachycardia): Tachycardia, poor perfusion (capillary refill >3 seconds, poor distal pulses), rales
- Evidence of acute dehydration: Weight loss, decreased urine output, orthostatic changes, poor perfusion
- Evidence of child abuse or neglect

APPROACH TO THE PATIENT

General goal is to decide if the crying represents a normal physiologic response, a protracted multifactorial physiologic/developmental response (colic), or a potentially pathologic problem.

- **Phase 1:** How urgent is the need for evaluation? A classic and difficult triage issue. One must identify the periodicity of the problem, associated symptoms, impression of wellness, and parental anxiety/reliability.
- **Phase 2:** When in doubt, particularly if colic seems unlikely, see the patient as soon as possible.

HISTORY

- **Question:** Colic?
- **Significance:**
 - Colic less likely as a cause if onset after 1 month of age or persistent in infants >4 months
 - Recurrent episodes, particularly with a diurnal or evening pattern, are more likely due to colic.
 - Crying shortly after feeding suggests aerophagia or gastroesophageal reflux; 1 hour after feeding suggests formula intolerance. A rare cause of postprandial crying is anomalous coronary arteries.
 - Overfeeding or underfeeding, excessive air swallowing, inadequate burping, and improper formula preparation may contribute to excessive crying.
- **Question:** Fever?
- **Significance:** Indicates potential need for evaluation of meningitis, other infections
- **Question:** Paradoxically increased crying (attempts at consolation make the crying worse, especially with lifting, rocking)?
- **Significance:** Can be seen in meningitis, peritonitis, long-bone fractures, arthritis

- **Question:** Stridor?
- **Significance:** Implies possible upper airway obstruction (mechanical, functional)
- **Question:** Expiratory grunting?
- **Significance:** Indicates higher likelihood of significant pathologic cause of crying (especially cardiac, respiratory, and/or infectious disease)
- **Question:** Cold symptoms and/or daycare attendance?
- **Significance:** Increase likelihood of otitis media
- **Question:** Vomiting?
- **Significance:** Increases likelihood of pathologic GI cause (e.g., obstruction, gastroesophageal reflux with possible esophagitis), particularly in infant <3 months, or CNS disease
- **Question:** Recent fall or trauma?
- **Significance:** May indicate possible fracture, increased intracranial pressure, abuse
- **Question:** Documented weight loss outside of the 2 week neonatal period?
- **Significance:** Suggests an organic cause

PHYSICAL EXAM

- **Finding:** Tympanic membrane with loss of landmarks, poor mobility, and swollen canal?
- **Significance:** Indicate otitis media, otitis externa, foreign body
- **Finding:** Tenderness on palpation of extremities, clavicle, or scalp, or painful or decreased range of motion of joints?
- **Significance:** Suggests fracture, subluxation, osteomyelitis, septic arthritis
- **Finding:** Conjunctival redness, eye tearing, scratches near the eye?
- **Significance:** Suggest corneal abrasion (fluorescein testing of eye warranted) or foreign body in eye (eversion of lid recommended)
- **Finding:** Impacted or bloody stool on rectal exam, abdominal mass?
- **Significance:** Suggest constipation or intussusception
- **Finding:** Geographic scars, frenulum tears, retinal hemorrhages, suspicious bruises, burns, decreased weight/height ratio?
- **Significance:** Suggest neglect/abuse (physical, emotional)
- **Finding:** Bulging or full fontanel (especially in upright, quiet infant)?
- **Significance:** Indicates possible increased intracranial pressure (meningitis, subdural hematoma, vitamin A toxicity)
- **Finding:** Edema of individual toes, fingers, or penis?
- **Significance:** Suggest hair tourniquet syndrome

- **Finding:** Tender swelling in inguinal or scrotal area?
- **Significance:** May indicate incarcerated hernia, testicular torsion
- **Finding:** Heart rate >200 with minimal variability?
- **Significance:** Indicates possible supraventricular tachycardia
- **Finding:** Hypothermia?
- **Significance:** Suggests infections or hypothyroidism

DIAGNOSTIC TESTS & INTERPRETATION

- **Test:** Stool for occult blood
- **Significance:** Possible intussusception, anal fissure
- **Test:** Fluorescein testing of eye
- **Significance:** Corneal abrasion (may occur without significant conjunctival redness)
- **Test:** Urinalysis/urine culture
- **Significance:** UTI
- **Test:** Urine toxicology screen
- **Significance:** Drug withdrawal (neonatal), ingestions, passive exposures (e.g., cocaine)
- **Test:** Pulse oximetry
- **Significance:** Hypoxia (from cardiac causes) may cause increased irritability.
- **Test:** Electrolyte panel/blood glucose
- **Significance:** Endocrine or metabolic disturbance, especially if abnormal sodium, hypoglycemia, significant acidosis, or elevated anion gap

CODES

ICD9

- 780.92 Excessive crying of infant (baby)
- 789.7 Colic

ICD10

- R10.83 Colic
- R68.11 Excessive crying of infant (baby)

CLINICAL PEARLS

- History and physical exam, rather than extensive lab testing, is the key to the diagnosis. In Freedman's ED study of 237 excessively crying infants, fewer than 1% had testing contribute to the diagnosis in the absence of a suggestive clinical picture.
- Be certain that the infant or child is completely undressed so that dermatologic clues will not be missed.
- Quality of cry: Subjective interpretation can be helpful.
 - High-pitched (shrill, piercing) crying in short bursts: Associated with CNS pathology, especially with increased intracranial pressure
 - High-pitched crying in longer bursts: Seen in small-for-gestational age infants, neonatal drug withdrawal
 - Hoarse crying: Seen in hypothyroidism, laryngeal diseases, hypocalcemic tetany
 - Weak crying: May be seen in neuromuscular disorders, infant botulism, and/or the very ill infant
 - Catlike cry: Can be associated with cri du chat syndrome (5p syndrome or absence of short arm of chromosome 5)
- Cessation of crying with ophthalmic anesthetic drops while doing fluorescein staining suggests corneal injury as a cause.
- Bruises are rare in preambulatory children (particularly <6 months); if present, consider inflicted injuries.
- Colic is a diagnosis of exclusion. Be wary of the infant who, despite a period of observation, is not noted at any point to be awake and calm.
- Factors that may help alert you to make a referral include:
 - Infant appears ill (e.g., pallor, grunting, poor arousability, poor response to social overtures)
 - Weight loss or abnormal development (implies much higher likelihood of an organic cause)

CRYPTOCOCCAL INFECTIONS

Samir S. Shah

BASICS

DESCRIPTION

Cryptococcosis, an opportunistic fungal infection caused by *Cryptococcus neoformans*, may involve several organ systems, including the CNS, lungs, bones, visceral organs, and skin.

EPIDEMIOLOGY

- Most pediatric infections occur in immunocompromised hosts, including those with malignancy, HIV, and solid-organ or bone marrow transplantation; 20% of infections requiring hospitalization occur in normal hosts.
- There is no person-to-person spread of the infection.

Incidence

- Occurs in 5–15% of HIV-infected adults, usually with CD4+ lymphocyte counts <50 cells/mm³. Occurs in 0.8–2.3% of HIV-infected children. The lower infection rate in children reflects their lower exposure to sources of *C. neoformans*. The overall seroprevalence is 0% in neonates and 4.1% in school-aged children, compared to 69% in adults.
- 1–3% of solid-organ transplant recipients develop *C. neoformans* infections; typically >1 year after transplantation.

GENERAL PREVENTION

- Most studies on prevention address HIV-infected patients.
- Use of highly-active antiretroviral therapy (HAART) prevents most cases of cryptococcosis in HIV-infected patients.
- Primary prophylaxis with fluconazole prevents new-onset cryptococcal disease in HIV-infected patients. However, primary prophylaxis is not routinely recommended except for those with limited access to HAART and those with high levels of antiretroviral drug resistance.
- Maintenance (suppressive) therapy after completion of therapy for cryptococcal infection is recommended for HIV-infected patients. In those with low CD4+ lymphocyte counts, relapse rates are 100% without maintenance antifungal therapy, 18–25% with amphotericin B or itraconazole, and 2–3% with fluconazole.
 - Prophylaxis may be discontinued in patients receiving HAART with CD4+ lymphocytes >100 /mm³ and undetectable viral loads.
- There is no consensus on the duration of fluconazole suppressive therapy after treatment of cryptococcosis in HIV-negative immunocompromised patients. Most experts provide maintenance (suppressive) antifungal therapy with fluconazole PO (6 mg/kg/d) for at least 1 year after the completion of acute treatment and then reassess its ongoing use based on the level of current immunosuppression.

PATHOPHYSIOLOGY

- Primary infection occurs through the inhalation of aerosolized soil particles containing the yeast forms. The skin and GI tract are also portals of entry.
- Protective immune response requires specific T-cell-mediated immunity.
- CNS infection with *C. neoformans* results from hematogenous dissemination.

COMMONLY ASSOCIATED CONDITIONS

- *C. neoformans* is the most common cause of fungal meningitis in the US.
- Disseminated infection occurs more commonly among immunocompromised hosts.
- Concurrent *Pneumocystis carinii* pneumonia was detected in 13% of adults with cryptococcal meningitis.
- Pulmonary involvement is asymptomatic in up to 50% of cases, and disease may be either focal or widespread.
- Bone involvement occurs in 10% of cases of disseminated cryptococcal infection.
- Cutaneous involvement mimics acne-type eruptions that ulcerate, and results from hematogenous spread of the organism or from direct extension of bone infection.

DIAGNOSIS

HISTORY

- Cryptococcal meningitis may present as either an indolent infection or acute illness.
- Symptoms of cryptococcal meningitis include headache, malaise, and low-grade fever. Nausea, vomiting, altered mentation, and photophobia are less common. Stiff neck, focal neurologic symptoms (e.g., decreased hearing, facial nerve palsy, or diplopia), and seizures are rare.
- Primary pulmonary cryptococcal disease is not well described in children because most cases are disseminated at the time of diagnosis. 50% of adults have cough or chest pain, and fewer have sputum production, weight loss, fever, and hemoptysis.
- In immunocompromised hosts, the onset of infection is more rapid and the course more severe. Pulmonary involvement is minimal when dissemination occurs quickly.

PHYSICAL EXAM

- None of the presenting signs of cryptococcal infection are sufficiently characteristic to distinguish it from other infections, particularly in immunocompromised patients.
- CNS involvement: Nuchal rigidity, photophobia, and focal neurologic deficits
- Respiratory tract involvement: Cough, tachypnea, grunting, and subcostal or intercostal retractions. Decreased breath sounds or dullness to percussion may be present, or the lung exam may be normal.
- Cutaneous manifestations: Erythematous or verrucous papules, nodules, pustules, acneiform lesions, ulcers, abscesses, or granulomas. Lesions can occur anywhere on the body, but are found most often on the face and neck.
 - Mucocutaneous findings are present in 10–15% of cases of disseminated disease.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Lumbar puncture: Diagnose cryptococcal meningitis
 - CSF should be sent for cell count and differential; protein; glucose; cultures for bacterial, fungal, and viral pathogens; and cryptococcal antigen (India ink stain is less commonly performed).
 - Examination of the CSF reveals <500 WBC/mm³ (usually <100 WBC/mm³), mostly mononuclear leukocytes, with minimal changes in protein. CSF glucose is <50 mg/dL in ~65% of patients.
 - Budding yeast are seen on India ink stain in 50% of cases.
 - CSF cultures are positive in ~90% of patients.
 - The latex agglutination test for cryptococcal polysaccharide antigen is specific, sensitive, and rapid. Titers $\geq 1:4$ suggest the diagnosis of cryptococcal infection if appropriate controls (to exclude the presence of rheumatoid factor or other nonspecific agglutinins) are negative.
 - HIV-infected patients with pneumonia and CD4+ T-lymphocyte counts <200 cells/mm³ should be evaluated with sputum fungal culture, blood fungal culture, and a serum cryptococcal antigen test. A lumbar puncture to exclude the possibility of occult meningitis should be considered. If any test is positive for *C. neoformans*, then a lumbar puncture should be performed to exclude cryptococcal meningitis.
- Blood culture and serum cryptococcal antigen titers: Diagnose disseminated cryptococcal infection. Serum cryptococcal antigen tests are positive in $>85\%$ of patients with cryptococcal meningitis.
- Sputum culture: Diagnose cryptococcal pneumonia
- Skin or bone biopsy: Diagnose cutaneous or osteoarticular cryptococcal infection
- HIV testing: Evaluation for immunodeficiencies, including HIV, is warranted in any patient with cryptococcosis.
- CBC with differential: May reveal hypereosinophilia (absolute eosinophil count $>1,500$ /mm³)
- Serum electrolytes: Detect hyponatremia, a complication of cryptococcal meningitis

Imaging

- Chest x-rays (anteroposterior and lateral): Nodules, diffuse infiltrates, and pleural effusions may be seen in cryptococcal pneumonia.
- Head CT or MRI: May demonstrate granulomatous lesions (cryptococcomas; ~15% of patients with meningitis) or elevated intracranial pressure. MRI reveals dilation of perivascular spaces in almost half the cases.

DIFFERENTIAL DIAGNOSIS

- Although cryptococcosis occurs most commonly in HIV-infected patients with low CD4+ lymphocyte counts, the diagnosis warrants consideration in all febrile immunocompromised children (e.g., solid-organ transplant, leukemia)
- Meningitis: Viruses and *Mycobacterium tuberculosis*
- Pneumonia: Other pulmonary mycoses, including aspergillosis, histoplasmosis, and blastomycosis. Also consider *Mycoplasma pneumoniae* and *M. tuberculosis*.
- Bone: Osteogenic sarcoma
- Cutaneous: Molluscum contagiosum, herpes simplex virus infection, pyoderma gangrenosum, and cellulitis

**TREATMENT**

- Clinical management depends on extent of disease and immune status of the host.
- Pulmonary and extrapulmonary disease, HIV-negative, nontransplant:
 - Normal hosts with isolated pulmonary nodules may not need treatment if the serum cryptococcal antigen is negative and the patient is asymptomatic.
 - Patients with symptoms, extensive pulmonary disease, or evidence of extrapulmonary disease require treatment.
 - Fluconazole 6–12 mg/kg/d PO (max. 400 mg) for 6–12 months for mild/moderate disease. Alternate regimen: Itraconazole 4–10 mg/kg/d PO (max. 400 mg) for 6–12 months (monitor drug levels); or amphotericin B 0.7–1 mg/kg/d PO for 3–6 months.
 - Same as CNS for severe disease
 - Maintenance therapy with fluconazole should be considered for immunocompromised patients (see “Prevention”).
- CNS, HIV-negative, nontransplant:
 - Induction/consolidation: Amphotericin B (0.7–1 mg/kg/d) plus flucytosine (100–150 mg/kg/d PO, divided q6h) for 4 weeks, then fluconazole PO (10–12 mg/kg/d) for a minimum of 8 weeks followed by maintenance therapy with fluconazole PO (6 mg/kg/d) for 6–12 months. Alternate induction/consolidation regimen: Amphotericin B plus flucytosine for 6–10 weeks.
- Pulmonary and extrapulmonary disease, HIV-infected or transplant:
 - Fluconazole (PO) 6–12 months for mild/moderate disease; same as CNS infection for severe disease.
 - Consider surgical debridement for patients with persistent or refractory pulmonary or bone lesions.

- CNS disease, HIV-infected or transplant:
 - Induction/consolidation: Amphotericin B (IV) plus flucytosine (PO) for at least 2 weeks, followed by fluconazole PO (10–12 mg/kg/d) for at least 8 weeks; consider subsequent suppressive therapy with fluconazole PO (6 mg/kg/d).
 - Intrathecal amphotericin B is very toxic but may be used in refractory cases.
 - HIV-infected patients require continuation of antifungal drugs indefinitely because of the high recurrence rate of cryptococcosis.
 - Liposomal amphotericin (5 mg/kg/d) or amphotericin B lipid complex (5 mg/kg/d) IV may be substituted for amphotericin B, especially in patients with pre-existing renal dysfunction and those receiving calcineurin inhibitors.
 - Flucytosine is used only in combination with amphotericin B and not as a single agent because of the rapid emergence of drug resistance.
- Voriconazole, a new triazole antifungal agent, demonstrates excellent in vitro activity against *C. neoformans* but requires clinical study.
- Caspofungin, a new echinocandin antifungal agent, is not active against *C. neoformans*.

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

- Because of the risk of relapse, patients should be seen at 3-month intervals for 12–18 months following treatment. Immunocompromised patients should be evaluated every 2–3 months, even while on suppressive therapy, to monitor clinically for relapse.
- Repeat lumbar punctures documenting a decrease in CSF cryptococcal antigen and sterility of culture are useful in evaluating response to treatment. During therapy for acute meningitis, an unchanged or increased titer of CSF antigen correlates with clinical and microbiologic failure to respond to treatment. Serum antigen titers are not helpful for this purpose.
- Evaluate patients with cryptococcal meningitis for neurologic sequelae.
- HIV-infected patients require suppressive antifungal therapy (see “Prevention”).

PROGNOSIS

- Mortality is rare in patients with isolated pulmonary or cutaneous disease.
- In-hospital mortality is ~20% for cryptococcal meningitis and ~8% for non-CNS cryptococcal infections.
 - In normal hosts with meningitis, poor prognostic factors include serum or CSF cryptococcal titers > 1:32 or CSF WBC < 20/mm³.
 - In HIV-infected patients with meningitis, poor prognostic factors include hyponatremia, concomitant growth of *C. neoformans* from another site, increased intracranial pressure, and any alteration of mental status.
- Up to 40% of patients with cryptococcal meningitis have residual neurologic deficits.
- Relapse rates are high in HIV-infected patients (see “Prevention”).

COMPLICATIONS

- Elevated intracranial pressure with meningitis
- Pulmonary, cutaneous, and bone involvement may occur (see “Associated Conditions”).
- In solid-organ transplant patients, those receiving tacrolimus immunosuppression are less likely to have CNS involvement and more likely to have skin, soft-tissue, or osteoarticular involvement.

**CODES**

ICD9
117.5 Cryptococcosis

ICD10

- B45.0 Pulmonary cryptococcosis
- B45.8 Other forms of cryptococcosis
- B45.9 Cryptococcosis, unspecified

FAQ

- Q: What are the sources of *Cryptococcus* in nature?
- A: Pigeon droppings and soil. Naturally acquired infections occur in lower mammals, especially cats. However, neither animal-to-human nor human-to-human infections have been reported.
- Q: Should all children with *Cryptococcus* be evaluated for immunodeficiency?
- A: Yes

CRYPTORCHIDISM

Hsi-Yang Wu
Thomas F. Kolon

BASICS

DESCRIPTION

An undescended testis is one that does not remain at the bottom of the scrotum after the cremaster muscle has been fatigued by overstretching. This is commonly confused with a retractile testis, one that may not always lie in the scrotum, but that will stay in the bottom of the scrotum after overstretching the cremaster.

EPIDEMIOLOGY

Incidence

- 3% of full-term boys have cryptorchidism.
- This percentage falls to 1% by 3 months of age.

Prevalence

- There are 2 peaks for detection of undescended testes: At birth, and at 5–7 years of age. The latter group probably represents those patients with low undescended testes that become apparent with linear growth.
- Bilateral undescended testes occur in 10% of patients with undescended testicles.
- Unilateral anorchia is found in 5% of patients.

Genetics

Of boys with undescended testes, 4% of their fathers and 6–10% of their brothers also had undescended testes. There is a 23% prevalence of cryptorchidism in family members of cases compared to 7.5% of relatives of controls. Androgen receptor gene mutations are not linked to isolated cryptorchidism. Abnormalities in *HOXA10*, *HOXA11*, *HOXD13*, *ESR1*, *INSL3*, and the *LGR8/GREAT* receptor genes are being investigated in patients with cryptorchidism.

PATHOPHYSIOLOGY

- Normal descent occurs during the 7th month of gestation.
- The majority of testes that will descend spontaneously do so by 3 months of age, possibly due to the gonadotropin surge that is responsible for maturation of the germ cells.
- The undescended testis fails to show normal maturation at both 3 months and 5 years of age.
 - At 3 months of age, the fetal gonocytes are transformed into adult dark spermatogonia.
 - At 5 years of age, the adult dark spermatogonia become primary spermatocytes.
 - Both of these steps are abnormal in the undescended testis, and to a lesser extent, the contralateral descended testis.
 - Previous beliefs that the undescended testis was normal between birth and 1 year of age are incorrect, since they were derived from counts of all germ cells without taking into account whether maturation was occurring.
 - After 2 years of age, thermal effects on the testis being left out of position are seen independent of the endocrinologic effects.

ETIOLOGY

- A multifactorial mechanism of occurrence involving 2 types of theories have been postulated:
 - Hypogonadotropic hypogonadism
 - Abnormal mechanical factors (gubernaculum, epididymis, genitofemoral nerve innervation, intra-abdominal pressure)
- Although boys with undescended testes do have abnormal attachment of the gubernaculum, the mechanical theories do not consistently explain the testis histology found in cryptorchidism.
- Many boys with cryptorchidism have lower morning urinary luteinizing hormone and a decreased luteinizing hormone/follicle-stimulating hormone response to gonadotropin-releasing hormone, corresponding to the abnormal germ cell development in both the undescended and contralateral descended testis.
- The normal initial postnatal gonadotropin surge at 60–90 days of age is absent or blunted in some boys with cryptorchidism. Without this surge, Leydig cells do not proliferate, testosterone does not increase, germ cells do not mature, and infertility may develop. This indicates that a mild endocrinopathy is responsible, and cryptorchidism may be a variant of hypogonadotropic hypogonadism.
- Secondary undescended testes can occur after inguinal surgery, either due to scar tissue or difficulty in diagnosing an undescended testis in a young boy with a hernia.
- Patients with prune belly, Klinefelter, Noonan, and Prader–Willi syndromes have undescended testes.

DIAGNOSIS

HISTORY

- Prematurity
- Exogenous maternal hormones (used in infertility treatments)
- Use of oral contraceptives
- CNS lesions
- Previous inguinal surgery
- Family history for urologic abnormalities
- Neonatal deaths
- Precocious puberty
- Infertility
- Consanguinity

PHYSICAL EXAM

- The undescended testis may be found at the upper scrotum, in the superficial inguinal pouch, or in the inguinal canal. For treatment purposes, the main distinction that needs to be made is whether or not the testis is palpable.

- The patient should be examined sitting in the frogleg position.
 - With warmed hands, check the size, location, and texture of the contralateral descended testis.
 - Begin the examination of the undescended testis at the anterior superior iliac spine.
 - Sweep the groin from lateral to medial with the nondominant hand.
 - Once the testis is palpated, grasp it with the dominant hand, and continue to sweep the testis toward the scrotum with the other hand.
 - With a combination of sweeping and pulling, it is sometimes possible to bring the testis to the scrotum.
 - Maintain the position of the testis in the scrotum for a minute so that the cremaster muscle is fatigued.
 - Release the testis, and if it remains in place, it is a retractile testis.
 - If it immediately pops back, it is an undescended testis.
- For the difficult-to-examine patient (chubby 6-month-olds or obese youths), having them sit with heels together and knees abducted can help relax the cremaster. Wetting the fingers of the nondominant hand with lubricating jelly or soap can increase the sensitivity of the fingers in palpating the small, mobile testis.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- For the typical patient with a unilateral palpable or nonpalpable undescended testis, no further laboratory evaluation is necessary.
- For the patient with bilateral undescended testis, with 1 testis palpable, no further workup is necessary.
- The patient with bilateral nonpalpable testes should have a chromosomal and endocrinologic evaluation, as should the patient with 1 or 2 undescended testes and hypospadias.
- If the patient has bilateral nonpalpable testes and is <3 months of age, serum luteinizing hormone, follicle-stimulating hormone, and testosterone levels will determine whether testes are present.
- After that age, human chorionic gonadotropin stimulation will result in a measurable serum testosterone if testes are present. A failure to respond to human chorionic gonadotropin stimulation in combination with elevated luteinizing hormone/follicle-stimulating hormone levels is consistent with anorchia.

Imaging

Ultrasound, CT, and MRI can detect testes in the inguinal region, but this is also the region where they are most easily palpable. They are only 50% accurate in showing intra-abdominal testes. Imaging is rarely necessary preoperatively, because, for nonpalpable testes, exam under anesthesia, open inguinal exploration, or laparoscopy is necessary to confirm the presence of testes.

DIFFERENTIAL DIAGNOSIS

- Retractable testes are commonly confused with undescended testes. The key to distinguishing them from undescended testes is the physical exam. All retractile and many undescended testes can be delivered into the scrotum. The retractile testis will stay in the scrotum after the cremaster muscle has been overstretched. The low undescended testis will immediately pop back to its undescended position after being released.
- Atrophic or “vanishing” testes are found anywhere along the normal path to the scrotum. They are believed to be due to neonatal vascular ischemia. The contralateral testis can be hypertrophied in these boys, but this is not a reliable diagnostic sign.
- On evaluation, 80% of nonpalpable testes are present in either the abdomen or in the inguinal canal. A child with bilateral nonpalpable testes should have an endocrine evaluation to rule out anorchia or disorder of sex development (DSD).
- Cryptorchidism associated with hypospadias should also raise the possibility of DSD states, which occurs in 30–40% of patients, mainly consisting of defects in gonadotropin or testosterone synthesis.

**TREATMENT****ADDITIONAL TREATMENT****General Measures**

- Patients with undescended testes should be referred for surgical evaluation no later than 3 months of age.
- Hormonal therapy:
 - This was widely used in Europe for inducing descent of undescended testes. Both gonadotropin-releasing hormone and human chorionic gonadotropin were used, with long-term success rates of 20%. Treatment is most successful for low undescended testes, but there is a 25% relapse rate. More recent recommendations from European pediatric endocrinologists indicate that surgery is the preferred therapy.
 - For these reasons, as well as the fact that gonadotropin-releasing hormone and human chorionic gonadotropin are not approved for this indication in the USA, most therapy in the USA aimed at bringing the testis down to the scrotum is surgical (orchiopexy).
 - The use of hormonal therapy after orchiopexy to improve semen analyses in high-risk patients is in its preliminary stages of investigation in Europe and the USA.

SURGERY/OTHER PROCEDURES

Goals in bringing the testis into the scrotum:

- Prevent ongoing thermal damage to the testis.
- Treat the associated hernia sac.
- Prevent testis torsion/injury against the pubic bone.
- Achieve a good cosmetic result/avoid psychological effects of empty scrotum.
- Allow the older child to perform testicular self-exam for cancer.

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

After successful orchiopexy, patients are examined at 6–12 months to check on testicular size and position. They are rechecked at puberty to explain the technique and need for monthly testis self-exam concerning early recognition of testis cancer. Patients with retractile testes should be examined annually until age 7, because ~5% will be found to have a testis out of the scrotum.

PROGNOSIS

- Surgery cannot reverse the maturational failure of the undescended testis, but it can prevent ongoing thermal injury.
- Parents are often concerned about future fertility:
 - In patients who have undergone orchiopexy at an early age, it appears that 90% of boys with unilateral cryptorchidism and 65% with bilateral cryptorchidism will achieve paternity.
 - Patients who are interested in their risk for infertility may have a semen analysis performed at age 18.
- Surgery decreases the relative risk of testicular cancer from 5.4 to 2.2 if the surgery is performed before 13 years of age.
 - All patients should be taught proper monthly testicular self-exam at the time of puberty. Some patients with cryptorchidism are at a higher risk of cancer (prune belly syndrome, ambiguous genitalia, karyotypic abnormalities, or the postpubertal boy).

**CODES****ICD9**

752.51 Undescended testis

ICD10

- Q53.9 Undescended testicle, unspecified
- Q53.10 Unspecified undescended testicle, unilateral
- Q53.20 Undescended testicle, unspecified, bilateral

FAQ

- Q: If there is only 1 testicle in the scrotum, will fertility be affected?
- A: In general, the outlook for paternity is good in a patient with only 1 descended testicle. Paternity is more significantly affected with a history of 2 undescended testicles.
- Q: Why do patients with retractile testes require follow-up?
- A: The ability to distinguish between retractile and undescended testes can be difficult in some patients. Some of the patients will be found to have true undescended testes as they grow. Boys should be taught how to perform a monthly testicular self-exam at puberty.

CRYPTOSPORIDIOSIS

Abby M. Green
Jane Gould (5th edition)

BASICS

DESCRIPTION

Cryptosporidiosis is a diarrheal illness caused by a gastrointestinal parasite. In an immunocompetent patient, disease is manifested as a self-limiting gastroenteritis. However, immunocompromised patients can develop protracted severe gastroenteritis, which can lead to severe malnutrition and is potentially life-threatening.

ETIOLOGY

Gastrointestinal illness is caused by ingestion of oocysts of the coccidian protozoa, *Cryptosporidium hominis* (formerly *Cryptosporidium parvum* human genotype or genotype I) which can only infect humans or *C. parvum* (genotype II) which can infect humans, cattle, and other mammals.

EPIDEMIOLOGY

- Oocysts of *Cryptosporidium* shed in stool. They are infectious, thus person-to-person transmission occurs.
- Water sources—drinking or recreational—contaminated with oocysts provide reservoirs for transmission.
- Infection may be transmitted from animals, especially young mammals, to humans via fecal–oral route.
- *Cryptosporidium* has been found in all parts of the world and is a cause of traveler’s diarrhea.
- Cryptosporidiosis is self-limited based on host immune response, but without a competent immune system, infection may become severe as in the case of patients with HIV, innate immune defects, or immune-suppressing medications.
- Young children are more often affected, possibly due to a relatively immature immune system.
- Between 2005 and 2007, 8,000 cases per year were reported in the US.

RISK FACTORS

- Outbreaks have been associated with swimming pools, lakes, water recreation parks, drinking water supplies, day camps, contaminated food products, and daycare centers.
- Other risk factors include exposure to livestock, dogs, cats, reptiles, and traveling abroad.

GENERAL PREVENTION

- Isolation of hospitalized patient:
 - Contact precautions (i.e., gown and gloves for all patient contact) are recommended for the length of the hospital stay. Bathrooms should not be shared.
- Community prevention:
 - Public water supplies should be adequately filtered in order to ensure oocyst removal.
 - Communities without filtration devices equipped to filter a particle size of 1 μm or smaller are at increased risk for outbreaks.
 - Homeowners with well water should consider installing drinking water filtration systems.
 - Symptomatic patients should not swim in public pools until 2 weeks after symptoms have resolved since chlorine is not effective in disinfecting the water. If a recreational water supply becomes contaminated, it should be closed for proper decontamination measures.
 - Good handwashing after contact with animals
- Control measures:
 - Handwashing, especially after changing diapers
 - Disinfection of diapering areas after each use and frequent disinfection of toys, tabletops, and highchairs during outbreaks is recommended.
 - Oocysts can survive for long periods and are resistant to many disinfectants including chlorine, iodine, and dilute bleach. Boiling water or full-strength bleach disinfectant is most effective.
 - Daycare outbreaks are common; children should not return until diarrhea has resolved.
- Immunocompromised persons:
 - Avoid contact with any person or animal with cryptosporidiosis.

PATHOPHYSIOLOGY

- Transmission occurs when oocysts contaminating food or water are ingested, or through fecal–oral transmission from person to person.
- The infectious dose for humans is low, possibly as little as 10 or fewer oocysts. The incubation period is 1–30 days with a median of 7 days, and oocyst shedding may occur for weeks to months after symptoms resolve. In the majority of people, shedding stops after 2 weeks. Immunocompromised patients can shed for several months.

- Invasion of intestinal epithelial cells—of primarily the small intestines and proximal colon—leads to a secretory diarrhea. Intestinal destruction occurs with villous atrophy and subsequent malabsorption and increased intestinal permeability.
- Parasites may be found in the epithelium of the biliary and respiratory tracts of immunocompromised individuals.
 - Respiratory tract disease is often asymptomatic.
 - Biliary tract involvement may be manifested as sclerosing cholangitis, acalculous cholecystitis, or pancreatitis.

DIAGNOSIS

HISTORY

- Acute onset of watery, nonbloody diarrhea, crampy abdominal pain, low-grade fever, and occasionally nausea and vomiting. Other symptoms can include fatigue, anorexia, and weight loss. Fever and vomiting are symptoms more commonly found in children and can lead to the misdiagnosis of viral gastroenteritis.
- Exposure to any of the transmission sources discussed above
- Primary immunodeficiency, HIV, or immune suppression secondary to medications

PHYSICAL EXAM

- Acute weight loss
- Fever
- Tenderness to palpation of abdomen
- Dehydration as manifested by tachycardia, dry mucous membranes, sunken eyes, poor capillary refill
- Immunocompromised patients may exhibit respiratory symptoms such as dyspnea or biliary tract involvement such as colicky right upper quadrant pain.

DIAGNOSTIC TESTS & INTERPRETATION

- Detection of organism in stool specimen is diagnostic. Oocysts are small and may be missed on routine microscopic examination of stool.
 - Modified acid-fast stains detect oocysts as red or pink.
 - Fluorescent stains such as auramine O are fast but have a high rate of false-positives.
 - Immunofluorescent assays and enzyme-linked immunosorbent assays for antigen detection are being used more frequently for detection of oocysts.
- For routine stool culture, laboratory staff should be notified that *Cryptosporidium* is a possible diagnosis so special staining and examination is done.
- Organisms may be identified in intestinal biopsy specimens.
- In immunocompromised hosts, consider:
 - Examination of respiratory secretions for oocysts
 - Abdominal ultrasound, bilirubin measurement, diagnostic endoscopic-retrograde cholangiopancreatography (ERCP)

DIFFERENTIAL DIAGNOSIS

- Other infectious etiology of diarrheal illness:
 - Viral gastroenteritis including rotavirus, adenovirus, astrovirus, Norwalk virus, cytomegalovirus
 - Bacterial gastroenteritis including *Salmonella*, *Shigella*, *Yersinia*, *Campylobacter*, enterotoxigenic *Escherichia coli*, *Vibrio cholerae*
 - *Clostridium difficile* enterocolitis
 - Parasitic gastroenteritis including *Giardia*, *Entamoeba*, *Cyclospora*, *Isospora*, *Microsporidia*
- Noninfectious etiology of diarrheal illness:
 - Allergic colitis, inflammatory bowel disease, irritable bowel syndrome, appendicitis, intussusception, malrotation/volvulus

**TREATMENT****MEDICATION (DRUGS)**

- Disease is often self-limited, and no treatment is necessary for immunocompetent patients.
- Nitazoxanide, a broad-spectrum oral antiparasitic medication, has been licensed by the Food and Drug Administration (FDA) for treatment of children ≥ 12 months of age with the disease.
- A 3-day course is recommended.
- Dosage for children 1–3 years old is 100 mg b.i.d.; for children 4–11 years old, 200 mg b.i.d.; and for adults, 500 mg b.i.d.
- Paromomycin, a nonabsorbed oral aminoglycoside antibiotic, has not been definitively shown to be efficacious in reducing symptoms or fecal shedding in any patients, regardless of immune status.
- For immunosuppressed patients, oral administration of human immune globulin or bovine immune globulin may reduce symptoms, though no studies definitively prove benefit with this treatment. Improving the CD4 T lymphocyte count in HIV-positive patients with antiretroviral therapy can improve the course of cryptosporidial disease in these patients.

ADDITIONAL TREATMENT**General Measures**

- Fluid and electrolyte replacement. For protracted cases, patients may eventually require parenteral nutrition.

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

- Because the oocysts can be shed in the stool for a long time after clinical resolution, it is not necessary to check follow-up convalescent stools. However, it is important to realize that asymptomatic patients can still transmit the infection to household and daycare contacts.
- Requiring patients whose diarrhea has resolved to have a negative stool test for *Cryptosporidium* before re-entry to daycare has not been evaluated as an outbreak control measure. Repeated testing is expensive.

PROGNOSIS

- For immunocompetent hosts, gastrointestinal disease is self-limited, usually lasting approximately 10 days. Supportive therapy is usually all that is necessary.
- For immunocompromised patients, diarrhea can be severe, debilitating, and often life-threatening. Aggressive supportive therapy is usually required, along with antimicrobial therapy and immune reconstitution.

A07.2 Cryptosporidiosis

FAQ

- Q: For whom should cryptosporidiosis be considered as a differential diagnosis?
- A: For anyone with acute onset of watery diarrhea with any of the mentioned risk factors
- Q: When is it safe for a child with cryptosporidiosis to return to daycare?
- A: When the diarrhea has resolved

CUSHING SYNDROME (ADRENAL EXCESS)

J. Nina Ham

Lorraine E. Levitt Katz

BASICS

DESCRIPTION

Cushing syndrome is a state of cortisol or glucocorticoid excess. This may be caused by exogenous steroid use or endogenous production. Endogenous hypercortisolism may be associated with excess production of other adrenal hormones, such as androgens and mineralocorticoids.

EPIDEMIOLOGY

- Cushing disease: Female > male in adults, but prepubertally, male > female
- Adrenocortical carcinoma: Female > male
- Cushing disease: Most common cause of endogenous Cushing syndrome, accounting for 80% of Cushing syndrome in adults and children >7 years of age
- Adrenal tumor: Adrenocortical carcinomas account for >50% of Cushing syndrome in children <7 years of age. These tumors are less common in adults and children >7 years of age.

Incidence

- 0.1–0.5/1,000,000 new pediatric cases per year
- 10 times more common in adults

PATHOPHYSIOLOGY

- Cushing disease: Pituitary ACTH oversecretion, usually due to pituitary adenoma, with resultant bilateral adrenal hyperplasia
- Primary nodular adrenal hyperplasia: Rare cause of Cushing syndrome, can be seen in association with multiple endocrine neoplasia syndrome type 1, McCune-Albright syndrome, Carney complex
- Adrenal tumors
- Adrenal adenomas: Benign tumors that secrete mainly cortisol
- Adrenal cortical carcinomas: Usually large, rapidly growing tumors, which produce a variety of hormones including cortisol and androgens. Children with adrenocortical tumors should be evaluated for Li-Fraumeni syndrome (p53 mutation).
- Ectopic ACTH production: A rare cause of Cushing syndrome in pediatrics. Small cell carcinoma, pheochromocytomas, medullary thyroid carcinoma, and carcinoid tumors can all secrete ectopic ACTH.
- Exogenous steroids: Iatrogenic Cushing syndrome is the most common cause in pediatrics. Cushing syndrome can be caused by chronic systemic, topical, or intranasal steroid use, or ACTH use.

DIAGNOSIS

HISTORY

- Growth arrest
- Weight gain, gradual onset
- Weakness and fatigue
- Emotional or mental changes
- Use of oral, topical, inhaled, or intranasal steroids

PHYSICAL EXAM

- Growth arrest: Most consistent finding
- Obesity: Cervicodorsal fat; localized (e.g., moon facies, truncal obesity)
- Thin skin with striae, facial plethora: Sign of cortisol excess
- Hirsutism, acne: Sex hormone effect
- Pubertal arrest/menstrual disorders: Common finding
- Hypertension: Mineralocorticoid effect
- Bruising: Capillary friability
- Hyperpigmentation: Seen in association with high ACTH levels
- Virilization/feminization: Sex hormone effect

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Diagnostic tests:
 - Midnight salivary cortisol level: Patients are instructed to collect saliva by chewing a commercially available cotton swab at midnight. This provides a convenient, 1st-line screening test. Establishes hypercortisolism, but positive results should be confirmed with urine free cortisol level.
 - Urinary 24-hour free cortisol: Correct for creatinine and body surface area. 2 or 3 separate collections are preferable. Establishes the diagnosis of hypercortisolism with high sensitivity, but lower specificity. False positives may be seen with pseudo-Cushing states, obesity, and depression.
 - Urinary 24-hour 17-hydroxysteroids >6 mg/g creatinine: Establishes the diagnosis of hypercortisolism
 - Overnight dexamethasone suppression test: Dexamethasone 15 mcg/kg (max 1 mg) given at 11 p.m.; check cortisol level at 8:00 a.m. the following morning. Plasma cortisol >5 mcg/L suggests hypercortisolism, but can be falsely negative.
 - Low-dose dexamethasone suppression test: Dexamethasone 0.5 mg q6h × 48 hours (<40 kg, give 30 mcg/kg/d), with serum cortisol measured at 0 and 48 hours.
 - Loss of diurnal variation of plasma cortisol in older children: Normally, the 11:00 p.m. cortisol is <50% of the 8:00 a.m. value. The majority of patients with Cushing syndrome have mean elevated plasma cortisol, without diurnal variation.

- Differentiate causes:
 - ACTH level: Cushing disease (increased ACTH with increased cortisol level), adrenal tumor (low ACTH and increased cortisol)
 - Androgen levels: Often high in adrenocortical carcinoma. Androgen levels are low in benign, cortisol-secreting adenomas.
 - Dexamethasone suppression tests. Low-dose dexamethasone (30 mcg/kg/d) divided q6h PO for 2 days, followed by high-dose (120 mcg/kg/d) divided q6h PO for 2 days. Collect 24-hour urine for cortisol and 17-hydroxysteroids throughout. Non-Cushing states usually suppress urine free cortisol and 17-hydroxysteroids to 50–90% of baseline values after low dose. Majority of pituitary tumors are suppressible after high dose. Adrenal source: Hypercortisolism will not suppress.

Imaging

Tumor location:

- Abdominal CT/MRI will demonstrate adrenal carcinoma, adrenal adenomas, or bilateral hyperplasia/nodules resulting from Cushing disease.
- Abdominal ultrasound may be useful as initial imaging for adrenal tumor.
- Pituitary MRI with gadolinium may demonstrate a pituitary adenoma.
- Cavernous sinus sampling for ACTH: Utility in lateralizing pituitary microadenoma in pediatric patients may be limited.

DIFFERENTIAL DIAGNOSIS

- Cushing disease: Pituitary ACTH oversecretion
- Adrenal tumors:
 - Adrenal adenomas
 - Adrenal cortical carcinomas
- Exogenous glucocorticoid treatment
- Exogenous obesity can cause false elevation of urine free cortisol.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Cushing disease:
 - Transsphenoidal pituitary surgery: 70–80% success, may be less in some series, perioperative glucocorticoid replacement required, postoperative complications can include transient diabetes insipidus and, rarely, hypopituitarism or permanent diabetes insipidus
 - Pituitary radiation: 6–18 months for effect. Remission in 45–85% of individuals. Remission rate improved if combined with o,p'DDD. Hypopituitarism is the most common side effect.
 - Bilateral adrenalectomy: Indicated in patients with Cushing disease who fail surgery or radiotherapy. May result in Nelson syndrome (i.e., pituitary adenoma growth and hyperpigmentation); long-term glucocorticoid and mineralocorticoid replacement required

- Drug therapy: Ketoconazole (inhibits multiple adrenal enzymes), o,p’DDD (mitotane, an adrenolytic agent), metyrapone (11-hydroxylase inhibitor), aminoglutethimide (20,22-desmolase inhibitor), trilostane (3- β -hydroxysteroid dehydrogenase inhibitor), RU-486 (glucocorticoid receptor antagonist). Drug combinations may reduce individual doses and lessen side effects.
- Bilateral nodular hyperplasia:
 - Bilateral adrenalectomy: High rate of surgical complications. Long-term glucocorticoid and mineralocorticoid replacement will be needed.
- Adrenal tumor:
 - Aggressive surgical resection, chemotherapy for carcinoma: Cyclophosphamide (Cytoxan), doxorubicin (Adriamycin), 5-fluorouracil (5-FU), methotrexate (MTX)
 - Drug therapy to control hypercortisolism: o,p’DDD at high doses may lower recurrence risk in patients with complete tumor resection. In those with residual or recurrent disease, it may improve hypercortisolism, but not survival.
 - Glucocorticoid and possibly mineralocorticoid replacement

 **ONGOING CARE**

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Acute glucocorticoid replacement: 10–12 mg/m²/d divided as b.i.d. to t.i.d. until recovery of hypothalamic/pituitary function (6–12 months). Parents should be taught to triple the dose for stress, fever, illness, or vomiting. Injectable hydrocortisone should be given for emergency use. Taper corticosteroid treatment gradually.
- Chronic glucocorticoid replacement: Patients treated with bilateral adrenalectomy or with o,p’DDD require lifelong steroid replacement and stress-dose steroids.
- Reassess 24-hour urinary cortisol/ketosteroid secretion during the 1st week after treatment and at 6 weeks.
- In the week after effective pituitary surgery, cortisol should be undetectable and ACTH <5 pg/mL, 24 hours after last hydrocortisone dose. Stimulation and suppression tests are performed 6 weeks after surgery (holding hydrocortisone dose).

- Frequent follow-up to monitor for recurrence. Monitor for cortisol withdrawal symptoms, hypopituitarism. Consider medical treatment for persistent hypercortisolism.
- Monitor growth carefully. Linear growth is often compromised in Cushing syndrome. Growth hormone deficiency can result from transsphenoidal surgery or pituitary irradiation.

ALERT

- False-positive tests for hypercortisolism: Stress, lack of suppression, depression, anorexia, primary glucocorticoid resistance
- False-negative tests: Incomplete urine collection, periodic or intermittent cortisol hypersecretion, slow metabolism of dexamethasone
- Aberrant renal metabolism
- Repeat if suspicion is strong.

PROGNOSIS

- The prognosis for cure is good with Cushing disease and adrenal adenoma.
- The prognosis for adrenal carcinoma is poor because of the frequency of micrometastases and high recurrence rate.

COMPLICATIONS

- Growth arrest
- Obesity
- Pubertal arrest
- Glucose intolerance
- Osteoporosis
- Adrenal carcinomas: Metastatic spread

E24.9 Cushing’s syndrome, unspecified

FAQ

- Q: What clinical features help distinguish patients with pituitary Cushing disease from patients with adrenal tumors?
- A: Cushing syndrome and hyperpigmentation suggest an ACTH effect. Cushing syndrome and virilization suggest adrenal carcinoma.
- Q: What physical characteristics most clearly differentiate children with exogenous obesity from those with Cushing syndrome?
- A: Exogenous obesity is associated with robust linear growth, while Cushing syndrome is associated with growth failure.

CUTANEOUS LARVA MIGRANS

Ross Newman
Jason Newland

BASICS

DESCRIPTION

Infestation of the epidermis by the infectious larvae of certain nematodes. Humans are accidental hosts, with the primary hosts being dogs and cats.

EPIDEMIOLOGY

Worldwide distribution, but most frequent in warmer climates, including the Caribbean, Africa, South America, Southeast Asia, and southeastern USA

RISK FACTORS

- Contracted from soil contaminated with dog and cat feces
- Occupational exposures occur from crawling under buildings, such as among plumbers and pipefitters.
- Route of spread:
 - Primary host (dog or cat) passes eggs to ground through feces
 - Warm, sandy soil acts as an incubator
 - Eggs mature into *rhabditiform larvae* (noninfectious), which molt in 5 days to *filariform larvae* (infectious)
 - Incubation period from infection to symptoms usually 7–10 days, although can range up to several months

PATHOPHYSIOLOGY

- Humans are accidental hosts.
- *Filariform larvae* penetrate the epidermis either through hair follicles or fissures or through intact skin with the use of proteases.
- Larvae are unable to penetrate the basement membrane of the dermis; therefore, the infection remains limited to the epidermis.

- Larvae cannot complete their life cycle in the human host and die within weeks to months.
- Diagnosis is usually clinical. Organisms are rarely recovered from biopsy and antibody titers are unreliable because symptoms are due to hypersensitivity to the organism or its excreta, and immunity usually does not develop.

ETIOLOGY

- Most common organism is the dog or cat hookworm, *Ancylostoma braziliense*.
- Other species include *Ancylostoma caninum*, *Uncinaria stenocephala*, and *Bunostomum phlebotomum*.

COMMONLY ASSOCIATED CONDITIONS

- Most common manifestation is an intensely pruritic, linear, reddened, elevated, serpiginous skin lesion known as a “creeping eruption”
- Most common complication is secondary bacterial infection of the involved skin
- Rare cases of a peripheral eosinophilia with pulmonary infiltrates (Löffler syndrome) occur when the larvae invade the bloodstream..

DIAGNOSIS

HISTORY

- Incubation period
 - Usual time from infection to symptoms is 7–10 days, but may last for up to several months.
- Rash:
 - It is intensely pruritic, raised, serpiginous, and linear. Most commonly located on feet, buttocks, and abdomen. Also found on face, extremities, and genitalia.
- Pruritus:
 - Symptoms typically begin with some tingling in the affected area with the development of the typical rash with intense pruritus.

- Speed at which rash spreads:
 - Rash typically lengthens by a few millimeters to 2–3 cm daily.
- Source of infection:
 - Most frequently contracted from beaches in tropical countries where dogs are frequently found. In the USA, most frequently contracted from moist soil in the southeastern USA contaminated with animal feces.

PHYSICAL EXAM

The classic rash is described as an erythematous, raised, serpiginous rash. In addition, it may begin as vesicular and/or form bullae along the track. Tracks under the skin reflect the course of the larvae. The active end is not part of the track.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Biopsy: Not indicated, because it rarely yields organisms
- Serologic testing: Not helpful
- Diagnosis based on clinical presentation

DIFFERENTIAL DIAGNOSIS

- Cutaneous larva migrans should be considered in anyone with an intensely pruritic, raised, serpiginous, linear cutaneous eruption.
- Hookworm infections (*Strongyloides stercoralis*, *Uncinaria stenocephala*, *Bunostomum phlebotomum*, *Gnathostoma spinigerum*)
- Free-living nematodes (*Pelodera strongyloides*), and insect larvae
- Other cutaneous eruptions that may mimic cutaneous larva migrans include scabies, tinea pedis, erythema chronicum migrans of Lyme disease, jelly fish stings, contact dermatitis, and photosensitivity.

TREATMENT

General Measures

- First-line treatment is topical thiabendazole: 10% suspension of 500 mg/5 mL applied four times a day for 10 days
- Alternatively, oral thiabendazole: 25–50 mg/kg/d q12h for 2 days. Not well tolerated
- Ivermectin: 12 mg in a single dose. May repeat if symptoms persist
- Albendazole: Not approved for use in the USA, is available in other countries and is administered as 400 mg/day for 3 days in adults

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Symptoms persist for 8 weeks, but up to 1 year in untreated patients.
- Those with extensive involvement should be seen after treatment to be certain of improvement in symptoms.

PROGNOSIS

- This is a self-limited disease and will resolve without treatment when the larvae die.
- There is a 98% response rate to topical thiabendazole, a 97% cure rate with ivermectin, and an 89% response rate reported with oral thiabendazole.

COMPLICATIONS

- Most common complication is secondary bacterial infection of the skin.
- Self-limited disease: If untreated, larvae die within 2–8 weeks, but may persist for up to 1 year.
- Rarely, the larvae can invade the dermis and, subsequently, the bloodstream, leading to a peripheral eosinophilia and pulmonary infiltrates (Löffler syndrome).

ADDITIONAL READING

CODES

ICD9

- 126.2 Ancylostomiasis due to *ancylostoma braziliense*
- 126.9 Ancylostomiasis and necatoriasis, unspecified (cutaneous larva migrans not otherwise specified)

ICD10

- B76.0 Ancylostomiasis
- B76.9 Hookworm disease, unspecified

FAQ

- Q: Can children spread the infection to each other?
- A: The usual spread of infection is from direct contact with the larvae. Spread from 1 individual to another does not occur.

CYCLOSPORA

Jessica Newman

Jason Newland

BASICS

DESCRIPTION

Cyclospora catayensis, a coccidian protozoan, causes a diarrheal illness first described in humans in 1979.

GENERAL PREVENTION

Fresh produce, especially raspberries, should be washed thoroughly before being eaten, although this still may not entirely eliminate the risk of transmission.

EPIDEMIOLOGY

- Worldwide distribution, with areas of endemic infection (Nepal, Peru, Haiti, Guatemala, Indonesia)
- People living in endemic areas have a shorter illness or may be asymptomatic carriers.
- Cyclospora is an opportunistic infection in human immunodeficiency virus patients.
- In the USA, infection occurs primarily in spring and summer.
- In the USA and Canada, cases are associated with consumption of imported fresh produce.

PATHOPHYSIOLOGY

- Infected patients excrete noninfectious unsporulated oocysts in their stool.
- Sporulation then occurs days to weeks after release into the environment.
- Ingestion of sporulated oocysts occurs and sporozoites are released that invade the intestinal epithelial cells.
- Sporozoites develop into trophozoites which undergo schizogony and form merozoites.
- Merozoites may develop into macro- or microgametes which become fertilized, resulting in oocysts.
- Entire life cycle is completed in the host.
- Incubation period is between 1 and 11 days, with an average of 7 days.

ETIOLOGY

- Outbreaks have been associated with the consumption of raspberries, mesclun (young salad greens), and basil.
- Infection occurs through the consumption of contaminated food and water.
- Transmission does not occur through person-to-person spread.

DIAGNOSIS

HISTORY

- Fever:
 - Fever is present in ~50% of cases.
- Clinical prodrome:
 - Acute onset of diarrhea is typical, but a flulike prodrome may occur.
- Nature of the diarrhea:
 - Profuse, nonbloody, watery diarrhea that may be foul smelling. Can alternate with constipation.
- Other symptoms experienced:
 - Abdominal cramping, fatigue, anorexia, flatulence and vomiting
- Foods that have been consumed in the past 2 weeks:
 - Illness has been attributed to contaminated raspberries, water, mesclun, snow peas and basil.

PHYSICAL EXAM

Dehydration:

- Due to profuse diarrhea, signs of dehydration (tachycardia, dry mucous membranes, sunken eyes, poor skin turgor, and weight loss) may be present.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Ova and parasites with modified acid fast staining: Identification of *Cyclospora*, *Isospora*, and *Cryptosporidium*
- PCR testing available from the CDC.
- Ova and parasites: Identify common protozoans including *Giardia*
- *Cryptosporidium* and *Giardia* antigen test: Immunoassay with high sensitivity and specificity
- Electron microscopy of stool: Gold standard for diagnosing microsporidia
- Bacterial stool cultures: Identify common bacterial pathogens
- Stool for *Clostridium difficile* PCR: Identify a common cause of diarrhea
- Electrolytes, blood urea nitrogen, creatinine: Determine extent of dehydration

DIFFERENTIAL DIAGNOSIS

- *Cryptosporidium*:
 - Outbreaks associated with contaminated water sources (municipal pools)
 - Person-to-person transmission may occur.
 - Clinically indistinguishable from *Cyclospora*
- *Isospora belli*:
 - Outbreaks associated with food and water
 - Clinically indistinguishable from *Cyclospora*, though fever may be more common
- *Microsporidium*:
 - Outbreaks associated with contaminated water sources
 - Chronic diarrhea occurs in immunocompromised patients, especially HIV patients.
 - Fever is uncommon.

- *Giardia lamblia*:
 - Community epidemics associated primarily with contaminated water sources
 - Person-to-person transmission may occur and has led to outbreaks in day care centers.
 - Clinical presentation may vary from occasional acute watery diarrhea to a severe, protracted diarrheal illness.
- Viral gastroenteritis:
 - Rotavirus
 - Adenovirus 40/41
- Bacterial gastroenteritis:
 - *Clostridium difficile*
 - *Vibrio cholera* and noncholera *Vibrio* species
 - *Escheria coli* (especially toxin-producing strains)
 - *Shigella* species
 - *Salmonella* species
 - *Yersinia enterocolitica*
 - *Campylobacter* species

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Immunocompetent patient: Trimethoprim (5 mg/kg)–sulfamethoxazole twice a day for 7–10 days
- HIV patient: Trimethoprim–sulfamethoxazole four times a day for 10 days and then prophylactic dosing 3 times per week to prevent relapse
- Ciprofloxacin or nitazoxanide for 7 days may be alternatives in patients with sulfa allergy.
- Based on severity of dehydration, treatment with IV fluids may be indicated.

IN-PATIENT CONSIDERATIONS

Admission Criteria

Moderate to severe dehydration

ONGOING CARE

PROGNOSIS

- Most cases are self-limited.
- Diarrhea may last up to 3 months in untreated patients who acquired the parasite in a foreign country where *Cyclospora* is endemic.
- In US outbreaks, the average duration of diarrhea ranged from 10 to 24 days.
- Relapses may occur in untreated patients.
- Patients with HIV have more severe and prolonged diarrhea, which may recur.

COMPLICATIONS

- Dehydration and weight loss are the most common complications.
 - Severe, prolonged diarrhea may lead to dehydration.
 - Malabsorption of D-xylose and excretion of fecal fat occurs, leading to weight loss.
- May cause ascending biliary tract disease in AIDS patients
- Rare associated complications:
 - Guillain–Barré syndrome
 - Reactive arthritis

PATIENT MONITORING

- Infected patients need to be observed closely for dehydration.
- Relapse may occur in HIV patients, so close follow-up is essential.

ICD10

A07.4 Cyclosporiasis

FAQ

- Q: Does routine ova and parasites testing detect *Cyclospora*?
- A: Rarely; therefore, modified acid–fast staining must be done to improve the laboratory's ability to detect the oocysts
- Q: Can person-to-person transmission occur in cyclospora illness?
- A: No. It takes days to weeks for oocysts to sporulate and become infectious.

CYSTIC FIBROSIS

Samuel B. Goldfarb

Bruce A. Ong

BASICS

DESCRIPTION

Cystic fibrosis (CF) is an inherited, autosomal recessive disorder, characterized by chronic obstructive lung disease, pancreatic exocrine insufficiency, and elevated sweat chloride concentration.

ALERT

- Most common pitfall is failure to diagnose. Neonatal screening is not performed in all states.
- Not uncommon to delay making the diagnosis in patients with mild symptoms

EPIDEMIOLOGY

- Most common lethal inherited disease in the Caucasian population
- Carrier frequency of mutations in the CF transmembrane conductance regulator (CFTR) gene:
 - 1:29 in Caucasians
 - 1:49 in Hispanics
 - 1:53 in Native Americans
 - 1:62 in African Americans
 - 1:90 in Asians

Incidence

- 1:3,300 in Caucasians
- 1:9,500 in Hispanics
- 1:11,200 in Native Americans
- 1:15,300 in African Americans
- 1:32,100 in Asians

RISK FACTORS

Genetics

CFTR gene:

- Located on the long arm of chromosome 7
- Most common mutation results in deletion of phenylalanine at position 508 in the CFTR glycoprotein.
- The $\Delta 508$ mutation occurs in ~70% of CF patients.
- > 1,500 mutations have been reported in the CFTR gene.
- Presence of gene modifiers may cause incomplete phenotypic presentations.

GENERAL PREVENTION

Prepregnancy carrier detection

PATHOPHYSIOLOGY

- CFTR:
 - Membrane glycoprotein, which functions as a cyclic AMP-activated chloride channel at the apical surface of epithelial cells
 - An abnormality in CFTR results in defective chloride conductance.
 - May have other roles in the regulation of membrane channels and the pH of intracellular organelles. May affect cell apical sodium channel regulation
 - CFTR abnormalities may act as binding sites for *Pseudomonas aeruginosa*, promoting proinflammatory responses in the lung.

- In the respiratory system:
 - Lungs are morphologically normal at birth.
 - Increased mucus viscosity
 - Early bacterial colonization despite a robust neutrophilic inflammatory response
 - Mucous plugging and atelectasis
 - Bronchiectasis and emphysema develop.
 - Abnormal nasal sinus development
- In the GI tract:
 - Progressive pancreatic damage from ductal and acinar secretions lead to exocrine pancreatic insufficiency
 - Endocrine pancreatic dysfunction
 - Focal biliary cirrhosis of the liver
 - Hypoplasia of the gallbladder and impaired bile flow

DIAGNOSIS

HISTORY

- Most common presenting respiratory symptoms: Chronic cough, recurrent pneumonia, nasal polyps, chronic pansinusitis
- Most common presenting GI symptoms:
 - Meconium ileus (15–20% of patients present with this symptom); pancreatic insufficiency occurs in 85% of patients. In infants, fat malabsorption may lead to chronic diarrhea and failure to thrive.
 - In older patients, pancreatitis, rectal prolapse (occurs in 2% of the patients, must consider CF until proven otherwise, commonly seen between 1 and 5 years of age)
 - Distal obstruction of the small intestine (meconium ileus equivalent, seen in older children and adults)
- Evidence of heat intolerance: In summer, increased sweating may lead to dehydration with hyponatremia or hypochloremic metabolic alkalosis.

PHYSICAL EXAM

- Respiratory findings:
 - Frequent cough, often productive of mucopurulent sputum
 - Rhonchi, crackles, wheezing, hyperresonance to percussion
 - Nasal polyposis
- Other common findings:
 - Digital clubbing
 - Hepatosplenomegaly in patients with cirrhosis
 - Growth retardation
 - Hypertrophic osteoarthropathy
 - Delayed puberty
 - Osteoporosis

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Sweat test: Keystone for the diagnosis of CF; sweat chloride >60 mEq/L is abnormal.
- Sweat test: keystone for diagnosis of CF:
 - <40 mmol/L – Negative
 - 40 mmol/L to 60 mmol/L – borderline
 - >60 mmol/L – Consistent with CF
 - In infants up to 6 months of age:
 - 30 mmol/L to 60 mmol/L – borderline
 - 60 mmol/L – Consistent with CF

- Diagnostic criteria include:
 - One or more phenotypic features of CF
 - OR
 - Sibling with CF
 - OR
 - Positive newborn screening test
 - AND
 - 2 positive sweat tests
 - OR
 - 2 CF mutations on genetic screening
 - OR
 - Nasal potential difference (NPD) consistent with CF
- Other causes of elevated sweat chloride:
 - Malnutrition
 - Adrenal insufficiency
 - Nephrogenic diabetes insipidus
 - Ectodermal dysplasia
 - Fucosidosis
 - Hypogammaglobulinemia
 - False negatives seen in CF patients with edema
- Mutation analysis: Can detect >90% of CF patients. Failure to identify 2 mutations reduces, but does not eliminate, the possibility of CF. Immunoreactive trypsinogen test (IRT) is used for newborn screening. In the IRT test, blood drawn 2–3 days after birth is analyzed for trypsinogen. Positive IRT tests must be confirmed by sweat test and/or genetic testing.
- Frequently recovered organisms in sputum cultures:
 - *Haemophilus influenzae*
 - *Staphylococcus aureus*
 - MRSA (methicillin-resistant *S. aureus*)
 - *P. aeruginosa* (nonmucoid and mucoid)
 - *Burkholderia cepacia*
 - *Stenotrophomonas maltophilia*
 - *Aspergillus* species
- Pulmonary function test: Usually reveals obstructive lung disease, although some patients may have a restrictive pattern
- Analysis of stimulated pancreatic secretions: Degree of pancreatic exocrine deficiency
- Fecal elastase measurements can detect pancreatic insufficiency.
- 72-hour fecal fat measurement: Fat malabsorption

Imaging

- Chest radiography:
 - Typical features include hyperinflation, peribronchial thickening, atelectasis, and bronchiectasis.
- CT scan:
 - Early bronchiectasis

DIFFERENTIAL DIAGNOSIS

- Pulmonary:
 - Recurrent pneumonia or bronchitis
 - Asthma
 - Aspiration pneumonia
 - Ciliary dyskinesia
 - Airway anomalies
 - Chronic sinusitis
 - Chronic Aspiration
 - Non-CF bronchiectasis
 - Allergic Bronchopulmonary Aspergillosis
 - Alpha-1 antitrypsin disease

- GI:
 - Failure to thrive
 - Celiac disease
 - Protein-losing enteropathy
 - GERD
 - Chronic pancreatitis
- Other:
 - Metabolic alkalosis
 - Immune deficiency
 - Shwachman-Diamond Syndrome

TREATMENT

MEDICATION (DRUGS)

First Line

- Antibiotic therapy based on sputum culture results and clinical improvement:
 - Oral antibiotics:
 - Cephalexin
 - Linezolid
 - Trimethoprim-sulfamethoxazole
 - Ciprofloxacin, inhaled tobramycin, colistin, or aztreonam in selected patients
 - IV antibiotics:
 - To treat *S. aureus*, consider oxacillin, ticarcillin with clavulanic acid, linezolid, or vancomycin.
 - To treat *P. aeruginosa* and *B. cepacia*, consider aminoglycoside plus ticarcillin, ceftazidime, or piperacillin.
 - Severe cases with resistant strains may benefit from aztreonam, imipenem, or meropenem.
 - Synergistic antibiotic studies can be performed in patients with multiresistant organisms.
 - Regular azithromycin treatment may be used for both anti-inflammatory purposes to improve lung function.
- Clearance of pulmonary secretions:
 - Chest physical therapy, or with high-frequency oscillatory vest device. Adjunct therapy such as Flutter valve, Acapella, or PEP mask may also be used.
 - Bronchodilator: Aerosol or metered-dose inhaler (β_2 -agonist)
 - Mucolytics: RhDNase
 - Anti-inflammatory: Short-term oral steroid course. Inhaled corticosteroids may benefit patients with asthma and/or demonstrating an oral steroid response.
 - Hypertonic saline
- GI disease:
 - Pancreatic enzyme replacement therapy: Used in CF patients who are pancreatic insufficient; dosage adjusted for frequency and character of the stools and for growth pattern; generic substitutes are not bioequivalent to name brands. The maximum recommended dose is 2,500 U of lipase/kg per meal.
 - Vitamin supplements: Multivitamin supplement, fat-soluble vitamins A, D, E, and K
 - Patients with cholestasis may benefit from therapy with ursodeoxycholic acid.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Specialized care should be at a CF center.
- Frequency of visits depends on age and severity of illness:
 - Infants should be seen at least once monthly for 1st 12 months, then every 2–3 months thereafter.

DIET

- High-calorie diet with added salt
- Lifelong nutritional support usually required
- Duration of antibiotic therapy is controversial; more frequent use is required as pulmonary function deteriorates.

PROGNOSIS

- Current median survival is ~38 years.
- Variable course of the disease
- The median survival has been increasing for the past 4 decades, although the rate of increase in age has slowed in the past decade.

COMPLICATIONS

- Respiratory complications:
 - Recurrent bronchitis and pneumonia
 - Atelectasis
 - Bronchiectasis
 - Pneumothorax
 - Hemoptysis
 - Chronic sinusitis and nasal polyps
- GI complications:
 - Pancreatic insufficiency in 85–90% of CF patients
 - Patients usually have steatorrhea, poor growth, and poor nutritional status.
 - Decreased levels of vitamins A, E, D, and K
 - Rectal prolapse
 - 10–15% of patients have meconium ileus.
 - Distal intestinal obstruction syndrome
 - Clinically significant focal biliary cirrhosis; hepatobiliary disease in 5% of CF patients
 - Esophageal varices
 - Splenomegaly
 - Hypersplenism
 - Cholestasis
- Reproductive complications:
 - Sterility in 98% of males, due to absence or atresia of the vas deferens
 - Slight decrease in fertility for females secondary to abnormalities of cervical mucus
- Endocrine complications:
 - Glucose intolerance
 - CF-related diabetes occurs with increasing frequency in adolescent and adult patients.
- Skeletal complications:
 - Osteoporosis

FAQ

- Q: Should relatives be tested?
- A: All siblings should have a sweat test.
- Q: How well will a child with CF do?
- A: The course of the illness is variable. It is difficult to predict the course of disease in an individual.
- Q: How should a borderline sweat test be interpreted?
- A: Borderline sweat tests should always be correlated with other findings such as physical exam, sputum cultures, pulmonary function, radiographic findings, nutritional evaluation, and/or mutation analysis.

CYTOMEGALOVIRUS INFECTION

Sujit S. Iyer

Rakesh D. Mistry

BASICS

DESCRIPTION

Cytomegalovirus (CMV) is a ubiquitous double-stranded DNA virus that is a member of the herpesvirus family. Establishes latency in peripheral mononuclear cells.

EPIDEMIOLOGY

- Increased rates of primary infection are seen in early childhood, adolescence, and childbearing years.
- Transmission may occur by contact with infected respiratory secretions, urine, or breast milk, sexual contact, solid-organ transplantation, or transfusion of infective blood products.

Prevalence

Seroprevalence varies with socioeconomic status; 50% of middle- and 80% of lower-socioeconomic-status adults are seropositive.

GENERAL PREVENTION

- Drainage and secretion, and pregnant women precautions, should be instituted for hospitalized patients known to be shedding CMV.
- Seriously ill neonates should receive blood products from cytomegalovirus-negative donors.
- CMV-seronegative solid-organ or bone marrow transplantation recipients should receive organs (and all blood products) from CMV-negative donors whenever possible.
- Controversy exists over the role of hyperimmune globulin to prevent disseminated CMV disease in CMV-negative recipients of CMV-positive transplantation.

PATHOPHYSIOLOGY

Infection leads to intranuclear inclusions with massive enlargement of cells. Almost any organ may become infected with CMV in severe disseminated infection.

COMMONLY ASSOCIATED CONDITIONS

- Congenital infection:
 - Occurs in 1% of newborns
 - Intrauterine transmission more common in mothers with primary infection during pregnancy (40–50%) compared to recurrent infection (<1%). Controversy over postnatal acquisition of CMV via breast milk and whether it precludes breastfeeding in premature infants (has a lower risk for neurologic sequelae)
 - 10% of infected infants are symptomatic at birth, with severe disease characterized by growth retardation, hepatosplenomegaly, thrombocytopenia, and CNS involvement.
 - 10–20% of infants who are asymptotically infected at birth will develop long-term sequelae.
 - Of symptomatically infected infants, 90% will have neurologic sequelae. Degree of impairments may be predicted by CT findings and FOC at birth.

- Mononucleosis syndrome:
 - CMV can cause a mononucleosis-like syndrome similar to that caused by Epstein–Barr virus (EBV) infection.
 - The most common symptoms are malaise (67%) and fever (50%). ~70% of patients have abnormal liver enzymes.
 - Pharyngitis and splenomegaly less common and severe than observed with EBV-induced mononucleosis.
- Interstitial pneumonitis:
 - Seen primarily in immunosuppressed children and adults
 - Begins with fever and nonproductive cough, but may progress to dyspnea and severe hypoxia over 1–2 weeks
 - Mild, self-limited pneumonitis may occur in immunocompetent patients.
- Retinitis:
 - Seen in ~30% of infants with symptomatic congenital infection
 - Immunosuppressed children should have regular eye exams.
- Hepatitis:
 - Occurs in healthy individuals with primary infections and in immunosuppressed patients with either primary or reactivated disease
 - Fever, mild elevation of liver enzymes and hepatomegaly, are typical. Jaundice and severe hepatitis are uncommon.
- GI disease:
 - Severely immunosuppressed patients may experience esophagitis, gastritis, colitis, or pancreatitis.
 - Diagnosis requires endoscopy with biopsy.
- CNS disease:
 - Commonly seen in infants with symptomatic congenital infection
 - Characterized by microcephaly, periventricular calcifications, seizures, developmental delay, and sensorineural hearing loss
 - Encephalitis or meningoencephalitis may occur postnatally in either healthy or immunocompromised patients.
- Deafness:
 - CMV is the most common cause of congenital deafness.
 - Onset of deafness often seen after first month of life and is progressive. May be missed by newborn hearing screen (if only done in 1st 2 weeks of life)

DIAGNOSIS

HISTORY

- Day care attendance:
 - Increased risk of infection
- Recent blood transfusion:
 - Transfusion-associated CMV
- Use of immunosuppressive medications:
 - Increased use of serious infection
- Prolonged fever:
 - Mononucleosis-like syndrome
- Blurred vision:
 - CMV retinitis
- Cough, dyspnea, wheezing:
 - CMV pneumonitis
- Vomiting, abdominal pain, diarrhea (watery or bloody):
 - CMV colitis

PHYSICAL EXAM

- Microcephaly:
 - Congenital infection
- White, perivascular retinal infiltrates and hemorrhage:
 - Retinitis
- Deafness (may require audiogram, brainstem evoked auditory responses):
 - Congenital infection
- Photophobia, headache, nuchal rigidity:
 - Meningitis
- Tachypnea, rales:
 - Pneumonitis
- Hepatomegaly and/or splenomegaly:
 - Mononucleosis-like syndrome
- Rash:
 - Petechiae, purpura, “blueberry muffin” lesions, rubelliform rash
- Adenopathy:
 - Mononucleosis-like syndrome

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Viral culture: Virus may be isolated from nasopharyngeal/oropharyngeal secretions, urine, stool, WBC. Isolation may take up to 4 weeks. Urine or saliva samples are most common way to diagnose congenital disease.
- Shell-vial assay system (staining for early antigen production) allows detection of virus 24–72 hours after inoculation

- Quantitative antigenemia assay: Detection of circulating CMV-infected mononuclear cells by indirect immunofluorescence. In an immunocompromised patient, may monitor response to therapy or identify viral reactivation
- Serology: Enzyme-linked immunosorbent assay or indirect fluorescent antibody assay to detect the presence of CMV IgM or IgG. CMV IgM usually persists for 6 weeks following primary infection, although it may persist up to 6 months.

ALERT

- Due to frequency of asymptomatic shedding, mere isolation of virus does not necessarily establish an etiologic association.
- Severely immunocompromised patients who are actively infected with CMV may be seronegative. 4-fold rise in CMV IgG is not diagnostic of primary infection. Increased antibody titers may occur with reactivation.

Imaging

Noncontrast head CT:

- Periventricular calcifications, cystic abnormalities, ventriculomegaly, periventricular leukomalacia
- Fetal Brain MRI has higher sensitivity than ultrasound for brain abnormalities, and greater predictor of symptomatic infection.

DIFFERENTIAL DIAGNOSIS

- Congenital infection:
 - Congenital rubella syndrome
 - Toxoplasmosis
 - Syphilis
 - Neonatal herpes simplex virus
 - Human immunodeficiency virus
 - Enteroviral infection
- Mononucleosis syndrome:
 - EBV infection
 - Toxoplasmosis
 - Hepatitis A or B infection
- Interstitial pneumonitis:
 - Respiratory syncytial virus
 - Adenovirus
 - Measles
 - Varicella
 - Pneumocystis carinii
 - Chlamydia
 - Mycoplasma
 - Fungal
 - Drug/toxin-induced pneumonitis
- Retinitis:
 - Ocular toxoplasmosis
 - Candidal retinitis
 - Syphilis
 - Herpes simplex virus
- Hepatitis:
 - EBV infection
 - Hepatitis A, B, or C infection
 - Enterovirus
 - Adenovirus
 - Herpes simplex virus
 - Drug/toxin-induced

- GI disease:
 - Herpes simplex virus
 - Adenovirus
 - Salmonella
 - Shigella
 - Campylobacter
 - Yersinia
 - Clostridium difficile
 - Giardia
 - Cryptosporidium
- CNS disease:
 - Congenital disease (see “Congenital Infection,” above)
 - Meningoencephalitis in immunocompetent host: Herpes simplex virus, EBV, varicella-Zoster virus, enterovirus, arbovirus
 - Meningoencephalitis in immunocompromised host: In addition to organisms listed previously, should include HIV encephalitis, fungal meningitis, toxoplasmosis

**TREATMENT**

Majority of transplant experts prefer prophylaxis over preemptive therapy in high risk patients (Donor CMV positive, recipient negative).

MEDICATION (DRUGS)**First Line**

- Ganciclovir will suppress viral replication but not eradicate virus (virostatic agent)
 - Indications: CMV chorioretinitis in immunocompromised patients; tissue diagnosis (hepatitis, enteritis, pneumonitis) of CMV infection or isolation of CMV from buffy coat of immunocompromised patient; consider for neonate with documented CNS disease to prevent progressive postnatal hearing loss
 - Side effects: Neutropenia (50%), thrombocytopenia (~5%)
- Foscarnet—virostatic agent
 - Indications: CMV chorioretinitis, pneumonitis, hepatitis, enteritis (biopsy proven) in immunocompromised patient who has failed to improve on ganciclovir therapy or who has experienced significant bone marrow toxicity related to ganciclovir use
 - Side effects: Renal impairment (25%), headache (25%), seizures (10%)

**ONGOING CARE****PROGNOSIS**

Varies with nature of infection (see “Associated Conditions”)

COMPLICATIONS

Varies with nature of infection (see “Associated Conditions”)

**CODES****ICD9**

- 078.5 Cytomegaloviral disease
- 771.1 Congenital cytomegalovirus infection

ICD10

- B25.8 Other cytomegaloviral diseases
- B25.9 Cytomegaloviral disease, unspecified
- P35.1 Congenital cytomegalovirus infection

FAQ

- Q: Should children with congenital cytomegalovirus infection be excluded from day care settings?
- A: No. Due to the high frequency of shedding of cytomegalovirus in the urine and saliva of asymptomatic children, especially those under 2 years of age, exclusion from out-of-home care is not justified for any child known to be infected with cytomegalovirus. Careful attention to hygienic practices, especially hand washing, is important.

DAYTIME INCONTINENCE

Amanda K. Berry

Michael Carr

Seth L. Schulman (5th edition)

BASICS

DESCRIPTION

- Daytime wetting in a child ≥ 5 years of age warrants evaluation.
- Causes of functional incontinence include an array of bladder storage and voiding disorders.
- Voiding dysfunction is abnormal behavior of the lower urinary tract without a recognized organic cause, generally in the form of pelvic floor hyperactivity or bladder-sphincter uncoordination.
- Dysfunctional elimination syndrome describes the association between abnormal bladder and bowel behavior.

ALERT

- Failure to recognize and manage constipation before attempting to manage wetting
- Failure of anticholinergic medication in children with significant postvoid residuals or with constipation
- Use of anticholinergic medications in children with benign frequency of childhood is generally ineffective.
- Increased risk of urinary tract infections (UTIs) when child is placed on anticholinergic medication, due to infrequent voiding/incomplete emptying

EPIDEMIOLOGY

Prevalence

- Studies in children 6–7 years of age have shown that 3.1% of girls and 2.1% of boys had an episode of wetting at least once per week.
- Spontaneous cure rate of 14% per year without treatment
- Of all children who wet, 10% have only daytime wetting, 75% wet only at night, and 15% wet during the day and at night.

RISK FACTORS

- Constipation
- Recurrent UTIs
- Diabetes mellitus/diabetes insipidus
- Attention deficit disorder/attention deficit hyperactivity disorder (ADD/ADHD)
- Developmental delay

Genetics

- Only anecdotal relationships have been seen in functional daytime incontinence, unlike studies showing genetic tendencies in nocturnal enuresis.
- Increased rates of daytime wetting have been reported in urofacial (Ochoa) syndrome, an autosomal-recessive condition, and Williams syndrome which is the result of a deletion involving the elastin gene in chromosome #7.

ETIOLOGY

- Neurogenic bladder (e.g., myelomeningocele)
- Anatomic anomalies (e.g., ectopic ureter)
- Obstructive uropathy (e.g., posterior urethral valves)
- Bladder irritability caused by UTI
- Constipation
- Increased urinary output—polyuria
- Infrequent or deferred voiding
- Overactive bladder
- Low functional bladder capacity, with detrusor instability during filling
- Temperamental factors (e.g., short attention span, inattentiveness to body signals) in children who ignore the urge to void
- Developmental differences in age at which toilet training is achieved
- Vaginal reflux with subsequent leakage of urine
- Giggle incontinence

COMMONLY ASSOCIATED CONDITIONS

- Constipation
- Nocturnal enuresis
- UTIs
- Vesicoureteral reflux is more common in children with voiding dysfunction, due to elevated detrusor pressures that overcome a marginal vesicoureteral junction.

DIAGNOSIS

HISTORY

- Onset (primary vs. secondary)
- Frequency of voiding
- Frequency and degree of wetting
- Presence or absence of any dry interval
- Signs of urgency; use of hold maneuvers; waiting until the last minute to void

- Description of stream (i.e., strong/weak, continuous/interrupted)
- Straining or pushing during voiding
- Frequency and description of bowel movements
- Quality and quantity of fluid intake
- History of soiling
- History of UTIs, vesicoureteral reflux
- ADD/ADHD, learning disabilities, or developmental delays
- Level of concern on part of child/family
- Medications
- Signs and symptoms:
 - Urgency:
 - Posturing; Vincent's curtsy
 - Frequent urination
 - Deferred voiding
 - Weak or intermittent stream
 - Large, hard, or infrequently passed bowel movements
 - Recurrent UTIs

PHYSICAL EXAM

- Abdomen: Signs of constipation; distended bladder
- Rectal: If constipation is suspected
- Spine: Sacral abnormalities
- Genitalia: Labial adhesions, labial erythema, phimosis, urethral stenosis
- Neurologic: Sensation, reflexes, and gait

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- First morning urinalysis to check concentrating ability, rule out occult renal disease
- Urine culture to rule out infection

Imaging

- Renal and bladder ultrasound in children who wet with a history of UTIs and in children with persistent wetting despite regular voiding
- Kidneys, ureter, and bladder (KUB) x-ray to assess for constipation
- MRI of lumbosacral spine if sacral abnormality or refractory to treatment

Diagnostic Procedures/Other

- Uroflowmetry and assessment of postvoid residual urine
- Invasive urodynamic testing is not indicated in neurologically normal children unless refractory to treatment.

DIFFERENTIAL DIAGNOSIS

- UTI
- Constipation
- Developmental variations in toilet training
- Neurogenic bladder
- Spinal cord abnormality
- Giggle incontinence
- Genitourinary tract abnormality (posterior urethral valve, ectopic ureter)
- Vaginal reflux
- Benign increased urinary frequency (pollakiuria)
- Sexual abuse

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Aggressive management of bowels so that child is passing at least 1 soft bowel movement daily (see “Constipation”)
- Elimination schedule, with voids every 2–3 hours and time to defecate at least once a day. A reminder watch may be helpful.
- Voiding diary provides concrete data and focus for child.
- Positive reinforcement for regular voiding
- Avoid acidic/diuretic beverages (caffeine, carbonation, chocolate, citrus)
- Adequate hydration
- Local management of perineal irritation/vulvovaginitis to ensure comfort during voiding
- Girls with postvoid dribbling due to vaginal reflux should void with their legs wide apart, sitting backward on the toilet when possible, to minimize backflow of urine into the vagina. Wipe after standing up.

MEDICATION (DRUGS)

- A trial of an anticholinergic may be indicated if the child wets despite conservative medical/behavioral management.
- Extended-release formulations are available.
- Common side effects include dry mouth, decreased diaphoresis with flushing, and constipation. Blurred vision and dizziness are less common.

First Line

- Oxybutynin (Ditropan/Ditropan XL): 5–15 mg/d
- Tolterodine (Detrol/Detrol LA): 2–4 mg/d
- Solifenacin (Vesicare): 5–10 mg/d
- Darifenacin (Enablex): 7.5–15 mg/d

ISSUES FOR REFERRAL

Referral to pediatric urologist:

- When wetting is refractory to behavioral management, child may benefit from a noninvasive urodynamic evaluation to assess flow pattern, voiding mechanics, and ability to empty the bladder.

ONGOING CARE

PROGNOSIS

- Spontaneous cure rate of 14% per year without treatment
- 72% of patients sustained improvement 1 year after simple behavioral therapy.

COMPLICATIONS

- Local irritation and inflammation of the perineum
- Functional daytime incontinence is primarily a social problem that affects children’s self-esteem and interactions with peers.

CODES

ICD9

- 307.6 Enuresis
- 788.30 Urinary incontinence, unspecified
- 788.91 Functional urinary incontinence

ICD10

- F98.0 Enuresis not due to a substance or known physiol condition
- R32 Unspecified urinary incontinence
- R39.81 Functional urinary incontinence

FAQ

- Q: What findings can distinguish functional incontinence from an ectopic ureter?
- A: An ectopic ureter usually empties below the sphincter or elsewhere, such as in the vagina. Therefore, these girls wet all the time, with no dry period. They do not have symptoms such as urgency. Because in most cases the ureter draining the kidney is duplicated, an ultrasound or IV pyelogram (IVP) may provide more information.
- Q: What is a normal bladder capacity for a child?
- A: Normal bladder capacity (in mL) can be estimated as the child’s weight (in kg) × 7. A child’s bladder capacity can be determined by measuring voided volumes for 2 consecutive days when the child is well hydrated. The largest voided volume is considered the child’s maximum functional capacity.
- Q: When is an MRI of the spine indicated?
- A: Spinal cord imaging should be considered in children with refractory daytime wetting and signs and symptoms suggestive of neuropathic voiding dysfunction, including difficulty voiding, significant postvoid residual urine, or impaired bladder sensation. It should also be considered when ultrasound reveals a thickened bladder wall and hydroureteronephrosis is present in the absence of an obstruction such as posterior urethral valves.

DEHYDRATION

Marc H. Gorelick

BASICS

DESCRIPTION

- Dehydration is a negative balance of body fluid, usually expressed as a percentage of body weight. Mild, moderate, and severe dehydration correspond to deficits of <5%, 5–10%, and >10%, respectively.
- Dehydration is classified into 3 types on the basis of serum sodium concentration: Isotonic (Na 130–150 mmol/L), hypotonic (Na <130 mmol/L), and hypertonic (Na >150 mmol/L)

GENERAL PREVENTION

Many cases of frank dehydration may be prevented by early institution of adequate oral maintenance fluid therapy in children with gastroenteritis, with particular attention to replacement of ongoing stool losses and slow administration of fluids to children with vomiting. Use of appropriate solutions is essential to prevent electrolyte disturbance and worsening of diarrhea.

EPIDEMIOLOGY

Incidence

- ~10% of children in the USA with acute gastroenteritis develop at least mild dehydration.
- Although it accounts for 10% of all nonsurgical hospital admissions for children younger than 5 years, up to 90% of cases can be managed on an outpatient basis.

PATHOPHYSIOLOGY

- Dehydration is caused by either excessive fluid losses or inadequate intake of fluids.
- Some conditions leading to dehydration include:
 - GI losses: Vomiting, diarrhea (most common cause of dehydration in pediatric patients)
 - Renal losses: Diabetes mellitus, diabetes insipidus, diuretic agents
 - Insensible losses: Sweating, fever, tachypnea, increased ambient temperature, large burns
 - Poor oral intake: Stomatitis, pharyngitis, anorexia, oral trauma, altered mental status
- Note that infants and debilitated patients are at particular risk due to lack of ability to satisfy their thirst freely.

DIAGNOSIS

HISTORY

- Frequency and duration of emesis and/or diarrhea will give a rough estimate of risk of dehydration.
- If there were large quantities of water taken, be alert for hypotonic dehydration. If inadequate free water is used for hydration, patient may have hypertonic dehydration
- Frequency and quantity of urination may be difficult to estimate in infants with diarrhea.
- Decreased urination indicates possibility of dehydration.
- Fever increases insensible water loss.
- Exertion or heat exposure increases insensible water loss.

PHYSICAL EXAM

- Acute change in weight is the best indicator of fluid deficit. If the child's recent preillness weight is not available for comparison, a reasonable estimate of the degree of dehydration may be made from physical findings.
- General appearance: Lethargy, irritability, thirst
- Vital signs: Tachycardia; orthostatic increase in heart rate or hypotension; hyperpnea
- Skin: Prolonged capillary refill at fingertip (<2 sec is normal in warm environment); mottling; poor turgor
- Eyes: Decreased or absent tears; sunken eyes
- Mucous membranes: Dry or parched
- Anterior fontanelle: Sunken

ALERT

Diagnostic pitfalls:

- Physical signs generally appear when the deficit is as small as 2%.
- No single finding is pathognomonic of dehydration. A reasonable guideline is that the presence of 3 or more findings indicates at least mild dehydration. The number and severity of physical signs increase with the degree of dehydration.
- Urine output decreases early in the course of dehydration, and a history of decreased urination is a sensitive but nonspecific finding.
- Capillary refill time is a specific but insensitive indicator. It may be falsely prolonged by cool ambient temperature [$<20^{\circ}\text{C}$ ($<68^{\circ}\text{F}$)]. It is not affected by fever.
- Children with a deficit >15% will show signs of cardiovascular instability such as severe tachycardia and hypotension.
- Physical findings may be more significant for a given degree of dehydration in children with hyponatremia, leading to overestimation of the deficit. Conversely, the clinical picture is reported to be somewhat moderated in hypernatremia.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Diagnosis of dehydration is best made on clinical grounds. The following laboratory tests are sometimes helpful adjuncts.
- Serum sodium:
 - Classifies type of dehydration
 - Hyponatremia and hypernatremia are uncommon in dehydration due to gastroenteritis (<5% of cases).
 - Measure sodium levels in cases of clinically severe disease, or if risk factors are present (e.g., infant <2 months, history of excessive free water intake, children with significant neurologic impairment limiting their ability to regulate their own intake).
- Rapid glucose test or serum glucose: To detect hypoglycemia due to prolonged fasting
- Urine specific gravity: This is elevated early in dehydration, but may not become elevated at all in young infants or in children with sickle cell disease.
- Serum bicarbonate: This is frequently low with diarrheal illness, even in the absence of dehydration. Useful to detect significant acidosis when dehydration is clinically severe
- Blood urea nitrogen (BUN): May rise late in dehydration in children

TREATMENT

ADDITIONAL TREATMENT

General Measures

Oral rehydration therapy (ORT):

- Most children can be managed successfully with oral rehydration therapy, either at home or in a health care setting.
- Use rehydration solution containing 2.0–2.5% glucose and 75 mmol/L Na (e.g., WHO solution), or 45–50 mmol/L Na [e.g., Pedialyte (Ross Laboratories, Columbus, OH), Infalyte (Mead Johnson, Evansville, IN)].
- Replace entire deficit in 4–6 hours: For mild dehydration, 50 mL/kg; for moderate to severe dehydration, 80–100 mL/kg. Include ongoing losses, ~5 mL/kg for each diarrheal stool.
- Begin with slow administration, with strict limits when vomiting is present: 5 mL q1–2min. For infants, use a syringe or spoon rather than a bottle. After 1 hour, if the oral liquids have been tolerated, increase the volume and rate.
- Have the child's caregiver participate in giving the fluids, and provide education with regard to fluid replacement and signs of dehydration.
- Monitor weight, intake and output, and clinical signs. Failure of oral rehydration therapy includes intractable vomiting, clinical deterioration, or lack of improvement after 4 hours.

IV Fluids

- IV fluids are required when ORT fails or is contraindicated, such as in severe dehydration or shock, poor gag or suck, depressed mental status, severe hypernatremia ($\text{Na} > 160$ mmol/L), suspected surgical abdomen.
- Administer IV bolus of normal saline or Ringer lactate, 20 mL/kg, over 10–30 minutes. Repeat as needed to restore cardiovascular stability. Avoid dextrose-containing solutions for boluses except to correct documented hypoglycemia.
- Calculate maintenance fluid requirements: 100 mL/kg for the 1st 10 kg, plus 50 mL/kg for the next 10 kg, plus 20 mL/kg over 20 kg.
- Calculate fluid deficit based on clinical estimate or known weight loss. For isotonic or hypotonic dehydration, give 1/3–1/2 normal saline with 5% dextrose, at a rate adequate to provide maintenance and replace deficit over 24 hours. For hypertonic dehydration, replace deficit over 48 hours, using 1/5–1/4 normal saline with 5% dextrose.
- Monitor weight, intake and output, and clinical signs. With hypernatremia, measure serum sodium q4–6h; do not exceed rate of fall of 1 mmol/L/h.
- For mild to moderate isonatremic dehydration, rapid replacement of deficit over 2–6 hours may be possible. Give normal saline at a rate to replace the estimated deficit at a rate of 25–50 cc/kg/h.

MEDICATION (DRUGS)**First Line**

Most children with dehydration do not require specific medication therapy. For children with significant vomiting, several studies indicate that ondansetron 0.15 mg/kg PO decreases vomiting and facilitates oral rehydration.

IN-PATIENT CONSIDERATIONS**Admission Criteria**

- Failure of oral or IV rehydration within 4 hours
- Severe hypernatremia
- Substantial ongoing losses indicating a high likelihood of recurrence of dehydration

Discharge Criteria

After initiating ORT, children who are tolerating oral fluids at an acceptable rate to replace their deficit over 4–6 hours may be discharged with a willing and reliable caregiver and complete the ORT at home.

**ONGOING CARE****PROGNOSIS**

Excellent with appropriate rehydration therapy

COMPLICATIONS

- Severe dehydration may lead to hypovolemic shock and acute renal failure.
- Hyponatremia is associated with hyponatonia, hypothermia, and seizures.
- Overly rapid correction of hypernatremia can produce cerebral edema.

PATIENT MONITORING

- After rehydration, children with ongoing losses, as in gastroenteritis, should receive a maintenance solution in addition to regular feedings to maintain a positive fluid balance.
- Recommend 5–10 mL/kg for each diarrheal stool. Avoid clear liquids with excessive glucose, such as fruit juices, punches, and soft drinks, as these can promote osmotic fluid losses in the stool.
- In infants <6 months old, do not give large amounts of plain water, which can lead to hyponatremia.

22Q11.2 DELETION SYNDROME (DIGEORGE SYNDROME)

Erin E. McGintee

BASICS

DESCRIPTION

22q11.2 deletion syndrome, formerly known as DiGeorge syndrome, is characterized by thymic and parathyroid aplasia or hypoplasia, cardiac outflow tract abnormalities, cleft palate, velopharyngeal insufficiency, speech delay, and facial dysmorphism. T-cell immunodeficiency is observed in 80% of children with DiGeorge syndrome:

- Patients with complete DiGeorge syndrome have a severe T-cell defect.
- Partial DiGeorge syndrome occurs when the T-cell defect is partial or transient.

RISK FACTORS

Genetics

- Heterogeneous
- 6–10% of cases are familial.
- Most common associated chromosomal abnormalities are heterozygous microdeletions of 22q11.2.

PATHOPHYSIOLOGY

DiGeorge is believed to be a developmental defect of the 3rd and 4th pharyngeal arches.

DIAGNOSIS

HISTORY

- Neonatal hypocalcemia secondary to hypoparathyroidism
- Recurrent viral and opportunistic infections: Diarrhea, candidiasis, respiratory infections, *Pneumocystis carinii* pneumonia (PCP)
- Cardiac defects, particularly interrupted aortic arch, septal defects, tetralogy of Fallot, and truncus arteriosus
- Failure to thrive

PHYSICAL EXAM

Facial dysmorphism (micrognathia; low, rotated ears; fish-shaped mouth; short philtrum, anteverted nares, broad nasal bridge, and hypertelorism):

- Cleft lip and palate
- Heart murmur
- Renal abnormalities
- Skeletal abnormalities
- Central nervous system malformations
- Cognitive/behavioral disorders
- Major immunologic features present at birth: Lymphopenia, T-cell dysfunction; antibody levels and function are variable.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC with differential:
 - Immediately after birth, a lymphocyte count of $<1,200/\text{mm}^3$ is suspicious.
 - Serum calcium
 - Evaluation of parathyroid function, if necessary

- Lymphocyte markers:
 - To determine absolute numbers of T and B cells and their subsets
- Mitogen studies:
 - To study the functional abilities of T and B cells. In DiGeorge syndrome, you may see a variably depressed response to phytohemagglutinin, concanavalin A, and pokeweed mitogen.
- Quantitative immunoglobulins (IgG, IgA, IgM, and IgE):
 - Often the humoral system will be abnormal if there is helper T-cell dysfunction.
- Fluorescence in situ hybridization (FISH) for 22q11 deletion:
 - Most common chromosomal defect

Imaging

Chest radiograph study to evaluate for cardiac malformation and also for the presence of a thymic shadow

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Depending on the defects or deficiencies the child manifests, some issues may need to be addressed:
 - Cardiology for the cardiac malformations
 - Otolaryngology and feeding specialist for cleft palate
 - Endocrinology for follow-up of hypoparathyroidism
 - Speech and cognitive intervention for speech delay
 - Immunology to monitor T-cell disorder and recurrent infections
 - Severe immunodeficiency may require matched sibling bone marrow transplant or thymic transplant.

- Special consideration with infections: Children with the complete DiGeorge syndrome are at increased risk of morbidity and mortality from viral infections either from vaccines or natural infections:
 - Avoid live viral vaccines in cases of severe T-cell dysfunction. These patients may need immunoglobulin replacement therapy to protect from infections.
 - Most patients with CD4+ cell counts >500 cells/mm³ can be safely and effectively vaccinated with live viral vaccines.
 - Consider varicella immune globulin in a patient with either unknown humoral immunity status or definitive humoral abnormalities and a history of exposure. IV acyclovir may be necessary if varicella develops and patient has severe T-cell defect.
- Special consideration with blood transfusions:
 - Because these patients are at risk for graft-versus-host disease, it is best to use cytomegalovirus-negative, irradiated blood.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Monitor growth.
- Monitor hearing.
- Monitor development.

PROGNOSIS

Prolonged survival is seen in most patients after the spontaneous improvement of T-cell numbers and function. Patients with complete DiGeorge syndrome may have more severe and persistent T-cell dysfunction. Complications may include an increase in autoimmune phenomena and neurologic sequelae.

COMPLICATIONS

In the newborn period, patients present with hypocalcemic tetany, manifestation of cardiac abnormality, and recurrent infections. Later on, patients present more commonly with neurologic and developmental or behavioral issues. Patients are at increased risk for development of autoimmune disease.

CODES

ICD9
279.11 DiGeorge syndrome

ICD10
D82.1 Di George's syndrome

FAQ

- Q: Is there a definitive test to distinguish between partial and complete DiGeorge syndrome?
- A: Over time, patients with partial DiGeorge syndrome will reconstitute their T cells and acquire improved function based on mitogen and antigen studies.

DENTAL/ORAL PAIN AND URGENCIES

Hugh Silk

Sheila Stille

Ciarán DellaFera

BASICS

DESCRIPTION

Dental urgencies consist of a number of acute issues that occur in the mouth. These include dental caries, cavities, worsening infections, such as abscesses and cellulitis, trauma, and other sources of referred pain.

EPIDEMIOLOGY

- Dental caries are the most common chronic disease of childhood: 19% of 2–5 year olds and 52% of 5–9 year olds
- 30% of preschoolers have suffered a dental trauma to primary teeth
- 25% of 12 year olds have injured their permanent teeth

Incidence

- Peak incidence of dental injury occurs between ages 2 and 4 years
- 80% of caries in children between ages 5–17 occur in 25% of all children, those with the most risk factors

DIAGNOSIS

HISTORY

- Details of when, where and mechanism of injury or infection; determine tetanus status
- Assess symptoms: Pain, swelling, change in occlusion, difficulty opening mouth
- Children may not be able to localize pain and may exhibit vague symptoms (e.g., not eating second to pain or dysphagia or trismus)

PHYSICAL EXAM

- Urgency/emergency Triage
 - Airway first (ABCs)
 - Assess for other life-threatening injuries
 - Assess the Cervical Spine
 - Neurologic exam
 - Check for skull, orbit, or zygomatic fractures
 - Ask/assess primary versus permanent teeth
 - Note availability of dental care
- Examine mouth – systematic approach
 - Irrigate to remove blood, clots, and debris
 - Soft tissues
 - Teeth: Primary or Permanent
 - Bony structures
- Specifically assess for:
 - Tenderness, swelling, erythema
 - Lacerations or ulcers
 - Damaged or mobile teeth
 - Occlusion
 - Mobile jaw segments/step-off abnormalities
 - Pain or limitation on opening
 - Referred pain sources (ear, sinus)

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Rare; culture and sensitivity for complicated infection

Imaging

- See 'Treatment' below for specifics
- May require individual periapical films, panoramic views or CT

Diagnostic Procedures/Other

- General Goals
 - PHASE ONE: Stabilize patient (if necessary)
 - PHASE TWO: Make specific diagnosis; rule out differential diagnoses
 - PHASE THREE: Create patient-centered management plan focusing on alleviating pain/disease
- Hints for Screening Problems
 - Screening/education is key for prevention:
 - Ask and advise about oral hygiene promotion and dental surveillance
 - Education about medical/dental connections
 - Educate about mouth guard use; consult against oral piercings/secondary prevention (remove piercing for sports, don't click on teeth, treat infected piercing early)

DIFFERENTIAL DIAGNOSIS

• INFECTIONS

- Reversible pulpitis: A carious lesion (cavity) which approaches the dental pulp
- Irreversible pulpitis: A carious lesion which continues into the dental pulp
- Periapical abscess: A localized purulent erosive area of bone at apex of tooth root secondary to necrotic pulp of tooth
- Periodontal abscess: A localized purulent form of periodontitis secondary to loss of supporting structure (ligament, gum)
- Cellulitis/facial abscess: Second to progression of periapical abscess
- Pericoronitis: Gum flap traps food and plaque over partially erupted molar or impacted wisdom teeth leading to local inflammation and infection

ALERT

Secondary infections: Submental, sublingual, and submandibular space (Ludwig's angina); fistulas; facial cellulitis; meningitis

• TRAUMA

- To the teeth
 - Concussion: Tooth is tender but not displaced or mobile
 - Intrusion: Tooth pushed deep into gum/socket
 - Extrusion: Tooth is partially displaced (outward) from the gum/socket
 - Subluxation: Tooth is mobile but majority of ligament attachment is in place
 - Luxation: Tooth is mobile; no or some displacement; ligament support is severely damaged
 - Avulsion: Tooth is completely detached and extruded from mouth
 - Tooth fracture: Four basic types based on depth of break: Enamel only; enamel and dentin; enamel, dentin and pulp; root
- To the jaw:

- Mandible fracture: Suspect in chin trauma; can break in 2 places along arch
- Maxillary fracture: Alveolar versus LeFort
- ALLERGY/INFLAMMATION/VASCULITIS
 - Gingivitis: Superficial inflammation of gums second to poor oral hygiene and plaque irritation, foreign body (food) between teeth and gum, or hormonal changes (OCPs, pregnancy)
 - Periodontitis: Inflammation of bone and supporting ligaments and gum resulting in bone loss
 - Acute necrotizing ulcerative gingivitis (Vincent's angina): Edematous, ulcerated gingival; bacterial etiology
 - Ulcers: Aphthous; infectious (viral: Herpetic, coxsackie; bacterial); traumatic (e.g., biting gum); drug reaction
 - Temporomandibular joint inflammation (TMJ)
- MISCELLANEOUS
 - Bruxism leading to teeth erosion or TMJ
 - Referred pain: Otitis media/externa, sinusitis

TREATMENT

Emergency Care

- Triage as above in "Physical Exam"
- Address pain early and often

ADDITIONAL TREATMENT

General Measures

- PAIN MANAGEMENT:
 - Acetaminophen, NSAIDs, with or without opioids (note mouth pain can be significant) based on body weight
 - Avoid irritating cold/hot drinks, food
- INFECTIONS:
 - Reversible pulpitis: Restoration (filing)
 - Irreversible pulpitis: Root canal and restoration or extraction
 - Periapical abscess: Local or regional anesthesia, incision and drainage, antibiotics if cellulitis; definitive treatment is root canal and restoration or extraction; antibiotics—penicillin 50 mg/kg/day divided tid, max 1.5 g/day for 10 days; clindamycin 10–25 mg/kg/day divided tid for penicillin allergy
 - Facial cellulitis second to dental infection: outpatient therapy with antibiotics (as above) for mild cases with adherent patients; close follow-up and dental referral for root canal, restoration or extraction
 - Pericoronitis: Irrigate under gum flap; removal of gum flap; extraction if impacted wisdom tooth

ALERT

Inpatient care for extensive cellulitis as spread to deep tissues can result in trismus, sepsis, or airway occlusion; consult Surgery/Oral Surgery, Infectious Diseases; IV broad spectrum antibiotics and analgesics; CT imaging; root canal, restoration or extraction

- **TRAUMA**
 - Don't assume missing teeth were lost at scene: Consider swallowed, aspirated, in sinus
- **Primary Teeth:**
 - Luxated teeth: Minimal mobility – monitor; very loose or interfere with occlusion – referral for extraction
 - Intrusion: Don't reposition, will re-erupt; requires imaging to assess damage to underlying permanent tooth; monitor
 - Avulsion: Do NOT re-implant
- **Permanent Teeth:**
 - Concussion of tooth: Monitor with dentist
 - Subluxation: Usually reposition, splint
 - Extrusion or lateral luxation: Reposition, splint, +/- root canal
 - Intrusion: Do not reposition, often associated with alveolar bone fracture; usually needs extraction after bone heals (4 months later)

ALERT

- **Avulsion:** A true dental emergency!
 - Hold tooth by crown, DO NOT touch root; Rinse off debris with saline or milk; Re-implant immediately; Bite on gauze or hold tooth in place; See dentist immediately for x-ray, splinting, and root canal treatment.
 - If can't re-implant on scene, transport in saline, milk, or buccal sulcus (not water!)
 - Fractures: Save all fragments for dentist; although, restoration of fragments may not be possible
 - Enamel only: Non-urgent dental referral to smooth rough edges
 - Enamel and dentin: Referral within 12 hours for restoration to protect pulp
 - Enamel, dentin, and pulp: Immediate referral for root canal, restoration or extraction
 - Root fracture: Immediate referral for imaging, root canal, restoration, or extraction
 - Mandibular condyle or alveolar bone fracture: Refer to oral surgeon within 1 hour for reduction; swelling makes more difficult
- **ALLERGY/INFLAMMATION/VASCULITIS**
 - Gingivitis: Remove any foreign bodies between teeth or in gingival crevice; advise to improve dental hygiene including brushing bid with fluoridated toothpaste and daily flossing; warm saline rinses; regular dental visits for cleaning, prevention. For necrotizing gingivitis refer for debridement; 0.012% chlorhexidine mouth rinses
- **PREVENTION**
 - Tetanus prophylaxis for intrusion, avulsion, deep laceration or contaminated wound if not updated in past 5 years
 - Remind patient – wear a mouth guard; avoid mouth piercings/jewelry; if already pierced, remove if possible for sports and avoid clicking on teeth; daily dental hygiene; regular dental visits

- High risk sports for dental trauma include: Hockey, football, soccer, boxing, wrestling, basketball, baseball, skateboarding, skiing, bicycling, in-line skating trampoline use
- Mouth guards come in many colors, styles; custom/fitted are better than boil and bite, which are better than stock, however custom are expensive

ISSUES FOR REFERRAL

- See "Treatment" for specifics
- Definitive treatment for ANY tooth-based infection is root canal or extraction of tooth
- Note: Pregnant teenagers can have dental x-rays, restoration, extractions, appropriate antibiotics and analgesics throughout pregnancy; all non-urgent treatment is best done during second trimester due to lowest risk for miscarriage and most comfortable in dental chair; first trimester, schedule appointments in afternoon due to nausea; third trimester, position patient on left side and keep visits short, avoid full recline of chair

SURGERY/OTHER PROCEDURES

Permanent teeth avulsion, tooth fractures involving the pulp or root, jaw fractures, extensive cellulitis require emergent referrals; all other emergencies can be referred next day or later

**CODES****ICD9**

- 521.00 Dental caries, unspecified
- 522.4 Acute apical periodontitis of pulpal origin
- 959.09 Injury of face and neck

ICD10

- K02.9 Dental caries, unspecified
- K04.7 Periapical abscess without sinus
- S09.93XA Unspecified injury of face, initial encounter

CLINICAL PEARLS

- Very few true dental emergencies: Spreading cellulitic dental infection; avulsed or fractured permanent tooth or jaw bone
- Definitive treatment for tooth infections is restorative root canal or extraction; must follow up all infections with dental referral
- Dental urgencies can be prevented with proper oral hygiene, preventive dental visits, avoidance of mouth piercings and use of mouth guards

DERMATOMYOSITIS/POLYMYOSITIS

Timothy Beukelman

Randy Q. Cron

BASICS

DESCRIPTION

The dermatomyositis/polymyositis complex includes a number of conditions in which muscle becomes damaged by a non-suppurative lymphocytic inflammatory process. Juvenile dermatomyositis (JDM) is the most common seen in the pediatric population.

EPIDEMIOLOGY

- The average age of onset is 7 years.
- Overall male-to-female ratio is 1:1.7; however, equal in children <10 years of age.

Incidence

- 1:200,000

RISK FACTORS

Genetics

HLA-DQ0301

ETIOLOGY

- Unknown
- Several potential mechanisms include:
 - Abnormal cell-mediated immunity
 - Immune-complex formation
 - Immunodeficiency
 - Infection
 - Microchimerism
 - Interferon-alpha

DIAGNOSIS

HISTORY

- Fever: Evidence of systemic illness
- Anorexia and weight loss: GI involvement
- Fatigue: Sign of muscle weakness
- Weakness: Difficulty rising from floor, climbing stairs, swallowing, regurgitation through nose
- Dysphonia: Sign of muscle weakness
- Rash could contain clue to diagnosis.

- Signs and symptoms:
 - Diagnosis requires the presence of the pathognomonic rash plus 3 additional criteria:
 - Progressive symmetric weakness of proximal muscles
 - Dermatitis-heliotrope rash over eyelids, Gottron papules over extensor surfaces of joints
 - Elevated serum level of muscle enzymes
 - Electromyograph (EMG) findings of myopathy and denervation
 - Biopsy demonstration of inflammatory myositis
 - Although not a criterion, T2-weighted MRI is useful in establishing active myositis.

PHYSICAL EXAM

- Muscle weakness/tenderness: Proximal and symmetric
- Rash:
 - 75% have pathognomonic rash, which usually appears several weeks after muscle weakness.
- Facial rash:
 - Violaceous, heliotropic changes over eyelids
- Extremities:
 - Gottron papules over extensor surfaces
- Nailfold telangiectasia:
 - Simultaneous dilated loops, dropout, and arborized capillary loops
- Physical exam tricks:
 - Gower sign: Inability to rise from floor without using hands
 - Use ophthalmoscope to examine nailfold for telangiectasia
 - Objective measure of strength: Duration of straight leg raise (normal = 20 seconds)

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Autoantibodies:
 - Normal rheumatoid factor, complement, and double-stranded DNA (dsDNA)
 - Antinuclear antibody: 10–50%
 - PM-1: 60% adult polymyositis; however, rare in children
 - Jo-1: Associated with interstitial lung disease

- Muscle enzymes:
 - Elevated in 95% cases
 - Creatine kinase
 - Aspartate aminotransferase
 - Aldolase
 - Lactate dehydrogenase

Imaging

- MRI:
 - Inflamed muscles are identified by signal enhancement.
 - Useful to direct biopsy
- Video swallow study:
 - To identify palatal or proximal esophageal weakness
- Pulmonary function tests/peak flow:
 - To evaluate pulmonary musculature and interstitial lung disease

Pathological Findings

- Skeletal muscle:
 - Group atrophy or perifascicular myopathy
 - Variation in fiber size due to concomitant degeneration and regeneration
 - Inflammatory exudate in perivascular distribution
 - Necrotizing vasculitis of arterioles, capillaries, and venules; probably due to immune-complex deposition
- Skin:
 - Epidermal atrophy
 - Vascular dilatation
 - Lymphocyte infiltration of the dermis

DIFFERENTIAL DIAGNOSIS

- Postinfectious:
 - Influenza A and B, coxsackievirus B, schistosomiasis, trypanosomiasis, toxoplasmosis
 - Bacterial/pyomyositis-focal
- Myositis with other connective tissue diseases:
 - Malignancy (rare in childhood)
 - Mixed connective tissue disease
 - Systemic lupus erythematosus

- Childhood neuromuscular diseases:
 - If no rash, consider muscular dystrophy, congenital myopathies, metabolic disorders (glycogen storage disease, carnitine deficiency, myoadenylate deaminase)
 - Neurogenic atrophies (spinal muscular atrophy and anterior horn, peripheral nerve dysfunction)
 - Neuromuscular transmission disorders
 - Inclusion body myositis

TREATMENT

MEDICATION (DRUGS)

- Aggressive early therapy
- 2 mg/kg/d of prednisone for 1 month, taper over months to years
- IV gamma globulin, efficacious for rash
- Plaquenil, particularly useful for the rash
- Methotrexate (PO, SC, or IV); avoid IM, which may alter serum levels of muscle enzymes
- Cyclosporine
- Mycophenolate mofetil
- Rituximab (experimental for refractory disease)

ALERT

- Steroid-induced myopathy
- Insidious onset
- Proximal and distal muscles, often large muscle groups such as hip flexors
- Normal serum muscle enzymes
- Minimal myopathic changes on electromyograph
- Type II fiber atrophy on muscle biopsy

ADDITIONAL TREATMENT

General Measures

Supportive care:

- Monitor for swallowing difficulty
- Respiratory compromise occasionally requires mechanical ventilation.
- Treatment of calcinosis may include colchicine, diltiazem, and bisphosphonates, but most are generally ineffective.

Additional Therapies

- Physical therapy
 - Initially to maintain range of movement
 - Strengthening only after acute inflammation resolves

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Function
- Muscle strength
- Joint range of movement
- Development of calcinosis
- Muscle enzyme levels

PROGNOSIS

- Normal to good: 65–80%
- Minimal atrophy and joint contractures: 24%
- Calcinosis: 20–40%
- Wheelchair dependent: 5%
- Death: 3%

COMPLICATIONS

- Myositis
- Rash
- Arthritis
- Calcinosis
- Raynaud syndrome
- Dysphagia and dysphonia
- Restrictive lung disease and aspiration pneumonia
- Myocarditis (rare)
- GI tract vasculitis
- Osteoporosis
- Joint contractures
- Skin infections
- Lipoatrophy

CODES

ICD9

- 710.3 Dermatomyositis
- 710.4 Polymyositis

ICD10

- M33.90 Dermatopolymyositis, unsp, organ involvement unspecified
- M33.00 Juvenile dermatopolymyositis, organ involvement unspecified

FAQ

- Q: Is it mandatory to perform a muscle biopsy to confirm the diagnosis?
- A: No. MRI (T2 or STIR imaging) can suffice.
- Q: Is there an associated risk of malignancy as for adults with this disorder?
- A: Extremely rare.

DEVELOPMENTAL DISABILITIES

Rita Panoscha

BASICS

DESCRIPTION

- Developmental delay is a descriptive term, not a specific diagnosis, comprising many disorders and encompassing a broad category of etiologies.
- The term describes any situation where a child is not meeting age-appropriate milestones as expected in 1 or more streams of development. These streams of development include gross motor, fine motor, receptive and expressive language, adaptive, and social.
- The key feature is that the rate of progress has been slow over time in the area(s) of delay.

ALERT

- Children with behavioral problems may also be masking developmental delays.
- Children with delays in 1 stream of development may also have delays in other areas of development. For example, language delay may be an indication of general cognitive delays.
- Hearing impairment may present as a delay in development.

EPIDEMIOLOGY

Found in both sexes and all racial and socioeconomic groups

Prevalence

This is a heterogeneous group of disorders with different prevalence rates.

GENERAL PREVENTION

There is no known prevention of developmental delays, although prevention of some of the underlying causes is possible.

PATHOPHYSIOLOGY

- This is highly variable depending on etiology, which can include genetic, familial, metabolic, infectious, endocrinologic, traumatic, anatomic brain malformations, environmental toxins, and degenerative disorders as causes. These disorders often result in some neurologic or neuromuscular injury causing the delay. In many cases, the etiology is never determined.
- Prevalence of this group of disorders may vary depending on how inclusive the definition is. The milder delays are quite common and can be found in any pediatric practice. Some disorders in this grouping are more prevalent in boys. The long-term outcome depends on the severity and type of delay, with the more involved children usually having lifelong disability.

ETIOLOGY

Specific etiologies are too numerous to list completely but a partial list of the more common causes includes:

- Genetic/familial:
 - Fragile X syndrome
 - Trisomy 21 (Down syndrome)
 - Other chromosomal abnormalities
 - Tuberous sclerosis
 - Neurofibromatosis
 - Phenylketonuria
 - Muscular dystrophy
- Nervous system anomalies:
 - Hydrocephalus
 - Lissencephaly
 - Spina bifida
 - Seizures
- Infections:
 - Prenatal cytomegalovirus
 - Rubella
 - Toxoplasmosis
 - HIV
 - Postnatal bacterial meningitis
 - Neonatal herpes simplex
- Endocrinologic:
 - Congenital hypothyroidism
- Environment:
 - Heavy metal poisoning such as lead
 - In utero drug or alcohol exposure
- Trauma/injury:
 - Closed head trauma
 - Asphyxia
 - Stroke
 - Perinatal cerebral hemorrhages

COMMONLY ASSOCIATED CONDITIONS

- There are numerous associated findings including seizures, sensory impairments, feeding disorders, psychiatric disorders (especially depression), and behavioral disorders.
- Having a child with significant developmental delays can also add stress to the family in terms of time, finances, and emotions.

DIAGNOSIS

HISTORY

A complete and detailed history is needed, including:

- Pregnancy history:
 - Maternal age and parity
 - Maternal complications (including infections and exposures)
 - Medications/drugs used
 - Tobacco or alcohol used, along with quantities
 - Fetal activity

- Birth history:
 - Gestational age
 - Birth weight
 - Route of delivery
 - Maternal or fetal complications/distress
 - Apgar scores
- General health:
 - Significant illnesses, hospitalizations, or surgeries
 - Accidents or injuries
 - Hearing and vision status
 - Medications used
 - Known exposures to toxins
 - Any new or unusual symptoms
- Developmental history:
 - Current developmental achievement in each stream of development
 - Age when developmental milestones were achieved
 - Any loss of skills
 - Where parents think their child is functioning developmentally
- Educational history:
 - Type of schooling and services received, if any
 - Any previous educational/developmental testing
- Behavioral history:
 - Any perseverative or stereotypical behaviors
 - Interaction skills
 - Attention and activity level
- Family history:
 - Anyone with developmental delays, neurologic disorders, syndromes, consanguinity

PHYSICAL EXAM

- A complete physical exam including growth parameters is needed looking for etiology.
- Key features to include:
 - Observation of interactions and behavior: Any atypical behaviors and general impression
 - Head circumference: Looking for macrocephaly or microcephaly
 - Skin exam: Looking for neurocutaneous lesions
 - Major or minor dysmorphic features: Any indication of a syndrome or anatomic malformation
 - Neurologic examination: Looking for cranial nerve deficits, neuromuscular status, reflexes, balance and coordination, and any soft signs
 - Developmental testing: Although considerable information will already be available on history and observation, a more formal developmental screening or testing should be done. Possible office tests would be the Ages & Stages Questionnaires, Denver-II Developmental Screening Test, the CAT/CLAMS, or the ELM. The latter test is basically for language screening. Referral to a specialist or a multidisciplinary team for more detailed testing is indicated when delay is suspected.

DIAGNOSTIC TESTS & INTERPRETATION**Lab****Initial lab tests**

- There is no specific laboratory test battery for general developmental delays. The testing needs to be tailored to the individual situation based on the history and physical exam. A high index of suspicion should be maintained for any associated findings and delays in the other streams of development.
- Some of the more common studies ordered for developmental delay workup:
 - Genetic testing: Warranted for any dysmorphic features, a family history of delays or genetic disorder. A karyotype and fragile X DNA should be considered, particularly for significant cognitive delays. The comparative genomic hybridization (CGH) microarray is now increasingly recommended as a first-line test for developmental delays.
 - Metabolic tests: Tests such as quantitative plasma amino acids, quantitative urine organic acids, lactate, pyruvate, or ammonia should be considered if there is any loss of skills or indication of a metabolic disorder.
 - Thyroid function tests: Most infants will have had screening for hypothyroidism shortly after birth. This should be rechecked if symptoms indicate.

Imaging

Head MRI: Consider a head MRI for head abnormalities, significant neurologic findings, loss of skills, or for workup of a specific disorder such as trauma or leukodystrophy.

Diagnostic Procedures/Other

- Audiologic: Hearing should be checked in any child with speech and language and/or cognitive delays.
- EEG: An EEG should be considered if there is any concern about seizures.
- Subspecialists: Referral to other medical specialists may also be indicated. These specialists may include developmental pediatrics, neurology, genetics, orthopedics, or ophthalmology.

DIFFERENTIAL DIAGNOSIS

- The differential can be extensive and may become more evident with further workup.
- Broad diagnoses include:
 - Mental retardation
 - Developmental language disorder
 - Autism
 - Learning disability
 - Cerebral palsy
 - Attention deficit hyperactivity disorder
 - Significant visual or hearing impairment
 - Degenerative disorders

**TREATMENT****ADDITIONAL TREATMENT****General Measures**

- Therapy should include appropriately treating any medical conditions and associated findings, for example, anticonvulsants for seizures or hearing aids when appropriate for hearing impairment. In addition, traditional therapy has included early intervention or special education services specifically addressing the areas of delay.
- Therapy could include physical therapists, occupational therapists, speech/language therapists, special educators, psychologists, and audiologists, depending on the needs of the child.

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

- General pediatric care for well-child visits and to monitor any underlying medical conditions is indicated.
- These children need ongoing monitoring of their therapy and educational programs to ensure that it is still meeting their individual needs, as these needs change over time.
- The families will also need ongoing counseling and support in dealing with a child having special needs.

PROGNOSIS

Variable depending on the type and severity of delay and the etiology

**CODES****ICD9**

- 315.8 Other specified delays in development
- 315.9 Unspecified delay in development (developmental disorder not otherwise specified)

ICD10

- F89 Unspecified disorder of psychological development
- F88 Other disorders of psychological development

FAQ

- Q: When do you test a child for delays?
- A: A child can have developmental assessments at any age, including infancy. Making a specific diagnosis, for example, for level of mental retardation, may need to wait until the child is older.
- Q: When can a child start receiving services?
- A: Children who qualify can receive therapy services starting at birth and in some cases extending up to age 21 years.
- Q: The parents are raising a concern about delays, but the general impression in the office is that the child is doing okay. What should be done next?
- A: Parents or grandparents may be the first to express concerns, especially in a child with milder delays. A more detailed developmental history and more formal developmental screening or testing would be indicated as an initial step.

DEVELOPMENTAL DYSPLASIA OF THE HIP

John M. Flynn

BASICS

DESCRIPTION

A range of congenital hip disorders: From mild acetabular dysplasia to dislocation of the femoral head from the acetabulum

ALERT

Pitfalls:

- Missed early diagnosis can result in more complicated management and less favorable outcome.
- Missing an associated syndrome or condition (e.g., tethered cord, arthrogryposis)
- Mistaking a “click” for instability

Incidence

Incidence of hip dysplasia is 0.5–2% of live births; however, true dislocation occurs in 0.1–0.2% of live births.

Genetics

Many patients are first-born females, with familial history of affected first-degree relative.

PATHOPHYSIOLOGY

Owing to mechanical forces, abnormal growth, or underlying laxity, the spatial and biomechanical relationship between the femoral head and the acetabulum is altered.

ETIOLOGY

- Mechanical factors:
 - Breech position
 - Oligohydramnios
 - Packing phenomenon (e.g., first-born child)
 - Postnatal positioning (e.g., swaddling in extension and adduction)
- Laxity or genetic factors:
 - Female
 - Family history (~20%)
 - Certain ethnic groups
 - Generalized ligamentous laxity

DIAGNOSIS

HISTORY

- Much higher incidence of developmental dysplasia of the hip in breech delivery
- 10–20% of patients have familial history.

PHYSICAL EXAM

- Infants are tested with the Ortolani and Barlow tests. These maneuvers involve feeling a “clunk” with either gentle reduction of the dislocated femoral head with abduction and anterior force (Ortolani) or gentle dislocation or an unstable femoral head with adduction with posterior force (Barlow).
- Check for torticollis, metatarsus adductus, and other “packaging” abnormalities.
- Check for an abnormal sacral dimple.
- Although a baby with a dislocated hip may have asymmetric thigh or gluteal folds, many babies with normal hips have such asymmetry.
- Children >4–6 months may have a negative Ortolani, but have limited abduction on the affected hip. The Galeazzi sign may be positive (comparing the femoral lengths by flexing the hip and knee in the supine position).
- Walking-age children may have a Trendelenburg gait (lurching to the side) and a leg length inequality.
- Physical examination tricks:
 - The infant should be as relaxed as possible, preferably sleeping. Check the hips first. When the baby is active or crying, it is difficult to get a good exam.
 - The infant should be examined on a firm surface. The pelvis is stabilized with the opposite hand.

ALERT

- Examination may be normal initially. Consequently, hip evaluation should be performed as part of infant physical examination through 12 months of age.
- Many babies have “clicks” when their hips or knees are manipulated. These high-pitched snapping sensations should not be mistaken for the instability felt on a properly performed Ortolani or Barlow test.

DIAGNOSTIC TESTS & INTERPRETATION

Imaging

- AP pelvis radiograph
 - Recommended after 6 months of age; prior to 6 months of age, radiographs may appear normal because of difficulty determining hip/acetabulum relation in cartilaginous femoral head
- Hip ultrasound:
 - Best test for infants 0–6 months old
 - Can determine hip laxity, subluxation, dislocation, reducibility, presence of interposed tissue, and status of the acetabulum. Can request ultrasound of the lumbosacral spine if there is a deep, abnormal sacral dimple raising concern about tethered cord
 - False positives: Hip “clicks” will be present in 10% of infants; only a small percentage will have hip dysplasia.

DIFFERENTIAL DIAGNOSIS

- Infection
- Spastic hip dislocation due to cerebral palsy, closed head injury, or anoxic brain injury

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Triple diaper:
 - No longer considered to be effective treatment
 - Expensive for parents
- Pavlik harness:
 - Up to 95% effective if used <6 months of age
 - Harness is worn 24 h/d.
 - Exam or ultrasound should be performed 2–3 weeks after initiating the harness for a dislocated hip to prove that the hip is reduced in the harness.
 - Adjust straps every 3 weeks to accommodate growth.
 - After 6 consecutive weeks of treatment, reassess with physical examination and ultrasound. Wean if hip is then stable.
 - Complications include avascular necrosis of proximal femur, femoral nerve palsy (resolves spontaneously), skin irritation
- Closed or open reduction:
 - For patients who present >6 months of age

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- When to expect improvement:
 - Usually after ~6 weeks of treatment in the Pavlik harness
- Signs to watch for:
 - A plain radiograph (anteroposterior pelvis X-ray view) is performed at 6 and 12 months. Measure the acetabular index and check for subluxation or dislocation. Depending on the presence of residual dysplasia, later annual visits may be appropriate.

PROGNOSIS

If diagnosed in infancy, prognosis is generally excellent.

COMPLICATIONS

- When congenital hip dysplasia results in hip subluxation or dislocation, complaints include limp, pain, and accelerated degenerative disease of the hip.
- Avascular necrosis of the femoral head is a complication of treatment.

CODES

ICD9

- 754.30 Congenital dislocation of hip, unilateral
- 755.63 Other congenital deformity of hip (joint)

ICD10

- Q65.2 Congenital dislocation of hip, unspecified
- Q65.89 Other specified congenital deformities of hip

FAQ

- Q: Why is follow-up needed if the looseness disappears on examination?
- A: Follow-up examinations and radiographs periodically detect late instability or acetabular dysplasia.
- Q: How effective is the Pavlik harness if used within the first 4 months of life?
- A: In patients with reducible hip dysplasia, the current success rate of the Pavlik harness is ~95%.

DIABETES INSIPIDUS

Sogol Mostoufi-Moab

Sheela N. Magge

BASICS

DESCRIPTION

Polyuria and polydipsia caused by inability to produce or respond to antidiuretic hormone (ADH); also called arginine vasopressin

EPIDEMIOLOGY

Incidence

Because most cases are secondary to another disease, the incidence depends on the primary cause.

RISK FACTORS

Genetics

- Rare genetic causes of central diabetes insipidus (DI) are usually autosomal dominant mutations, and rarely recessive.
- Nephrogenic DI is usually familial (autosomal recessive or dominant and X-linked).

PATHOPHYSIOLOGY

- Antidiuretic hormone stimulates the formation of cyclic adenosine monophosphate (cAMP) in the renal collecting ducts, thereby increasing water permeability and increasing reabsorption of free water.
- Lack of antidiuretic hormone effect results in urinary loss of free water.
- Patients with an intact thirst mechanism drink copiously (polydipsia) to compensate for free water loss.
- If the thirst mechanism is not present or if access to free water is limited (e.g., infants or vomiting), severe dehydration can occur.

ETIOLOGY

- Insufficient antidiuretic hormone secretion:
 - Traumatic or postsurgical
 - Nonaccidental injury in children
 - Related to tumor invasion of posterior pituitary
 - Extension from anterior pituitary/suprasellar: Optic glioma, rarely adenomas
 - Hypothalamic: Germinoma, craniopharyngioma, meningioma
 - Lymphoma
 - Granulomas: Histiocytosis X, sarcoidosis
 - Metastatic carcinoma
 - Post-severe ischemic or hypoxic injury to the brain
 - Familial (autosomal dominant)
 - Congenital malformation of CNS
 - Infection
 - Viral encephalitis
 - Meningitis
 - Tuberculosis
 - Increased metabolic clearance of antidiuretic hormone (gestational diabetes insipidus)
 - Drug or toxin related: Snake venom, tetrodotoxin
 - Autoimmune disorders: Hypophysitis
 - Psychogenic: Excessive water drinking
 - Idiopathic: Must observe for many years to exclude slow-growing tumors

- Unresponsive to antidiuretic hormone:
 - Familial or nephrogenic (X-linked dominant and autosomal recessive forms)
 - Tumor related
 - Urinary tract obstruction, especially in utero
 - Renal medullary cystic disease
 - Electrolyte disturbances: Hypokalemia, hypercalcemia (hypercalciuria)
 - Drugs: Usually reversible (diuretics, diphenylhydantoin, reserpine, cisplatin, rifampin, lithium [may become permanent], demeclocycline, ethanol, chlorpromazine, volatile anesthetics, foscarnet, amphotericin B)
 - Loss of the medullary concentrating gradient due to excessive free water intake relative to solute intake

ALERT

Pitfalls:

- Management of patients without an intact thirst mechanism and of newborns is difficult.
- Patients with psychogenic polydipsia may fail a water deprivation test because prolonged excessive water intake can wash out the renal medullary gradient required for concentrating the urine.
- Surreptitious water intake during water deprivation test
- Idiopathic, acquired diabetes insipidus can be caused by slowly growing brain tumors not visible on the initial magnetic resonance image.

DIAGNOSIS

HISTORY

- Abnormal growth can be a sign of diabetes insipidus.
- Waking up during the night to drink or void:
 - True diabetes insipidus is associated with polyuria throughout the day and night. Enuresis may be the 1st sign in a child who previously acquired bladder control. Patients, including infants, prefer cold water to other liquids such as juice, soda, or milk.
- Number of hours the patient goes without drinking:
 - Patients with complete diabetes insipidus do not voluntarily stop drinking for > 1–2 hours unless the thirst mechanism is also abnormal.
 - Patients with diabetes insipidus have such overwhelming thirst, they will drink anything, including bath and toilet water.
- Volume of urine output in a day (not just frequency of urination):
 - The daily volume of urine can be as high as 4–10 L. Younger or dehydrated children with diabetes insipidus tend to make less urine daily than older or hydrated children with diabetes insipidus.

- Familial history of diabetes insipidus:
 - Nephrogenic diabetes insipidus will typically affect maternal uncles during infancy, and mothers may have a mild form
- Frequent episodes of dehydration requiring medical attention:
 - Families may disregard the polydipsia as normal behavior. Repeated episodes of severe dehydration can damage the brain.
- Treatment of adrenal insufficiency in a patient with panhypopituitarism can unmask diabetes insipidus.

PHYSICAL EXAM

- Signs of dehydration:
 - Diabetes insipidus is typically associated with dry, pale skin and mucous membranes. Because this is hyperosmolar dehydration, the patient may not look as severely dehydrated as she or he is.
- Complete neurologic exam:
 - Check for impaired visual fields, which can be the 1st sign of brain tumor.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Morning urinary osmolality with simultaneous serum sodium and serum osmolality:
 - If urine osmolality is at least 2 times higher than serum osmolality, patient does not have complete diabetes insipidus, but may still have partial diabetes insipidus.
- Water deprivation test:
 - Though definitive, it requires admission to the hospital for controlled testing under the close supervision of a pediatric endocrinologist. Patient fails test if urinary osmolality cannot concentrate more than twice serum osmolality at the same time that serum osmolality exceeds 305 mOsm/kg; serum osmolality exceeds 305 mOsm/kg at any time; patient loses > 5% of body weight and becomes symptomatic from hypovolemia.
 - Once patient fails the water deprivation test, a dose of aqueous vasopressin should be given followed by close monitoring of urinary osmolality to document responsiveness to antidiuretic hormone.
 - Never attempt a water deprivation trial at home. Tell parents to allow free access to water at home in any suspected cases.
- Urinary specific gravity (nonspecific):
 - Insufficient by itself and nondiagnostic during a water deprivation test
- 24-hour urine collection (home testing):
 - To obtain accurate urinary volume while patient has free access to water

Imaging

MRI of the brain with and without contrast, with special cuts of the pituitary and hypothalamus - to confirm the bright spot normally seen in the posterior pituitary and to search for tumors. Its absence is not pathognomonic of diabetes insipidus.

ALERT

Do not restrict water intake unless the patient is in the hospital under close surveillance!

DIFFERENTIAL DIAGNOSIS

- Psychogenic polydipsia
- Abnormal thirst mechanism (dipsogenic diabetes insipidus)
- Hypernatremic dehydration
- Diabetes mellitus
- Polyuric renal failure (e.g., renal tubulopathy)
- Hypercalcemia
- Adrenal insufficiency
- Cerebral salt wasting

TREATMENT

MEDICATION (DRUGS)

- DDAVP: Intranasal spray or oral tablets
- Aqueous vasopressin: SC:
 - Comes as 4 mcg/mL solution and doses range from 0.05 mcg up to 1 mcg SC b.i.d. daily. Titrate dose as you would with DDAVP.
- Duration of action of DDAVP is variable from patient to patient. Titration and frequency of dosing should be made by the family under the supervision of an endocrinologist.
- Control of diabetes insipidus in infants is more difficult because these patients may increase fluid intake because of hunger or increase caloric intake because of thirst, thereby causing an imbalance between free water intake and output. Infants can be treated with diluted formula—the volume and frequency of feedings will be increased, but intake of free water will better match urine output. DDAVP should not be used in infants. In some cases, low renal solute load formula (e.g., Similac PM 60/40) and/or thiazide diuretics have been used in infancy. Strict record keeping of intake/output and accurate daily weighing are usually necessary for infants or patients without an intact thirst mechanism. All infants with diabetes insipidus must be treated by providers experienced with diabetes insipidus of infancy.
- Nephrogenic diabetes insipidus may be treated with diuretics and solute restriction as these patients are resistant to DDAVP.

- Side effects:
 - Facial flushing
 - Increased BP
 - Headache
 - Nasal congestion
 - Hyponatremia: Caused by water overdose (intoxication), not by overdose of drug. Taking a higher dose of DDAVP will generally extend the period of antidiuresis, but will not cause hyponatremia. Drinking too much water in the setting of antidiuresis causes hyponatremia. Water intoxication most often occurs in antidiuresed patients who also are on intravenous fluids, lack an intact thirst mechanism, or have psychogenic polydipsia.
- Duration:
 - Lifelong generally. Some tumors regress with radiation, allowing recovery of antidiuretic hormone secretion.
- Possible conflicts with other treatments:
 - Nasal congestion or GI illness can affect the absorption of DDAVP administered.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Depends on the patient and underlying disease causing diabetes insipidus
- When to expect improvement:
 - Effects of DDAVP are immediate.
 - Most cases of diabetes insipidus are lifelong. 1 exception is diabetes insipidus that occurs during the 7–10 days immediately after neurosurgery, since this postsurgical diabetes insipidus may resolve spontaneously within 1–2 weeks after surgery (part of triple-phase response).
- Signs to watch for:
 - Lethargy
 - Somnolence
 - Irritability
 - Hyperpyrexia
 - Any sign of dehydration
 - Seizures

DIET

- Patients with an intact thirst mechanism should drink only when thirsty.
- Patients without an intact thirst mechanism should drink only a carefully calculated fluid volume.

PROGNOSIS

- Generally good, but depends on the primary cause
- May cause developmental delay if the hyponatremia is prolonged

COMPLICATIONS

- Without treatment and without access to water:
 - Hypernatremia
 - Dehydration
 - Coma
- When overdosed with water:
 - Hyponatremia
 - Seizures
 - Cerebral edema

FAQ

- Q: In a patient with an intact thirst mechanism and partial diabetes insipidus, is the use of DDAVP necessary?
- A: No, as long as the patient has constant access to free water.
- Q: How does therapy of diabetes insipidus affect daily life? Is it easily integrated into normal activity and eating patterns?
- A: DDAVP is used in a patient with an intact thirst mechanism to facilitate the daily routine as well as to allow patients to sleep without the need to void frequently during the night.
- Q: Is there a longer-acting preparation or an implantable pump for dosing?
- A: The longest-acting form of antidiuretic hormone is an injected medication and can have effects for 3 days, increasing the risks of hyponatremia. Home use of the nasal spray or tablets, therefore, is easier and safer than the use of injections.

DIABETES MELLITUS

David R. Langdon

BASICS

DESCRIPTION

Diabetes mellitus (DM) is a disorder of absolute or relative insulin deficiency that results in hyperglycemia and disrupts energy storage and metabolism. Severe insulin deficiency can lead to ketosis, acidosis, dehydration, shock, and death.

EPIDEMIOLOGY

- Most common endocrine disorder of childhood
- Type 1 DM: More common in whites of Northern European descent
- Type 2 DM: More common in obese African Americans, Latinos, and Native Americans with strong family history

Incidence

- Type 1 DM:
 - Annual US incidence is ~19/100,000 in children 10–19 years old.
 - Incidence of type 1 DM is rising by 3% per year, but faster in young children.
- Type 2 DM:
 - Incidence is increasing rapidly in adolescents.
 - May be 8–45% of new cases of diabetes in youth, depending on location

Prevalence

- Type 1 DM: Prevalence of type 1 diabetes in youth 0–19 years in US is ~2/1,000.
- Type 2 DM:
 - Estimated prevalence of type 2 DM in youth of 4.1/1,000
 - Estimated prevalence of impaired glucose tolerance (IGT) in youth at least 2/1,000
 - At least 2% of diabetes in children may be due to monogenic diabetes of youth (MODY) or other genetic forms

RISK FACTORS

Genetics

- Susceptibility to type 1 diabetes associated with HLA region of chromosome 6, 5-fold greater risk with MHC antigen types DR3 and DR4
- Multiple genetic defects associated with type 2 diabetes have been identified.
- MODY is a group of autosomal dominant syndromes of partial insulin deficiency due to monogenic defects of pancreatic development or insulin secretion; they make up a small fraction of childhood diabetes.

PATHOPHYSIOLOGY

- Type 1 DM:
 - Loss of pancreatic β cells results in insulin deficiency, leading to hyperglycemia, and predominance of catabolic processes.
 - Hyperglycemia causes hyperosmolality, polyuria, and damage to small blood vessels.
 - Catabolic processes produce ketosis, weight loss, and metabolic acidosis.
- Type 2 DM: Insulin resistance and relative deficiency lead to hyperglycemia, β -cell exhaustion, and changes similar to those in type 1, but initially with greater potential for temporary reversibility.

ETIOLOGY

- Type 1 DM:
 - In genetically susceptible child, an environmental trigger (likely viral) induces expression of DR antigens on β -cell surface.
 - Recruitment of cytotoxic lymphocytes
 - Production of anti-insulin and anti-islet cell antibodies (GAD65, ICA512)
 - Progressive inflammatory, autoimmune loss of β -cell mass results in insulin deficiency.
- Type 2 DM:
 - Insulin sensitivity diminishes owing to obesity and other factors.
 - Insulin resistance leads to compensatory hyperinsulinemia to maintain euglycemia.
- In genetically susceptible persons, insulin secretion fails to match demand, resulting in relative deficiency and hyperglycemia.

COMMONLY ASSOCIATED CONDITIONS

- Type 1 DM: Autoimmune thyroid disease
- Type 2 DM:
 - Obesity
 - Depression
 - Hypertension
 - Fatty liver
 - Hyperlipidemia
 - Sleep apnea
 - Polycystic ovary syndrome

DIAGNOSIS

HISTORY

- Polyuria, nocturia, and enuresis are related to hyperglycemia > 180 mg/dL.
- Polydipsia: Due to polyuria, hyperosmolality
- Duration of symptoms varies by age: May be days in toddlers, months in adolescents
- Polyphagia: Appetite amplified by loss of calories from glycosuria; this is often absent.
- Weight loss: Dehydration, loss of calories
- Malaise, nausea, vomiting, abdominal pain, hyperventilation, lethargy due to ketosis, acidosis, electrolyte depletion, hyperosmolality
- Type 2 diabetes may present like type 1 or may be entirely asymptomatic.
- MODY is usually asymptomatic.

PHYSICAL EXAM

- Weight loss may occur in type 1 diabetes.
- Candidal vaginitis and balanitis common in young children with type 1 diabetes
- In ketoacidosis: Dehydration, hyperventilation
- Obesity and acanthosis nigricans (hypertrophic skin pigmentation of neck) in type 2

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Diagnosis based on blood glucose (BG) level: Fasting BG \geq 126, random BG \geq 200 mg/dL, or 2-hour BG \geq 200 on oral glucose tolerance test (OGTT), and exclusion of stress hyperglycemia
- Glycosuria may be intermittent.
- Ketonuria may occur with both types 1 and 2.
- Hemoglobin A1c reflects BG levels of previous 2–3 months and is nearly always elevated at diagnosis of both types.
- GAD, islet cell, and/or insulin autoantibodies nearly always positive in type 1 diabetes, but sometimes in type 2 as well
- In some patients presenting with hyperglycemia and ketosis, it is not possible to distinguish type 1 or type 2 until the course over several months has been followed.
- Some, but not all, adolescents with IGT or impaired fasting glucose (IFG) will progress to type 2 diabetes.
 - IGT is 2-hour glucose between 140 and 200 during OGTT.
 - IFG is fasting glucose between 100 and 125.

DIFFERENTIAL DIAGNOSIS

- UTI (polyuria)
- Renal glycosuria
- Stress-related hyperglycemia
- Drug-induced hyperglycemia (steroids)
- Psychogenic polydipsia
- Pneumonia (in diabetic ketoacidosis [DKA])
- Sepsis (in DKA)
- Acute surgical abdomen (in ketoacidosis)

TREATMENT

MEDICATION (DRUGS)

(See insulin regimens under “General Measures.”)

In type 2 diabetes, insulin is usually used for symptomatic hyperglycemia. Oral antidiabetic agents may be effective for milder hyperglycemia:

- Metformin is the only oral agent approved for children; it reduces hepatic glucose output.
- Other agents may be useful in certain circumstances: Sulfonylureas, glinides, thiazolidinediones, α -glucosidase inhibitors, exenidin, dipeptidyl protease inhibitors.

ADDITIONAL TREATMENT

General Measures

Insulin is given as a fixed or flexible regimen:

- Total daily dose (TDD) usually ~0.7–1.2 U/kg/d; choose higher range for ketoacidosis presentation, obesity, and puberty.
- Dose may decline during “honeymoon period.”
- Fixed insulin regimens require fewer shots, but consistent schedule and eating.

- Common fixed regimen is split-mixed: 2/3 of TDD in morning (1/3 as short acting and 2/3 long acting), and 1/3 of TDD in evening (with 1/2 as short acting and 1/2 as long acting), either at dinner or split between dinner and bedtime.
- Flexible insulin regimens consist of basal insulin plus a short-acting bolus for every carbohydrate meal and for high blood sugar.
- Basal dosing: 40–50% of TDD is given as 1 injection of a long-acting insulin such as glargine (Lantus) or detemir (Levemir).
- Boluses of short-acting insulin (lispro or aspart) are given for meals and snacks based on carbohydrate content and BG. Carbohydrate coverage (grams of carbohydrate covered by 1 unit) can be estimated by dividing the TDD into 500. Hyperglycemia coverage can be estimated by dividing the TDD into 1,800 to find how much 1 unit may lower blood sugar.
- SC insulin infusion by pump is another flexible method: Dosing is similar.

SURGERY/OTHER PROCEDURES

Weight loss from bariatric surgery may reverse type 2 diabetes.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Regular appointments with diabetes specialist every 3 months to assess management:
 - Is diabetes interfering with emotional health, family relationships, school attendance, athletic activities, or social development?
 - Is family minimizing hospitalization risks from hypoglycemia or DKA with appropriate adjustment of insulin, recognition of lows, glucagon availability, ketone testing, and telephone contact?
 - Is family reducing long-term complication risk by keeping HbA1c lower and by avoiding or treating other risk factors?
 - Exam: Growth, weight, pubertal status, blood pressure, thyromegaly, liver size, injection sites, feet, skin lesions
- Meet with nutritionist periodically or as needed to reassess meal plan.
- Meet with psychologist or social worker as needed to address psychosocial issues.
- Annual screening for long-term complications:
 - Urine for microalbumin
 - Lipid profile, T₄, TSH, celiac screen
 - Eye exam to detect early retinopathy

DIET

- Dietary education for type 1 diabetes is directed toward healthy distribution and matching of carbohydrate intake with insulin action:
 - Recommended distribution of calories: 55% from carbohydrates (mostly complex); 30% from fats; 15% from protein
 - Fixed insulin regimens require snacks spaced between meals and before bedtime.
 - Carbohydrate counting is essential for flexible insulin regimens and helpful for maintaining consistency for fixed regimens.

- In type 2 diabetes, dietary education is directed toward promoting weight loss.
- Reduction of saturated and trans fats, rapidly digested carbohydrates, and salt may be beneficial in both types of diabetes.

PATIENT EDUCATION

- Home BG monitoring before meals, when feeling hypoglycemic or ill
- Insulin injection and site rotation
- Oral carbohydrate for mild hypoglycemia; glucagon 1 mg IM for severe hypoglycemia
- Activity:
 - Frequent exercise reduces BG and insulin requirements in both types of diabetes.
 - Exercise may require extra eating or reduced insulin to prevent hypoglycemia in type 1 diabetes.
 - Detecting or preventing hypoglycemia during or after physical exercise
- Diet: Carbohydrate counting
- Prevention: Checking urine for ketones when blood sugar is high or child feels ill; extra insulin for ketones

COMPLICATIONS

- DKA: Most common cause of hospitalization and death in type 1 diabetes in childhood. See “Diabetic Ketoacidosis.”
- Hypoglycemia: This most common acute complication limits achievable glycemic control. If severe, may cause seizure, unconsciousness
- Long-term harm may be reduced by better glycemic control:
 - Nephropathy: Microalbuminuria and hypertension are 1st manifestations before adulthood.
 - Retinopathy: Blood vessel changes may occur in childhood, but not vision loss.
 - Neuropathy: Diminished nerve conduction velocity common; paresthesias are earliest symptoms.
 - Vasculopathy: Large-vessel disease begins in childhood, but clinical effects occur in adults.
 - Prenatal harm to infants of diabetic mothers: Birth defects occur early, large size late.
 - Growth failure (Mauriac syndrome) and delayed sexual maturation
- Depression, family stress, higher divorce rate

CODES

ICD9

- 250.00 Diabetes mellitus without mention of complication, type II or unspecified type, not stated as uncontrolled
- 250.01 Diabetes mellitus without mention of complication, type I [juvenile type], not stated as uncontrolled
- 250.02 Diabetes mellitus without mention of complication, type II or unspecified type, uncontrolled

ICD10

- E10.8 Type 1 diabetes mellitus with unspecified complications
- E10.9 Type 1 diabetes mellitus without complications
- E11.8 Type 2 diabetes mellitus with unspecified complications

FAQ

- Q: What is the newest management tool?
- A: Continuous glucose sensors allow patients to avoid symptomatic high and low glucoses by detecting trends, to see the outcome of management decisions, and to reduce the risk of severe nocturnal hypoglycemia.
- Q: What is the risk of diabetes in a sibling or child of a person with type 1 DM?
- A: It is 5–10% in 1st-degree relatives (siblings, offspring) and 40–50% in identical twins.

DIABETIC KETOACIDOSIS

David R. Langdon

BASICS

DESCRIPTION

- Severe metabolic derangement that occurs in patients with diabetes mellitus, either type 1 or untreated type 2, secondary to insulin deficiency and stress hormone excess
- Principal features are hyperglycemia, ketosis, metabolic acidosis, dehydration, and electrolyte deficits.

EPIDEMIOLOGY

Incidence

- Up to 67% of diabetic ketoacidosis (DKA) occurs at diabetes onset; higher percentage in children <4 years and in families with lower socioeconomic status (SES)
- Annual hospitalization rates for DKA are around 10/100,000 children per year.
- Risk of DKA in established type 1 diabetes is 1–10% per patient per year.
- DKA accounts for 65% of all hospital admissions in diabetic children <19 years old.
- DKA accounts for >50% of childhood deaths from diabetes.

RISK FACTORS

- Poor metabolic control
- Previous episodes of DKA
- Adolescent girls
- Lower SES

GENERAL PREVENTION

- Timely recognition of new diabetes in children, especially toddlers, with polyuria and polydipsia
- Anticipatory illness management education to check ketones when feeling ill or glucose is high, to take extra insulin, and to call if ketones persist
- Parental supervision of insulin injections and early ketone testing can prevent most recurrent DKA. Psychosocial assessment and family counseling may be useful but are no substitute for parental participation in the diabetes care.
- Recognition of insulin omission to control weight, and appropriate education or counseling
- Understanding by patient and family that interruption of insulin pump for more than 8 hours may result in DKA.

PATHOPHYSIOLOGY

- DKA results from a combination of insulin deficiency and metabolic stress effects.
- Insulin deficiency may be absolute (new diabetes or omitted insulin) or relative (insufficient dose to offset illness stress).
- Metabolic stress involves counterregulatory hormones glucagon, cortisol, and epinephrine, triggered by acute illness or insulin deficiency.

- Counterregulatory hormones amplify glucose production, impair peripheral uptake, and increase proteolysis and lipolysis.
- Lipolysis and ketosis produce metabolic acidosis. Hyperglycemia produces hyperosmolality, leading to osmotic diuresis, dehydration, and urinary electrolyte loss.
- Approximate deficits per kilogram of body weight:
 - Water: 100 mL/kg
 - Na: 6–10 mEq/kg, K: 3–5 mEq/kg
 - Cl: 3–5 mEq/kg, PO₄: 5–7 mmol/kg

ETIOLOGY

- Insulin deficiency due to unrecognized development of either type 1 or type 2 diabetes
- Inappropriate withholding or reduction of insulin during acute illness
- Overwhelming acute illness
- Insulin omission due to parental disengagement, eating disorder, psychosocial stress, substance abuse, or interruption of insulin pump

COMMONLY ASSOCIATED CONDITIONS

Candidal vaginitis or balanitis

DIAGNOSIS

HISTORY

- Polyuria, polydipsia from hyperosmolality
- Nausea, vomiting, and abdominal pain are related to acidosis and electrolyte disturbance.
- Precipitating event (e.g., intercurrent illness) should be identified if possible.

PHYSICAL EXAM

- Dehydration effects: Tachycardia, dry mucous membranes, sunken eyes, poor skin turgor, poor distal perfusion, hypotension
- Acetone odor to breath from ketosis
- Deep Kussmaul hyperventilation is respiratory compensation for metabolic acidosis.
- Abdominal tenderness due to ketosis, acidosis
- Altered mental status, obtundation due to hyperosmolality, dehydration
- Body temperature is typically low.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Glucose: >200 mg/dL (typically 400–1,200)
- Urinalysis: Marked glycosuria and ketonuria
- Sodium: Initial Na may be low, normal, or high:
 - Serum Na reflects duration and severity of hyperglycemia, duration and degree of dehydration, and degree of hyperlipidemia.
 - Prolonged hyperglycemia depresses Na by about 1.6 mEq/L for every 100 mg/dL of elevation, but Na may rise as dehydration becomes extreme (BUN >30 mg/dL).
 - Disproportionately low initial Na may indicate severe hyperlipidemia or adrenal crisis.
 - Whole-body Na is depleted.

- Potassium: Initial serum levels are usually elevated but may be normal or low. Regardless of initial K, body K is depleted.
- Total CO₂ or bicarbonate reflects degree of metabolic acidosis and is a useful index of severity:
 - HCO₃ <4 mmol/L is severe, reflects pH <7
 - HCO₃ 4–14 mmol/L is moderate, will require >8 hours of treatment to reverse
 - HCO₃ 15–20 mmol/L is mild, may respond to a few hours of fluids and insulin
- Phosphate: Initially normal, high, or low:
 - Despite initial level, whole-body P is depleted.
- Arterial blood gas reflects metabolic acidosis, with low pH (<7.3) and low pCO₂ (10–20 mmol/L).
- CBC: Stress may increase white cell count to 35,000/mm³ even without infection.
- β -Hydroxybutyrate and serum ketones are elevated (BOHB typically >5 mmol/L).
- Hypertriglyceridemia may be high enough to depress electrolyte levels in unseparated plasma.
- Liver enzymes (ALT, AST) may be mildly elevated.
- Amylase and lipase are often mildly elevated.
- Plasma osmolality is high, and can be estimated by $2(\text{Na} + \text{K}) + (\text{BUN}/2.6) + (\text{glucose}/18)$.

DIFFERENTIAL DIAGNOSIS

- Gastroenteritis
- Acute abdomen (pancreatitis, appendicitis)
- UTI
- Pneumonia
- Stress hyperglycemia
- Salicylate ingestion
- Inborn error of metabolism
- Nonketotic hyperosmolar coma
- Adrenal crisis

TREATMENT

ADDITIONAL TREATMENT

General Measures

Use of a DKA protocol improves outcomes.

ISSUES FOR REFERRAL

Refer to a pediatric endocrine service for initial diabetes education or for recurrent DKA.

IN-PATIENT CONSIDERATIONS

Initial Stabilization

- Assess and ensure airway and breathing.
- Restore circulation: Normal saline bolus of 10–20 mL/kg; repeat as needed to maintain perfusion:
 - Urine output and specific gravity do not reflect hydration because of osmotic diuresis.
 - Avoid giving more fluids than necessary to reverse or prevent shock. Rapid osmolar correction may incur cerebral edema risk.
 - Determine adequacy of hospital support or arrange transfer. Management of moderate or severe DKA requires frequent nursing attention and rapid availability of physician.

IV Fluids

- Amount and rate of IV fluids:
 - Assume 10% dehydration, 15% in infants.
 - Replace evenly over 24–48 hours.
 - Add maintenance rate to rehydration rate for total IV rate but do not add additional fluid to replace ongoing urine output.
 - Increase rate for inadequate renal or body perfusion. Decrease rate for suspected cerebral edema or pulmonary edema.
- Composition of IV fluids: Tonicity and Na:
 - Start with normal saline. Change to 1/2 normal when circulation is secure and Na is > 130.
 - IV fluids should contain K after the 1st hour, or when anuric renal failure or extreme hyperkalemia is ruled out.
- Composition of IV fluids: Potassium:
 - Should contain K at 40 mEq/L, often 1/2 KCl and 1/2 K phosphate (never all phosphate)
 - Problems from inadequate or excessive K are rare if K replacement is begun early by gradual infusion without boluses, riders, or high central line concentrations.
- Composition of IV fluids: Glucose:
 - Add 5% dextrose to IV stock when blood glucose < 300 mg/dL.
 - Change to 10% dextrose when glucose < 200 mg/dL so that full insulin rate can continue.

 **ONGOING CARE**

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

For severe DKA, the following monitoring measures are usually warranted:

- Nearly continuous observation to detect changes of mental status or respiration or perfusion
- Cardiorespiratory monitor with hourly blood pressure
- Hourly intake and output
- Hourly glucose checks
- Electrolytes every few hours

PROGNOSIS

Mortality of DKA in children is ~0.2–0.3%.

COMPLICATIONS

- Death in childhood DKA results from cerebral edema (57–87%) or cardiovascular collapse.
- Cerebral edema refers to several forms of acute neurologic catastrophe, especially brainstem herniation and stroke:
 - Highest-risk patients are youngest, and those with most severe dehydration and acidosis.
 - Cause of brain swelling still unsettled: Hypotheses include water influx as osmolality falls or excessive blood flow.
 - Commonly occurs 6–18 hours into treatment, often as patient is improving
 - Heralded as headache, change in mental status, focal neurologic signs, rising blood pressure, or unexpected drop of serum Na
 - From neurologic changes, brain herniation and respiratory arrest may occur rapidly.
 - Treatment of suspected cerebral edema includes slowing of IV fluids, mannitol 0.5–1.0 g/kg by IV infusion over 15 minutes.
 - Obtain CT scan to confirm brain swelling only if patient can be treated during procedure.
 - Prepare to intubate and ventilate if arrest occurs.

- Cardiovascular collapse and death from shock usually due to delay or interruption of IV fluids, or to inadequate fluid rates:
 - Leads to hypovolemic shock and shock damage to kidneys, other organs
 - Give isotonic IV fluid to restore perfusion.
- Some complications are largely avoidable:
 - Hypo- and hyperkalemia can cause arrhythmias. Hypokalemia often from delayed K replacement. Hyperkalemia can occur if K boluses given as “catch-up,” or renal failure or rhabdomyolysis.
 - Hypoglycemia can be avoided with frequent glucose checks.
 - Hypocalcemic tetany usually results from excessive phosphate replacement.
 - Hypermnatremia reflects prolonged normal saline or bicarbonate, or inadequate water.
- Other complications, not directly attributable to treatment, can occur in severe cases:
 - Pulmonary edema or acute respiratory distress syndrome (ARDS)
 - Pneumomediastinum from hyperventilation
 - Rhabdomyolysis
 - Thrombosis, especially at central line site
 - Disseminated intravascular coagulation (DIC)
 - Rhinocerebral mucormycosis
 - Gastric atony and dilatation
 - Pancreatitis

 **CODES**

ICD9

- 250.10 Diabetes with ketoacidosis, type II or unspecified type, not stated as uncontrolled
- 250.11 Diabetes with ketoacidosis, type I [juvenile type], not stated as uncontrolled

ICD10

- E10.10 Type 1 diabetes mellitus with ketoacidosis without coma
- E13.10 Other specified diabetes mellitus with ketoacidosis without coma
- E13.11 Other specified diabetes mellitus with ketoacidosis with coma

FAQ

- Q: What are the usual triggers for DKA?
- A: Mismanagement of minor illness, or omissions of insulin due to lack of parental education or participation.
- Q: What are the most common management errors that contribute to a poor outcome?
- A: Failure to recognize early DKA, prolonged telephone management, delayed fluid start, excessive fluid in emergency department, delayed K replacement, bolus bicarbonate use, inadequate fluids for fear of cerebral edema, failure to monitor closely, failure to respond quickly to mental status changes.
- Q: Does an episode of DKA mean that the usual daily insulin regimen is inadequate?
- A: No. The usual regimen is best assessed by hemoglobin A1c and hypoglycemia frequency. DKA indicates missed insulin or a failure to respond to an unusual situation.

DIAPER RASH

Kara N. Shah

BASICS

DESCRIPTION

Also known as diaper or napkin rash, diaper dermatitis is a general term that encompasses a spectrum of skin disorders of varying etiologies that share a common distribution. Diaper dermatitis is not necessarily associated with wearing diapers.

ALERT

- Often the caretaker believes the rash is a result of inadequate cleansing of the skin and subsequently attempts to wash the skin more. This causes additional irritation and exacerbates the underlying dermatitis.
- Severe cases of diaper dermatitis may be complicated by bacterial or fungal infection and may require treatment with topical or systemic antibiotics.

EPIDEMIOLOGY

Prevalence

- Diaper dermatitis is significantly more common in infants and children who are still in diapers and generally resolves when diapers are no longer worn.
- It affects 7–35% of the infant population at any given time and is most commonly found in the 9–12-month age group.

RISK FACTORS

- Concomitant skin disease, such as seborrheic dermatitis and atopic dermatitis
- Acute or chronic conditions associated with increased stooling, diarrhea, or urinary incontinence, such as infectious gastroenteritis and enuresis

GENERAL PREVENTION

- Proper skin care with gentle cleansing with a mild, nonsoap cleanser such as Cetaphil should be encouraged.
- The use of superabsorbent diapers may be suggested along with frequent diaper changes. It is unclear whether there is any difference in the prevalence of diaper dermatitis when disposable versus cloth diapers are used.
- Use of infant wipes may aid in the removal of urine and feces from the skin and they are generally less irritating than use of water and washcloths, although irritant and allergic contact dermatitis has been reported with several of the chemicals used in these products.
- The regular use of barrier creams containing zinc oxide helps to protect the skin from external irritants, including urine and feces.

PATHOPHYSIOLOGY

Diaper rashes are the result of several different processes, alone and in combination:

- Friction and maceration: Rubbing of wet diapers against exposed skin in areas such as the inner surface of the thighs, genitals, buttocks, and abdomen may result in chafing and irritation.
- Irritation: Prolonged exposure to irritants such as feces, urine, and skin cleansers can cause skin breakdown that predominantly affects exposed areas under the diaper, sparing intertriginous areas. Occlusion potentiates the effects of irritants.
- Inflammation: Both infectious and noninfectious processes can trigger an acute or chronic inflammatory response in the diaper area.

ETIOLOGY

- Infection:
 - *Candida albicans*: Infection is common during or immediately after use of systemic antibiotics and with any moderate to severe diaper dermatitis. It is often seen in combination with oral candidal infections (thrush).
 - Group A β -hemolytic *Streptococcus*: The most common bacteria associated with diaper dermatitis
 - *Staphylococcus aureus*: Increasingly recognized as a potential cause of infection in the diaper area
- Inflammation:
 - Seborrheic dermatitis: In infants, usually involves the scalp (cradle cap) and face as well as the diaper area and other intertriginous areas. It is presumably related to an inflammatory response to skin colonization with the common skin yeast *Malassezia*.
 - Allergic contact dermatitis: May be caused by exposure to detergents, fragrances, or dyes in diapers, wipes, or topical medications used in the diaper area
 - Granuloma gluteale infantum: Believed to be caused by chronic application of topical steroids to the diaper area, this self-limiting inflammatory dermatitis is rarely seen today.
- Irritant:
 - Jacquet erosive dermatitis: A severe erosive form of diaper dermatitis that results from chronic and severe inflammation and can be confused with herpes simplex infection

DIAGNOSIS

HISTORY

- A history of acute or chronic diarrhea should suggest a primary irritant dermatitis.
- Antecedent use of oral antibiotics can change the normal bowel and skin flora and may cause diarrhea, which can irritate the skin and predispose to infection with *C. albicans*.
- Prolonged use of topical corticosteroids may modify the appearance of the rash, mask superficial infections, or cause skin atrophy. It can also contribute to the development of granuloma gluteale infantum.

- Chemicals, dyes, and fragrances in lotions, wipes, diapers, and detergents can cause irritant or allergic contact dermatitis.
- Frequent bathing can lead to worsening of a pre-existent dermatitis. Parents often think a diaper rash represents poor hygiene and as a result increase the cleansing of the affected area, further contributing to irritation.
- Signs and symptoms:
 - Irritant diaper dermatitis and that caused by group A β -hemolytic *Streptococcus* or *S. aureus* can be painful.
 - Rarely, seborrheic dermatitis and psoriasis can be mildly pruritic but are generally asymptomatic.

PHYSICAL EXAM

- The location of the rash should be carefully noted:
 - Exposed surfaces: Allergic or irritant contact dermatitis, *S. aureus* infection
 - Intertriginous areas: Seborrheic dermatitis, candidal infection, group A β -hemolytic *Streptococcus* infection
 - Perianal: Group A β -hemolytic *Streptococcus* (more common); *S. aureus* (less common)
- The morphology of the dermatitis is of primary importance:
 - Greasy erythema and scaling suggests seborrheic dermatitis.
 - Well-demarcated, shiny, erosive erythematous perianal patches suggest group A β -hemolytic *Streptococcus*.
 - Scattered inflammatory papules or pustules suggest *S. aureus*.
 - Erythematous patches with peripheral erythematous papules with scaling suggest a candidal infection.
 - Indurated red-brown subcutaneous nodules suggest granuloma gluteale infantum.
- A complete physical exam may reveal other features of the underlying diagnosis:
 - The presence of scalp seborrhea (cradle cap) suggests seborrheic dermatitis.
 - The presence of thrush (oral candidiasis) should raise the possibility of a candidal infection.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Rarely helpful
- Candidal infections may be verified by a potassium hydroxide preparation of a skin scraping or by a fungal culture.
- Group A β -hemolytic *Streptococcus* and *S. aureus* infection can be confirmed by a bacterial culture obtained by swabbing the affected area.

Pathological Findings

- Skin biopsy is rarely required.
- Can be helpful in diagnosing psoriasis, Langerhans cell histiocytosis, or a nutritional deficiency. Skin biopsy may be nondiagnostic in the case of allergic or irritant contact dermatitis and seborrheic dermatitis.

DIFFERENTIAL DIAGNOSIS

- Scabies: Pruritic, erythematous papules and nodules may involve the diaper area; often there is a family history of multiple affected family members and more widespread involvement.
- Psoriasis: May involve the diaper area either exclusively in infants or may occur in the setting of more diffuse presentation, including other intertriginous areas and the face and scalp. A family history of psoriasis or the presence of psoriasiform plaques elsewhere may suggest the diagnosis.
- Herpes simplex virus: Can present with multiple punched-out erosions in the diaper area, which can be confirmed by specific viral studies such as PCR or DFA. If confirmed, an evaluation for child abuse is mandatory.
- Langerhans cell histiocytosis: Usually presents with multiple reddish-brown crusted papules and/or vesicles and petechiae in conjunction with hepatosplenomegaly. Oral lesions may also be present.
- Nutritional and metabolic disorders: Acrodermatitis enteropathica, which is caused by impaired zinc metabolism (either inherited or acquired), leads to an erosive acrodermatitis involving the face in a perioral and periocular distribution, the diaper area, and the hands and feet. Multiple carboxylase deficiency, essential fatty acid deficiency, and biotinidase deficiency can also present in a similar manner.
- Kawasaki disease: The characteristic diaper rash appears as a scaling, desquamative erythema.
- Child abuse: An unusual history or morphology should suggest the possibility of abuse, especially if the lesions appear geometric or resemble scalds or burns.

**TREATMENT****ADDITIONAL TREATMENT****General Measures**

- Proper skin care is the primary treatment modality.
- When soiled, the skin should be gently washed with a mild cleanser and/or infant wipe and patted dry or air dried. Vigorous rubbing of the skin or use of washcloths may cause further irritation and skin breakdown.
- Frequent diaper changes are helpful in minimizing exposure to irritants. The diaper should be kept off and the skin exposed to air as much as possible.
- Routine use of a bland barrier ointment containing zinc oxide with each diaper change is recommended.
- Candidal infections should be treated with topical nystatin cream or a topical antifungal cream such as econazole, ketoconazole, or clotrimazole cream. There is some evidence to suggest that topical clotrimazole may be less efficacious than the use of other topical antifungal agents.

- If the skin is very inflamed or if there is evidence of an allergic contact dermatitis or seborrheic dermatitis, use of a small amount of a low-potency topical corticosteroid such as 1% hydrocortisone cream for a few days can be helpful.
- Topical application of sucralfate suspension or 10% cholestyramine in petrolatum has been used in severe cases. These agents function as a physical barrier and may neutralize bile acids and pepsin.

ALERT

- The prolonged use of topical corticosteroids in the diaper area is contraindicated. The side effects of topical steroids, including skin atrophy, are potentiated when used under occlusion as occurs in the diaper area.
- When topical steroids are required, they are best given as a separate prescription that can be stopped at an earlier time (usually when the rash starts to improve) as opposed to a prescription for a combination product should use of a topical antibacterial or antifungal agent also be required.
- Talcum powder can worsen skin irritation and may be aspirated by both baby and caretaker. Its use should be discouraged.
- If a candidal diaper infection is resistant to topical treatment and thrush (monilia infection of the mouth) is present, oral nystatin or fluconazole may be considered. An evaluation of the mother for a candidal infection of the nipples should also be considered since the mother may transmit the infection to her infant.

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

With proper treatment, the rash should improve within 4–7 days. Failure of resolution of rash indicates that another process may be complicating the diaper rash, and further evaluation is warranted.

PROGNOSIS

- Diaper dermatitis usually resolves with the institution of appropriate skin care and the treatment of any underlying cause.
- Irritant diaper dermatitis completely resolves once the child is potty trained and out of diapers.

COMPLICATIONS

- Generally none, although secondary bacterial or fungal infections may lead to ulceration.
- The chronic use of topical corticosteroids in the diaper area may lead to skin atrophy and striae.

**CODES****ICD9**

691.0 Diaper rash

ICD10

L22 Diaper dermatitis

FAQ

- Q: Should I switch from cloth to disposable diapers (or vice versa)?
- A: This is controversial, although there are some studies that indicate that the superabsorbent disposable diapers may be better for preventing diaper rashes. Cloth diapers used with plastic overpants probably irritate the skin more because they trap moisture against the skin. Frequent changing of diapers is very helpful, along with not wearing diapers at all when practical.
- Q: Is the diaper rash due to not keeping the skin clean enough?
- A: Although the combination of stool and urine may release enzymes that help break down skin integrity, probably more harmful to skin is vigorous and frequent scrubbing with relatively abrasive materials on the macerated, easily damaged skin typically found in the diaper area. This rough cleaning allows introduction of bacteria and yeast into the skin and results in a diaper rash. Parents should be advised to use soft cleaning materials (such as cotton balls) to gently clean stool from the diaper area. It is not usually necessary to clean the skin of urine every time; rather, patting the infant dry with a soft cloth and then replacing the diaper is all that is generally required.

DIAPHRAGMATIC HERNIA (CONGENITAL)

Howard B. Panitch
Gordana Lovrekovic

BASICS

DESCRIPTION

- Defect in the diaphragm allowing herniation of abdominal contents into the thoracic cavity, causing varying degrees of pulmonary hypoplasia
- 4 types of congenital diaphragmatic hernia (CDH):
 - Bochdalek hernia (posterolateral location)
 - Morgagni hernia (lateral retrosternal location)
 - Pars sternalis (medial retrosternal)
 - Anterolateral

EPIDEMIOLOGY

- Bochdalek hernia:
 - ~90% of all CDHs
 - 70–90% are left-sided
 - May be more common in males
 - 40% of cases associated with some type of other congenital malformation:
 - Heart defect in 10–35%
 - Genitourinary system abnormalities in 23%
 - GI malformations (e.g., malrotation) in 14%
 - CNS abnormalities (e.g., hydrocephalus, spina bifida, anencephaly) in 10%
 - Recognizable syndromes (Beckwith-Wiedemann, Fryns, PAGOD, etc.) in 10%
 - Chromosomal abnormalities (trisomy 13, 18, or 21; Turner syndrome; tetrasomy 12p) in 33%
- Morgagni hernia:
 - Accounts for 2–5% of all diaphragmatic hernias
 - More common in females in series where it is not discovered until adulthood

Incidence

1:2,500–4,000 live births, or 3.3–3.8/10,000 total births

RISK FACTORS

Genetics

- As isolated condition, usually sporadic
- Estimated recurrence rate <2% in 1st-degree relatives: Isolated series in consanguineous families suggest an autosomal recessive inheritance pattern, whereas others have described autosomal dominant or X-linked patterns.
- When associated with syndromes, inheritance pattern is that of the syndrome.
- When CDH detected prenatally, amniocentesis for fetal karyotype contributes important prognostic information for nondirectional prenatal counseling

PATHOPHYSIOLOGY

- Bochdalek hernia more commonly (70–90%) left-sided: Left pleuroperitoneal folds close later than right sided
- Morgagni hernia more commonly right sided: Left-sided defects covered by the heart
- Mortality and morbidity of CDH, in absence of nonpulmonary defects, relate to the degree of pulmonary hypoplasia and pulmonary hypertension.
- Pulmonary hypoplasia:
 - Degree of hypoplasia variable, from mild to incompatible with life
 - Worse on ipsilateral side, but also present on contralateral side
 - Associated with smaller lungs, fewer airway branches, fewer alveoli per terminal lung unit, and decreased surfactant production
 - Less severe in Morgagni hernias than in Bochdalek hernias

– Unclear if hypoplasia is the result of lung compression by herniated abdominal viscera or a primary event that occurs before gastrointestinal contents enter the thorax

- Pulmonary hypertension:
 - Smaller arterioles with excessive muscularization
 - Abnormal response to oxygen (failure to dilate)
 - Can lead to persistence of the fetal circulation postnatally

ETIOLOGY

- True cause: Unknown
- Diaphragm forms between 4 and 12 weeks gestation
- Diaphragm arises from 4 elements:
 - Septum transversum, which becomes the central tendon of the diaphragm
 - Pleuroperitoneal membranes, which extend from the lateral body wall and grow medially and ventrally to fuse with the septum transversum and esophageal mesentery
 - Mesentery of the esophagus, which becomes the crura of the diaphragm
 - Lateral body wall, from which myocytes migrate to muscularize the diaphragm
- Anything that interferes with formation of the diaphragm can result in herniation of abdominal contents into the thorax.
- Bochdalek hernia develops when the pleuroperitoneal membranes fail to fuse before return of the midgut to the abdominal cavity. Failure of fusion of the pleuroperitoneal membranes with other components of the diaphragm results in a communication between thoracic and abdominal cavities.
- Morgagni hernia develops when a defect develops in the septum transversum.
- Pars sternalis hernia usually also includes pericardioperitoneal and sternal defects, as well as omphalocele; may also have cardiac defect

DIAGNOSIS

HISTORY

- Prenatal imaging:
 - CDH is frequently detected by fetal ultrasonography during a routinely scheduled exam or by ultrafast fetal MRI.
 - Herniation of the liver into the chest is the single most reliable predictor of severity, including need for ECMO, and mortality.
 - Some data suggest a sonographically determined lung area-to-head circumference ratio (LHR) <1.4 mm in infants with a left-sided CDH is associated with higher postnatal mortality and overall poorer outcome.
- Bochdalek hernia: Usually presents at birth; patient typically presents with severe cardiorespiratory distress. Rarely can present late (>1 month of age)
- Morgagni hernia:
 - Usually asymptomatic in the newborn period
 - If symptomatic, most commonly presents with recurrent chest infections, but rarely can present with neonatal respiratory distress
 - Older child or adult presentation usually includes vague abdominal discomfort, vomiting, growth failure, chest pain, dyspnea, cough, and recurrent respiratory infections.

PHYSICAL EXAM

- Bochdalek hernia:
 - Severity of illness manifests within hours of birth.
 - Neonatal presentation:
 - Polyhydramnios
 - Scaphoid abdomen (abdominal contents in thoracic cavity)
 - Respiratory distress
 - Decreased breath sounds on the affected side
 - Dullness to percussion on the affected side
 - Bowel sounds heard in the chest
 - Heart sounds shifted to the contralateral chest
 - Cardiac point of maximal impulse shifted away from affected side
 - Asymmetry of chest wall
 - Tachypnea, tachycardia, cyanosis
 - Late presentation (>1 month of age):
 - Cough
 - Recurrent chest infections
 - Feeding intolerance
 - Vomiting, abdominal pain, diarrhea
 - Growth failure
 - Intestinal malrotation
 - Gastric volvulus
- Morgagni hernia: Exam may be normal.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Arterial blood gas:
 - Significance:
 - pO₂ low: Reflects significant hypoxemia
 - pCO₂ high: Reflects inadequate ventilation
 - pH, bicarbonate, lactate: Reflect significant respiratory and metabolic acidosis
- Karyotype:
 - Significance: 1/3 of neonates with CDH are reported to have chromosomal abnormalities.

Imaging

- Chest radiograph:
 - Bochdalek hernia:
 - Loops of bowel in the thoracic cavity
 - Heart and mediastinal structures shifted away from the affected side
 - Decreased lung volumes (ipsilateral lung more than contralateral lung)
 - Atelectasis of the contralateral lung
 - Unable to visualize diaphragm on the ipsilateral side
 - In left-sided hernias, a nasogastric tube inserted into the stomach will be seen in the thoracic cavity.
 - Bowel remaining in the abdomen usually gasless
 - Morgagni hernia:
 - A mass can be seen in the anterior mediastinum: May be solid or gas-filled
 - Lesion better seen on lateral view
- Echocardiogram: Reduced left ventricular mass in left-sided hernias; can estimate the degree of pulmonary hypertension and exclude congenital heart defects
- Ventilation/perfusion scan: Reduced ventilation and perfusion, especially to the ipsilateral lung. Ventilation increases to a greater degree than does perfusion to the ipsilateral lung over time.
- Fetal ultrasound: Abdominal viscera in the thoracic cavity; polyhydramnios. Can be used to estimate severity of lesion (liver in chest, low LHR portend more severe disease). Also important to rule out other lesions (congenital heart defect, CNS abnormality)

- Ultrafast fetal MRI: Useful when the diagnosis is suspected but cannot be confirmed by fetal ultrasound

DIFFERENTIAL DIAGNOSIS

- Pulmonary:
 - Congenital cystic adenomatoid malformation
 - Pulmonary cyst
 - Pneumatocele
 - Congenital lobar emphysema
 - Pulmonary sequestration
 - Diaphragmatic eventration
 - Hiatal hernia
 - Atelectasis
 - Pulmonary agenesis
 - Pneumothorax
 - Anterior mediastinal mass
 - Pneumonia
 - Pleural effusion
- Cardiac:
 - Dextrocardia
 - Congenital heart disease

TREATMENT

ADDITIONAL TREATMENT

General Measures

Bochdalek hernia:

- Endotracheal intubation; minimal bag mask ventilation to avoid distension of bowel and further pulmonary compromise
- Decompression of the intrathoracic bowel (placement of a nasogastric tube to low suction allows the bowel to decompress, thus letting the ipsilateral hypoplastic lung expand)
- Oxygenation: Preductal saturation >85%
- Ventilation: Permissive hypercapnia with spontaneous assisted breaths, pressure control ventilation with peak pressures ≤25 cm H₂O and low mandatory rates; avoidance of paralysis
- Correction of acidosis; pH >7.30
- Normalization of BP

ISSUES FOR REFERRAL

- Pulmonary:
 - Chronic lung disease:
 - ~25% have obstructive lung disease at age 5 years.
 - ~50% have airway hyperreactivity.
 - Diminished perfusion in the ipsilateral lung with progressive increase in ventilation, as detected by ventilation/perfusion scans
 - Lung function can be normal or show a mild restrictive or obstructive pattern.
 - Recurrent respiratory infections
- GI/nutrition:
 - Gastroesophageal reflux (45–90%): May need surgical repair
 - Oral aversion
 - Failure to thrive (>40% at 2 years of age)
- Neurodevelopmental:
 - Greater risk in those with large defects or those requiring ECMO
 - Hypotonia
 - Motor delays (tend to improve with time)
 - Sensorineural hearing loss
- Chest wall: Pectus deformity and scoliosis
- Recurrence of hernia (in up to 50%): Risk greater in those who required patch closure

SURGERY/OTHER PROCEDURES

- Surgical repair of the defect:
 - Decreased morbidity and mortality if the patient is stabilized prior to surgical repair

- Large defects require placement of a prosthetic patch
- Therapies of possible but not proven benefit:
 - ECMO (extracorporeal membrane oxygenation)
 - Inhaled nitric oxide
 - Sildenafil and other pulmonary vasodilators
 - High-frequency oscillatory ventilation
 - Liquid ventilation
- Fetal surgery (either tracheal occlusion or primary repair of the diaphragmatic hernia) has not been shown to improve outcomes
- Morgagni hernia: Surgical repair indicated, even if the patient is asymptomatic, because of the high rate of strangulation of the intrathoracic bowel (10%)

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Development of pulmonary hypertension in the postoperative period
- Sudden development of hypoxemia in association with pneumothorax
- Bronchospasm
- Worsening course resulting from gastroesophageal reflux and recurrent aspiration

ALERT

- Bochdalek hernias:
 - Inability to stabilize the patient (suggestive of severe pulmonary hypoplasia and/or pulmonary hypertension)
 - Iatrogenic injury to hypoplastic lungs; aggressive ventilation causing barotrauma
 - Delay in transferring patient to an appropriate medical center
 - Lack of recognition of other congenital malformations or chromosomal abnormalities that may affect the patient's ultimate outcome or represent a contraindication to surgical repair
- Morgagni hernias: Not considering the diagnosis when abnormalities are seen on chest radiograph

PROGNOSIS

- Bochdalek hernia:
 - Dependent on the degree of pulmonary hypoplasia and pulmonary hypertension
 - If the patient survives the perioperative period, 55–65% survival (as high as 90% in the most advanced centers)
 - Poor prognostic factors:
 - Polyhydramnios
 - Liver herniation into the chest
 - LHR <1.4 mm (<1.0 mm in some studies)
 - Early postnatal presentation (i.e., presenting in the 1st 6 hours vs. after 24 hours)
 - Coexistence of cardiac, CNS, or chromosomal abnormalities
 - Persistently elevated pCO₂ or decreased pO₂
- Morgagni hernia: Excellent

COMPLICATIONS

- Perinatal:
 - Pulmonary hypoplasia
 - Pulmonary hypertension
 - Persistence of the fetal circulation
 - Chylothorax
 - Chronic respiratory failure
 - Gastroesophageal reflux
 - Death
- Long term:
 - Chronic lung disease
 - Bronchospasm
 - Pneumonia

- Pulmonary hypertension
- Growth failure
- Gastroesophageal reflux, oral aversion, feeding difficulties
- Developmental delay and behavioral disorders
- Sensorineural hearing loss
- Recurrence of the diaphragmatic hernia
- Chest wall deformities (e.g., pectus excavatum, pectus carinatum, asymmetry) and scoliosis

• Q79.1 Other congenital malformations of diaphragm

FAQ

- Q: What is the long-term pulmonary function in survivors of Bochdalek hernias?
- A: Most studies report evidence of a mild obstructive process in adolescents or young adults with a history of CDH, with up to 50% also demonstrating significant bronchodilator responsiveness. Less commonly, reports of a mild restrictive defect or normal lung function have been reported. Follow-up ventilation-perfusion studies demonstrate reduced perfusion to the ipsilateral lung.
- Q: What is the optimal time for surgical repair in neonates with Bochdalek hernias?
- A: Delayed surgical repair until the patient is stabilized, avoidance of hyperventilation to achieve alkalinization, and use of pressure-controlled ventilation have been shown to decrease mortality significantly in neonates who meet ECMO criteria (up to 90%).

DIARRHEA

Daniel H. Leung
Sabina Mir

BASICS

DEFINITION

- Diarrhea is an increase in frequency, volume, or fluidity of a patient's stool as compared to the normal bowel movement pattern.
- Diarrhea can be classically categorized as acute or persistent.
- Acute diarrhea typically presents abruptly with increased fluid content of the stool > 10 mL/kg/d and lasts < 14 days.
- Persistent diarrhea can also begin acutely and last for ≥ 14 days. Tenesmus, perianal discomfort, and incontinence may occur.
- Diarrhea is caused whenever there is disruption of the normal absorptive and secretory functions of intestinal mucosa resulting in water and electrolyte imbalance. Malabsorption, maldigestion, cellular electrolyte pump dysfunction, and intestinal colonization or invasion by microorganisms can cause diarrhea.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Acute diarrhea:

- **Dietary causes**
 - Sorbitol, fructose, lactose, and intolerance to specific foods (beans, fruit, peppers, etc.)
- **Infectious causes**
 - Bacterial (e.g., *Escherichia coli*, *Clostridium difficile*) and viral (e.g., rotavirus, Norwalk agent, adenovirus)
 - Parasites (*Giardia*, *Cryptosporidium*, *Entamoeba*)
- **Medications**
 - Antibiotics, laxatives
- **Vitamin deficiency**
 - Zinc, niacin

Chronic diarrhea:

- **Allergic/autoimmune**
 - Milk/soy protein allergy, eosinophilic enteritis, Henoch–Schönlein purpura (HSP), celiac disease, or autoimmune enteropathy
- **Immunodeficiency**
 - HIV/AIDS, chronic granulomatous disease, hyper IgM, severe combined immunodeficiency
- **Anatomic abnormalities**
 - Short intestinal tract (e.g., h/o necrotizing enterocolitis or Hirschsprung s/p repair), malrotation
- **Bile salt malabsorption**
- **Congenital**
 - Cystic fibrosis, microvillus inclusion disease, tufting enteropathy, or IPEX syndrome
- **Encopresis**
- **Endocrine disorders**
 - Hyperthyroidism, diabetes, congenital adrenal hyperplasia
- **Bacterial overgrowth (e.g., blind loop, ostomy)**
- **Inflammatory bowel disease**
 - Ulcerative colitis, Crohn's disease
- **Intestinal lymphangiectasia**
 - Primary and secondary

- **Irritable bowel syndrome**
- **Lactose intolerance**
 - Primary, secondary, and congenital
- **Pancreatic exocrine dysfunction**
 - Shwachman–Diamond syndrome, cationic trypsinogen deficiency, Jeune syndrome, Pearson syndrome, and Johanson–Blizzard syndrome
- **Postinfectious enteropathy**
- **Secretory tumors**
 - VIPoma, somatostatinoma, gastrinoma

APPROACH TO THE PATIENT

It is important to determine the type of diarrhea (osmotic vs. secretory) as this will alter your diagnostic and therapeutic plan.

- **Phase 1:** Secretory diarrhea: Absorption of intestinal fluid and electrolytes is accomplished through multiple cellular pumps transporting sodium, glucose, and amino acids. Factors that interrupt these pumps (e.g., cholera toxin, prostaglandin E, vasoactive intestinal peptide, secretin, acetylcholine) can cause a severe active isotonic secretory state manifested by profuse diarrhea, dehydration, and acidosis.
- **Phase 2:** Osmotic diarrhea: In general, the solute composition of intestinal fluid is similar to that of plasma. Osmotic diarrhea occurs when poorly absorbed or nonabsorbable solute is present in the intestinal lumen. This can occur with the ingestion of nonabsorbable sugars (e.g., sorbitol), cathartics (e.g., magnesium citrate), carbohydrate malabsorption secondary to mucosal damage (e.g., lactose), maldigestion (e.g., pancreatic dysfunction), rapid transit of intestinal fluid, or with a rare congenital transport defect.

HISTORY

- **Question:** Duration?
- **Significance:** A distinction should be made between acute and chronic diarrhea. The cause of acute diarrhea is almost always related to an infection, a medication, or the addition of a new food.
- **Question:** Travel history?
- **Significance:** Questions should be asked regarding travel to areas where drinking water is contaminated (e.g., *Entamoeba* in Mexico) or food handling/preparation is prolonged or unsanitary (e.g., *Campylobacter*, *Bacillus cereus*, or *E. coli*). Exposure to freshwater streams or ponds (e.g., *Cryptosporidium*, *Giardia*) may also be important to address.
- **Question:** Recent use of antibiotics?
- **Significance:** A variety of antibiotics cause *C. difficile* colitis or antibiotic-related diarrhea.
- **Question:** Adolescents?
- **Significance:** Questions should be asked regarding body image and weight. Laxative abuse causing an osmotic diarrhea is common among adolescents who have an eating disorder or athletes attempting to lose weight rapidly.
- **Question:** Family history?
- **Significance:** Conditions with genetic susceptibility (e.g., inflammatory bowel disease, celiac disease)
- **Question:** Systemic symptoms?

- **Significance:** Questions regarding fever, GI bleeding, rashes, or vomiting are vital. Certain GI infections and inflammatory bowel disease have specific associated systemic symptoms.
- **Question:** Hematochezia?
- **Significance:** The occurrence of acute, bloody stools and fever generally indicates a bacterial infection. However, these same symptoms coupled with fatigue, poor urine output, and history of easy bruising may suggest hemolytic uremic syndrome. Bloody stools in combination with a history of crampy abdominal pain, arthritis, and purpuric rash can indicate HSP, a completely different entity. The quantification and description of the bloody stool may also be helpful (e.g., currant jelly-like stools of intussusception vs. bright red blood from milk protein allergy). Chronic bloody diarrhea, abdominal pain, and weight loss are characteristic of inflammatory bowel disease.
- **Question:** Steatorrhea?
- **Significance:** Indicates fat malabsorption (e.g., cystic fibrosis)
- **Question:** Age?
- **Significance:** The age of the child is important because a number of diseases present between birth and 3 months of life including cystic fibrosis, milk or soy protein allergy, and congenital enteropathies.
- **Question:** Previously well infant with recent viral illness and subsequent protracted diarrhea?
- **Significance:** Postviral enteritis should be suspected. This disorder is characterized by severe mucosal injury resulting in transient disaccharidase deficiency and potentially prolonged malabsorption.
- **Question:** Normal preschool-aged children who have 2–10 watery stools per day without other symptoms and/or cause who have increased juice intake?
- **Significance:** Chronic nonspecific diarrhea of childhood or "toddler's diarrhea" should be considered.
- **Question:** Lactose intolerance?
- **Significance:** Commonly occurs in many older children and adults, with >95% occurrence rate in some ethnic groups.
- **Question:** Chronic diarrhea with weight loss?
- **Significance:** Inflammatory or immunologic disorders such as ulcerative colitis, Crohn's disease, and celiac disease must be ruled out. Celiac disease is an immune-mediated enteropathy caused by a permanent sensitivity to gluten and related prolamine in genetically susceptible individuals. It occurs in roughly 1:130 of the US population with a genetic predisposition and should be considered in any child with chronic diarrhea and poor weight gain.

PHYSICAL EXAM

- **Finding:** Child's growth parameters?
- **Significance:** Previous measurements and growth curves are necessary to make an accurate evaluation. Findings of a chronically malnourished child with years of weight loss or poor growth velocity would indicate a divergent differential diagnosis from that of a healthy-appearing child with a history of normal growth.

- **Finding:** Arthritis and rash?
- **Significance:** Diarrhea accompanied by these signs can occur in diseases such as inflammatory bowel disease, celiac disease, HSP, and specific bacterial infections.
- **Finding:** Oral ulcers?
- **Significance:** Occur in inflammatory bowel disease and celiac disease
- **Finding:** Hydration?
- **Significance:** Capillary refill >3 seconds, tachycardia without pain or fever, and dry mucous membranes provide clues to dehydration.
- **Finding:** Nail bed clubbing?
- **Significance:** This finding may direct questioning to rule out cystic fibrosis or chronic inflammatory bowel disease.
- **Finding:** Masses?
- **Significance:** A right lower quadrant mass could suggest an abscess (e.g., terminal ileitis in Crohn's disease or appendiceal abscess) or intussusception (e.g., irritable child with currant jelly-like stools).

DIAGNOSTIC TESTS & INTERPRETATION

- **Test:** Stool culture
- **Significance:** Stool examination for blood, mucus, inflammatory cells, and microorganisms is an important first step in determining the cause of the diarrhea. Stool cultures for parasites (e.g., *Giardia*, *Cryptosporidium*, *Entamoeba*), bacterial pathogens (e.g., *Salmonella*, *Campylobacter*, *Shigella*, *Yersinia*, *Aeromonas*, *Plesiomonas*), viral particles, and *C. difficile* toxin should be appropriately obtained in all children with unexplained diarrhea.
- **Test:** Stool pH and reducing substances
- **Significance:** These tests are useful in identifying carbohydrate malabsorption. A stool pH <5–6 and stool reducing substances >0.5–1% is suggestive.
- **Test:** Stool osmolality and electrolytes
- **Significance:**
 - Stool osmolality, stool Na, and stool K can be used to calculate an ion gap and differentiate between secretory and osmotic diarrhea.
 - Stool osmotic gap = measured stool osmolality – estimated stool osmolality
 - Estimated stool osmolality = 2 (Na stool + K stool)
 - An increased stool osmotic gap is >50 mOsm/kg.
- **Test:** Hemoccult
- **Significance:** Sensitive and specific test is helpful in distinguishing truly heme + stools from ingested foods/drinks with artificial or natural red coloring. Stool positive for blood is suggestive of infectious (C diff) and organic etiologies (Inflammatory bowel disease)
- **Test:** 72-hour quantitative fecal fat evaluation
- **Significance:** This is a sensitive test for steatorrhea. Patients need to be placed on a high-fat diet (2–4 g/kg) for a minimum of 1 day prior to testing. Over 3 days, all stool is collected, refrigerated, and tested. A diet record needs to be performed for the 3 days that correspond to the stool collection period. The coefficient of fat absorption is calculated: Grams of fat ingested – grams of fat excreted/grams of fat ingested × 100. Normal values are as follows: Premature infants: 60–75%; newborns: 80–85%; children 10 months to 3 years: 85–95%; children >3 years: 93%. When fat malabsorption is present, disorders of pancreatic function (e.g., cystic fibrosis, Shwachman syndrome) or severe intestinal disease should be suspected.

- **Test:** Lactose breath test
- **Significance:** This noninvasive test measures hydrogen levels. It is based on the principle that hydrogen gas is produced by colonic bacterial fermentation of malabsorbed carbohydrates. When abnormal in older healthy-appearing children, primary lactase deficiency is likely. However, in young children, a secondary lactase deficiency should be considered and small-bowel disease should be ruled out.
- **Test:** D-xylose test
- **Significance:** This serum test is an indirect measure of functional small bowel surface area. D-xylose absorption in the blood occurs independent of bile salts, pancreatic enzymes, and intestinal disaccharidases. A specific dose of D-xylose (1 g/kg, maximum 25 g) is given orally after an 8-hour fast, and the serum level of D-xylose is determined after 1 hour. Levels <15–20 mg/dL in children is abnormal and suggestive of disorders that alter or disrupt intestinal mucosa absorption.
- **Test:** Fecal calprotectin
- **Significance:** Calprotectin is a neutrophilic protein detected in stools in inflammatory conditions.
- **Test:** Endoscopy and colonoscopy (optional)
- **Significance:** Direct visualization of the intestinal mucosa as well as intestinal culture, disaccharidase collection, and biopsies can provide clues to diagnosis.
- **Test:** Celiac panel
- **Significance:** This includes a tissue transglutaminase, IgA level, and endomysial antibody.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- The key elements in treatment of diarrhea are: (a) correction of hydration, (b) correction of electrolytes, and (c) specific treatment of underlying cause when indicated.
- Rehydration is the cornerstone of treatment.
- Oral rehydration therapy with glucose concentrations of 111 mmol/L and 90 mmol/L sodium is recommended.
- IV rehydration is indicated for patients who are severely dehydrated and unable to tolerate oral feedings.

ISSUES FOR REFERRAL

Children who present with growth failure, noninfectious heme-positive diarrhea, or unexplained chronic diarrhea should be considered for referral to a pediatric gastroenterologist.

IN-PATIENT CONSIDERATIONS

Initial Stabilization

Diarrhea can lead to significant dehydration and electrolyte imbalance. Any child suspected of clinical dehydration should be closely observed. Only if oral rehydration is ineffective is IV therapy indicated. Culture-negative GI bleeding associated with severe abdominal pain and diarrhea should always be treated urgently.

- **Antibiotics**
 - *Vibrio cholerae*, *Shigella*, and *Giardia lamblia* require antimicrobial therapy (i.e., trimethoprim/sulfasoxazole, azithromycin, tetracycline, ciprofloxacin, metronidazole).
 - Prolonged courses of enteropathogenic *E. coli*, *Yersinia* in sickle cell patients, and *Salmonella*

species infections in the very young febrile or bacteremic infant require antimicrobial therapy.

ONGOING CARE

DIET

- Breastfeeding should continue during episodes of gastroenteritis, as it promotes mucosal healing and recovery.
 - It was traditionally believed that bowel rest was beneficial for formula-fed infants. Many studies have now shown that return feeding after 4–6 hours promotes a faster recovery.
- **Micronutrient supplementation**
 - Zinc supplementation during episodes of acute diarrhea has been shown to decrease severity and duration as well as preventing future episodes in malnourished children.
- **Probiotics**
 - *Lactobacillus rhamnosus GG* has been shown to shorten the duration of diarrheal illness and viral shedding (e.g., rotavirus).

DIPHTHERIA

Michael J. Smith

BASICS

DESCRIPTION

Acute infectious disease caused by *Corynebacterium diphtheriae*; affects primarily the membranes of the upper respiratory tract with the formation of a gray-white pseudomembrane

EPIDEMIOLOGY

- The single known reservoir for *C. diphtheriae* is humans; disease is acquired by contact with either a carrier or a diseased person.
- Most cases occur during the cooler autumn and winter months in individuals <15 years who are unimmunized.
- Recent outbreaks have occurred, most notably in the new independent states of the former Soviet Union, and supply additional evidence that disease occurs among the socioeconomically disadvantaged living in crowded conditions.

Incidence

Though the disease is distributed throughout the world, it is endemic primarily in developing regions of Africa, Asia, and South America. In the Western world, the incidence of diphtheria has changed dramatically in the past 50–75 years as a result of the widespread use of diphtheria toxoid after World War II. The incidence has declined steadily and is now a rare occurrence.

GENERAL PREVENTION

Active immunization with diphtheria toxoid is the cornerstone of population-based diphtheria prevention. Current recommendations from the Advisory Committee on Immunization Practices (ACIP) of the Centers for Disease Control and Prevention:

- Ages 2 months to 7 years: 5 doses of diphtheria vaccine (with tetanus toxoid and acellular pertussis):
 - First 3 given as DTaP vaccine 0.5 mL IM at 2-month intervals beginning at 2 months of age
 - 4th dose of DTaP should be given at 15–18 months of age.
 - 5th dose of DTaP or DTP at 4–6 years of age
- In 2005, 2 tetanus toxoids, reduced diphtheria toxoid, and acellular pertussis (Tdap) vaccines were licensed for use in adolescents 11–18 years of age.
- 1 booster dose of Tdap should be given to all adolescents at the 11–12-year-old visit, provided they have completed the childhood series. Subsequent tetanus and diphtheria (Td) boosters should be administered every 10 years.
- Tdap should replace the 1st dose of Td in children 7–10 years of age who are undergoing primary immunization
- Isolation of patients with diphtheria is required until culture from the site of infection is negative on 3 consecutive specimens.

PATHOPHYSIOLOGY

- The initial entry site for *C. diphtheriae* is via airborne respiratory droplets, typically the nose or mouth but occasionally the ocular surface, genital mucous membranes, or pre-existing skin lesions.
- Following 2–4 days of incubation at one of these sites, the bacterium elaborates toxin.
- Locally, the toxin induces formation of a necrotic coagulation of the mucous membranes (pseudomembrane) with underlying tissue edema; respiratory compromise may ensue.
- Elaborated exotoxin may also have profound effects on the heart, nerves, and kidneys in the form of myocarditis, demyelination, and tubular necrosis, respectively.

ETIOLOGY

C. diphtheriae, a Gram-positive pleomorphic bacillus

DIAGNOSIS

- Respiratory tract diphtheria:
 - Nasal diphtheria starts with mild rhinorrhea that gradually becomes serosanguineous, then mucopurulent and often malodorous; occurs most often in infants.
 - Tonsillar and pharyngeal diphtheria begin with anorexia, malaise, low-grade fever, and pharyngitis. A membrane appears within 1–2 days. Cervical lymphadenitis and edema of the cervical soft tissues may be severe. Disease course varies with extent of toxin elaboration and membrane production. Respiratory and cardiovascular collapse may occur.
 - Laryngeal diphtheria most often represents extension of a pharyngeal infection and clinically presents as typical croup. Acute airway obstruction may occur, and in severe cases, the membrane may invade the entire tracheobronchial tree.
 - Cutaneous diphtheria occurs in warmer tropical regions. It is characterized by chronic nonhealing ulcers with gray membrane and may serve as a reservoir in endemic and epidemic areas of respiratory diphtheria.
- Other sites: Rarely vulvovaginal, conjunctival, or aural forms occur.

HISTORY

- Exposure to an individual with diphtheria is not necessarily elicited because contact with an asymptomatic carrier may be the only source of infection.
- Incubation period:
 - Incubation period is 1–6 days.
 - Respiratory diphtheria, depending on the site of infection, may begin with nasal discharge alone or with pharyngitis accompanied by mild systemic symptoms.
 - Progression of symptoms thereafter occurs as outlined above (see “Diagnosis”).
- Previous diphtheria immunization history, diphtheria exposure

PHYSICAL EXAM

- Classic findings:
 - Nasal discharge
 - Nasal or pharyngeal membrane
 - Heart rate out of proportion to body temperature
 - Respiratory distress
 - Stridor
 - Cough
 - Hoarseness
 - Palatal paralysis
 - Neck swelling
 - Cervical lymphadenitis
 - Attempt to remove any membrane present results in bleeding.
- Conjunctival diphtheria: Palpebral conjunctival involvement with a red, edematous, membranous appearance
- Aural diphtheria: Otitis externa with a purulent, malodorous discharge
- Cutaneous diphtheria: See “Diagnosis.”

DIAGNOSTIC TESTS & INTERPRETATION

Diagnosis should be on clinical grounds: Delay in treatment increases morbidity and mortality.

Lab

- Culture of material from the membrane or beneath the membrane: If a strain of *C. diphtheriae* is isolated, additional testing for presence or absence of toxin production should be done by a laboratory prepared to conduct an animal neutralization test or, alternatively, neutralization (with antitoxin) in tissue culture.
- Examination of a methylene blue-stained lesion: Metachromatic granules may be helpful if performed by an experienced technician.
- Fluorescent antibody testing and counterimmunoelectrophoresis: Previously performed in state laboratories; no longer widely available

DIFFERENTIAL DIAGNOSIS

- Nasal diphtheria:
 - Common cold
 - Nasal foreign body
 - Sinusitis
 - Adenoiditis
 - Snuffles (congenital syphilis)

- Tonsillar or pharyngeal diphtheria:
 - Streptococcal pharyngitis
 - Infectious mononucleosis
 - Primary herpetic tonsillitis
 - Thrush
 - Vincent angina
 - Post-tonsillectomy faucial membranes
 - Oropharyngeal involvement caused by toxoplasmosis, cytomegalovirus, tularemia, and salmonellosis
- Laryngeal diphtheria:
 - Croup
 - Acute epiglottitis
 - Aspirated foreign body
 - Peripharyngeal and retropharyngeal abscess
 - Laryngeal papillomas
 - Other masses

TREATMENT

MEDICATION (DRUGS)

Antibiotic therapy: Use in addition to, not in place of, diphtheria antitoxin (DAT)

- Respiratory diphtheria:
 - Penicillin G
 - Aqueous crystalline 100,000–150,000 U/kg/d in 4 divided doses for 14 days
 - Procaine 25,000–50,000 U/kg/d in 2 divided doses for 14 days or
 - Erythromycin 40–50 mg/kg (maximum 2 g/d) PO or parenterally for 14 days
- Cutaneous diphtheria: Requires local care of the lesion with soap and water and administration of antimicrobials for 10 days

IN-PATIENT CONSIDERATIONS

Initial Stabilization

- DAT antiserum, produced in horses, must be administered as soon as possible. DAT is available from the CDC. (Note: For patients with known horse serum sensitivity, a test dose should be administered first, and if positive, the patient should be desensitized.)
- Pharyngeal or laryngeal disease of <48 hours duration: 20,000–40,000 units IV
- Nasopharyngeal lesions: 40,000–60,000 units IV
- Extensive disease of ≥3 days duration or diffuse neck swelling: 80,000–120,000 units IV

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Mild cases: After membrane sloughs off in 7–10 days, recovery is usually uneventful.
- More severe cases: Recovery may be slower; serious complications may occur.

PROGNOSIS

- Most strongly dependent on the immunization status of the host. Those without prior adequate immunization have significantly higher morbidity and mortality.
- Delay in onset of treatment also increases mortality. When appropriate treatment has been administered on day 1 of illness, mortality may be as low as 1%. When treatment has been delayed until day 4, the mortality rate is ≤20-fold higher.
- Organism virulence: Toxigenic strains are associated with more severe disease and a poorer prognosis.
- Location of membrane: Laryngeal diphtheria has a higher mortality due to airway obstruction.
- A megakaryocytic thrombocytopenia and WBC count <25,000 are associated with poor outcome.

COMPLICATIONS

- Cardiac toxicity: Myocarditis may develop secondary to elaborated toxin anytime between the 1st and 6th week of illness. Though cardiac failure may occur, most cases are transient.
- Neurologic toxicity occurs secondary to toxin elaboration and mainly reflects bilateral motor involvement.
- Paralysis of the soft palate is most common, but ocular paralysis, diaphragm paralysis, peripheral neuropathy of the extremities, and loss of deep tendon reflexes also occur.
- The frequency of all complications, including those listed above, increases with increasing time between symptom onset and antitoxin administration and also with extent of membrane formation.

FAQ

- Q: What is the incidence of diphtheria in the US?
- A: No locally acquired case of respiratory diphtheria has been reported in the US since 2003.
- Q: Are there currently places in the world where diphtheria is a problem?
- A: Yes, an epidemic began in 1990 in Russia, spread in 1991 to Ukraine, and during 1993 and 1994, spread to the remaining new independent states of the former Soviet Union. Other endemic regions include the Middle East and Asia, and some countries in Africa and Central and South America. Travelers to these regions should check the CDC website for the latest information.
- Q: What precautions should be taken by travelers to areas of the world with diphtheria outbreaks?
- A: The ACIP recommends that travelers to such areas be up-to-date with diphtheria immunization. Infants traveling to areas where diphtheria is endemic or epidemic should ideally receive 3 doses of DTaP before travel.

DISKITIS

Timothy Beukelman

Randy Q. Cron

BASICS

DESCRIPTION

Often benign, self-limited inflammatory process of an intervertebral disk

EPIDEMIOLOGY

>50% of the cases occur in children <4 years.

Incidence

Peak incidence is between 1 and 3 years of age.

Prevalence

Rare

PATHOPHYSIOLOGY

- Probably of infectious etiology by an indolent organism
- Usually none identified; occasionally *Staphylococcus aureus*, *Moraxella*, or the Enterobacteriaceae are cultured.

ETIOLOGY

Idiopathic or initiated by low-grade infection

DIAGNOSIS

HISTORY

- Uncomfortable child
- Refusal to walk
- Fever
- Back or abdominal pain
- Symptoms of short duration prior to presentation

PHYSICAL EXAM

- Usually, rigid posture and pain elicited on movement (sits in tripod position)
- Focal tenderness to palpation
- Most common locations: L4–5 and L3–4

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Initial lab tests

- Purified protein derivative (PPD)
- WBC count
- Erythrocyte sedimentation rate (ESR)
- Blood cultures

Imaging

- Plain radiographic studies: Usually normal, though may demonstrate disk narrowing as illness progresses
- Bone scan: Demonstrates increased uptake at affected area
- MRI: Useful in atypical situations to confirm location of pathology (demonstrates disk edema)

DIFFERENTIAL DIAGNOSIS

- Infection:
 - Vertebral osteomyelitis (e.g., *Staphylococcus*, *Salmonella*)
 - Potts disease (tuberculous spondylitis)
- Environmental trauma:
 - Fracture
 - Disk herniation
- Tumors: Osteoid osteoma
- Vascular: Avascular necrosis of vertebral body
- Congenital: Spondylolisthesis
- Immunologic: Ankylosing spondylitis
- Miscellaneous: Scheuermann disease (osteochondritis of the vertebral bodies)

ALERT

Difficulty separating early vertebral body osteomyelitis from diskitis

TREATMENT

MEDICATION (DRUGS)

- Usually quite responsive to NSAIDs
- Rarely, antibiotics are indicated.

COMPLEMENTARY & ALTERNATIVE THERAPIES

- Physical therapy
 - Patient should be immobilized during acute period.
 - Casting may be required.

IN-PATIENT CONSIDERATIONS

Initial Stabilization

Duration:

- Follow CBC and ESR
- Continue treatment until child is asymptomatic

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- When to expect improvement: Most patients are asymptomatic in 6–8 weeks.
- Signs to watch for:
 - Recurrence of symptoms due to reactivation of the disease
 - Progressive loss of disk height
 - Destruction of adjacent vertebral bodies

PROGNOSIS

- Usually excellent
- Scoliosis may occur.
- Rarely, facet joint symptoms occur years later.

COMPLICATIONS

- Occasionally, scoliosis or kyphosis
- Rarely, facet joint degenerative disease

FAQ

- Q: When are a biopsy and tissue culture indicated?
- A: If there is bony destruction of adjacent vertebral bodies or if clinical course is prolonged.
- Q: When are antibiotics indicated?
- A: Obviously, in situations with positive cultures, or if course is atypical or prolonged.

DISORDERS OF SEX DEVELOPMENT

Thomas F. Kolon

BASICS

DESCRIPTION

Chromosomal sex is established at fertilization, which then directs the undifferentiated gonads to develop into testes or ovaries. Phenotypic sex results from the differentiation of internal ducts and external genitalia under the influence of hormones and transcription factors. If there is any discordance among these three processes (i.e., chromosomal, gonadal, or phenotypic sex determination), then ambiguous genitalia develop.

RISK FACTORS

Genetics

- Inactivating or loss-of-function mutations in 5 genes involved in steroid biosynthesis can cause congenital adrenal hyperplasia (CAH): CYP21, CYP11B1, CYP17, HSD3B2, and StAR. Each of these genetic defects is inherited in an autosomal recessive pattern.
- 46XY disorders of sex development (DSD) can result from Leydig cell unresponsiveness to human chorionic gonadotropin luteinizing hormone (hCG-LH) because the production of testosterone by the Leydig cells is critical to male differentiation of the wolffian ducts and the external genitalia. Familial studies are consistent with autosomal recessive transmission. Multiple cases have been described, and conversion and nonsense mutations have been identified in homozygous and compound heterozygous individuals.
- The androgen receptor (AR) gene is located on the long arm of chromosome X. The majority of AR gene mutations affect the steroid-binding domain and result in receptors unable to bind androgens or that bind androgens but exhibit qualitative abnormalities.
- The SRD5A2 gene, which accounts for most fetal 5 α -reductase activity, is on chromosome 2. 5 α -Reductase 2 deficiency is heterogeneous, and >40 mutations have been reported. Consanguinity has also been described in up to 40% of patients' families. Three genetic isolates of this disorder have been described in the Dominican Republic, the New Guinea Samba Tribe, and Turkey.
- Persistent Müllerian duct syndrome (PMDS) is inherited in a sex-limited autosomal recessive manner caused by a mutation in the antimüllerian hormone (AMH) or AMH-receptor genes. These mutations are most common in Mediterranean or Middle Eastern countries with high rates of consanguinity.
- Mutations or deletions of any of the genes involved in the testis determination cascade (SRY, DSS, DAX1, XH2, SOX9, SF1, WT1) have been identified in dysgenetic 46XY DSD.
- 47XXY males may develop through nondisjunction of the sex chromosomes during the 1st or 2nd meiotic divisions in either parent or, less commonly, through mitotic nondisjunction in the zygote at or after fertilization. These abnormalities almost always occur in parents with normal sex chromosomes.

- Categories of 46XX sex reversal include classic XX male individuals with apparently normal phenotypes, nonclassic XX males with some degree of sexual ambiguity, and XX true hermaphrodites. 80–90% of 46XX males result from an anomalous Y to X translocation involving the SRY gene during meiosis. However, 8–20% of XX males have no detectable Y sequences, including SRY.
- XY gonadal dysgenesis (GD; XY sex reversal or Swyer syndrome) is a heterogeneous condition that can result from deletions of the short arm of the Y chromosome, SRY gene mutations, alterations in autosomal genes, or duplications of the DSS locus on the X chromosome.
- A 45X karyotype may be due to nondisjunction or chromosome loss during gametogenesis in either parent resulting in a sperm or ovum without a sex chromosome. 45X/46XX mosaicism may be present in up to 75% of Turner syndrome patients.
- In true hermaphroditism (TH), the most common karyotype is 46XX followed by 46XX/46XY chimerism, mosaicism, and 46XY. Most 46XX ovotesticular DSDs are SRY negative, and the genes responsible have not yet been identified. A mutated downstream gene in the sex determination cascade likely allows for testicular determination.

PATHOPHYSIOLOGY

- A testis that is poorly formed is called a dysgenetic testis, and an ovary that is poorly formed is called a streak gonad.
- A dysgenetic testis usually has discontinuity of the tunica albuginea with hilar disorganization, hypoplastic or disordered tubules, and fibrotic stroma.
- Streak gonads contain ovarianlike stroma with occasional primordial follicles.
 - A patient with a Y chromosome is at high risk to develop a tumor in a streak or dysgenetic gonad.
 - Gonadoblastoma is the most common tumor. Although it is a benign growth, it can give rise to a malignant tumor called a dysgerminoma. The risk of tumor formation can be up to 35% and is age related (older more at risk).
- An ovotestis has evidence of both seminiferous tubules and ovarian stroma and follicles.

ETIOLOGY

- Currently, 4 main categories of DSDs are described: 46XX DSD; 46XY DSD; gonadal dysgenesis—pure GD (PGD) or mixed GD (MGD); and ovotesticular DSD.
- 46XX DSD is the most common DSD disorder. The ovaries and Müllerian derivatives are normal, and the sexual ambiguity is limited to masculinization of the external genitalia. A female fetus is masculinized only if exposed to androgens, and the degree of masculinization is determined by the stage of differentiation at the time of exposure. These changes may also be secondary to exogenous maternal steroids. Congenital adrenal hyperplasia (CAH) accounts for the majority of 46XX DSD patients (most commonly 21 α -hydroxylase or 11 β -hydroxylase deficiencies).

- 46XY DSD is a heterogeneous disorder in which testes are present but the internal ducts and/or the external genitalia are incompletely masculinized. The phenotype ranges from completely female external genitalia to mild male ambiguity (such as hypospadias or cryptorchidism). 46XY DSD can result from 8 basic etiologic categories:
 - Testicular unresponsiveness to hCG and LH (Leydig cell agenesis/hypoplasia due to hCG/LH receptor defect)
 - Enzyme defects in testosterone biosynthesis, some of which are common to CAH (StAR, HSD3B2, CYP17, 17 β -HSD3)
 - Defects in androgen-dependent target tissues (androgen insensitivity syndrome)
 - Defect in the enzymatic conversion of testosterone (T) to dihydrotestosterone (DHT) (5 α -reductase deficiency)
 - Defects in the synthesis, secretion, or response to Müllerian-inhibiting substance (MIS or antimüllerian hormone), resulting in persistent müllerian duct syndrome
 - Aberrations in testicular gonadogenesis (testicular dysgenesis)
 - Primary testicular failure (vanishing testes)
 - Exogenous insults (maternal ingestion of progesterone/estrogen or environmental hazards)
- GD disorders comprise a spectrum of anomalies ranging from complete absence of gonadal development to delayed gonadal failure. Complete or pure GD includes failed gonadal development in genetic males and females due to abnormalities of sex or autosomal chromosomes. Partial GD refers to disorders with partial testicular formation at some point in development including MGD, dysgenetic testes, and some forms of testicular or ovarian regression.
- Ovotesticular DSD requires the presence of both ovarian and testicular tissue in the individual and can result from sex chromosome mosaicism, chimerism, or Y-chromosomal translocation. This uncommon condition may be classified into three groups: Lateral (testis and ovary, usually left), bilateral (ovotestis and ovotestis), and unilateral (most common; ovotestis and testis or ovary). The genital development is ambiguous with hypospadias, cryptorchidism, and incomplete fusion of labioscrotal folds. Genital duct differentiation generally follows that of the ipsilateral gonad.

DIAGNOSIS

HISTORY

Prematurity, exogenous maternal hormones (used in infertility treatments), use of oral contraceptives, CNS lesions, and family history for urologic abnormalities, neonatal deaths, precocious puberty, infertility, or consanguinity.

PHYSICAL EXAM

- Any abnormal virilization or cushingoid appearance of the child's mother should be noted.
- The patient should be examined supine in the frog-leg position with both legs free.
 - Note any dysmorphic features including a short, broad neck or widely spaced nipples. Abnormal phallic size should be documented by width and stretched length measurements.

- Describe the position of the urethral meatus and amount of chordee (ventral curvature):
 - Note the number of orifices: 3 in normal girls (urethra, vagina, and anus) or 2 in boys (urethra, anus). A rectal exam should always be performed for palpation of a uterus.
- With warmed hands, begin the inguinal exam at the anterior superior iliac spine. Sweep the groin from lateral to medial with the nondominant hand:
 - When a gonad is palpated, grasp it with the dominant hand, and continue to sweep toward the scrotum with the other hand to attempt to bring the gonad to the scrotum.
 - Check the size, location, and texture of both gonads if palpable. Wetting the fingers of the nondominant hand with lubricating jelly or soap can increase the sensitivity of the fingers.
- The undescended testis may be found in the inguinal canal, in the superficial inguinal pouch, at the upper scrotum, or (rarely) in the femoral, perineal, or contralateral scrotal regions. For differential diagnosis and treatment purposes, the distinction needs to be made whether or not the testis is palpable. Unless associated with a patent processus vaginalis, ovaries and streak gonads do not descend, although testes, and rarely ovotestes, may be palpable.
- Document development and pigmentation of the labioscrotal folds.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

All patients require serum electrolytes, 17OH progesterone (17OHP), T, LH, follicle-stimulating hormone (FSH), karyotype. If 17OHP is elevated, 11 deoxycortisol and deoxycortisol (DOC) will help differentiate 21 α - from 11 β -hydroxylase deficiency. If 17OHP is normal, T/DHT ratio along with androgen precursors pre-/post-hCG stimulation (if >3 months) will help elucidate the 46XY DSD etiology. A failure to respond to hCG in combination with elevated LH/FSH levels is consistent with anorchia.

Imaging

- Ultrasound can detect gonads in the inguinal region (where they are also most easily palpable) but are only 50% accurate in showing intra-abdominal testes:
 - These tests are also helpful in identifying a uterus.
- A genitogram may be performed to evaluate a urogenital sinus including the entry of the urethra and vagina:
 - A cervical impression can be identified on the vaginogram.
- Although more expensive, a gadolinium-enhanced MRI may also help to delineate the anatomy.

DIFFERENTIAL DIAGNOSIS

The differential diagnosis initially depends on the palpability of gonads on presentation:

- If no gonads are palpable, all 4 categories are possible:
 - Of these, 46XX DSD is most commonly seen, followed by MGD.
- If 1 gonad is palpable, 46XX DSD and PGD are ruled out because ovaries and streak gonads do not descend. MGD, ovotesticular, and 46XY DSD remain possibilities.

- If 2 gonads are palpable, 46 XY DSD and (rarely) ovotesticular DSD are the most likely diagnoses:
 - In 46XY boys, hypospadias and cryptorchidism without an underlying intersex etiology would be a diagnosis of exclusion after a full evaluation.

TREATMENT

Much current research is aimed at understanding the influence of androgens on the fetal/newborn brain and its relationship to gender identity. Diagnosis and management of these children is individualized and should always involve a “team effort” including the pediatric urologist, endocrinologist, geneticist, and psychologist and the child’s parents immediately after birth.

ADDITIONAL TREATMENT

General Measures

- Treatment of the newborn with CAH involves correction of dehydration and salt loss by electrolyte and fluid therapy with mineralocorticoid replacement. Glucocorticoid replacement is generally added upon confirmation of the diagnosis.
- Estrogen replacement is begun after puberty in girls with complete AIS.
- Testosterone replacement may be needed in some cases of XY DSD (partial AIS, testicular dysgenesis, primary testicular, or Leydig cell failure) to aid in pubertal changes and for maintenance through adulthood.

SURGERY/OTHER PROCEDURES

- Until further data are available, the current recommendation for a girl with CAH is to continue a female sex of rearing and perform a feminizing genitoplasty depending on the degree of masculinization:
 - This surgery has 3 main aims: Increasing the opening of the vagina with separation from the urethra, reconstructing the female labia, and reducing the size of the enlarged, masculinized clitoris if significant.
 - Most cases need early surgery to separate the urinary system from the genital system for technical and psychological reasons.
- Some gonads need to be removed owing to the risk of tumor formation. Controversy exists concerning the best time to perform orchiectomies in a child with complete AIS reared as female (at diagnosis vs. after puberty). Streak gonads in the presence of a Y chromosome and dysgenetic abdominal testes should be removed. All other undescended testes need to be anchored in the scrotum by abdominal or inguinal orchidopexy. Dysgenetic testes in the scrotum need to be followed closely.
- Urethral reconstruction of hypospadias is performed in all children raised as boys at about 6 months of age.

ONGOING CARE

PROGNOSIS

- The overall prognosis for somatic, sexual, and psychosocial growth and development is good with careful management of most of these children. Any thoughts of gender reassignment should only be entertained after thoughtful discussion with the child’s parents and all medical staff involved.
- Except for girls with CAH, many of these patients are infertile.
- Long-term management of mineral and glucocorticoids is by the pediatric endocrinologist. The vaginal introitus in CAH should be re-examined after puberty to assess adequacy of width and depth.
- Undescended testes, especially dysgenetic testes, have an increased risk of tumor formation even after orchidopexy (seminoma-UDT, gonadoblastoma/dysgerminoma-dysgenetic testis). These boys need to learn testis monthly self-exam after puberty.
- Hypospadias repairs are followed at least through potty training to ensure good voiding habits and absence of meatal stenosis or urethrocutaneous fistulae.

DISSEMINATED INTRAVASCULAR COAGULATION

Char Witmer

BASICS

DESCRIPTION

- Disseminated intravascular coagulation (DIC) is an acquired syndrome that is always secondary to an underlying etiology.
- It is a systemic life-threatening process characterized by an uncontrolled activation of the coagulation and fibrinolytic systems with excessive thrombin generation and the consumption of coagulation factors and platelets.
- Widespread deposition of microthrombi can compromise perfusion and lead to organ failure.
- Ongoing activation and consumption of coagulant factors and platelets can result in diffuse and profuse bleeding.

EPIDEMIOLOGY

- Most commonly secondary to infections
- Overall incidence is difficult to determine secondary to the many conditions that cause DIC.

PATHOPHYSIOLOGY

- Not a disorder in itself; occurs as a result of various initiating events
- Characterized by microvascular thrombosis and hemorrhage
- May be acute (e.g., meningococemia) or chronic (e.g., malignancy/leukemia)
- There is a systemic intravascular deposition of fibrin as a result of increased thrombin generation, suppression of anticoagulant pathways, impaired fibrinolysis, and activation of inflammatory pathways.
- The initiation of coagulation activation leading to thrombin formation in DIC is mediated via the tissue factor/factor VIIa pathway.
- The tissue factor/factor VIIa pathway is activated via tissue factor expression from damaged endothelial cells.
- Anticoagulant pathways are diminished because of a decrease in the plasma levels of antithrombin and the protein C system through impaired production and increased destruction.
- The increase in fibrinolytic activity is likely secondary to the release of plasminogen activators from damaged endothelial cells.

ETIOLOGY

Most common causes are sepsis (particularly Gram-negative), hypotensive shock, and trauma (particularly head trauma).

- Sepsis/severe infection:
 - Bacterial Gram-negative and -positive sepsis
 - Meningococemia
 - Malaria: *Plasmodium falciparum*
 - Fungal: *Aspergillus*
 - Rickettsial: Rocky Mountain spotted fever
 - Viral
- Trauma
 - Multiple fractures with fat emboli
 - Massive soft tissue injury
 - Severe head trauma
 - Multiple gunshot wounds
- Malignancies:
 - Acute promyelocytic leukemia
 - Acute monoblastic or myelocytic leukemia
 - Widespread solid tumors (e.g., neuroblastoma)
- Obstetric:
 - Retained intrauterine fetal death
 - Preeclampsia/eclampsia
 - Amniotic fluid embolism
 - Abruptio placentae
 - Post hemorrhagic shock
- Neonatal:
 - Necrotizing enterocolitis
 - Perinatal asphyxia
 - Amniotic fluid aspiration
 - Obstetric complications (placenta abruption, preeclampsia, intrauterine twin demise)
 - Sepsis (bacterial and viral) Erythroblastosis fetalis
 - Respiratory distress syndrome
- Vascular Malformations:
 - Kasabach–Merritt syndrome
 - Large vascular aneurysms
- Miscellaneous:
 - Acute hemolytic transfusion reaction
 - Snake bite
 - Homozygous protein C deficiency (purpura fulminans)
 - Transplant rejection
 - Severe collagen vascular disease
 - Recreational drugs
 - Profound shock or asphyxia
 - Hypothermia or hyperthermia
 - Extensive burn injuries
 - Fulminant hepatitis/hepatic failure
 - Severe pancreatitis

DIAGNOSIS

HISTORY

- Presence of one of the underlying conditions (see “Etiology”)
- Abrupt onset of bleeding
- Prolonged bleeding from venipuncture sites
- Bleeding from multiple sites, especially venipunctures, cutdown sites, mucous membranes, skin, GI tract, and genitourinary tract
- Pulmonary or intracranial hemorrhage
- Major organ dysfunction: Pulmonary, renal, hepatic

PHYSICAL EXAM

- Signs of underlying disease
- Generally, a very toxic-appearing patient
- Ecchymosis and petechiae
- Bleeding from previously intact venipuncture sites
- Skin infarctions (purpura fulminans) secondary to thrombosis of dermal vessels
- Pulmonary hemorrhage, gastrointestinal bleeding, bleeding from surgical wounds, hematuria
- Intraabdominal and pleural hemorrhages

DIAGNOSTIC TESTS & INTERPRETATION

Lab

The following should be followed closely because results change rapidly:

- CBC: Decreased platelet count is often the earliest abnormality.
- Peripheral smear: Schistocytes, microspherocytes (50% of cases)
- PT, aPTT, and thrombin times: Prolonged
- Fibrinogen: in the initial phase could be increased as an acute-phase reactant and then decrease with consumption
- Fibrin degradation products or fibrin split products: Increased
- Soluble fibrin monomer complexes (D-dimers): Increased
- Antithrombin or protein C levels: Decreased
- Factor VIII: In the initial phase could be increased as an acute-phase reactant and then decrease with consumption. Factor VIII should be normal in coagulopathy associated with liver disease.

- There is no single test that can reliably diagnose DIC.
- The following lab abnormalities can be seen:
 - Prolonged PT in 50–75% of patients with DIC
 - Prolonged aPTT in 50–60% of patients with DIC
 - Elevated fibrin degradation products sensitivity 90–100%, but low specificity
 - Elevated d-dimer in 93–100% of patients with DIC
- Thrombocytopenia: Range $20\text{--}100 \times 10^9/\text{L}$
- Additional findings include decreased coagulation factors, fibrinogen, antithrombin, and protein C/S
- Multiple scoring systems utilizing common laboratory results have been developed to help determine if a patient is in DIC. These scoring systems have not been validated in pediatric patients.

DIFFERENTIAL DIAGNOSIS

- Coagulopathy of liver disease
- Vitamin K deficiency
- Pathologic fibrinolysis
- Microangiopathic disease, e.g., thrombotic thrombocytopenic purpura or hemolytic uremic syndrome

TREATMENT

ADDITIONAL TREATMENT

General Measures

- The most important therapy for DIC is to treat the underlying disorder.
- Supportive therapy may be required to treat symptomatic coagulation abnormalities.
- Replacement therapy:
 - Cryoprecipitate, platelets, and fresh frozen plasma to control bleeding.
 - Fresh frozen plasma also replaces anticoagulants—antithrombin, protein C and S.
- The role of heparin for DIC is controversial. It has been used in chronic DIC, arterial thromboses, or large-vessel venous thromboses.
- Antithrombin at supraphysiologic dosing has been studied with mixed results. Antithrombin is currently not recommended for the treatment of DIC in pediatric patients.

- In pediatric DIC recombinant activated protein C has not been shown to be beneficial.
- Off label use of recombinant activated factor VII has been reported for patients with severe bleeding that is refractory to replacement therapy. There are significant concerns about the prothrombotic potential of this medication.
- Antifibrinolytic agents (aminocaproic or tranexamic acid) have been used for patients with intense fibrinolysis (e.g., Kasabach Merritt or acute promyelocytic leukemia). There are concerns about the prothrombotic potential of this medication.
- Supportive care: Manage other organ system failure.

ONGOING CARE

PROGNOSIS

- Poor unless underlying disease is treated
- The intensity and duration of DIC depend on the degree of activation of the coagulation system, liver function, blood flow, and ability to reverse underlying etiology that has led to DIC.

COMPLICATIONS

- Hemorrhage:
 - Pulmonary
 - Intracranial
- Thrombosis
- Multiorgan system failure

DOWN (TRISOMY 21) SYNDROME

Esther K. Chung

BASICS

DESCRIPTION

Syndrome 1st described by John Langdon Down in 1866 consisting of multiple abnormalities, including hypotonia, flat facies, upslanting palpebral fissures, and small ears; also called "Trisomy 21." Other abnormalities include:

- Congenital heart disease (40–50%; most not symptomatic as newborn):
 - Atrioventricular (AV) canal (60% of those with congenital heart disease)
 - Ventriculoseptal defect (VSD)
 - Patent ductus arteriosus (PDA)
 - Atrioseptal defect (ASD)
 - Aberrant subclavian artery
 - Tetralogy of Fallot
- Hearing loss (66–75%): Sensorineural and conductive
- Strabismus (33–45%)
- Nystagmus (15–35%)
- Fine lens opacities (by slit-lamp exam, 59%), cataracts (1–15%)
- Refractive errors (50%)
- Nasolacrimal duct stenosis
- Delayed tooth eruption
- Tracheoesophageal fistula
- GI atresia (12%)
- Celiac disease
- Meckel diverticulum
- Hirschsprung disease (<1%)
- Imperforate anus
- Renal malformations
- Hypospadias (5%)
- Cryptorchidism (5–20%)
- Testicular microlithiasis
- Thyroid disease (15%): Congenital hypothyroidism, hyperthyroidism
- Transient myeloproliferative disorder, neonatal (leukemoid reaction)
- Neonatal polycythemia
- Leukemia (<1%; 10–30 times greater risk than in general population)
- Retinoblastoma and testicular germ cell tumors (slightly greater risk than in general population)
- Infertility, especially in males
- Obesity
- Alopecia areata (10–15%)
- Seizures (5–10%), usually myoclonic
- Alzheimer disease (nearly all age >40 years)
- Mild to moderate mental retardation (IQ range 25–70)
- Dry, hyperkeratotic skin (75%)

EPIDEMIOLOGY

- Male > female (1.3:1)
- Best recognized and most frequent chromosomal syndrome of humans
- 1 of the 3 most common autosomal trisomies in humans (others are Trisomy 18 and 13)
- Most common autosomal chromosomal abnormality causing mental retardation
- >50% of Trisomy 21 fetuses are spontaneously aborted in early pregnancy.

Incidence

1/600–1/800 live births, although incidence varies with maternal age:

- 1/1,500 for maternal ages 15–29 years
- 1/800 for maternal ages 30–34 years
- 1/270 for maternal ages 35–39 years
- 1/100 for maternal ages 40–49 years

RISK FACTORS

Genetics

- 94–97% of cases are the result of chromosomal nondisjunction (failure to segregate during meiosis in the maternal DNA).
- <5% of cases are the result of paternal nondisjunction.
- Of live births, 2.4% are mosaic (nondisjunction occurs after conception; 2 cell lines are present); generally less severely affected.
- Remainder of cases are the result of translocations between chromosome 21 and 14 [t(14q21q)]; rarely between 21 and 13 or 15; 50% of translocations are sporadic de novo events; 50% result from balanced translocations in 1 parent.

DIAGNOSIS

HISTORY

- Check for previous history of infant with Down syndrome in the family.
- Growth and developmental status
- Feeding problems
- Snoring, signs of sleep apnea (e.g., restless sleep)
- Stool habits
- Hearing concerns

PHYSICAL EXAM

The phenotype is variable from person to person.

- General:
 - Short stature
 - Hypotonia (80–100%), with an open mouth and a protruding tongue
 - Midface hypoplasia
- Head:
 - Brachycephaly with a flattened occiput
 - Microcephaly
 - False fontanel (95%)
- Eyes:
 - Upslanting palpebral fissures (98%)
 - Inner epicanthal folds
 - Brushfield spots (speckling of the iris)
 - Fine lens opacities on slit-lamp exam
 - Cataracts, refractive error, strabismus, and nystagmus
- Ears: Small, prominent, low set; overfolding of upper helix and small canals
- Nose: Small (85%); flat nasal bridge
- Tongue:
 - Relative but not true macroglossia (tongue mass is normal)
 - Fissuring
- Mouth: High-arched or abnormal palate
- Teeth:
 - Missing (50%), small, hypoplastic
 - Irregular placement

- Neck:
 - In infancy, excess skin at the nape
 - Short appearance
 - Occasionally webbed
- Heart: Assess for murmur, arrhythmia, cyanosis.
- Abdomen:
 - In neonate, distention may be present due to obstruction or atresia.
 - Diastasis recti
- Genitals:
 - In adolescents, straight pubic hair
 - In males, small penis, cryptorchidism
- Extremities:
 - Broad hands, with short metacarpals and phalanges
 - 5th finger with hypoplasia of the midphalanx (60%) and clinodactyly (50%)
 - Simian crease (single transverse palmar crease) in ~50%. A newborn with a simian crease has a 1 in 60 chance of having Down syndrome.
 - Wide gap between the 1st and 2nd toes (96%)
 - Syndactyly of 2nd and 3rd toes
 - Hyperflexibility of joints
- Skin:
 - Cutis marmorata (43%)
 - In older children, hyperkeratotic dry skin (75%)
 - Fine, soft, sparse hair

DIAGNOSTIC TESTS & INTERPRETATION

- ECG: Done within the 1st month of life to rule out cardiac disease
- Auditory brainstem response: Done within the 1st 3 months of life to rule out hearing loss

Lab

- 2nd-trimester prenatal triple screen test (α -fetoprotein [AFP], unconjugated estriol, and human chorionic gonadotropin [hCG]):
 - Performed at 15–18 weeks
 - These 3 serum markers together can detect ~60% of the pregnancies affected by Trisomy 21, with a false positive of ~5%.
 - A positive test is an indication for karyotyping with amniocentesis.
- 1st-trimester maternal serum screening (pregnancy-associated plasma protein A and free β -hCG): When these 2 tests are conducted together, it has been shown in multiple studies to have higher sensitivity than 2nd-trimester prenatal screens (91% vs. 70%).
- Chromosomal karyotype on cultured lymphocytes from peripheral blood: May be performed postnatally for confirmation if there is a clinical suspicion of Down syndrome.
- CBC:
 - In the newborn period to check for polycythemia and transient myeloproliferative disorder; repeat test in adolescence.
 - Down syndrome patients may have an increased mean corpuscular volume (MCV), making the diagnosis of iron deficiency anemia difficult.
- Thyroid function tests: To rule out hypothyroidism or hyperthyroidism

Imaging

- 1st-trimester ultrasound measurement of nuchal translucency: Performed in the 1st trimester along with maternal serum screening (see “Lab”)
- Fetal ultrasound:
 - May show polyhydramnios if bowel obstruction is present
 - A thickened nuchal fold, an absent nasal bone in the 1st trimester, and echogenic intracardiac foci have been associated with an increased risk for Down syndrome.
- Echocardiography and chest radiography: Done in the 1st month of life to rule out cardiac disease
- Lateral cervical spine radiographs in flexion, neutral, and extension: To rule out atlantoaxial instability, defined as >5-mm space between atlas and odontoid process of the axis. Important measures include:
 - Atlantodens interval (ADI; normal <4.5 mm): The distance between the posterior surface of the anterior arch of C1 and the anterior surface of the dens
 - Neural canal width (NCW; normal \geq 14 mm): The distance between the posterior surface of the dens and the anterior surface of the posterior arch of C1
 - Distance of subluxation at the occipitoatlantal joint: Normally \geq 7 mm

Diagnostic Procedures/Other

- Prenatal karyotyping via amniocentesis (16–18 weeks’ gestation) or chorionic villus sampling (9–11 weeks’ gestation):
 - Performed for any woman who presents with a positive triple or quad screen
 - May be offered if prenatal ultrasound reveals a finding associated with Down syndrome
 - Because this test fails to detect 10–15% of Down syndrome cases in older women, amniocentesis is typically offered to all women >35 years.
- Tissue sample other than blood (usually skin): To check for mosaicism

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS**

- Genetic counseling is recommended.
- Many organizations (e.g., Down Syndrome International) are available to families of children with Down syndrome.

Patient Monitoring

- Growth and development:
 - Specific growth charts for Down syndrome should be used.
 - Average age for acquiring developmental milestones differs from normal population.
 - Late closure of fontanelles
 - Consider Early Intervention program for hypotonia and developmental delay.
- Cardiac:
 - Early evaluation in newborn period, with follow-up until the presence or absence of disease is evident.
 - Subacute bacterial endocarditis prophylaxis for patients with certain types of cardiac disease.

- Ophthalmologic:
 - Early evaluation for cataracts and glaucoma
 - Visit to ophthalmologist by 6 months, then every 2 years
- Ear, nose, and throat (ENT)/audiologic:
 - Annual audiologic evaluation in the 1st 3 years of life, then every other year
- Orthopedic: Screen for atlantoaxial instability with radiography in preschool years, then every decade; evaluate for atlantoaxial instability prior to participation in contact sports (e.g., Special Olympics).
- Endocrine: Thyroid function tests in newborn period, ages 6 months and 12 months, then yearly

ALERT

- Use caution with endotracheal intubation if absence or presence of atlantoaxial instability is unknown to avoid spinal cord injury, which may be seen in rare cases.
- Hearing loss may be misinterpreted as a behavioral problem.
- Use care with atropine and pilocarpine for ophthalmologic evaluation because of possible cholinergic hypersensitivity.

PROGNOSIS

- Life expectancy is mildly decreased, with many living into the 6th decade; median age of death is 49 years.
- Alzheimer disease affects ~15% after the 4th decade.
- As adults, most patients with Down syndrome can work in supported positions.

COMPLICATIONS

- Otitis media with effusion (50–70%)
- Sinusitis
- Tonsillar and adenoidal hypertrophy
- Obstructive airway disease with associated sleep apnea (33–75%), cor pulmonale
- Obstructive bowel disease (12%, newborn period)
- Constipation (due to low tone and decreased gross motor mobility)
- Subluxation of the hips (secondary to ligamentous laxity)
- Atlantoaxial instability (10–20%; secondary to ligamentous laxity, which is most severe prior to age 10 years)

**CODES****ICD9**

758.0 Down’s syndrome

ICD10

Q90.9 Down syndrome, unspecified

FAQ

- Q: Why was Down syndrome referred to as mongolism in the past?
- A: There was a mistaken notion about a racial cause for this syndrome because of the facial appearance, which was thought to be similar to that of those of Mongoloid origin.
- Q: Do all children with Down syndrome have mental retardation?
- A: No. Though all persons with nonmosaic Down syndrome have some degree of cognitive disability, some have IQs >70 and are not considered to have mental retardation.
- Q: Can a normal cardiac exam rule out the presence of a cardiac anomaly?
- A: No. The American Academy of Pediatrics recommends that all patients with Down syndrome have a cardiology consultation within the 1st month of life. Timely surgery may be necessary to prevent serious complications.
- Q: Are patients with atlantoaxial instability symptomatic?
- A: No. Most are asymptomatic, but symptoms of cord compression may be seen in 1–2% of patients.
- Q: I have seen growth charts for Down syndrome patients that allow for plotting of lengths, heights, and weights. Are there special growth charts available for plotting head circumference?
- A: Yes. If appropriate growth charts are not used for plotting head circumference, head growth may appear abnormal. Head circumference growth charts are available through the Internet: <http://www.growthcharts.com/>

DROWNING

Mercedes M. Blackstone

BASICS

DESCRIPTION

- Drowning is defined as respiratory impairment from submersion in a liquid medium.
- The term “drowning” does not imply outcome; a victim may live or die after a drowning incident.
- Historically “near drowning,” or submersion injury, was defined as survival, at least temporarily, after suffocation by submersion in water.
 - The World Congress on Drowning and the World Health Organization advocate abandoning confusing terms such as “near drowning,” “wet drowning,” and “dry drowning”; they suggest that the literature should only use the term “drowning.”

EPIDEMIOLOGY

- Drowning is second only to motor vehicle collisions as the most common cause of death from unintentional injury in childhood.
- For every drowning death, several children are hospitalized and many more have submersion events with no significant morbidity.
- Bimodal age distribution with peak in children <5 years and again among adolescents 15–19 years
- Bathtub drowning is common in babies, and child neglect or abuse should be considered.
- Adolescent submersion injuries usually involve substance abuse or risk-taking behavior.
- Highest incidence in males, African Americans, children of low socioeconomic status, and residents of southern states.

RISK FACTORS

- Children <5 years of age, especially toddlers and boys, who cannot swim and have direct access to swimming pools, are at highest risk.
- Use of alcohol and illicit drugs
- Inadequate adult supervision
- Children with seizure disorders
- Children with primary cardiac arrhythmias such as long QT syndrome

GENERAL PREVENTION

- Most drownings are preventable.
- Legislation to require adequate 4-sided isolation fencing and rescue equipment for public and residential pools
- Restriction of sale and consumption of alcohol in boating areas, pools, and beaches
- Life vests for children of all ages near bodies of water
- Parental education regarding adequate supervision during bathing and around swimming pools
- Cardiopulmonary resuscitation (CPR) courses for pool owners, parents and older children
- Swimming lessons for young children may also be helpful

PATHOPHYSIOLOGY

- Drowning begins with a loss of the normal breathing pattern as panic ensues and subsequent apnea, laryngospasm, or aspiration occurs.
- Water aspirated into the trachea and lungs washes out surfactant, and leads to atelectasis, intrapulmonary shunting, poor lung compliance, increased capillary permeability, and hypoxemia ultimately resulting in acute respiratory distress syndrome (ARDS).
- Severe hypoxemia is the final common pathway and results in multisystem organ failure
- Cerebral hypoxia results in cerebral edema and increased intracranial pressure and causes the majority of morbidity and mortality associated with drowning.

COMMONLY ASSOCIATED CONDITIONS

- Cervical spine injuries should be considered in older children who have experienced diving accidents.
- Signs of child abuse or neglect should be sought in young children.
- Adolescents may have associated toxic ingestions.
- Comorbid conditions such as epilepsy, long QT syndrome, and autism with mental retardation may be associated with an increased risk of drowning.

DIAGNOSIS

HISTORY

- Mechanism:
 - History of diving or other high-impact injury
 - Intoxication
 - Seizure disorder
 - Cardiac arrhythmia
 - Child abuse
- Prognostic indicators; the following have been correlated with a poor prognosis:
 - Age <3 years
 - Length of submersion >5 minutes
 - Time to effective CPR >10 minutes
 - Lack of vital signs at the scene
 - Length of resuscitation >25 minutes
 - Warmer water: Submersion in very cold water (<5°C [41°F]) may have a good prognosis despite submersion time >5 minutes

PHYSICAL EXAM

- Vital signs with core temperature
- Drowning victims with unclear histories must be treated as trauma victims
- Neurologic:
 - Pupillary response, cranial nerve findings, Glasgow coma scale (GCS) score, gag reflex
 - Serial neurologic exams should be performed to assess neurologic outcome. Children with a GCS score <5 after resuscitation usually have a poor neurologic outcome.
- Respiratory:
 - Lower airway findings (rales, tachypnea, wheezing, retractions, nasal flaring)
 - Drowning victims may have deteriorating pulmonary involvement despite an initially normal exam. Watch closely for signs of lower airway involvement.

- Circulation:
 - Perfusion, strength of distal pulses, capillary refill, urine output
- GI tract:
 - Abdominal distention from swallowed water or ventilation
- Musculoskeletal:
 - Neck injuries in high impact drownings

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Arterial blood gases:
 - To detect and facilitate treatment of metabolic acidosis in the child with respiratory distress or apnea
- Electrolytes:
 - Not indicated in the seemingly well child; aspiration of huge amounts of water are required to generate electrolyte shifts
- Blood glucose:
 - An elevated level correlates with poor outcome for comatose submersion victims
- Anticonvulsant levels for victims with seizure disorders
- Toxicology screening when ingestion suspected

Imaging

- A chest radiograph is indicated for children with any signs of pulmonary involvement and following intubation
 - Caution: Initial chest radiographs may be normal in the drowning victim.
- Cervical spine films are indicated for victims of high-impact events.
- Neuroimaging for cerebral anoxic injury

Diagnostic Procedures/Other

- ECG to document normal function and evaluate for prolonged QTc if indicated by history
- Serial pulse oximetry to detect early signs of pulmonary involvement

DIFFERENTIAL DIAGNOSIS

Children with smoke inhalation or hydrocarbon ingestion may have similar presentations. However, the history and the physical exam should easily determine the diagnosis.

TREATMENT

MEDICATION (DRUGS)

- Prophylactic antibiotics or steroids are not indicated.
 - In patients that do develop pneumonia, antimicrobial therapy should cover water-borne pathogens such as *Pseudomonas* and *Aeromonas*.
- Seizures should be aggressively controlled with antiepileptics since they increase oxygen consumption.

ADDITIONAL TREATMENT

General Measures

- Attempts to remove water from the lungs such as abdominal thrusts are not helpful and should not delay administration of rescue breaths.
- Patients who are breathing spontaneously should be placed in the right lateral decubitus position to prevent aspiration.

- Even patients who respond well to bystander resuscitation need to be transported to an emergency department for further monitoring.
- Search for pulses carefully since they may be very weak and slow due to hypothermia; some common arrhythmias such as sinus bradycardia and atrial fibrillation need no immediate treatment.
- The hypothermic patient who is a warm-water (>20°C [86°F]) drowning victim does not have a good prognosis or need vigorous rewarming.

IN-PATIENT CONSIDERATIONS

Initial Stabilization

- Airway:
 - Protect the cervical spine if indicated by history.
 - Ensure a patent airway in the comatose victim or patient in cardiac arrest.
- Breathing:
 - Supplemental oxygen for oxygen saturations by pulse oximetry <95%
 - The drowning victim should be intubated if apneic, unable to maintain a PaO₂ >60 mm Hg on high fractions of supplemental oxygen, or for airway protection
 - Treatment of bronchospasm
- Circulation:
 - For the victim with cardiopulmonary arrest, the asystole protocol should be followed
 - Since capillary leak may occur after an ischemic/anoxic episode, isotonic fluids (e.g., normal saline solution or Ringer lactate, 10-mL/kg aliquots) should be given for signs of intravascular volume depletion (tachycardia, poor perfusion) until normalized.
 - ECG monitoring should be provided with appropriate response to dysrhythmias, especially for the hypothermic, cold-water drowning victim.
 - For severely hypothermic patients with a core temperature <28°C (82.4°F), aggressive rewarming is indicated. Electrical defibrillation and pharmacotherapy may not be successful.
- Disability:
 - Maintenance of eucapnia and adequate oxygenation to prevent further hypoxemia
 - Elevate the head of the bed once c-spine is cleared
- Other measures for reducing intracranial pressure (ICP) have not proven effective, likely because the brain injury and swelling is secondary to hypoxic cell injury as opposed to a traumatic lesion.
- Exposure:
 - The drowning victim should be dried and warmed.
 - Most thermometers do not register temperatures below 34°C (93.2°F) so a hypothermia thermometer may be necessary:
 - For core temperatures 32°C (89.6°F) to 35°C (90.5°F), active external rewarming with heating blankets or radiant warmers
 - For <32°C (89.6°F), active internal rewarming added (heated aerosolized oxygen and IV fluids, gastric and bladder lavage with warm saline)
 - For severe hypothermia (<28°C [82.4°F]) and where available, peritoneal dialysis or hemodialysis, mediastinal irrigation, and cardiac bypass
 - The cold-water drowning victim with hypothermia must be rewarmed to a temperature >34°C (89.6°F) before CPR is terminated.
- Remember: The saying, “The patient is not dead until he or she is warm and dead” only applies to drownings in very cold water.

Admission Criteria

- Severely ill children require admission to the intensive care unit
- Children who were apneic, cyanotic, or pulseless at the scene should be admitted to the hospital for close observation even if they appear well.
- A subset of well appearing children may be discharged from the emergency department after being monitored for 6–8 hours

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Long-term follow-up of apparently neurologically intact survivors has shown mild coordination or gross-motor deficiencies.
- Drowning victims may be at increased risk for chronic lung disease, depending on the degree of pulmonary involvement.

Patient Monitoring

- Victims who appear well:
 - Monitor with pulse oximetry for progressive respiratory distress
 - If asymptomatic at 6–8 hours postimmersion, can be discharged
- Victims with significant neurologic injury: Key is to prevent secondary injury:
 - Maintain euvoolemia and euglycemia

PROGNOSIS

- Most children (about 75%) recover with intact neurologic survival.
- Duration and severity of initial hypoxic insult are most important determinants of brain injury and death.
- See prognostic factors above under History section. Additional indicators of poor prognosis include:
 - Coma on arrival
 - Needing CPR in the emergency department
 - Initial arterial blood pH <7.1
- Children with warm-water submersion time >4 minutes, who do not receive CPR at the scene, and who have absent vital signs or a GCS score <5 in the emergency department, usually have a poor prognosis.
- Victims who have prolonged submersions in very cold water (<5°C [41°F]) may have a good prognosis because of core cooling with a concomitant decrease in metabolic rate while the brain is still being perfused.
- A good prognostic indicator is continuing improvement in the neurologic examination over the first several hours.

COMPLICATIONS

- Pneumonia
- Pneumomediastinum or pneumothorax in the patient undergoing ventilation therapy
- Brain injury secondary to hypoxia
- Pulmonary injury with intrapulmonary shunting secondary to damage of the alveoli
- ARDS
- Metabolic acidosis secondary to hypoxemia
- Ischemic injury to organs such as liver, kidneys, and intestines

- Disseminated intravascular coagulation secondary to ischemia
- Electrolyte abnormalities uncommon; may occur if a large volume of freshwater is in the stomach and not removed
- Hypothermia in cold water drowning

CODES

ICD9

994.1 Drowning and nonfatal submersion

ICD10

- T75.1XXA Unsp effects of drowning and nonfatal submersion, init
- T75.1XXD Unsp effects of drowning and nonfatal submersion, subs
- T75.1XXS Unsp effects of drowning and nonfatal submersion, sequela

FAQ

- Q: Should the drowning victim who arrives at the hospital with cardiopulmonary arrest be resuscitated?
- A: Yes, a brief (10–15 minutes) attempt at resuscitation is indicated until circumstances of the drowning and core temperature are known. Warm-water drowning victims who require CPR in the emergency department may rarely (0–25%) have good neurologic recovery, but these patients usually respond quickly (<15 minutes) to therapy.
- Q: Is artificial surfactant useful in drowning victims?
- A: Although useful in neonates, surfactant has not been found to be beneficial for acute lung injury. Further investigation is needed before it can be recommended for clinical use.

DYSFUNCTIONAL UTERINE BLEEDING

Leonard J. Levine
Jonathan R. Pletcher

BASICS

DESCRIPTION

- Bleeding beyond the range of normal menses, with “normal” defined as duration of 2–8 days, occurring every 21–40 days, with blood loss of 20–80 mL/cycle
- May vary in presentation from heavy, long menses followed by long periods of amenorrhea to short, heavy menses occurring every 1–2 weeks
- Most commonly results from anovulatory cycles, which are secondary to an immature hypothalamic–pituitary–ovarian axis

EPIDEMIOLOGY

- Most commonly occurs within the first 2 years of menarche when >50% of cycles are anovulatory
- Later age at menarche results in longer duration of anovulation
- Most females who experience anovulatory cycles do not develop dysfunctional uterine bleeding (DUB).

RISK FACTORS

Genetics

- Familial history of anovulatory cycles is common.
- Patients with disorders, such as blood dyscrasias and polycystic ovary syndrome (PCOS), usually have familial histories including these disorders.

PATHOPHYSIOLOGY

- In most cases presenting within 2 years of menarche, anovulation (failure to ovulate) results in absence of the corpus luteum. Without the secretory effect of progesterone from the corpus luteum, endometrial proliferation continues because of unopposed estrogen.
- The thickened endometrium eventually outgrows support from the basal endometrium, resulting in sloughing of the highest endometrial levels. Alternatively, cyclic estrogen withdrawal may occur, which will lead to sloughing of the endometrium in the absence of progesterone.
- As subsequent levels of endometrium are shed, bleeding increases. Profuse bleeding may result when the basal endometrium is exposed.

DIAGNOSIS

HISTORY

- Abnormal bleeding:
 - Assessing the amount and site of bleeding will help determine the nature and extent of the problem.
 - Important to know when bleeding began and how much bleeding has occurred to know if the patient is at risk for hemodynamic instability
- The pattern of DUB in relation to the menstrual cycle can help guide the diagnostic workup:
 - Normal cyclic intervals with increased bleeding during each cycle may suggest a bleeding disorder.
 - Normal intervals with bleeding between cycles may suggest infection or foreign body.
 - Abnormal intervals with no cycle regularity may suggest anovulatory cycles, endocrinopathy, or hormonal contraception.

- Cramping suggests ovulation and the presence of progesterone; anovulatory cycles are thus less likely.
- Increased time lapse between menarche and onset of DUB lessens the likelihood of anovulatory cycles.
- Easy bruisability, epistaxis, and/or bleeding gums may be suggestive of a bleeding disorder.
- A family history of thyroid disease, bleeding disorder, PCOS, or DUB will help guide the laboratory workup.
- Ask about sexual abuse when conducting the sexual history. Sexual abuse not only may result in bleeding from trauma but also may be a source of sexually transmitted diseases and pregnancy.

PHYSICAL EXAM

- Often normal in patients with DUB
- Assess vital signs, including orthostatic BPs, for signs of cardiac instability resulting from severe blood loss.
- Skin or mucosal pallor, elevated heart rate, or flow murmur may be indicative of anemic state.
- Assess sexual maturity rating (SMR, or Tanner stage). Menarche usually does not occur before SMR 3, so bleeding before this stage suggests a nonmenstrual source of bleeding.
- Look for signs of androgen excess (e.g., hirsutism, acne), which may be reflective of disrupted ovulatory function.
- Bitemporal hemianopsia is suggestive of a pituitary adenoma leading to hyperprolactinemia. Only 1/3 of adolescents with hyperprolactinemia will experience galactorrhea.
- Assess for evidence of thyroid disease, hematologic disorder (e.g., bruising, petechiae), or systemic disease (e.g., poor nutritional status).
- Speculum-assisted pelvic examination may help determine source of bleeding. Bimanual examination is helpful in assessing ovarian or uterine masses, cervical motion or adnexal tenderness, and uterine sizing.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Obtain urine or serum-human chorionic gonadotropin (β -HCG), regardless of sexual history. Urine-HCG testing can reliably detect pregnancy as early as 2 weeks postconception; however, it may be positive for up to 2 weeks following an abortion.
- CBC: Degree of anemia guides treatment plan. Assess for thrombocytopenia. In the setting of acute blood loss, a normal hemoglobin may be falsely reassuring. It is wise to recheck hemoglobin after IV hydration as decreases may be dramatic.
- For *Chlamydia trachomatis* and *Neisseria gonorrhoeae*, obtain cervical cultures or use nucleic acid amplification tests (e.g., PCR or LCR) on urine, vaginal, or cervical swabs. Be careful to check with laboratory or NAAT manufacturers’ information as to reliability with blood in sample and based on collection site.

- Wet mount or vaginal swab may be unreliable but should be attempted for presence of WBCs and trichomonas. In some labs *Trichomonas vaginalis* antigen tests may be available.
- Consider prolactin level and thyroid function tests: Hyperprolactinemia may have several causes, including pituitary microadenoma, and result in amenorrhea or DUB.
- Prothrombin and partial thromboplastin time, von Willebrand factor: To assess for hematologic causes of bleeding
- Androgen levels, including testosterone (total and free); dehydroepiandrosterone sulfate (DHEAS); androstenedione: Abnormal levels are supportive of PCOS or other hyperandrogenic state.

Imaging

- Pelvic ultrasound:
 - Indicated when pregnancy is suspected (ectopic or intrauterine)
 - Consider when a pelvic mass is felt, uterine anomaly is being considered, or bimanual examination cannot be completed.
- MRI of the pelvis: Indicated for patients with a suspected pelvic mass when ultrasonography does not clearly define the anatomy

DIFFERENTIAL DIAGNOSIS

- ~80% of abnormal uterine bleeding in adolescents can be attributed to anovulatory cycles. However, it is important to rule out other causes of irregular or heavy vaginal bleeding.
- Pregnancy: Should be considered and ruled out in every patient, regardless of patient’s reported sexual history
 - Ectopic pregnancy
 - Threatened abortion, incomplete abortion
 - Placenta previa
 - Hydatidiform mole
- Infection:
 - Vaginitis (e.g., trichomoniasis)
 - Cervicitis or endometritis (e.g., gonorrhea or chlamydia)
 - Pelvic inflammatory disease
- Hematologic conditions:
 - Bleeding disorders often present as heavy periods from time of menarche.
 - Thrombocytopenia (e.g., immune thrombocytopenic purpura [ITP], leukemia)
 - Platelet dysfunction
 - Coagulation defect (e.g., von Willebrand disease)
- Endocrinologic disorders:
 - Thyroid disease, especially hypothyroidism
 - Hyperprolactinemia
 - PCOS
 - Adrenal disorders
- Trauma: Laceration to vagina or cervix
- Foreign body: Usually associated with strong, foul odor

- Medications:
 - Direct effect on hemostasis (e.g., Coumadin, chemotherapeutic agents)
 - Hormonal effects (e.g., oral contraceptives, Depo-Provera)
- Systemic disease:
 - Disruption of hypothalamic–pituitary–ovarian axis
 - Other examples include systemic lupus erythematosus and chronic renal failure.
- Primary gynecologic disorders:
 - Endometriosis
 - Uterine polyps, submucosal myomas
 - Hemangioma, arteriovenous malformation

ALERT

Pitfalls:

- Neglecting to perform pregnancy testing in an adolescent who denies sexual activity
- Neglecting to reassess hemoglobin concentration after volume expansion
- Neglecting to consider a retained foreign body (e.g., tampon)
- Neglecting to provide both estrogen and progesterone in a timely fashion
- If there is a recurrent course of DUB, consider PCOS, thyroid disease, or other endocrinopathy.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- For mild DUB (inconvenient, unpredictable bleeding, and the patient has a normal hemoglobin in setting of hemodynamic stability):
 - Reassurance until ovulatory cycles resume. Encourage maintenance of a menstrual calendar, with follow-up in 3–6 months.
 - Iron supplementation
 - If inconvenience and anxiety are unresponsive to reassurance, hormonal therapy with a daily combined oral contraceptive pill (OCP), 1 tablet daily, should be considered to regulate menstrual cycle. If estrogen is contraindicated, may use progesterone-only pill, medroxyprogesterone acetate 10 mg/d PO for 10–14 days every month.
- For moderate DUB (irregular, prolonged, heavy bleeding with a hemoglobin > 10 g/dL):
 - Hormonal therapy, as described previously. May start OCP containing 35 µg of ethinyl estradiol twice a day until bleeding stops, then taper to once a day.
 - Menstrual calendar with follow-up every 1–3 months
- For severe DUB (i.e., heavy, prolonged bleeding with a hemoglobin < 10 g/dL), treatment depends on the presence of active bleeding:
 - If no active bleeding, hemodynamically stable patients can be started on daily OCPs and iron supplementation, with follow-up in 1–2 months.
 - In the presence of active bleeding: Hormonal therapy, using combined OCP containing higher dose of estrogen (50 mg ethinyl estradiol)—1 pill q.i.d. until bleeding stops, followed by pill taper (q.i.d. for 4 days, t.i.d. for 3 days, b.i.d. for 2 weeks, then 1 pill daily); switch to lower-dose pill

(30–35 mg) after taper complete—antiemetic therapy necessary for high doses of estrogen. Hospitalization of patient during treatment if severe anemia (hemoglobin < 7 g/dL), if hemodynamically unstable, or compliance concerns. Blood transfusion as necessary. If patient is unstable and unable to tolerate oral pill regimen, can give IV conjugated estrogen q4h for 24 hours to stop bleeding. Add OCP with progesterone as soon as patient is able to tolerate oral regimen to prevent excessive withdrawal bleeding.

- Iron supplementation
- Dilation and curettage rarely necessary, although may be needed if hormonal therapy fails

• Possible side effects:

- Estrogen, given in high doses, will cause nausea and/or vomiting. An appropriate antiemetic should be used for prophylaxis against these symptoms.
- High-dose estrogen may have vascular side effects and should be used with caution in patients particularly at risk for vascular events (e.g., patients with a history of lupus, stroke, or thrombotic phenomena; and those who smoke cigarettes). In these cases, consult a gynecologist or adolescent medicine specialist for an alternative progesterone-only therapy.

IN-PATIENT CONSIDERATIONS

Initial Stabilization

If DUB is attributed to anovulatory cycles, or if a complete workup fails to yield a diagnosis, treatment is guided by the severity of DUB and the presence of active bleeding.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

When to expect improvement:

- Bleeding usually tapers after the first few doses of hormone therapy.
- After 6–12 months, if patient does not wish to remain on OCPs, a trial off medication might reveal normal ovulatory cycles.

PROGNOSIS

DUB persists for 2 years in 60% of patients, 4 years in 50%, and up to 10 years in 30%.

COMPLICATIONS

Mild-to-severe anemia resulting from blood loss

CODES

ICD9

- 626.2 Excessive or frequent menstruation
- 626.4 Irregular menstrual cycle
- 626.6 Metrorrhagia

ICD10

- N92.0 Excessive and frequent menstruation with regular cycle
- N93.8 Other specified abnormal uterine and vaginal bleeding
- N93.9 Abnormal uterine and vaginal bleeding, unspecified

FAQ

- Q: If most girls have anovulatory cycles, why do only some present with DUB?
- A: Most girls do have an irregular menstrual cycle during the first 2 years after menarche. However, in most of those girls, the negative-feedback system of estrogen will lead to cyclic endometrial shedding in an anovulatory pattern.
- Q: If DUB from anovulatory cycles is caused by lack of progesterone, why does the initial treatment of severe DUB with active bleeding involve large doses of estrogen?
- A: Estrogen has procoagulation effects that promote hemostasis (e.g., effects on platelet aggregation and levels of fibrinogen and clotting factors). In addition, severe DUB may lead to an exposed endometrial base that bleeds profusely; for progesterone to exhibit its secretory effects, the endometrium in that area must be restored by estrogen.
- Q: When hormonal therapy fails, and the basal endometrium continues to bleed, how does a dilation and curettage act as the final treatment?
- A: The curettage removes any remaining bleeding vessels and stimulates local prostaglandins to create a uterine contracture that inhibits bleeding. This is rarely needed in adolescent patients, as they usually respond to hormonal therapy.

DYSMENORRHEA

Esther K. Chung

Marney Gundlach (5th edition)

BASICS

DESCRIPTION

Painful menses, usually presenting as cramping pain in the lower abdomen or back:

- Primary dysmenorrhea—in absence of any hormonal or pelvic disease
- Secondary dysmenorrhea—due to hormonal or pelvic disease, most commonly endometriosis

EPIDEMIOLOGY

- Primary dysmenorrhea
 - Typically begins in adolescence; prevalence rates decrease progressively after age 24 years.
 - Less common in the first 2–3 years following menarche; more prevalent in mid- to late-adolescence when cycles are ovulatory.
- Secondary dysmenorrhea is less common in adolescence, and more common in adults.

Prevalence

- Affects up to 90% of adolescents
- 15% of adolescents report that the pain is “severe”

RISK FACTORS

- Young age (<20 years)
- Family history of dysmenorrhea
- Early menarche
- Menorrhagia (heavy menstrual flow)
- Nulliparity
- Smoking
- Long menstrual periods
- Alcohol use
- Depression
- Anxiety

Genetics

- Dysmenorrhea is more common in patients with a positive family history.
- Certain polymorphisms are associated with higher rates of dysmenorrhea.

PATHOPHYSIOLOGY

- Ovulation leads to increased progesterone release in the second half of the menstrual cycle. Progesterone levels fall prior to menstruation, increasing prostaglandin (PG) synthesis.
 - After menarche, anovulatory cycles are common; dysmenorrhea is typically absent in the first few cycles.
- Endometrial PGs cause uterine contractions, increased uterine muscle tone, and blood vessel constriction, resulting in hypoxia, ischemia, and pain.
 - $PGF_{2\alpha}$ is thought to stimulate the myometrium and cause vasoconstriction. Severity of dysmenorrhea is directly proportional to endometrial $PGF_{2\alpha}$ concentrations.
 - PGs can stimulate the GI tract, causing nausea, diarrhea, and vomiting.
- Leukotrienes are thought to increase uterine pain fiber sensitivity, vasoconstriction, and cause uterine hypercontractility. Leukotrienes are elevated among women with dysmenorrhea.
- Vasopressin, also elevated among women with dysmenorrhea, may play a secondary role by potentiating uterine contractions and ischemic pain.

- Women may have increased uterine basal tone, elevated pressures during contractions, increased frequency of contractions, and uncoordinated contractions. Any combination of these may lead to poor reperfusion and oxygenation, leading to pain.

DIAGNOSIS

- Primary dysmenorrhea: Painful, often spasmodic cramps in the lower abdomen or back, of varying severity, starting hours to a few days prior to menses lasting up to 2–3 days after the start of menses. Pain is strongest in intensity initially, waning by the end of menses. Referred pain to lower back or thighs may occur.
- Secondary dysmenorrhea: May present with similar pain and symptoms but starts 1–2 weeks earlier in the cycle, and often lasts through the entire menses.

HISTORY

- Given the high prevalence, screen all adolescent females for dysmenorrhea; <15% will seek medical attention.
- Pain: Ask about quality and intensity of pain (use pain scales); constant or intermittent occurrence; location; onset, timing, and duration; aggravating or alleviating factors; extent to which the pain limits activities (social, school, sports, work).
- Menstrual:
 - Age at menarche: More common in girls with earlier menarche (more time to progress to ovulatory cycles)
 - Menstrual flow: More common in women with heavy menstrual flow (menorrhagia)
 - Last menstrual period (and previous one, if known)
 - Length of menstrual flow and total cycles
 - Cycle regularity
 - Amount of menstrual flow
- Sexual history: Parity, current sexual activity, contraception, and history of STDs or pelvic inflammatory disease (PID). Adhesions may cause painful menses.
- Associated symptoms: Missing school; nausea, vomiting, diarrhea, headache, irritability, fatigue, breast tenderness, dizziness, weakness, or bloating
- History of sexual, physical, or emotional abuse
- Family history of GYN diseases, including dysmenorrhea, GYN or breast cancer, and complications with oral contraceptive pills (OCPs) including deep vein thrombosis (DVT), stroke, or myocardial infarction
- Medications (including OCPs) including name, dose, when taken in relation to pain, if scheduled or taken as needed, perceived effectiveness
- Diet: Higher intake of polyunsaturated fatty acids correlates with increased menstrual pain.

ALERT

- Pain that started at menarche is not likely primary dysmenorrhea, as most girls are still having anovulatory cycles.
- Progressively worsening pain with each subsequent cycle may indicate endometriosis.
- Cigarette smoking may increase the duration of dysmenorrhea.

PHYSICAL EXAM

- Abdominal exam:
 - Lower abdomen/suprapubic pain
 - Periumbilical pain suggests a GI, not a GYN, source.
 - Enlarged uterus can be palpated in vaginal outlet obstruction.
- Inspection of external genitalia
- Imperforate hymen/hematocolpos
- Pelvic exam:
 - Typically normal in primary dysmenorrhea; may have mild diffuse uterine tenderness
 - Consider deferring in younger girls with mild, classic symptoms and normal external genitalia who have never been sexually active
 - Perform in women with history suggesting secondary dysmenorrhea, a history of sexual intercourse, and those who need a Pap smear, or who have failed NSAIDs

DIAGNOSTIC TESTS & INTERPRETATION

- Lab studies are generally not warranted.
- Consider testing for STIs, pregnancy, PID, or inflammatory bowel disease (IBD) as indicated by history and physical exam.

Imaging

- Consider ultrasound (US) for patients who fail a trial of NSAIDs. US can rule out genital tract abnormalities, ovarian pathologies, or obstructive lesions.
- Transvaginal US provides better images of pelvic anatomy:
 - Discuss the expectations, especially with teens who have never been sexually active or ever used tampons.

Diagnostic Procedures/Other

Consider laparoscopy to establish the diagnosis for patients with adnexal or cul-de-sac pelvic tenderness, first-degree relative with endometriosis, persistent pain despite treatment with NSAIDs and OCPs, significant disability due to pain, or plans for another surgical procedure

DIFFERENTIAL DIAGNOSIS

Primary dysmenorrhea is a diagnosis of exclusion; secondary dysmenorrhea should be ruled out based on history and physical exam, and imaging if warranted.

- Genital: Adenomyosis, congenital vaginal or uterine anomalies, ectopic pregnancy, endometriosis, Mittelschmerz, ovarian cysts or tumors, pelvic adhesions, PID, uterine adhesions, fibroids, or polyps
- GI: Constipation, diverticulitis, IBD, irritable bowel syndrome (IBS)
- Urologic: Interstitial cystitis, kidney stones, urinary tract infection
- Neurologic: Fibromyalgia, herniated disk, lower back pain

TREATMENT

MEDICATION (DRUGS)

First Line

- NSAIDs: PG synthetase (cyclo-oxygenase) inhibitors. In randomized controlled trials (RCTs), NSAIDs are superior to placebo at relieving pain and reducing activity restrictions and school/work absenteeism. Ibuprofen, naproxen sodium, and mefenamic acid are considered to be effective.
- If a patient fails to respond to the first choice at a therapeutic level, try a different NSAID.
- 90% of patients have relief with proper dosing.
- Most effective when used on a regular and not PRN basis for the first 2–3 days of menses
- Start 1 day prior or at the onset of menses
- Choices:
 - Ibuprofen: 400–600 mg PO q6–8h
 - Naproxen: 500 mg PO then 250 mg PO q6–8h
 - Mefenamic acid: 500 mg PO then 250 mg PO t.i.d.; approved for children ≥ 14 years
- Side effects:
 - Black-box warnings: Increased risk of adverse cardiovascular events, including myocardial infarction, stroke, and new onset or worsening of pre-existing hypertension; increased risk of GI irritation, ulceration, bleeding, and perforation
 - Other side effects include drowsiness, dizziness, headache, mouth dryness, nausea, and indigestion.

Second Line

- OCPs:
 - OCPs suppress ovulation and decrease uterine PG secretion following reduction in progesterone levels.
 - OCPs with medium-dose estrogen (~35 mcg) and first- or second-generation progestogens (levonorgestrel, norethisterone, norgestrel) are more effective than placebo at pain relief and reducing school/work absenteeism. There are few studies on lower dose estrogen and newer progestin formulations.
 - Patients may need 3 months to see improvement. Patients with improvement are more likely to be compliant with OCPs.
 - Good choice for patients who fail NSAIDs as monotherapy, desire pregnancy prevention, or who have acne
 - Extended cycling OCPs: Can prescribe Seasonale (91-day cycle) or use multiple OCP packs to achieve same effect
 - Side effects:
 - Nausea, vomiting, breast tenderness, weight gain, break-through menstrual bleeding, headaches from the estrogen
 - Acne, hirsutism, and depression from the progestogen
 - Rare: DVT, stroke, myocardial infarction
- Secondary dysmenorrhea is treated by addressing the underlying cause.

ISSUES FOR REFERRAL

Consider referral to adolescent gynecologist for consideration of laparoscopy or management of endometriosis, including gonadotropin-releasing hormone (GnRH) agonist treatment

COMPLEMENTARY & ALTERNATIVE THERAPIES

- Stronger evidence exists for:
 - Vitamin B1:
 - Vitamin B1 deficiency can cause muscle cramps, fatigue, and decreased pain tolerance.
 - 100 mg/d PO shown in a single large RCT to be effective at reducing pain
 - Magnesium:
 - Thought to inhibit synthesis of $\text{PGF}_{2\alpha}$, promote vasodilation and muscle relaxation
 - May reduce pain and need for additional medication
 - No consistent dose used in studies; consider 500 mg/d PO
 - Transcutaneous electrical nerve stimulation (TENS): Electrodes on the skin stimulate nerves at different current frequencies and intensities. Thought to alter pain perception, rather than to directly affect uterine contractions.
 - High-frequency TENS (low-intensity pulses at a frequency of 50–120 Hz): Effective at pain relief compared to placebo (but not at reducing need for analgesics); not superior to ibuprofen.
 - Low-frequency TENS is no more effective than placebo.
 - Side effects: Headaches, muscle twitches, and localized redness, burning, or pain
- According to a recent Cochrane review, acupuncture may reduce pain in primary dysmenorrhea.
- Exercise may help to reduce symptoms of dysmenorrhea but more research is needed.
- Weaker evidence exists for Vitamin B6, fish oil, and vitamin E. No evidence exists for spinal manipulation, biofeedback, black cohosh, fennel oil, or evening primrose oil.

SURGERY/OTHER PROCEDURES

Laparoscopy may be used as treatment for primary dysmenorrhea:

- Laparoscopic uterine nerve ablation (LUNA) is effective for long-term (≥ 12 month) pain relief in primary dysmenorrhea.
- Laparoscopic presacral neurectomy is more effective than LUNA for pain relief at ≥ 6 months follow-up but has significant side effects (especially constipation); should only be performed with pelvic laparoscopic surgeons with special training.

ALERT

There are a number of OTC medicines that are marketed for treating cramps in women. Only those formulations that contain NSAIDs are effective in treating dysmenorrhea. Encourage patients to read labels looking for medications containing ibuprofen or naproxen.

ONGOING CARE

PATIENT EDUCATION

- Stress to patients the importance of keeping a pain diary indicating days of menses, days of pain, pain ratings (0–10 scale), days of limited activities (school or work) due to pain, and associated symptoms.
- Websites for Patient Education Materials:
 - ACOG. Dysmenorrhea. <http://www.acog.org/~media/For%20Patients/faq046.pdf?dmc=1&ts=20120215T1659240616>
 - ACOG. Chronic pelvic pain. <http://www.acog.org/~media/For%20Patients/faq099.pdf?dmc=1&ts=20120215T1700537765>

PROGNOSIS

Improvement in symptoms may occur after child birth.

COMPLICATIONS

Missed school or work; decreased academic performance, sports participation, and peer socialization

CODES

ICD9

625.3 Dysmenorrhea

ICD10

- N94.4 Primary dysmenorrhea
- N94.5 Secondary dysmenorrhea
- N94.6 Dysmenorrhea, unspecified

FAQ

- Q: What percentage of patients report dysmenorrhea?
- A: Although dysmenorrhea affects up to 90% of adolescents, <15% will seek medical care. It is important to screen all adolescent women for dysmenorrhea. Barriers for seeking physician advice include fears of pelvic exam, lack of knowledge of effective treatments, and confidence in home remedies.

DYSPNEA

Charles Schwartz

BASICS

DEFINITION

Shortness of breath. A subjective feeling of having difficulty breathing.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- **Congenital**
 - Subglottic stenosis
 - Vocal cord paralysis
 - Macroglossia
 - Pierre Robin sequence
 - Laryngeal atresia
 - Pulmonary sequestration
 - Pulmonary hypoplasia
- **Infectious**
 - Lower airway: Bronchiolitis, pertussis, pneumonia, tuberculosis
 - Upper airway: Croup, epiglottitis, tracheitis, peritonsillar abscess
- **Toxic, environmental, drugs: Aspiration**
 - Fluid
 - Foreign body
 - Carbon monoxide poisoning
 - Methemoglobinemia
 - Smoke inhalation
- **Tumors/cysts**
 - Head/neck: Dermoid cysts, branchial cleft cysts, lingual thyroid, hemangioma, teratoma, papilloma, brainstem tumor
 - Thoracic: Teratoma, cystic hygroma, bronchogenic cyst, pericardial cyst, neurogenic tumor, lymphoma, leukemia
 - Abdominal mass: Hepatic mass, hepatoblastoma, neuroblastoma
- **Allergy: Anaphylaxis**
- **Pulmonary**
 - Asthma
 - Atelectasis
 - Pneumothorax
 - Pleural effusion
 - Hemorrhage
 - Embolism
- **Cardiac**
 - Pulmonary edema

- **Renal**
 - Renal failure causing fluid overload
 - Metabolic acidosis
- **Hematologic**
 - Anemia
 - Sickle cell crisis/acute chest syndrome
- **Muscle weakness**
 - Duchenne muscular dystrophy
 - Spinal muscle atrophy
- **Miscellaneous**
 - High altitude
 - Exercise
 - Psychogenic hyperventilation
 - Anxiety/panic disorders

ALERT

In a child who presents with dyspnea, anxiety or panic disorder should be considered only after the more serious causes have been ruled out.

APPROACH TO THE PATIENT

General goal is to identify the organ system responsible for the dyspnea and to determine whether the process is acute or chronic:

- **Phase 1:** Determine if the cause is respiratory or cardiac in nature. If it is 1 of these 2, is the patient clinically stable and can he or she protect his or her airway? It is important to identify those who will need intensive/emergency care and those who can be worked up in the office.
- **Phase 2:** Inquire about the duration of symptoms and the circumstances around the onset of the dyspnea. History and physical exam should focus on respiratory and cardiology. If these 2 have been ruled out, other causes must be evaluated.
- **Phase 3:** Inquire about other medical problems of the patient.

HISTORY

- **Question:** Onset of dyspnea and what the patient was doing at the time of onset (if acute)?
- **Significance:**
 - In a small child, acute onset may be related to aspiration of a foreign body or liquid.
 - If the patient was unsupervised, foreign body is a high probability.
 - If the dyspnea occurred over days, other respiratory, cardiac, or renal causes should be suspected.

- **Question:** Any fever, cough, chest pain, or runny nose?
- **Significance:** Suggests an infectious cause. Chest pain could be related to a pneumothorax, which may occur spontaneously in some individuals.
- **Question:** Anyone at home who is sick or has respiratory problems/illness?
- **Significance:** Leads toward infection; however, in some cases of congenital heart disease, a respiratory virus such as respiratory syncytial virus can make an otherwise stable patient into a critically ill child.
- **Question:** Children who have a history of wheezing or asthma?
- **Significance:** Likely to re-exacerbate their lung disease
- **Question:** Children who have been hospitalized for respiratory problems in the past?
- **Significance:** Likely to have subsequent difficulty with other respiratory problems
- **Question:** Has the patient ever been diagnosed with a murmur or has a history of cardiac problems?
- **Significance:** In the absence of an infectious type or wheezing type of history, it may help the examiner focus on the cardiac exam.

PHYSICAL EXAM

Lungs

- **Finding:** Crackles or rhonchi on auscultation?
- **Significance:** Lower lung disease such as pneumonia or bronchiolitis. Fluid overload may cause bilateral crackles.
- **Finding:** Wheezing on auscultation?
- **Significance:** Usually heard on expiration; suggests an obstructive lung disease such as asthma or reactive airways disease, or anaphylaxis.
- **Finding:** Distant or absent breath sounds?
- **Significance:** Foreign body aspiration blocking air movement. Pneumothorax should also be suspected.
- **Finding:** Barking cough?
- **Significance:** Croup is usually caused by parainfluenza virus.
- **Finding:** Symptoms worse in supine position?
- **Significance:** May be secondary to pulmonary edema or compression by a mediastinal mass.
- **Finding:** Egophony on auscultation?
- **Significance:** Suspect pleural effusion

Heart

- **Finding:** Loud murmur or gallop on auscultation?
- **Significance:** Cardiac disease in which pulmonary edema may be cause of the dyspnea
- **Finding:** Cyanosis?
- **Significance:** Poor oxygen perfusion
- **Finding:** Low BP and poor skin perfusion?
- **Significance:** The patient may be in shock. Quick identification of the type of shock is needed to correct the underlying problem.
- **Finding:** Clubbing of the digits?
- **Significance:** Suggests chronic disease such as cystic fibrosis or cardiac disease
- **Finding:** Drooling with mouth open in an ill-appearing child?
- **Significance:** Suggests epiglottitis and need for careful evaluation (see "Epiglottitis")
- **Finding:** Abdominal mass palpated?
- **Significance:** May cause compression of lungs
- **Finding:** Ascites or edema?
- **Significance:** Fluid overload from either renal or cardiac cause.

DIAGNOSTIC TESTS & INTERPRETATION

- **Test:** Arterial blood gases
- **Significance:**
 - More detailed assessment of oxygenation and acidosis
 - Delineates metabolic vs. respiratory acidosis
 - May show if compensation has occurred
- **Test:** CBC with differential
- **Significance:**
 - Elevated WBC count with a left shift differential may be a sign of infection.
 - If the patient has pallor, evaluate the hemoglobin to see if the patient is anemic.
 - May be helpful in patients in whom leukemia or other oncologic diseases are suspected
- **Test:** Mantoux test with purified protein derivative
- **Significance:** Include with anergy panel for patients with family history of tuberculosis or who are immigrants from countries where tuberculosis is prevalent
- **Test:** Pulse oximetry
- **Significance:** Rapid assessment of oxygen perfusion

Imaging**Chest radiograph**

- Look for appearance of the lung fields for the different types of pneumonia
- Evaluate heart size and pulmonary vascularity for fluid overload
- Hyperinflation suggests an obstructive pulmonary disease such as asthma. A hyperinflated (usually right lobe), darkened lobe is suspicious for foreign body.
- A shift in the heart and presence of a lung edge are common in pneumothorax or effusion.
- Fluid in the costophrenic angle suggests an effusion.

**TREATMENT****ADDITIONAL TREATMENT****General Measures**

If hyperventilation is suspected, having the patient breathe into a brown paper bag can be useful in breaking the cycle of hypocarbia.

ISSUES FOR REFERRAL

- Unstable vital signs, inability to oxygenate, and need for critical care services
- Suspected foreign body aspiration; needs a surgical consultation for bronchoscopy
- If asthma is suspected, use criteria in the chapter on asthma.
- Patients with epiglottitis need an otolaryngologist to evaluate the patient under general anesthesia (see "Epiglottitis").
- Suspected oncologic process: Referral to a tertiary care center with a critical care unit staffed by a pediatric oncologist (see "Leukemia")

SURGERY/OTHER PROCEDURES

Patients with pneumothorax may need surgical aspiration or chest tube placement.

Initial Stabilization

Anaphylaxis is a medical emergency and mandates immediate action. Epinephrine, Benadryl, and possibly steroids are the drugs of choice for treatment.

**CODES****ICD9**

- 478.5 Other diseases of vocal cords
- 748.3 Other anomalies of larynx, trachea, and bronchus
- 786.09 Other respiratory abnormalities

ICD10

- J38.00 Paralysis of vocal cords and larynx, unspecified
- Q31.1 Congenital subglottic stenosis
- R06.00 Dyspnea, unspecified

FAQ

- Q: In most cases, is dyspnea pulmonary in nature?
- A: Yes, it is in most cases. However, if infectious, foreign body, and asthma causes are ruled out, nonrespiratory causes must be investigated.

DYSURIA

Rebecca Ruebner
Lawrence Copelovitch

BASICS

DEFINITION

Painful urination

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- **Congenital/anatomic**
 - Meatal stenosis
 - Urethral stricture
 - Posterior urethral diverticula
 - Urethral stones
 - Vesicovaginal fistula
- **Infectious**
 - Viral infection
 - Gonorrhea
 - Chlamydia
 - Herpes simplex
 - Tuberculosis
 - Cystitis
 - Candidiasis
 - Urethritis
 - Pinworms
 - Prostatitis
- **Toxic, environmental, drugs**
 - Bubble bath urethritis
 - Spermicides, douches
 - Cytosan
- **Trauma**
 - Diaper dermatitis
 - Foreign body
 - Bicycle injury
 - Masturbation
 - Sexual abuse
 - Irritation, e.g., from sand, tight pants
- **Tumor**
 - Sarcoma botryoides
- **Genetic/metabolic**
 - Cystinuria

- **Allergic/inflammatory**
 - Food allergy
 - Stevens–Johnson syndrome
 - Contact dermatitis, e.g., poison ivy
- **Functional**
 - Attention mechanism
- **Miscellaneous**
 - Appendicitis

APPROACH TO THE PATIENT

General goal: Determine the cause and begin treatment.

- **Phase 1:** Rule out common causes such as trauma, infection, chemical irritant, constipation, and masturbation.
- **Phase 2:** Continue investigation—look for congenital or acquired problems that cause infection, strictures, or calculi.
- **Phase 3:** Begin treatment.

Hints for Screening Problems

- Ask about medications and food allergies.
- Ask about special situations, e.g., sand in bathing suit causing irritation.

HISTORY

- **Question:** Do the symptoms occur any special time of day?
- **Significance:** May indicate an attention mechanism if occurs before school
- **Question:** What kinds of medication do you take?
- **Significance:** Some medications, e.g., Cytosan, may cause irritation of the urethra.
- **Question:** Have there been any new foods or known food allergens?
- **Significance:** Milk and citrus fruits may cause dysuria in certain patients. Best to determine whether symptoms regress on elimination of possible offending food.

- **Question:** Do you use bubble bath?
- **Significance:** Bubble bath may deplete the protective lipids in the urethra.
- **Question:** Any signs of bleeding?
- **Significance:** May indicate trauma, infection, or congenital anomalies. Calcium excretion may cause dysuria as well as hematuria.
- Use of spermicides or douches
- Family history of kidney stones
- **Question:** Fever?
- **Significance:** Fever is a common sign of urinary tract infection (UTI).
- **Question:** Frequency?
- **Significance:** Both frequency and dysuria are common findings in UTIs.
- **Question:** Past history of urologic operations?
- **Significance:** Antireflux surgery may have a side effect of dysuria.
- **Question:** What have you taken for discomfort?
- **Significance:** Although cranberry juice is used for many urinary problems, the volume needed is usually more than what can be easily ingested.
- **Question:** Quality and strength of the urinary stream?
- **Significance:** Patients with posterior urethral valves have small, frequent voidings, with low pressure because of the obstruction in the posterior urethra.
- **Question:** Sexual activity?
- **Significance:** Urethritis from gonorrhea or chlamydia

PHYSICAL EXAM

- **Finding:** Any signs of redness or ecchymoses?
- **Significance:** May indicate trauma from masturbation or abuse
- **Finding:** Any bleeding?
- **Significance:** Seen in trauma, tumors, and infection

- **Finding:** Any change in behavior?
- **Significance:** May be an attention-seeking device
- **Finding:** Abnormal swelling?
- **Significance:** May occur in trauma or rare tumors
- **Finding:** Abnormal urethra?
- **Significance:** Prolapsed urethra or diverticula
- **Finding:** Grapelike structures in vagina?
- **Significance:** Sarcoma botryoides
- **Finding:** Abdominal pain?
- **Significance:** Intra-abdominal abscess or low-lying inflamed appendix may cause dysuria.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- **Test:** Urinalysis
- **Significance:** In most UTIs, there are WBCs in the urine.
- **Test:** Urine culture
- **Significance:** Check for infection
- **Test:** Metabolic screens
- **Significance:** If sediment shows crystals or if familial history of metabolic disease
- **Test:** Urinary screen for gonorrhea and chlamydia
- **Significance:** DNA amplification by polymerase or ligase chain reaction on freshly voided urine has 95% sensitivity and 100% specificity.

Imaging

Ultrasound: Not routinely requested unless a congenital anomaly is suspected

TREATMENT

ADDITIONAL TREATMENT

General Measures

- See treatment of UTI, vaginitis, urethritis
- Phenazopyridine (Pyridium) may be used for symptomatic relief while documenting cause of dysuria.
- Warm water sitz baths may be helpful for symptomatic treatment.

ISSUES FOR REFERRAL

- Evidence of congenital anomaly
- Increasing severity of symptoms
- Failure to respond to symptomatic or specific treatment

ADDITIONAL READING

- Claudius H. Dysuria in adolescents. *West J Med.* 2000;172:201–205.

CODES

ICD9

- 598.9 Urethral stricture, unspecified
- 753.6 Atresia and stenosis of urethra and bladder neck
- 788.1 Dysuria

ICD10

- N35.9 Urethral stricture, unspecified
- Q64.39 Other atresia and stenosis of urethra and bladder neck
- R30.0 Dysuria

FAQ

- Q: How does bubble bath cause dysuria?
- A: The bubble bath depletes lipids that protect the urethra, causing the tissue to swell and become inflamed.
- Q: Can allergies cause dysuria?
- A: It is difficult to directly prove allergies as a cause of dysuria. However, in some cases, elimination of certain foods such as spices, citrus fruits, or known skin allergens has improved symptoms.
- Q: How do children get infected with gonorrhoea?
- A: This is a red flag for sexual abuse, which must be investigated.
- Q: Which viruses cause dysuria?
- A: Adenovirus has been identified.

CLINICAL PEARLS

- Sometimes difficult to differentiate dysuria from frequency, which may cause an uncomfortable feeling or pressure that is described by the child as pain.
- Discharge with dysuria suggests gonococcal or chlamydial infection.
- Low-lying inflamed appendix may cause bladder irritation and dysuria.
- Urethral prolapse may present as hematuria or frequency.

EARACHE

Vanessa S. Carlo

BASICS

DEFINITION

- Otolgia, classified as primary or secondary, means ear pain or an earache.
- Primary otalgia is ear pain that originates inside the ear, either from the external auditory canal or from the middle ear structures.
- Secondary (or referred) otalgia is ear pain that originates from outside of the ear. Any anatomic area that shares innervation with the ear can be the primary source of perceived ear pain.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Primary otalgia:

- **Infectious**
 - Acute otitis media (AOM)—most common cause of otalgia in children
 - Otitis externa—inflammation of external auditory canal, usually associated with swimming and/or localized trauma; second most common cause of otalgia in children
 - Cellulitis of the auricle—usually caused by *Streptococcus pyogenes*; typically involves the earlobe
 - Perichondritis—inflammation of the auricle without earlobe involvement
 - Furunculosis—infection of the cartilaginous portion of the external auditory canal. Most commonly caused by *Staphylococcus aureus*. Pain is usually made worse by chewing.
 - Mastoiditis—now a rare complication of AOM, characterized by the auricle being pushed out and forward, away from the head
 - Myringitis (bullous myringitis)—inflammation of the tympanic membrane, usually with painful blisters on the eardrum
 - Varicella and herpes zoster infection within the ear
 - Herpes simplex virus infection within the ear
- **Trauma**
 - Blunt trauma
 - Laceration or abrasion—if inside the ear canal, usually due to cleaning with cotton swabs
 - Thermal injury—frostbite of the ear or burn from a heat source
 - Barotrauma—associated with airplanes and scuba diving
 - Traumatic perforation of the tympanic membrane—frequently presents with tinnitus
- **Tumors**—rare; usually associated with weight loss, voice changes, dysphagia, and persistent cervical lymphadenopathy
- **Allergic/inflammatory**
 - Otitis media with effusion
 - Eczema
 - Psoriasis
 - Allergic reaction to topical antibiotics and cerumenolytic agents

- **Functional**
 - Eustachian tube dysfunction—symptoms are due to pressure differences between the middle ear and the Eustachian tube
- **Miscellaneous**
 - Foreign body—can lead to pain, fullness, and minor hearing loss
 - Impacted cerumen—may cause pain if the cerumen presses against the tympanic membrane

Note: Serous otitis media or otitis media with effusion (OME) is common in pediatrics but is usually painless. Children usually complain of fullness or hearing loss.

Secondary otalgia:

- **Infectious**
 - Dental infections—cavities, abscesses, gingivitis
 - Pharyngitis
 - Parotitis
 - Tonsillitis
 - Peritonsillar abscess
 - Retropharyngeal abscess
 - Sinusitis
 - Cervical lymphadenitis
 - Neck abscess
 - Stomatitis
 - Sialadenitis
 - Ramsay Hunt syndrome—viral neuritis of the facial nerve secondary to herpes zoster infection
- **Trauma**
 - Dental trauma
 - Postsurgical—tonsillectomy, adenoidectomy
 - Oropharyngeal trauma—penetrating injuries, burns
 - Neck and cervical spine injuries
- **Allergic/inflammatory**
 - Allergic rhinitis
 - Cervical spine arthritis
 - Subacute thyroiditis
 - Esophagitis—secondary to gastroesophageal reflux
 - Bell palsy
- **Functional**
 - Temporomandibular joint (TMJ) dysfunction—less common in children. Pain is usually unilateral and aggravated by chewing and biting.
- **Miscellaneous**
 - Foreign body—in oropharynx or esophagus
 - Aphthous ulcers
 - Esophagitis
 - TMJ disease
 - Migraine
 - Aural neuralgia
 - Pillow otalgia (otalgia from sleep position)
 - Psychogenic pain

APPROACH TO THE PATIENT

The first decision that must be made is whether the patient's symptoms require emergent, urgent, or non-urgent intervention. Emergency treatment is rarely required for pediatric patients with otalgia.

- **Phase 1:** Thorough history—must include a full assessment of ear symptoms, followed by questions to determine possible involvement of other head and neck structures
- **Phase 2:** Physical exam—thorough examination of external and internal ear, followed by inspection of the head, neck, and inside of the mouth
- **Phase 3:** Treatment of identifiable conditions
- **Phase 4:** Referral to otolaryngologist (ENT physician), dentist, or other specialist as needed

HISTORY

- **Question:** Duration of symptoms?
- **Significance:** Acute (more likely infection or trauma) vs. chronic
- **Question:** Quality of the pain?
- **Significance:**
 - Constant (more likely otogenic) vs. intermittent (more likely referred)
 - Dull (more likely due to inflammation) vs. sharp (more likely due to trauma or neuralgia)
- **Question:** Severity of pain?
- **Significance:**
 - Severe—usually otogenic
 - Mild to moderate—more likely to be referred

Worsening factors

- **Question:** Movement of auricle or pressure on tragus?
- **Significance:** Characteristic of otitis externa; can also be associated with furunculosis.
- **Question:** Movement of the jaw (biting, chewing)?
- **Significance:** TMJ dysfunction; furunculosis

Associated symptoms

- **Question:** Fever?
- **Significance:** Infection
- **Question:** URI symptoms?
- **Significance:** AOM or OME
- **Question:** Sore throat?
- **Significance:** Referred otalgia
- **Question:** Ear discharge, tinnitus, or vertigo?
- **Significance:** Otogenic causes
- **Question:** Mouth pain?
- **Significance:** Dental issues or stomatitis
- **Question:** Hoarseness?
- **Significance:** Gastroesophageal reflux
- **Question:** Multiple somatic complaints?
- **Significance:** Psychogenic
- **Question:** Recent swimming?
- **Significance:** Otitis externa

- **Question:** Recent travel? Hobbies?
- **Significance:**
 - Barotrauma from scuba diving or air travel
 - Wrestling—auricular trauma
- **Question:** History of recurrent AOM or OME?
- **Significance:** Cholesteatoma

PHYSICAL EXAM

- **Finding:** Erythematous, dull, bulging tympanic membrane, with decreased mobility?
- **Significance:** Suggestive of AOM
- **Finding:** Retracted, immobile tympanic membrane?
- **Significance:** Suggestive of OME or Eustachian tube dysfunction
- **Finding:** Pain with pressure on the tragus or traction on the pinna?
- **Significance:** Suggestive of otitis externa or furunculosis
- **Finding:** Erythema and edema of the external auditory canal?
- **Significance:** Suggestive of otitis externa
- **Finding:** Purulent discharge in external auditory canal?
- **Significance:** Suggestive of otitis externa or AOM with a ruptured tympanic membrane
- **Finding:** Redness, swelling, and/or tenderness of the auricle?
- **Significance:**
 - With earlobe involvement—cellulitis
 - Without earlobe involvement—perichondritis
- **Finding:** Swelling behind the pinna with its lateral displacement?
- **Significance:** Suggestive of mastoiditis
- **Finding:** Normal ear exam?
- **Significance:** Suggestive of secondary otalgia, thus other possible sources must be carefully examined
- **Finding:** Multiple dental caries?
- **Significance:** May be the source of pain; can indicate the presence of a dental abscess
- **Finding:** Foreign body within the ear or in the oropharynx?
- **Significance:** May be the source of pain from direct pressure or secondary to inflammation
- **Finding:** Enlarged, asymmetrical tonsils or uvular deviation from midline?
- **Significance:** Suggestive of tonsillitis or peritonsillar abscess

Look for signs of trauma, inside or outside of the ear.

DIAGNOSTIC TESTS & INTERPRETATION

Labs, imaging studies, and other diagnostic tests are usually unnecessary as a thorough history and physical exam can lead to a diagnosis in the majority of cases.

- **Test:** Culture of ear discharge
- **Significance:** Indicated when otitis externa or AOM with perforation of the tympanic membrane does not resolve as expected with routine antibiotic treatment

- **Test:** Audiometry
- **Significance:** Evaluate for hearing loss, which would suggest primary otalgia
- **Test:** Tympanometry
- **Significance:** Evaluate for OME, Eustachian tube dysfunction, or tympanostomy tube obstruction

Imaging

- CT scan
 - CT of neck—evaluate for retropharyngeal abscess, mass, or hematoma
 - CT of sinuses—evaluate for sinusitis
 - CT of temporal bone—evaluate for AOM, mastoiditis, and other bony pathology
- MRI: Rarely needed unless intracranial lesion is suspected

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Therapy is directed at the identified underlying cause.
- Pain medications, such as topical benzocaine, acetaminophen, and ibuprofen, are always important since many of the infectious causes are exquisitely painful.
- Observation without antibiotic therapy (“watchful waiting”) is indicated in certain groups of children with AOM.

EMERGENCY CARE

- Rarely needed with most causes of otalgia but may be required if:
 - Potential airway compromise from foreign body, mass, or abscess
 - Significant trauma—possible basilar skull fracture
 - Infection with a toxic-appearing child
- For all of the above situations, first establish “ABC’s” as needed, hospitalize and consult ENT promptly.

ISSUES FOR REFERRAL

Alerts to make a referral to ENT when otalgia is primary in origin:

- Pain with unexplained hearing loss, vertigo, or tinnitus
- Unexplained or persistent otorrhea
- Suspected neoplasm
- History suggestive of severe barotrauma
- AOM with complications
- Foreign bodies that cannot be removed easily from the ear
- Potential for auricle destruction (e.g., perichondritis may lead to permanent deformation, cauliflower ear)
- Persistent ear pain without an identifiable source should prompt a referral.

CODES

ICD9

- 388.70 Otalgia, unspecified
- 388.71 Otogenic pain
- 388.72 Referred otogenic pain

ICD10

- H92.01 Otalgia, right ear
- H92.02 Otalgia, left ear
- H92.09 Otalgia, unspecified ear

FAQ

- Q: What are the most common organisms that cause AOM?
- A:
 - *Streptococcus pneumoniae*
 - *Haemophilus influenzae*
 - *Moraxella catarrhalis*
 - Viruses
- Q: What are the most common organisms that cause otitis externa?
- A:
 - *Pseudomonas aeruginosa*
 - *S. aureus*
 - *Staphylococcus epidermidis*
 - Gram-negative rods
 - Fungal (*Aspergillus*) or yeast (*Candida*)—rare
- Q: What is the most common cause of referred ear pain?
- A: Dental disease

EDEMA

Rebecca Ruebner
Lawrence Copelovitch

BASICS

DEFINITION

Presence of abnormal amount of fluid in the extracellular spaces of the body; usually secondary to low albumin, obstruction of venous or lymphatic channels, or trauma

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- **Localized**
 - Trauma: Pressure or sun damage
 - Infection
 - Allergy
 - Lymphatic obstruction (less common):
 - Filariasis
 - Bee stings or insect bites
 - Sickle cell dactylitis
- **Generalized**
 - Congenital: Lymphatic obstruction of legs or thoracic duct
 - Infection: Hepatitis and liver failure; pericarditis
 - Toxic, environmental, drugs:
 - Sodium poisoning
 - Toxic effect on liver and/or heart (chemotherapy)
 - Cirrhosis
 - Drug reaction
 - Tumor:
 - Obstruction of venous return from enlarged abdominal lymph nodes or tumor
 - Allergic/inflammatory: Protein-losing enteropathy
 - Renal:
 - Nephrotic syndrome
 - Renal failure
 - Cardiac:
 - Congestive heart failure (CHF)
 - Pericarditis
 - GI:
 - Intestinal protein loss
 - Postpericardiotomy or congenital heart surgery
 - Hepatobiliary diseases
 - Endocrine: Sodium retention, hypothyroidism

ETIOLOGY

- **Excessive losses of protein**
 - Renal losses
 - GI losses
- **Inadequate production of protein**
 - Liver disease
 - Malnutrition
- **Local trauma**
- **Increased hydrostatic pressure**
 - CHF
 - Cirrhosis
 - Pericardial effusion
 - Postcardiac surgery
 - Venous obstruction
 - Superior vena caval syndrome
 - Deep vein thrombosis
- **Lymphatic obstruction**

APPROACH TO THE PATIENT

Determine the cause of swelling: Is it localized? Are there any losses of protein? Is there underproduction of protein?

- **Phase 1:** Is the swelling localized as seen in trauma, lymphatic, or venous obstruction?
- **Phase 2:** Are there urinary or GI losses?
 - Associated with decreased serum albumin
 - Most likely source of loss is renal disease, less frequently GI losses
- **Phase 3:** Search for other causes of edema, such as CHF, cirrhosis, lymphatic obstruction

HISTORY

- **Question:** Is the edema localized or generalized?
- **Significance:** See “Differential Diagnosis”
- **Question:** Is the patient asymptomatic or in some distress specifically because of the edema?
- **Significance:** Determine treatment urgency
- **Question:** Evidence of cardiac, renal, or GI disease?
- **Significance:** Major causes of edema
- **Question:** Waist size has become larger, difficulty putting shoes on?
- **Significance:** Evidence of edema in body
- **Question:** Excess salt intake in diet?
- **Significance:** In some patients, contributes to edema
- **Question:** Shortness of breath?
- **Significance:** There may be ascites, which compresses the diaphragm or causes pleural effusions.
- **Question:** Chronic diarrhea?
- **Significance:** Seen in protein-losing enteropathy or lymphatic obstruction
- **Question:** Has any urinalysis been performed in the past?
- **Significance:** May help date the onset of the problem
- **Question:** Swelling around the eyes or face?
- **Significance:** Allergies

PHYSICAL EXAM

- **Finding:** Lumbosacral area, pretibial, scrotum/labia?
- **Significance:** Dependent edema
- **Finding:** Percussion of chest?
- **Significance:** Pleural effusion
- **Finding:** Shifting dullness?
- **Significance:** Early sign of ascites

- **Finding:** Soft ear cartilage?
- **Significance:** Common finding in nephrotic syndrome
- **Finding:** Pitting edema?
- **Significance:** Seen in cases of protein loss
- **Finding:** Venous/lymphatic obstruction or salt poisoning?
- **Significance:** May cause non-pitting edema

DIAGNOSTIC TESTS & INTERPRETATION

- **Test:** Dipstick urinalysis
- **Significance:** If there is generalized edema with heavy proteinuria and hypoalbuminemia, the presumptive diagnosis is always nephrotic syndrome until proven otherwise.
- **Test:** Serum albumin
- **Significance:**
 - If there is generalized edema with no proteinuria but hypoalbuminemia, consider cardiac, GI, or hepatobiliary disease and direct additional studies to evaluate these 3 organ systems specifically.
 - If there is either localized edema or generalized edema but a normal urinalysis and a normal serum albumin, consider other unusual causes for edema, such as mechanical or lymphatic obstruction, certain endocrine disorders, or the effects of drugs or toxins.
- **Test:** Stool albumin
- **Significance:** Seen in protein-losing enteropathy
- **Test:** Cholesterol
- **Significance:** Only high in hypoalbuminemia associated with nephrotic syndrome

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Moisturize skin
- Avoid pressure sores
- Decrease sodium intake
- Active or passive leg exercise to avoid venous thromboses

- If edema is massive, the patient may awaken with swollen eyelids. Place blocks under the head of the bed to keep the patient's head elevated.
- If there is scrotal edema, jockey shorts will help support the scrotum and protect the skin from breaking down.
- For severe edema with respiratory distress, severe abdominal discomfort, or severe scrotal edema, consider treatment with albumin and/or lasix infusion.

ISSUES FOR REFERRAL

- Nephrotic syndrome—pediatric nephrologist
- Protein-losing enteropathy or hepatobiliary disease—pediatric gastroenterologist
- CHF—pediatric cardiologist
- Endocrine-mediated edema—pediatric endocrinologist
- Lymphatic or other mechanical obstructions—vascular surgeon or pediatric surgeon

INITIAL STABILIZATION

Any child or adolescent with an edema-forming state that compromises either cardiorespiratory function or the vascular integrity of a peripheral organ or limb should be referred immediately to an appropriate specialist for emergency care.

CODES

ICD9

782.3 Edema

ICD10

- R60.0 Localized edema
- R60.1 Generalized edema
- R60.9 Edema, unspecified

FAQ

- Q: At what level of serum albumin does edema occur?
- A: Edema is generally associated with serum albumin <2.5 g/dL.
- Q: Why does pericardial effusion cause edema?
- A: Pericardial effusion is associated with decreased lymphatic flow and increased venous pressure.
- Q: Is there a certain group of allergens that cause edema?
- A: No, special allergens are associated with edema. The usual causes include foods such as peanuts and drugs such as penicillin.

EHRlichiosis AND ANAPLAsmosis

Senbagam Virudachalam
Jeffrey P. Louie (5th edition)

BASICS

DESCRIPTION

Zoonotic infection caused by 4 microorganisms of the family Anaplasmataceae. The 2 most common clinically described infections are human monocytic ehrlichiosis (HME), caused by *Ehrlichia chaffeensis*, and human granulocytic anaplasmosis, caused by *Anaplasma phagocytophilum*. *Ehrlichia ewingii*, causes a milder form of ehrlichiosis in immunocompromised patients. A 4th organism, *Neorickettsia sennetsu*, causes a mononucleosis-like syndrome, but rarely causes disease in humans.

GENERAL PREVENTION

- Avoid tick-infested areas.
- Clothes should cover arms and legs.
- Use tick repellents, but with caution in young children.
- A thorough body search should always be done after returning from a tick-infested area:
 - If a tick is found, the area should be cleaned with a disinfectant, and the tick should be removed immediately.
 - To remove the tick, grasp the tick at the point of origin with forceps, staying as close to the skin as possible.
 - Applying steady, even pressure, slowly pull the tick off the skin. After the tick has been removed, clean the skin with a disinfectant.
- Instruct parents to seek medical attention only if symptoms develop.
- No vaccine is available.

EPIDEMIOLOGY

- HME typically occurs in the mid-Atlantic, south central, and southeastern USA, mirroring the pattern of Rocky Mountain spotted fever (RMSF). In addition, it has been found in Europe, South America, Asia, and Africa.
- HGA typically occurs in the northern north central and northeastern USA. In addition, it has been found in northern CA, the mid-Atlantic, and Europe.
- *E. ewingii* only occurs in regions where *E. chaffeensis* occurs.
- *N. sennetsu* has been described in south and Southeast Asia.
- Most patients are infected during April through September, the months of greatest tick and human outdoor activity.
- A second peak of HGA occurs from late October to December.

Incidence

- Varies by state.
- HME: 3.4 cases per million persons (US average, 2008)
- HGA: 4.2 cases per million persons (US average, 2008)
- Incidence is underestimated because 2/3 of both HME and HGA cases are asymptomatic, or only mildly symptomatic.

Prevalence

- Again, difficult to estimate because majority of illnesses are asymptomatic or mild.
- A sero-prevalence study showed that, in endemic areas, 20% children without a history of clinical illness had antibodies to *E. chaffeensis*.

PATHOPHYSIOLOGY

- Obligate intracellular bacteria, pleomorphic, Gram-negative
- Transmission to humans by a tick vector
- Incubation period from 2 to 21 days
- HME infects monocytes and macrophages, whereas HGA infects neutrophils.
- The bacteria reside and divide within cytoplasmic vacuoles of circulating leukocytes, called morulae.
- There is over-induction of the inflammatory and immune response, resulting in clinical manifestations of disease, including multi-organ-system involvement.

ETIOLOGY

- HME is transmitted by *Amblyomma americanum*, the Lone Star tick. The White-tailed deer is the major reservoir.
- HGA is transmitted by *Ixodes scapularis*, a deer tick, or *Dermacentor variabilis*, a brown dog tick. Small mammals such as the white-footed mouse are the major reservoirs.
- Congenital infection is very rare, but has been described in case reports.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Classic presentation: Fever, headache, and myalgias, followed by the development of a progressive leukopenia, thrombocytopenia, and anemia.
- Fevers are found in all children.
- A pleomorphic rash occurs in ~66% of pediatric patients:
 - Rash is described as macular, maculopapular, petechial, erythematous, vesicular, or a combination of these.
 - Usually distributed on the trunk and extremities; spares palms, soles, and face.
- Chills and myalgia are found in most children.
- Severe headache is often described.
- Abdominal pain, vomiting, anorexia, and diarrhea can be noted.
- Arthralgia (without arthritis)
- Cough and sore throat are often described.
- Mental status change due to meningoencephalitis is a less common, but potentially fatal, presentation.

HISTORY

History of tick bite or exposure to wooded areas that are endemic for tick-borne diseases is helpful, but is not always present.

PHYSICAL EXAM

- Mental status changes/irritability
- Nuchal rigidity
- Cardiac murmur (II/VI systolic ejection murmur at the left lower sternal border)
- Hepatosplenomegaly
- Poor perfusion with hypotension (shock) has been described in a few children as a presenting symptom.
- Conjunctival or throat injection
- Rash as described

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC with differential (with smear):
 - Thrombocytopenia, $<150,000/\text{mm}^3$ (77–92% incidence)
 - Lymphopenia, $<1,500/\text{mm}^3$ (75%)
 - Neutropenia, $<4,000/\text{mm}^3$ (58–68%, and is more indicative of HGA)
 - Anemia, hematocrit $<30\%$ (38–42%)
 - Intracytoplasmic morulae within leukocytes (20–60%)
- Electrolytes with BUN and creatinine: Hyponatremia (33–65%)
- Liver function tests: Elevated alanine aminotransferase, >55 U/L (90%)
- Coagulation labs, type and cross, as indicated
- CSF:
 - Leukocytosis, with an average cell count of $100/\text{mm}^3$
 - Lymphocytic predominance
 - Elevated protein and borderline low glucose (less common in children, more common in adults)
 - Microbiology cultures are negative.
 - Intraleukocyttoplasmic *Ehrlichia* micro-organisms (morulae) have been described on CSF smears.
- Serum studies:
 - HME and HGA titers are available through state health departments, the Centers for Disease Control and Prevention, or a reference laboratory.
 - Acute and convalescent antibody titers of *Ehrlichia* (a 4-fold rise or fall is considered positive), obtained 2–4 weeks apart
 - An acute antibody titer of $\geq 1:128$ is considered diagnostic.
 - Polymerase chain reaction is also available for both HME and HGA.
 - The detection of intraleukocyttoplasmic *Ehrlichia* microcolonies (morulae) on peripheral blood monocytes or granulocytes is diagnostic, but is not present in all patients.

Diagnosis Procedures/Surgery

- Bone marrow biopsy is not necessary to diagnose the Ehrlichioses, but may be carried out amid concern for other hematologic diseases.
- Bone marrow is usually hypercellular, but normocellularity and hypocellularity have also been found.

ALERT

- Failing to consider the diagnosis of ehrlichiosis or a delay in treatment pending confirmatory serum titers increases morbidity and mortality.
- Thus, treatment should be started if infection is suspected on the basis of history, physical, and initial laboratory data.
- Alternative diagnoses should be considered in children who do not rapidly improve with doxycycline.
- Simultaneous infections have been documented with ehrlichiosis and Lyme disease. Therefore, in patients diagnosed with ehrlichiosis, Lyme titers should also be measured to determine whether there is a dual infection. A study from Wisconsin documented a 12% coinfection rate.
- Other coinfections with ehrlichiosis have also been documented with either RMSF or babesiosis.

DIFFERENTIAL DIAGNOSIS

- Tick-borne infection:
 - RMSF
 - Tularemia
 - Relapsing fever
 - Lyme disease
 - Colorado tick fever
 - Babesiosis
- Other infection:
 - Toxic shock syndrome
 - Kawasaki disease
 - Meningococemia
 - Pyelonephritis
 - Gastroenteritis
 - Hepatitis
 - Leptospirosis
 - Epstein–Barr virus
 - Influenza
 - Cytomegalovirus
 - Enterovirus
 - Streptococcus pharyngitis
- Miscellaneous:
 - Leukemia
 - Idiopathic thrombocytopenia purpura
 - Hemolytic uremic syndrome

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Volume and BP medications as needed
- Intubation for respiratory failure
- Dialysis for renal failure
- Platelets for thrombocytopenia
- Packed red blood cells for anemia
- Fresh frozen plasma, cryoprecipitate, and vitamin K for DIC
- Antifungal or antibiotics for secondary infections

MEDICATION (DRUGS)

First Line

- Doxycycline, either PO or IV
- Drug of choice regardless of age of child who is severely ill
- Dose: 4.4 mg/kg/day divided q12h (max dose 200 mg q12h)
- Treatment duration: minimum 5–10 days. Continue for 3–5 days after defervescence, longer if there is CNS involvement.

Second Line

- Rifampin has been reported to be an effective antibiotic for children <8 years of age who are less toxic and are experiencing an HGA infection.
- Dose: 20 mg/kg/day divided q12h for 5–10 days.
- This is also the drug of choice for pregnant mothers.
- Unlike Lyme disease, neither amoxicillin nor ceftriaxone has been shown to be effective for the treatment of ehrlichiosis.

ONGOING CARE

PROGNOSIS

- >60% of patients are hospitalized.
- Case fatality rate for HME is 2–5%; for HGA, 7–10%.
- Elevated BUN and creatinine have been associated with a more severe course.
- Children appear to have an excellent outcome: Blood, renal, and liver abnormalities resolve in 1–2 weeks after initiating antibiotics.
- Cognitive and behavioral problems have been reported.
- Neuropathy has been described.

COMPLICATIONS

- Neurologic:
 - Headache, described as severe
 - Mental status changes
 - Seizures
 - Coma
 - Focal neurologic findings
 - Cognitive learning deficits
- Hematologic:
 - Disseminated intravascular coagulopathy (DIC)
 - Thrombocytopenia
 - Leukopenia
 - Lymphopenia
 - Anemia
- GI:
 - Hemorrhage
 - Elevated liver enzymes
 - Hepatosplenomegaly
- Respiratory:
 - Pulmonary hemorrhage
 - Interstitial pneumonia
 - Pleural effusions
 - Noncardiogenic pulmonary edema

- Infectious:
 - Fungal superinfection
 - Nosocomial infections
 - Opportunistic infections
- Renal:
 - Renal failure
 - Proteinuria
 - Hematuria
- Cardiac:
 - Cardiomegaly
 - Murmurs

- A77.41 Ehrlichiosis chafeensis [E. chafeensis]
- A77.49 Other ehrlichiosis

FAQ

- Q: If a tick is removed from my child, should antibiotics be started?
- A: Unlike with Lyme disease, this has yet to be defined. Antibiotics should be started if a child becomes symptomatic.
- Q: What is the most common chief complaint in children with ehrlichiosis?
- A: Intense, unremitting headache:
 - In patients with fever, headache, and flulike illness in the spring to early fall, consider the diagnosis.
 - Laboratory abnormalities of leukopenia, thrombocytopenia, and hepatitis should lead to presumptive therapy until the diagnosis is clear.

ENCEPHALITIS

William V. Raszka, Jr.

A. G. Christina Bergqvist (5th edition)

BASICS

DESCRIPTION

Encephalitis inflammation of the brain parenchyma with neurologic dysfunction. Rarely confirmed histologically, encephalitis is suggested by clinical evidence of brain dysfunction coupled with laboratory or neuroimaging findings suggestive of inflammation. Causes are myriad and include infection, neoplasia, and autoimmune disease. This chapter will focus on infectious and postinfectious causes.

EPIDEMIOLOGY

Incidence

As encephalitis is not reportable and a specific diagnosis infrequently made, the exact incidence is unknown. Reported incidence rates vary with age, geographic location, season, type of exposure, and immunologic status. In the US ~1,400 deaths/year are attributed to encephalitis. Children, the elderly, immunocompromised hosts, and individuals with significant arbovirus exposure have the highest reported incidence rates.

GENERAL PREVENTION

- Immunization against measles, mumps, rubella, and varicella zoster virus (VZV)
- Avoidance of exposure to arthropod vectors during transmission seasons (summer months in US temperate zones)
- Use of insect repellants and topically applied insecticides if exposed to arthropod vectors in hyperendemic areas (e.g., DEET or permethrin)
- Immunocompromised hosts should avoid consuming high-risk foods (e.g., undercooked beef or pork products).
- Cesarean section for women with 1st-time herpes genitalis at the time of parturition
- Travelers or individuals with unique exposures may benefit from specific vaccines (e.g., Japanese encephalitis or rabies).

PATHOPHYSIOLOGY

- Infecting organisms may (1) always cause encephalitis in the absence of systemic findings (e.g., rabies), (2) infrequently but reliably cause encephalitis (e.g., Eastern equine encephalitis), or (3) frequently cause localized or systemic disease and infrequently, as part of the infection, cause encephalitis (enterovirus and herpes simplex virus [HSV]).
- Organisms may invade the brain parenchyma via the systemic circulation, following meningitis, or through retrograde spread along neural pathways (e.g., rabies, HSV).
- Invasion/infiltration leads to activation of the host immune response and cytokine release.
- Light microscopy may show neuronal involvement and inclusion bodies.
- In postinfectious encephalitis, usually diagnosed as acute disseminated encephalomyelitis, no organism can be identified in the brain parenchyma. Histopathologic exam usually demonstrates perivascular inflammation and evidence of demyelination, suggesting that a host immune response is responsible for the clinical findings.

ETIOLOGY

- In the majority of patients, no etiologic agent is identified. In patients with confirmed encephalitis, a specific infectious agent has been either confirmed or deemed probable in 16% and thought possible in another 13%. In the US, viruses are the most common infectious agents (70%) followed by bacteria (20%).
- The most commonly isolated viruses are enterovirus and HSV. Other common viral agents not listed below include Epstein-Barr virus (EBV) and influenza. Worldwide, measles, mumps, and rubella remain important pathogens.
- Viral pathogens associated with specific seasons (summer and fall) are enterovirus, Eastern equine, Western equine, St. Louis, La Crosse, and West Nile viruses.
- Viral pathogens causing sporadic disease include HSV, HIV, VZV, and rabies.
- Pathogens associated with disease in immunocompromised hosts include cytomegalovirus (CMV), JC virus, and VZV.
- Nonviral causes include *Mycoplasma pneumoniae*, *Bartonella henselae*, *Listeria monocytogenes*, *Mycobacterium tuberculosis*, *Borrelia burgdorferi*, *Rickettsia*, *Toxoplasma gondii* (in immunocompromised), and *Taenia solium* (more commonly in immigrants). *Mycoplasma* is the most common possible bacterial cause (usually diagnosed on a single elevated IgM).
- A specific causal organism is infrequently identified in postinfectious encephalitis.

DIAGNOSIS

HISTORY

- Inquire about fever, headache, photophobia, increased somnolence, depressed or altered mental status, irritability, confusion, gait disturbance, seizures, and personality changes.
- Ask for symptoms suggestive of a recent or ongoing viral illness such as cough, coryza, malaise, anorexia, diarrhea, nausea, vomiting, and rashes.
- Inquire about recent travel, animal exposures, tick or mosquito bites, immunizations, and immune status, and in neonates, symptoms of HSV in the mother.

PHYSICAL EXAM

- A complete neurologic exam is critical. Abnormal brain function is a hallmark of encephalitis (and helps distinguish it from meningitis). Patients may present with anything from mild confusion to stupor and coma. Distinguishing infectious from postinfectious encephalitis usually cannot be done on clinical grounds particularly as some viral agents can cause both (e.g., measles, VZV, influenza).
- Specific neurologic findings that may suggest an etiologic agent include the following: focal seizures and focal neurologic findings (HSV); hydrophobia, pharyngeal spasms, and mood disturbance (rabies); facial nerve palsy (Lyme disease); flaccid paralysis or polioliike syndrome (West Nile virus); and ataxia (VZV).

- Nonneurologic findings that may suggest an etiologic agent or syndrome include meningismus or positive Kernig or Brudzinski signs (meningoencephalitis); pulmonary rales or rhonchi (*Mycoplasma*); adenopathy and splenomegaly (EBV); petechial skin rash (*Rickettsia*); morbilliform rash (measles); erythematous maculopapular rash (enterovirus); and parotitis (mumps).
- Hypertension, bradycardia, or apnea may suggest impending herniation due to brain swelling.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Routine labs such as serum electrolytes, glucose, BUN, creatinine, liver function tests, calcium, magnesium, and complete blood count with differential are recommended, although they infrequently help confirm or exclude a diagnosis.
- Ammonia and blood pH
- Serologic testing (depending on the suspected agent (e.g., West Nile virus and *Mycoplasma*)
- Toxicology screen

Imaging

MRI (or if not available, CT) of the brain with and without contrast medium. Imaging is performed urgently to rule out surgically remediable conditions (e.g., abscess or hematoma). While neuroimaging can be normal in patients with encephalitis, studies often help exclude particular conditions or demonstrate findings suggestive of encephalitis. Typical changes in encephalitis include focal or diffuse parenchymal enhancement (HSV has a preference for the medial temporal lobe).

Diagnostic Procedures/Other

Lumbar puncture:

- Often performed emergently. Defer until the airway, gas exchange, and circulation have been stabilized or if clinical signs and symptoms suggest increased intracranial pressure.
- Measure opening pressure (frequently elevated).
- Send for cell count and differential (lymphocytic predominance suggests a viral process while neutrophilic predominance suggests bacterial or early viral processes). The presence of red blood cells is suggestive of necrotizing encephalitis (often associated with HSV).
- Measure protein (usually elevated) and glucose.
- Send CSF for Gram stain and bacterial culture (20% of patients with suspected encephalitis are diagnosed with bacterial meningitis).
- In immunocompromised hosts, fluid should be sent for fungal stains and culture (and serum for cryptococcal serum antigen).
- In most patients with suspected encephalitis and particularly if there is a lymphocytic CSF pleocytosis, CSF should be sent for HSV polymerase chain reaction (PCR) assay. Other PCR-based tests on CSF, including assays for enterovirus, *Borrelia burgdorferi*, and West Nile virus, may be considered depending on the situation.

- EEG: Performed nonurgently. Findings of periodic lateralizing epileptiform discharges (PLEDs) are suggestive but not diagnostic of herpes.
- Brain biopsy: Now rarely performed

ALERT

- Never assume that a CSF pleocytosis is secondary to seizures.
- Institute antiviral and/or antibacterial therapy promptly; it can always be discontinued after an organism is identified or cultures/PCR are negative.
- The absence of CSF pleocytosis does not exclude encephalitis.
- Save extra CSF and serum obtained at the time of presentation for future testing (very useful if the initial tests are nondiagnostic).
- Children with immunodeficiency or unique exposures (e.g., travel) have an expanded differential diagnosis and may require serologic, culture, or PCR testing not commonly performed to reach a diagnosis.

DIFFERENTIAL DIAGNOSIS

Several toxic, metabolic, vascular, and epileptic syndromes may resemble encephalitis:

- Acute electrolyte disturbance, especially hyponatremia
- Acute obstructive hydrocephalus or ventriculoperitoneal shunt obstruction
- Bacterial meningitis
- Brain abscess
- Cerebral vasculitis, stroke, or septic embolization (endocarditis)
- Hypothyroid crisis
- Ingestions
- Intracranial hemorrhage
- Malignant hyperthermia
- Pituitary infarction
- Reye syndrome
- Sinus thrombosis
- Status epilepticus
- Subdural empyema
- Viral meningitis

TREATMENT

MEDICATION (DRUGS)

- Almost all patients with suspected encephalitis should be started on empiric intravenous acyclovir unless the history, clinical findings, and initial laboratory tests either exclude the diagnosis of HSV or strongly point to an alternative diagnosis.
- Patients with confirmed HSV encephalitis are continued on IV acyclovir for 21 days.
- Patients with suspected encephalitis of unknown etiology and CSF pleocytosis (particularly if the CSF shows a predominance of neutrophils) are usually started on empiric antibiotic therapy for possible bacterial meningitis (the combination of ceftriaxone and vancomycin for all children outside the neonatal age group) until bacterial culture results are negative or a viral cause confirmed.

- Specific anti-infective therapy is available for neuroborreliosis (ceftriaxone), rickettsial disease (doxycycline regardless of age), and toxoplasmosis (pyrimethamine plus sulfadiazine). Whether acyclovir is beneficial in VZV is controversial as in most situations, VZV leads to a postinfectious syndrome. Ganciclovir is used in CMV encephalitis but the outcome remains dismal.
- Anticonvulsants are reserved for clinical or electrographic evidence of seizure/epileptic activity:
 - Choices include lorazepam, phenytoin, phenobarbital, and carbamazepine.

IN-PATIENT CONSIDERATIONS

Initial Stabilization

Most patients are admitted to the hospital and often the intensive care unit for initial stabilization and management.

IV Fluids

- Correct any fluid deficits; thereafter, maintain a euolemic state. Avoid hypotonic fluids.
- Closely monitor electrolytes, anticipating possible syndrome of inappropriate antidiuretic hormone or diabetes insipidus.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Physical and occupational therapists should be consulted early in the course and will be helpful during the convalescence.
- Neuropsychologic testing is helpful to identify cognitive deficits and direct appropriate services.
- Follow-up with speech pathologists and developmental pediatricians may be indicated.

PROGNOSIS

Outcome varies greatly and depends on age, etiologic agent, and disease severity at the time of presentation (e.g., patients presenting in coma do worse). Outcomes range from complete recovery to focal neurologic deficits, persistent vegetative state, and death.

COMPLICATIONS

- Aphasias
- Ataxia
- Developmental delay
- Learning disabilities
- Quadriplegia/hemiparesis
- Seizure disorders, focal or generalized

CODES

ICD9

- 049.9 Unspecified non-arthropod-borne viral diseases of central nervous system
- 062.0 Japanese encephalitis
- 323.9 Unspecified causes of encephalitis, myelitis, and encephalomyelitis

ICD10

- A83.0 Japanese encephalitis
- A86 Unspecified viral encephalitis
- G04.90 Encephalitis and encephalomyelitis, unspecified

FAQ

- Q: My child has been diagnosed with encephalitis; will he be mentally retarded?
- A: The complications following encephalitis vary greatly from severe mental retardation and cerebral palsy to full recovery. There is a correlation between degree of brain destruction and outcome; however, children frequently recover better than adults with a similar degree of illness.

ENCOPRESIS

Victor M. Pineiro-Carrero (5th edition)

Amanda Muir

BASICS

DESCRIPTION

- Repeated unintentional soiling of underwear
- Most commonly associated with functional constipation with severe stool retention and subsequent overflow incontinence:
 - 90% of cases of encopresis fall into this category
- Another less common type of encopresis refers to the entity of repeated passage of feces into inappropriate places (usually clothing or floor) after the age of 4 years in the absence of constipation and structural or inflammatory diseases, also known as functional nonretentive fecal incontinence (FNRFI).

EPIDEMIOLOGY

- The reported ratio of boys to girls ranges from 2:1 to 6:1. Boys are more likely to experience nonretentive fecal incontinence than girls at a ratio of 9:1.
- There is no association with family size, ordinal position in the family, age of parents, or socioeconomic status.

Prevalence

Encopresis is reported in 1.5–2.8% of children >4 years. Between 10% and 30% of children with encopresis have nonretentive fecal incontinence.

RISK FACTORS

Genetics

Monozygotic twins have a 4-fold higher incidence than do dizygotic twins.

ALERT

- Constipation with a rectal fecal mass is most common risk for encopresis.
- Children with FNRFI have more behavioral problems, poor self-esteem, and higher prevalence of attention deficit disorder.

PATHOPHYSIOLOGY

Chronic constipation with fecal impaction results in overflow incontinence and reduced sensation secondary to rectal distention. The pattern of holding fecal matter, leading to chronic constipation and overflow incontinence, may result from a variety of causes, such as a painful experience from a fissure, difficult toilet training, or refusal to use school bathrooms. However, the history often does not reveal a triggering event.

ETIOLOGY

- Chronic constipation leads to a dilated rectum, decreased rectal sensation, shortening of the anal canal, and decreased anal sphincter tone in some patients.
- Findings on anorectal manometry include increased rectal sensory threshold and paradoxical contraction of the external anal sphincter during attempts at defecation (known as *anismus*).

- FNRFI occurs in children without constipation. The soiling may be a manifestation of an emotional disturbance, and it may be associated with specific triggers (person or place) or may represent an impulsive action triggered by unconscious anger. All studies in these patients are normal, including normal anorectal manometry and normal colonic transit times.

COMMONLY ASSOCIATED CONDITIONS

Enuresis is more frequently seen in patients with FNRFI (45% have daytime and 40% have nighttime enuresis) compared to constipated children.

DIAGNOSIS

HISTORY

- Toileting habits:
 - Constipation: Frequency and size of bowel movements (large-diameter bowel movements are common in children with encopresis associated with functional constipation)
 - Bowel movements that obstruct the toilet and/or chronic abdominal pain relieved by enemas or laxatives
 - Retentive posturing: Avoiding defecation by contraction of pelvic floor, squeezing the buttocks together (leg scissoring, crossing the legs, standing on tiptoes)
- Irritability, abdominal cramps, decreased appetite (symptoms improve after passage of large stool)
- Onset: Elicit history of triggering events (perianal infection, diet changes, toilet training, avoidance of school bathrooms, sexual abuse, or other stressful events).
- Enuresis (secondary daytime enuresis may occur in patients with megarectum compressing the bladder)
- Timing in the neonatal period of meconium passage, as well as past surgeries, medical history, and medications, are relevant.
- Unsteady or clumsy gait may suggest a neuromuscular disorder.
- Children with FNRFI do not have any history of constipation and have daily bowel movements. The incontinence is diurnal, usually in the afternoon.

PHYSICAL EXAM

- Encopresis with functional constipation:
 - Fecal mass palpable in 40% of patients; fecal soiling in the perianal region
 - Dilated rectum but a normally positioned anus
 - Anal sphincter tone may be normal or slightly decreased; the anal canal is usually shorter than normal.
 - Hard stool or a large amount of “mushy” stool present in rectal vault

- FNRFI:
 - No palpable fecal mass
 - Normal-size rectum
 - Normal sphincter length
- Examine deep tendon reflexes, anal wink, rectal exam, lumbosacral spine exam to look for sacral dimpling, and documentation of normal growth.
- In patients with extreme fear of anal exam, attempt a perianal inspection and obtain a plain radiograph of the abdomen to establish a fecal impaction. In children who fear painful defecation, the necessity of a rectal exam remains debatable.

DIAGNOSTIC TESTS & INTERPRETATION

Referral to a pediatric gastroenterologist for further evaluation, including anorectal manometry, is often a useful adjunctive modality for patients recalcitrant to standard management.

Lab

No tests are needed if both the history and physical exam are consistent with functional constipation and associated encopresis. If the patient’s history or physical exam is atypical and a systemic disorder is suspected, appropriate diagnostic tests should be done.

Imaging

- Abdominal radiography is often necessary for patients who refuse a rectal exam, or when a rectal impaction is not palpable on abdominal exam (e.g., in obese patients).
- Enema with water soluble contrast material can be both helpful diagnostically to look for areas of narrowing and therapeutically as a clean-out procedure.
- MRI of the spine can be done for children with suspected spinal abnormalities. This is rarely necessary if the neurological exam is normal.
- Colonic transit study with radio-opaque markers to confirm the patients complaints or assess for slow transit constipation

Diagnostic Procedures/Other

- Rectal suction biopsy can be performed to evaluate for ganglion cells within the colonic mucosa and evaluate for Hirschsprung disease.
- Anorectal manometry can be done in selected cases to evaluate anorectal function. The main indication is to demonstrate the rectoanal inhibitory reflex to exclude Hirschsprung disease and ultra-short-segment Hirschsprung disease. It may also show an increased threshold to rectal sensation, providing important information to the patient and the parents.

DIFFERENTIAL DIAGNOSIS

Determine whether stool leakage is caused by functional constipation or an underlying anatomic, metabolic, or neurologic abnormality. Fecal incontinence may be secondary to diarrheal diseases or defective neuromuscular control, such as in children with spinal defects.

- Neuromuscular:
 - Spinal cord tumor
 - Tethered spinal cord
 - Meningocele
- Anal abnormalities:
 - Anteriorly displaced anus
 - Ectopic anus
- Inflammatory:
 - Proctitis (infectious or ulcerative)
 - Fistula secondary to Crohn disease
 - Celiac disease
- Stricture (after necrotizing enterocolitis or inflammatory bowel disease)
- Abdominal pelvic mass (sacral teratoma, meningocele)
- Hypotonia (cerebral palsy, amyotonia congenita, familial visceral myopathy)
- Hirschsprung disease (constipation common, fecal incontinence rarely seen) or ultra-short-segment Hirschsprung disease
- Postsurgical repair of imperforate anus or Hirschsprung disease
- Endocrine:
 - Hypothyroidism
 - Panhypopituitarism
 - Diabetes mellitus
- Constipating drugs:
 - Opiates
 - Calcium supplements
 - Psychotropics

**TREATMENT****MEDICATION (DRUGS)**

- Disimpaction must be achieved with either enemas or sedated manual disimpaction to avoid increased encopresis and abdominal pain:
 - Severe cases may require polyethylene glycol ingestion by NG tube after disimpaction in a hospital setting.
- Stimulant laxatives:
 - Magnesium citrate
 - Bisacodyl
 - Senna
- Stool softeners:
 - MiraLAX (0.75 mg/kg/d) is the preferred agent because of its palatability and lack of taste.
 - Milk of magnesia (0.5–1 mL/kg/d) is a good option.
 - Mineral oil (5–20 mL in divided doses) may also be used in older children who have no risk of aspiration.
 - Lactulose (2.5–10 mL/d for infants and 40–90 mL/d in older children)

ISSUES FOR REFERRAL

Patients with nonretentive fecal incontinence usually require referral to a mental health professional for more intensive behavioral intervention.

COMPLEMENTARY & ALTERNATIVE THERAPIES

Behavior modification: Decrease family stress. Have the child sit on toilet for defined amount of time (1 minute/year of age to a maximum of 10 minutes) 1–2 times per day (ideally after a meal, tailored to the age of the child) and try to perform a Valsalva maneuver. Have young children blow into a pinwheel or a balloon to try to make them bear down. Delay toilet training if the child is in diapers (to reduce stress). Motivate using positive reinforcement strategies. Biofeedback can be successful in some cases.

IN-PATIENT CONSIDERATIONS**Initial Stabilization**

Management combines pharmacology, behavioral modification, and dietary alterations.

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

- 1st follow-up visit is at 2 weeks to ensure compliance and success with the initial management.
- If the fecal impaction has been successfully removed, a reward system is started.
- The patient is followed at monthly intervals to ensure motivation and to be supportive.
- Treatment with stool softeners is needed until behavior and diet have improved and until rectal dilation has resolved.
- Medication is often needed for 6 months or longer.

ALERT

- Parents may misconstrue stool-withholding behavior as an attempt to defecate.
- Parents may think that the soiling represents diarrheal illness, causing a delay in diagnosis and treatment.
- Parents may think their child's soiling is deliberate. They may not understand that the child can neither feel the passage of stool nor prevent it. The usual urge to defecate, which comes from stretching of the ampulla and internal anal sphincter, is not felt because the rectal ampulla is massively distended.
- Patients or their parents often stop stool softeners as soon as a normal stool pattern starts. If therapy has been ended prematurely, the patient's constipation and encopresis returns immediately because rectal tone is still poor and no other behavior or dietary modifications have been made.

DIET

- High fiber
- Adequate fluid

COMPLICATIONS

- Social problems
- UTIs, especially in girls
- Abdominal discomfort
- Decreased appetite and weight loss

**CODES****ICD9**

- 307.7 Encopresis
- 787.60 Full incontinence of feces
- 787.62 Fecal smearing

ICD10

- F98.1 Encopresis not due to a substance or known physiological condition
- R15.1 Fecal smearing
- R15.9 Full incontinence of feces

FAQ

- Q: Is the medicine addictive?
- A: Stool softeners, rather than cathartics, are chosen for long-term therapy because the colon does not become dependent.
- Q: Will my child become sick if this problem is not resolved?
- A: Most children with chronic constipation and encopresis grow well and do not develop other health problems. The major problems are social and should be taken seriously. Social development is crucial for the school-aged child.

ENDOCARDITIS

Jenifer A. Glatz

BASICS

DESCRIPTION

Infective endocarditis (IE) is a microbial infection of the endocardium of the heart.

EPIDEMIOLOGY

Incidence

- IE is relatively uncommon. The estimated incidence is 0.3 per 100,000 children per year.
- The overall incidence of endocarditis decreased with the advent of antibiotics. However, a recent increase in frequency has been associated with improved survival of patients with congenital heart disease and the more widespread and often prolonged use of central vascular catheters, especially in premature infants.

RISK FACTORS

- Preexisting heart disease (congenital or acquired)
- Prior history of endocarditis
- Cardiac surgery
- Intracardiac pacemakers and implantable cardioverter-defibrillators
- Prosthetic valves or conduits
- Indwelling catheters/IV drug use

GENERAL PREVENTION

- Dental hygiene
- Minimal use of central lines
- Correction of the cardiovascular anomaly by surgery or interventional catheterization techniques
- Subacute bacterial endocarditis (SBE) prophylaxis regimens as per the 2007 American Heart Association recommendations. Give as a single dose 30–60 minutes prior to procedure:
 - Oral: Amoxicillin (50 mg/kg, max 2.0 g)
 - IV or IM: Ampicillin (50 mg/kg, max 2.0 g) or ceftriaxone/cefazolin (50 mg/kg, max 1.0 g)
 - Oral for penicillin-allergic patients: Cephalexin, if no history of urticaria, angioedema, or anaphylaxis (50 mg/kg, max 2.0 g), clindamycin (20 mg/kg PO/IV, max 600 mg) or azithromycin/clarithromycin (15 mg/kg PO, max 500 mg)
 - IV or IM for penicillin-allergic patients: Cefazolin, ceftriaxone, or clindamycin (doses as above)
- SBE prophylaxis is recommended by the AHA only for the following cardiac conditions:
 - Prosthetic cardiac valve or prosthetic material used for cardiac valve repair
 - Prior history of infective endocarditis
 - Unrepaired cyanotic congenital heart disease, including palliative shunts and conduits
 - Congenital heart defect repaired with prosthetic material or device for the 1st 6 months after the procedure
 - Repaired congenital heart disease with residual defect near the site of prosthetic patch or device
 - Cardiac transplantation recipients with cardiac valvulopathy

- SBE prophylaxis is recommended only for the following procedures:
 - Dental procedures involving manipulation of the gingival or periapical region of teeth or perforation of the oral mucosa
 - Invasive respiratory tract procedures involving incision or biopsy, such as tonsillectomy/adenoidectomy or abscess drainage
 - Surgery involving prosthetic intravascular or intracardiac material, including heart valves
- Procedures that do not require SBE prophylaxis:
 - Placement of removable prosthodontic or orthodontic appliances
 - Bleeding from trauma to the lips or oral mucosa or shedding of deciduous teeth
 - Routine anesthetic injections through noninfected oral mucosa tissues
 - Bronchoscopy without a biopsy
 - GI or GU procedures: Prophylaxis solely to prevent IE is not recommended

PATHOPHYSIOLOGY

- Infective endocarditis is primarily seen in patients with preexisting heart disease (congenital or acquired) who develop bacteremia with organisms that are likely to cause infection.
- IV drug abusers and patients with indwelling central venous catheters may develop endocarditis even in the absence of prior heart disease.
- Local turbulence secondary to the cardiovascular abnormality is thought to result in damage of the endocardial surface. The development of a fibrin and platelet network occurs in which bacteria may then become entrapped, causing infection.
- Bacteremia may be a complication of focal infection (e.g., pneumonia, cellulitis, or UTI) or may be associated with various dental and surgical procedures. Bacteremia, however, also occurs spontaneously with usual activities, such as chewing, flossing, and brushing teeth.
- Peripheral manifestations in chronic endocarditis are mediated by immune complex reactions.

ETIOLOGY

- Gram-positive cocci account for 90% of culture-positive endocarditis. There has been a recent shift in the microbial etiology, corresponding with a more acute presentation:
 - *Staphylococcus aureus* is now responsible for most cases of infective endocarditis in all age groups.
 - α -Hemolytic streptococci (*Streptococcus viridans*) are the 2nd most common pathogen in children > 1 year.
 - Other organisms that can cause endocarditis are coagulase-negative staphylococci, β -hemolytic streptococci, enterococci, the HACEK group (*Haemophilus aphrophilus*, *Haemophilus paraphrophilus*, *Haemophilus parainfluenzae*, *Actinobacillus actinomycetemcomitans*, *Cardiobacterium hominis*, *Eikenella corrodens*, *Kingella species*), *Candida species*, *Aspergillus species*, *Pseudomonas species*, pneumococci, and *Neisseria species*.
- <20% of endocarditis cases are reported as culture negative.

DIAGNOSIS

- The Modified Duke Criteria define diagnostic categories (definite endocarditis, possible endocarditis, and rejected cases) based on combinations of major and minor criteria.
- Criteria:
 - Major: Organism specific for IE demonstrated by positive blood culture or histologic specimen and definitive echocardiographic data.
 - Minor: Predisposing heart disease, fever, vascular/immunologic phenomena, or microbiologic evidence not within major criteria.
- Definitive endocarditis requires 2 major, or 1 major plus 3 minor, or 5 minor criteria.
- Several studies have confirmed the high sensitivity and specificity of these criteria.

HISTORY

- Fever
- Malaise
- Anorexia
- Weight loss
- Heart failure symptoms
- Arthralgia/Myalgia
- Neurologic symptoms
- GI symptoms
- Chest pain
- Occasionally, a recent infection, dental visit, or surgical procedure can be identified.
- Acute endocarditis is associated with a more rapidly progressive, fulminant course.

PHYSICAL EXAM

- General:
 - Fever (usually low grade with α -hemolytic streptococci and high grade with *S. aureus*)
 - Petechiae (occurring in 1/3 of cases)
- Embolic or immunologic phenomena:
 - Renal: Glomerulonephritis, infarct
 - Splinter hemorrhages
 - Retinal hemorrhages (Roth spots)
 - Osler nodes (painful)
 - Janeway lesions (painless)
 - Splenomegaly (occurring in about 50% of cases)
 - Arthralgia/Arthritis
 - Neurologic: Cerebral infarction, embolism or hemorrhage. Mycotic aneurysms may also occur.
- Cardiac/Valvulitis:
 - New or change in heart murmur
 - Signs of CHF
- Newborns with IE may present with feeding difficulty, respiratory distress, tachycardia, hypotension, seizures, apnea, and septic emboli.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Blood cultures:
 - Most important diagnostic test for endocarditis
 - Positive in 85–90% of reported cases
 - Obtain 3–5 sets from different sites during the 1st 24 hours of suspected endocarditis.
 - Collect the largest volume that is clinically reasonable.
 - The bacteremia of endocarditis is continuous; therefore, it is not necessary to wait to obtain the blood cultures during a fever spike.
- Nonspecific data:
 - Elevated ESR (80%) and C-reactive protein
 - Anemia (44%)
 - Positive rheumatoid factor (38%)
 - Hematuria (35%) and red cell casts
 - Leukocytosis
 - Decreased complement

Imaging

- Echocardiography, transthoracic:
 - Valuable noninvasive technique in the identification of vegetations
 - Specificity is 98% but sensitivity is <60%, so a negative echocardiogram does not rule out endocarditis.
 - Also invaluable for follow-up, including evaluation for potential cardiac complications
- Echocardiography, transesophageal:
 - Especially in older or obese patients, provides better visualization of smaller vegetations, with sensitivity of 76–100%.
 - Recommended in patients with an inconclusive transthoracic study but a high index of suspicion for endocarditis.

ALERT

- The absence of vegetation(s) by echocardiography does not rule out endocarditis.
- In patients with a prosthetic valve, echocardiography is not always helpful, as there is frequently artifact from the prosthetic valve. Abnormal movements of the valve leaflets may suggest a vegetation.
- The ESR may remain elevated for some time, even after cessation of bacteremia.

Diagnostic Procedures/Other

ECG: New-onset abnormalities such as atrioventricular block (even 1st-degree) may represent conduction system and myocardial involvement from invasive disease.

DIFFERENTIAL DIAGNOSIS

- Other infections
- Acute rheumatic fever
- Malignancy
- Connective tissue disorders

TREATMENT

MEDICATION (DRUGS)

Antibiotics:

- Prolonged IV therapy (at least 4 weeks) is needed.
- Choice of antibiotic(s) and duration of treatment depend on the infecting organism, sensitivity pattern, and patient risk factors.
- For staphylococcal or fungal endocarditis, IV therapy is given for at least 6–8 weeks.

SURGERY/OTHER PROCEDURES

Potential indications (mostly adult data):

- Severe/worsening CHF
- Valvar disease with unstable hemodynamics
- Failing medical therapy
- Large (> 10 mm), mobile vegetations
- ≥2 major embolic events
- Fungal endocarditis
- Abscess formation/periannular extension
- Prosthetic valve endocarditis

IN-PATIENT CONSIDERATIONS

Initial Stabilization

- Rest
- Antipyretics
- Optimal nutrition and hydration
- Careful dental hygiene

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Obtain repeat blood cultures after a few days of antibiotic or antifungal therapy to ensure the eradication of bacteria.
- Obtain blood cultures again 2 months after completion of a full course of antibiotic therapy.

PROGNOSIS

If diagnosed in a timely fashion and appropriate therapy is instituted, prognosis is relatively good for bacterial endocarditis. *S. aureus* and fungal endocarditis are associated with higher morbidity and mortality.

COMPLICATIONS

Despite improvements in diagnosis and treatment, IE continues to be a disease with significant morbidity and mortality (~10–20%):

- Cardiac: Valve destruction and perforation leading to incompetence, abscess and fistula formation, heart failure, or conduction abnormalities.
- Embolic events (22–50%) may occur to multiple organ systems (CNS, bowel, coronary arteries, kidneys, spleen, skin, lungs).

CODES

ICD9

- 421.0 Acute and subacute bacterial endocarditis
- 421.9 Acute endocarditis, unspecified
- 424.90 Endocarditis, valve unspecified, unspecified cause

ICD10

- I33.0 Acute and subacute infective endocarditis
- I33.9 Acute and subacute endocarditis, unspecified
- I38 Endocarditis, valve unspecified

FAQ

- Q: I forgot to give my child antibiotics prior to the procedure. Should I give him a dose afterward?
- A: The dosage may be administered up to 2 hours after the procedure.
- Q: My child has an innocent heart murmur. Does he need SBE prophylaxis?
- A: SBE prophylaxis is not indicated.
- Q: SBE prophylaxis is recommended for my child, but she already is on long-term antibiotic therapy with that recommended antibiotic. Should she use an additional antibiotic or increase her current dose for the procedure?
- A: An antibiotic from a different class should be selected.

BASICS

DESCRIPTION

Involuntary micturition after age of expected bladder control; generally reserved for children ≥ 6 years:

- Generally refers to monosymptomatic nocturnal enuresis or bedwetting—urinary incontinence only at night.
- ~20% of children may also exhibit both daytime symptoms (urgency, frequency, incontinence) and nighttime wetting, and this is termed dysfunctional voiding
- Monosymptomatic nocturnal enuresis may be primary or secondary:
 - Primary enuresis: Never continent of urine on consecutive nights for at least 6 months (daytime, nocturnal, or both)
 - Secondary enuresis: Had continent period of at least 6 months, then relapse of enuresis
- Most (80%) of nocturnal enuresis is primary.

EPIDEMIOLOGY

- Male > Female (3:1)
- Frequency, severity, longevity of primary nocturnal enuresis (PNE) increases with positive family history.

Incidence

- 43–47% if 1 parent was enuretic
- 15% if neither parent was enuretic
- Twice as high in monozygotic twins as dizygotic twins
- Incidence increased among children also diagnosed with ADHD

Prevalence

- At age 5, 15% of children have PNE.
- ~15% of children with enuresis spontaneously remit each year:
 - By age 10, only 5% still have nocturnal enuresis.
- ~1% of adolescents have nocturnal enuresis.

RISK FACTORS

Genetics

- An autosomal dominant variant of nocturnal enuresis is described in a Danish population.
- Generally, however, no specific genetic abnormality is identified.

ETIOLOGY

- PNE:
 - Underlying treatable cause uncommon
 - Any condition causing polyuria (e.g. diabetes insipidus, diabetes mellitus)
 - Theories: Deep sleep with failure of signal of increased bladder pressure to reach consciousness; maturational delay with bladder emptying at lower volume secondary to small bladder capacity; failure to concentrate urine or to decrease urinary volume at night compared with dry peers

- Daytime incontinence and enuresis, day and night:
 - As above. More concerning for underlying urologic and neurologic disorder
 - Urinary reflux into vagina with seepage after conclusion of voiding
 - Insertion of ureter into urethra or vagina
 - Incontinence with increased abdominal pressure (laughing, coughing, increased intravesicular pressure)
- Secondary enuresis:
 - Any condition causing polyuria
 - UTI
 - Encopresis
 - Emotional stress or trauma including physical and sexual abuse, divorce, depression, new sibling, household moving, new school

DIAGNOSIS

HISTORY

- Onset:
 - Nocturnal versus diurnal
 - Dry period (even if only weeks)
 - Frequency
 - Pattern of urination:
 - Constantly wet pants (dribbling)
 - Frequent small amounts of urine
 - Dysuria
 - Frequency
 - Hesitancy
 - Dry when sleeping away from home
- Past medical history:
 - Obstipation/constipation/stool incontinence (encopresis)
 - Behavioral/developmental history
 - Toilet training history
 - Medications
 - Neurologic symptoms
 - Other medical problems
- Family history:
 - 1 parent or 2
 - Child awareness
- Social history:
 - For whom does this pose problem—parent or child?
 - Effect on child:
 - Ability to sleep away from home without embarrassment
 - Teasing at school
 - Emotional effects
- Social changes:
 - Divorce
 - New significant other for parent
 - New sibling
 - Household move
 - Change in school
 - Death or illness in family
 - Other change in home environment
- Past interventions and effectiveness:
 - Attempt at treatment or punishment and its effectiveness

PHYSICAL EXAM

- Vital signs
- Growth parameters and pattern
- Neurologic exam:
 - Gait, tone, sensory, motor, deep tendon reflexes, cremasteric reflex
 - With funduscopy: To rule out intracranial pressure
- Abdominal exam: To rule out masses, especially renal mass
- Genitalia: Rule out adhesions, vulvovaginitis, balanitis, stenosis, foreign bodies.
- Urinary stream
- Rectal exam: Tone, perianal sensation, anal wink
- Spine: Bony defects, cutaneous signs of underlying spinal defects

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis:
 - Specific gravity
 - Glucose
 - Protein
 - Blood
 - Urine:
 - 1st morning void for specific gravity and protein
- Urine culture: Usually not necessary if no symptoms

Imaging

- Rarely necessary in monosymptomatic primary enuresis
- Only if suggestion of anatomic or functional abnormality of genitourinary system

ALERT

Laboratory evaluation rarely yields specific diagnosis. Balance risks and costs with unlikelihood of yield. Evaluation should generally involve no more than urinalysis.

DIFFERENTIAL DIAGNOSIS

- UTI/Urethritis
- Obstipation/constipation
- Water intoxication
- Diabetes mellitus
- Diabetes insipidus
- Sickle cell disease or trait
- Nephritis/Nephrosis
- Anatomic abnormalities of the urinary tract
- Sleep disorders
- Depression
- Anxiety
- Behavioral disorders
- Medications (sedatives, soporifics, antihistamines, diuretics, caffeine, methylxanthines)
- Spinal cord disease
- Cognitive disorders
- Seizure disorders
- Legitimate safety issues in going to bathroom alone
- Substandard living conditions (cold bathrooms, poor facilities)

TREATMENT

MEDICATION (DRUGS)

- Avoid medication intervention before age 6–8 years
- Desmopressin (DDAVP):
 - Can be used intermittently only on sleep-out nights
 - Effective in 70% of PNE
 - If used chronically, monitor electrolytes and fluid status appropriately.
 - Oral formulation only (nasal formulation associated with increased risk of hyponatremia and seizures)
- Imipramine:
 - Tricyclic antidepressant
 - 80% effective
 - No longer 1st- or 2nd-line choice for benign condition because of risk of QTc prolongation and controversial risk of sudden cardiac death and risk of ingestion in siblings
- Oxybutynin: Used in patients with documented detrusor instability

ADDITIONAL TREATMENT

General Measures

- If the problem is affecting only the parents and child is not affected, the treatment should be education and support for the parents:
 - Prognosis for self-resolution
 - Benign nature
 - Available interventions if child becomes concerned
- Avoid all negative interventions.
- Fluid restriction before bed—controversial:
 - May create arguments with parents
 - Success rate low
- Retention training/bladder stretching exercises—controversial
- Cognitive behavioral interventions:
 - Formal programs developed and used by pediatric psychologists: High rate of success; involve “Over Correction Techniques”—frequent practice and rewards for voiding procedures along with enuresis alarm
 - Positive reinforcement for dry nights
 - Use of praise, stickers, token economies
 - Bell-and-pad alarm systems: Most effective of behavioral interventions more effective in conjunction with formal behavioral program; high relapse rate after remission and cessation of alarm usage; 2nd remission very frequent with reintroduction of alarm system; 2nd relapse rare

- Hypnotism:
 - Appears to work by increasing subconscious awareness of bladder pressure during sleep, allowing increased awareness during sleep of intravesicular pressure
 - Use of bell-and-pad alarm may increase success rate

IN-PATIENT CONSIDERATIONS

Initial Stabilization

Specific therapy to address specific anatomic, infectious, or functional renal problems

ALERT

Decision to treat is a balance of the effect on the child of nontreatment (social, emotional) with the potential side effects of medication.

ONGOING CARE

PROGNOSIS

- 99% percent of cases resolve without treatment.
- Spontaneous resolution is ~15% per year after age 5.

COMPLICATIONS

- Physical:
 - Vulvovaginitis
 - Diaper dermatitis
- Emotional:
 - Embarrassment
 - Poor self-esteem
 - Reluctance to sleep out with peers or nonimmediate family
 - Depression

CODES

ICD9

- 307.6 Enuresis
- 788.30 Urinary incontinence, unspecified
- 788.36 Nocturnal enuresis

ICD10

- N39.44 Nocturnal enuresis
- R32 Unspecified urinary incontinence

FAQ

- Q: Do the medications cure the enuresis?
- A: None of the medications cures the problem. DDAVP increases reabsorption of water in the kidney, resulting in decreased bladder volumes. Tricyclic antidepressants cause urinary retention by the noradrenergic effects on bladder contraction and detrusor relaxation. Oxybutynin decreases detrusor irritability, resulting in larger bladder capacity before emptying. The medications result in nonemptying of the bladder during sleep, but do not affect the underlying cause. Any resolution that occurs after cessation of medication treatment is probably from the natural resolution of the problem with age.
- Q: Isn't it important to cure the enuresis when the parents bring it up as a problem?
- A: Developmental resolution of nocturnal enuresis occurs at a range of ages, and in almost all cases, the enuresis resolves spontaneously. The most important historical point is for whom is the enuresis a problem. If the child is not affected by the enuresis, and it is only the parents who desire a cure, the important intervention is to educate them on the natural history of the problem and to let them know about the available interventions and their success rates, for when the child desires a cure.
- Q: Are there any other interventions available for use only on sleep-out nights?
- A: One helpful tip is to allow the child to take a sleeping bag with him or her on sleep-outs. Inside the sleeping bag is a pull-up. When the child gets into the sleeping bag, he or she can change into the pull-up without anyone knowing. In the morning, the child puts his or her underwear back on, leaving the damp pull-up in the sleeping bag; the parent can take it out when the child gets home.

EOSINOPHILIC ESOPHAGITIS

James P. Franciosi

Chris A. Liacouras

BASICS

DESCRIPTION

- Eosinophilic esophagitis (EoE) is clinical, pathologic diagnosis characterized by a localized eosinophilic inflammation of the esophagus.
- Esophageal endoscopic biopsies are required to establish the diagnosis.
- On endoscopic mucosal biopsies, EoE is defined as the presence of at least 15 eosinophils per high-powered field isolated to the esophagus that does not respond to acid blockade medication or with a normal pH/impedance probe test.
- EoE has been associated with variants at chromosome 5q22.

EPIDEMIOLOGY

The incidence and prevalence of EoE in children 0–19 years of age is thought to be respectively 1 and 10 per 10,000 children

PATHOPHYSIOLOGY

The pathophysiology EoE is unknown; however, it has been linked to an allergic response to food antigens that does not follow a typical IgE mediated pattern.

DIAGNOSIS

- Symptoms can be similar to gastroesophageal reflux (GERD).
- Typically occurs in toddlers and older children, and is considered distinct from infant milk protein allergy:
 - Vomiting
 - Regurgitation
 - Dysphagia
 - Nausea
 - Epigastric pain
 - Heartburn
 - Chest pain
 - Esophageal food impaction
 - Irritability/feeding difficulties
 - Nighttime cough
 - Abdominal pain
- Complications that can occur with EoE include:
 - Failure to thrive
 - Malnutrition
 - Feeding intolerance
 - Esophageal strictures
 - Hiatal hernia
 - Small-caliber esophagus
 - Esophageal perforation
 - Esophageal fungal or viral superinfection

ALERT

Any patient who is being considered for surgical correction of gastroesophageal reflux (fundoplication) should first be evaluated endoscopically for EoE to prevent unnecessary surgery.

HISTORY

- Eosinophilic Esophagitis EoE in the infant and younger child:
 - Irritability
 - Weight
 - Vomiting
 - Feeding difficulties
 - Personal or family history of atopic disease (asthma, allergic rhinitis, eczema)
- Special questions:
 - Personal or family history of atopic disease?
 - Family history of EoE, dysphagia, severe GERD, esophageal food impactions or dilations?
 - No relief/response to acid blockade medication (minimum of 6–8 weeks)?
- EoE in the older child and adolescent:
 - Heartburn
 - Nausea
 - Vomiting
 - Epigastric pain
- EoE should be considered in any child presenting with dysphagia or food impaction, particular foods avoided or difficulty with eating, personal and family history of atopic disease, and food allergy and esophageal food impaction or dilation.
- Special questions:
 - Personal or family history of atopic disease?
 - Family history of EoE?
 - No relief/response to acid blockade medication?
 - Slow eater? Does the child avoid specific foods?
 - Any sensation of food sticking or difficulty swallowing?
 - Personal or family history of esophageal food impaction?

PHYSICAL EXAM

- Typically normal
- Growth failure (rare, occurs if appetite decreased significantly)
- Allergic shiners, reactive airway disease
- Eczema

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other

- Upper endoscopy (esophagoduodenoscopy, EGD):
 - The gold standard for diagnosis of eosinophilic esophagitis. Typically performed after a trial of acid blockade medication for 6–8 weeks.
 - Endoscopic mucosal biopsies should be obtained from the proximal and distal esophagus (minimum of 2 from each location), the stomach and duodenum. A pathologist who has experience with EoE should examine the mucosal biopsies for the presence of ≥ 15 eosinophils per high-powered field isolated to the esophagus.
- Upper GI series radiography:
 - Typically performed before endoscopy to exclude other etiologies of vomiting. May demonstrate esophageal stricture, corrugated esophagus, foreshortened esophagus, hiatal hernia, a small caliber esophagus, or esophageal perforation. However, none of these findings is specific to EoE.
- pH/Impedance probe:
 - Should be normal in patients with EoE. Considered a gold standard for evaluation of acid reflux disease, but of limited role in the evaluation of EoE
- Blood tests:
 - Peripheral eosinophilia is present in <50% of patients. Currently, there are no widely available serum markers for EoE.
- Food allergy testing:
 - Radio-allergosorbent test (RAST): Serum testing for food specific IgE antibodies; low sensitivity, limited role
 - Skin testing: Percutaneous prick puncture testing for food-specific IgE-mediated reactions
 - Patch testing (atopy patch testing): Allergen in prolonged contact with the skin in patches with the same concentration of food that is ingested
 - Tests for food-specific non-IgE-mediated reactions
 - Food allergy testing is typically only performed after endoscopic confirmation of EoE. Causative food antigens can be identified in 70% of patients through skin prick and patch testing. Although EoE is considered a mixed IgE- and non-IgE-mediated disease, most reactions occur through non-IgE-mediated pathways.

DIFFERENTIAL DIAGNOSIS

- GERD
- Inflammatory bowel disease
- Eosinophilic gastroenteritis
- Celiac disease
- Parasitic infection
- Connective tissue disease
- Drug allergy
- Hypereosinophilic syndrome
- Autoimmune enteropathy
- Candida esophagitis
- Viral esophagitis (herpes or CMV)
- Should exclude other causes of vomiting, failure to thrive

TREATMENT

MEDICATION (DRUGS)

- Fluticasone propionate:
 - A topical or ingested steroid that is an alternative to dietary therapy. Aerosolized fluticasone spray is swallowed instead of being inhaled. Patients do not eat, drink, or rinse their mouth for 30 minutes after using this medication. Achieves histologic remission in >50% of patients. However, with discontinuation of the medication, almost all patients relapse. Reported side effects include esophageal candidiasis, epistaxis, and dry mouth. Long-term effects on growth, bone health, and esophageal fibrosis currently not known. Recommended doses are 110–220 μg (swallowed) b.i.d. for children <6 years of age, and 440–880 μg b.i.d. for children >6 years of age.
- Oral viscous budesonide (OVB):
 - An equally effective alternative swallowed steroid administered in a slurry formulation that is made using Splenda (5 packets/500 mcg) to improve taste and consistency for topical esophageal administration. Pediatric randomized, double-blind, placebo-controlled trial using OVB showed 86.7% histologic response rate in the OVB group compared to none of the controls. Symptom scores were also significantly improved. Dosing of the budesonide was 1 and 2 mg divided b.i.d. based on the respective height classification of <or >5 feet.
- Corticosteroids:
 - An effective treatment for EoE, but symptoms and histologic eosinophilia return when these medications are discontinued. Given the extensive side-effect profile, long-term corticosteroids are not considered an ideal treatment option for EoE. Short courses of oral steroids may have a role in treating emergent EoE patients who present with significant esophageal strictures, severe weight loss, or the inability to eat most foods/liquids. The recommended dose of prednisone is 1–2 mg/kg/d (maximum 60 mg/d).

ADDITIONAL TREATMENT

General Measures

- Several modes of dietary and medication therapy are available depending on disease presentation and therapy.
- Proton pump inhibitors (PPI):
 - 2007 Consensus Guidelines for EoE define this condition as persistent clinicopathologic findings consistent with EoE despite 6–8 weeks of PPI therapy. Retrospective data and adult studies suggest a PPI response rate of 25–40%. No pediatric clinical trials have been conducted to date.

COMPLEMENTARY & ALTERNATIVE THERAPIES

- Endoscopic therapy: Esophageal dilatation is a useful therapy for EoE patients with fixed esophageal strictures. Care must be taken when performing dilatation as significant esophageal mucosal lacerations, tearing, and perforation have been reported. Whenever possible, diagnostic endoscopy followed by a trial of dietary or steroid therapy is recommended prior to esophageal stricture dilation.
- Patients presenting with esophageal food impaction should have the food bolus removed endoscopically, and esophageal biopsies should be obtained to investigate for EoE.

ONGOING CARE

DIET

- Elimination diet has been shown to be effective for treatment of eosinophilic esophagitis. Whenever possible, specific allergen testing (skin and patch testing) should be performed to identify and remove specific causative food antigens. However, food allergen testing may be falsely negative, and empiric removal of highly antigenic foods is reported to be successful in >75% of children. The 6 foods that are considered the most antigenic for EoE include milk, soy, nuts, egg, wheat, and fish/shellfish.
- Some patients require an elemental diet. Patients are allowed to drink only water and an amino acid-based formula until the esophageal eosinophilia resolves; subsequently, food is gradually reintroduced. This method frequently requires nasogastric tube feeding as these formulas are often unpalatable. Success with the elemental diet occurs in >95% of patients.

ICD10

K20.0 Eosinophilic esophagitis

FAQ

- Q: Is EoE considered a life-long disease or will it resolve over time?
- A: The long-term outcome for children with EoE is currently unknown. Currently, the natural history of the disease suggests that EoE is a chronic disease that can be controlled with diet or medical therapy.
- Q: Is there any harm in not treating asymptomatic patients with ongoing histologic EoE?
- A: There is much debate about the progression of untreated EoE. The concerns are that, if left untreated, ongoing esophageal eosinophilic may lead to dysphagia, strictures, and esophageal fibrosis.
- Q: Is EoE a genetic or environmental disease?
- A: EoE is more common white males, >50% of patients have atopic disease (such as asthma, eczema, or allergic rhinitis), and 30–50% of patients with EoE have a family history of EoE or atopic disease.
- Q: Is the incidence of EoE increasing?
- A: There has been a significant rise in the number of pediatric and adult EoE diagnoses over the last 5 years. The most likely reason is an improved recognition of this disease among gastroenterologists, allergists, and pathologists. A rising incidence of new cases may also be occurring that is similar to the increase seen in other allergic disorders.

EPIGLOTTITIS

Mark L. Bagarazzi

BASICS

DESCRIPTION

Acute life-threatening bacterial infection consisting of cellulitis and edema of the epiglottis, aryepiglottic folds, arytenoids, and hypopharynx, resulting in narrowing of the glottic opening.

EPIDEMIOLOGY

Disease due to *Haemophilus influenzae* type B occurs most often between the ages of 2 and 7 years (overall range: infancy to adulthood).

- Epiglottitis and other invasive disease secondary to *H. influenzae* have been reduced by 99% since the introduction of the conjugate vaccines in 1989 (approved at 15 months) and 1990 (approved at 2, 4, and 6 months).
- Nontypeable *H. influenzae* now appears to be a more common cause of invasive disease than type B.
- Year-round occurrence
- Affects males and females equally
- All geographic areas
- Rare in populations in which the peak incidence of meningitis is shifted toward infancy (e.g., Alaskan Eskimos, Native Americans)
- Occasionally secondary cases in households or child care centers
- May be more frequent in children with sickle cell anemia, asplenia, immunoglobulin defects, or hematologic malignancies (e.g., leukemia)
- Disease due to *Streptococcus pyogenes* occurs most often in early school-age children during the winter and early spring and has now been seen as a complication of varicella infection.

Incidence

- Incidence of epiglottitis due to any organism has declined substantially (e.g., 20.9/100,000 per year to 0.9/100,000 per year from 1987 to 1996 in Sweden)
- Incidence rate in children 18 and younger is also on the decline in the US based on data through 2006, although overall rates are steady. Rates in infants may be on the rise.

GENERAL PREVENTION

- Rifampin: 20 mg/kg/d in single dose for 4 days to eradicate *H. influenzae* type B colonization (see "Control measures").
- Universal immunization with *H. influenzae* type B capsular polysaccharide conjugate vaccines at 2, 4, and 6 months, with booster at 12 to 18 months
- Isolation of hospitalized patient: Droplet precautions should be continued for at least 24 hours from the initiation of effective therapy.
- Control measures: Prophylaxis for *H. influenzae* type B index case and susceptible children in household and child care setting, and intimate contacts

PATHOPHYSIOLOGY

Erythema and edema of the uvula, aryepiglottic folds, arytenoids, epiglottis, and vocal cords include an exudate rich in neutrophils and fibrin, which usually proceeds to organization and fibrous scarring.

ETIOLOGY

- *H. influenzae*, nontypeable and type B (accounted for >90% of cases prior to the introduction of HiB vaccine)
- *Staphylococcus aureus*
- *Streptococcus pneumoniae*
- *S. pyogenes* (group A β -hemolytic streptococcus)
- Group C and G β -hemolytic streptococcus (rare)
- *Candida albicans* may be an etiologic agent in immunocompromised patients.
- *Pasteurella multocida* has been implicated in a few cases after exposure to nasopharyngeal secretions from a cat.
- There have been recent reports of epiglottitis due to *Neisseria meningitidis*.
- Other rare isolates: *Moraxella catarrhalis*, *Klebsiella pneumoniae*, *Pseudomonas* species
- The inhaled anesthetic sevoflurane has been implicated in a few cases of epiglottitis.

DIAGNOSIS

HISTORY

- Abrupt onset of high fever (39–40°C), sore throat, and dysphagia
- Very limited or no prodrome of mild upper respiratory tract infection (URI)
- "Hot potato" voice
- Rapid onset of toxicity and respiratory distress
- Cough and hoarseness are late symptoms, if they occur at all.
- Time from onset of symptoms to presentation with progressive respiratory distress is generally <12 hours.
- Immunization against *H. influenzae* type B
- Child's preferred way of sitting or positioning himself or herself (i.e., sitting upright, leaning forward with chin hyperextended)
- Exposure to cats

PHYSICAL EXAM

- Extremely anxious appearance
- Child prefers to remain sitting up.
- Child often leaning forward with chin hyperextended to maintain airway in a "tripod" position
- Slow and labored respiratory effort
- Drooling is seen as a manifestation of dysphagia.
- Inspiratory stridor, retractions, and late cyanosis
- Diagnosis can be suspected on history and observation of child's appearance alone.
- Do not attempt to examine the throat if epiglottitis is a serious consideration.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Complete blood count: Increased white blood cell count with left shift
- Cultures of blood (positive in up to 90%) and epiglottis (performed only in the operating room): May be positive for the causative organism

Imaging

Lateral neck radiography: Characteristic "thumb sign" of edematous epiglottitis, with narrowing of the posterior airway and ballooning of the hypopharynx (should not be performed until airway team is in place)

ALERT

- A radiograph is indicated only when the diagnosis is in doubt and should not delay airway management.
- Avoid blood collection until the airway has been secured so as not to upset the child unnecessarily.
- Ensure appropriate airway management prior to any other interventions, including laryngeal exam, radiographs, and laboratory studies.
- Finding of stridor in a child with varicella infection may indicate epiglottitis due to *S. pyogenes* (group A β -hemolytic streptococcus).

DIFFERENTIAL DIAGNOSIS

- Viral laryngotracheobronchitis (croup) with or without secondary bacterial tracheitis
- Severe parainfluenza or influenza infection
- Uvulitis
- Peritonsillar, retropharyngeal, or lingual abscess
- Foreign body aspiration in a child with URI
- URI, including croup, in a child with a congenital or acquired airway problem (e.g., premature infant with subglottic stenosis, laryngeal web, vascular ring, tracheal stenosis)
- Hereditary angioedema (deficiency of complement C1 esterase inhibitor) can present with edema of the airway including the epiglottis.
- Diphtheria: Rare in US
- Laryngeal infections, including laryngeal tuberculosis

TREATMENT

MEDICATION (DRUGS)

First Line

- Empiric antibiotic coverage to include gram-positive cocci and β -lactamase-producing *H. influenzae* type B:
 - Cefuroxime: 150 mg/kg/d divided q8h
 - Ampicillin/Sulbactam: 200 mg/kg/d divided q6h
- Duration of therapy: 7–10 days for all but staphylococcal disease (14–21 days)
- Switch may be made to oral medication after extubation and resumption of feeding.

Second Line

- Chloramphenicol: 75–100 mg/kg/d divided q6h
- Ampicillin: 100–200 mg/kg/d divided q6h for non-β-lactamase-producing *H. influenzae* type B (~80% of isolates)
- Penicillin: 100,000–200,000 U/kg/d divided q4h to q6h for streptococcal disease
- Oxacillin: 100–200 mg/kg/d for staphylococcal disease

ISSUES FOR REFERRAL

Airway should be secured by clinician most skilled in airway management (e.g., otolaryngologist, anesthesiologist) prior to any attempt to transport a child with expected epiglottitis

IN-PATIENT CONSIDERATIONS

Initial Stabilization

- Airway management: Maintain child upright, never supine. Personnel experienced in airway management should accompany the child at all times, including during transport and in radiology.
- Rapid assembly of a team, which should include an anesthesiologist, an otolaryngologist, and a pediatrician, if possible. In a recent review of almost 3 million pediatric discharges from 36 states, ~12% of cases of epiglottitis in children required an artificial airway, and 63% of the children were <2 years old.
- Allow the child to assume his or her most comfortable position (usually in the mother’s arms/lap).
- Oxygen by mask or blown by face
- Transport to operating room as soon as possible for anesthesia and intubation, followed by positive pressure ventilation as necessary.
- Institute intravenous catheterization and blood collection, and culturing of epiglottis only after the airway is secured.
- Perform emergent cricothyrotomy if obstruction occurs prior to controlled airway management.
- Use fluid resuscitation in cases of septic shock.

Admission Criteria

Admit all children with suspicion of epiglottitis for airway management.

 **ONGOING CARE**

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Extubation is usually possible within 24–48 hours. Criteria include decreased erythema and edema of the epiglottis on direct inspection and development of an air leak around the endotracheal tube.
- Defervescence is usually prompt after initiation of appropriate antimicrobial therapy.

PROGNOSIS

- Mortality is estimated to be 8% in hospital series.
- Virtually all cases in which arrest occurred prior to transfer to tertiary center resulted in fatality.

COMPLICATIONS

- Without prompt medical intervention: Complete airway obstruction leading to respiratory arrest, hypoxia, and death
- Necrotizing cervical fasciitis (rarely)
- Therapeutic complications:
 - Aspiration
 - Endotracheal tube dislodgment and extubation
 - Tracheal erosion or irritation
 - Pneumomediastinum
 - Pneumothorax
 - Pulmonary edema
- Complications of *H. influenzae* type B bacteremia:
 - Septic shock
 - Pneumonia
 - Cervical lymphadenopathy
 - Rarely, arthritis and pericarditis

- J05.10 Acute epiglottitis without obstruction
 - J05.11 Acute epiglottitis with obstruction

FAQ

- Q: What is the incidence of epiglottitis since the introduction of conjugate vaccines against *H. influenzae* type B?
- A: Because *H. influenzae* type B caused 90% of epiglottitis and the incidence of all invasive disease due to *H. influenzae* type B has decreased by 99% in children <5 years of age, it is estimated that the incidence of epiglottitis has been reduced by more than 90%.
- Q: Have there been reports of epiglottitis caused by *H. influenzae* type B after complete vaccination?
- A: Yes. Several cases due to *H. influenzae* type B have been reported in the US and abroad after partial and complete vaccination. Therefore, even a history of having received a full vaccination series does not eliminate the possibility of HiB-associated epiglottitis.
- Q: How many cases of invasive disease due to *H. influenzae* type B occur in children with inadequate vaccination?
- A: During 1994 and 1995, 47% of children <4 years of age were too young (aged 5 months or younger) to have completed a primary series for HiB vaccine:
 - Among children old enough to have been fully vaccinated, 63% of those developing disease were undervaccinated, and the remainder (37%) had completed a primary series in which vaccine failed.
 - In a recent report from Australia, 34 of 412 cases (8%) of invasive HiB disease (including epiglottitis) were reported as vaccine failures.
 - Therefore, HiB cannot be ruled out as a cause of epiglottitis in a fully vaccinated child, although the overwhelming majority of cases occur in unvaccinated children.
 - An increase in cases of epiglottitis due to *H. influenzae* type B has been reported in relation to dropping immunization rates with a subsequent fall in cases resulting from improved vaccination rates.
- Q: Should a fully vaccinated child who develops invasive disease due to *H. influenzae* type B be tested for an underlying immunodeficiency?
- A: Probably. In one study, about 1/3 of children diagnosed with invasive disease due to *H. influenzae* type B were found to have a previously undiagnosed immunoglobulin deficiency.
- Q: Can epiglottitis recur?
- A: Yes, but rarely.
- Q: Are corticosteroids of any value in the management of epiglottitis?
- A: There appears to be no benefit.

EPSTEIN–BARR VIRUS (INFECTIOUS MONONUCLEOSIS)

Jessica Newman

Jason Newland

Kevin C. Osterhoudt (5th edition)

BASICS

DESCRIPTION

A double-stranded DNA virus implicated as the causative agent for infectious mononucleosis by an infected laboratory worker in 1968

GENERAL PREVENTION

- No vaccine is clinically available.
- Standard precautions should be utilized in the hospitalized patient.
- Restriction of intimate contact with immunosuppressed individuals may be advisable.
- Patients with recent Epstein–Barr virus (EBV) infection, either proven or suspected, should not donate blood or solid organs.

EPIDEMIOLOGY

- Worldwide distribution
- Humans are the only known reservoir.
- Transmission occurs through saliva and, occasionally, via blood transfusions
- Incubation period is 4–7 weeks.
- Antibodies to EBV are almost universally present in adult populations.
- Areas with a high population density or low socioeconomic status usually become primarily infected within the first 3 years of life.

Incidence

In developed countries, acquisition of EBV is biphasic:

- Initial peak in incidence occurs before the age of 5 years.
- Second peak occurs during adolescence, coinciding with an increased frequency of intimate oral contacts.

Prevalence

90–95% of adults have demonstrable EBV titers

PATHOPHYSIOLOGY

- Replicates initially in the oropharyngeal epithelium
- Selective infection of B lymphocytes occurs.
- The clinical syndrome of infectious mononucleosis results from proliferation of cells in the tonsils, lymph nodes, and spleen.
- Nonspecific humoral immune responses include the formation of heterophile antibodies and autoantibodies.
- Specific antibodies to EBV antigens are produced.
- Despite humoral responses, cellular immunity is responsible for controlling EBV infection.
- Latent, lifelong infection of B lymphocytes occurs.
- Latent virus may be reactivated during periods of immunosuppression.

COMMONLY ASSOCIATED CONDITIONS

- Subclinical infection:
 - Most EBV infections in children, and even in adolescents, are clinically inapparent.
 - Mild, nonspecific symptoms may include coryza, diarrhea, and/or fever.
 - Immunologic seroconversion does occur.
- Infectious mononucleosis (“glandular fever”): Most commonly observed with late primary acquisition of EBV. The classically defined illness is characterized by:
 - Fatigue
 - Malaise
 - Fever
 - Tonsillopharyngitis (often exudative)
 - Lymphadenopathy
 - Splenomegaly
 - Usually associated with increased numbers of atypical lymphocytes in the peripheral blood
- Rare illnesses of the nervous system have been reported including:
 - Guillain–Barré syndrome
 - Bell palsy
 - Aseptic meningitis
 - Meningoencephalitis
 - Peripheral and/or optic neuritis
- Hematologic complications have been reported in association with EBV:
 - Aplastic anemia
 - Hemolytic anemia
 - Agranulocytosis
 - Hemophagocytic syndrome
- Other illnesses associated with EBV in case reports include:
 - Hemolytic–uremic syndrome
 - Hepatitis
 - Pancreatitis
 - Myocarditis
 - Mesenteric adenitis
 - Orchitis
 - Genital ulcerative disease
- Lymphoproliferative disorders:
 - Burkitt lymphoma
 - Nasopharyngeal carcinoma
 - Lymphoma and non-Hodgkin lymphoma (in immunocompromised children)
 - Lymphomatoid granulomatosis
 - Posttransplant lymphoproliferative disorders (PTLD)
 - X-linked lymphoproliferative disease (Duncan disease)

DIAGNOSIS

HISTORY

- A prodrome may occur:
 - Most often, lasts 3–5 days
 - Malaise, fatigue, with or without fever
- In the acute phase, the following features are common:
 - Fever: Begins abruptly, lasts 1–2 weeks
 - Fatigue
 - Malaise
 - Anorexia
 - Sore throat
 - “Swollen glands”
 - Rash; more common with ampicillin administration
- Young children are more likely to have rash or abdominal pain.

PHYSICAL EXAM

- Tonsillopharyngitis:
 - May be exudative and mimic streptococcal pharyngitis
 - Often accompanied by palatal petechiae
- Lymphadenopathy:
 - Occurs in 90%
 - Most prominent in cervical chains
 - May be diffuse
 - Usually nontender, nonerythematous, and discrete
- Hepatosplenomegaly:
 - Splenomegaly occurs in more than half the cases
 - Even if not palpable, splenomegaly may be demonstrated on ultrasound
 - Most prominent in 2nd to 4th week of illness
 - Hepatomegaly is less common

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Complete blood count with differential:
 - Leukocyte count up to 20,000/mm³
 - Lymphocytosis
 - Atypical lymphocytes often constitute >10% of total leukocyte count.
 - Thrombocytopenia may occur.
 - False-positives: Atypical lymphocyte counts >10% of the total leukocyte count also occur with cytomegalovirus and toxoplasmosis infections.
- Liver enzymes:
 - Mild hepatitis is often found.
 - Jaundice is rare.
- “Monospot” (mononucleosis rapid slide agglutination test for heterophile antibodies):
 - Detects heterophile antibodies (nonspecific IgM antibodies to unrelated antigens)
 - Appears in first 2 weeks of illness, usually slow decline over 6 months
 - Often negative in children <4 years of age
 - Detects 85% of cases in adolescents and adults
 - False-positives: Infrequent; heterophile antibodies are also produced in serum sickness and neoplastic processes; heterophile antibodies may persist for months after acute infection and be indicative of past illness.

- EBV serology:
 - Usually reserved for heterophile-negative patients or children <4 years of age when strong clinical suspicion persists
 - Antibodies detected by indirect immunofluorescence or enzyme-linked immunosorbent assay techniques
 - Acute or past infection can usually be detected and differentiated.
- Other technology:
 - Tissue culture of EBV is difficult and, therefore, not clinically useful.
 - Polymerase chain reaction (PCR) may detect EBV genetic material.
 - Real-time PCR may quantify the amount of EBV genome present, which is useful in patients with PTLD.

ALERT

- Heterophile antibodies may not appear early in the illness.
- Up to 10% of patients with acute EBV infection may have no heterophile response 3 weeks into the illness.
- The heterophile response is less common in infants and children and should not be used in children <4 years of age.

DIFFERENTIAL DIAGNOSIS

- Infectious:
 - Group A streptococcus
 - Adenovirus
 - Cytomegalovirus
 - *Toxoplasma gondii*
 - Human herpes virus-6
 - *Mycoplasma pneumoniae*
 - Human immunodeficiency virus
 - Rubella
 - Diphtheria
 - Viral hepatitis (A,B,C)
- Noninfectious:
 - Leukemia/Lymphoma

TREATMENT

MEDICATION (DRUGS)

- Acetaminophen or ibuprofen reduces fever and provides analgesia.
- Corticosteroids (prednisone 1 mg/kg/d—maximum of 20 mg/d) may reduce swelling of lymphoid tissues (see “FAQ”):
 - Indicated for patients with impending airway obstruction
 - May be considered for patients with severe tonsillopharyngitis requiring IV hydration
 - May be considered for patients with rare, life-threatening manifestations of EBV infection, such as hepatitis, aplastic anemia, and central nervous system dysfunction
 - 7-day treatment followed by tapering
- Acyclovir has not been shown to provide clinical benefit; sometimes, used in cases of active replicating EBV in posttransplant situations
- Patients with PTLD should have immunosuppression reduced
- Advise avoidance of contact sports until resolution of symptoms and no further splenomegaly

IN-PATIENT CONSIDERATIONS

Admission Criteria

- Respiratory distress secondary to airway obstruction
- Dehydration secondary to severe pharyngitis and poor oral intake

Discharge Criteria

- Resolved airway obstruction
- Good oral intake

ISSUES-FOR-REFERRAL

- PTLD
- EBV in immunocompromised host
- EBV associated lymphoproliferative disorders
- Considering steroid use as treatment

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Immunocompetent individuals usually recover uneventfully in 1–4 weeks.
- Recovery is often biphasic, with a worsening of symptoms after a period of improvement.
- Splenomegaly may persist for weeks after primary infection (see “FAQ”).
- Fatigue may persist months after recovery.

PROGNOSIS

- Most patients with primary EBV infection will recover uneventfully in 1–4 weeks.
- Long-lasting immunity generally ensues.
- Prognosis of patients with unusual manifestations of EBV infection depends on the severity of the illness and the organ system involved.
- Patients with inherited or acquired immunodeficiency are at higher risk of complications and neoplasms.

COMPLICATIONS

- Dehydration:
 - Severe pharyngitis often limits fluid intake.
 - Most common problem requiring hospitalization
- Antibiotic-induced rash:
 - Morbilliform in appearance
 - Most common after administration of ampicillin or amoxicillin
 - Rare association with penicillin
 - Usually benign, resolves with discontinuation of the aminopenicillin
- Splenic rupture:
 - Incidence of ~1 in 1,000 patients
 - More common in males
 - 50% of the cases of splenic rupture are spontaneous; 50% follow blunt trauma,
- Airway obstruction: May result from massive lymphoid hyperplasia and mucosal edema

CODES

ICD9
075 Infectious mononucleosis

ICD10

- B27.90 Infectious mononucleosis, unspecified without complication
- B27.92 Infectious mononucleosis, unspecified with meningitis
- B27.99 Infectious mononucleosis, unsp with other complication

FAQ

- Q: Should all patients with infectious mononucleosis be given corticosteroids?
- A: Although children may feel tired, weak, and ill, symptomatic EBV infection is most often self-limited and requires only symptomatic care.
- Long-term effects from the use of steroids to treat EBV are not known.
- EBV has been linked to certain lymphoproliferative disorders, and theoretic risks to modulating the host immune response with corticosteroids have been proposed.
- Q: How long after infectious mononucleosis may a patient return to athletic activity?
- A: More than half of patients with “mono” will have a boggy, enlarged spleen, which is prone to rupture even if it is not palpable.
- All athletic activity should be restricted until no evidence exists for a clinically enlarged or tender spleen. If this criterion is met, and the patient feels subjectively better, light (noncontact) activities may be resumed.
- Return to contact sports is not advised until at least 4–6 weeks after resolution of all signs and symptoms of illness.
- Some experts recommend ultrasound study of the spleen before a return to heavy contact sports such as rugby, football, lacrosse, and hockey.

ERYTHEMA MULTIFORME

James Treat

Albert C. Yan (5th edition)

BASICS

DESCRIPTION

- An acute self-limited cutaneous eruption with many different or multiform lesions
- Characterized classically as a target or iris lesion but may appear as erythematous macules, papules, vesicles, and bullae and can be associated with mucosal involvement
- There are many triggers of erythema multiforme (EM), which is thought to encompass a spectrum of disease from relatively mild disease (EM minor) to severe forms with more severe mucosal surface involved (EM major).
- Although they can both present with targetoid skin lesions, many authors now feel Stevens Johnson Syndrome (SJS) and toxic epidermolysis (TEN) are separate entities from typical erythema multiforme. SJS and TEN involve ≥ 2 mucous membranes, and extensive skin blistering or sloughing ($< 10\%$ is SJS, $10\text{--}30\%$ is SJS-TEN overlap and $> 30\%$ is TEN). SJS and TEN have significant morbidity and mortality, whereas EM is typically self-limited.

EPIDEMIOLOGY

- Believed by some to occur more frequently in spring and summer, with the more severe form of EM major occurring in winter
- Occurs predominantly in young adults

Incidence

Male = Female (some studies suggest a slightly higher incidence of EM minor in women)

Prevalence

Seen in $\sim 1\%$ of all dermatology patients

RISK FACTORS

Genetics

Emerging evidence shows strong genetic predisposition for EM in patients with certain HLA subtypes.

ETIOLOGY

- The major causes of EM, which is thought to be an immune-mediated reaction, include drugs such as sulfa, penicillin, and phenytoin and infections such as herpes simplex virus and *Mycoplasma*.
- There are a host of other etiologic factors, including exposure to various chemicals and tumors. The eruption usually occurs 1–2 weeks after initial exposure.
- Often the causative factor is not identified.
- Recurrent EM is generally secondary to herpes simplex virus.

DIAGNOSIS

HISTORY

- Cutaneous findings are sometimes preceded by a prodrome with fever and malaise.
- A careful drug and exposure history, as well as any signs or symptoms of infection or herpetic lesions, may reveal the cause.
- Inquire in detail about the patient's drug history, OTC preparations, and signs or symptoms of infection or herpetic lesions.

PHYSICAL EXAM

- EM classically appears as target lesions characterized by a dark, dusky center surrounded by a pale zone and then a zone of erythema:
 - The lesions are typically acrally distributed.
- Lesions occur in many forms and may appear as red macules, papules, urticarial lesions, or vesicles and bullae.
- Oral involvement is typically seen.
- Mucosal involvement with superficial denudation may also occur in the eyes, nasopharyngeal mucosal, or anogenital region.

DIAGNOSTIC TESTS & INTERPRETATION

No diagnostic laboratory tests; however, biopsy is often helpful, and other tests may help identify a cause.

Lab

- A WBC count with differential, looking for eosinophilia, may help identify a drug as causative.
- Direct fluorescent antibody testing, polymerase chain reaction, or cultures to evaluate for herpes or chest radiographic studies to evaluate for pneumonia or infectious cause of EM
- Cold agglutinins, serology, and polymerase chain reaction associated with *Mycoplasma*
- Erythrocyte sedimentation rate may be elevated, but is nonspecific.

Diagnostic Procedures/Other

Biopsy of lesion not usually needed

Pathological Findings

- Vary according to the lesion examined:
- Biopsy reveals necrosis of keratinocytes to varying degrees, depending on the clinical lesion biopsied
- Moderate to severe papillary dermal edema with mild to moderate perivascular dermal infiltrate composed predominantly of mononuclear cells and also some eosinophils (particularly if drug related)
- Subepidermal blistering may be seen.
- Extravasated blood cells are found, but there is no evidence of vasculitis.
- Hydropic degeneration of the basement membrane also may be seen, as may epidermal spongiosis.

DIFFERENTIAL DIAGNOSIS

Classic presentation with targetoid lesions and mucosal involvement is generally not a diagnostic challenge; however, given the many forms of presentation, the diagnosis of EM may be difficult. The differential diagnosis may be extensive depending on the presentation and includes:

- Viral exanthem
- Bullous impetigo
- Staphylococcal scalded-skin syndrome

- Bullous pemphigoid
- Urticaria
- Urticarial vasculitis
- Systemic lupus erythematosus
- Serum sickness
- Pemphigus vulgaris
- Secondary syphilis
- Chickenpox
- Rocky Mountain spotted fever
- Acute neutrophilic dermatosis
- Lyme disease
- Fixed drug eruption

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Mild forms:
 - Oral lesions are often painful, and oral preparations to swish and spit, made of diphenhydramine or viscous lidocaine, may provide relief.
 - Treatment of the underlying process is helpful (eg, acyclovir for herpes simplex virus–associated cases).
- EM major:
 - Supportive care, ophthalmology consultation, monitoring of fluid and electrolyte balance, local wound care, and vigilant observation for infection are necessary.
 - The use of systemic steroids is controversial, but when helpful, they are given early in the course of disease for ~2 weeks when there is no contraindication, such as infection.

IN-PATIENT CONSIDERATIONS

Initial Stabilization

- Mild EM: Resolves spontaneously without scarring and require only supportive therapy, including antihistamine or topical steroid for pruritus associated with the lesions
- EM major may be life-threatening and may require hospitalization.
- SJS/TEN: Higher associated mortality (than EM) is often secondary to infection given the larger body surface area involvement; care is ideally at a burn center, with careful attention to infection and to fluids and electrolytes.

Admission Criteria

Severe mucositis with inability to adequately hydrate.

ONGOING CARE

PROGNOSIS

- Mild forms of EM are acute and self-limited, with lesions resolving in 2–4 weeks with postinflammatory hyperpigmentation or hypopigmentation.
- Sequelae owing to mucosal scarring may occur.
- When recurrent, EM is often associated with herpes simplex virus.

COMPLICATIONS

- EM minor is generally self-limited, with rare complications.
- In EM major, mucosal involvement may lead to stricture formation of the urethra, trachea, and esophagus, as well as conjunctivitis, corneal erosions, and rarely, blindness.

ERYTHEMA NODOSUM

James R. Treat
Albert C. Yan (5th edition)

BASICS

DESCRIPTION

Delayed, cell-mediated hypersensitivity panniculitis characterized by red, tender, nodular lesions that are usually seen on the pretibial surface of the legs and occasionally on other areas of the skin where subcutaneous fat is present.

EPIDEMIOLOGY

- Girls are affected more often than boys.
- Most cases are seen in the 3rd decade, but not uncommon after age 10.

Incidence

Greatest seasonal incidence in spring and fall

PATHOPHYSIOLOGY

- Septal panniculitis: Lymphocytic perivascular infiltrate in the dermis; lymphocytes and neutrophils in the fibrous septa in the subcutaneous fat
- In older lesions, histiocytes, giant cells, and occasionally plasma cells are seen on histopathology.
- No fat cell destruction or vasculitis is present.

ETIOLOGY

- Thought to be a result of a host hypersensitivity immune response to circulating immune complexes secondary to infectious and/or inflammatory stimuli, which then results in chronic injury to the blood vessels of the reticular dermis and subcutaneous fat
- There are many associated triggering/underlying diseases:
 - Infectious:
 - Bacterial: Streptococcal infection is the most common cause in children.
 - Other bacteria: Psittacosis, yersiniosis, lymphogranuloma venereum, cat-scratch disease, rickettsial diseases including conorii and tsutsugamushi.
 - Mycobacterial: Tuberculosis and atypical mycobacteria
 - Fungal: Histoplasmosis, coccidioidomycosis

- Systemic:
 - Sarcoidosis
 - Inflammatory bowel disease
 - Hodgkin disease
 - Behçet disease
- Pregnancy
- Medications: Oral contraceptives, sulfonamides, phenytoin, and halides

DIAGNOSIS

HISTORY

- In >50% of patients, a history of arthralgia is noted 2–8 weeks prior.
- Prodromal symptoms of fatigue/malaise or upper respiratory infection often proceed by 1–3 weeks.
- Patients often present with pain and tenderness of extremities, sometimes to the point of difficulty in ambulation.
- Special questions:
 - Recent streptococcal infection
 - Medication history (oral contraceptives, sulfonamides, iodides/bromides)
 - Last menses (erythema nodosum is seen in pregnancy)
 - History of diarrhea (inflammatory bowel disease or infectious diarrhea)
 - Tuberculosis exposure

PHYSICAL EXAM

- Red, often tender nodules on anterior lower legs, 2–6 cm in diameter, can also affect the extensor arms and face.
- Overlying skin is normal except for erythema.
- Initially, lesions are bright to deep red with palpable warmth.
- Later, lesions develop a brownish red or violaceous, bruise-like appearance.
- Smaller lesions are slope-shouldered nodules.
- Larger lesions are flat-topped plaques.

- Exam pearls:
 - Erythema nodosum never ulcerates or suppurates.
 - Palpation is very important to feel the painful nodules.
 - Usually, there are no more than 6 lesions at a time.
 - As a rule, both legs are affected.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Throat culture
- Antistreptolysin-O titer
- Purified protein derivative
- CBC
- ESR
- Stool culture, if history of diarrhea
- Serologic testing, if yersiniosis, rickettsial disease, histoplasmosis, or coccidioidomycosis suspected

Imaging

Chest radiographic study, if diagnosis is in doubt

Diagnostic Procedures/Other

Excisional biopsy specimen for histopathology and bacterial, mycobacterial, and fungal cultures is helpful but not always needed.

Pathological Findings

False-positives: Bilateral hilar adenopathy may also be seen with sarcoidosis, coccidioidomycosis, histoplasmosis, tuberculosis, streptococcal infection, or lymphomatosis.

DIFFERENTIAL DIAGNOSIS

- Infection:
 - Erysipelas/cellulitis
 - Superficial or deep thrombophlebitis
 - Erythema induratum (nodular vasculitis)
 - Deep fungal infection
 - Angiitis
 - Leprosy

- Environmental (poisons)
- Tumors
- Trauma: Accidental or from child abuse
- Bruise
- Palmoplantar hidradenitis
- Metabolic:
 - Panniculitis secondary to pancreatic disease
 - Congenital
- Immunologic:
 - Major insect bite reaction
 - Psychosocial (self-injection with foreign material)
- Sarcoidosis
- Polyarteritis nodosa
- Granuloma annulare
- Miscellaneous
- Weber-Christian (thighs and trunk) lesions may suppurate and heal with atrophy/localized depression.

TREATMENT

MEDICATION (DRUGS)

- Salicylates or other NSAIDs, such as ibuprofen, naproxen, or indomethacin
- Potassium iodide 300 mg PO t.i.d. for 3–4 weeks, especially for cases diagnosed early in course
- Corticosteroids are effective but rarely necessary:
 - Duration: 2–4 weeks

ADDITIONAL TREATMENT

General Measures

Bed rest and leg elevation

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- When to expect improvement:
 - Within 2–3 days
 - Return visit in 1 week
- Signs to watch for: If lesions recur after cessation of treatment, underlying infection may worsen as well.
- If atypical locations or exuberant or suppurative nodules are present, a biopsy is warranted to rule out a disseminated infection.

PROGNOSIS

- Most individual lesions will completely resolve in 10–14 days.
- In general, erythema nodosum resolves in 3–6 weeks with or without treatment unless the underlying cause is a chronic infection or systemic disorder.
- Aching of legs and swelling of ankles may persist for weeks; rarely, symptoms may persist for up to 2 years.
- In children, the recurrence rate is 4–10% and is often associated with repeated streptococcal infection.

CODES

ICD9

695.2 Erythema nodosum

ICD10

L52 Erythema nodosum

FAQ

- Q: Will the lesions leave a scar?
- A: Erythema nodosum virtually always heals without scarring.

EWING SARCOMA

Edward F. Attiyeh

BASICS

DESCRIPTION

- Represents a family of tumors including:
 - Ewing sarcoma of bone
 - Extrasosseous Ewing sarcoma (arises in soft tissue adjacent to bone)
 - Peripheral neuroectodermal tumor (PNET) of bone or soft tissue
- May develop in any bone of the body, with equal involvement of flat and long bones (unlike osteosarcoma, which arises more commonly in long bones):
 - ~25% have detectable metastases at diagnosis:
 - Lung
 - Bone
 - Bone marrow

EPIDEMIOLOGY

- 2nd most common malignant bone tumor of children and young adults
- More common in males than in females
- Associations (rare):
 - Skeletal anomalies (enchondroma, aneurysmal bone cyst)
 - Genitourinary anomalies (hypospadias, duplicated renal collecting system)

Incidence

- ~110 new cases are diagnosed in the US each year.
- Most (~65%) occur in the 2nd decade of life:
 - Rare under the age of 5 years
- 96% of cases occur in the white population:
 - Extremely rare in Asians and blacks

Prevalence

Accounts for ~2–5% of all childhood cancers

RISK FACTORS

Genetics

- Most cases occur sporadically.
- Not associated with familial cancer syndromes

PATHOPHYSIOLOGY

- One of the “small round blue cell” tumors of childhood
- Rearrangement of the EWS (Ewing Sarcoma) gene is detected in >95% of cases.
 - Usually (85%) through a t(11;22) translocation resulting in a fusion EWS-FLI1 protein
 - Other translocation partners include other members of the ETS transcription factor family such as ERG (21q; 10% of cases).
- A large soft tissue component is often present.
- Necrosis and hemorrhage are common.
- The PNET variant has more neural differentiation.

DIAGNOSIS

HISTORY

- Presenting symptoms and their frequency of occurrence:
 - Local pain (85%)
 - Local swelling (60%)
 - Fever (30%)
 - Paraplegia, back pain (2%)
- Systemic symptoms (fever, weight loss) are more common among patients with metastatic disease.
- Delay between 1st symptom and diagnosis is quite common; the duration of symptoms ranges from 4 weeks to 4 years, with an average of 9 months.

PHYSICAL EXAM

- Distribution of primary sites include the following:
 - Extremities (53%):
 - Usually begins in the midshaft
 - Lower extremities affected more than upper extremities
 - Central axis (47%):
 - Pelvis (45%)
 - Chest wall (34%)
 - Spine or paravertebral (12%)
 - Head or neck (9%)
- Extraskelatal Ewing sarcoma is rare; however, it may be found in most soft tissue regions of the body.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC
- Serum lactate dehydrogenase (LDH) is often elevated at diagnosis.
- Electrolytes, liver function tests, and renal function tests in anticipation of starting chemotherapy

Imaging

- To evaluate primary site and confirm diagnosis:
 - Radiography:
 - Bony destruction with “onion skinning” appearance most often seen
 - Raising of the periosteum may result in a Codman triangle
 - Diaphyseal location
 - CT or preferably MRI scan
- To evaluate for evidence of distant metastases (present in 25% of patients at diagnosis):
 - Chest radiograph and CT scan
 - 99m-Tc-diphosphonate bone scan
 - PET scan

Diagnostic Procedures/Other

- Biopsy:
 - Should be performed by an experienced orthopedic surgeon:
 - Avoid contamination of surrounding tissues (use of a longitudinal incision is important).
 - Ensure adequate tissue sampling to make the diagnosis.
 - In addition to routine morphologic and immunohistochemical stain assessments, analysis of tumor genetics by traditional cytogenetics, fluorescent in situ hybridization, or reverse transcriptase PCR is helpful in making the diagnosis and may provide information regarding prognosis.
 - Because of the importance of these studies, consultation with a pediatric oncologist before the biopsy is essential.
- Bilateral bone marrow aspirates and biopsies

DIFFERENTIAL DIAGNOSIS

- Malignant:
 - Osteosarcoma
 - Neuroblastoma
 - Non-Hodgkin lymphoma
 - Rhabdomyosarcoma
- Nonmalignant:
 - Osteomyelitis
 - Tendonitis
 - Trauma/fracture
 - Langerhans cell histiocytosis (eosinophilic granuloma)
 - Benign bone tumor (giant cell tumor) or cyst

TREATMENT

MEDICATION (DRUGS)

- All patients with localized disease at diagnosis also have tumor cells outside the primary site that cannot be detected by standard measures; chemotherapy is therefore essential for cure.
- Common agents used include vincristine, dactinomycin, cyclophosphamide, doxorubicin, etoposide, and ifosfamide. Other agents, such as irinotecan, are being investigated.
- Most patients require placement of an indwelling central venous catheter for the duration of their therapy.

ADDITIONAL TREATMENT

General Measures

- Therapy is multimodal with chemotherapy, radiation therapy, and surgery. Typically structured as:
 - Neoadjuvant chemotherapy
 - Local control (surgery, radiation therapy)
 - Adjuvant chemotherapy
- Most children are treated according to large cooperative group protocols at pediatric oncology centers.
- Treatment is characterized by significant side effects, including increased susceptibility to infection, severe mucositis, and poor nutritional status.
- Experimental therapies such as immunotherapy (vaccination with fusion-gene peptide products) and antiangiogenic therapies are being investigated in clinical trials for patients with high-risk or relapsed disease.

Additional Therapies

Radiotherapy:

- Ewing sarcomas are generally radiosensitive.
- Radiation therapy can be used to aid in local control and for control of metastatic disease.

ISSUES FOR REFERRAL

Consultation with a pediatric oncologist is essential before any attempt is made at a diagnostic biopsy.

SURGERY/OTHER PROCEDURES

- Goal is to remove the entire tumor with adequate tissue margins.
- Surgical approach depends on the affected site.
- Limb salvage surgery is often possible but may not be best in some cases:
 - Amputation may be the only way to ensure complete resection and a chance for cure.
 - The morbidity associated with limb salvage is sometimes unacceptable, especially when combined with the effects of radiation therapy.
 - Limb salvage is often associated with longer recovery times and the need for more physical therapy.
 - Amputation with a mechanical prosthesis may provide more function (especially in the lower extremities).

ONGOING CARE

PROGNOSIS

- Overall, 50–70% of patients will be disease free at 5 years from diagnosis.
- Unfavorable prognostic features:
 - Age > 12 years
 - Primary tumor site: Pelvis
 - Larger primary tumor
 - Metastatic disease at diagnosis, especially involving bone or bone marrow (<30% disease-free survival)
 - Elevated LDH at diagnosis
 - Poor histologic response to chemotherapy:
 - Assessed at the time of surgical resection

COMPLICATIONS

- Cord compression secondary to vertebral involvement
- Metastatic spread is seen in 25% of cases at diagnosis. Sites include lung, bone, and bone marrow; liver and lymph nodes are less often involved.
- Acute effects of therapy:
 - Frequent admissions to the hospital for chemotherapy or complications of the therapy
 - Bone marrow suppression:
 - Transfusions are usually necessary.
 - Neutropenia: Increased risk of bacterial and fungal infections; granulocyte colony-stimulating factor is usually administered daily following chemotherapy to shorten the duration of neutropenia.

- Complications from the GI side effects of chemotherapy or radiotherapy:
 - Nausea and vomiting, relieved with ondansetron and other antiemetic agents
 - Malnutrition secondary to reduced appetite and mucosal ulcerations; nutritional supplements (oral, nasogastric, gastrostomy tube or parenteral) may be necessary.
- Complications from radiotherapy
 - Skin erythema or breakdown
 - Pathologic fracture
- Late effects of therapy:
 - Cardiomyopathy:
 - Anthracyclines (doxorubicin) weaken cardiac muscle, leading to reduced left ventricular function many years after therapy.
 - ~5% of patients receiving cumulative doses of doxorubicin >500 mg/m² will develop CHF.
 - Radiation to the heart can lower the cumulative dose threshold to 300 mg/m².
 - Any patient who has received an anthracycline should be cautioned against initiating strenuous physical activity without adequate preparation. Pregnant women who have received anthracyclines in the past should inform their obstetrician so that appropriate cardiac assessment can be completed prior to vaginal delivery.
 - Kidney and bladder damage:
 - Urinalysis should be performed to detect hemorrhagic cystitis or tubular damage with spilling of sugar, protein, and phosphate into the urine.
 - BP should be monitored in patients who received irradiation to the kidneys; vascular damage and hypertension may develop many years after therapy.
 - Infertility and delayed puberty:
 - Reduced or absent gonadal function is related to high doses of alkylating agents (cyclophosphamide, ifosfamide): Males are at high risk of azoospermia; females may be fertile but are at risk for premature menopause.
 - Low-dose estrogen therapy with oral contraceptive medications may be necessary for amenorrheic women.
 - 2nd malignant neoplasms:
 - Sarcomas may occur within the radiation field.
 - Myelodysplastic syndromes and acute myeloid leukemia may occur secondary to chemotherapy.
 - Growth abnormalities/functional defects at the primary site:
 - Radiation doses >20 Gy will cause growth retardation in prepubertal children.
 - Scoliosis may occur if the vertebrae are involved in the radiation field.
 - Risk for pathologic fractures or aseptic necrosis of joints remains elevated.

CODES

ICD9

170.9 Malignant neoplasm of bone and articular cartilage, site unspecified

ICD10

C41.9 Malignant neoplasm of bone and articular cartilage, unspecified

FAQ

- Q: At what time point is a child with Ewing sarcoma considered cured?
- A: Typically, cure is measured as 5-year survival without evidence of disease. However, late relapses or 2nd tumors do occur in children with Ewing sarcoma.
- Q: Should a Ewing sarcoma be completely resected at the time of diagnosis?
- A: Most times, this is not recommended as Ewing sarcoma is very sensitive to chemotherapy, facilitating an improved delayed surgical resection.
- Q: What factors determine whether to amputate or attempt a limb salvage procedure?
- A: In determining the best surgical approach, one must consider:
 - The chance of a complete resection with clean margins
 - Maximizing function
 - The effect of potential radiation therapy on the surgical site
 - Patient and family preferences

EXSTROPHY OF THE BLADDER, CLOACAL EXSTROPHY, AND EPISPADIAS

Matt Christman

Aseem Shukla

Douglas Canning

BASICS

DESCRIPTION

An anomaly in which the open bladder is part of the anterior abdominal wall. Presents as part of a complex of anomalies including male and female epispadias and wide separation of the pubis symphysis. The most severe variant of this complex is cloacal exstrophy, in which there is a large omphalocele, split bladder, imperforate anus, shortened colon, and multiple upper urinary tract and limb anomalies. Epispadias is less common than bladder exstrophy and presents with the urethral meatus at the penopubic junction, or rarely more distal on the dorsum of the penis.

EPIDEMIOLOGY

Incidence

- Estimated to be between 1/20,000 and 1/50,000 live births for classic bladder exstrophy
- Male:female ratio for classic bladder exstrophy is between 2:1 and 4:1.
- Cloacal exstrophy is exceedingly rare, with an incidence of 1/200,000 births (incidence continues to decrease because of prenatal diagnosis and termination).
- Male:female ratio for cloacal exstrophy is between 1:1 and 2:1
- Male epispadias: 1/117,000 male births
- Female epispadias: 1/484,000 female births
- Risk of bladder exstrophy in offspring of individuals with bladder exstrophy and epispadias is 1/70 births (500-fold greater than the general population).
- Risk of 2nd affected family member is 3.6%.

PATHOPHYSIOLOGY

Embryology:

- Normal development:
 - Cloacal membrane is located at the caudal end of the infraumbilical abdominal wall by 2 weeks' gestation.
 - Mesenchyme from the primitive streak migrates between the layers of the cloacal membrane to reinforce the abdominal wall as the cloacal membrane regresses.

- Bladder exstrophy:
 - Pathogenesis is still unclear, but represents an error in embryogenesis.
 - It is proposed that an abnormal overdevelopment of the cloacal membrane prevents medial migration of the mesenchymal tissue and normal lower abdominal wall development.
 - Because the membrane lacks reinforcement, it ruptures. The timing of this rupture determines the variant of the exstrophy–epispadias complex. In bladder exstrophy, rupture of the membrane occurs after the urorectal septum has descended.
- Cloacal exstrophy: Abnormally large cloacal membrane ruptures prior to division of the cloaca by the urorectal septum.

DIAGNOSIS

PHYSICAL EXAM

- Bladder exstrophy:
 - All cases have widening of the symphysis pubis caused by outward rotation of the innominate bones.
 - Triangular defect caused by premature rupture of the abnormal cloacal membrane is occupied by the exstrophied bladder and posterior urethra and bounded by the umbilicus superiorly, the 2 separated pubic bones laterally, and the anus inferiorly:
 - The distance between the umbilicus and anus is shortened in exstrophy.
 - Indirect inguinal hernia and incarceration are common in boys:
 - Perineum is short and broad with the compromised pelvic support structures.
 - Male genital anomalies:
 - Penis in boys with exstrophy is short and wide.
 - Corpora cavernosa are short and widely separated.
 - Marked dorsal chordee causes upward curvature of the penis with a short urethral plate.
 - Epispadias is nearly always present with the urethral meatus located on the dorsum at the penopubic junction.

- Female genital anomalies:
 - Overall less complex
 - Mons pubis is displaced laterally, with bifid clitoris.
 - Vagina and introitus are displaced anteriorly.
 - Uterus and vagina may be duplicated. May be at risk of uterine prolapse if exstrophy closure fails
 - Epispadias may be less obvious.
- Urinary defects:
 - Bladder mucosa at birth usually appears normal.
 - Ectopic bowel mucosa or polyp may be present in rare exstrophy variants.
 - Exstrophic bladder may exhibit maturational delay that improves following closure.
 - Upper urinary tract usually normal
 - Horseshoe, pelvic, hypoplastic, solitary, or dysplastic kidney occasionally occurs.
 - Most children with exstrophy have vesicoureteral reflux requiring correction.
- Cloacal exstrophy:
 - 2 halves of the exstrophied bladder separated by an exstrophied ileocecal bowel segment that represents the hindgut
 - Prolapsed ileum superiorly and blind-ending colon stump inferiorly
 - Imperforate anus
 - Penis may be duplicate or diminutive.
 - Bifid vagina and uterine abnormalities likely
 - Large omphalocele usually present
 - Upper urinary tract anomalies seen in up to 70% of children
 - Vertebral and neurologic abnormalities present in >50% of children

DIAGNOSTIC TESTS & INTERPRETATION

Imaging

- Prenatal sonographic findings by 20 weeks consistent with absence of a normal fluid-filled bladder, an anterior abdominal mass increasing in size, low-set umbilicus, and wide pubic ramus are suggestive of bladder exstrophy.
- A baseline renal ultrasound should be obtained after birth and a KUB will demonstrate the extent of pubic symphysis diastasis.

TREATMENT

SURGERY/OTHER PROCEDURES

Goals: Provide urinary continence and preserve renal function; surgically reconstruct the male penis to provide an erection straight enough for vaginal penetration and upright voiding:

- Complete primary repair of exstrophy (CPRE):
 - Bladder closure, bladder neck reconstruction, and epispadias repair completed in single procedure. May be performed with or without bilateral posterior iliac and anterior innominate osteotomy
 - May be postponed until 4–6 weeks of age to allow maternal bonding and to facilitate surgical planning to include orthopedic and pediatric urologic support
 - Regaining popularity as initial approach in neonates
 - Total penile disassembly involves total mobilization of the urethra to its ventral position without tension, and the bladder and urethra are closed in continuity.
 - Prophylactic antibiotic therapy should be continued in all children until antireflux procedure is completed or until vesicoureteral reflux resolves.
 - Practical advantage of allowing more normal bladder cycling that may facilitate bladder development
 - Results and complications: Daytime continence and volitional voiding in selected patients in up to 76% over 5 years of age; additional bladder neck surgery to gain continence is often required; > 50% require subsequent hypospadias repair and bladder neck fistula rate is up to 40%.
- Staged closure of bladder exstrophy:
 - In the early neonatal period, bladder, posterior urethra, and abdominal wall closure is performed with or without osteotomy.
 - Results and complications: Daytime continence in 60–80% following bladder neck surgery, may require clean intermittent catheterization (long-term follow-up)—bladder capacity strong predictor of continence and previous failed bladder closure increases risk of incontinence; minimal risk for upper urinary tract changes or hydronephrosis

- Epispadias repair at 6 months to 1 year of age:
 - Bladder neck reconstruction with an antireflux procedure delayed until 3.5–4 years to facilitate adequate bladder growth and development
 - Results and complications: Cosmetic and functional success with a straight penis with erections ranges from 60–95%; urethral strictures and urethrocutaneous fistula are the most common complications of epispadias repair seen in ≤25% of patients.
- Complications for both types of closure:
 - Dehiscence, stone formation, and hydronephrosis requiring urethral dilation or vesicostomy may occur. Patients must be followed carefully.
 - Initial closure success very important for continence: 2nd attempt at closure delayed 6 months; expectation for continence decreases with each closure attempt.
 - Failed bladder neck repair in 20–50% may require further reconstruction.
 - Adenocarcinoma of the bladder occurs in patients with exstrophy 400 times more than in the normal population. This disease is not reported in adults who have had bladder closure after infancy.
- Fertility and pregnancy:
 - Sexual function and libido in exstrophy patients are normal following successful reconstruction.
 - Up to 87% of boys have erections following epispadias repair.
 - Retrograde and small-volume ejaculation should be expected.
 - Successful impregnation has been achieved with assisted reproductive techniques.
 - Pregnancy is commonly achieved in women with bladder exstrophy, but uterine and cervical prolapse are common following pregnancy. Cesarean section is recommended in females completing reconstruction.

IN-PATIENT CONSIDERATIONS

Initial Stabilization

Postnatal and nursery care:

- Tie umbilical cord with 2-0 silk to avoid traumatizing the bladder mucosa with an umbilical clamp.
- Cover bladder with a hydrated gel dressing or plastic wrap to prevent mucosa from sticking to clothing or diapers.
- Immediate transfer to an appropriate center for evaluation by a pediatric urologist and surgical correction.

ONGOING CARE

PROGNOSIS

Prospective parents of children with bladder exstrophy should be counseled as to excellent overall prognosis and favorable long-term outcome with early intervention by a pediatric urologist.

- Q64.12 Cloacal extrophy of urinary bladder

FAILURE TO THRIVE

Michelle Terry

BASICS

DEFINITION

- Failure to thrive (FTT): Refers to a child whose physical growth is significantly less than that of peers.
- There is no official consensus on what constitutes FTT. Failure to thrive usually refers to a child whose growth is below the 5th percentile for their age or whose growth has fallen off precipitously and crossed 2 major growth percentiles (e.g., from above the 75th percentile to below the 25th percentile) as measured on standard growth charts, or if the child is 20% below the ideal weight for height. As defined, FTT is a sign of medical or environmental dysfunction vs. a definitive diagnosis or disease state.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- **Inadequate caloric intake**
 - Incorrect preparation of formula
 - Inadequate breast milk supply or inefficient lactation techniques
 - Unsuitable feeding habits (i.e., food fads)
 - Disorganized mealtime routine
 - Behavior problems affecting eating
 - Poverty and food shortages
 - Disturbed parent–child or caregiver–child relationship
 - Mechanical feeding difficulties in the child (swallowing dysfunction, craniofacial anomalies, CNS injury, gastroesophageal reflux)
 - Voluntary restriction of intake/eating disorder
 - Child abuse and neglect
- **Inadequate caloric absorption**
 - Biliary atresia or liver disease
 - Celiac disease
 - Cystic fibrosis
 - Food allergies
 - Gastroesophageal reflux disease
 - Inflammatory bowel disease
 - Malrotation of the gut
 - Necrotizing enterocolitis or short-gut syndrome
 - Pyloric stenosis
 - Parasitic infection
 - Vitamin or mineral deficiencies

- **Increased metabolic expenditure**
 - Chromosomal abnormalities
 - Congenital or acquired heart disease
 - Cancer
 - Kidney disease
 - Chronic systemic disease (i.e., systemic lupus erythematosus [SLE], idiopathic juvenile arthritis, sickle cell disease, thalassemia)
 - Chronic or recurrent systemic infections (i.e., tuberculosis, hepatitis, AIDS and other immune deficiency syndromes, recurrent urinary tract infections, recurrent sinusitis)
 - Chronic respiratory insufficiency (i.e., obstructive sleep apnea, chronic lung disease)
 - Chronic metabolic disorders (i.e., aminoacidurias, organic acidurias, glycogen and lysosomal storage diseases, diabetes mellitus, adrenal insufficiency, pituitary disease, thyroid disease)

APPROACH TO THE PATIENT

General Goals

Determine if the child has growth failure and, if present, explore its etiology in order to provide the appropriate therapy.

- **Phase 1:** Is the malnutrition acute or chronic? With acute malnutrition, weight loss is evident first, and with chronic malnutrition, height and then head circumference are compromised. In order to thoroughly evaluate growth failure, the prenatal, developmental, feeding, and review of systems histories must be completely documented. The physical exam also provides clues as to the etiology of the growth failure in any of the following domains—general appearance, vital signs, head and neck, chest, abdomen, genitourinary, musculoskeletal, neurologic, and skin systems.
- **Phase 2:** If the medical database (history and physical exam) indicates a possible medical cause for FTT, then the appropriate diagnostic workup should be done in consultation with the relevant medical specialists.
- **Phase 3:** If no organic medical condition is identified as a reason for growth failure, then begin intensive nutritional and family support services.

HISTORY

Important aspects of the medical history include:

- **Question:** Pre- and perinatal history?
- **Significance:** Low birth weight, intrauterine growth restriction, perinatal illnesses, and prematurity are important predisposing factors to FTT. In addition prenatal exposures (e.g., alcohol, street drugs, and herbal supplements) may compromise growth and/or affect parent–child interactions.

- **Question:** Past medical history?
- **Significance:**
 - Presence of genetic or chronic diseases may hinder nutritional intake, nutrition absorption, or caloric expenditure; chronically malnourished children may be more susceptible to infection, and chronic infections may indicate immunodeficiency.
 - Family history should include the height and weight of parents and biologically related siblings and the constitutional rate of growth if known.
 - A careful review of systems history may give historical cues of potential significance.
- **Question:** Detailed information regarding diet and feeding?
- **Significance:**
 - Timing, location, and duration of mealtimes
 - Type of foods served
 - Quantity of food consumed
 - The dietary history should be as complete as possible with information, for example, regarding how a formula is mixed, or the volume of fruit juice consumed.
- Medical history symptoms that may be of particular significance:
 - Vomiting, diarrhea, and/or chronic constipation
 - Snoring or mouth breathing
 - Frequent infections
 - Frequent urination
 - Recent travel to a developing country
 - “Picky” eater preferences
 - Dietary restrictions because of food allergies
 - Child care attendance
 - Homelessness
- Psychosocial conditions that may be of particular significance:
 - Poverty
 - Parental depression
 - Parental substance abuse
 - Parental developmental delay
 - The psychosocial history should include an assessment of family composition, family stressors, and community supports.

PHYSICAL EXAM

A complete physical exam is necessary for the workup of FTT. A few examples of significant findings are as follows:

- **Finding:** Dysmorphic features (e.g., microcephaly, small palpebral fissures, flat philtrum, and thin upper lip)?
- **Significance:** Clinical or genetic syndrome associated (e.g., fetal alcohol syndrome or trisomy 21)

- **Finding:** Cataracts?
- **Significance:** Congenital infection, galactosemia
- **Finding:** Oropharyngeal lesions (e.g., dental caries, tongue enlargement, small jaw, tonsillar hypertrophy, defects in soft or hard palate)?
- **Significance:** May cause difficulties with suck and swallow
- **Finding:** Wheezing, crackles, prolonged expiratory phase, barrel-shaped chest?
- **Significance:** Diseases that contribute to chronic lung disease, e.g., asthma, cystic fibrosis.
- **Finding:** Cardiac murmur, rub, gallop?
- **Significance:** Congenital or acquired heart disease
- **Finding:** Abdominal distension, hepatosplenomegaly?
- **Significance:** Liver disease, glycogen storage disease, malignancy
- **Finding:** Bony deformities (abnormal skull shape, beading of the ribs, scoliosis, bowing of the legs or distal radius and ulna, enlargement of the wrist), scaling skin, spoon-shaped nails?
- **Significance:** Vitamin and mineral deficiencies (e.g., rickets, zinc deficiency, iron deficiency)
- **Finding:** Bruises and/or burns in characteristic object marks?
- **Significance:** Possible child physical abuse

DIAGNOSTIC TESTS & INTERPRETATION

Accurately measure the child:

- Measure the child's weight, length/height, and head circumference accurately using properly calibrated equipment and plot the measurements on a standard growth grid before tracking the data points over time.
- Perform a developmental screen: Assess the child's physical skills such as rolling over, sitting, standing, and walking. In older children it is important to assess the child's social, emotional, and cognitive skills as well.

Order laboratory tests based on the data gathered in the history and physical exam.

- **Test:** CBC
- **Significance:** To identify anemia
- **Test:** Serum electrolytes, protein, albumin, calcium, magnesium, phosphorus, blood urea nitrogen, and creatinine
- **Significance:** To evaluate for potential metabolic problems and renal insufficiency; the values are useful to follow to prevent re-feeding syndrome in severe malnutrition. Re-feeding syndrome includes electrolyte and mineral disturbances in severely malnourished individuals who are provided with enteral nutrition too quickly.

- **Test:** Hemoglobin electrophoresis
- **Significance:** To determine the presence of conditions such as sickle cell disease
- **Test:** Hormone studies including thyroid function tests
- **Significance:** To evaluate for hormonal dysfunction
- **Test:** X-rays to determine bone age
- **Significance:** To determine stunting of growth by premature maturation of long bones
- **Test:** Urinalysis and urine culture
- **Significance:** To screen for urinary tract infection and renal tubular acidosis

TREATMENT

EMERGENCY CARE

Children who meet criteria for severe malnutrition should be hospitalized, and a feeding plan should be determined in consultation with a registered dietician in order to avoid the risk of re-feeding syndrome. In addition children who are suspected to have growth failure as a result of child neglect or abuse should be hospitalized for their safety, and child welfare workers should be notified immediately.

ISSUES FOR REFERRAL

- Consider referring children with a specific organ disease or genetic syndrome to the appropriate pediatric medical specialty clinics.
- Physicians are considered "mandatory reporters" by every jurisdiction in the US, so if child abuse or neglect is suspected, the child's condition must be reported to the local version of child and family welfare protective services and/or law enforcement.
- In some medical centers, multidisciplinary teams consisting of physicians, nutritionists, occupational/speech therapists, social workers, psychologists, and clinical nurse practitioners work together to care for a child and the family.

CODES

ICD9

- 779.34 Failure to thrive in newborn
- 783.41 Short stature

ICD10

- R62.51 Failure to thrive (child)
- P92.6 Failure to thrive in newborn

FAQ

- Q: What are the long-term effects of FTT?
- A: Poor physical growth can lead to multi-organ dysfunction as well as developmental delays.
- Q: What are the treatments for FTT?
- A: The treatment depends on the cause of the delayed growth and development. Delayed growth due to nutritional factors can be resolved by providing a well-balanced diet. Delayed growth due to medical disease can be addressed by treating the illness. Delayed growth due to psychological factors may improve by addressing family dynamics and improving living conditions.

CLINICAL PEARLS

- FTT may be due to inadequate caloric intake, inadequate caloric absorption, or excessive metabolic demand.
- Organic and environmental causes of FTT frequently co-exist.
- A medical reason for FTT is found <50% of the time.
- If the period of FTT has been short, and the cause is determined and can be corrected, normal growth and development will resume. If FTT is prolonged, the effects may be long-lasting, and normal growth and development may not be achieved.

FEEDING DISORDERS

Diane Barsky

BASICS

DESCRIPTION

- Feeding disorder: Inability to consume by mouth in quantity or quality nutrition that is developmentally appropriate for that child
- Dysphagia: Disorder of swallowing characterized by difficulty in oral preparation for the swallow or in moving food or liquid from the mouth to the stomach
- Aspiration: Food or fluid falling below vocal cords proceeding to lungs
- Penetration: Food or fluid remaining above vocal cords and cleared by patient through coughing to prevent aspiration

RISK FACTORS

- Congenital heart disease
- Cystic fibrosis
- Metabolic disorders
- Autism spectrum disorder
- Developmental delay/Cerebral palsy
- Prolonged tube feeders (>4 weeks)
- Prematurity
- Neuromotor dysfunction
- Anatomic deformities (i.e., Pierre Robin sequence, laryngomalacia, tracheotomy)
- GI disorders: Gastroesophageal reflux
- Tachypnea (respiratory rate >40 breathes per minute)
- Oral motor disorder: Inability to manipulate age-appropriate diet; often related incoordination of facial muscles and/or tongue
- Pharyngeal dysphagia: Inability to protect airway during swallow; may be due to anatomic abnormality or neurological dysfunction
- Voluntary food or fluid refusal due to learned fear when caregiver pushes foods or textures before the child is developmentally or medically ready; may result in maladaptive interactions at meals

GENERAL PREVENTION

- Monitor weight, height, head circumference, weight for height, and BMI percentiles at regular interval office visits to identify changes in nutritional status early, especially in high-risk populations.
- Selective eater: Educate parents on age-appropriate portion sizes and foods.
- Provide vitamin and mineral supplementation or refer to nutritionist for complete assessment if patient is at risk for deficiencies.
- Developmental delay: Evaluate diet and feeding skills to manipulate nutrition provided.
- Ensure foods offered match developmental age if different than chronological age.

DIAGNOSIS

HISTORY

- Medical diagnoses past and present
- Treatments in past or present, especially those aversive to face and upper body and face (i.e., suctioning, tracheostomy, intubation)
- 24-hour diet: Recall food and fluid consumed over a 24-hour period
- Previous hospitalizations, especially respiratory illnesses
- Allergies or food intolerances
- Growth history
- Developmental history
- History of snoring or sleep apnea: May indicate adenoidal or tonsillar hypertrophy
- GI history: Stool pattern, vomiting, gagging, spitting up, pain
- Previous diagnostic testing
- Family history: GI disease, allergies, developmental delays, genetic abnormalities
- Failure to thrive:
 - Poor linear growth
 - Sucking and swallowing incoordination: Infant should demonstrate 1:1:1 suck, swallow, breathe pattern when sucking from breast or bottle.
 - Recurrent pneumonia
 - Coughing during or after feeding
 - Refractory asthma
 - Drooling
 - Refusal to drink or eat
 - Feeding selectivity
 - Difficulty with texture progression

PHYSICAL EXAM

- HEENT: Dysmorphic facial features, shape of head and sutures, facial tone, intact soft and hard palate, shape of mandible, tonsillar size, patency of nares, movement of lips and tongue, presence of stridor, mouth closure, dentition, drooling
- Pulmonary: Rate of breathing, use of accessory muscles for respiration, rales
- Cardiac: Murmur, rate and rhythm
- GI: Bowel sounds, masses, stool palpable, tenderness, distension
- Neurologic: Tone, positioning, cranial nerves, gait, affect, head control
- Extremities: Subcutaneous stores, muscle development, adipose tissue
- Skin: Rashes, alopecia

DIAGNOSTIC TESTS & INTERPRETATION

Perform feeding observation: Watch caregiver feed child, preferably thru 1-way observation mirror. Monitor child's behavioral response to placement in the feeding chair and presentation of bottle, breast, or cup and a variety of food types and textures; observe parental reaction to child's behaviors; child's ability to manipulate foods and fluids

Lab

- Based on nutritional and/or developmental concerns.
- Failure to thrive: Celiac panel, CBC, comprehensive metabolic panel, lead, urine analysis, thyroid function. Other tests if suspect vitamin or mineral deficiency (i.e., zinc, iron)
- Developmental and/or genetic concerns: Chromosomes, FISH test for 22Q11 deletion, FISH test for Prader-Willi syndrome, Fragile X (males), serum and urine organic acids, lactate, pyruvate, CPK
- Sweat test if suspected cystic fibrosis: Failure to thrive, diarrhea, and/or recurrent pulmonary infections

Imaging

- Tests indicated based on history and physical
- Suspected pharyngeal dysphagia: modified barium swallow study (MBSS) (also known as videofluoroscopic swallow study) evaluates swallow function and can visualize aspiration during swallow; usually performed by radiologist and speech therapist. Study visualizes function of pharyngeal muscles and structures. See below:
 - Upper GI series ensures normal anatomy of esophagus, stomach, and duodenum.
 - Chest x-ray: Determine if infiltrates or atelectasis is present; right upper and/or middle lobe changes indicative of potential aspiration.
 - Gastric emptying scan: Assess gastric emptying and assess if gastroparesis is present.
 - Salivagram: Radionuclide study to evaluate if patient aspirating oral secretions
 - Chest CT scan: Allows detection of subtle changes from silent aspiration not detectable by pulmonary exam or chest x-ray.

Diagnostic Procedures/Other

- MBSS: Speech therapist feeds a variety of textures: Thin and thickened liquid of honey and nectar consistency, thin and thick purees and chewable foods to determine safety of oral feeding. Allows visualization of oral and pharyngeal phases of swallowing. Can determine appropriate positioning, type of infant bottles and cups to minimize the risk for aspiration.
 - Timing of aspiration is evaluated to determine if volume and fatigue result in aspiration, patient may be safe to drink or eat for short periods of time before the swallow becomes uncoordinated and leads to aspiration.
- Fiberoptic endoscopic evaluation of swallowing (FEES): Usually performed by ENT specialist. Direct visualization of airway structures and swallowing mechanism. Provides information on pharyngeal phase of swallowing but not oral phase. Best used if pharyngeal or laryngeal abnormality is suspected, tracheostomy in place, and there is difficulty managing secretions. Can observe food or fluid falling below vocal cords, resulting in aspiration
- Bronchoscopy: Visualizes tracheobronchial tree and lungs, sample for lipid-laden macrophages in lungs indicative of aspiration
- Endoscopy: To perform esophageal, gastric, and small bowel biopsies to determine presence of eosinophilic esophagitis, celiac disease (positive or inconclusive celiac panel), or presence of gastroesophageal reflux disease (GERD)

DIFFERENTIAL DIAGNOSIS

- **Cardiorespiratory:**
 - Congenital heart disease:
 - Infectious pneumonia
 - Bronchopulmonary dysplasia
- **Neurological:**
 - Diencephalic syndrome:
 - Congenital myopathy
 - Arnold-Chiari malformation
 - Hypoxic-ischemic encephalopathy
- **GI/Nutritional:**
 - GERD
 - Gastroparesis
 - Eosinophilic esophagitis
 - Failure to thrive
 - Celiac disease
- **Metabolic syndromes**
- **Psychological disorders:**
 - Behavioral refusal
 - Psychosocial deprivation
 - Anxiety disorder
- **Food allergies**
- **Anatomic:**
 - Laryngeal cleft
 - Tracheoesophageal fistula
- **Genetic disorders**
- **Developmental disorders:**
 - Autistic spectrum disorder
 - Sensory integration disorder

 **TREATMENT**

- **Pharyngeal dysphagia:** Pulmonary referral, oral stimulation program, NPO as indicated by clinical exam and studies, initiate tube feeds; monitoring by speech therapist
- Feeding disorders are complex and should be evaluated and managed by multidisciplinary team involving medical, nutrition, psychology, occupational therapy, and speech therapy.

MEDICATION (DRUGS)

- Appetite enhancing medications are not routinely recommended.
- Medications are administered to treat underlying medical condition (e.g., GERD); refer to specific sections for treatment of identified medical issues resulting in feeding disorder.

ADDITIONAL TREATMENT

General Measures

- Calorie counts
- Ensure adequate hydration

Additional Therapies

- Obtain a list of all supplemental vitamins, minerals, herbs, etc. that the parent may be providing to the patient.
- Investigate if parent is following any special diets (e.g., casein/gluten-free diet in autistic spectrum disorder).
- Note that the current literature does not support special diets or excessive dosing of vitamin and/or mineral supplements in developmental disorders unless indicated in treatment of a specific metabolic disorder.

COMPLEMENTARY & ALTERNATIVE THERAPIES

- **Speech therapy:** Evaluate oral motor skill and safety of swallowing mechanism; perform MBSS when indicated.
- **Occupational therapy:** Evaluate fine motor skills, sensory processing, and posture to support feeding.
- **Psychology:** May identify behaviors interfering with food acceptance and recommend strategies to improve oral acceptance
- **Nutrition:** Perform complete nutritional assessment, including evaluation of growth parameters, identifying patient’s nutrition requirements, and adequacy of current diet. The nutritionist can develop a care plan to meet patient’s nutritional requirements and monitor intake and weight gain during hospitalizations.

SURGERY/OTHER PROCEDURES

- Consider gastrostomy tube placement if tube feedings for >3 months are anticipated.
- For GERD not responding to medications, consider bypassing stomach and feeding into intestine with jejunostomy tube or Nissen fundoplication.

IN-PATIENT CONSIDERATIONS

Initial Stabilization

- Prior to initiation of behavioral program, ensure weight gain and growth are adequate.
- Evaluate and treat vitamin and mineral deficiencies.
- If weight-for-height or BMI is <5%, inappropriate weight gain crossing down 2 percentiles on growth chart occurs, or weight loss occurs, consider initiating supplemental nasogastric tube feeds.
- If aspiration pneumonia is suspected, obtain blood cultures, chest x-ray; keep NPO and start IV fluids and antibiotics. Measure oxygen saturation and initiate supplemental oxygen if <95%.

 **ONGOING CARE**

FOLLOW-UP RECOMMENDATIONS

Appointment with multidisciplinary feeding team, if available within reasonable geographic radius

Patient Monitoring

- Patient’s weight should be checked within 2 weeks of discharge.
- Pediatrician should monitor patients with respiratory difficulties related to aspiration every 2 weeks until stable.

DIET

- Keep patient NPO if aspiration is suspected, until further evaluation (MBSS) can be performed.
- Order diet appropriate for child’s current level of feeding skills (i.e., accepts baby food; may trial pureed diet).
- If nutritional intake is inadequate, offer nutritional supplements, monitor calorie counts, and initiate supplemental nasogastric tube feeds if unable to meet nutritional requirements.
- Caregiver education regarding administration of supplemental tube feeds

PROGNOSIS

- Nutritional rehabilitation can be achieved with tube feedings if patient is monitored closely.
- Patients with pharyngeal dysphagia resulting in aspiration may improve over time.
- Structural abnormalities, as seen with CHARGE association or subglottic stenosis, may improve over 1st 2–3 years of life or require surgical intervention prior to oral feeding.
- Static or degenerative neurological conditions resulting in aspiration generally do not resolve.
- Patient demonstrating dysphagia during illness may improve when healthy.

 **CODES**

ICD9

- 307.59 Other disorders of eating
- 779.31 Feeding problems in newborn
- 787.21 Dysphagia, oral phase

ICD10

- F98.29 Other feeding disorders of infancy and early childhood
- P92.9 Feeding problem of newborn, unspecified
- R13.11 Dysphagia, oral phase

FAQ

- **Q:** What is the difference between aspiration and penetration in a swallowing disorder?
- **A:** Penetration occurs when food or fluid enter the trachea but remains above the vocal cords and is cleared by the patient. Aspiration occurs when the food or fluid falls below the vocal cords thus entering the lungs.
- **Q:** How is a modified barium swallow study used to evaluate dysphagia?
- **A:** A speech therapist in conjunction with the radiologist feeds the patient a variety of textures, including thin and thickened liquids, thin honey and nectar, thick purees, and chopped food if indicated, visualizing the pathway during swallowing to determine if it moves safely into the esophagus without entering the airway. The speech therapist also will engage in therapeutic endeavors, such as repositioning the patient, to determine if they can eliminate aspiration.

FETAL ALCOHOL SYNDROME

Michelle E. Melicosta

Janet M. Li-Tempest (5th edition)

BASICS

DESCRIPTION

- Pattern of structural, behavioral, and neurocognitive abnormalities in individuals exposed to alcohol in utero.
- The four major features are:
 - Facial malformations
 - Growth abnormalities
 - Neurodevelopment symptoms
 - Maternal alcohol use during pregnancy.
- First described in 1973; has since been recognized that fetal alcohol syndrome (FAS) is the “tip of the iceberg” of a larger spectrum of disorders, from subtle to serious:
 - In 1996, the Institute of Medicine addressed this with a classification system which differentiated FAS from “partial FAS,” alcohol-related birth defects (ARBD), and alcohol-related neurodevelopmental disorder (ARND).
 - Currently, the CDC, with the National Task Force on FAS/FAE, has developed a set of standardized diagnostic criteria for FAS; the other categories do not thus far have a uniformly accepted set of diagnostic criteria.

EPIDEMIOLOGY

Incidence

Ranges from 0.2–2.0 per 1,000 live births. Higher rates, up to 3–5 per 1,000, are found among selected subgroups (e.g., lower socioeconomic level, Native Americans).

RISK FACTORS

Genetics

- Maternal polymorphisms of the alcohol dehydrogenase gene (ADH): The presence of the ADH1B*3 allele appears to protect the fetus.
- Concordance of FAS is higher in monozygotic than in dizygotic twins; differential sensitivities to in utero alcohol exposure in different strains of mice.
- Other factors that contribute to variable susceptibility include older maternal age/parity, nutritional status, and concomitant use of other drugs.

GENERAL PREVENTION

- Studies have shown that up to 15% of women report alcohol use during pregnancy.
- The highest risk for FAS occurs in children whose mothers consume ≥ 5 drinks per occasion per week (peak blood alcohol level is more important than a lower sustained blood alcohol level).
- No minimum safe level of alcohol consumption has been determined.
- Recent FASD prevention research has focused on finding and treating women who drink alcohol during pregnancy (e.g., using a screening questionnaire to assess problem drinking in women, and then intervening at a level determined by the level of drinking).
- Good maternal nutritional status may be protective of the fetus in mothers who drink alcohol.

PATHOPHYSIOLOGY

- May involve increased susceptibility to cell damage by free radicals in the developing tissues, leading to cell death or decreased cellular proliferation
- Alcohol and its metabolite, acetaldehyde, are embryotoxic and teratogenic, capable of reducing fetal growth and inducing malformations during critical periods in the development of the fetus.
- Exposure in the 1st trimester affects organogenesis and craniofacial development, resulting in characteristic facial features and birth defects.
- Exposure at varying times can cause CNS neurodevelopmental effects, because brain formation and neuronal maturation occur throughout pregnancy.
- Exposure also causes prenatal and postnatal growth retardation, probably by inhibiting protein and DNA synthesis.

DIAGNOSIS

HISTORY

- Neurodevelopmental symptomatology is very age and development-dependent.
- Birth history, birth and subsequent growth parameters (weight, height, head circumference)
- Maternal history of alcohol use (binge drinking, average number of drinks per day, timing in pregnancy), and other drug use
- Family history: Neurobehavioral abnormalities should *not* be typical of other family members who were not exposed to ETOH prenatally.
- Learning/behavior problems, infancy:
 - May or may not have ethyl alcohol withdrawal as newborn
 - Irritability, irregular sleep, poor feeding, hypotonia, delayed motor function
- Learning/behavior problems, preschool and school age:
 - Hyperactivity
 - Slow verbal learning
 - Slow visual-spatial learning
 - Poor abstract thinking (planning and organizing)
 - Perseveration (inability to abandon ineffective strategies)
 - Attention problems
 - Difficulty with peer interactions
- Learning/behavior problems, adolescence and adulthood:
 - Substance abuse
 - Criminal behavior
 - Inability to work
 - Inability to live independently
 - Difficulty managing time and money
- Child in a high-risk living situation:
 - Keep in mind that external influences, such as poverty, unstable home environment, poor emotional support, and lack of educational resources, contribute to behavioral problems.

PHYSICAL EXAM

- Weight, height, head circumference
- Microcephaly persists throughout life.
- Weight can often be improved by interventions.
- History of growth deficits is required for diagnosis.
- Facial exam (short palpebral fissures, ptosis, flat midface, upturned nose, smooth philtrum, thin upper lip)
- Facial features become less prominent in adolescence and adulthood.

DIAGNOSTIC TESTS & INTERPRETATION

Neuropsychological testing:

- Simple IQ tests cannot distinguish children with FAS from those with other developmental disabilities.
- Tests of executive functioning most consistently show deficits; these include the WISC-III mazes and the Wisconsin category test.

Lab

No laboratory marker exists for FAS.

Diagnostic Procedures/Other

- FAS diagnosis requires all three of the following markers.
- I. Facial features:
 - Short palpebral fissures (≤ 10 th percentile)
 - Thin vermilion border upper lip (score of 4 or 5 on the lip/philtrum guide [Astley, 2000])
 - Smooth philtrum (4 or 5 on lip/philtrum guide).
 - Other findings, such as ptosis, maxillary hypoplasia, and short, upturned nose are not diagnostic but are commonly seen in children with FAS.
- II. Documentation of growth deficits:
 - Height or weight ≤ 10 th percentile at any time in patient's history.
- III. Documentation of CNS abnormality (any 1 below):
 - Structural:
 - Microcephaly at birth OFC < 10 th percentile, or disproportionate to height; or
 - Structural brain abnormalities (eg, agenesis of corpus callosum, cerebellar hypoplasia)
 - Neurological:
 - Seizures, poor coordination, impaired memory, or other soft neurological signs not attributable to postnatal insult or fever.
 - Functional: Performance substantially below that expected for an individual's age and circumstances, as evidenced by either:
 - Global cognitive deficits (IQ or developmental delays in multiple domains) > 2 standard deviations below the mean, *OR*
 - Functional deficits 1 SD below the mean in at least 3 specific domains (e.g., attention, executive functioning, motor functioning, social skills, language, or specific learning disabilities)

- Maternal alcohol exposure:
 - Confirmed maternal exposure to alcohol is defined as substantial regular intake or heavy episodic drinking. Evidence may include self-report or that of a reliable informant; medical records showing an elevated blood alcohol level or alcohol-related medical problems (e.g., hepatic disease); legal problems related to drinking.
 - If there is no available history, or conflicting reports, then described as “Unknown maternal exposure.”
 - If maternal alcohol abstinence can be confirmed (rare, for example, if mother incarcerated for entire pregnancy), then FAS is eliminated as a diagnosis.

DIFFERENTIAL DIAGNOSIS

- By physical features:
 - Aarskog syndrome
 - Williams syndrome
 - Noonan syndrome
 - Brachmann-De Lange syndrome
 - Dubowitz syndrome
 - Fetal valproate syndrome
 - Fetal hydantoin syndrome
 - Maternal phenylketonuria fetal effects
 - Toluene embryopathy
- By neurobehavioral features:
 - Fragile X syndrome
 - 22q11 deletion syndromes
 - Turner syndrome
 - Opitz syndrome

TREATMENT

ADDITIONAL TREATMENT

General Measures

- The role of the pediatrician is early identification (with help from specialists), appropriate referrals, and development of a multidisciplinary case plan, including the pediatrician, specialists, early intervention providers, psychologists, and social and educational resources in the community to support family and child.
- Specific medical referrals should include:
 - Comprehensive neuropsychologic evaluation (IQ, achievement, executive function, memory, adaptive function, language, reasoning and judgment, behavior)
 - Ophthalmologic exam (consider routine screening prior to school, then every 2 years)
 - Hearing test (consider brainstem auditory evoked response [BAER] at 6–12 months)

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Growth and nutrition in infancy: Failure to thrive is a common problem.
- Regular evaluations of vision and hearing: Problems occur at a high rate.
- As indicated by other medical/psychologic problems

PROGNOSIS

- 50% are mentally retarded (IQ <70). Average IQ in individuals with FAS is in the 60s (mild mental retardation); however, a wide range of IQ exists, from 16–115.
- 62% have severe behavioral problems, even if a normal IQ exists.
- The major disabilities of FAS caused by the neurocognitive/neurobehavioral effects leading to poor academic performance, legal problems, employment difficulties, and secondary mental health problems.
- Many are unable to live independently as adults.

CODES

ICD9

760.71 Alcohol affecting fetus or newborn via placenta or breast milk

ICD10

Q86.0 Fetal alcohol syndrome (dysmorphic)

FAQ

- Q: What is FAE (fetal alcohol effect)?
- A: FAE originally described abnormalities seen in animal studies, then was adopted by clinicians, who widely used the term to refer to behavioral and cognitive problems in children exposed to alcohol in utero, but without the typical diagnostic features of FAS.
- Because of lack of diagnostic criteria for FAE and the imprecise use of this term, IOM replaced FAE with the terms ARND and ARBD.
 - Use of the terms ARND and ARBD remains controversial in that they imply that confirmed maternal alcohol exposure is causative of the associated abnormalities, which at present, is not proven.
 - In summarizing the problem list for an individual who may not meet the criteria for FAS or partial FAS, many leading dysmorphologists recommend listing the elements separately without attribution, rather than using the confusing terms FAE or ARND/ARBD. Example: Impression 1, prenatal alcohol exposure; 2, cleft lip and palate, complete bilateral; 3, cognitive deficit.
- Q: How much alcohol does it take to produce damage?
- A: The highest risk for FAS occurs in children whose mothers consume ≥ 5 drinks per occasion at least once per week. However, NO minimum safe level of alcohol consumption has been determined
- Q: Do most children with FAS have ADHD?
- A: Although hyperactivity appears to be common in FAS, many of these children are misdiagnosed as having ADHD. Instead of difficulty focusing and sustaining attention, children with FAS often have difficulty shifting attention from one task to another. Use of stimulant medication is not routinely supported, although a small proportion may respond to stimulant medication in educational settings.

FEVER AND PETECHIAE

Lisa Mcleod

Evaline A. Alessandrini (5th edition)

BASICS

DEFINITION

- Petechiae:
 - Small hemorrhages into the superficial layers of the skin
 - <3 mm in size
 - Manifest as a reddish purple, macular, nonblanching skin rash
- Purpura:
 - Larger skin hemorrhages
 - Purple
 - Often macular like petechiae but may be raised or tender

EPIDEMIOLOGY

- Although there are no strong epidemiologic data, the presentation of fever and petechiae is rare compared with the presentation of fever alone.
- A great majority of patients (70–80%) presenting with fever and petechiae have defined or presumed viral infections, which are most often caused by enterovirus or adenovirus.
- Several prospective studies have documented that 2–15% of children presenting with fever and petechiae will have an invasive bacterial disease, most commonly *Neisseria meningitidis*.
- Infants and toddlers are at greatest risk of having an invasive bacterial infection with fever and petechiae.
- Teenagers and young adults are most commonly affected by outbreaks of meningococemia, presenting with fever and petechiae.
- Streptococcal pharyngitis may cause fever and petechiae in the well-appearing child.
- Recent epidemiologic investigations suggest that certain strains of Parvovirus B19 may be responsible for many cases of fever and generalized petechiae in children.
- Other etiologies, such as acute leukemia, idiopathic thrombocytopenic purpura (ITP), and Henoch–Schönlein purpura (HSP), are responsible for 5–10% of cases of fever and petechiae.

GENERAL PREVENTION

- Vaccine recommendations:
 - All children should complete the *Streptococcus pneumoniae* and *Haemophilus influenzae* type B immunization series that begins at 2 months of age.
 - Routine childhood immunization with meningococcal vaccine is now recommended for all children 11 years of age or older and for children ≥ 2 years who are at high risk, defined as asplenic, or with terminal complement deficiencies. A booster dose should be given 5 years later through age 21 years. Annual immunization against influenza viruses should be encouraged for all children > 6 months of age.
- Chemoprophylaxis is recommended for close contacts of patients with meningococcal disease. Ideally, treatment with rifampin, ceftriaxone, or ciprofloxacin should begin within 24 hours.

PATHOPHYSIOLOGY

Petechiae may result from several different mechanisms:

- Disruption of vascular integrity—due to infections, vasculitis, or trauma
- Platelet deficiency or dysfunction—typically thrombocytopenia due to sepsis, disseminated intravascular coagulation (DIC), ITP, or leukemia
- Factor deficiencies (more likely to manifest as ecchymoses and deep bleeding)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Viral infections (see “Etiology”)
- Invasive bacterial infections:
 - Most commonly *N. meningitidis*
 - Less often *Staphylococcus aureus*, *Escherichia coli*, *S. pneumoniae*, and *H. influenzae* type B. *S. pneumoniae* and *H. influenzae* type B are less common because of widespread childhood immunization.
- Streptococcal pharyngitis—due to *Streptococcus pyogenes*
- Rickettsial infections: Diagnosis aided by season, history of tick bite accompanied by fever, petechiae, headache, and myalgias
- Stress petechiae in the distribution of the superior vena cava (SVC) after significant coughing or vomiting
- Coining or other traumatic causes
- Acute leukemias: Diagnosis aided by clinical findings of pallor, adenopathy, hepatosplenomegaly, and laboratory findings
- ITP: Diagnosis aided by findings of mucous membrane bleeding and isolated thrombocytopenia on laboratory testing
- HSP: Diagnosis aided by clinical findings consistent with HSP, including palpable purpura on the buttocks and lower extremities, usually in the absence of fever
- Endocarditis: Diagnosis aided by a history of congenital heart disease, cardiac surgery, or rheumatic fever

ETIOLOGY

Petechiae, when accompanied by fever, most often have an infectious cause. Multiple organisms are associated with fever and petechiae. Less commonly, fever and petechiae may be caused by other entities such as acute leukemia, ITP, and bacterial endocarditis.

- Bacterial:
 - *N. meningitidis*
 - *S. pneumoniae*
 - *H. influenzae* type B
 - *S. aureus*
 - *S. pyogenes*
 - *E. coli*

- Viral:
 - Enterovirus
 - Adenovirus
 - Influenza
 - Parainfluenza
 - Parvovirus B19
 - Epstein–Barr virus (EBV)
 - Rubella
 - Respiratory syncytial virus
 - Hepatitis viruses
- Rickettsial diseases:
 - *Rickettsia rickettsii*
 - Ehrlichiosis

HISTORY

Important historical factors to obtain include:

- Age of the child
- Any underlying immunodeficiency
- Immunizations received
- Exposure to infectious contacts, particularly *N. meningitidis*
- Duration and height of fever
- Duration and progression of rash
- Excessive coughing or vomiting
- Pallor or other bleeding
- Level of activity, excess fatigue
- Travel or history of tick bites
- History of trauma in location of rash

PHYSICAL EXAM

- Important components on which to concentrate:
 - Vital signs, particularly noting tachycardia or hypotension
 - Mental status
 - Meningismus/nuchal rigidity
 - Character of rash: Petechiae or purpura, body distribution, number of lesions, progression during exam
- Important findings suggesting specific diagnoses:
 - **Finding:** Pallor, adenopathy, organomegaly
 - **Significance:** Suggesting leukemia, EBV infection
 - **Finding:** Mucous membrane bleeding
 - **Significance:** Suggesting thrombocytopenia, such as that which occurs in ITP
 - **Finding:** Myalgias, centripetal rash distribution
 - **Significance:** Suggesting Rocky Mountain spotted fever

DIAGNOSTIC TESTS & INTERPRETATION

All children with fever and petechiae require laboratory testing. At a minimum, children should receive a CBC with differential, C-reactive protein (CRP), and a blood culture.

- Children >12–18 months with fever and petechiae should have a throat culture.
- Children who are ill-appearing may warrant coagulation studies including prothrombin time (PT), partial thromboplastin time (PTT), and DIC screen.
- Viral testing, including cultures, serology, and antibody immunofluorescence, is not routinely required and may be ordered at the discretion of the managing practitioner based on exposures, need for specific therapeutic interventions, admission to the hospital, and severity of illness.
- Nontoxic-appearing children >2 years of age with fever and petechiae should have a CBC with differential, CRP, blood culture, PT, and PTT.
- Although no one factor is 100% sensitive in identifying children with invasive bacterial disease, a constellation of factors is useful in identifying children with fever and petechiae in whom invasive bacterial disease is unlikely:
 - Multiple studies have demonstrated that well-appearing children with a normal WBC count (between 5,000 and 15,000), a normal absolute neutrophil count (between 1,500 and 9,000), an absolute band count <500, and petechiae limited to above the nipple line are exceedingly unlikely to have an invasive bacterial infection. In general a CRP <5 mg/L has been shown to have a high negative predictive value for ruling out invasive bacterial infection.

ALERT

Unsuspected invasive bacterial disease is the most common pitfall with fever and petechiae. A thorough history and physical exam, accompanied by laboratory testing and a period of close observation, may minimize missed serious diagnoses.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Prudent antibiotic choices are effective against meningococcal and streptococcal diseases, including third-generation cephalosporins such as cefotaxime and ceftriaxone.
- Doxycycline should be administered if rickettsial disease is considered.
- Vancomycin should be administered to children with suspected pneumococcal meningitis.
- Empiric antibiotic use should be decided on a case-by-case basis. There are no studies investigating the efficacy of antibiotic therapy in the outpatient management of patients with fever and petechiae. However, this author advocates use of parenteral ceftriaxone since *N. meningitidis*, the most likely bacterial pathogen in this circumstance, has a high morbidity and mortality.

IN-PATIENT CONSIDERATIONS

Initial Stabilization

- The management of children who are ill-appearing and have meningismus or purpura consists of a full sepsis evaluation, admission to the hospital with parenteral antibiotics, and fluids and vasoactive infusions to maintain normal hemodynamics.
- Because sporadic as opposed to epidemic cases of meningococemia appear to occur in children in the first 2 years of life, and these children have less competent immune systems in fighting encapsulated organisms, full sepsis evaluation and admission for all children in this young age group are recommended.
- The well-appearing child with fever and petechiae and a positive streptococcal antigen test may be treated as an outpatient with antistreptococcal antibiotics.
- After a several-hour period of observation, children who remain well-appearing, are not tachycardic, have no progression of petechiae, and have normal lab studies may be considered for management as outpatients.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Children managed as outpatients:
 - Give instructions to return immediately for progression of rash or worsening illness
 - Follow-up in 12–18 hours
 - Monitor cultures closely
- Most children with viral causes have little progression of their petechiae and are clinically better within several days with the resolution of fever.

PROGNOSIS

- Depends on the underlying cause
- Since most cases of fever and petechiae are caused by viral infections, particularly enteroviruses and adenoviruses, the prognosis is excellent.
- Studies demonstrate that the mortality rate of meningococemia is 7–20%.

COMPLICATIONS

- Related to the underlying cause
- Most common complications of invasive bacterial disease causing fever and petechiae include sepsis and meningitis.
- Morbidity from *N. meningitidis* includes neurologic deficits, limb loss, and skin sloughing, necessitating skin grafts. Mortality is estimated to be 7–20%.

- R50.9 Fever, unspecified
- P54.5 Neonatal cutaneous hemorrhage

FAQ

- Q: What is the most common cause of fever and petechiae in children?
- A:
 - Viruses are the most common overall cause of fever and petechiae in children.
 - The most common invasive bacterial disease causing fever and petechiae in children in the 21st century is *N. meningitidis*.
- Q: Is there ever a role for outpatient management of children with fever and petechiae?
- A:
 - Practitioners may consider outpatient management in well-appearing children >2 years of age with all of the following criteria after a period of observation in which they have normal vital signs and no progression of petechiae:
 - A normal WBC count (between 5,000 and 15,000)
 - A normal absolute neutrophil count (between 1,500 and 9,000)
 - An absolute band count <500
 - Petechiae limited to above the nipple line

FEVER OF UNKNOWN CAUSE

Samir S. Shah

BASICS

DEFINITION

Fever of unknown origin (FUO) implies:

- A febrile illness (38.3°C on multiple occasions)
- Present for >14 days
- No apparent source despite careful history taking, physical exam, and preliminary lab studies

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

FUO is more often an unusual presentation of a common disease than a common presentation of an unusual disease. Possible causes include:

- **Common infectious causes**
 - Respiratory infections (otitis media, mastoiditis, sinusitis, pneumonia, pharyngitis, peritonsillar/retropharyngeal abscess)
 - Systemic viral syndrome
 - Urinary tract infection (UTI)
 - Bone or joint infection
 - Enteric infection (*Salmonella*, *Yersinia enterocolitica*, *Yersinia pseudotuberculosis*, *Campylobacter jejuni*)
 - Cat-scratch disease
- **Less common infectious causes**
 - Tuberculosis (TB)
 - Infectious mononucleosis (Epstein–Barr virus [EBV], cytomegalovirus [CMV])
 - Lyme disease
 - Rickettsial disease (Rocky Mountain spotted fever, ehrlichiosis)
 - Malaria
 - CNS infection (bacterial or viral meningoencephalitis, intracranial abscess)
 - Dental or periodontal abscess
 - Subacute bacterial endocarditis (SBE)
 - HIV infection
 - Acute rheumatic fever
- **Other infectious causes**
 - Q fever
 - Brucellosis
 - Toxoplasmosis
 - Syphilis
 - Parvovirus B19
 - Endemic fungi (histoplasmosis, blastomycosis, coccidioidomycosis)
 - Psittacosis
 - Chronic meningococemia

• Possible noninfectious causes

- Collagen-vascular disease (systemic juvenile idiopathic arthritis [JIA], systemic lupus erythematosus, dermatomyositis, sarcoidosis, vasculitis syndrome)
- Malignancy
- Kawasaki syndrome
- Inflammatory bowel disease (IBD)
- Drug fever
- Hyperthyroidism
- Factitious fever or Munchausen syndrome by proxy
- Centrally mediated fever
- Periodic fever syndrome
- Kikuchi–Fujimoto disease (histiocytic necrotizing lymphadenitis)

ETIOLOGY

Etiology has changed as the use of more sensitive tests (e.g., MRI, PCR tests) permits earlier detection of many conditions that caused FUO in the past. Fever resolves in 40–60% of children without identification of a specific cause.

APPROACH TO THE PATIENT

Find the cause of the fever and begin treatment of the underlying illness.

• Phase 1

- Document fever
- Thorough history and physical exam
- Determine whether constitutional symptoms (e.g., growth failure, developmental arrest) suggest a serious underlying disease.
- Create broad differential diagnosis
- Begin initial laboratory evaluation while tailoring the cadence of evaluation to patient's severity of illness.

• Phase 2

- Begin invasive studies to seek rarer forms of fever, such as lymphoma, brucellosis, and SBE.

• Phase 3

- Re-examine patient, consider additional testing, and reconsider causes such as systemic JIA, sarcoidosis, and factitious fever.

Repeat history and physical exam combined with the results of previous testing should guide the subsequent evaluation.

HISTORY

Initial studies should include a CBC, liver function tests, blood culture, urinalysis, urine culture, stool culture, and stool ova and parasite testing.

- **Question:** Temperatures and how they were measured (tympanic, oral, axillary, rectal)?
- **Significance:**
 - As many as 50% of children referred for evaluation of FUO have multiple unrelated infections, parental misinterpretation of normal temperature variation, or complete absence of fever at time of evaluation.
 - Parents are sometimes told to add a 1–2°F “correction” onto a temperature measured in the axilla to better approximate the core temperature. Such practices may further cloud the evaluation of the febrile child.
- **Question:** Exposure to animals?
- **Significance:**
 - Household exposures including pets and rodents
 - Recreational activities (e.g., hunting)
 - Household contacts with occupational exposure to animals
 - Consider cat-scratch disease, brucellosis, tularemia, leptospirosis, and lymphocytic choriomeningitis virus (from mice)
- **Question:** Ingestion of raw meat, fish, or unpasteurized milk?
- **Significance:** Trichinosis, brucellosis
- **Question:** Travel history, including past residence?
- **Significance:** Malaria, endemic fungi (e.g., coccidioidomycosis, blastomycosis), TB
- **Question:** Pica or dirt ingestion?
- **Significance:** *Toxocara canis* or *Toxoplasma gondii* infection
- **Question:** Change in behavior or activity?
- **Significance:** Brain tumor, TB, EBV, Rocky Mountain spotted fever
- **Question:** Pattern of fever?
- **Significance:** May correlate with underlying cause. A fever diary kept by the parent or caretaker may provide more objective documentation of the fever pattern than simple recall.
- **Question:** Medications (including OTC medications and eyedrops)?
- **Significance:** Drug fever, atropine-induced fever, methylphenidate, and antibiotics (especially penicillin, cephalosporins, and sulfonamides)
- **Question:** Well-water ingestion?
- **Significance:** Giardiasis

PHYSICAL EXAM

- **Finding:** Impaired weight gain or linear growth?
- **Significance:** Collagen-vascular disease, malignancy, IBD
- **Finding:** Toxic appearance?
- **Significance:** Kawasaki syndrome
- **Finding:** Conjunctivitis?
- **Significance:** Kawasaki syndrome, adenovirus, measles
- **Finding:** Ophthalmologic exam?
- **Significance:** Brain tumor, TB, systemic lupus erythematosus, Kawasaki syndrome (uveitis), sarcoidosis
- **Finding:** Sinus tenderness, nasal discharge, or halitosis?
- **Significance:** Sinusitis
- **Finding:** Pharyngitis?
- **Significance:** Kawasaki syndrome, EBV, SBE
- **Finding:** Tachypnea?
- **Significance:** SBE, pneumonia
- **Finding:** Rales?
- **Significance:** Histoplasmosis, sarcoidosis, coccidioidomycosis
- **Finding:** Cardiac murmur, gallop, or friction rub?
- **Significance:** SBE, acute rheumatic fever, pericarditis
- **Finding:** Hepatosplenomegaly?
- **Significance:** Hepatitis, EBV, CMV
- **Finding:** Rectal abnormalities?
- **Significance:** Pelvic abscess, IBD
- **Finding:** Arthritis?
- **Significance:** JIA, IBD
- **Finding:** Bony tenderness?
- **Significance:** Juvenile rheumatoid arthritis, leukemia, osteomyelitis

DIAGNOSTIC TESTS & INTERPRETATION

The laboratory evaluation for a child with FUO should be directed toward the most likely diagnostic possibilities. Consider the following initial studies:

- **Test:** CBC with differential and careful examination of WBC morphology
- **Significance:** Kawasaki syndrome, cyclic neutropenia, malignancy, ehrlichiosis, babesiosis
- **Test:** ESR, C-reactive protein, or procalcitonin
- **Significance:** Collagen-vascular disease, IBD, occult infection. Generally normal in drug fever and central fever.
- **Test:** Blood cultures
- **Significance:** Endocarditis, salmonellosis, other bloodstream infections
- **Test:** Urinalysis and urine culture
- **Significance:** UTI, Kawasaki syndrome (sterile pyuria)
- **Test:** Tuberculin skin test (by purified protein derivative)
- **Significance:** TB
- **Test:** Stool bacterial culture and examination for ova and parasites
- **Significance:** Salmonella, Giardia
- **Test:** Specific antibody testing
- **Significance:** Depending on clinical suspicion, consider:
 - First line: Streptococcal enzyme titers (antistreptolysin O, anti-DNase B), EBV, CMV, cat-scratch disease, Lyme disease, HIV, hepatitis A, B, or C
 - Second line: Rocky Mountain spotted fever; ehrlichiosis/anaplasmosis, toxoplasmosis, brucellosis, Q fever, leptospirosis, tularemia, dengue fever
- Viral testing of nasopharyngeal aspirates
- Evaluation for immune deficiency
- Bone marrow examination and culture: *Salmonella* infection, *Mycobacterium avium* complex, histoplasmosis, brucellosis, malignancy
- Lumbar puncture

Imaging

- Sinus CT: Sinusitis
- Chest radiograph: TB, endemic fungi, pneumonia
- Chest and/or abdominal CT scan: TB, liver abscess, hepatosplenic cat-scratch disease
- Pelvic or extremity MRI: Osteomyelitis, pyomyositis
- Gallium or bone scan: Osteomyelitis

FAQ

- Q: Do all of the above-mentioned tests need to be performed?
- A: A “shotgun” approach to testing is rarely useful in making the diagnosis.

FLOPPY INFANT SYNDROME

Garrick A. Applebee

BASICS

DESCRIPTION

- “Floppy infant” implies generalized hypotonia presenting at birth or early in life with decreased movement, decreased resistance to movement, or increased joint laxity.
- Neuropathology includes CNS, lower motor neuron, peripheral nervous system (PNS), and primary muscle disease.
- Nonspecific transient hypotonia occurs in nonneurologic illnesses and may suggest endocrine, GI, or metabolic disease.

EPIDEMIOLOGY

Prevalence

No comprehensive prevalence known for this heterogeneous syndrome; overall, diseases affecting the CNS are more common than the PNS.

RISK FACTORS

Genetics

Many heritable disorders, including those with autosomal dominant, autosomal recessive, X-linked, and non-Mendelian inheritance patterns, feature infantile hypotonia.

PATHOPHYSIOLOGY

Neurologic causes may be divided into 2 major categories:

- Nonparalytic hypotonia: Hypotonia without weakness generally resulting from CNS or other organ system pathology
- Paralytic hypotonia: Hypotonia due to weakness from neuromuscular pathology

COMMONLY ASSOCIATED CONDITIONS

- Hip dislocation/contractures/joint laxity
- Feeding difficulties
- Seizure disorders
- Developmental/motor delay
- Apnea/hypoventilation
- Hypersomnolence

DIAGNOSIS

HISTORY

- Prenatal period and delivery:
 - Prenatal period:
 - Family history
 - Parental consanguinity
 - Maternal illness
 - Drug/teratogen exposure
 - Polyhydramnios (poor prenatal swallow)
 - Fetal movements
 - Delivery:
 - Birth trauma
 - Shortened umbilical cord
 - Apgar scores
- Neonatal period:
 - Maternal perinatal infection
 - Seizures
 - Apnea

- Later infancy:
 - Delayed motor milestones
 - Delayed social, fine motor, or language milestones point to CNS defect.
 - Feeding difficulties

PHYSICAL EXAM

Exam findings will help determine if hypotonia is due to systemic or neurologic disease. If the latter is suspected, physical findings will help localize to specific region of nervous system (CNS vs. PNS).

Perform:

- General physical exam
- Neurologic exam

FINDINGS/SIGNS AND SYMPTOMS

- General physical exam:
 - Look for dysmorphism.
 - Alertness: Infants with neuromuscular disease (unlike CNS disease) are typically alert.
 - Poor spontaneous movement
 - Abnormal head size and/or shape
 - High-arched palate (neuromuscular disorders)
 - Tongue fasciculations (anterior horn cell)
 - Large tongue (storage disorders)
 - Ophthalmologic exam: Cataracts, pigmentary retinopathy (peroxisomal disorders), cherry-red spot (storage disorders)
 - Visceral enlargement (storage disorders)
 - Arthrogryposis (central, neuromuscular, or connective tissue disorders)
 - Hip dislocation (intrauterine hypotonia)
 - Joint laxity (connective tissue disorders)
- Neurologic exam:
 - Muscle tone:
 - Infants exhibit abnormal resting posture (abducted, externally rotated legs, flaccid arms) and prominent head lag with pull-to-sit.
 - Fisting indicates spasticity.
 - Posture and tone in supine position, ventral and horizontal suspension, and traction abnormal. Elbow may extend beyond midsternum easily (scarf sign).
 - Generalized hypotonia with increased tone in thumb adductors, wrist pronators, and hip adductors often noted in early cerebral palsy
 - Strength:
 - Strength of cry
 - Decreased expression indicates facial weakness (myotonic dystrophy, congenital muscular dystrophy, congenital myopathies).
 - Ptosis and ophthalmoplegia (myasthenic syndromes, congenital myopathies, and congenital muscular dystrophies)
 - Regional strength differences may suggest certain disorders. Spinal muscular atrophy (SMA) spares diaphragm, face muscles, and pelvic sphincters. Neuropathies present with distal limb weakness and proximal sparing. Myasthenic syndromes affect bulbar and oculomotor muscles.
 - Fatigability is a cardinal feature of myasthenic syndromes and may occur in other neuromuscular diseases.

- Reflexes:
 - Increased deep tendon reflexes (DTRs) imply central dysfunction.
 - In myopathic diseases, DTRs are diminished in proportion to degree of weakness.
 - Absent reflexes in setting of minimal weakness typical of neuropathic disease.

DIAGNOSTIC TESTS & INTERPRETATION

History and exam will guide both laboratory testing and imaging studies to establish a diagnosis.

Lab

- Initial tests may include:
 - Electrolytes (including Ca and Mg)
 - Thyroid function tests
 - Creatine kinase (CK)
 - Arterial blood gas
- Blood, urine, CSF cultures: Evaluate for infection.
- To identify an inborn error of metabolism:
 - Assays for uric acid, ammonia, and lactate (blood, urine, CSF)
 - Quantitative amino acid analysis (blood, urine)
 - Organic acid and acylcarnitine profiles (blood)
 - Assays of very-long-chain fatty acids (plasma)
- Molecular studies:
 - Karyotype: Chromosomal duplications, deletions, and trisomies
 - DNA microarray
 - DNA methylation, mutation analyses: A variety of diagnoses (Prader-Willi)
- Stool could be evaluated for *Clostridium* toxin when botulism suspected (endemic in Pennsylvania, some northwestern states).

Imaging

- MRI: Preferable to CT if CNS basis is suspected
- In some centers, muscle imaging is used to delineate a neuromuscular problem.

Diagnostic Procedures/Other

- Administration of an anticholinesterase in suspected myasthenia may be diagnostic.
- Electromyography (EMG) and nerve conduction velocity:
 - Useful tools in assessing the lower motor unit and localizing site of involvement

ALERT

Pitfalls:

- EMG and nerve conduction velocity in young infants require expertise to perform and interpret. Values change with development.
- Electroencephalogram, neuroimaging, if CNS abnormalities suspected
- Muscle biopsy for specific biochemical and immunohistochemical tests may reveal specific diagnoses.
- Electron microscopy may identify abnormal organelles, inclusions, or storage material.

Pathological Findings

Muscle biopsy: For suspected congenital myopathies, storage myopathies (acid maltase), muscular dystrophies (latter often feature high CK, and may be diagnosed via blood DNA testing)

DIFFERENTIAL DIAGNOSIS

Remember, many acute illnesses in infancy may present with decreased tone and/or weakness.

- Nonparalytic hypotonia:
 - Benign congenital hypotonia: Transient hypotonia without dysmorphology, weakness, or other neurologic, physical, or laboratory abnormalities
 - Connective tissue disorders:
 - Ehlers-Danlos syndrome
 - Marfan syndrome
 - Osteogenesis imperfecta
 - Chondrodysplasia
 - Benign joint laxity
 - Acute metabolic/systemic disorders:
 - Sepsis
 - Trauma
 - Malnutrition
 - Drug intoxication (maternal sedative, analgesic, and/or anesthetic exposure)
 - GI disease (obstruction, bleed)
- Chronic metabolic/systemic disorders:
 - Congenital heart disease
 - Endocrinopathies (e.g., hypothyroidism)
 - Renal tubular acidosis
 - Rickets
 - Hypercalcemia
 - Cystic fibrosis, malabsorption
 - Organic acidemias
 - Glycogen storage disease
 - Mucopolysaccharidoses
 - Peroxisomal disorders (cerebrohepato renal, neonatal adrenoleukodystrophy)
- Disorders involving cerebral cortex, cerebellum, brainstem, cord:
 - Congenital malformations (lissencephaly, holoprosencephaly)
 - Hypoxic-ischemic encephalopathy
 - Intracranial hemorrhage
 - Infections (meningitis, encephalitis)
 - Trauma
 - Metabolic encephalopathies
 - Chromosomal disorders (Angelman, Prader-Willi, and Down syndromes)
 - Neuronal migration disorders
 - Sphingolipidoses
- Disorders involving spinal cord:
 - Myelodysplasias (meningomyelocele, diplomyelia, diastematomyelia)
 - Traumatic injury
- Paralytic hypotonia: Paralytic causes must be considered in floppy infants whose physical exam reveals significant weakness and decreased or absent DTRs. This category includes disorders of anterior horn cell, peripheral nerve, neuromuscular junction, and muscle:
 - Disorders of anterior horn cell:
 - Spinal muscular atrophy
 - Arthrogryposis multiplex congenita
 - Pompe (glycogen storage type II)
 - Neonatal poliomyelitis
 - Disorders of peripheral nerve:
 - Dejerine-Sottas disease
 - Guillain-Barré syndrome
 - Familial dysautonomia
 - Congenital hypomyelinating neuropathy
 - Leukodystrophies
 - Leigh/mitochondrial disease

- Disorders of neuromuscular junction:
 - Myasthenia gravis (congenital, transient)
 - Toxic–metabolic defects (hypermagnesemia, antibiotics [especially aminoglycosides], nondepolarizing neuromuscular blockers)
 - Infantile botulism
- Disorders of muscle:
 - Congenital structural myopathies: Central core, nemaline, centronuclear myopathy
 - Congenital myotonic dystrophy
 - Congenital muscular dystrophies
 - Metabolic myopathies (mitochondrial disorders, glycosylation disorders, lipid storage disease, others)

**TREATMENT****MEDICATION (DRUGS)**

- Anticholinesterase medications may be required in treatment of myasthenic syndromes.
- IV immunoglobulin and plasmapheresis have been used in treatment of infants with Guillain-Barré syndrome

ADDITIONAL TREATMENT**General Measures**

- Address apnea, hypoventilation, hypoxia:
 - Intubation or positive pressure devices may be required.
 - Chest physical therapy, antibiotics, bronchodilators, and oxygen may be needed.
 - Hypermagnesemia can cause apnea.
 - Weak infants in car seats may be at risk of acute respiratory problems.
- Underlying toxic or metabolic causes should be addressed and treated appropriately.

COMPLEMENTARY & ALTERNATIVE THERAPIES

- Physical therapy:
 - May help maintain maximum muscle function and reduce secondary deformities
 - Orthopedic consultation to evaluate hips and contractures should be obtained.

SURGERY/OTHER PROCEDURES

Surgical intervention in later childhood to correct primary as well as secondary deformities

IN-PATIENT CONSIDERATIONS**Admission Criteria**

Respiratory insufficiency, feeding intolerance, failure to thrive, metabolic abnormality

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS**

Individualized multidisciplinary care including specialists in neurology, pulmonary, orthopedics, development, physical therapy, and nutrition ensures optimal outcomes.

DIET

Feeding and swallowing difficulties may necessitate nutritional supplementation and/or feeding tube placement.

PROGNOSIS

Many of the paralytic hypotonias are quite variable in their clinical course. Severity of disease depends on underlying cause and associated respiratory and nutritional factors.

COMPLICATIONS

- Respiratory insufficiency/recurrent pneumonia
- Orthopedic deformities
- Poor nutritional status

- 779.89 Other specified conditions originating in the perinatal period

ICD10

P94.2 Congenital hypotonia

FAQ

- Q: By what age should one expect resolution of benign congenital hypotonia?
- A: Hypotonia typically resolves by the time the infant is walking, up to 18 months of age.
- Q: What clinical sign can help distinguish between SMA and infantile botulism?
- A: Tongue fasciculations are seen in SMA. Also, decreased pupillary light reflex is seen in botulism.

FOOD ALLERGY

Jackie P-D. Garrett

Terri Brown-Whitehorn

Stephen McGeady (5th edition)

BASICS

DESCRIPTION

Food allergy has recently been defined as “an adverse health effect arising from a specific immune response that occurs reproducibly on exposure to a given food.” Most commonly, the protein component of the food is responsible for the adverse immunologic response.

- Classifications of food allergies:
 - IgE-mediated, including:
 - Anaphylaxis
 - Acute urticaria
 - Oral allergy syndrome
 - Non-IgE-mediated (cell-mediated), including:
 - Food protein enterocolitis syndrome (FPIES)
 - Food protein-induced allergic proctocolitis
 - Celiac disease
 - Mixed IgE and non-IgE-mediated, including:
 - Atopic dermatitis
 - Eosinophilic gastroenteropathies (eosinophilic esophagitis, eosinophilic gastroenteritis)
- Most common IgE-mediated food allergies:
 - Children:
 - Milk
 - Egg
 - Soy
 - Peanut
 - Wheat
 - Fish
 - Adults:
 - Peanuts
 - Tree nuts
 - Fish
 - Shellfish

- Most common non-IgE-mediated food allergies associated with food protein enterocolitis and proctocolitis:
 - Milk
 - Soy
 - Wheat
 - Rice
 - Oat

EPIDEMIOLOGY

Food-induced anaphylaxis is the most common cause of anaphylactic reactions treated in emergency departments in the U.S. Many studies suggest that the prevalence of food allergy has increased over the past 10–20 years.

Prevalence

- 5–8% of children <3 years of age, 4% of teens and adults
- Nearly 2.5% of infants have hypersensitivity reactions to cow’s milk during 1st year (thoughts are that 1/2 are GI diseases); outgrown by most (80%) by 5 years of age.
- 1.3% have egg allergy by 2.5 years (based on population-based studies); 66% of children outgrow egg allergy by 7 years of age.
- 0.6% of U.S. population have peanut allergy.
- 37% of children with moderate to severe atopic dermatitis have a food allergy.
- 34–49% of children with food allergy have asthma.
- 33–40% of children with food allergy have allergic rhinitis.
- Fatal and near-fatal reactions are associated with uncontrolled asthma.

RISK FACTORS

- Genetic
- Family history
- Presence of atopic dermatitis
- Other unknown factors suspected

ETIOLOGY

- Oral tolerance to food proteins believed to develop through T-cell anergy or induction of regulatory T cells. Food hypersensitivity develops when oral tolerance fails to develop or breaks down.
- IgE-mediated: T cells induce B cells to produce IgE antibodies that initially bind on the surface of mast cells and basophils; reexposure to the food protein binds to IgE antibodies, leading to degranulation of those cells, leading to release of histamine and other chemical mediators.
- Non-IgE-mediated (cell-mediated): T cells react to protein-inducing proinflammatory cytokines, leading to inflammatory cell infiltrates and increased vascular permeability. These factors lead to subacute and chronic responses primarily affecting the GI tract.
- Mixed IgE and non-IgE-mediated: Eosinophilic esophagitis and eosinophilic gastroenteropathy are characterized by eosinophilic infiltration of intestinal wall, occasionally reaching to serosa.

COMMONLY ASSOCIATED CONDITIONS

- Asthma (4-fold more likely)
- Allergic rhinitis (2.4-fold more likely)
- Other atopic diseases
- Dermatitis herpetiformis (celiac)

DIAGNOSIS

Vary depending on the individual and the type of food hypersensitivity (see Table for symptoms of specific illnesses)

- IgE-mediated:
 - Urticaria
 - Angioedema
 - Immediate GI reactions (emesis, cramping, etc.)
 - Oral allergy syndrome
 - Rhinitis
 - Anaphylaxis (hypotension, dyspnea, dysphonia, wheezing, coughing, angioedema)
 - Nausea, abdominal pain, colic vomiting develop within 2 hours of ingesting offending foods
 - Diarrhea: Develops within 2–6 hours
- Mixed IgE- and non-IgE (cell-mediated):
 - Eosinophilic gastroenteropathy:
 - Weight loss (key feature), pain, emesis, failure to thrive (FTT), anorexia
 - Some infants have large protein-losing enteropathy component causing low serum albumin and hypogammaglobulinemia.
 - Eosinophilic esophagitis:
 - Dysphagia
 - Food impaction
 - Intermittent vomiting
 - Food refusal
 - Abdominal pain
 - Irritability
 - Failure to respond to reflux medication
 - Failure to thrive
 - Gastroesophageal reflux

- Non-IgE-mediated:
 - Food protein enterocolitis:
 - Severe vomiting 2 hours after ingestion; profuse diarrhea
 - Shock due to fluid/electrolyte loss
 - Very ill appearing
 - Food protein proctocolitis:
 - Blood in stool
 - Food protein-induced enteropathy:
 - Diarrhea, bloating, FTT, anemia

PHYSICAL EXAM

- IgE mediated:
 - Hives/angioedema (in 12% of patients with anaphylaxis, there are no skin findings and often these are most severe cases)
 - Wheezing/dyspnea
 - Hypotension/tachycardia
 - Vomiting, abdominal tenderness
 - Ill-appearing
- Mixed IgE-mediated, non-IgE-mediated:
 - Eosinophilic esophagitis: Abdominal tenderness (variable), growth concerns (in some)
 - Eosinophilic gastroenteropathy:
 - Abdominal tenderness
 - Weight loss
- Cell mediated:
 - Food protein-induced enterocolitis
 - Abdominal distension
 - FTT
 - Severe dehydration (may present in shock)
 - Celiac disease:
 - Abdominal distension
 - FTT

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Initial lab tests

Depends on clinical presentation and patient symptoms; may include:

- CBC with differential:
 - Anemia in patients with enteropathy
 - Eosinophilia not consistently seen in patients with eosinophilic esophagitis, eosinophilic gastroenteritis, or enteropathy
- Serum IgE: May be elevated in:
 - IgE-mediated hypersensitivities
 - Eosinophilic esophagitis, eosinophilic gastroenteritis
- Albumin: Low with:
 - Protein-losing enteropathies
 - Non-IgE-mediated protein enterocolitis
 - Eosinophilic gastroenteritis
- Tryptase: May be elevated in anaphylaxis; obtain within 4 hours of initial reaction:
 - ImmunoCAP assay may be helpful in IgE-mediated illness
 - ImmunoCAP has many false-positives (do not send food allergy panels)

Diagnostic Procedures/Other

- Skin prick testing:
 - Used in conjunction with clinical history for IgE-mediated food allergies
 - 50% positive predictive value; 95% negative predictive value
 - Performed upon evaluation of patients with eosinophilic esophagitis
- Food challenges:
 - Gold standard for diagnosis of food allergy is double-blind placebo-controlled challenge but impractical in many clinical settings.
 - Most sites use single-blind or open food challenge.
 - Used to confirm food allergy in patients when unsure of diagnosis or to assess whether someone has outgrown food allergy (either IgE-mediated or food protein-induced enterocolitis)
 - Challenge must be performed in setting equipped to treat severe allergic reactions

- Endoscopy with biopsies of esophagus, stomach, and small bowel:
 - Patients should be on proton pump inhibitor prior to endoscopy if there are concerns of eosinophilic esophagitis as GERD may also lead to eosinophils in esophagus.
- Colonoscopy:
 - If lower GI symptoms present
- Patch skin testing:
 - May be used to evaluate for mixed (IgE/non-IgE-mediated) or cell-mediated sensitivities
 - Standards for interpretation and methods for reliability are under development.
- Elimination diets:
 - Should be conducted with care
 - May lack critical nutrients
 - Oral rechallenge should be carefully planned, because a more severe reaction may ensue after a food has been temporarily removed.

Pathological Findings

- Increased eosinophils in eosinophilic gastroenteropathy
- Presence of intraepithelial lymphocytes and variable villous damage in celiac disease

TREATMENT

MEDICATION (DRUGS)

First Line

- Anaphylaxis:
 - Epinephrine for severe allergic reaction or anaphylaxis
 - H₁-antihistamines (diphenhydramine) may be given for milder symptoms.
 - H₂ antihistamines may be given in conjunction with H₁ antihistamines.
 - Systemic steroids
- Eosinophilic gastroenteritis:
 - Systemic steroids (briefly)
 - Swallowed steroids
 - Elemental formulas
 - Dietary restrictions

ADDITIONAL TREATMENT

General Measures

- Avoidance of food allergen
- Anaphylaxis:
 - Full monitoring of vital signs
 - Epinephrine for severe allergic reaction or anaphylaxis given intramuscularly: May be repeated
 - IV fluid bolus
 - Antihistamines may be given for hives or mild skin swelling.
 - Antihistamines (H₁ and H₂ blocker) and bronchodilators may be used as adjunct to epinephrine for severe reactions.
 - Glucocorticoids may prevent biphasic reaction.
- Nonanaphylactic food allergies: Eosinophilic esophagitis
- Systemic steroids for a brief course, swallowed steroids (NPO for 30 minutes after use)
- Hydrolyzed or elemental formulas: Patients may respond to hypoallergenic formulas.

ISSUES FOR REFERRAL

Allergy/immunology and/or gastroenterology follow-up needed for most patients for diagnosis and long-term management

ONGOING CARE

DIET

Nonanaphylactic and anaphylactic food allergies:
Removal of the offending food agent from diet

PATIENT EDUCATION

- Epinephrine self-administration if anaphylaxis
- Anaphylaxis plan for families to know which medication to use when, along with education regarding emergency room avoidance
- Education regarding specific food avoidance and label reading

PROGNOSIS

- Generally good, after offending food antigens are removed from diet and adequate nutrients are ensured
- Tolerance to food allergens may develop over time.
- IgE-mediated disease may persist longer than non-IgE-mediated.
- Eosinophilic esophagitis and eosinophilic gastroenteritis are considered chronic illnesses.

COMPLICATIONS

- Food-protein allergy can be associated with:
 - Poor growth
 - Feeding disorder
 - Protein-losing enteropathy
 - Anemia
- Eosinophilic esophagitis:
 - Strictures
 - Hiatal hernia concerns
 - Poor growth
 - Feeding disorder
- Respiratory food-hypersensitivity reactions:
 - Heiner syndrome: Rare food-induced pulmonary hemosiderosis

Food Allergy/Hypersensitivity

Illness	Classification	Symptoms	Diagnosis
IgE mediated	Anaphylaxis	Rapid onset; nausea, vomiting; abdominal pain; hives, coughing, wheezing, involvement of other organ systems—skin, respiratory system	History + mediated skin-prick or ImmunoCAP test; oral challenge only in monitored setting with emergency access and anaphylaxis therapy
IgE mediated	Oral allergy syndrome (children and adults); due to cross-reactivity between food protein and pollen	Mild pruritus; angioedema of lips and oropharynx; sense of tightness in throat; rare systemic symptoms	History + skin-prick tests; oral challenge positive with fresh foods and negative with cooked foods
IgE and cell mediated	Allergic eosinophilic gastroenteritis	Failure to thrive; weight loss, abdominal pain, irritability, early satiety, vomiting, protein-losing enteropathy, edema, ascites	History + skin prick, endoscopy and colonoscopy with biopsy; elimination diet; monitor closely, may need immunosuppressants
IgE and cell mediated	Eosinophilic esophagitis	GERD with failure to respond to proton pump inhibitor; vomiting; FTT, dysphagia, intermittent abdominal pain; irritability	History, endoscopy with biopsy, elimination diet based on testing or history, elemental diet or swallowed steroids
Cell mediated	Allergic proctocolitis “breast-milk colitis” (infants)	Bloody stool, melena in first few months of life; no diarrhea or failure to thrive	Elimination of food (cow’s milk or soy most commonly) clears bleeding in 72 hours; reexposure causes recurrence; RAST/skin prick not helpful; typically outgrown by 12–18 months of age
Cell mediated	Food protein induced enterocolitis syndrome (FPIES)	Severe symptoms; vomiting 2 hours after meal, severe vomiting; 6–8 hours later, diarrhea +/- blood, abdominal distention, failure to thrive dehydration, hypotension	Elimination of protein clears symptoms in 1–3 days ImmunoCAP/skin prick NOT helpful; patch testing may be helpful
Cell-mediated	Food protein enteropathy (infants)	Diarrhea, steatorrhea, abdominal distention, flatulence, failure to thrive or weight loss, nausea/vomiting oral ulcers	Endoscopy with biopsy; elimination diet resolves symptoms. Similar symptoms to celiac, but resolves by 2 years of age.
Celiac disease (infants to adults)	Diarrhea, steatorrhea, failure to thrive, abdominal distention, flatulence, weight loss, nausea/vomiting, oral ulcers	Endoscopic biopsy when patient is on gluten; gluten-free diet resolves symptoms. Anti-gliadin and TTG antibodies; HLA-DQ2 & DQ8 are often found.

ICD-9 CODES

- 530.13 Eosinophilic esophagitis
- 558.3 Allergic gastroenteritis and colitis
- 693.1 Dermatitis due to food taken internally

ICD10

- L27.2 Dermatitis due to ingested food
- T78.1XXA Other adverse food reactions, not elsewhere classified, initial encounter
- Z91.018 Allergy to other foods

FAQ

- Q: What are the most common food allergens leading to IgE mediated allergic reactions in childhood?
- A: The most common allergens to which children are sensitive are milk, egg, soy, wheat, fish, peanuts, and nuts.
- Q: Do you recommend elimination diets?
- A: Elimination diets are recommended when necessary to treat underlying disease. Nutrition evaluation is often necessary to avoid nutrient-deficient diets and malnutrition. They are used only in extreme circumstances because they can result in nutrient-deficient diets and malnutrition without identifying the offending allergen. Double-blinded food challenges are a better method for identifying the offending agent.

FOOD POISONING OR FOODBORNE ILLNESS

Christina B. Bales

BASICS

DESCRIPTION

Any illness resulting from the ingestion of food or drink contaminated with an infectious organism or associated toxin

GENERAL PREVENTION

- Vaccination:
 - Oral rotavirus vaccine
 - Inactivated hepatitis A vaccine
- Preventive strategies:
 - Hand washing
 - Proper food handling (adequate cooking and refrigeration)
 - Avoidance of unpasteurized dairy products and juices
 - Avoidance of raw or undercooked eggs, meat, and shellfish
 - Avoidance of honey in children <1 year old
 - Avoidance of well water, which may contain nitrates, in preparing infant formulas

EPIDEMIOLOGY

Incidence (US Annual Estimates)

- 48 million illnesses
- 128,000 hospitalizations
- 3,000 deaths

PATHOPHYSIOLOGY

- Bacteria (often causes secretory diarrhea):
 - Invades intestinal epithelium
 - Elaborates toxin into the GI tract
 - Elaborates toxin into food (preformed toxin is ingested)
- Virus (often causes osmotic diarrhea): Invasion analysis of intestinal epithelial cells, leaving predominantly immature cells with inadequate disaccharidase activity

ETIOLOGY

- Viruses including calciviruses (noro and astro)
- Bacteria and/or associated toxins. Most common (in descending order):
 - *Salmonella* (nontyphoid)
 - *Clostridium perfringens*
 - *Campylobacter*
 - *Staphylococcus aureus*
- Parasites

DIAGNOSIS

SIGN AND SYMPTOMS

- GI illness:
 - Nausea and vomiting
 - Diarrhea (watery vs. mucoid vs. bloody)
 - Abdominal pain or cramping
 - Constitutional symptoms (fever, malaise,)
 - Jaundice (may be present in hepatitis A)
- Botulism:
 - Impaired cranial nerve activity (sluggish or fixed pupils, ptosis, diminished corneal and oculovestibular reflexes, facial weakness, diminished gag, weak cry)
 - Constipation
 - Hypotonia with progressive symmetric descending paralysis
 - Absent deep tendon reflexes
 - Apnea

HISTORY

- Similarly exposed persons with related symptoms
- Timing of illness in relation to ingestion
- Duration of illness
- Type of food ingested

PHYSICAL EXAM

- Detailed neurologic examination
- Assessment of dehydration status (examination of mucous membranes, skin turgor)
- Assessment of potential liver involvement (hepatomegaly, jaundice, icterus)
- Careful abdominal examination

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Organism culture within:
 - Stool
 - Vomitus
 - Food (10^5 organisms/g)
 - Hand lesions of food handlers
 - Intestinal tissue
- Toxin identification in stool
- Serum antibody identification (e.g., HAV IgM in hepatitis A)
- Polymerase chain reaction (PCR) identification of viral RNA (e.g., norovirus) in stool or vomitus
- Virus identification via electron microscopy (e.g., norovirus)
- Latex agglutination tests (e.g., *Brucella*)

Diagnostic Procedures/Surgery

- Electrophysiology (botulism)
- Electroneurography (ENG): Normal
- Electromyography (EMG): Incremental response with repetitive stimulation

DIFFERENTIAL DIAGNOSIS

- Non-foodborne infection:
 - GI
 - Urinary tract
 - Upper respiratory (e.g., otitis media)
- Food intolerance or allergy:
 - Cow's milk (protein allergy)
 - Carbohydrate intolerance (e.g., lactose)
- Dietary manipulations:
 - Hyperosmolar formulas
 - Food additives (dyes, processing materials, coloring)
 - Caffeine
 - Overfeeding
 - Low fat intakes
 - Excessive fluids
- Miscellaneous:
 - Antibiotic induced
 - Malnutrition

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Gastroenteritis:
 - Treat dehydration with oral rehydration solution (ORS):
 - Standard ORS contains 75–90 mEq of sodium and 74–111 mmol/L of glucose.
 - Alternative ORS, including rice-based carbohydrate or amylase-based solutions, may be more effective for *Vibrio cholerae* infections.
 - Transition rapidly (after 3–4 hours of ORS tolerance) to regular diet (see below).
 - Continue breastfeeding infants if possible.
- Botulism:
 - Continuous cardiac and respiratory monitoring
 - Endotracheal intubation and assisted ventilation in cases of respiratory insufficiency
 - Naso- or orogastric tube feeding

DIET

- BRATT diet (bananas, rice, apple sauce, toast, tea): Inappropriate due to low calorie, protein, and fat contents
- Balanced, varied diet, providing easily digestible, complex carbohydrates will promote improved stool consistency.

SPECIAL THERAPY

Botulism:

- Foodborne: Equine-derived immunoglobulin
- Infant: Human-derived immunoglobulin (BABY BIG) reduces hospital stay, duration of ventilation, duration of tube feeding, and cost.

IV Fluids

- If patient is unable to be rehydrated via oral route (because of ileus, circulatory failure, CNS complications) or
- If >10% dehydration

Complementary and Alternative Therapies

- Probiotics (especially lactobacillus) have been shown to reduce duration of less severe, nonrotavirus diarrhea and hospital stays.
- Zinc supplementation may be beneficial in malnourished children.

MEDICATION (DRUGS)

Use of antibiotics is:

- Always indicated:
 - *Shigella*
 - *Brucella*
 - *Listeria monocytogenes* (invasive disease)
 - *Salmonella typhi*
 - *Cyclospora cayetanensis*
 - *Trichinella*
 - *Entamoeba histolytica*
 - *Giardia lamblia*
 - Sometimes indicated:
 - *Escherichia coli* (prolonged enterotoxigenic)
 - *Vibrio cholerae* (moderate to severe cases)
 - *Campylobacter* (Early treatment limits duration, prevents relapse, and shortens duration of shedding.)
 - Non-typhi *Salmonella* (Only patients who are <3 months old, are immunocompromised, have hemoglobinopathy, or have chronic GI conditions should be treated. Other patients should not be treated as antibiotics prolong organism shedding in the stool and promote disease spread.)
 - *Yersinia pestis* (sepsis)
 - *Toxoplasma gondii* (pregnant and immunocompromised patients)
 - Cryptosporidium (severe, <12 years of age)
- Contraindicated: *Clostridium botulinum* (aminoglycosides potentiate paralytic effects)

 **ONGOING CARE**

PROGNOSIS

- Most gastroenteritis secondary to food poisoning is mild and self-limited.
- Recovery is complete in 2–5 days in most individuals.
- In the very young, prognosis is more guarded because these patients can become dehydrated quickly.
- After the patient has survived the paralytic phase of botulism, the outlook for complete recovery is excellent.

REPORTING REQUIREMENTS

- Foodborne diseases and conditions designated as notifiable at the national level include:
 - Notifiable bacterial foodborne diseases and conditions: Botulism, Brucellosis, Cholera, *Enterohemorrhagic E. Coli*, Hemolytic uremic syndrome, Listeriosis, Salmonellosis (other than *S. typhi*), Shigellosis, Typhoid fever (*S. typhi* and *S. paratyphi* infections).
 - Notifiable viral foodborne diseases and conditions: Hepatitis A.
 - Notifiable parasitic foodborne diseases and conditions: Cryptosporidiosis, Cyclosporiasis, Trichinellosis, Giardiasis
- In the US, additional reporting requirements may be mandated by state and territorial laws and regulations. Details on specific state reporting requirements are available from state health departments and from the Council of State and Territorial Epidemiologists (<http://www.cste.org/nndss/reportingrequirements.htm> or phone 770-458-3811)

FAQ

- Q: What are the most common causes of food poisoning?
- A: Viruses, particularly Norovirus, are the leading cause of forborne illnesses. The most common bacterial infections include *Salmonella*, *C. perfringens*, and *Campylobacter jejuni*.
- Q: How are the signs and symptoms of food poisoning different from those of a viral gastroenteritis?
- A: The signs and symptoms of food poisoning and gastroenteritis are similar in that the patient displays diarrhea, vomiting, and fever. Historically, food poisoning is distinguished by its association with a common food that affects multiple individuals who consumed it.
- Q: Which foods are most likely to be contaminated?
- A: Poorly cooked foods (eggs, meats, fish, shellfish), unpasteurized milk and juices, inadequately washed fresh produce, home canned goods, soft unpasteurized cheeses. Use of well water, which may be contaminated with nitrates, to prepare infant formula can result in infant methemoglobinemia

FRAGILE X SYNDROME

Chad R. Haldeman-Englert

Marni J. Falk

BASICS

DESCRIPTION

- Most common cause of inherited intellectual disability
- Caused by mutations in the *FMR1* gene on chromosome Xq27.3

EPIDEMIOLOGY

- Fragile X syndrome accounts for 1.2% of males with intellectual disability and 30% of X-linked intellectual disability cases
- Affects ~16–25/100,000 in males; prevalence in females is ~1/2 that in males.
- Carrier prevalence in females for *FMR1* premutation is 1:382 and for intermediate allele(s) is 1:143.

RISK FACTORS

Genetics

- Caused by loss-of-function mutations in the *FMR1* gene on chromosome Xp27.3
- >99% of affected individuals have a trinucleotide (CGG) repeat expansion (>200 repeats) within exon 1 of the *FMR1* gene
- Repeat size categories (based on guidelines from the American College of Medical Genetics):
 - Normal number of repeats: 5–44
 - Intermediate (“gray zone”): 45–54
 - Premutation: 55–200
 - Full mutation: >200
- Other *FMR1* gene mutations may rarely occur (<1% cases).
- Genetic counseling:
- Fragile X syndrome is inherited in an X-linked manner, but may not always follow typical inheritance patterns.
- Fragile X is a CGG trinucleotide repeat disorder that shows anticipation, in which the phenotype can be more severe in subsequent generations due to an expansion in the number of CGG repeats.
- Expansion only may occur in the germline of mothers who carry a premutation range repeat allele of *FMR1*.
 - Expansion does not always occur in offspring of female premutation carriers. In general, the larger the number of CGG repeats (>50), the higher the probability that expansion to a full mutation will occur.
- A male with a premutation will pass on the premutation to 100% of his daughters and none of his sons.
- Females with a full mutation are typically less severely affected than males because their 2nd *FMR1* allele is typically normal and, assuming random X-inactivation occurs, produces variable amounts of Fragile X mental retardation protein (FMRP).
- Males with mosaicism for the *FMR1* full mutation (some cells with the full-mutation and other cells with the premutation) are generally less severely affected (average IQ 60) relative to males with the full mutation in all of their cells.

- Males with the full mutation who have >50% of cells unmethylated have higher FMRP levels and are generally less severely affected (average IQ 88).
- Patients with larger chromosomal deletions involving *FMR1* and other nearby genes typically have a more severe phenotype.

GENERAL PREVENTION

- Prenatal diagnosis by chorionic villous sampling (~10–12 weeks’ gestation) or amniocentesis (~16–20 weeks’ gestation) is possible for at-risk pregnancies.
- Preimplantation genetic diagnosis in the setting of *in vitro* fertilization is possible for at-risk couples, but requires a familial *FMR1* mutation be known.

PATHOPHYSIOLOGY

Residual FMRP protein levels directly correlate with the severity of Fragile X syndrome manifestations:

- Absence of FMRP results in characteristic facial, neurologic, and connective tissue abnormalities.
- Decreased FMRP levels may also cause long-term depression of hippocampal synaptic transmission via specific glutamate receptors, with resulting behavioral and neuronal phenotypes.

COMMONLY ASSOCIATED CONDITIONS

Other *FMR1*-related disorders include Fragile X-associated tremor/ataxia syndrome (FXTAS) and premature ovarian failure (POF):

- FXTAS can be seen in older (>age 50 years) male and female premutation carriers. Clinical features include intention tremors, abnormal gait with frequent falling, cerebral atrophy, and memory deficits.
- POF can be seen in 20–25% of female premutation carriers, with menopause occurring prior to age 40.

DIAGNOSIS

HISTORY

- Birth/Neonatal history:
 - Normal to increased birth weight
 - May have large head circumference at birth
 - Feeding problems and frequent emesis due to gastroesophageal reflux may occur, but improves with growth.
 - Irritability may result from sensory integration difficulties and tactile defensiveness.
- Past medical history:
 - Strabismus and hyperopia occur in 40%
 - Frequent ear infections in 60%: Conductive hearing loss is possible
 - Mitral valve prolapse and aortic root dilation can occur, typically in adults.
 - Seizures occur in ~20% of children and may resolve by adolescence.
 - Periventricular heterotopia seen on magnetic resonance imaging (MRI)
 - Pes planus
 - Scoliosis

- Developmental/Behavioral history:
 - Motor delay due to hypotonia
 - Speech may be absent to minimally affected.
 - Autism (60% of males with full mutation)
 - Intellectual disability
 - Severe intellectual disability in males (average IQ of males with the full mutation is 41, with range of 30–55)
 - Borderline or mild intellectual disability in 50% of females with the full mutation (IQ range 70–85)
 - Tantrums occur around age 2 years.
 - Hyperactivity can be severe during childhood.
 - Obsessive and compulsive behaviors also common
 - Often require a routine for daily activities
 - Social anxiety; patients are shy and easily overwhelmed by noisy environments
- Family history:
 - Fragile X syndrome
 - Intellectual disability or autism, especially in males related through the maternal side
 - Tremors or ataxia developing >50 years
 - Premature ovarian failure in females <40 years
 - No male–male transmission

PHYSICAL EXAM

- Growth parameters:
 - Height, weight, and head circumference
- Characteristic facial features:
 - Large head
 - Prominent forehead
 - Long face
 - Large and protruding ears
 - High palate
 - Prominent chin (after puberty)
- Murmur or midsystolic click (mitral valve prolapse)
- Large testicles (after puberty)
- Joint hypermobility, pes planus, scoliosis
- Skin often feels soft and smooth

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Initial lab tests

- Consider *FMR1* mutation testing in:
 - Males or females with features of autism, developmental delays, or intellectual disability
 - Males or females with clinical findings consistent with Fragile X syndrome
 - Family history of Fragile X syndrome, recurrent intellectual disability or autism, especially through the maternal side
 - Males or females with tremor and/or ataxia developing >age 50
 - Females with premature ovarian failure <age 40
- Southern blot or PCR-based analyses are the first-line genetic tests to determine if there is a repeat expansion and define the number of CGG repeats within the *FMR1* gene.

Follow-Up & Special Considerations

- Methylation status can be determined by using a restriction enzyme that selectively cuts nonmethylated DNA or by methylation-sensitive PCR techniques. This study may be helpful in higher-functioning males who have a full mutation to establish their degree of *FMR1* methylation.

- Standard karyotype analysis will typically not be able to detect the repeat expansion.
- If the patient has many clinical features of Fragile X syndrome and the Southern blot is normal, consider further molecular techniques to detect point mutations or whole/partial *FMR1* gene deletions.

Diagnostic Procedures/Other

- Echocardiogram if cardiac exam is consistent with mitral valve prolapse (usually in adults)
- Aortic root dilation may be seen, but typically does not progress or require specific treatment.
- Evaluate for hypertension.
- Assess for seizure activity.
- Developmental evaluations
 - Feeding assessment in infants
 - Education planning:
 - Speech and language, including hearing assessment
 - Occupational and physical therapy
 - Behavioral and neuropsychological testing

DIFFERENTIAL DIAGNOSIS

- In early childhood, the symptoms of Fragile X syndrome are often nonspecific.
- Other genetic syndromes with overlapping features include:
 - Fragile XE syndrome (FRAXE): These patients have a milder degree of intellectual disability, as well as less specific physical characteristics compared to patients with typical Fragile X syndrome (FRAXA)
 - Mutations of the *FMR2* gene on chromosome Xq28 are associated with FRAXE
 - Sotos syndrome: Patients have overgrowth (macrocephaly), intellectual disability, behavioral abnormalities, and cardiac and renal defects. Mutations or deletions of the *NSD1* gene are causative of this syndrome.
 - Prader-Willi syndrome: A few patients with Fragile X syndrome have features that are similar to those in Prader-Willi syndrome, such as obesity and hyperphagia. Other features of Prader-Willi syndrome include hypotonia in infancy, developmental delay, cognitive deficits, and behavioral abnormalities. Abnormal parent-specific imprinting of chromosome 15q11-q13 causes this syndrome.
 - A range of other genes is now recognized to cause X-linked intellectual disability. Clinical diagnostic testing for many of these disorders is now available (www.genetests.org).

TREATMENT

MEDICATION (DRUGS)

- No specific medications are available.
- Some medications are used to treat specific symptoms in individual patients:
 - Stimulant medications (e.g., methylphenidate) or clonidine for hyperactivity
 - Selective serotonin reuptake inhibitors (e.g., fluoxetine) can be used for obsessive and compulsive behaviors, social phobia, anxiety, and depression.
 - Atypical psychotic medications (e.g., risperidone) if psychotic or paranoia symptoms
 - Valproic acid or carbamazepine for seizures or mood stabilization

ADDITIONAL TREATMENT

General Measures

- Treatment is aimed at supportive measures.
- Early developmental services:
 - Physical therapy
 - Occupational therapy
 - Speech and language therapy
 - Social integration therapy
 - Learning support classroom
- Some patients do well in a mainstream school with appropriate support, whereas others require a school for children with special needs.
- Behavioral therapies involve avoidance of overstimulation and providing positive reinforcement.

Additional Therapies

Experimental therapies:

- Fenobam, a glutamate receptor antagonist, was given to adults with Fragile X syndrome. The treated patients showed calmer behavior with reduced anxiety and hyperactivity.

SURGERY/OTHER PROCEDURES

- Myringotomy tubes if frequent ear infections and evidence of conductive hearing loss
- Inguinal hernia repair, if present
- Strabismus repair, if necessary
- Corrective lenses for refractive errors

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Routine evaluation for strabismus, nystagmus, and ptosis. If abnormal, referral to an ophthalmologist is indicated.

Patient Monitoring

- Regular follow-up with a behavioral and developmental pediatrician, as well as a psychiatrist/psychologist is recommended for patients with significant behavioral abnormalities.
- Hypertension can occur in adults with Fragile X syndrome. Therefore, blood pressure and cardiac exam should be performed annually in these patients. Hypertension can be treated with typical medications used in the general population. If hypertension is refractory to treatment, evaluate for other causes of high blood pressure (e.g., renal).

DIET

No specific dietary requirements

PROGNOSIS

Most patients generally have a normal lifespan.

CODES

ICD9

- 315.9 Unspecified delay in development
- 759.83 Fragile X syndrome

ICD10

- F89 Unspecified disorder of psychological development
- Q99.2 Fragile X chromosome

CLINICAL PEARLS

- Expansion of a CGG triplet repeat premutation *FMR1* allele can only occur in the offspring of female carriers. No expansion occurs in the germline of premutation carrying males, who will pass on the premutation size allele to each of their daughters and none of their sons.
- Fragile X syndrome cannot be diagnosed on routine karyotype. Specific genetic testing has to be requested to evaluate for this syndrome.

FAQ

- Q. Why is it called "Fragile X syndrome"?
- A. Early cytogenetic studies of male patients with intellectual disability identified a site on the X chromosome that would appear constricted when the patient's cells were grown with special culture techniques to induce "fragile" sites.
- Q. How many repeats are necessary to cause the full mutation that results in Fragile X syndrome?
- A. >200.
- Q. What are typical facial features seen in patients with Fragile X syndrome?
- A. Prominent forehead, long face, protruding ears, and a prominent chin.
- Q. When does the macroorchidism associated with Fragile X syndrome typically develop?
- A. After puberty.

FROSTBITE

Denise A. Salerno

BASICS

DESCRIPTION

- Localized injury of epidermis and underlying tissue resulting from exposure to extreme cold or contact with extremely cold objects
- Distal extremities and unprotected areas (i.e., fingers, toes, ears, nose, and chin) most commonly affected
- Feet and hands account for 90% of frostbite injuries.
- Classified according to severity:
 - Superficial, 1st degree: Partial skin freezing
 - Superficial, 2nd degree: Full-thickness skin freezing
 - Deep, 3rd degree: Full-thickness skin and subcutaneous tissue freezing
 - Deep, 4th degree: Full-thickness skin, subcutaneous tissue, muscle, tendon, and bone freezing
- New classification of severity at day 0 has been proposed based on findings that correlate extent of frostbite with outcome of involved body part along with results of bone scans:
 - 1st degree: Leads to recovery
 - 2nd degree: Leads to soft-tissue amputation
 - 3rd degree: Leads to bone amputation
 - 4th degree: Leads to large amputation with systemic effects

RISK FACTORS

- Alcohol use
- Arthritis
- Atherosclerosis
- Constricting clothing
- Diabetes mellitus
- High altitude
- Hypothermia
- Immobilization
- Improper use of aerosol sprays
- Previous cold injury
- Smoking tobacco
- Trauma
- Vasoconstrictive drugs
- Body parts most affected:
 - Fingers
 - Toes
 - Nose
 - Cheeks
 - Ears
 - Male genitalia
- Groups at risk:
 - Mentally ill patients
 - Patients with impaired circulation
 - Winter sports enthusiasts and fans
 - Homeless persons
 - Very thin individuals
 - Malnourished people
 - Outdoor laborers
 - Military personnel, especially those of African American and Afro-Caribbean descent, exposed to cold, wet climates
 - Elderly people
 - Very young people

GENERAL PREVENTION

- Avoid prolonged cold exposure whenever possible.
- Maintain adequate nutrition and hydration when spending time in cold weather.
- Dress appropriately for cold weather:

- Dress in layers: Clothing should be made of material that absorbs perspiration and prevents heat loss, and outerwear should be windproof and water repellent.
- Cover head, ears, and neck.
- Mittens help to conserve heat better than gloves do.
- Footwear should be water-repellent and insulated.

PATHOPHYSIOLOGY

- Tissue damage and cell death result from initial freeze injury and inflammatory response that occurs with rewarming.
- Direct cellular damage can occur from frostbite. As temperature of freezing tissue approaches -2°C , extracellular ice crystals form and cause increased osmotic pressure in the interstitium, leading to cellular dehydration. As freezing continues, these shrinking, hyperosmolar cells die due to abnormal intracellular electrolyte concentrations. With rapid freezing, intracellular ice crystal formation occurs, resulting in immediate cell death.
- Indirect cellular damage results from progressive microvascular insult. Initial tissue response to extreme cold exposure is vasoconstriction. Blood flow to extremities is reduced as freezing continues. Ice crystals form in plasma, blood viscosity increases, and decreased circulation and formation of microthrombi occur in distal extremities, resulting in hypoxia, tissue damage, and ischemia.
- Oxygen free-radicals and inflammatory mediators, especially prostaglandin F₂ and thromboxane A₂, contribute to tissue injury following rewarming and reperfusion of damaged tissue.
- Most severe injuries are seen in tissues that freeze, thaw, and freeze again.

DIAGNOSIS

- Depends on severity
- Superficial, 1st degree: Transient tingling, stinging, and burning followed by throbbing and aching with possible hyperhidrosis (excess sweating)
- Superficial, 2nd degree: Numbness, with vasomotor disturbances in more severe cases
- Deep, 3rd degree: No sensation initially, followed by shooting pains, burning, throbbing, and aching
- Deep, 4th degree: Absence of sensation, presence of muscle function, pain, and joint discomfort

HISTORY

- Was there prolonged exposure to cold environment? In frostbite, history of prolonged cold exposure is typical.
- Was there contact with a cold object, especially metal? Metal will drain heat from skin through conduction and increase the risk of frostbite.
- What was the timing and duration of exposure?
- Was there any treatment prior to presentation?
- Does the patient have any underlying conditions or behaviors that put him or her at risk?
 - (Peripheral vascular disease, medications, smoking, etc.)

PHYSICAL EXAM

- Superficial, 1st degree: Waxy appearance, erythema, and edema of involved area without blister formation
- Superficial, 2nd degree:
 - Erythema, significant edema, blisters with clear fluid within 6–24 hours
 - Desquamation may occur with eschar formation 7–14 days after initial injury.

- Deep, 3rd degree: Hemorrhagic blisters, necrosis of skin and subcutaneous tissues, skin discoloration in 5–10 days
- Deep, 4th degree: Initially, little edema with cyanosis or mottling; eventually, complete necrosis, then becomes black, dry, and mummified; occasionally results in self-amputation

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Usually not necessary, but may be indicated when infection is suspected

Imaging

- No diagnostic studies done immediately after rewarming can accurately predict amount of nonviable tissue.
- Radionuclide angiography with ^{99m}Tc-pertechnetate or triple-phase bone scanning with ^{99m}Tc-methylene diphosphonate 1–2 weeks after initial injury is advocated by some to assess tissue viability in cases of 3rd- and 4th-degree frostbite.
- MRI and MRA are being advocated by some as superior techniques for severe frostbite. They allow for direct visualization of occluded vessels and tissue, giving a more clear-cut demarcation of ischemic tissue injury, which may allow for earlier surgical intervention.

DIFFERENTIAL DIAGNOSIS

- Frostnip: Mild form of cold injury with pallor and painful, tingling sensation. Warming of cold tissue results in no tissue damage.
- Hypothermia
- Thermal injury: Easily excluded based on history, but can result from warming techniques.

TREATMENT

MEDICATION (DRUGS)

- Tetanus prophylaxis: dT, dTap, or DT/DTaP, depending on age, and tetanus immunoglobulin if patient not fully immunized
- NSAIDs: Recommended by some to prevent prostaglandin-induced platelet aggregation and vasoconstriction
- Pentoxifylline (a phosphodiesterase inhibitor) should be considered with severe frostbite. It has been shown to enhance tissue viability by increasing blood flow and reducing platelet activity.
- Analgesics: As indicated
- Antibiotics: Given prophylactically by some; others recommend waiting for signs of infection or necrotic tissue.
- Tissue plasminogen activator (tPA) is being used by frostbite specialists within 24 hours of acute, severe frostbite. Studies have shown it can significantly reduce digital amputation rates.

ADDITIONAL TREATMENT

General Measures

- Check core temperature to rule out hypothermia, which would need to be addressed first.
- Rapid rewarming in warm water ($40\text{--}42^{\circ}\text{C}$) for 15–45 minutes
 - Do not rewarm slowly.
 - Rewarming is complete when skin is soft and sensation returns.
 - Usually all that is needed for superficial, 1st-degree frostbite

- Apply dry, sterile dressings to affected areas and between frost-bitten toes and fingers.
- Intact nontense clear blisters should be left in place and wrapped with loosely applied dry gauze dressings. Rupturing may increase the risk of infection.
- Tense or hemorrhagic blister may be carefully aspirated but this increases the risk for infection
- Ruptured blisters should be debrided and covered with antibiotic ointment and nonadhesive dressings.
- Elevate affected parts to minimize edema.
- Daily hydrotherapy with hexachlorophene or povidone-iodine added to water
- Topical application of aloe vera (for its antiprostaglandin effect) to débrided blisters and intact hemorrhagic blisters, to minimize further thromboxane synthesis

ALERT

- Prohibit nicotine use because of its vasoconstrictive properties.
- Full extent of injury may not be apparent at presentation. Close observation is important

SURGERY/OTHER PROCEDURES

- Conservative surgical intervention: Recommended because it usually takes 6–8 weeks for injured tissue to declare viability
- Escharotomy: Performed on digits with impaired circulation or movement
- Fasciotomy: Performed if significant edema causes compartment syndrome
- Early amputation and debridement with closure of wound site: Necessary for uncontrolled infection
- Débridement of mummified tissue: Performed after 1–3 months

IN-PATIENT CONSIDERATIONS

Initial Stabilization

- Do not rub the area; may cause mechanical injury.
- Do not expose the area to direct heat; may cause burn injury.
- Refreezing after thawing leads to increased injury.
- Remove wet clothing and constricting jewelry.

ONGOING CARE

PROGNOSIS

- Depends on degree of cold injury
- Superficial, 1st-degree frostbite heals in a few weeks.
- Favorable indicators: Sensation in affected area, healthy-looking skin color, blisters filled with clear fluid
- Unfavorable indicators: Cyanosis, blood-filled blisters, unhealthy-looking skin color

COMPLICATIONS

- Arthritis
- Changes in skin color
- Chronic numbness
- Chronic pain
- Cold hypersensitivity
- Digital deformities
- Gangrene
- Growth-plate abnormalities (only in children)
- Hyperesthesias
- Neuropathy
- Reduced sensitivity to touch
- Rhabdomyolysis
- Squamous cell carcinoma (rare)

- Tetanus
- Tissue loss
- Wound infection

ICD-9 CM CODES

ICD9

- 991.0 Frostbite of face
- 991.1 Frostbite of hand
- 991.3 Frostbite of other and unspecified sites

ICD10

- T33.09XA Superficial frostbite of other part of head, initial encounter
- T33.529A Superficial frostbite of unspecified hand, initial encounter
- T33.90XA Superficial frostbite of unspecified sites, initial encounter

FAQ

- Q: What type of clothing can protect my child from getting frostbite?
- A: Dress your child in layers of clothes. Outer garments should be waterproof and windproof, and make sure your child is wearing a hat, scarf, and mittens. To protect their feet, they should wear thick socks and warm waterproof boots.
- Q: I've heard that your eyes can get frostbite. Is that true?
- A: Frozen corneas (the surface layer of the eye) have been reported in persons partaking in high wind-chill activities such as snowmobiling and skiing. Prevention is possible with the use of protective goggles/sunglasses.
- Q: My children's doctor recommended that we use sunscreen when we go skiing. Will the sunscreen help prevent frostbite?
- A: Although sunscreen is necessary to prevent getting sunburn that can occur from the sunlight's reflection off the snow, it will not decrease the risk for frostbite from the cold exposure.
- Q: I live in Buffalo, New York, where the winters are very cold and the wind-chill factor is often below zero. My children like playing outside, especially in the snow. How can I prevent them from getting frostbite?
- A: Because there is a risk of frostbite with a wind-chill factor of -25°C , try to encourage indoor play when the temperature dips this low. It is important to have the children come inside frequently to warm up, and for you to check for signs of cold injury.

- Q: My family members are avid skiers. While traveling in Europe last winter, I purchased a protective emollient that was sold there. Can protective emollients prevent frostbite if used on the face and exposed areas while skiing?
- A: No. Research has shown that the use of "protective" emollients and creams leads to a false sense of safety and leads to an increased risk of frostbite. This is thought to be due mostly to the failure to use more efficient protective measures when the emollients and creams are used.
- Q: If my child has had frostbite in the past, can she get it again?
- A: Yes. Children who have had a previous frostbite injury are at increased risk for repeat injury, especially in the location of previous damage. Appropriate clothing and limitation of cold exposure should be strictly enforced.
- Q: To prevent frostbite, is there a temperature below which I should not let my child go out to play?
- A: Although body tissue freezes more quickly at lower temperatures, the degree of damage from frostbite is related to the length of time tissue remains frozen. Therefore, the amount of time spent outside during cold weather should never be prolonged.
- Q: How can I tell if my child has frostbite or just cold fingers?
- A: Cold fingers are red and may be painful but do not become numb or white. Frostbitten fingers are painful, white, and waxy prior to rewarming and turn red with rewarming. The sequential development of digital blanching, occasional cyanosis, and erythema of the fingers or toes following cold exposure and subsequent rewarming is known as Raynaud phenomenon.
- Q: If I suspect frostbite in my child and we are outdoors without access to warm water, are there any options for treatment?
- A: If there is a delay in reaching shelter, you can start to thaw your child's body part by using your body as a warmer by placing the exposed body part under your armpit and keeping it there until further care can be initiated. Before starting the rewarming process you must be sure refreezing will not recur.
- Q: When should I call the doctor?
- A: The doctor should be called if, after rewarming, the skin is not soft and/or sensation does not return to normal. Call the doctor immediately if the skin is discolored and cold, blisters develop during rewarming, or there are signs of infection, such as the appearance of red streaks leading from the affected area, pus accumulation, or fever.
- Q: We are going on a winter vacation this year and expect to spend a lot of time outside skiing and sledding. What types of clothing should I pack for my 6-year-old son?
- A: It would be a good idea to pack a few pairs of waterproof mittens, a ski suit or ski pants, waterproof boots, thick cotton socks, and cotton thermal under garments. Try to make sure your son stays dry and warm. Take frequent breaks indoors to warm up and check your child for any early signs of cold injury.
- Q: Is frostnip the same thing as frostbite?
- A: No. Frostnip is the mildest form of cold injury, which commonly occurs on exposed parts of the body, such as the fingers, nose, and ears. The symptoms of frostnip are numbness and pallor of the involved body parts. Warming of these areas is the only treatment that is needed, and there is no associated tissue damage.

FUNCTIONAL DIARRHEA OF INFANCY OR TODDLER'S DIARRHEA

Vered Yehezkely Schildkraut
Raanan Shamir

BASICS

DESCRIPTION

- Benign chronic diarrhea in a toddler or a preschool child who appears healthy and is normally active and growing without evidence of systemic illness, infection, malabsorption, or malnutrition.
- Also known as chronic nonspecific diarrhea of childhood, toddler's diarrhea, and irritable bowel of childhood

RISK FACTORS

Genetics

Family members often report nonspecific GI complaints or functional bowel disorders.

GENERAL PREVENTION

- Limit the consumption and delay the introduction of sorbitol or fructose-rich fruit juices to the infant diet.
- In the treatment of acute gastroenteritis, parents should be instructed to give an oral rehydration solution (ORS) and resume normal feeding early, avoiding diet restrictions.
- Avoid restrictive diets that may cause caloric deprivation.

PATHOPHYSIOLOGY

- Carbohydrate malabsorption:
 - Diarrhea is often preceded by acute gastroenteritis or other viral infection that results in dietary restrictions. Increased oral fluids, including juices, are used to compensate for stool losses and to prevent dehydration.
 - Capacity of the small intestine to absorb fructose is limited. Foods that contain equivalent amounts of fructose and glucose are more readily absorbed because of the additive effect of a glucose-dependent fructose co-transport mechanism. Excessive consumption of juices high in sorbitol (which inhibits fructose absorption) and those with a high fructose/glucose ratio (e.g., apple juice) result in fructose malabsorption and increased intraluminal gas caused by fermentation. The end result is abdominal distension, excessive flatulence, and diarrhea.
 - Colonic function: Possibly, disruption of colonic ability to ferment unabsorbed carbohydrates into short-chain fatty acids (SCFA), which maintain colonic function and prevent colon-based diarrhea
- Disturbed motility: Short mouth-to-anus transit time
 - Persistence of immature bowel motility pattern. Failure of initiation of normal postprandial delayed gastric emptying.
 - Low-fat meals. Meals with high dietary fat delay gastric emptying.
 - Excess fluid intake. Infant's colon already operates in high efficiency (in children, higher volume of fluids reach the caecum). Excessive fluids can lead to diarrhea.
 - Low-fiber diet. Dietary fiber serves as a bulking agent.
 - Excessive fecal bile acids. Rapid transit resulting in excess conjugated bile salt entering the colon. Bacterial degradation produces unconjugated bile salts, which decrease net water absorption in the colon.

ETIOLOGY

- Nutritional factors: Excessive consumption of fruit juice; high-carbohydrate, low-fat, and low-fiber diet
- Disordered intestinal motility (i.e., variant of irritable bowel syndrome of infancy) with rapid transit

DIAGNOSIS

- The typical age is 12 to 36 months, but range is 6 months to 5 years.
- Diagnostic criteria (Rome III):
 - Daily, painless, recurrent passage of ≥ 3 large unformed stools
 - Symptoms that last > 4 weeks
 - Onset of symptoms that begins between 6 and 36 months of age
 - Passage of stools that occurs during waking hours
 - There is no FTT if caloric intake is adequate:
 - There is no definite diagnostic test. The diagnosis is primarily clinical based on age of onset, the history, symptoms, clinical course, and limited number of laboratory tests. Usually, it is an evident condition and not a diagnosis of exclusion.

HISTORY

- Nutritional history is essential, with attention to the 4 Fs (fiber, fluid, fat, and fruit juices) and dietary changes.
- Diarrhea:
 - For a toddler, it may not be abnormal to have > 3 soft and occasionally loose stools a day with visible food remnants.
 - Children typically have intermittent symptoms and are often diagnosed with recurrent viral gastroenteritis
- Stool characteristics:
 - Stools that smell foul and contain undigested food particles. Presence of blood or mucus suggests another diagnosis.
- Timing of diarrhea:
 - No stools passed at night, and typically the 1st stool of the day is large and has firmer consistency than those occurring later on in the day.
- Recent enteric infection:
 - Presence of other affected family members, history of travel, day care, and infectious contacts suggests infectious cause.
- Signs and symptoms:
 - Thorough history is required because all illnesses in the differential diagnosis are associated with morbidity if diagnosis is delayed.

PHYSICAL EXAM

- Normal: Children look healthy, eat well, and are growing normally according to serial plots on the growth chart.
- There are no signs of malnutrition or malabsorption. Weight might be influenced by the dietary measures.
- Fecal matter found on abdominal palpation should alert for constipation.

DIAGNOSTIC TESTS & INTERPRETATION

- The following tests would be helpful only if indicated by history and physical exam:
 - Cystic fibrosis: Sweat test, stool for pancreatic enzymes, and genetic testing
 - Celiac disease is common and warrants a high level of suspicion: Serology (antiendomysial antibodies, tissue transglutaminase antibodies with IgA serum levels)
 - CBC, iron studies, vitamin levels, serum albumin
 - Inflammatory markers
- Diarrhea as the sole symptom of malabsorption in a normally thriving child is rare.

Lab

- Stool tests and culture: Negative for white blood cells, blood, fat, and pathogens including ova, parasites, and *Giardia* antigen.
- Celiac serology: Negative
- CBC normal: No anemia
- Serum electrolytes normal: No dehydration

Imaging

Usually unnecessary: Plain abdominal radiograph could demonstrate colonic fecal retention.

Diagnostic Procedures/Other

- A trial of lactose and fruit juice-free diet done separately is practical and diagnostic.
- Breath hydrogen test has limited benefit and is inferior to a trial of milk avoidance.
- Small bowel biopsy is rarely indicated unless strong evidence suggests another cause (e.g., positive celiac serology).

DIFFERENTIAL DIAGNOSIS

- All causes of chronic diarrhea should be considered.
- Infection: Bacterial, viral*, and parasite (giardiasis*, cryptosporidiosis)
- Celiac disease*
- Malabsorption: Carbohydrate: Postinfectious secondary lactose intolerance*, sucrase-isomaltase deficiency
- Pancreatic: Cystic fibrosis*, Shwachman-Diamond syndrome, Johanson-Blizzard syndrome, chronic pancreatitis
- Bile acid disorders: Chronic cholestasis, terminal ileum disease, bacterial overgrowth*
- Immunologic: Cow's milk and soy protein intolerance*, food allergy*, immunodeficiency
- Miscellaneous: Antibiotic-associated diarrhea, laxatives, fecal retention constipation*, UTI, abetalipoproteinemia, inflammatory bowel disease, short-bowel syndrome, hormone-secreting tumors, Munchausen by proxy
- Common conditions that may cause diarrhea without FTT: Constipation, lactose intolerance, and persistent infective diarrhea
- Constipation-related diarrhea is frequently overlooked. Consider it if diarrhea alternates with hard stools.

* More common conditions to be considered

TREATMENT

MEDICATION (DRUGS)

- Medications are unwarranted for a condition primarily caused by food that does not hamper growth.
- Metronidazole may be beneficial for patients with undetected giardiasis
- Loperamide is effective in normalizing bowel patterns, but only for duration of therapy.

ADDITIONAL TREATMENT

General Measures

Daily diet and defecation diary may document a specific food responsible for loose stools.

Additional Therapies

Reassure parents that there is no underlying GI disease, infection, or inflammation.

ISSUES FOR REFERRAL

- Failure of response to diet
- Weight loss despite adequate intake
- Presence of other symptoms (e.g., anorexia, irritability, fever, vomiting)
- Fat, blood, and mucus in the stool

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Improvement with dietary changes confirms the diagnosis and reassures the parents.
- Follow-up phone call to parents within a few days of instituting diet. If no improvement within 2 weeks despite good compliance with dietary recommendations, then reconsider diagnosis; consider more diagnostic tests and referral to a specialist.

Patient Monitoring

- Follow growth parameters.
- Monitor symptoms indicating nonfunctional illness.

DIET

- The child's feeding pattern should be normalized according to the 4 Fs:
 - Overconsumption of *fruit juices* should be discouraged, especially those that contain sorbitol and a high fructose/glucose ratio (e.g., apple juice, pear nectar).
 - Cloudy apple juice or white grape juice may be safe as alternatives.
 - *Fiber intake* should be normalized by introduction of whole-grain bread and fruits.
 - Increase *dietary fat* to at least 35–40% of total energy intake. Substitution of low-fat milk with whole milk may be sufficient.
 - Restrict *fluid intake* to <90 mL/kg/d if history is significant for fluid consumption >150 mL/kg/d.
- Improvement occurs within a few days to a couple of weeks after initiating the above therapy.

PROGNOSIS

- Good
- Symptoms resolve by school age.
