Starting in the mid-1970s, the primacy given to race content in social work education was challenged with the emergence of activism and analysis of additional oppressed groups (CSWE, 2001), such as women and sexual minorities. Those who critiqued the focus on race and antiracism content garnered some consensus for an integrated approach that was inclusive of, and made connections with, other forms of oppression (Keating, 2000). Since then, social work education has broadened its conceptualization and coverage of oppression content. Between 1975 and 1984, CSWE established a commission on women and mandated content on gender issues, including feminist practice theories and methods (Schiele, 2007). Between 1985 and 1995, the CSWE championed sexual orientation issues and established a Commission on Gay, Lesbian, Bisexual and Transgender Issues (Schiele, 2007). Since 1995, the CSWE has continued to broaden its content on oppression issues. In 2001, CSWE’s Policy and Accreditation Standards (EPAS) identified 14 types of diversity as possible sources of oppression, including age, class, color, culture, disability, ethnicity, gender, gender identity and expression, immigration status, political ideology, race, religion, sex and sexual orientation (CSWE, 2012).

The equal treatment and inclusion of all forms of oppression has been referred to as an *equality-of-oppressions* paradigm (Schiele, 2007). The equality-of-oppressions paradigm emphasizes the interconnectedness of all forms of oppression (i.e., sexism, racism, homophobia, classism, etc.) and asserts that it is impossible to

view one form of oppression in isolation (Schiele, 2007). The 2001 *equality-of-oppressions* framework replaced the *hierarchy-of-oppressions* model of the 1960s and 1970s, which supported the inclusion of content dedicated specifically to racism and people of color. Although both models are empirically supported in the literature, the movement away from a dedicated focus on anti-racism remains a source of contention. Critics assert that it contributes to a denial of racism within the field (Schiele, 2007) and that the distinct severity, frequency, and endemic nature of racism warrant specific attention.

In addition to changes in the way that oppression is conceptualized, the profession has also made changes to the way it engages with oppression and members of oppressed groups. In the 1960s, the cultural competence model was employed, which focused on changing the beliefs and behaviors of individual practitioners to promote cross-cultural sensitivity and understanding (Abrams & Moio, 2009). Among critiques of this framework are that it only focuses change efforts at the level of the individual and not the institutional and systemic levels; it assumes that increased cultural knowledge and skills will enhance practice, without questioning whether the practices and interventions themselves are appropriate; and it has limited empirical evidence (Abrams & Moio, 2009). In contrast, the antioppression model targets change efforts at the individual, institutional, and systemic levels (Abrams & Moio, 2009). Currently, the social work profession is thought to utilize a combination of cultural competence and AOP frameworks.

GOALS FOR ANTI-OPPRESSIVE SOCIAL WORK

Much of the literature on antioppressive practice in social work focuses on what not to do. The term “antioppressive” itself is defined by what it is not, rather than what it is. It is imperative that social workers have a vision for what the short- and long-term goals and ideals of AOP are. Without a clear understanding of what the profession seeks to achieve through AOP, there will continue to be ambiguity, and social workers may be unable to attain it. Some of the goals for AOP in social work include:

- **Above all, do no harm.** In no way should the social worker be the source or onset

of harm or trauma because of anything related to practice. The helping profession cannot unwittingly perpetuate trauma or disenfranchisement within its own client base. Social workers should also promote emotional, psychological, and physical safety among clients, families, and communities and work to eradicate the causes, and not just the consequences, of internalized and external oppression.

- **Sustainability:** Social workers need to consider the long-term impact of their work in the community and work with clients toward being self-sustainable. Practitioners and clients should work toward transforming, and/or not having dependence on, institutions and systems that oppress (J. Suleman, personal correspondence, July 13, 2013).
- **Empowerment:** Individuals should have a sense of control over their own lives (Dustin & Montgomery, 2010) and be able to exercise self-determination and choice. Social workers should challenge institutional practices that disempower clients, work to resolve power imbalances (van Wormer & Snyder, 2007) and understand their role in empowerment. Social workers cannot “liberate the oppressed,” which can represent cultural invasion (Freire, 1970); they can only assist individuals in achieving their own liberation.
- **Social Justice:** The dignity and worth (NASW, 2013) and human rights of each human being should be protected and individuals should have equal rights concerning their land, resources, politics, and bodies (van Wormer & Snyder, 2007). Dominant and subordinate binaries should be eliminated and replaced with equal spaces and respect for all forms of diversity. Freire (1970) suggested a vision of “bringing into the world a new being, no longer oppressor, no longer oppressed, but human in the process of achieving freedom” (p. 31).

Types & Forms of Oppression Social Workers May Encounter in Practice

The Social Work Dictionary defines oppression as: “The social act of placing severe restrictions on an individual, group, or institution. The oppressed individual or group is devalued, exploited, and deprived of privileges by the individual or group

who has more power” (van Wormer & Snyder, 2007, p. 21). Oppression is maintained through socially constructed and institutionalized ideologies and doctrines (van Wormer & Snyder, 2007), which privilege certain groups at the expense of “others.” If an individual is oppressed, it is by virtue of his or her membership in a particular group (or groups), not because of any individual failure or deficiency (Mullaly, 2001).

Below are two tables. Table 124.1 lists 21 types of oppression that social workers may encounter in practice. The 14 sources of oppression that the CSWE mandates in social work education are included, along with seven additional sources of oppression about which social workers may want to be cognizant. These additional seven sources of oppression include criminal history, mental health status, chemical dependency status, family structure, marital status, appearance, and size.

Table 124.2 lists 11 forms of oppression. This table shows the many forms of oppression, including those that operate below the surface and cannot be readily seen. Several key points that might be taken from an understanding of various forms of oppression include the following:

- Oppression is a system, not just individual acts of prejudice or discrimination.
- Oppression does not have to be seen to exist.
- In spite of good intentions, one can unknowingly act oppressively or enact behaviors with oppressive consequences.
- Unless one is consciously opposing oppression, one is probably upholding it.
- A practitioner’s perception of a client’s relationship to oppression may not mirror the client’s perception of her or his relationship to oppression.

Note: The types and forms of oppression listed within these tables are comprehensive, but not exhaustive.

Moving from –ism to Action

An antioppressive model moves beyond an understanding and classification of the types and forms of oppression. Classification of oneself and “others” itself has been central to the maintenance of oppression through the use of the categorizations and discourse of dominant groups (Campbell, 2003). The following theories, approaches, and practice principles bridge

TABLE 124.1 Types of Oppression

Oppression Source	Oppression Type
Age	Prejudice or discrimination based on a person's age (ageism)
Political ideology	Prejudice or discrimination based on a person's political ideology
Chemical dependency status	Prejudice or discrimination based on one's current or prior history with substance abuse or dependency
Class	Prejudice or discrimination based on a person's social or economic class (classism)
Color	Prejudice or discrimination based on a person's skin color (colorism)
Criminal history	Prejudice or discrimination based on a person's current involvement in the criminal justice system or past criminal history
Culture	Prejudice or discrimination based on a person's culture
Disability	Prejudice or discrimination based on a person's disabilities (ableism)
Ethnicity	Belief in the superiority of one's own ethnic group (ethnocentrism)
Family structure	Prejudice or discrimination based on family structure, including parent-status
Gender	Prejudice or discrimination based on gender
Gender identity & expression	Prejudice or discrimination based on gender-identity and expression (cisgenderism)
Marital status	Prejudice or discrimination based on marital status
Mental health status	Prejudice or discrimination based on current or previous mental health status
Native-born or immigrant status	Prejudice or discrimination based on native-born or immigrant status (nativism)
Physical appearance	Prejudice or discrimination based on physical appearance that falls outside of societal notions of beauty (lookism)
Race	Prejudice or discrimination based on race (racism)
Religious	Prejudice or discrimination based on religion
Sex	Prejudice or discrimination based on sex (sexism)
Sexual orientation	Prejudice or discrimination based on sexual orientation
Size	Prejudice or discrimination based on size and in particular, weight (sizeism)

the –“isms” with the action needed to transform oppressive dynamics.

APPROACHES AND THEORIES FOR ANTIOPPRESSIVE PRACTICE

Antioppressive practice encompasses a range of practices and theories, as opposed to one practice

approach. An antioppressive framework may include, but is not limited to, the following practice approaches and theories:

Radical Approach: The radical approach to social work seeks structural and revolutionary transformation, as opposed to social workers functioning as “caretakers” while working with, rather than against, oppressive systems

TABLE 124.2 Forms of Oppression

Form of Oppression	Definition
Covert oppression	A less public and less obvious form of discrimination that often works subconsciously and/or subliminally to not be seen, known, or “found out.”
External oppression	The exploitation, degradation, and/or inhumane treatment of an individual or group based on their membership in a nondominant group (van Wormer & Snyder, 2007).
Horizontal oppression	When individuals of nondominant groups project the pain and anger of being oppressed onto individuals within their own group or other oppressed groups.
Ideological oppression	The idea that a dominant group is superior, entitled, and has a right to control “other” groups; and the attribution of opposite and inferior qualities to nondominant groups, such as stupid, lazy, incompetent, and worthless (Bell, 2013).
Institutional oppression	The mistreatment and control of certain groups by dominant groups is embedded and enforced in the laws, education system, criminal justice system, employment policies, housing development, media images, political processes, public policies and other institutions (Bell, 2013). Institutions can create oppressive consequences regardless of whether or not the individuals within them have oppressive intentions (Cheney, LaFrance, & Quinteros, 2006).
Internalized oppression	Individuals within a non-dominant group enforce disempowerment or oppression on one’s self, one’s family and/or one’s community as a psychological consequence of external oppression (Bailey, Chung, Williams, Singh, & Terrell, 2011). According to Bailey et al. (2011), components of internalized oppression may include: “internalization of negative stereotypes, self-destructive behaviors, devaluation of one’s worldview; belief in the biased representation of history; and alteration of physical appearance” (p. 481).
Interpersonal oppression	Individual members of the dominant group mistreat or disrespect individuals of nondominant groups because of a conscious or unconscious belief that their own group is superior. Typically, members of the dominant group will have internalized negative conceptions of nondominant groups, resulting in a perception that their oppressive behavior is “normal” and not oppressive (Bell, 2003).
Invisible oppression	The absence of information or resources applicable or relevant to individuals of nondominant groups, such as data and official statistics, social policies, published guidelines, practice models, and research (Fish, 2008).
Overt oppression	A public, conscious act to harm an individual or group based on their group membership.
Silent oppression	Negative thoughts and attitudes about nondominant groups by individuals of dominant groups who may or may not be perceived, or perceive themselves, as oppressive (Trepagnier, 2001).
Symbolic oppression	Widespread, societally sanctioned ideologies and images used to justify and reinforce stereotypes and relations of domination and subordination (Sanders, 2013).

(Dreikosen, 2009). This approach is informed by a class analysis and critique of capitalism.

Structural Approach: The structural approach situates social problems within a specific societal context and does not attribute them

to individual failures (Mullaly, 1997). It promotes empowerment, consciousness raising, an understanding of issues from a global perspective, and an awareness of capitalism’s impact on shaping conditions and relationships (Mullaly, 1997).

Feminist Approach: The feminist approach focuses on the ways women experience their existence and how social forces shape these experiences by depriving women of access to resources, power, and emotional fulfillment (Dominelli & McLeod, 1989). Practice models are grounded in a feminist analysis of social problems and prioritize social change and social justice for women (Dominelli & McLeod, 1989).

Critical Approach: The critical approach is concerned with practices that will eliminate domination, exploitation, and oppression from society (Fook, 2002). It is interested in understanding how social constructions, relations, and structures are used to dominate, and in leveraging this knowledge to disrupt dominant structures (Fook, 2002).

Antiracist Approach: An antiracist approach recognizes the institutional nature of racism (Maiter, 2009). It acknowledges the social construction and social effects of race and challenges pathological explanations of its effects on people of color (Maiter, 2009). It questions and critiques White supremacy, as well as the marginalization and de-legitimization of the voices, experiences, and knowledge of people of color. It rejects the stipulation that people of color can only access power as White society dictates (Maiter, 2009). An antiracist framework challenges individuals in power, including social workers, for their role in perpetuating institutional racism, and calls for change at all levels of social work practice (Abrams & Gibson, 2007).

Afrocentric Framework: An Afrocentric framework centers and validates the worldview and experiences of African Americans and is grounded in philosophical and traditional African concepts (Schiele, 1996). It combats negative stereotypes, values collectivity, acknowledges feelings as a source of knowledge, upholds the spiritual nature of human beings, and facilitates societal transformation (Schiele, 1996).

Empowerment Theory: Empowerment theory explores the environmental context of social problems and focuses on individual strengths as opposed to “blaming the victim” or focusing on risk factors (Perkins & Zimmerman, 1995). Practitioners are engaged as collaborators in promoting client wellness and facilitate client involvement in social and political change (Perkins & Zimmerman, 1995).

Critical Race Theory: Critical Race Theory (CRT) utilizes critical reflection to promote awareness of unearned privilege and its consequences

(Abrams & Moio, 2009). Practitioners engage in active opposition to institutional oppression rather than encourage clients to passively accept and conform to oppressive systems (Abrams & Moio, 2009).

Strengths Perspective: Strengths perspective identifies and emphasizes the strengths and resources that all individuals, families, and communities possess and can leverage (Rankin, 2006). Challenges and problems are reframed as opportunities (Rankin, 2006).

Social Theory: Social theory supports an understanding of the context of a client’s situation through an identification of the social forces (historical, political, cultural) that have shaped the client’s life (Dustin & Montgomery, 2010).

Intersectionality Theory: Intersectionality theory holds that social constructions of privilege and oppression, such as race, class, gender, sexual orientation, and ability, intersect to create systems of domination and social injustice on multiple and simultaneous levels (Murphy, Hunt, Zajicek, Norris, & Hamilton, 2009). The theory posits that an understanding of a client’s experience based on their social location within these systems will capture the complexity, individuality, and nuances of their actions, choices, and outcomes (Murphy et al., 2009).

PRACTICE PRINCIPLES AND CONSIDERATIONS FOR ANTIOPPRESSIVE SOCIAL WORK

Apply knowledge of oppression: Oppression is not a fixed, permanent reality. It is socially constructed, and therefore, can be deconstructed and transformed (Freire, 1970). Social work is a profession and a social institution with the capacity to either perpetuate or transform oppressive social relations (Campbell, 2003). Social workers should be aware of the multitude of forms and effects of oppression on oppressed persons, including its internalization (Mulally, 2001), and examine their own roles in maintaining privilege and oppression in their own environments and the environments of the people they serve (Nicotera & Kang, 2009). Such an understanding needs to be integrated intellectually, emotionally, and practically (Maidment & Cooper, 2002). Although an analysis of oppression is necessary, it is insufficient to enact social change. Knowledge of the structural dynamics of oppression, as well as one’s own role in maintaining it, should then

be translated into social change and social justice initiatives (van Wormer & Snyder, 2007). Social workers should be equipped to apply the various antioppressive frameworks (i.e., radical, critical, structural, antiracist, etc.) to all aspects of practice. Approaches geared at resolving the symptoms of oppression one individual at a time are reactionary and support the maintenance of the status quo. Social problems are not the result of personal deficiencies, but weaknesses in the social structure, and structural problems require structural solutions (Mullaly, 1997). Oppression can only be eliminated by addressing its root and structural causes, and thus, change should be directed at entire policy systems (van Wormer & Snyder, 2007).

Challenge positions of dominance: Although it is critical to strive toward an understanding of the experiences of oppressed groups, it is imperative also to focus on countering positions of dominance, such as White supremacy (Butler, Elliott, & Stopard, 2003). A focus on resolving issues within nondominant groups ignores the problematic and oppressive dynamics that need to be resolved by and within dominant groups.

Be cognizant of the implications of language when speaking with or about clients. The role of language in subjugating the oppressed through dominant discourses should be understood, as well as the way that professional, diagnostic, and pathological vocabularies disempower clients (Mullaly, 2001). Language should be empowering and easily understood. Encourage, support, and “center” ways of knowing outside of the dominant Eurocentric discourses. Create spaces in which the subjugated discourses of clients can be included and heard (Mandell, 2008). When the primary language of clients is different than the primary language spoken at the agency, the assistance of translators should be employed to minimize communication barriers. Language issues have been shown to be a major impediment to immigrants being able to access and effectively utilize services (Graham, Bradshaw, & Trew, 2009).

In addition to understanding the self within the frame of oppressor/oppressed identities, engagement in critical reflection into one’s own personhood, including individual developmental history and multiple social identities is important (Mandell, 2008). The personal, social, and professional dimensions of a worker are intertwined and influence

the social worker’s own experience as well as the client’s experience of the social worker (Mandell, 2008). Social workers need to be aware of the ways in which their own experiences, biases, self-concept, cultural background, values, and emotional history shape their perception, judgment, emotions, and behavior (Mandell, 2008), and how this impacts every client interaction. In addition, social workers should be aware of the ways in which they themselves are oppressed or experience oppression and how that impacts their work. The reflective process may entail asking questions of oneself and then analyzing those answers critically (Mandell, 2008). Examples of questions that could be asked include: In what ways did I stereotype and make conscious or unconscious assumptions about this client and how did that impact my interactions and treatment of the client? What part of my interactions with the client met my own needs versus met the client’s needs? Did I impose my notion of what was “right” and what the client “should” do or did I value and foster the client’s self-determination? Did I maintain, exacerbate, or improve the situation the client is in? How would I do it differently next time? Are there systemic changes or changes in agency policy that could be made to better meet the needs of this client or group?

Treating everyone the same is not equal treatment: Treating everyone the same assumes everyone is the same and requires disadvantaged groups to approximate the characteristics of dominant groups (Fish, 2008). Within the framework of race, this is known as the “color-blind” approach because it “does not see color,” and therefore, does not take into account structural racism or the differing needs of various groups (Fish, 2008). Oppressed groups then either are forced to assimilate into dominant groups and lose their identities, or to remain different and consequently marginalized as “inferior” (Fish, 2008). If practitioners are unaware of how they might identify and be inclusive of the differing cultural needs of various individuals or groups, they can start by asking the individual. Because not everyone within a particular group has the same needs, it is important to not generalize or make assumptions about individuals based on perceptions of group needs.

Cultural groups are not homogenous and there are many variations of within-group diversity: Just as all groups possess different characteristics and have different needs, so do individuals within a group. To illustrate this

point, Graham et al. (2009) describe the major diversities fundamental to working with Muslim clients within and across Muslim communities:

A myriad of approaches to faith, depending both on official streams and denominations and on personal adherence to these creeds; countless cultural, ethnic, geographic, and religious origins; and different experiences from one community, one family, and one individual to the next. Profound differences, likewise, will occur from one geographic region to the next, and one agency setting to the next (be it child welfare, mental health, physical health, etc.); differences between mandated and voluntary clients; and differences in relation to the degree of client acculturation, age cohort status, level of religious observance, and other areas of diversity. When dealing with unfamiliar cultural groups, it is all too easy for practitioners to see members of the cultural group as homogenous... There is no easy set of rules, no 'one size fits all' scenarios. (p. 549)

Apply knowledge of how social, economic, and political factors shape client experience. When assessing clients, begin where the client is and avoid a focus on pathological explanations or client dysfunction while minimizing macrocontextual factors such as poverty (Mulally, 2001). Social workers should start by asking, "What has happened to this person?" not "What is wrong with this person?" (Dustin & Montgomery, 2010), and ground problems and solutions in the client's lived realities (Mulally, 2001). Practitioners should understand how behaviors can represent coping or defense mechanisms to marginalization, subjugation, and being treated as inferior when a member of an oppressed group (Mulally, 2001). In addition, it is imperative to understand the connotations, consequences, and stigmatization inherent in labeling clients with a diagnosis or disorder. Baines (1997) described the process used by him and his colleagues in resisting "the dominant discourse that blames individuals for all their problems" by continually reframing "our problems and our clients' problems to be the result of structural and systemic forces" and seeking "solutions that went beyond those just for individual cases" (p. 314).

Establish coalitions of like-minded colleagues: Progressive social work literature and practitioners suggest that the most crucial aspect of carrying out antioppressive practice and protecting oneself from the risks inherent in carrying out acts of resistance is to establish and

maintain coalitions with like-minded colleagues (Mulally, 2001). Having access to such support can alleviate the tremendous mental and emotional burden associated with constant introspection while also providing a forum to discuss and process possible challenges in carrying out AOP.

Involve clients in decision-making: A key step in avoiding practice-based oppression is to treat the client as expert. Clients should be engaged in decisions that affect themselves, their families, and their communities. Rather than social workers imposing their perspectives of what a client needs, client input should be meaningfully involved in all areas of practice, including assessment, treatment planning, and treatment evaluation (A. Barnes, personal communication, July 19, 2013). When the insights that clients have into their own lives are acknowledged and valued, the social worker avoids being paternalistic. The social worker should avoid assuming superior "knowing" positions (Butler, et al., 2003) or the role of "expert" and instead be a partner in a mutual-learning process (van Wormer & Snyder, 2007).

Practice critical reflexivity and critical thinking: Be aware of the socially constructed and subjective nature of knowledge and reality, and the socially situated relationship with the client. Reflect critically upon the impact that actions, assumptions, and values have on the client and how they can serve to either reproduce or deconstruct structures of oppression (Campbell, 2003).

Take responsibility for power dynamics. Understand professional power in practice and the dynamics inherent in the identity constructions of social worker as "helper" and client as "needy" and "other" (Mandell, 2008). Be cognizant of which actions are for the benefit of oneself and one's position, versus the benefit of the client, and the ways in which practitioners can use their power to harm and further disenfranchise clients. Identify ways in which power can be operationalized and channeled constructively (Bundy-Fazioli, Oujano, & Bubar, 2013) to empower the client and transform practices and institutions, rather than destructively, to sustain oppressive practices (Keating, 2000). Practitioners need to know where their power lies, within and outside of their organizations, and how to channel it to facilitate client empowerment (Dustin & Montgomery, 2010). Client power can be developed by highlighting client strengths; expanding client networks and linkages to resources; asserting the ways in which the client has agency,

choice, and privileges, both within and outside the professional relationship; and promoting the leadership abilities of the client (Rankin, 2006).

Question what is not working and think outside of the box: Each client and situation is unique so meeting client needs may require creativity and flexibility (Dustin & Montgomery, 2010). There is no “universal formula” or “one-size-fits-all” approach. Be able to apply and adapt social work theories and best practices to best suit the needs of each individual situation, context, and client. It is critical to question traditional assumptions, practices, and policies that are not working (Mulally, 2001).

Employ active listening in all clinical interactions. Active listening promotes understanding of the client’s unique perspective, context, background, cultural values, and current situation (Graham, et al., 2009). It also provides insight that can be used to tailor interventions to individual values, comfort levels, and needs.

Offer services that are accessible to the individuals and communities served, in terms of location, fees, and scheduling. Many clients have to work during the day so an agency that is only open between “normal” business hours may create significant economic and financial barriers to clients. These types of barriers are significant and may impede or entirely prohibit service attainment, or exacerbate a client’s situation by putting them at risk of work-related challenges from taking time off or arriving or departing from work early to avail themselves of the social services. In addition, services that are prohibitive in terms of cost or location maintain oppression by only being available to certain communities.

Raise client consciousness: Raising a client’s understanding of his or her situation, in terms of its social, economic, and political context, can empower the client (Dustin & Montgomery, 2010). Freire referred to this as “conscientization” (Freire, 1970). A client who understands the social aspects of his situation, and the decisions he has made versus the decisions that have been made for him, is better equipped to assess his current situation and how it can be navigated (Dustin & Montgomery, 2010).

Do not treat clients by the labels or stereotypes society has attached to them (Dustin & Montgomery, 2010). Everyone’s experiences are situated in distinct historical times, places, and social contexts. Although individuals may share some experiences with other people, each individual has a distinct identity and value system that

has been shaped differently from anyone else’s (Clifford & Burke, 2005). Social workers should relate to clients as individuals and not just to the oppression they experience (Butler et al., 2005). Essentialist perceptions of clients do not allow for change to occur (Dustin & Montgomery, 2010).

BARRIERS TO SUCCESSFUL ANTIOPPRESSIVE PRACTICE

Practitioners are unaware of their own racism, heterosexism, and other “-isms” and how these impact their practice. Many people are unaware of forms of oppression that are not overt, and/or resist acknowledgement of the positions of privilege they occupy. Resistance toward acknowledging one’s privileged status may arise because of the difficulty in recognizing and challenging the benefits received from group identities and the notion that one is “entitled” to privilege or has “earned” these advantages (van Wormer & Snyder, 2007). For example, multiple research studies have shown that White social workers who maintain racist attitudes and beliefs may not perceive themselves as racist (Schiele, 2007). A 2001 study found that highly educated White women who considered themselves opponents of racism, enacted silent racism through stereotypical images and paternalistic assumptions (Trepagnier, 2001). Trepagnier (2001) suggests that people should view themselves on a continuum from “less racist” to “more racist,” and never as “not racist,” because of how habitual, systemic, and engrained racism is in the United States (Trepagnier, 2001). A separate study of Masters of Social Work (MSW) students by Van Soest (1997) found that the majority (71%) of White students identified their own privilege as being a barrier to acknowledging and learning about oppression. Once one does become aware of one’s own racism/-isms, a long and dedicated process is required to unlearn years of conditioning and socialization (Abrams & Gibson, 2007).

The profession’s emphasis on 14 types of diversity and discrimination in social work education is a barrier to being able to cover content on any of the groups meaningfully. Roberts and Smith (2002) warned: “a definition which includes everything is in danger of meaning nothing at all” (p. 197). Similarly, Schiele (2007) cautions that addressing an increasing number of oppressed groups prevents a substantive analysis of each one.

Insufficient time and resources to focus on practitioner well-being and systems change:

The funding constraints of social services means that agencies are often understaffed and practitioners are often overworked and underpaid (Mulally, 2001). This leaves little opportunity for social workers to connect the day-to-day focus on individual change with larger social and political change efforts. The time and resource constraints can also impede the ability of practitioners to optimize the well-being of clients, critically reflect on their practice, and foster their own well-being. Research has found that when social workers become burnt-out or emotionally exhausted, they depersonalize and distance themselves from their clients, which clients, in turn, experience as dehumanizing (Mandell, 2008). Practitioners need to take responsibility for, and be supportive of, their own emotional and professional well-being. Change starts from within one's own self and a personally empowered practitioner is far more effective in being able to assist clients (J. Suleman, personal correspondence, July 19, 2013).

There is a contradiction between AOP and sustaining the field of social work. Social work is often funded by, and a function of, the government. Many agencies are also reliant upon funding from corporate-based foundations. Involvement in social and political change initiatives can mean opposition to government and corporate interests, which poses a challenge for the profession. Also, because the client base of social workers is predominantly comprised of oppressed groups, working toward the elimination of oppression creates a paradox by working toward the elimination of the profession itself (J. Suleman, personal correspondence, July 19, 2013).

Effective analysis does not always translate into effective action. Although there has been significant research and intellectualizing over oppression and antioppression, it is questionable how much this information has actually been applied within the field. Language and rhetoric appear to have changed more than anything else (Butler et al., 2005). Within social work education, for example, in spite of CSWE's mandate to include content on oppression, challenges arise in transmitting content into meaningful learning (Phan, Vugia, Wright, Woods, Chu, & Jones, 2009) and then translating learning into social action (Hancock, Kledaras, & Waites, 2012).

There remains division among social work professionals rooted in marginalized

voices and needs of oppressed groups. The National Association of Black Social Workers (NABSW) was created as a separate entity from the National Association of Social Workers during the civil rights movement in the 1960s (National Association of Black Social Workers [NABSW], 2013). NABSW became dedicated to issues impacting the Black community, including White supremacy, racism, and Eurocentric-focused human services and social welfare systems (NABSW, 2013). NABSW was compelled to create its own space in order to become a leading advocacy group for the Black community, because it did not have that space within NASW. A half a century later, NABSW remains a separate entity.

THE FUTURE OF ANTI-OPPRESSIVE SOCIAL WORK

A critical, ongoing focus on anti-oppressive practice will be imperative to its sustainability and effectiveness within the field. Some of the possible future directions for AOP within the profession might include:

- **Transform the Eurocentric framework of social work pedagogy.** “Center” diverse ways of knowing and create space for marginalized voices.
- **Evaluate the implementation and effectiveness of AOP.** Define quality assurance standards, clear outcome goals, and measurement tools.
- **Liberate social work research from oppression.** Understand the background, agenda, funding sources, and motives of the research used to inform practice. Eliminate research priorities and processes that reproduce oppressive structural conditions and benefit the researcher or the organization/entity sponsoring the research more than the individuals or communities of inquiry (Strier, 2006). Expand research initiatives done by and for oppressed groups so that the research relied upon for “evidence-based” practice is not predominantly comprised of Eurocentric studies done on dominant (White, hetero, etc.) populations. Increase the practice and application of research processes that empower clients and communities, including participatory, action, and emancipatory research. Participatory research facilitates the active inclusion and participation of under-represented populations

in the inquiry process (Strier, 2006). This collaboration is aimed at promoting the skills and knowledge needed to influence organizational and institutional policies and to participate in economic, political, and cultural life (Strier, 2006). Action research values the self-determination of participants and utilizes experiential learning and action to build community and enhance quality of life (Strier, 2006). Emancipatory research seeks to transform the power imbalance between researchers and participants and facilitate social liberation and empowerment (Letherby, 2006).

The nature of oppression and our understanding of it are always changing, as are the social and cultural contexts in which it is situated (Butler et al., 2005). The evolving nature of oppression, coupled with new forms of resistance to social change efforts and growing diversity within the population, makes antioppressive practice an ongoing, critical area of focus for the social work profession.

125 Effective Practice with Refugees and Immigrants

Miriam Potocky

Social work practice with refugees and immigrants requires understanding of four fundamental elements: (1) the distinction between the two groups; (2) the stages of migration; (3) the role of culture, ethnicity, and minority status; and (4) the importance of evidence-based practice. An understanding of these fundamental elements lays the foundation for effective practice with these populations. This discussion addresses these fundamental elements, using two case examples for illustration. Then, necessary components of effective practice are presented and their practice implications for the two cases considered.

CASE EXAMPLES

Lakshmi, age 37 years, came to the United States six years ago from India as a legal immigrant accompanying her husband, a software engineer who was hired by a U.S.-based multinational corporation. The couple has two sons, ages 10 and 12 years. Lakshmi does not work outside the home. Both parents are fluent in English, and the family has a comfortable socioeconomic status. Recently, Lakshmi's 75-year-old mother-in-law came from India to live with the family. The mother-in-law requires some assistance from Lakshmi in her activities of daily living. Additionally, some family conflicts have arisen due to the mother-in-law's disapproval of the boys' Americanized behaviors. Lakshmi is also concerned about her own mother, who still lives in India and is in poor health. Lakshmi has been experiencing migraine headaches recently and has sought medical care from her physician.

Fernando, age 30 years, came to the United States from Cuba four months ago. He arrived in

Florida following a three-day boat journey during which he became sunburned and dehydrated and two of his companions drowned. In Cuba, Fernando had been a journalist and had been imprisoned for a year for writing an article critical of the Cuban government. On arrival in the United States, he was granted refugee status. He now lives with a sister and her family, who had come to the United States previously. He has minimal English ability and is presently employed as a parking valet. He has begun drinking heavily.

FUNDAMENTAL ELEMENTS

Immigrants versus Refugees

There is a fundamental distinction between immigrants and refugees (Devore & Schlesinger, 1999). Immigrants leave their countries voluntarily in search of better economic opportunities or family reunification, as illustrated in the case of Lakshmi. In contrast, refugees are forced out of their countries because of human rights violations against them, as illustrated by Fernando. Immigrants may be further divided into legal and illegal. Whether a person is a legal or illegal immigrant or a refugee has implications for his or her experiences during the migration process, as will be described shortly.

Stages of Migration

The migration process consists of three major stages: premigration and departure, transit, and resettlement (Drachman, 1992).

Premigration and departure. The premigration stage entails loss of family and friends and loss of a familiar environment. Both Lakshmi and Fernando have experienced these losses. Generally,

the losses are greater and the premigration and departure experience is more traumatic for refugees than for immigrants. Because refugees live in politically oppressive conditions or in the midst of war, they may have been subject to discrimination, violence, rape, torture, death of family members, or imprisonment, as in Fernando's case.

Refugees often leave under hurried, chaotic, and dangerous conditions. In many cases, they flee in the midst of armed conflict. They may be victims of violence or may have witnessed violence, rape, torture, or killing. In some cases, refugees leave in mass movements, with hundreds or thousands of people. Because refugees flee under these the chaotic conditions, they usually must leave almost all their possessions behind. Thus, they lose their homes and other assets. Furthermore, refugees do not know when, if ever, they will be able to return to their countries. Thus, leaving behind family and friends is particularly painful because they know they may never see them again. Fernando left Cuba in a boat on short notice, and he fears that if he returned he would be imprisoned again.

In contrast, immigrants typically are able to plan their departure well in advance, and they leave under relatively calm conditions. They do not have to abandon their possessions; they can take some assets, especially money, with them, and they retain ownership of their property. Typically, there are no political barriers to prevent them from returning to their country, so they know they can return, even though it may not be for a long time. Nonetheless, the separation from home and family is painful, as illustrated by Lakshmi, who is likely feeling some guilt about leaving her mother behind.

Not all refugees and immigrants experience all the losses and traumas that can occur during this stage. However, some degree of loss occurs in all cases. The experiences during this stage influence the later stages of the migration process. In particular, these experiences affect people's health and mental health later.

Transit. The transit stage involves the physical move from one country to another. Again, this experience is usually more traumatic for refugees than immigrants. The experience also differs between legal and illegal immigrants. For legal immigrants, the transit usually entails arrival by plane and is typically not traumatic, as in Lakshmi's case. However, for illegal immigrants and refugees, the transit may be dangerous or life-threatening. Immigrants who enter the United States illegally often experience a dangerous transit where they are at the mercy of paid

smugglers. Refugees may pass through areas of armed conflict and may be subject to or witness the same atrocities as in the premigration and departure stage. They may undertake a lengthy journey on foot, during which they may face starvation, dehydration, hypothermia, or other physical hardships. Some refugees leave by boat. Often, these boats are in poor condition and overloaded. Sinking, drowning, and illness or death due to sun exposure is not uncommon, as in Fernando's case. In many cases, refugees are placed in refugee camps in neighboring countries before they are sent to a permanent home in the United States or another country. These camps usually consist of tent cities. They are often overcrowded and have poor sanitation. Diseases and violence in the camps are not uncommon. Refugees may remain in such camps for years before obtaining permission to enter the United States. Refugees who arrive directly in the United States requesting asylum may be placed in a detention center while their case is decided. In some cases, such individuals have remained in detention for months or years.

Again, not all legal immigrants, refugees, and illegal immigrants have the same transit experiences. Trauma experienced during the transit can affect the person's adaptation in the later stage, namely, resettlement.

Resettlement. Resettlement is the last stage of the migration process. This stage can be seen as lasting throughout people's stay in the new country, which may be the rest of their lives. This is the stage during which social workers in the United States encounter and work with immigrants and refugees such as Lakshmi and Fernando. Issues that arise during this stage include adaptation to the cultural norms of the new country; health and mental health problems; language, education, and employment issues; changing family dynamics; and discrimination, racism, and xenophobia from members of the host society. Many of these challenges are evident in Lakshmi's and Fernando's cases. Again, these issues are usually more difficult to cope with for refugees than for immigrants.

Culture, Ethnicity, and Minority Status

Culture refers to the norms of conduct, beliefs, traditions, values, language, art, skills, and interpersonal relationships within a society (Lum, 2010). For example, Lakshmi's culture places high importance on obligations of adult children to their parents, as reflected in her situation. *Ethnicity* refers to groupings of people based on shared elements

such as physical appearance, culture, religion, and history. Most immigrants and refugees can also be considered *minorities*, meaning that they are disadvantaged and receive unequal treatment in the host society (Lum, 2010). Culture, ethnicity, and minority status affect people's life experiences, including their utilization and response to formal helping systems. For example, Fernando may not actively seek formal help due to the significance attached to *machismo* (i.e., a strong sense of masculine pride) in traditional Hispanic cultures.

Evidence-based Practice

Many interventions have not been specifically evaluated for refugee and immigrant clients. Therefore, social workers must have knowledge of the existing empirical literature and be able to determine what interventions, or modifications of interventions, appear most promising for immigrant or refugee clients based on demonstrated effectiveness for other populations. Social workers then need to adapt existing interventions or programs to make them culturally compatible with the ethnic backgrounds of immigrant or refugee clients. To determine whether these adaptations were successful, social workers need understanding of various evaluation methods.

COMPONENTS OF EFFECTIVE PRACTICE

The foregoing elements provide the foundation for effective practice with refugees and immigrants. Such practice consists of specific sets of attitudes and beliefs, knowledge, and skills. These necessary components are summarized next, based on a synthesis of the literature on culturally competent practice (Potocky-Tripodi, 2002), adapted specifically for refugees and immigrants.

Attitudes and Beliefs for Effective Practice with Refugee and Immigrant Clients

Effective social workers:

- Are aware that practice cannot be neutral, value-free, or objective
- Are aware of and sensitive to their own cultural heritage
- Are aware of how their own cultural backgrounds and experiences, attitudes, values, and biases influence psychological processes
- Are aware that their decisions may be ethnocentric
- Are aware of their negative emotional reactions toward refugee and immigrant groups that may prove detrimental to their clients
- Are aware of stereotypes and preconceived notions that they may hold toward refugee and immigrant groups
- Are willing to make purposive changes in their feelings, thoughts, and behaviors toward refugee and immigrant groups
- Value and respect differences that exist between themselves and clients in terms of ethnicity, culture, and beliefs, and are willing to contrast their own beliefs and attitudes with those of their immigrant and refugee clients in a nonjudgmental fashion
- Respect clients' religious and/or spiritual beliefs and values about physical and mental functioning
- Respect indigenous helping practices and respect ethnic community intrinsic help-giving networks
- Value bilingualism and do not view another language as an impediment to practice
- Value the social work profession's commitment to social justice
- Value the importance of evidence-based practice
- Are able to recognize the limits of their competencies and expertise.

Knowledge for Effective Practice with Refugee and Immigrant Clients

Effective social workers are knowledgeable about:

- Multiple theories of social science, human behavior, and social work practice
- Their own racial and cultural heritage and how it personally and professionally affects their definitions and biases of normality, abnormality, and the practice process
- How oppression, racism, discrimination, and stereotyping affect their work and them personally
- How their communication style may clash with or facilitate the practice process with refugee and immigrant clients and how to anticipate the impact it may have on others
- Demographic characteristics, life experiences, cultural heritage, and historical backgrounds of various refugee and immigrant groups

- Family structures/hierarchies, values, and beliefs of various refugee and immigrant groups
- The effects of culture, ethnicity, and minority status on personality formation, life choices, manifestation of psychological disorders, help-seeking behavior, and the appropriateness or inappropriateness of practice approaches
- Culture as a source of cohesion, identity, and strength as well as strain and discordance
- A refugee or immigrant group's adaptive strategies
- Ethnic community characteristics and community resources
- How a person's behavior is guided by membership in families, groups, organizations, and communities
- How sociopolitical influences, such as immigration issues, poverty, racism, stereotyping, discrimination, and powerlessness, impact the lives of refugee and immigrant clients and may influence the practice process
- The cultural characteristics of generic social work practice and how they may clash with the cultural values of different refugee and immigrant groups
- Potential bias in assessment instruments and diagnostic systems
- Institutional barriers that prevent refugees and immigrants from using health, mental health, and social services
- Empirical literature on intervention effectiveness
- Program and practice evaluation methods.
- Use appropriate self-disclosure
- Identify the client's problem in terms of wants or needs, levels, and details
- Use ethnographic interviewing skills to help identify the problem
- Assess the problem within the client's total bio-psychosocial context
- Help clients determine whether a problem stems from racism or bias in others so that clients do not inappropriately blame themselves
- Assess stressors and strengths relevant to the problem and its resolution
- Use assessment and testing instruments appropriately
- Actively involve their clients in goal-setting and contracting
- Help clients prioritize problems
- Educate their clients about the processes of intervention, such as goals, expectations, legal rights, and the worker's orientation
- Establish culturally acceptable goals and objectives
- Formulate multilevel intervention alternatives
- Identify and use the client's definition of successful coping strategies and problem resolution strategies
- Select culturally appropriate, empirically based interventions
- Formulate explicit contracts
- Enhance or restore a client's psychosocial functioning and seek to redress structural inequities at the societal level
- Tailor intervention strategies to differences in help-seeking patterns, definition of problems, and selection of solutions
- Use a blend of formal and informal helping resources
- Consult with traditional healers or religious and spiritual leaders and practitioners when appropriate
- Explore issues of authority or equality in the therapeutic relationship
- Aim to increase personal, interpersonal, or political power of individuals, families, groups, and communities through empowerment techniques
- Aim to promote a sense of the collective; increase access to resources and to codeveloped client-worker solutions
- Exercise institutional intervention skills on behalf of clients to eliminate biases, prejudices, and discriminatory practices

Skills for Effective Practice with Refugee and Immigrant Clients

Effective social workers:

- Take responsibility for providing the language requested by the client
- Have a dependable ability to develop client mutual respect/acceptance and regard
- Are able to overcome client feelings of suspicion, distrust, or anger
- Use a positive and open communication style
- Use appropriate terms and words, visual clues, tone, facial expressions, and cadence
- Follow culturally appropriate relationship protocols
- Sincerely convey signals of respect congruent with the client's cultural beliefs

- Monitor intervention implementation and client progress
- Review progress and growth with clients
- Refer clients to other workers or agencies if they believe they are unable to help
- Evaluate problem change and attainment of objectives
- Evaluate intervention effectiveness
- Address the client's and worker's feelings about termination
- Help clients establish goals and tasks for the future
- Connect clients with other community resources
- Establish a follow-up plan
- Evaluate agency effectiveness
- Facilitate maintenance of client change
- Implement follow-up contacts
- Collect client information during follow-up
- Evaluate follow-up data
- Reinstate intervention if necessary.

Case Example Practice Implications

Lakshmi has come to her physician seeking help for migraine headaches. Her doctor may identify stress as a potential contributing factor to the pain. The physician may offer medication and may also refer Lakshmi to a social worker for a stress reduction intervention. Being familiar with the foregoing practice principles, the social worker should recognize the multiple stressors in Lakshmi's life and explore these with her. The client's stress stems from the various experiences in the different stages of her migration process, and from the generational conflicts in her household due to differential acculturation of family members. The social worker may suggest family counseling to address this issue. The worker should also explore whether Lakshmi has a support system outside her family; if not, the worker should connect Lakshmi with other immigrant women from India, who will probably be able to provide mutual support. The worker should also discuss with Lakshmi various alternatives for the care of both her mother-in-law and her own mother, bearing in mind the cultural values relevant to this.

As a recently arrived refugee, Fernando is probably receiving initial resettlement assistance from a government program. Such a program primarily focuses on employment. The social worker should recognize that Fernando is underemployed and may be feeling depressed due to the loss of his occupational status. The worker

should help him enroll in English classes and a retraining program that will help him attain a job commensurate with his skills. The worker should also realize that Fernando is likely traumatized by his past imprisonment and by witnessing the drowning of his boat companions. Thus, the worker should explore the possibility of mental health counseling, bearing in mind that Fernando is not likely to be initially receptive to the idea due to cultural values. The worker should also explore alternate housing for Fernando, given that living with his sister and her family may be creating additional stress for all of them.

CONCLUSION

Effective social work practice with refugees and immigrants is based on an understanding of certain fundamental factors, combined with the development of specific attitudes, beliefs, knowledge, and skills. The development of these competencies is a continuous learning process. Social workers should continually evaluate their practice and the policies and procedures within their agencies to determine how they might better serve and be more effective with refugee and immigrant clients.

126 Social Work Practice with Native Americans

Teresa A. Evans-Campbell & Gordon E. Limb

THE CULTURAL CONTEXT OF PRACTICE WITH AMERICAN INDIANS/ALASKA NATIVES

Terminology

Numerous terms are used to describe the indigenous people of North America, including Native American, American Indian/Alaska Native (AIAN), and First Nations. While Native American is more generic, American Indian is the term used by the federal government in all policies and treaties. First Nations is a term used in Canada and by some tribes. However, many Native people instead prefer to identify by their specific tribal affiliation. Although there is no one, universally accepted term, most Native people have strong preferences regarding terminology, and it is incumbent upon social workers to ask clients which term they prefer. In this chapter, the terms *AIAN* and *Native* are used interchangeably.

Diversity among American Indians/Alaska Natives

The term *AIAN* encompasses an extremely diverse group of people. In the United States, there are currently 566 federally recognized tribes, including 229 village groups in Alaska and close to 200 unrecognized tribes (Bureau of Indian Affairs, 2012). The size of tribal nations varies widely, ranging from only two members (in several California tribes) to over 100,000 members (U.S. Bureau of the Census, 2010). According to the 2010 Census, 5.2 million people in the United States identify as AIAN, either

alone or in combination with one or more other races. Out of this total, 2.9 million people identified as AIAN alone. The AIAN (in combination) population experienced rapid growth, increasing by 39% since 2000 (U.S. Census Bureau, 2010).

Contrary to common portrayals in the media, two-thirds of all AIAN people now live in urban settings (U.S. Bureau of the Census, 2010). The urbanization of the Native population has occurred over the past several decades, often as the result of federal policies including tribal termination and relocation. Although urban AIAN research is growing, the majority of literature on social work practice with AIANs continues to be based on experiences with reservation-based populations.

Though there are some generally shared norms and values among Native people, each tribal nation is distinct in terms of culture, language, and social customs, and each nation itself encompasses a diverse population of tribal members. At the same time, American Indian families are increasingly multitribal, multicultural, and multiracial, and there is also tremendous variation in the level of acculturation among AIAN people. Though such diversity exists, Natives have endured generations of concerted stereotyping, and non-Natives often carry profound misconceptions about AIAN people and AIAN cultures. Given the great diversity among Native people, social workers must utilize a strengths perspective and place a strong focus on cultural affiliation and cultural identity in the assessment phase, relying on Native clients to best articulate how they identify culturally (Weaver, 2003).

THE HISTORICAL CONTEXT FOR PRACTICE WITH AMERICAN INDIANS/ALASKA NATIVES

Historical Trauma

An understanding of the historical context in which contemporary Native people live is imperative for culturally relevant social work practice. Over successive generations, Native people have endured a series of traumatic assaults that have had profound consequences for families and communities. An extensive body of literature documents these assaults, which have included community massacres, forced relocation, the forced removal of children through Indian boarding school policies, foster care and adoption policies that promoted the removal of Native children from their families, and the prohibition of spiritual and cultural practices (Cross, Earle, & Simmons, 2000; Stannard, 1992).

As an example, the Indian boarding school era, which began in the late 19th century, involved separating children from their parents and sending them to schools operated by religious organizations or the Bureau of Indian Affairs (BIA). The schools prohibited the use of Native language, required students to wear uniforms, and enforced discipline in an authoritarian manner completely foreign to traditional Native child-rearing practices. The mission of boarding schools was the forcible assimilation of Native children into the mainstream society. The boarding school era has been linked to losses related to Native language, religion, beliefs, customs, and social norms—the foundation of the AIAN worldview and identity. Today, nearly one-half of all AIANs either attended boarding schools or who had parents who attended boarding schools (Limb, 2004).

Although AIAN peoples have demonstrated enormous resilience in spite of this history, such events have taken a toll on the mental health and wellness of Native families. Our ability to understand the full impact of these traumatic events and develop relevant interventions is constrained by conceptual and empirical limitations within commonly used models of trauma and traumatic response. Standard diagnostic categories capture some trauma-related symptoms experienced by AIANs (e.g., nightmares about traumatic events) but are limited in their ability to explore the effects of multiple, intergenerational, and culturally unique traumatic events. Moreover, current models of trauma focus primarily on negative

responses to trauma and are only beginning to explore the ways people cope and maintain wellness.

A number of different terms have been used to describe the multigenerational nature of distress in Native communities, including collective trauma, intergenerational trauma, multigenerational trauma, and historical trauma (Evans-Campbell, 2008). Recently, social workers have begun to view the concept of historical trauma as an important consideration in wellness among historically oppressed communities. Scholarship exploring historical trauma in Native communities draws from the seminal work of Maria Yellow Horse Brave Heart and her colleagues (Brave Heart 1999a,b, 2000; Brave Heart, Chase, Elkins, & Altschul, 2011; Brave Heart & DeBruyn, 1998). Historical trauma is defined as the cumulative emotional and psychological wounding across generations, including the lifespan, which emanates from massive group trauma (Brave Heart et al., 2011). It is conceptualized as a collective complex trauma inflicted on a group of people who share a specific group identity or affiliation—ethnicity, nationality, and religious affiliation.

Brave Heart and her colleagues explored the impacts of a range of historically traumatic events on mental health among the Lakota and documented a collection of common responses that they call “historical trauma response.” This response is similar to symptomatology identified among Jewish Holocaust survivors and their descendants and includes rumination over past events and lost ancestors, survivor guilt, feeling numb in response to traumatic events, anger, depression, and intrusive dreams and thoughts (Brave Heart, 1999a,b, 2000; Brave Heart & DeBruyn, 1998). Growing evidence suggests, however, that although some Native people have negative reactions associated with historically traumatic events, they also exhibit many areas of resilience and strength.

In addition to intergenerational losses, contemporary Native communities also suffer from some of the highest rates of lifetime traumatic events, including interpersonal violence (e.g., Tjaden & Thoennes, 2000), suicide (Olson & Wahab, 2006), child abuse and neglect (Cross, Earle, & Simmons, 2000), poor health and mental health (Walters, Simoni, & Evans-Campbell, 2002), and an ongoing barrage of microaggressions and racist stereotypes. Given both the historical context and the high rate of contemporary stressors faced by Native people, it is not surprising that AIANs have among the highest rates

of mental health disorders in the United States (Substance Abuse and Mental Health Services Administration [SAMHSA], 2001).

Tribal Sovereignty

Another important element of the historical context for practice with AIANs is an understanding of tribal sovereignty. Throughout American history, AIANs have had a unique relationship with the United States government. One of the most important aspects of this relationship is the concept of AIAN self-government or sovereignty. From an AIAN perspective, tribal sovereignty was instrumental in the passage of a number of policies that have allowed AIANs to practice their traditional culture. The federal government views tribal sovereignty as a political or legal dimension—“including the power to adopt its own form of government; to define the conditions of citizenship/membership in the nation; to regulate the domestic relations of the nation’s members... to levy dues, fees or taxes upon citizens of the tribe; [and] to administer justice” (Wilkins, 1997, p. 20).

Tribal Sovereignty has many of the same elements as the ethical standard of *self-determination* in the National Association of Social Workers (NASW) Code of Ethics (2008) endorsed by the social work profession. An understanding and respect for tribal sovereignty allows social workers the opportunity to utilize cultural elements in their practice with AIANs and shifts attention away from deficit models in favor of models of cultural strength (Red Horse & Limb, 2004; Weaver, 2003).

EVIDENCE-BASED INTERVENTIONS RELEVANT TO SOCIAL WORK PRACTICE WITH AMERICAN INDIANS/ALASKA NATIVES

There is clearly a critical need for effective models of practice with Native people. Increasingly, the field of social work is moving toward the use of evidence-based practice interventions and strategies with diverse populations. Unfortunately, the use of evidence-based interventions with AIAN people is complicated by the lack of intervention research that either includes Native clients or examines Native-specific practice models. Instead, practitioners often rely on evidence-based interventions that have shown success with non-Natives and then adapt these for work with

Native populations. In some cases, the work to adapt interventions culturally is extensive and involves active participation from Native community members and practitioners. Numerous culturally adapted programs have been empirically tested and have shown success with Native populations (e.g., The American Indian Life Skills Development suicide prevention curriculum, several trauma-related treatment models developed by the Indian Country Child Trauma Center). In other cases, cultural adaptation is only superficial—using Native words or Native images in media materials, for example—and the core strategies used in work remain culturally inconsistent.

When working with Native people, social workers might also consider practices that are considered promising in that there is emerging empirical evidence of their success. There are a growing number of Native-designed programs designated as promising practice models by agencies such as the Indian Health Service and SAMHSA. In addition, many indigenous practice models have strong support in tribal communities but still lack empirical validation. In these cases, taking a broader perspective on what constitutes evidence can be helpful. For example, support for many indigenous healing practices may also come in the form of practice-based evidence, including the historical use of healing strategies, community acceptance, and the integration of a healing strategy into the culture of a community (BigFoot, 2007).

PRACTICE COMPETENCIES FOR WORK WITH AMERICAN INDIAN/ALASKA NATIVE INDIVIDUALS, FAMILIES, AND COMMUNITIES

To help provide an empowering context for practice with Native families, a number of indigenous social work practice competencies are outlined. Several of these strategies have been adapted from a set of decolonizing practice competencies presented by Evans-Campbell and Walters (2006). These strategies are not meant to be exhaustive but should be seen as a base to build on in work with families and communities.

Using a Culturally Relevant Framework for Practice

Social work practice with AIAN people requires familiarity with Native norms and values, an

understanding of the history of colonization, and an appreciation of the diversity both among and within Native communities. Accordingly, each intervention should be culturally specific and tribally relevant. Thus, social workers should not assume that a program designed for practice with Lakota people will be effective with Yakama tribal members. Interventions must also be aligned with the level of cultural connection (Weaver, 2003, 2004) and identity needs of each individual. Though many Native people are closely tied to their communities, others have a more tenuous connection, which may influence their choice in services. Moreover, some Native people feel alienated from their tribal culture and experience identity-related mental health issues, including depression, low self-esteem, and anxiety. To help those suffering from feelings of alienation, social workers can connect families with Native cultural and social resources in their area. In many cities, Native organizations run programs specifically targeted to Native people (e.g., talking circles for Native parents and Native youth programs), and nearby tribal communities may offer their services to Native families who are not tribal members.

Enacting a Historically Relevant Framework for Practice

Social workers should have training around the history of colonization in the United States and its impact on Native wellness and family processes. Through the process of exploring cultural narratives and history, practitioners can work with clients to identify traditional ways of addressing trauma as well as cultural strengths that can be built on in practice. It is also essential that workers gain a fundamental understanding of how social work has played a role in the institutional racism that Native people have experienced (e.g., discriminatory child welfare policies and practices).

Documenting Historically Traumatic Events and Colonial Trauma

Though the lives of Native people are contextualized within a history of colonization and historically traumatic events, many people are not aware of the specific events that have impacted their communities and families. Practitioners can assist clients in learning about their histories by

completing genograms, historical narratives, and historical timelines with individuals and families. These charts can document births, deaths, cultural events, specific historically traumatic events, as well as corresponding responses at the individual and familial level. Through such exercises, family survival strategies, coping patterns, and anniversary reactions to historically traumatic events are made explicit and can be clearly linked to traumatic events.

Focusing on Resilience and Strength

Although all indigenous people share a history of historical trauma and contemporary stress, these experiences do not define Native people. Native families have tremendous histories of strength and intergenerational resiliency, which should be a core focus of work. Social workers are in a unique position to help illuminate family strengths and identify how these strengths are currently manifested in the family system.

Taking Time to Build Trust

Studies show that Native people have high levels of mistrust around public social service agencies, including Child Protective Services (CPS), mental health agencies, and health care settings (e.g., Carter, 2010; Evans-Campbell, under review). This may be especially true in the field of child welfare where generations of Native children have been impacted by policies designed to assimilate them or remove them from the care of Native families, including the Indian boarding school movement, the Indian Adoption Project, not following the Indian Child Welfare Act, and the long history of CPS intervention in Native families. Such views are not surprising in light of this history and might even be reframed as a healthy reaction to what was historically a real threat. Accordingly, practitioners should be prepared to spend a significant amount of time building trust, especially in initial sessions with Native people. Intervention models that rely on client-initiated goals and objectives (e.g., motivational interviewing) may be especially helpful in this regard.

Communicating about Historical Trauma

Communication around historically traumatic events is an integral piece of healing. At certain

times, responses such as denial or anger may be quite functional and protective responses to trauma, especially while a person is attempting to survive major catastrophic traumas such as boarding school or genocide (Brave Heart et al., 2011; Danieli, 1998). However, the maintenance of such responses can undermine individual and family health over time. When individuals are emotionally prepared and ready, social workers can assist in exploring historical losses and making links to current family functioning. An important area of focus may be intergenerational anniversary patterns, which are often unconscious to individuals and families. For example, a Native mother may become anxious or preoccupied with the safety of her children around the anniversary of the time her parents were taken to Indian boarding school.

Supporting Clients in the Use of Traditional Healing Methods

Native clients may prefer to work with, or need additional assistance from, traditional healers or Native practitioners, and social workers should be prepared to help identify appropriate traditional resources. In addition, some communities have lost important cultural tools and rituals that historically addressed loss and grief. Although it would be inappropriate for non-Native workers to attempt to impart cultural knowledge, practitioners can be invaluable as they support community members in reclaiming or relearning traditions and creating new ways to heal (Gray & Rose, 2012).

Endings in Practice with Native People

Termination with Native clients often requires a relatively extended time frame as well as worker flexibility around commemorating the worker–client relationship. As noted previously, Native clients tend to establish trust with workers slowly and may invest a substantial amount of energy into relationship building. After a lengthy process of building trust, termination may require more time and planning on the part of the worker. The loss of the therapeutic relationship may also trigger feelings related to earlier losses (both lifetime and intergenerational) experienced by the client. Moreover, workers should be flexible about the process of termination and

associated rituals. In many AIAN communities, the end of a significant relationship is usually acknowledged and celebrated, and Native clients may wish to commemorate the termination with a traditional practice, event, or gift.

CASE EXAMPLE

June is an Oneida woman who recently relocated with her two school-aged children from a large reservation community to a major metropolitan area. June is working full-time at a department store and is enrolled in two college courses. The family lives with her sister, who watches the children after school and in the evenings while June attends class. June has a strong work history and has always done well in school, but she feels unable to concentrate on anything right now. She reports having symptoms of depression and anxiety for the past several months and feels “overwhelmed” with her life. June has usually relied on traditional practitioners to support her wellness, but she feels disconnected from other Natives in the city. Although she misses her family and friends on the reservation, June states that her family home is not a healthy place for her children right now due to her mother’s alcoholism and erratic behavior. In addition, she feels that she needs to be in the city to support her sister, who recently finished a drug treatment program. June reports that she attended Indian boarding school in elementary school and was physically abused there. She came to see you after getting a referral from her primary physician and has never seen a social worker or mental health professional before.

Goals in Assessment Phase

- Assess cultural affiliation and identity, especially in relation to treatment preferences and options.
- Assess length and extent of symptoms related to depression and anxiety.
- Begin exploring possible sources of stress for the client.
- Explore family strengths and coping strategies successfully used in the past.
- Develop a timeline documenting significant life events, historically traumatic community events, ceremonies, and rites of passage in the family. Work with the client to document related individual and familial reactions.

- Conduct an assessment utilizing an appropriate assessment tool (e.g., Congress & Kung, 2013; Hodge & Limb, 2011) to help assess cultural needs related to wellness, social support, and the provision of mental health services.
- Consider how societal oppression and institutionalized racism have impacted the client's life and her community.
- Anticipate spending considerable time building trust.

Treatment Goals

- Intervention strategies that focus on having clients themselves determine goals and objectives (e.g., solution-focused work) may be especially helpful in helping empower Native clients (Lettenberger-Klein, Fish, & Hecker, 2013).
- Build on positive coping strategies and develop new strategies to combat stress and anxiety.
- Help identify strengths and resiliencies in the client's family and community history (Goodluck, 2002).
- Honor the client's commitment to Native traditional spirituality (Limb & Hodge, 2008) and support her work with traditional practitioners in addition to, or in place of, social work interventions.
- Explore relevant treatment resources at tribal or Native agencies in the region.
- Explore cultural and social events that may be of interest.

CONCLUSION

In summary, culturally relevant social work practice with Native people will require commitment and creativity. All social workers must increase their understanding of how current life stressors are experienced within the context of historical trauma in Native communities (Hodge, Limb, & Cross, 2009). Workers must also be committed to developing and empirically testing potentially effective treatments for lifetime and historical trauma with Native communities. Finally, and perhaps most importantly, social work practitioners and scholars should continue to investigate community strengths as well as resilience and healing strategies found effective in Native communities. There is a growing literature exploring

the strengths and resiliencies that result from survival in the face of historical traumas, and it could be argued that in indigenous communities, historical events have enhanced community ties and underscored the importance of retaining culture and tradition. Social workers must ask themselves how best to build on these strengths to support wellness.

127 Social Work Practice with Asian and Pacific Islander Americans

Halaevalu F. Ofahengaue Vakalahi & Rowena Fong

INTRODUCTION

The Asian and Pacific Islander population is a diverse group often mistakenly lumped together and insufficiently differentiated. Asian Americans themselves are a varied group composed of dozens of nationalities and ethnic groups from East Asia, South Asian, and Southeast Asia. East Asians include individuals from the countries of China, Japan, Korea, and the Philippines. South Asians arrive from Pakistan, India, Sri Lanka, Bangladesh, Nepal, and Bhutan. The Southeast Asians come from Burma/Myanmar, Singapore, Thailand, Laos, Cambodia, Vietnam, Indonesia, East Timor, and Brunei. Most of these nations are, in turn, composed of numerous tribal and ethnic groups, such as the Hmong, who emigrated in significant numbers from Laos to the United States in the aftermath of the Vietnam War.

Pacific Islanders include individuals from the South Pacific island groups of Polynesia, Micronesia, and Melanesia (Laville & Berkowitz, 1944; Narokobi, 1983). Pacific Islanders have historically struggled with navigating daily colonialization and immigration, which often results in experiences with oppression, exploitation, and marginalization, and which has led to enormous mistrust of foreign systems. The historical trauma of colonization and its impact on Pacific People's overall physical health and mental health continues to be a challenge with each generation (Hurdle, 2002).

Those who migrate to the United States, in particular, experience the consequences of cultural conflicts in the forms of language barriers, disintegration of cultural identity, disproportionately poor health status, underemployment and

undereducation, as well as oppression, exploitation, and discrimination (Yoshihama, 2001). Apparently, every new generation of Pacific Islander immigrants encounters some type of discrimination or prejudice from government systems and/or Caucasian American communities (Millett & Orosz, 2001) that blocks access to the opportunities that might facilitate a transition from surviving to thriving in their respective communities. According to the U.S. Bureau of the Census (2007), Pacific Islander Americans are one of the most economically, educationally, and politically disadvantaged populations in the United States today. Though there is great heterogeneity among Asians and Pacific Islanders in terms of social class, educational achievement, and professional occupation, the majority of Asians and Pacific Islanders do experience aspects of racism and discrimination that contribute to their disadvantaged status.

Despite oppressive encounters, this group possesses cultural strengths that can inform culturally relevant and sensitive practice, policy, education, and research. Examples of these cultural strengths include close family relationships, extended family network, love for children, respect for the elderly, reciprocity and sharing, and communal responsibility (Vakalahi, Godinet, & Fong, 2006). Family is first and the center of all relationships; it is the agent of socialization where honor, respect, nurturing, and collaboration are taught and practiced (Fong & Furuto, 2001). It is a basic cultural belief in most Asian and Pacific Islander groups that a house without children is a house without life. Children are embraced, paid attention to, and seldom left alone when crying. From their earliest years, children

are taught to respect the elderly. In terms of collective, the good of the whole and interdependency are valued above individual benefits and achievements (Lee, 1997; Mokuau, 1991). Of great value to Pacific Islanders who reside in countries outside of the Pacific is the notion of transnationalism, whereby Pacific people maintain ties to their nation of origin, which serves as a mechanism for indigenous cultural preservation and for sustaining relationships across families and communities in two or more geographic locations (Vakalahi & Godinet, 2014).

CASE ILLUSTRATIONS

Case 1: The Problem of Cultural Conflict

Seini is a 17-year-old Tongan female, born in Tonga, raised in Hawaii, and living with her parents and brothers in a low-income area in Honolulu. Her family migrated from Tonga when she was 10 years old. Her annual family income is about \$20,000, primarily from her father's seasonal employment. The primary language spoken in her home is Tongan. She is a senior in high school but struggles to earn enough credits to graduate on time. Seini is currently working with a probation officer due to her involvement in multiple fights in school, allegedly associated with gang violence. She has described to her school counselor the struggles of living in dual cultures that demand one thing at home and another in school. She has experienced conflict with Tongan cultural traditions and customs imposed by her family and community, her family's low socioeconomic status, the negative impact of her low-income neighborhood, and the peer pressure to be tough.

Seini talks about the overwhelming demands for giving to family, community, and church members, which often result in insufficient funds to meet her family's own needs. She often feels resentful of this cultural practice because she feels that it adds unnecessary pressure on her parents and additional responsibilities on her and her siblings. Seini feels that her Tongan culture is very important, but there have to be limits to the demands and expectations. On the other hand, her parents are intimately involved in community, cultural, and church functions. They live by cultural values of reciprocity, sharing, discipline, respect for parents and the elders, and taking responsibility for family and extended family.

They discipline their children through spanking, scolding, and grounding, which are acceptable in the Tongan culture. Interestingly, Seini accepts such disciplinary methods as appropriate and beneficial for teaching her what is wrong and right. Nonetheless, she feels that she does not fit into either her American or Tongan culture. This experience with acculturative stress is a well-documented contributing factor to deviant behavior.

Consequences of the immigration experience hinder some of the cultural practices that Tongans are accustomed to observing in Tonga. Collectivity and reciprocity are easier to practice in Tonga because families live in close proximity and because of the perspective that it is an honor and a responsibility to care for one another. In the United States, family members live far apart, often by necessity, and lifestyle demands are more complex. The immigration experience also entails language barriers and the responsibility for Seini to translate for her parents in many instances. When Seini interprets for her parents in the larger society, the parent-child role is reversed. Furthermore, living in a multigenerational home with other immigrant family members brings about additional responsibilities for Seini's parents. Scarce resources are definitely an issue. Unfortunately, even if one person breaks the low-income cycle, that person is expected to contribute more back to the family, which perpetuates the scarcity of resources and the low-income cycle.

Despite these risk factors, Seini does have access to protective factors from which a service provider can draw strength, even if she does not realize it. In relation to the Tongan culture, the practice of reciprocity, sharing, unconditional love for children, and parents' wishes for their children to stay in school, as well as Seini's respect for her parents and other family members, and her desire to someday change her situation of low-income status, negative peer pressure, and gang violence are all protective factors for Seini.

Case 2: The Intervention of Family Group Conferencing

Kaimana is a 16-year-old part-Hawaiian male who was removed from his home and placed in the custody of Child Protective Services (CPS) for alleged physical and emotional abuse by his stepfather. He lived with his stepfather, who is Caucasian, and his mother, who is part Hawaiian,

in Waianae farmland. His family had extremely limited material resources and social support systems. His family worked on the farm, earning an annual income of approximately \$15,000. Kaimana and his siblings often missed school; their dirty fingernails and uncombed hair made them appear to be physically neglected.

CPS decided that family reunification was the planned outcome, and a family group conferencing intervention was held. In organizing the conference, individuals involved from the family's side included Kaimana, his parents, his stepfather's sister, his neighbors, and the family social worker from a private agency. Other members of the conference included Kaimana's CPS worker, the CPS supervisor, a mental health specialist, and the conference facilitator, who was from a neutral agency.

Initiating the conference, the facilitator explained the family group conferencing process to all involved parties. Kaimana's parents were given the choice of starting with a prayer or *pule*, as it is called in the Hawaiian language, which they declined. In the effort to clarify any misunderstanding and decrease mistrust of the system, social work professionals explained to the family their obligations to uphold the law to report abuse and protect children. They explained that their involvement as professionals was not intended to disrespect the family, and asked for the family's cooperation in working together for Kaimana. The social workers then identified the goal of the family group conference, which was to reunite Kaimana and his family, ensuring Kaimana's safety, developing specific goals and objectives that were culturally relevant, and identifying resources necessary to meet those goals.

First, the facilitator met with Kaimana's family, and together they developed specific goals and objectives for family reunification and safety and identified resources necessary to meet those goals. Simultaneously, social work professionals met in a separate session with the same tasks to complete. Second, after the individual sessions, both groups came together, and the perspectives of each group were shared. For a period of time, processing, dialogue, negotiations, and explanations took place among the groups to reach a common plan. At the end of the processing session, the common plan consisted of a step-by-step documentation of tasks, timelines, and each person's responsibility. This document became the contract. For example, Kaimana was required to continue attending therapy for his anger problem and establish a personal safety plan. His stepfather was required to

attend anger management courses and continue meeting with the social worker from the private agency to focus on improving communication with his spouse and children and to explore the conflicts brought on by differing cultural values. The social worker was then required to follow up on the family's progress.

PRACTICE CONSIDERATIONS

In both case examples of working with Asian and Pacific Islander children and families, cultural values play a major role in understanding the conflict of the case, handling the case, and choosing the intervention applied.

General guidelines for service providers to consider include:

- Historical and cultural experiences with colonization and immigration, and social and economic consequences
- Within-group diversity and the need for bicultural and bilingual skills that respond to cultural duality and population changes
- The reality of living in the United States, yet being embedded in the culture of origin
- The reality of transnational and transcultural relationships that are built between two geographic locations
- The need to understand the influence of cultural values, customs, lifestyles, and practices on behavior
- The need to understand Asian and Pacific Islanders' perspectives on the shame and stigma associated with seeking mental health services
- The cultural emphasis on collaboration, collectivity, reciprocity, and interdependency
- The need to carefully bridge the community with multiple systems of help and interagency collaboration
- Developing appropriate assessment-to-treatment options, based on consultation with the community to understand cultural taboos and protocols for social and family interactions
- The effects of living within a multigenerational home and family hierarchy
- The prominent position of spiritual, religious, and church leaders in the lives of community members

- The reduction of barriers to service use by advocating for the hiring of Asian and Pacific Islander employees or contractors, building workforce capability and capacity, and designing physical space that reflects respect for diversity
- The need to develop relevant cultural competency objectives and quality services

Treatment Plan

- Each step of the individual treatment plan needs to encompass cultural values, beliefs, and practices, as well as the lifestyles and social realities of Asians and Pacific Islanders.
- Treatment plans need to consider the role of family close by and afar, the ethnic community, and the religious and church community, whenever it is appropriate to include their contributions.

Assessment

- Social workers need to conduct a full assessment of the bio-psychosocial–spiritual dimensions of the self and relevant systems including the person, family, peers, community/neighborhood, school, and culture.
- Social workers need to ask questions regarding family characteristics and lifestyle, perception about mental health service seeking, relationships in the community and with the church and religious community, time of migration to the United States, and preference for a service provider.
- Social workers need to inquire about the role of the family and the ethnic community as well as the preference for ethnic-related resources. Questions to ask are: “Tell me about your family. Tell me about your community. What are your needs and what do you need to meet those needs? Are you involved in your church and religious community? When did you migrate to the United States? Do you have any preferences for a particular type of worker to work with you? Is there anyone in the family or community that you would like to involve in our work with you? How connected is your family to your Asian or Pacific Islander culture?”

Treatment Goals

The following are suggested treatment goals.

- Increase overall social functioning in the family, community, and larger society.
- Increase consistent access to culturally relevant services.
- Reduce family, community, and cultural barriers to continuous physical health and mental health.
- Maintain positive cultural and transnational connections.
- Develop capability and capacity to function positively in a dual/multiple culture.
- Reduce the impact of acculturative stress.
- Increase problem-solving options and capabilities.
- Develop the skills to increase needed resources.
- Find a balance in meeting individual and collective needs by developing win-win solutions.

Intervention Strategies

Although there are many evidence-based intervention strategies that will work with Asian and Pacific Islander individual and family clients, the following three are examples of strategies that are grounded in cultural values of community and family sharing and responsibility, reciprocity, and collectivity.

- Outreach is the action of reaching out to family and community members to engage in and implement interventions with the assistance and support of individuals.
- *Ho’oponopono* is the Hawaiian process of family problem solving, including prayer, food sharing, and forgiveness of wrongdoings (Mokuau, 1991).
- Family group conferencing is an intervention used with biological family members and fictive kin to discuss how the treatment plan will be implemented and followed through by persons committed to the family’s preservation (Wilcox, Smith, Moore, Hewitt, Allan, Walker, Ropata, Monu, & Featherstone, 1991).

Two additional approaches are also introduced as follows:

- *Ifoga* is an indigenous Samoan healing practice emphasizing reconciliation through forgiveness, compassion, and respect. The ceremony gathers the victim and his/her

family to confront the offender and his/her family, whereby the offender and his/her family accept responsibility and generate solutions to restore the power of the victim and his/her family. A proposed term of peace, requesting forgiveness, and granting forgiveness is required. The mediator is a person with power such as a *matai* or chief, elder, or person assigned by the family (Jantzi, 2001; Vakalahi & Godinet, 2008).

- *Fakalelei* is a Tongan healing practice on all levels—spiritual, social, emotional, and biological. Peace in relationships by gathering the victim offender, and families to collectively create a solution. The offender and his/her family are accountable to the victim and his/her family, but then power to accept or reject an apology lies with the victim. The facilitator is a person with power in the family or community such as the *ulumotu'a* or granduncle, or an elder in one's father's family (Jantzi, 2001; Vakalahi & Godinet, 2008).

CONCLUSION

Social work practitioners and service providers, both Asian and Pacific Islander and non-Asian and Pacific Islander, need to be competent with the necessary values and beliefs, knowledge, and skills to provide quality services for Asians and Pacific Islanders. It is recommended that the following practices be used with Asian and Pacific Islander clients:

- Show genuine nonjudgmental respect for people and their cultures; cultures are not deficient, just different. This act will open doors.
- Use multiple treatment strategies, including outreach and family conferencing and other culturally relevant approaches, as necessary.
- Understand Asian and Pacific Islander cultural processes, development, protocols, and taboos.
- Understand the particular Asian or Pacific Islander group involved and their values and beliefs, customs, traditions, and practices.
- Consider the historical trauma or colonization and immigration experiences that help or hinder the treatment process.
- Facilitate and work with large and small family and community groups.

- Work across generations, while recognizing that positions of power lie with the elders.
- Work as a team member and maintain the flexibility to switch roles when necessary (i.e., active involvement or observer only).
- Gain experience working within Asian and Pacific Islander communities.
- Be bicultural or of Asian and Pacific Islander ancestry.
- Be bilingual in any of the Asian and Pacific Islander languages.

128 Social Work Practice with Latinos

Ilze A. Earner & Alan Dettlaff

INTRODUCTION

Latinos are the largest ethnic minority group in the United States and the fastest-growing segment of the U.S. population. Among Latino adults, 52% are foreign-born immigrants who migrated to the United States (Pew Hispanic Center, 2012). However, among Latino children, only 8% are foreign-born. Yet, it is important to note that although the large majority of Latino children are born in the United States, more than half (52%) of Latino children have at least one immigrant parent (Fry & Passel, 2009). Overall, the Latino population is relatively youthful compared with other racial and ethnic groups in the United States: the median age of Latinos in the United States in 2010 was 27 years, compared to 42 years for Whites, 32 years for Blacks, and 35 years for Asians (Pew Hispanic Center, 2012).

Geographically, more than three-quarters of Latinos live in the South (36%) and the West (41%), with over half of Latinos in the United

States residing in just three states—California, Texas, and Florida (Ennis et al., 2011). A similar pattern exists among foreign-born Latinos. However, recent trends in migration patterns suggest that immigrants who once settled in large urban centers are now moving to suburban and rural communities with little history or experience with immigrants. In fact, over the past 10 years, states in the Midwest, Rocky Mountains, and Southeast have experienced more than a 200% increase in their immigrant population (Fortuny, Capps, Simms, & Chaudry, 2009).

Among Latinos, migration to the United States is predominately driven by economic reasons. Other reasons include political and social instability in their home country, war-related hardship, as well as family conflict and persecution related to sexual orientation (Organista, 2007). Among foreign-born Latinos in the United States in 2010, nearly three-quarters were legal immigrants (72%), while just over one-quarter (28%) were without documentation. Mexicans

(58%) and other Latin Americans (23%) account for the majority of the immigrant population without documentation in the United States (Passel & Cohn, 2011). Immigrants without legal documentation represent a particularly vulnerable population given the risks of deportation, exploitation, and restricted access to health and social services.

Consistent with other historically marginalized populations, Latino children and families are at disproportionate risk of experiencing poverty. As of 2010, more than one in four (26.6%) U.S. Latinos lived in poverty, an increase of more than 5% since 2007 (DeNavas-Walt, Proctor, & Smith, 2011). Among children in the United States, more Latino children are living in poverty than any other racial or ethnic group. In 2010, Latino children represented 37.3% of all poor children, while 30.5% were White and 26.6% were African American (Lopez & Velasco, 2011). This marked the first time in history that the largest proportion of poor children in the United States was not White.

Most Latinos in the United States speak Spanish (82%), which both maintains connections with their cultures of origin and facilitates connections between diverse Latino groups (Taylor, Lopez, Martinez, & Velasco, 2012). However, generation in the United States is associated with language use and is an important factor to consider when practicing with Latinos. For example, first generation or immigrant Latinos account for most of the Spanish-speakers in the United States. The second generation is largely bilingual, while the third or higher generations speak predominately English (Suro & Passel, 2003).

Although Latinos are a highly diverse group in terms of culture, they do share certain values as a result of their common history of Spanish colonization and influence from the Catholic Church. Particularly relevant to the context of practice with Latino families, *familismo* is considered one of the most important cultural values across Latino populations. *Familismo* involves a strong identification and attachment with nuclear and extended family, along with a deep sense of family commitment, involvement, and responsibility. The family offers emotional security and a sense of belonging to its members, and is the unit to which individuals turn for help first in stressful or difficult situations.

Many Latinos also share a common faith, with Catholicism being the predominant religion

among most Latinos (Sanchez & Jones, 2010). This faith is deeply rooted in Latino culture, and although it may be expressed differently and with various levels of participation in organized activities, the values and practices of the Catholic Church have important cultural significance for many Latinos, and can be an important source of strength. Representatives of the Church, such as priests or nuns, can serve as important cultural liaisons because they are seen as individuals who may be trusted and are not connected to government authorities.

Yet, although Latinos share a colonial past, a common language, and similarity of certain values, Latinos are a highly diverse group, representing more than 20 countries of origin with distinct cultural values, traditions, and worldviews. Latinos of Mexican (63%), Puerto Rican (9.2%), and Cuban (3.5%) origin represent the nation's three largest Hispanic groups. However, the population of several other groups has grown considerably since 2000. For example, Latinos of Salvadoran origin, the fourth largest group, grew by 152% between 2000 and 2010. Similarly, the Dominican population grew by 85%, Guatemalans by 180%, and Colombians by 93% (Ennis et al., 2011).

Added to this variation are differences in social class, education, age, gender, sexual orientation, acculturation, migration history, and other individual and family differences. As a result, it is important to remain aware that although one may recognize generalities about a particular culture, assumptions cannot be made about a particular individual or family. Rather, knowledge of a particular culture represents a hypothesis about a particular member of that culture, which needs to be individually assessed and explored, including when a client is a member of one's own cultural group. Ultimately, helping professionals need to be aware of cultural issues, while at the same time avoiding stereotypes and generalizations that take away from their clients' individuality.

Mariella, Her Two Children and Domestic Violence

Mariella is a 30-year-old Mexican woman with two children who has lived in the United States for 15 years. She is fluent in English. She was referred to a faith-based social services agency by a friend after the latest incident of domestic violence between herself and her fiancé, a 35-year-old American of Dominican descent

with whom she was living. Mariella and her fiancé have a daughter who is nine months old; Mariella's older daughter, six years old, is from a previous marriage. Mariella has undocumented immigration status.

Mariella followed her parents over the border in 1998 as a teenager and lived with them in New York City until she married at the age of 20 in 2003. Mariella dropped out of school at the age of 17; unable to understand English well enough to be able to follow what was going on, she saw no point in continuing school and instead went to work to help support her family—both in the United States, as well as some extended family still in Mexico—including one younger brother who lives in Mexico with a grandmother. Mariella has two younger sisters who were both born in the United States and are citizens. This has had a distinct effect on the trajectory of their lives; unlike Mariella, her U.S.-born siblings will be able to get financial aid for school, work legally, open bank accounts, obtain credit, and travel freely.

Mariella married Omar, a man 10 years older than she, also from Mexico and also undocumented; Omar worked in construction as a day laborer. Soon afterward, Mariella gave birth to her first child, Elena, also a U.S. citizen. In 2008 the economic crisis slowed the construction industry considerably and Omar, who had previously been able to work steadily and support his family, was having a harder and harder time finding work. His cousin, living in Houston, offered to help find work for him there, so Omar left Mariella and their daughter to go to Texas. He told Mariella he would send for them as soon as he was established. Afraid to travel because of immigration status, Omar never returned to New York and Mariella never visited him in Texas. By the time two years had passed, Mariella stopped hearing from him, and the monthly support payments he had been sending also evaporated. His cousin's phone number was disconnected and Mariella lost all contact with Omar—she has no idea where he is. Now a single mother, Mariella went back to work to support herself and her daughter. With a phony Social Security card and driver's license, she found waitressing work in a restaurant in East Harlem, an increasingly upscale Latino neighborhood in New York. It was here that Mariella met Roberto, an American of Dominican descent.

Roberto's parents emigrated from the Dominican Republic in the mid-1970s, settling

in the Washington Heights neighborhood of New York, where Roberto was born in 1978. Briefly married, Roberto is now divorced and living with his mother, a disabled diabetic, to help support her. His father is deceased. Roberto, an only child, does not have children and according to Mariella liked his freedom to pursue a lifestyle not dissimilar to the one enjoyed by many young adults in New York City—he dated casually, went to clubs, enjoyed sports events, and often had a beer out with friends. Roberto's parents obtained U.S. citizenship via the Immigration and Control Act (IRCA) in 1986, an amnesty program signed into law by then President Ronald Reagan. Roberto's mother receives Supplemental Security Income benefits and Medicaid and lives in an apartment provided by the New York City Housing Authority in Washington Heights, a neighborhood with a large population of Dominicans.

Roberto and Mariella began dating. According to Mariella, they shared a sense of living in two worlds—one bounded by culture and obligation to set aside personal desires in order to focus on caring for the family and the other reflective of the dominant culture in the United States, with an emphasis on personal freedom and individual well-being. Six months after they started dating Mariella became pregnant. Although the prospect of caring for a child made Roberto extremely nervous, there was never a question of whether or not to go ahead with the pregnancy; Roberto and Mariella became engaged. Mariella, still a fiancé and not divorced from her missing husband, gave birth to her second daughter Estrella in 2012.

Living in Roberto's mother's apartment with their newborn daughter, and Mariella's six-year-old daughter, Elena, from her previous marriage, soon became very stressful. Roberto's mother was often in pain and the infant's crying got on her nerves; the apartment was small and Elena, a very active child, had no room of her own in which to play. Mariella's parents, who strongly did not approve of her relationship with Roberto, had become estranged from her. Mariella expected Roberto to be more helpful around the house, but he felt that with the extra work that he was doing managing the restaurant on weekends and nights he was already doing enough to support them. She increasingly resented his going out with friends and leaving her at home with a cranky grandmother and two young children. She began to believe that he was

out flirting with other women, which only made her angrier. They began to fight often, and the fights soon became physical.

The violence between Mariella and Roberto escalated from name-calling—Roberto would often hurl ethnic slurs at Mariella—to throwing objects at one another to one night Roberto punching Mariella and shoving her down a flight of stairs. Mariella was bruised and had a black eye that neighbors noticed, but she refused to call the police—she was afraid that she would get arrested on account of her immigration status and be deported. Additionally, she feared that she would lose custody of her daughters because they were U.S. citizens and she was not. Mariella endured the situation as long as possible and then fled to her friend's house in Queens with her two young children. Her friend shared a tiny apartment with her boyfriend and had little room for Mariella and her children; she indicated that although Mariella could stay for a while, she wanted Mariella to get settled somewhere else. Mariella's friend arranged for her to meet with a social worker from the neighborhood social services agency—a faith-based organization affiliated with the Catholic Church.

ASSESSMENT

Assessment of Mariella's situation required attention to the following issues:

- Acculturation
- Help-seeking behavior
- Domestic violence
- Identity, values, and norms
- Immigration status
- Family strengths and resources
- Migration history

Mariella is an immigrant from Mexico; she has, however, resided continuously in the United States from the age of 15 years onward. Her adult identity, therefore, largely has been formed within the cultural context of the United States, and as a result she presents as an acculturated Latina woman who speaks English fluently. Process of migration frameworks are useful in placing individuals and families within the context of migration based on their personal circumstances and migration histories. At the same time, they allow social workers to identify expectable issues and problems along the

immigration trajectory (Drachman, 1992). For example, although Mariella has adopted many mannerisms that are mainstream American, she maintains a strong personal connection to the cultural values of *familismo* (family-centered values) common to many Latinos (Delgado, 2007). Mariella exemplifies that divided sense of self that many children of immigrants who have grown up in the United States, as well as second-generation immigrants, often describe as a feeling that they live in two worlds with competing norms, expectations, and roles. It is important for social workers to recognize and assess which factors are most important and/or relevant to their clients.

Immigration status has a profound effect on individuals and families. Social work practice with immigrants requires skill in assessing immigration status, knowledge of various immigration statuses, and of any possibilities for adjustment of status. Access to expert legal resources is critical because immigration laws are complex and change often. Immigrant clients must know and understand not only the implications of their immigration status, but have up-to-date information on options for addressing problems realistically. For example, an undocumented immigrant victim of domestic violence might be able to petition for immigration relief under the Violence Against Women Act (VAWA) of 2013. In Mariella's case, she falls under the category of being the abused parent of a U.S. citizen. If successful, such relief would give Mariella work authorization and access to public benefits, and would help ensure that she does not have to stay in an abusive relationship because she is afraid of being deported, or because she does not have any other viable choices to support herself.

TREATMENT INTERVENTION AND GOALS

Individual and family counseling services are being provided to Mariella and her children and are based on the following treatment interventions and goals:

- Crisis intervention and advocacy to address domestic violence
- Legal services for immigration status issues
- Formal and informal support networks
- Basic needs for shelter, food, clothing
- Supportive counseling

- Afterschool, recreational, and out-of-home care options for children.

The goals of this intervention are:

- Ensure safety and well-being of Mariella and her children.
- Provide short-term shelter, followed by transitional and permanent housing.
- Explore options for adjustment of immigration status.
- Expand family support networks and resources.
- Empower Mariella to explore future personal and family goals through education and vocational training.
- Provide children with safe care programs or options when parent is working.
- Engage Mariella in culturally appropriate supportive counseling.

Highly distrustful of any organization that might have connections to the “government,” Mariella only agreed to meet with the social worker at the agency because it was affiliated with a religious institution that for personal and cultural reasons Mariella identified as “safe”. Such “cultural liaisons,” whether religious institutions, mutual aid associations, or ethnic leaders are important partners for social workers who practice in immigrant communities to facilitate engagement and develop trust with at-risk populations (Earner, 2007). In this case, the faith-based organization contracted with attorneys who spoke Spanish to provide pro bono legal services to immigrants; astonishingly they had an attorney who was also a nun.

The immediate need for Mariella is shelter for herself and her children, Immigration status does not prevent battered immigrant women from being able to access crisis shelters and an array of domestic violence services; however, the long-term effects of remaining an undocumented person will keep Mariella and her children at risk for deportation, living on the margins of society, and possibly staying in unsafe situations for lack of choice. Mariella’s legal options for addressing immigration status are limited; she may be able to petition for immigration status adjustment (making her status legal but not necessarily permanent) through relief offered by either a U visa

or under VAWA (Immigrant Legal Resource Center, 2012). Even if immigration status cannot be adjusted, it is important to advise parents who are undocumented on steps that they can take to protect their family relationships should the parent(s) be subject to deportation. This includes giving power of attorney rights to extended family or friends, setting up legal guardianships and health care proxy forms to protect and provide for minor children (Ayon, Aisenberg, & Cimino, 2013).

Lastly Mariella is being offered culturally appropriate supportive counseling to address a number of personal issues including re-engagement with her family of origin, her experience of domestic violence (Randell, Bledsoe, Shroff, & Pierce, 2012), expanding her informal and formal support network (Xu & Brabeck, 2012), as well as exploring educational and vocational opportunities that can help her move toward establishing an independent life for herself and her children (Organista, 2009).

CONCLUSION

The case of Mariella, an undocumented immigrant from Mexico living in the United States for 15 years, her two U.S.-born children, and her experience of domestic violence, illustrates the complex and conflicting issues that affect Latino clients in need of social work services. Assessment incorporates a person-in-environment perspective to consider multiple problem levels and solutions that are reflective of Latino-relevant and culturally competent knowledge about this population—its strengths, assets, stressors, and barriers to services. A stages-of-migration framework can also be a helpful paradigm to understand the processes of individual acculturation, adjustment, and family functioning for immigrant populations. Critical to intervention is knowing how immigration status affects individuals and families, especially in mixed-status families. For battered immigrant women, access to domestic violence shelters and services is often compromised by factors such as language access, cultural issues, and confusion about eligibility. Narrative and supportive therapeutic techniques include a focus on family strengths, cultural assets, resources, and resilience around the struggle to negotiate identity as a Latino immigrant in America.

129 Social Work Practice with African Americans

Sadye M. L. Logan

AN OVERVIEW AND PROFILE OF THE AFRICAN AMERICAN COMMUNITY

Given the diverse values, educational levels, incomes, lifestyles, and perceptions found within the African American community, it is extremely challenging, if not impossible, to write a definitive article that captures clinical social work practice with this ethnic group (McAdoo, 2007; Robinson, 2010). It is, therefore, important for readers using this information to approach this chapter with the understanding that it contains a generic or holistic conceptualization with applications to a diverse group of people and will require modifications in order to be applied effectively.

Within the above context, it is important also to acknowledge that African Americans constitute one of the largest ethnic groups of color in the United States of America, with a population numbering 13% of the total U.S. population or 33.8 million people (McKinnon, 2003). The vast majority of this amazingly resilient and diverse group of people came to the United States as enslaved Africans and remained in bondage for over 200 years. It is generally believed that the majority, if not all, of the enslaved Africans were taken from the Western parts of the African continent (Gutman, 1975). The process of enslavement is believed to have resulted in what is defined today as posttraumatic stress disorder (PTSD), which has produced an intergenerational impact on the emotional health of African Americans (Logan, Denby, & Gibson, 2007; Logan, 2001; Waites, 2008). This process, which included institutional racism, discrimination, and oppression has produced a schizophrenic type of existence for the enslaved Africans and their descendants.

Although the majority of the Africans remained enslaved, some were able to purchase their freedom and remain free. Others were forced back into slavery; many were fathered by their White owners and looked White; and some of those who looked like their White fathers prospered and were in some instances also owners of slaves (Johnson & Roark, 1984). The majority of the enslaved Africans lived in the Southern parts of the United States, where more than 50% of the African American population still reside today (McKinnon, 2003). A significant proportion of this population consists of female-headed households with children under 18 years of age. Many of these female-headed families live below the poverty level (McKinnon, 2003).

Social work practice will most likely occur with those African Americans experiencing the impact of PTSD, poverty, mental illness, and other forms of problems-in-living. Social work practice with these families and children, and with adult African American clients, will not only require that practitioners be culturally responsive, but that they embrace an integrated, holistic, and ethnically sensitive approach. Such an approach reflects a strengths-based bio-psychosocial-spiritual orientation to helping. Practice experience has shown that a multicontextual approach, embracing the whole client, is necessary in order to address the multifaceted concerns most African Americans persons will bring to the helping encounter (Boyd-Franklin, 1989; Logan, Freeman, & McRoy, 1990; Logan & Freeman, 2004). These multicontextual issues (see Table 129.1) serve as a framework for guiding the practice process. The inclusion of an ethnic-sensitive (Devore & Schlesinger, 1998), strengths-based (Saleebey, 2012), spiritually

TABLE 129.1 Multicontextual Framework

oriented (Logan & Freeman, 2004) perspective expands the traditional bio-psychosocial orientation, thereby being more responsive to the needs and experiences of African American clients. The ethnic-sensitive, strengths-based, spirituality-oriented approach is based on the following concepts: African Centeredness, Spirituality, Strengths, and Empowerment.

African Centeredness. This perspective acknowledges African culture, expression, values, beliefs, and instructions. It underscores interconnectedness as a way of being in the world that suggests wholeness and balance. Ultimately, it affirms a conscious as well as an unconscious connection of people of African descent with their past and present.

Spirituality. This orientation is concerned with the belief in the wholeness of what it means to be human, a belief that relates to a person's search for a sense of meaning and a morally fulfilling relationship with the world in which they live.

Strengths Perspective. This perspective builds on the belief that within every human being exists an inner or inherent energy or life force that is available to guide and support us in living our lives in productive, fulfilling ways.

Empowerment. This perspective serves as a treatment process and a treatment goal. It emphasizes clients' abilities and desires to take control of their lives and to view themselves positively and competently. Within this broad context, empowerment incorporates these themes: A developmental process, a psychological state, and liberation from oppression.

CLINICAL ISSUES

The primary clinical issue for working effectively with African American clients is the social worker's willingness to embrace a paradigm shift that incorporates the worldviews of African Americans. Worldviews are typically defined as one's perceptions of oneself in relation to other people, nature, objects, and institutions. Scholars on black family life have conceptualized worldviews of African Americans as African centered and strengths based (See Table 129.2). This perspective is based on the values and ethos of the people of Africa and the people of African descent

(Turner, 1996). However, it is important to note that Black families and children vary in the extent to which they exemplify Africentric values, attitudes, beliefs, and characteristics. It has been shown that this information can be useful to practitioners in the assessment and intervention phases of their work.

PRACTICE APPROACHES AND INTERVENTION TECHNIQUES

The search for effective practice approaches and intervention strategies for working with clients of African descent has been ongoing. The first definitive textbooks addressing this subject were published in the late 1980s (Boyd-Franklin, 1989) and the early 1990s. These authors proposed a culturally specific framework or perspective (Logan, Freeman, & McRoy, 1990). This perspective expanded the traditional psychosocial perspective and embodies a bio-psychosocial-spiritual orientation. Emphasis is placed on the cultural and spiritual, which includes cultural identity, cultural explanation of illness and health, natural support systems, worship or faith-based centers and institutions, ethnic community and social organizations, and cultural factors between the client and worker (Lum, 2003). Within this context, an Africentric and strengths-based orientation is proposed. As indicated earlier, this orientation not only includes the history, culture, and worldviews of African Americans, but also provides a multidimensional or multilevel framework for practice, assessment, and intervention. Emergent and traditional practice approaches support this orientation. These include:

- Solution-focused brief therapy
- Solution oriented therapy
- Gender sensitive therapy
- Cognitive behavioral therapy
- Psycho-educational family therapy
- Task-centered treatment
- Structural family therapy
- Collaborative language systems approaches
- Narrative therapy
- Empowerment and strengths perspectives
- Crisis treatment (Walsh, 2009).

Given the range of practice approaches for working with African American clients, it is important to note that the practice interventions may overlap. It is, therefore, important to

realize that despite the similarities, these strategies may have very different purposes (Walsh, 2009). In addition to the more generic strategies identified in the various practice approaches, the African-centered genogram, the cultural eco-map, cognitive restructuring, culturally relevant readings, and family albums are more specific practice strategies for working with African American clients (Logan and Freeman, 2004).

The treatment plan flows naturally from the assessment process (see Table 129.3) and is based on a collaborative partnership (Lipchick, 2011). In this regard, the social worker should:

1. Identify and understand the cultural identity of African American families and their unique history of enslavement and the continuing impact of living in an environment of oppression, racism, and gross inequality.
2. Assume the existence of strengths for the family, search for exceptions, and support the family's strengths through the inclusion of significant others and through affirmations and an emphasis on solutions.
3. Walk and work side-by-side with client systems as partners (Logan & Freeman, 2004).

As the social worker and the African American client work toward a clear definition of presenting concerns, the identification of specific, concrete, achievable treatment goals, treatment strategies selected from the diverse range of practice approaches may reflect micro, meso, and/or macro levels of intervention. Microlevel interventions include empowerment, crisis intervention, family treatment, solution finding, existentialism, and competitive restructuring. Mesolevel interventions involve the expanded family, fictive kin, places of worship, schools, and various community support systems. Macrolevel interventions address policy, planning, community organizing, policy, advocacy, and administration.

The treatment plan, based on the identified needs of the client systems and culturally diverse treatment strategies, includes the treatment goals, desired outcome, expected change, and agreement or contracting between all parties involved in the change process. As indicated earlier, assessment and treatment tools may consist of the following:

1. *The cultural eco-map.* The cultural eco-map highlights the family as a unit and focuses

on both the immediate or the African American ethnic group environment and larger extended environments beyond the individual or family's environment (Logan & Freeman, 2004; Raider & Pauline-Morand, 1998). In focusing on these three broad aspects of the map, the social worker may be guided by questions such as those related to:

- a. The individual or family unit basic needs, food and shelter, preventive health care and good medical resources, satisfactory work experiences, and unit's ability to agree on and fulfill functional roles while meeting individual needs
 - b. The nature and quality of African Americans ethnic group environment (Is the neighborhood safe and reasonably pleasant to live in?), quality of family ties, intergenerational issues, and membership in social clubs.
 - c. The nature and quality of relationship to the broader extended environment with respect to the educational and vocational enrichment, availability and assessment of needed resources, meaningful connections with other ethnic groups, feelings of inclusiveness, and the ability to deal with an oppressive and racist environment.
2. *The African-centered genogram* is based on two major assumptions about family relationships. These assumptions address kinship, including fictive kinds (those not related by blood or marriage) and functional relationships (Watts-Jones, 1997 p. 377).
 - a. In African American families, kinship must be regarded and understood as it is constructed by the ethnic or racial group of the particular family, and
 - b. Functional relationships are as important to represent in a genogram as biological relationships. Functional relationships are based on performances and interactions. For example, a biological grandmother may function as a functional role mother to her grandchild.

Together these culturally sensitive tools serve as useful instruments not only in assessing the strengths and presenting concerns of the African American client, but also provide new insight and information about the family's cultural heritage, cultural and ethnic identity, intergenerational patterns and ways of being in the world.

ASSESSMENT AND TREATMENT PLANS

In working with African American clients, a culturally responsive social worker will seek to understand and apply the African-centered approach to the three phases of process (See Table 129.3). In this process, Lum (2003) suggests that the social worker not only reinterprets and reconceptualizes psychosocial factors as socio-environmental impacts and psycho individual reactions, but also acknowledges cultural strengths that include the cultural and the spiritual. Additionally, the following factors may serve to strengthen the social assessment skills of the social worker:

- A worker should think about clients in terms of group characteristics and group strengths as well as clinical pathology and agency protocols of problem resolution.
- A worker should examine group strengths as they are understood by community members themselves, and should view the client as a

potential teacher to the worker as well as the recipient of services.

- A worker should openly use indigenous sources of help, which may mean granting credence to lay practitioners from ethnic communities.
- A worker should have a systematic learning style and a supportive agency environment that recognize culturally distinctive modes of behavior and respond to them appropriately (Green 1995, pp. 80–81).

EVIDENCE OF PRACTICE EFFECTIVENESS

Evidence of practice is viewed by some as a movement within the social work profession (Walsh, 2009). Vandiver (2002) and others view it as a process utilizing a variety of sources in the professional literature to select interventions that are most likely to promote client change. It is suggested that the evidence-based practitioner should follow a three-tiered approach to selecting interventions to use with clients:

TABLE 129.3 An African-Centered Framework

Three Broad Areas of Work	Related Tasks
Assessment includes:	Individual, group, family and community history Religious/spiritual heritage Migration history Impact of racism and other forms of oppression Economic issues Cultural issues Environmental issues Self-image/ethnic identity issues
Intervention focuses on:	What the client system wants to see changed or different Empowerment: Individual, family, community Strengths, self help, positive change, and collaborative partnership Advocacy at the community level Schools and social service agencies: Responsiveness to the needs of families and communities Action-oriented strategies
Evaluation includes:	Concrete measurable culturally relevant goals agreed on by the client system African-centered diagnoses (incorporates client's ideas about illness and healing) Ongoing goal and task reviews

Source: Logan, S., & Freeman, E. (2004). An analysis, integration and application of Africentric and strengths approaches to Black families and communities. In E. Freeman and S. Logan, Eds. *Reconceptualizing the strengths and common heritage of Black families* (pp. 25–38).

1. The first tier of evidence-based practice is based on established practice guidelines or recommendations that are based on research findings.
2. The second tier of guidelines is based on the expert consensus of clinicians with expertise in a certain area of practice.
3. The third tier of evidence-based practice is based on self directed practice that is immediately available to the social worker such as experience, journal reports, and peer and supervisory input.

Despite the intention within the social work profession to use treatment strategies that have been shown to be effective, efforts to identify evidence-based practice models have been controversial (Walsh, 2009). Practice effectiveness with African American clients clusters around the third tier of evidence-based practice. However, research has consistently shown that structural family treatment is more effective than other clinical modalities with African American clients (Santisteban, Coatsworth, Perez-Vidal, Mitrani, Jean-Gilles, & Szapocznik, 1997). The client populations have included families with children and adolescents with substance problems and other behavioral issues and concerns.

Although structural family therapy provides a useful perspective for evidence-based practice with African American clients, a major concern relates to an inherent bias about what constitutes an "appropriate" family structure. This therapy was based on its founder's, Salvador Minuchin's, belief that many multi-problem families lacked strong executive authority and rules. This executive authority was relegated to the paternal figure or the father in the family who was viewed as the head of the household. This notion was challenged by a feminist critique in the 1980s and continues to be a precautionary point of reference for social workers. Given the increasing diversity in family forms worldwide, it is imperative that social work practitioners not hold specific assumptions about what constitutes family structures prior to a comprehensive assessment process.

CONCLUSION

Effective social work practice with African Americans is based on knowledge and understanding of the history and cultures of the

African American people. Recommended practice approaches and strategies incorporate aspects of traditional practice approaches and emergent approaches within an African-centered framework. Emphasis is placed on a collaborative, spiritually oriented empowerment perspective.

130 The Culturagram

Elaine P. Congress

INTRODUCTION

The increasing diversity of American society has been well documented in both professional literature and the media. Immigrants are entering the United States in record numbers; between 2000 and 2007, 10.3 million immigrants arrived, the highest number ever recorded in U.S. history within an eight-year period (U.S. Bureau of the Census, 2007). Almost 40 million immigrants (naturalized citizens, “green card” holders, undocumented people, and refugees) now live in the United States, accounting for 13% of the total U.S. population (U.S., Census Bureau, 2012.) Although there are immigrants in every state, most live in California, New York, Texas, and Florida. It is estimated that one out of three immigrants are undocumented, while more than half of the immigrants who entered the country since 2000 are undocumented (U.S. Bureau

of the Census, 2007). One in eight U.S. residents are immigrants, and in large metropolitan areas such as New York City, the majority of the population already originates from countries in Asia, South and Central America, and the Caribbean (New York City Department of City Planning, 2004).

Since the profession’s beginning, particularly its work in settlement houses, social workers have always sought to advance the well-being of immigrant populations. The National Association of Social Work (NASW) code of ethics stresses the importance of avoiding discrimination based on race, ethnicity, national origin, and immigration status. Social workers are also advised to pursue culturally competent practices (NASW, 2008).

Not only has there been a growing literature in social work practice and education on cultural competency, but professional literature on immigrants and immigration also has increased

dramatically in the past decade. A review of social work abstracts for the past 10 years on immigrants in the United States yielded 231 articles, 130 of which had been written in the past five years. Most articles focused on specific issues in working with various immigrant populations, including Latino populations (Arbona, Olvera, Rodriguez et al., 2010; Parsai, Nieri, & Villar, 2010; Shobe, Coffman, & Dmochowski, 2009), South Asians (Bhattacharya, 2004), Chinese elders (Kang, Boyas, & Salehin, 2012), Korean immigrants (Kang, Basham, & Kim, 2013), African immigrants (Wamwara-Mbugua & Cornwell, 2010), and Arab immigrants (Jamil & Ventimiglia, 2010). A number of articles have looked at challenges for older immigrants (Martin, 2009; Lee & Yoon, 2011; and Lee & Chan, 2009), while others concentrate on child rearing and education issues (Fawley-King, 2010; Lim, Yeh, Liang, Lau, & McCabe, 2009; Kim & Chao, 2009). Few articles considered immigration issues in general.

BACKGROUND OF CULTURAGRAM

The culturagram, a family assessment instrument, grew out of the recognition that families are becoming increasingly culturally diverse and social workers must be able to understand cultural differences between and within families. When attempting to understand culturally diverse families, it is important to assess the family within a cultural context. Assessing a family only in terms of a specific cultural identity, however, may lead to overgeneralization and stereotyping (Congress & Kung, 2013). A Puerto Rican family in which all members are American citizens and have lived in the United States for 20 years is very different from an undocumented Mexican family that emigrated last month. Yet both families are considered Hispanic/Latino. Even within the same family group, each member has had a different immigration and acculturation experience, given that family members often immigrate at different times. Furthermore, family members who regularly work or attend school in a larger, more diverse community may be more acculturated than those who stay at home.

Although the eco-map (Hartman, 1995) and genogram (see Chapter 53) are useful tools in assessing the family, neither emphasizes the important role of culture in understanding the

family. The culturagram was developed to help in understanding the cultural background of culture in families (Congress, 1994, 1997; Congress & Kung, 2013). This tool has been applied to work with people of color (Lum, 2004), battered women (Congress & Brownell, 2007), children (Congress, 2001), older people (Brownell & Fenley, 2009), families in crisis (Congress, 2000), Mexican families (Congress, 2004a), Latino and Asian families (Congress & Kung, 2013), immigrant families with health problems (Congress, 2004b; Congress, 2013), and in family development theory (Congress, 2008).

Creation of the Culturagram

The culturagram represents an attempt to individualize culturally diverse families (Congress & Kung, 2013). Completing a culturagram on a family can help a clinician develop a better understanding of the family. Revised in 2007, the culturagram (see Figure 130.1) examines the following areas:

- Reasons for relocation
- Legal status
- Time in community
- Language spoken at home and in the community
- Health beliefs and access to health care
- Impact of trauma and crisis events
- Contact with cultural and religious institutions, holidays, food, and clothing
- Oppression, discrimination, bias, and racism
- Values about education and work
- Values about family—structure, power, myths, and rules.

Reasons for relocating vary among families. In his classic article on why people migrate Lee (1966) identifies various push and pull factors. While push factors encourage people to migrate, pull factors explain what attracts them to another location. Some of the main push factors are unemployment, natural disasters (famine, drought, flooding), man-made traumas (war, violence, torture, forced labor), and lack of medical care. Pull factors include job opportunities, better education, greater security, and political freedom.

Many families come because of greater economic opportunities (pull factor) in the United States, while refugees and asylum seekers primarily relocate because of political and religious discrimination in their country of origin (push

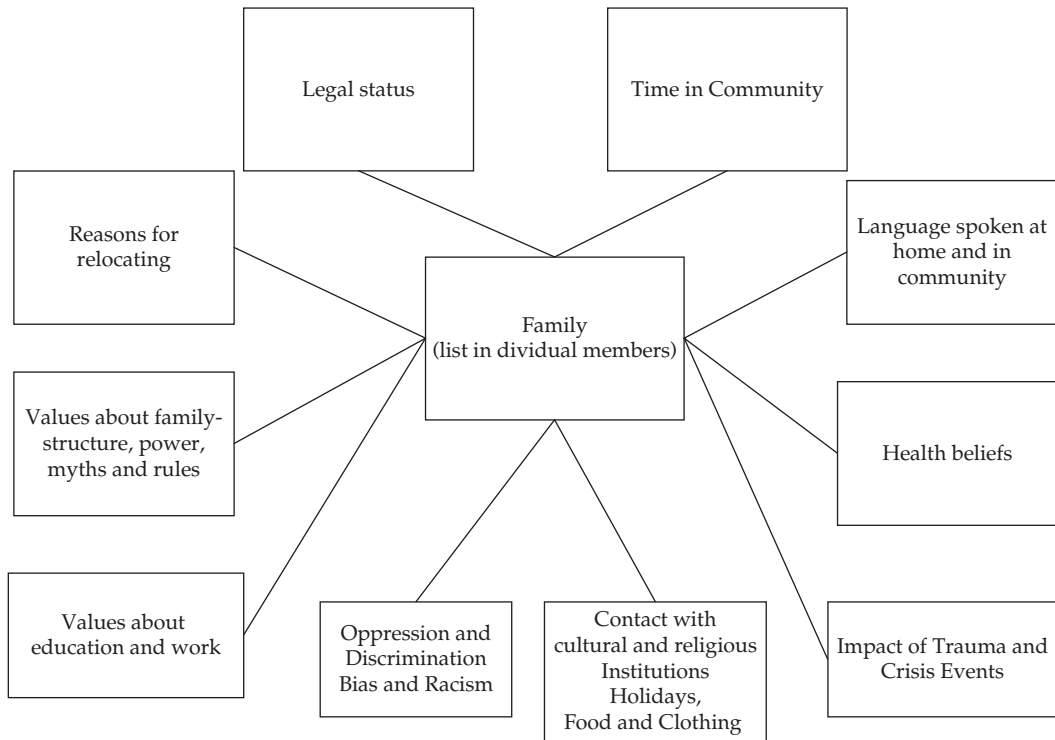

Figure 130.1 Culturagram.

factor). For some families, it is possible to return home again, and they often travel back and forth for holidays and special occasions. Others, especially undocumented people, know they can never go home again. Often the main reason why families migrate to a particular location is because a family member or friend has preceded them.

Immigrants can have various legal statuses, including U.S. naturalized citizens, legal permanent residents (green card holders), undocumented, refugees, or asylum seekers (Chang Mui, 2009). The legal status of a family may have an effect on both individuals and the family as a whole. If a family is undocumented and fears deportation, members may become secretive and socially isolated. Latency-age children and adolescents may be discouraged from developing peer relationships because of the fears of others knowing their immigration secret.

The length of time in the community may differ among individual family members. Usually, family members who have arrived earlier are more assimilated than other members. A current phenomenon involves mothers first immigrating to the United States and then sending for their children. These circumstances can certainly impact individual and family

development. A young infant left in the care of relatives in the home country may have difficulties developing trust because of the lack of continuity in parenting during this crucial early period. Also, the family with young children that is disrupted when the mother migrates to America may face challenges in reuniting as a family after a long separation. Another key factor is that family members are a variety of different ages at the time they relocate. Because of attending American schools and developing peer relationships, children are often more quickly assimilated than their parents. This may lead to conflictual role reversals in which children assume leadership roles.

Language is the mechanism by which families communicate with one another. Often, immigrant families use their native language at home, but begin to use English in contacts with people in the outside community. Children sometimes may prefer English because they see knowledge of this language as most helpful for survival in their newly adopted country. This may lead to conflict in families. A truly literal communication problem may develop when parents speak no English and children speak their original native tongue only minimally.

Families from different cultures have varying beliefs about health, disease, and treatment (Congress & Lyons, 1992; Congress, 2004b; Congress, 2013). Often, health issues impact on culturally diverse families, as for example when the primary wage earner is seriously injured and is no longer able to work, a family member has HIV/AIDS, or a child has a chronic health condition such as asthma or diabetes. Also, mental health problems may have a particular stigma, which can impact families negatively (Michultka, 2009). Refugees who have experienced torture, trauma, and loss in their countries of origin may suffer from posttraumatic stress disorders (Congress, 2012). Families from different cultures may encounter barriers in accessing medical treatment or may prefer alternative resources for diagnosing and treating physical and mental health conditions (Congress, 2013). Both legal and undocumented immigrants often lack health insurance and do not have financial resources to pay for needed health care (Smith, 2009). Many immigrants may use health care methods other than traditional Western European medical care involving diagnosis, pharmacology, X-rays, and surgery (Congress & Lyons, 1992; Congress, 2004b; Smith, 2009). Social workers who want to understand immigrant families must study the various health beliefs, health conditions, and access to health care characteristic of individual family members.

Families can encounter developmental crises as well as “bolts from the blue” crises (Congress, 2004a; Congress, 2008). Developmental crises may occur when a family moves from one life stage to another. Stages in the life cycle for culturally diverse families may be quite different from those for traditional middle-class families. For example, for many culturally diverse families, the “launching children” stage may not occur at all, as single and even married children may continue to live in close proximity to the parents. If separation is forced, this developmental crisis might be especially traumatic.

Families also deal with “bolts from the blue” crises in different ways. A family’s reaction to crisis events is often related to its cultural values. For example, a father’s accident and subsequent inability to work may be especially traumatic for an immigrant family in which a father providing for his family is an important family value. Whereas rape is certainly traumatic for any family, the rape of a teenage girl may be especially traumatic for a family who values virginity before marriage.

Immigrant individuals and families may have experienced traumatic events in their country of origin or during transit to the United States. Immigrant families often suffer from poverty and discrimination as they try to access needed educational, vocational, and social services. The current policies regarding undocumented immigrants certainly lead to continuing traumatic experiences for immigrant families. In understanding the impact of traumatic events on immigrant families it is best to make a longitudinal assessment that involves a study of individual members’ situations before migrating, in transit, as well as currently (Drachman & Pine, 2004).

Contact with cultural institutions often provides support to immigrant families. Individual family members may use cultural institutions differently. For example, a father may belong to a social club, the mother may attend a church where her native language is spoken, and adolescent children may refuse to participate in either because they wish to become more Americanized. Religion may provide a great deal of support to culturally diverse families, and the social worker will want to explore family members’ contact with formal religious institutions.

Each family celebrates particular holidays and special events. Some events mark transitions from one developmental stage to another—for example, a christening, a bar or bat mitzvah, a wedding, or a funeral. It is important for the social worker to learn the cultural significance of important holidays for the family, because these are indicative of what families see as major transition points within their families. These holidays are often associated with culture-specific foods or clothing.

Many immigrants have experienced oppression in their native countries, which has led to their departure from their homelands and immigration to the United States. Some immigrants may have been the majority population in their home country and thus never experienced prejudice until their arrival in the United States. Here, they may be the victim of discrimination and racism based on language or cultural and racial differences. The current U.S. policies on undocumented immigrants further serve to separate and discriminate this newcomer population from other Americans. After review of previous versions of the culturagram and feedback about the instrument, this area was added to the culturagram in 2007 because it was important to understanding the immigrant family experience.

All families have differing values about work and education, and culture is an important influence on such values. Social workers must explore what these values are in order to understand the family. Economic and social differences among family members between the country of origin and after immigration to the United States can affect immigrant families. For example, employment in a low-status position may be very denigrating to a male breadwinner. It may be especially traumatic for an immigrant family when the father cannot find work or only work of a menial nature. This frequently happens to undocumented immigrants who may have difficulties securing "on the books" positions.

Cultural differences in regard to education may emerge when American latency-age children attend large schools away from their communities and begin to develop peer relationships apart from their families. For culturally diverse families who come from backgrounds in which education has been minimal and localized, and where young children even were required to work and care for younger siblings, the American school system's focus on individual academic achievement and peer relationships may seem strange. Furthermore, immigrant children who bring a history of individual or family oppression may feel very isolated and lonely in their new environments.

Sometimes, immigrant families may experience a conflict in their own values about education. An example of this occurred when an adolescent son was accepted with a full scholarship to a prestigious university far away from home. Though the family had always believed in the importance of education, the parents believed that the family needed to stay together and they did not want to have their only child leave home, even to pursue education.

Each family has its unique structure, its beliefs about power relationships, myths, and rules. Some of these may be unique to the cultural background of the family. The social worker needs to explore what values are specific to a particular immigrant family and also understand them in the context of the family's cultural background. Culturally diverse families sometimes have differing beliefs about male-female relationships, especially within marriage. Immigrant families may be a source of conflict in American society with its more egalitarian gender relationships. This can result in an increase in domestic violence among culturally diverse families. Also,

child-rearing practices especially in regard to discipline can differ in culturally diverse families and result in increased reporting to Child Protective Services.

The following vignette illustrates how the culturagram can be used to better understand a family and its unique cultural background.

Statement of Problem

Mrs. Carmen Perez, 35 years old, contacted the Family Service Agency in her community because she was having increasing conflicts with her 14-year-old son, Juan, who had begun to cut school and stay out late at night. The past Christmas holidays had been especially difficult because Juan had disappeared for the whole New Year's weekend. She also reported that she had a 10-year-old daughter Maria who was "an angel." Maria was very quiet, never wanted to go out with friends, and preferred to stay at home helping her mother with household chores. Mrs. Perez indicated the source of much conflict was that Juan believed he did not have to respect Pablo, as the latter was not his real father. Juan complained that his mother and stepfather were "dumb" because they did not speak English. He felt it was very important to learn English as soon as possible because at school several students had made fun of his accent. He felt his parents did not understand how difficult his school experience was, as he believed that his teachers favored lighter-skinned Latinos. Juan had much darker skin than his mother, his stepfather, or his half-sister, Maria.

History

When she was 20 years old, Mrs. Perez had moved to the United States from Puerto Rico with her first husband, Juan Sr., because they were very poor in Puerto Rico and had heard there were better job opportunities here. Juan Sr. had died in an automobile accident on a visit back to Puerto Rico when Juan Jr. was two years old. Shortly afterward, she met Pablo, who had come to New York from Mexico to visit a terminally ill relative. After she became pregnant with Maria, they began to live together. Pablo indicated that he was very fearful of returning to Mexico, because several people in his village had been killed in political conflicts. Because Pablo was undocumented, he had been able to find only occasional day work. He was embarrassed

that Carmen had been forced to apply for food stamps. As a home care worker, Carmen was paid only minimum wage. She was very close to her mother, who lived with the family. Her mother had taken her to a spiritualist to help her with her family problems before she had come to the neighborhood agency to ask for help. Pablo has no relatives in New York, but he has several friends at the social club in his neighborhood.

Discussion

After completing the culturagram (see Figure 130.2), the social worker was better able to understand the Perez family, assess their needs, and begin to plan for treatment. For example, she noted that Pablo’s undocumented status was a source of continual stress in this family. She referred him to a free legal service that provided help for undocumented people in securing legal status. The social worker also recognized that there had been much conflict within the family because of Juan’s behavior. She had concern that Maria might have unrecognized problems. Finally, she was keenly aware of family conflicts between Pablo and Juan. To help the family work out its conflicts, the social worker referred them

to a family therapist who was culturally sensitive and had experience with intergenerational conflicts in immigrant families.

FUTURE DIRECTIONS

The culturagram has been seen as an essential tool in helping social workers work more effectively with families from many different cultures. Not only does it help the social worker achieve greater understanding of the culture of a family, it can also point the way toward future treatment. This case example demonstrates how the culturagram can be useful in arriving at decisions about treatment planning and intervention. While using the culturagram the practitioner is required to look at the family in the here and now. Sometimes it is helpful, however, to construct the culturagram at different points in time, first at the beginning of intervention and then at a future point. A retrospective approach also can be useful. To truly understand immigrant families, learning about an immigrant’s history is important. For example, the social worker can ask about the immigrants’ experience in their country of origin and in transit. Often, a developmental approach that looks

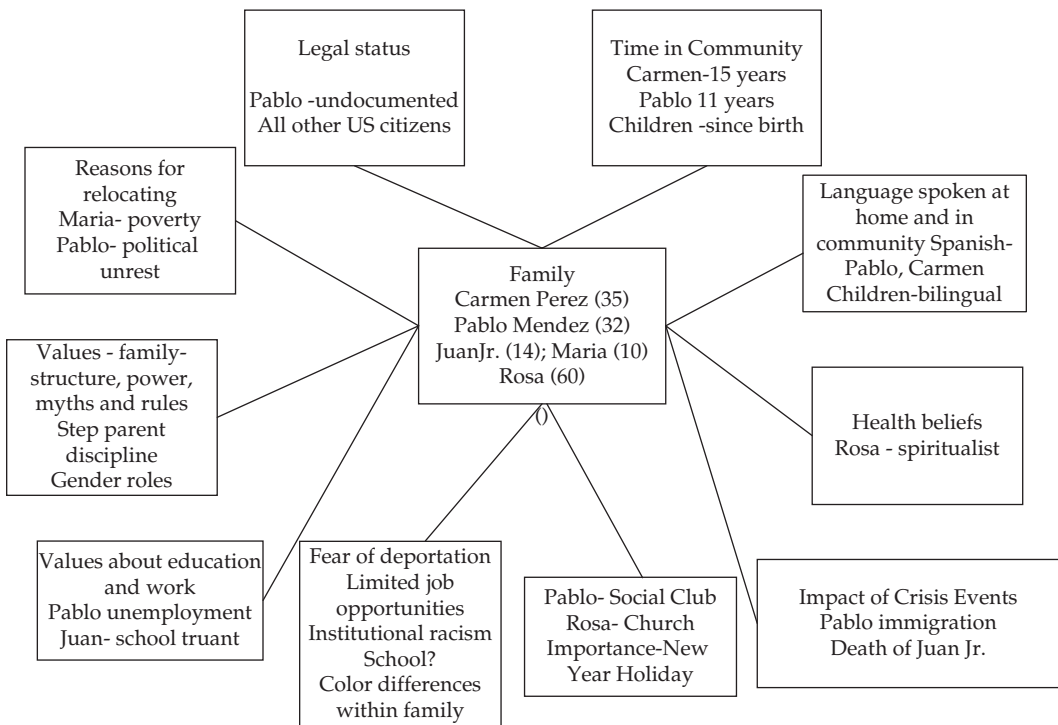

Figure 130.2 Completed Culturagram.

at three stages of immigration (pre-migration, transit, and current situation) is helpful in working with immigrants (Drachman & Pine, 2004). For example, refugees may have had particularly traumatic experiences in their country of origin, and undocumented immigrants may have experienced trauma during the transit period, all of which may affect their current psychological well-being in the United States.

Current practice looks to evidence that specific interventions are effective. Students and practitioners have used the culturagram in their professional practice with families and reported that it is helpful in engaging families in a non-threatening way. In the use of the culturagram culture is viewed through a multidimensional lens, rather than as a monolithic entity. Initial evaluation of the culturagram has been positive, and there are plans to assess further its effectiveness in promoting culturally competent practice.

With the increased number of immigrants in the United States, there will be greater demand for culturally competent practice with immigrant clients and families. Social workers will need to study what methods and models are the most effective. The culturagram emerges as a useful method to better understand and plan interventions with immigrant families.

131 Social Work Practice with Persons Living with HIV/AIDS

Neil Able

OVERVIEW

First recognized as a threat to human health and well-being in 1981, HIV/AIDS has captured the attention and galvanized the actions of the global community ever since. As the issue exploded from a few isolated cases to a full-scale pandemic, responses ranged from fear to grief to rage, from denial and repression to personal and collective action. The inescapable associations with sex and death have since progressed from early allusions to the illness as a “great equalizer” to an international case study in the consequences of inequality. From pressing a redefinition of what it means to be “family” to destabilizing national economies and threatening global security, HIV/AIDS has altered the landscape in unimaginable ways, and provided a broad spectrum of challenges and opportunities for social work practice.

In this chapter, I will overview key concepts and issues, aiming to familiarize social workers with the nature and progression of the illness, and with recommendations for professional response in prevention, intervention, and care. Steady advances in medical treatment have transformed the possibilities for a long and fulfilling life, while social and economic forces continue to pose barriers to access for all. If ever a topic cried out for career-long continuing education, this is it.

History of the Pandemic

Beginning with a few unexplained cases of young men in the United States with rapidly progressing, little-known cancers and lung infections, the Centers for Disease Control and Prevention (CDC) pooled a wide range of resources, and in

a politically contentious process (Shilts, 1987), scientists ultimately identified the *human immunodeficiency virus* (HIV) as the common culprit (Fan, Conner, & Villarreal, 2011). A key characteristic of the virus was rapid compromise of the immune system, dramatically impacting the ability of previously healthy individuals to fight off disease. Because the first cases were also associated with the sexual orientation of the patients, the CDC initially identified the condition as GRID (gay-related immune deficiency), a term which later evolved into the less pejorative *acquired immune-deficiency syndrome* (AIDS). As we will see, early wavering on naming this condition was a precursor of the shaming, blaming, and sometimes irrational fear associated with a condition whose origins were unknown, and widely attributed to everything from a racially inspired conspiracy to wipe out blacks (Ross, Essien, & Torres, 2006) to divine retribution for immoral behavior. Best scientific evidence today indicates that HIV mutated in equatorial Africans who while hunting became exposed to the blood of chimpanzees infected with simian immune-deficiency syndrome (SIDS) (Gao et al., 1999).

Epidemiology

The science of understanding disease prevalence is central to identifying the populations and regions most impacted. Epidemiology builds knowledge of factors correlated with disease, seeks to determine how it is spread by and to whom, and anticipates where it is likely to expand. This information can guide prevention efforts and help prioritize persons and locations most in need of resources and treatment. *Epidemics*

are designated when a disease is recognized as spreading rapidly within particular populations and/or regions, and become *generalized* when they reach beyond a group with specific identifying characteristics to a broader population. When epidemics cross continents, they become known as *pandemics* (Fan, Conner, & Villarreal, 2011).

Epidemiological data is established on state, national, and international levels with varying degrees of precision and currency. The information is vast, and the details dizzying. The most current global estimates indicate that there are 34 million people living with HIV around the world, including 0.8% of adults aged 15–49 years (Joint United Nations Programme on HIV/AIDS [UNAIDS], 2012). Although HIV prevalence rates are often reported inclusive of all stages of the disease, information may also be presented in a manner distinguishing cases that have progressed to a diagnosis of AIDS.

As of 2010, an estimated 872,990 persons were living with HIV infection in the United States (CDC, 2013). Of these, the highest percentage (44%) were blacks/African Americans, 67% of viral transmissions were attributed to men who have sex with men (MSM), and the largest percentage (22%) were among persons aged 45–49 years. Eighteen percent of those with an HIV infection in the United States are believed to be unaware of their status, and the number of new infections has held steady at approximately 50,000 per year for the last decade (Kaiser Family Foundation, 2013). An estimated 487,692 persons were living with an infection that had ever been classified as AIDS, of whom 43% were black/African American. The age group experiencing the largest percentage increase was persons aged 65 years and older.

No attempt is made here to be comprehensive; the key point is that data help map whom the disease is hitting hardest—and when, where, and how. Although there have been marked improvements in access to treatment, and consequently, enhanced survival rates, these gains have been unevenly distributed across populations and settings, and tremendous work remains to be done (Rountree, Zibalese-Crawford, & Evans, 2013).

Impact: Personal to Political

The impact of HIV-related disease spans those who are infected, affected, and indirectly connected. People *infected* with the virus have been known variously (and partially) over time as

AIDS victims, People with AIDS, People living with AIDS, and People living with HIV/AIDS (PLHA). Like the naming of the disease itself, this evolution signifies the progression of understanding and identification associated with the illness, and depicts both the depersonalization and ultimate claiming of status by those most directly impacted. Whitehorn and Terrell (2009) wrote eloquently in *POZ Magazine*, itself named in a spontaneous attempt to put a less stigmatizing spin on what it meant to be HIV positive (*HIV+*; infected with the virus), about the challenges and contradictions in trying to frame a deadly serious condition in terms that were simultaneously de-stigmatizing and inclusive of the spectrum of infected persons.

Many authors have categorized the areas of life altered by the disease (c.f. Poindexter, 2010; Bartlett & Finkbeiner, 2006; Clark, Maupin, Jr., & Hammer, 2004), and some issues, mostly psychosocial, have been remarkably persistent over time. HIV impacts the nature and quality of sexual expression; the intimacy and authenticity shared between life partners, friends, and casual acquaintances; decisions about reproduction and parenting; opportunity and capacity in the workforce; daily quality of life; and expectations regarding one's future and longevity.

For persons *affected* by HIV (family members, loved ones, and friends), the impact is also complex. In intimate relationships, *serodiscordant* partners (one HIV+, the other not) may be challenged by concerns of transmitting the virus during sexual contact, stresses and strains associated with disease management for the ill partner, and worries about reactions of others in work or social settings as they learn of the HIV+ partner's condition (Powers & Rowan, 2013). *Seroconcordant* partners (both HIV+) may benefit from the comfort of shared confidences and common challenges, while managing the risk of reinfection should one partner transmit a new strain of the virus to the other. Despite the defining aspect of a disease state, particularly a highly stigmatizing one, life for infected and affected people is subject to all the joys, sorrows, strengths, and frailties of life in the absence of illness. Social workers must bear in mind that daunting as it may seem to them, HIV is often not the largest or only problem a client may be managing, and remember to encounter people with these very particular needs with the same sensitivity and compassion they would bring to any other professional interaction.

Beyond the personal and interpersonal, the sweeping impact of the HIV/AIDS pandemic reached global economic and political proportions in 2000, when United Nations Security Council Resolution 1308, with the support of U.S. Vice President Al Gore,

took the topic from the new field of human security to the well-known 'old' fields of national and even global security by '[r]ecognizing that the spread of HIV/AIDS can have a uniquely devastating impact on all sectors and levels of society ... given its possible growing impact on social instability and emergency situations ... recognizing ... risk of exposure to the disease through large movements of people, widespread uncertainty over conditions, and reduced access to medical care, ... [s]tressing that the HIV/AIDS pandemic, if unchecked, may pose a risk to stability and security' (Gunduz, 2006, p. 68).

Changes over Time in Experience of Living with HIV

HIV disease is now rightly considered a chronic illness rather than a death sentence, at least for PLHA advantaged to live in societies with the will, capacity, and determination to make comprehensive care widely available. Still, it often coexists with depression, anxiety, disabling chronic pain, and risk of *comorbid* conditions that challenge the stamina of even the most determined on a day-to-day basis. There is no vaccine and no cure, and the corollaries of chronic disease management have led to reconsideration by some long-term survivors of whether the unexpectedly long life they have found themselves living has been worth the associated debilitation and isolation (Leland, 2013).

NATURE AND PROGRESSION OF HIV-RELATED ILLNESS

HIV is a type of *antigen*, a microbial agent that penetrates the body and is capable of triggering a response in the immune system. More specifically, it is a *retrovirus*, meaning that it is capable of "hijacking" the DNA structure of the host cell it penetrates, converting it so that instead of producing more copies of itself, it produces more of the invader (Bartlett & Finkbeiner, 2006). In the case of HIV, if we could personify the virus, it would be tempting to call it ingenious, because the host cell it seeks, the *CD4* (a white blood cell or *lymphocyte*, also known as a T4 or "helper"

cell) is key to an otherwise healthy immune response, which would mark the antigen as an intruder, identifying it for destruction and elimination from the body.

Following initial viral acquisition, HIV illness progresses through a series of stages (see Web Resources for greater detail) characterized largely by a fluctuating balance between the *CD4 count* (number per mm³) and the *viral load* (copies of the virus per milliliter of blood). Exposure to the virus occurs via transmission of one of the bodily fluids capable of supporting it (mainly blood, semen, pre-ejaculatory fluid, vaginal secretions, and breast milk). Initial infection is often experienced like any other flu or brief illness; the immune system fights off the symptoms, and the infected person dismisses the cycle as familiar and normal. Typically, *seroconversion* (production of antibodies to fight off the antigen) does not begin for several weeks, after which an untreated individual may experience an extended period (seven years or so) of *asymptomatic* illness (Fan, Conner, & Villarreal, 2011). This period is particularly dangerous because, with the condition undetected and untreated, the HIV+ person may look and feel well while becoming highly infectious, and undergoing a gradual erosion of immune system response capability. Essentially, he or she is an unrecognized threat to self and others, unfortunately contributing to the rational aspect of fears that lead to stigmatization of the disease.

Eventually, the CD4/viral load ratio deteriorates to the stage of *symptomatic* HIV illness, increasing the chances of detection for those with access to education and/or competent medical care. The HIV+ person, aware or not of his or her underlying condition, is subject to longer recovery times from common infections, night sweats and fevers, and chronic conditions that may or may not trigger testing for and discovery of the root infection.

If untreated, symptomatic progression continues until the manifestation of *opportunistic infections* (OIs), conditions that someone with a healthy immune system would not normally develop (Bartlett & Finkbeiner, 2006). Some of these comorbid conditions (i.e., pneumocystis pneumonia, cryptosporidiosis, mycobacterium tuberculosis) are more likely to manifest when HIV is the underlying mechanism of immune suppression, and may be the motivation for a patient first presenting for treatment (CDC, 2009).

When one or more of these “AIDS-defining illnesses” occur, and/or when the CD4 count drops below 200, the HIV+ person is diagnosed with AIDS. Thereafter, treatment becomes critical to stave off deterioration in physical, emotional, and mental status that can otherwise lead to death. Depression and anxiety are common psychological comorbid conditions (Spies, Asmal, & Seedat, 2013), exacerbated by co-occurring problems with substance abuse or injection drug use (Friedland, 2010). Despite the availability of HIV-specific *antiretroviral therapies* (ART), OIs continue to be a major cause of sickness and death. *Prophylaxis*, or efforts to prevent such conditions, can further complicate medical care. Due to underlying psychosocial or economic factors, or challenges associated with combining treatments for multiple conditions, PLHA may not take ART as prescribed and fail to benefit fully as a result (CDC, 2009). For social workers, multiple challenges exist in educating clients regarding overlapping risks they may face, and managing referrals such that clients have the best potential to follow through with medical care.

VIRAL TRANSMISSION

HIV is transmitted when the virus is introduced into the bloodstream of a receptive host by an HIV+ source. The primary infectious fluids are blood, semen, vaginal/cervical secretions, and breast milk. Although HIV has been detected in saliva and tears, the concentrations of viral particles are minute, and the volume of fluid that would be required to transmit the virus is so large as to make them an extremely low risk (Fan, Conner, & Villarreal, 2011).

Risk of exchanging infectious fluid occurs mostly between HIV+ mother and child, during “unsafe” sexual contact, or through the use of infected implements that penetrate the bloodstream (i.e., syringes or needles common in injection drug use, tattooing implements, or medical accidents) (Fan, Conner, & Villarreal, 2011). The common feature is contact through a port of entry. Though the bloodstreams of mother and fetus are separated by the placenta, during the third trimester, or during the birth process itself, tears or swallowing may occur, making the child receptive to infectious fluid. Breastfeeding poses related risks. During sexual contact, infectious fluids may gain entry through tears in delicate tissue, and sharing of needles may transfer such

fluids from one person to another by directly penetrating the bloodstream.

Contrary to enduring myth, HIV cannot be transferred by being sneezed or coughed upon, by casual contact such as hand-shaking, hugging, or closed-mouth kissing, or by daily activities such as eating together, sharing toilets, or living in the same household (Bartlett & Finkbeiner, 2006). Social workers have an obligation to understand what is and is not risky, to conduct themselves accordingly, and to educate infected and affected persons appropriately.

Distinguishing Behaviors from Identity to Minimize Stigma

As an outgrowth of epidemiology, the tendency to associate degrees of risk with particular populations is an understandable but avoidable driver of stigma. It is critical to distinguish so-called “risk groups” (i.e., MSM, injection drug users) from the risky behaviors they and others may enact (Fan, Conner, & Villarreal, 2011). Too often, encounters with feared others lead to cycles of labeling them as deviant, generalizing their undesirable characteristics through stereotyping, imposing an “us/them” out-group status to create a safe distance, and discriminating through harmful thoughts and actions (Link & Phelan, 2001). PLHA have long acknowledged the fear and loathing they sometimes encounter, including in health care settings (Green & Platt, 1997).

More recent efforts have adapted mindfulness principles to the cultivation of compassionate care through *awareness* of service providers’ own predispositions and biases, *acceptance* of their implications for the quality of care, and taking intentional *action* to support the needs and well-being of PLHA (Rutledge & Abell, 2005). The HIV/AIDS Provider Stigma Inventory (HAPSI) facilitates reflection on these aspects as a first step in reducing tendencies to reflexively judge or mistreat PLHA based on generalized characteristics (Rutledge, Whyte, Abell, Brown, & Cesnales, 2011).

TESTING

HIV testing is crucial to understanding one’s status, and circumstances before and after provide opportunities for supportive service provision. Pre- and post-test counseling guidelines can educate clients about how they may have

acquired (or can spread) the virus, can explain the meaning of test results, and can provide critical referrals to appropriate services (see Web Resources).

Initial testing is typically designed to detect the presence of *antibodies* (as evidence that an immune system response has been triggered). Because it may take three to six weeks for sero-conversion to occur, antibody testing should not be attempted until after a *window period* has transpired since the estimated time of first exposure (Bartlett & Finkbeiner, 2006). Otherwise, the risk of *false negative* results (indicating an HIV infection has not occurred when, in fact, it has) is increased. As a safeguard, it is wise to retest three to six months following the initial test. *Antigen* testing (confirming presence of the virus itself) is more typically reserved for determining or monitoring viral load, due in part to its cost.

Social workers should be able to explain that an HIV+ test result in itself does not equal a diagnosis of AIDS (clients need follow-up testing to determine the stage of their illness). They should also be ready to support persons testing HIV+ through the initial adjustment to the news, refer them to appropriate services, and explore the issue of *partner notification*. Whether, when, and how to let others know they may also have been exposed to the virus is a highly sensitive process with crucial implications for personal and public health.

PROVIDING EDUCATION, TREATMENT, AND SUPPORT

Notwithstanding assurances in the Universal Declaration of Human Rights that

Everyone has the right to a standard of living adequate for the health and well-being of himself and of his family, including ... medical care and ... the right to security in the event of ... sickness, (or) disability ... (United Nations, 1948, Article 25),

access to prevention, education, treatment, and support has varied widely across and within societies. Within the United States, delivery of services has too often been compromised by inequities related to poverty, moral judgments, and their corollaries in race, class, and gender (Poindexter, 2010). This, and the ever shifting demographics of the disease, may explain in part why the number of new cases in the United

States has held steady for the past decade, despite diverse and sustained prevention efforts.

Prevention through Behavior Change, Prophylaxis, and Evidence-based Interventions

HIV prevention education promotes behavior change in terms that are both generalized and tailored to risk demographics. Broad topics range from abstinence-only to comprehensive sex education, safe handling of needles and syringes, and relationship dynamics designed to reduce risk of exposure. Social workers should become familiar with factors associated with health behavior change, understand the critical information and resources needed to act on intentions to change, and be aware of evidence-based programs addressing the needs of particular populations.

Principles of Health Behavior Change

Fan, Connor, and Villarreal (2011) integrate existing theory and research, proposing a comprehensive approach to prevention education addressing the following principles:

- Cognitive: making sure to provide the facts. Understanding the nature of HIV, and how it is and is not spread so “rational” obstacles to change can be minimized
- Emotional: encouraging feeling good about behavior change rather than motivating through fear, and exploring more subjective resistance to new experiences or strategies
- Behavioral: becoming comfortable with sexual jargon so recommendations are clear and specific, recognizing that vague suggestions (i.e., “be safe!”) are functionally useless
- Interpersonal: recognizing that relational influences in one’s inner circle can “make or break” best intentions to change, and that power dynamics can undermine follow-through
- Social Ecological: broader group and cultural norms also shape behavior, so appreciating the influence of shared identities is essential to realistic plans for change
- Structural: making sure, for instance, that when someone decides to be tested or seek care, that nonstigmatizing, competent services and facilities are available.

Knowledge and Resources

Social workers must be able to present what they know in a manner that maximizes accessibility for, and inspires the self-interest of, the target group. This means, for instance, being respectful of individuals or environments preferring abstinence only sex education, while being prepared to detail levels of risk associated with “safer sex” behaviors (Bartlett & Finkbeiner, 2006). It may also mean knowing whether and where condoms can be made available, or when to consider more controversial prevention recommendations like use of ART as *pre-exposure prophylaxis* (PrEP) for men who have sex with men or transgender women (Arnold et al., 2012).

Evidence-based Interventions

The CDC has long promoted evidence-based interventions supporting HIV-related behavior change for diverse populations (see Web Resources). These are manualized programs for use in *community based organizations* (CBOs) and include, among many others:

- Healthy Relationships: using social cognitive theory to help men and women develop coping skills and positive expectations for new behaviors
- Sister to Sister: a single-session STI risk-reduction intervention for sexually active African American women ages 18–45 years, delivered during a routine medical visit
- RESPECT: utilizing “teachable moments” to motivate incremental HIV risk reduction behavior change in one-on-one brief counseling environments.

The Diffusion of Effective Behavioral Interventions (DEBI) programs are not without controversy (c.f. Owczarzak, J. & Dickson-Gomez, J., 2011), and the CDC continues to improve and update their content, research, and dissemination with CBO partners.

Medical Treatment

The development of antiretroviral medications (ART, previously referred to as *highly active antiretroviral therapy* or HAART) has transformed health outcomes for PLHA by making available classes of drugs taken as combination or “cocktail” therapies (Fan, Conner, & Villarreal,

2011). None of these medications cure; rather, they arrest various processes with a primary goal of reducing viral load until it is undetectable, while restoring the CD4 count to robust levels. The medications are associated with a host of side effects, ranging from tolerable to “deal breakers” (Bartlett & Finkbeiner, 2006, p. 85), and including gastrointestinal discomforts, debilitating headaches, painful neuropathy, and contraindications with other necessary medications. And ironically, as PLHA live longer, they become subject to other chronic conditions of aging, further complicating care.

Although prescribed regimens have improved dramatically over time as multiple medications are combined into single pills requiring fewer doses per day, social workers become a critical part of the care team in supporting long-term *adherence* (taking medications as prescribed). Returning to our notion of the virus as “ingenious,” when patients are unable to “stick with the program” to a very high degree (i.e., adhering $\geq 95\%$ of the time), they may develop *resistance* to their ART. As the virus mutates, immediate antiretroviral benefits erode, and ultimately, the medication and all others in its class become useless to the patient (PAGAA, 2013). He or she may then pass along this drug-resistant strain to others.

PLHA may have poor adherence due to untreated mental health problems, substance use or abuse, lack of education regarding consequences of missed doses, failing to keep regular medical appointments, unmanageable side effects, or fears about others learning their status by seeing them manage their medication (PAAGA, 2013). As case managers and counselors, social workers play critical roles in maximizing access to care, and in helping PLHA resolve behavioral, relational, or financial concerns that undermine adherence to ART.

Case Management and Counseling

The scope of knowledge necessary to function effectively as a case manager can seem overwhelming, and resources and references included here are meant as guides to the wealth of constantly updated information available on HIV/AIDS. It is definitely true that long-term success in this field requires stamina and determination, a balance between accessibility and well-managed interpersonal boundaries, and the willingness to seek support and supervision on

an ongoing basis. As with other high-demand fields, a sense of humor is essential, and the rewards of doing stimulating, meaningful work are great.

Traditional roles take on particular form in the context of personal, relational, and social circumstances faced by PLHA. Among the tasks social workers must consider are advocacy, referral and information provision, service planning and delivery, follow-up, skill building, teaching, and counseling. Taking a human rights perspective, social workers must strive to stand in solidarity with clients at risk of being stigmatized on multiple fronts, remain mindful of their own responsibilities in creating positive, compassionate contexts for service delivery, and seek out the knowledge, skills, and guidance necessary to provide competent care. And never forget to document, document, document (!).

On the federal level, the Ryan White HIV/AIDS Program provides critical funding for a host of services, specifying case management, and addressing primary outpatient care for PLHA, and family-centered outpatient care for HIV+ women, infants, children, and youth (Health Resources and Services Administration [HRSA], 2013a). The Affordable Care Act (also known as “Obama care”) expands access to Medicaid services, and ensures coverage of “essential health benefits” ranging from hospitalization to mental health and substance use services to prescription drugs and pediatric care (HRSA, 2013b, p. 4). Advocacy for full implementation of this act remains an ongoing challenge. Meanwhile, recognizing that engagement in care is vital for treatment success, that such engagement is often deficient in groups who are disproportionately burdened by the epidemic, and that missing clinical appointments increase the risk of poor health outcomes, social workers can take heart from evidence showing that case management services “play a crucial role in linkage to and retention in care” (Mugavero, 2008, p. 156).

CONCLUSION

Social workers have played a historic role in responding to the HIV/AIDS pandemic. Over time, the costs and consequences have been monumental, and progress steady and game-changing. Still, in the absence of vaccination or cure, millions suffering worldwide, and an average of 50,000 new cases each year in the

United States, “It ain’t over ‘til it’s over.” Let’s get going!

132 Social Work with Lesbian, Gay, Bisexual, and Transgendered Clients

Mary Boes & Katherine van Wormer

INTRODUCTION

Lesbian, gays, bisexuals, and transgendered persons seek social work services for the same reasons heterosexuals do—out of grief for the loss of a loved one, for depression and other mental conditions, for court-mandated substance-abuse treatment, for relationship issues. Additionally, lesbians, gays, bisexuals, and transgendered persons have unique issues pertaining to their sexual orientation and gender identity, the social stigma of their differentness, rejection by families and friends, the impact of AIDS on the lives of gay men, and coming-out issues for all age groups. Heterosexuals also seek help for matters related to homosexuality—for example, concern over gender-appropriate behavior in a young son, the shock of learning an offspring is gay or lesbian, or the discovery that a spouse is having an affair with someone of the same sex. Nevertheless, in the best tradition of the client-centered approach, social workers should follow the lead of the client in addressing the specific issue that propelled him or her to seek professional help in the first place (see Ski Hunter, 2012).

Two key principles attract such persons and their families to seek professional help: the promise of confidentiality and the tradition of nonjudgmental acceptance. Perhaps for these reasons, and owing to a reluctance to talk of these matters to family members, friends, or clergy, gays and lesbians are more likely than heterosexuals to see a therapist (Goldstein & Horowitz, 2003). African Americans seeking assistance related to their sexuality, however, are likely to

find few, if any, therapists of color with relevant training.

Few groups are as maligned in our society as those who are identified as or suspected of gender nonconformity or having a same-sex sexual orientation. The most extreme forms of discrimination, including ridicule and violence, are reserved for transgendered persons or those who have the psychological sense of being female when they are physiologically male or vice versa (see van Wormer, 2007).

In recognition of the homophobia (fear of homosexuality) and heterosexism in society, the social work profession strives to prepare practitioners who will promote respect for people of all sexual orientations. According to Carol Tully (personal communication), the three basic forms of homophobia are pervasive—*institutional* homophobia, which is perpetuated by the traditional structures of society; homophobia at the *individual* level, evidenced by insulting jokes and hate crimes; and *internalized* homophobia, which is awkwardness that gays and lesbians, especially teens, feel about themselves.

In its policy statement on lesbian, gay, and bisexual issues, the National Association of Social Workers (NASW) (2012) states its commitment to advancing policies and practices that will improve the status and well-being of all lesbian, gay, and bisexual people, including rights to inheritance, marriage, reproductive choices, and child custody.

Similarly, the American Psychological Association (APA) Committee on Lesbian, Gay, Bisexual, and Transgender Concerns endorses positive attitudes toward gays as a group. From

the brochure issued by the APA (2008, pp. 1–4) we learn that:

- Sexual orientation is most likely the result of a complex interaction of environmental, cognitive, and biological factors.
- Sexual orientation exists along a continuum that ranges from exclusive homosexuality to exclusive heterosexuality.
- Although persons can choose whether to act on their feelings, psychologists do not consider sexual orientation to be a conscious choice.
- Children reared by gay or lesbian parents are psychologically as well adjusted as children reared by heterosexual parents.
- Most pedophiles and child abusers are heterosexual men.

CASE ILLUSTRATIONS

(1) As a small child, Lee was very popular at school and sang in the school and church choirs. When puberty hit, however, he developed an identity crisis related to his sexuality and teasing by other kids who regarded him as a sissy. The bullying escalated to the extent that Lee started missing school; he faced a religious crisis as well.

The school social worker's assessment revealed that Lee was depressed, lonely, and at times suicidal, confused about his gender identity. She met with Lee weekly and referred him to an after-school facilitated group that helped students wrestle with issues related to gender identity. Intervention was planned with classmates who were engaged in bullying.

(2) The Williams had three sons; the youngest, age seven years, was extremely feminine, insisting that he was, in fact, a girl and begged to wear dresses. His favorite children's books were stories of mermaids. The child, who insisted on being called Rose, had been diagnosed by a psychiatrist as suffering from gender dysmorphia.

Mrs. Williams took Rose from psychologist to psychologist, hoping to find help somewhere for her daily struggles with the child who refused to act "normal." Finally, she was referred to a social worker who specialized in gender identity issues. The social worker educated the family about transgendered children and presented an option they had never considered—to let Rose live life as the girl her brain said she really was. Because the transformation was immensely complicated,

socially and medically, family members agreed to a plan for long-term counseling and consultation.

CONVERSION THERAPY VERSUS THE STRENGTHS APPROACH

Against the backdrop of an increasingly conservative political and religious climate, gay men and lesbians are sometimes persuaded to seek psychotherapy to change the focus of their sexual attraction. The basic tenets of conversion therapy are:

- Homosexuality is a sin, and salvation can come through faith in Jesus Christ.
- Psychotherapy can cure a mental disorder (secular therapists).
- The cause of homosexuality is a dominant mother and passive father.
- People can change their sexual identity through treatment.
- Converts who repudiate their former gayness can be role models to gays and lesbians to help them change.

Such claims are repudiated by NASW (2000, 2012) and the APA (2008) as completely invalid and ideologically based.

Because homosexuality is not a mental disorder, treatment to change one's sexual orientation is unwarranted. NASW (2000) issued a caveat against the resurgence in conversion therapies. Such therapies are viewed by the association as a violation of the social work code of ethics' requirements of competence and commitment to clients' self-determination. False claims by therapists of documented success stories in converting people to heterosexuality can lead to severe emotional damage, whether through the claims or through the treatments, according to NASW.

In sharp contrast to the dictates of "reparative" treatments is the strengths or empowerment perspective as it pertains to gay and lesbian practice. From a strengths perspective, we offer the following guidelines to practice with gays, lesbians, bisexuals, and transgendered persons.

- Seek the positive in terms of people's coping and survival skills, and you will find it.
- Listen to the personal narrative, the telling of one's own story in one's own voice, a story that ultimately may be reframed in light

of new awareness of unrealized personal strength.

- Validate the pain where pain exists and reinforce persistent efforts to alleviate the pain (including, if desired, *not* acting on the feelings and/or reducing isolation in multiple ways).
- Help people recover from the specific injuries of oppression, neglect, and domination.
- Do not dictate; collaborate through an agreed upon, mutual discovery of solutions among helpers, families, and support networks. Validation and collaboration are integral steps in the consciousness-raising process that can lead to healing and empowerment.
- Move from self-actualization to transformation of oppressive structure, from individual strength to higher connectedness.

Also using an empowerment approach, Tully (2000) and Hunter (2011) advocate a client–practitioner relationship built on mutual respect and reciprocity to uplift and empower gays and lesbians effectively in an oppressive, homophobic environment. Both researchers urge social workers to avoid the assumption of heterosexuality in the creation of a gay-friendly space. Among their recommendations are to:

- Use gender-neutral language, such as “relationship status” instead of “marital status,” on the forms provided.
- Avoid standardized face sheets and documents that presume everyone is heterosexual.
- Include some lesbian- and gay-friendly magazines, posters, or newspapers in the waiting area.
- Train staff to be gay-friendly and nonhomophobic.

SELECTED AREAS OF SOCIAL WORK PRACTICE

In this section, we focus on two areas of social work practice with special relevance to sexual minorities—social work with (1) adolescents and (2) family and couples counseling.

Social Work with Adolescents

Struggling to survive in environments (school, home, church) that are more often than not

hostile to their very being, gay and lesbian youth have many intense personal issues to resolve. The message sent by society, including one’s own community, is that gender nonconformity and gay or lesbian identity, unlike racial and ethnic identity, is a choice that can and should be concealed (van Wormer, 2011).

Among the most pressing issues concerning adolescent gays and lesbians, which we have gleaned from experience and the literature are:

- The turmoil involved in coming out to yourself, discovering who you are and who you are not
- Deciding whom to tell, when, and how to tell it
- Rebuilding relationships and grieving rejections when the truth is known
- Developing new and caring support systems
- Protecting oneself from a constant onslaught of attacks on one who is openly out or from the guilt feelings accompanying the secrecy and deception of being in the closet
- Coping with the school’s failure to be inclusive of youths struggling with gender issues and ridicule from their peers for being different
- Internalized homophobia (from the larger society)
- Problems with alcohol and other drug abuse as a means of self-medication
- For youths who do not come to terms with who they are or who are rejected by their parents, alcohol and other drug abuse, homelessness, unsafe practices, and suicide are major risks.

Typically, closeted gay youths are referred to treatment for symptoms of their distress, such as anxiety, drug use, and depression; rarely are they asked about their sexual concerns. Typically also, youth who are confused about their sexual identity are falsely reassured, as are their parents, that their confusion is just a passing phase. Such denial is harmful and compounds the risk for suicide (van Wormer, Wells, & Boes, 2000). Relevant facts as listed in a review of the literature by Sandra Anderson (2009) are:

- Compared with heterosexual youths, research has shown that sexual minority youth are twice as likely as their peers to consider and attempt suicide.

- Youths who report methamphetamine use (a popular drug in the gay/lesbian community) are several times more likely than others to have considered suicide.
- Of all adolescents, transgendered youth are the most vulnerable and the most likely to use addictive substances.

In the state of Massachusetts, thanks to the Safe Schools Initiative signed into law in 1993, about half the high schools have gay–straight alliances. Advisors meet with sexual minority and questioning students in small groups in which they discuss their sexuality and alcohol and drug use (Massachusetts Department of Education, 2008). In the absence of openly gay and lesbian teacher role models—a serious absence in itself—a community of adult-led gay and pro-gay students to provide peer support is essential.

For effective strengths-based practice, social workers in a school setting can:

- Help institute programs in the school to prevent bullying and verbal abuse of students who are deemed different.
- Challenge homophobic practices in the school setting.
- In individual counseling sessions, seek out stories of personal growth and resilience.
- Through empathetic listening and referral to affirming support groups and activist organizations, help open the door to new support systems.
- Be careful in prematurely assigning labels to youths such as gay, straight, or bi; help students discover their own identities.
- Make sure the school library contains helpful information about homosexuality and homophobia.
- Provide teacher workshops on homophobia and school bullying; organize gay/lesbian panels from a nearby college to address the school on a yearly basis
- Connect with PFLAG (Parents, Families, and Friends of Lesbians and Gays), which has implemented a program across North America to work with parent teacher associations and engage in speaker panels.

School Social Work

The one area of social work practice with the greatest relevance for youth suicide prevention is school social work. School counselors,

psychologists, and social workers can counsel high-risk students and bullies to get at the source of their displaced hostility: one exemplary program is found in Toronto, Canada, where approximately 90 school-based social workers work with a wide variety of issues, including those pertaining to sexual orientation and gender identity. *The Essential Guide to Bullying Prevention and Intervention* is a useful resource for school social workers; it is co-authored by Cindy Miller, a school social worker, and Cynthia Lowen, a filmmaker of the popular documentary, *Bully*. This film shows the pains of brutal victimization that children who are designated as “different” can experience when adults look the other way and fail to provide appropriate interventions. *Bully* was released in 2012 and is now shown in schools all across the United States.

To learn more about the making of this film, we authors interviewed Alan Heisterkamp (on March 5, 2013), a former Sioux City, Iowa school administrator, who served as consultant for the documentary. One of his roles was to work with the Sioux City school board to obtain permission for the shooting of the film on the school bus and other places where bullying occurred. In our interview, Heisterkamp spoke of the role that his wife, Pat, plays in the school system:

My wife, Pat, has been a school social worker for 15 years. She has done some amazing things to address bullying in middle schools. Namely, she has taught curriculum on problem solving, bystander education and prevention strategies, conflict resolution, anger management, empathy building, friendship groups and social skills with autistic students, healthy dating relationships, and understanding and recognizing violent masculinity. She conducted social skills groups at the middle school where the documentary, *Bully*, was filmed.

Strategies for school social workers are to:

- Foster a gay–straight alliance and other programs to involve the entire student body in bullying prevention.
- Ask students to contribute ideas to raise consciousness on the impact of bullying.
- Create peer mentor programs where leaders engage in bystander intervention to monitor the playground for instances of harassment.
- Encourage teachers to include antibullying messages in their curriculum.

- Establish restorative justice interventions for exchanges between students who have engaged in bullying and their victims (see Miller and Lowen, 2012).

Family Counseling

In working with families in therapy for whatever reason, social workers would do well to be alert to instances of sex role rigidity and homophobia, which restrict the emotional and sexual expression of individual members. In addition, virtually all marriage and family counselors will encounter the issue of sexual orientation from time to time, as members come in to discuss the crisis that pertains to disclosure, or work with lesbian and gay couples on issues unrelated to orientation. In any case, some typical family configurations known to family therapists are lesbian and gay parents with child custody or adoption issues; nongay parents with gay or lesbian children who have come out to them; gay or lesbian families with different ethnic traditions and in-law concerns; and couples experiencing domestic violence or substance abuse.

To be a family headed by a same-sex couple in a heterosexist society is to wrestle with weighty issues at every turn: childbearing or child custody arrangements; when and how to come out to children; and how much to tell people at church, school, work, or in the neighborhood. In other words, how does one walk the fine line between discretion and openness in dealing with the outside world? Issues of extended family acceptance, gender socialization of the children, and internalized homophobia in one or both partners can undermine the healthiest same-sex relationships. Forced to shape their own rituals and traditions, these unorthodox families are blazing the trail for themselves and others.

Effective work with lesbian and gay couples requires that workers be familiar with the unique norms of the lesbian and gay community to avoid pathologizing what may be normative behavior for couples in that community. Heterosexual therapists who lack personal experience and comfort in working with lesbians may react in ways that repeat the rejecting experiences with significant others in their lives (Goldstein & Horowitz, 2003).

Helpful guidelines for providing family therapy with gay and lesbian family members are provided by the Substance Abuse Mental Health and Services Administration (SAMHSA, 2004), as well as for work with transgendered populations dealing with issues of HIV/AIDS (SAMHSA, 2000).

For work with older lesbian, gay, and transgender couples, see Anderson (2009) and Witten & Eyer, (2012) who discuss relevant issues such as retirement, legal issues, and grandparenting. The significance of the passage of a federal antidiscrimination law comes to the forefront during the final stages of life. When one partner dies, the other may suffer heavy financial losses due to income tax and social security policies that deny spousal benefits to gay and lesbian partners, whether they are married under state law or not. Moreover, unmarried partners do not have the automatic right to make medical and financial decisions for their partners. Fortunately, recent national opinion polls show a shift in public opinion favoring the view that marriage should be a legal right for same-sex couples. According to the most recent national poll, 58% of Americans now believe it should be legal for gay and lesbian couples to marry, and the majority thinks the matter should be decided on the basis of the U.S. Constitution (Cohen, 2013).

Religion is an issue that is never far from the surface in the lives of gays and lesbians. A common theme woven through the gay and lesbian narrative is an upbringing in which the church, synagogue, or mosque was a kind of sanctuary from the cruelties of childhood. Ultimately, however, many gays and lesbians feel rejected by the orthodox religions of their childhoods. A therapist who is knowledgeable about biblical passages of love and acceptance can offer solace to the client steeped in a negative interpretation and out-of-context guides. A focus on love, not condemnation, and a grasp of spirituality as love toward oneself and others can offer an invaluable source of strength to sexual minorities and their families who are grappling with these truths. Anderson (2009) lists religious involvement as a potentially strong protective factor in preventing substance abuse among adolescents in general; it is not known how this affects sexual minority youth. Referrals to gay and lesbian clergy and to gay-friendly churches such as Metropolitan Community Churches, Unitarians, and Quakers or Friends Meetings can be a tremendous boon in helping clients regain the spirituality of their youth (van Wormer et al., 2000).

Finally, to help all family members move from denial and questioning ("what did we do wrong?") to acceptance and even advocacy, they should be encouraged to attend meetings of PFLAG. Scattered all across the United States, PFLAG chapters offer emotional support without criticizing visitors who are not ready to accept the sexual orientation of their loved one. Likewise, a

viewing of the movie *Prayers for Bobby* would be tremendously helpful to a family member struggling with a partner's or child's coming out. Shown on the Lifetime network in 2009, this film is based on a true story and delves into analysis of biblical passages related to homosexuality.

CONCLUSION

Within the clinical context, through the medium of a caring relationship, the practitioner seeks to boost the lesbian, gay, or bisexual client through the aforementioned steps of strengths-based practice: seek the positive; hear the narrative; acknowledge the pain; collaborate (not dictate); and pave the way for further growth through helping others. What lesbians and all sexual minorities have to overcome along with their practitioners is the long conspiracy of silence that has served to keep generations of people from sharing the truths about their lives and their loves.

Adherence to the social work mission and values demands that the profession, and those who represent it, take a strong and proactive position on individual, organizational, and educational levels on gay and lesbian issues. The goal that we in the helping professions are working toward is not mere acceptance or toleration but *celebration* of the strengths of this largely invisible minority, strengths that, at least to some extent, come from living both within society and apart from it. Like members of other groups rendered invisible in a patriarchal and highly puritanical society, gay men and lesbians have unique histories (both individually and as a whole), creative family forms, gender role flexibility, and vast social networks. The gay and lesbian contribution to underground culture as well as mainstream arts—art, music, dance, and literature—has been incalculable. To social work practitioners, the challenge is to discover and reinforce the special insights and resiliencies that have developed out of the uniqueness of lesbian and gay experience.

133 Global Perspectives on Gender Issues

Kristin Heffernan & Betty J. Blythe

Since the beginning of civilization, both women and girls have been treated inhumanly by men (as cited in Alabi, Baha, & Alabi, 2014), and while the United States is not without its issues of gender inequality, this chapter specifically focuses on international women's gender inequality as embedded in structural systems. In addition, it will present antioppressive practice (AOP) as a way to help the reader better understand how globalization should and does influence the practice of social work. In adapting an AOP framework we can enhance our understanding of the role of social workers as leaders in advancing human rights and gender equality while steering away from any conclusion that adopting a Westernized way of doing social work in other countries is acceptable.

This chapter is not an attempt to define or promote universal standards for global social work practice. Furthermore, the practice of social work has been and should continue to be framed within the cultural context of the nation in which it is practiced. As social workers, we promote and fight for human rights while possessing a clear understanding of the complexity of the local conditions that foster inequalities and constrain women's rights within their society. In this chapter, we will specifically concentrate on the overarching effects of patriarchy, specifically addressing the issues of violence against women, women's health, and education between the genders.

The boundaries between nation states have become increasingly porous. Social workers in both developing and developed countries need to understand how a range of national and international forces cause oppression and disadvantage for many women. In this chapter, we move away from a strictly clinical view of social work

to understand the macro practices that involve advocacy and community development for the purpose of combating oppression and promoting antidiscriminatory and antioppressive values toward women.

Using an antioppressive practice framework allows social workers to attend to social divisions and structural inequalities (Strier & Binyamin, 2013), including the unequal power relations between social workers and their clients. Key to an AOP approach is changing social relationships and the structural systems that perpetuate the exclusion of marginalized persons (Pollack, 2004). AOP requires that social workers be able to reflect on the power differential in their relationships with clients so that they can understand how the relationship in and of itself can be oppressive. This also helps social workers to recognize the problems faced by clients as rooted in the socio-political structure of society and not in the clients' personal characteristics, positioning social workers to work alongside clients in initiating social change.

At the forefront of this process is a continued exploration and evaluation of person-in-environment for the purpose of understanding how the experiences of different groups of women around the world, living in male-dominated societies, are structured based on the cultures in which they live (Penna, Paylor, & Washington, 2000). By raising awareness of the key issues faced by women around the world we hope to further develop a commitment from social workers to work toward providing culturally competent, quality services to women, while promoting a macro perspective on global change. The underlying theme laying the ground work for this chapter is the idea that women's lives are shaped by the intersectionality of patriarchy,

economic disadvantage, religious beliefs, and other discriminatory systems formed at local levels, which creates layers of inequality. These systems of inequality structure the relative positions of women within their respective cultures. Gender norms in many patriarchal societies limit women's opportunities to seek help if they are experiencing violence, if they want an education, or if they want to work outside the home. Male-dominated societies adhering to strict enforcement of the view that women are inferior often promote male gender preference (Das Gupta et al., 2003; Westley & Kim Choe, 2007), which can lead to such practices as female infanticide or female neglect from birth to the grave.

For females living in such societies, if they survive at birth, marry, and outlive their husbands, their fate does not necessarily improve. In many male-dominated cultures, widows lose their rights and their property upon their husband's death. One extreme example of male-gendered practices is "sati," which although outlawed is still practiced in some parts of India.

In the Hindu tradition, a husband dying before his wife signifies that the wife has committed some wrong in her current or past life. According to cultural beliefs, this brings about shame to the wife, which can only be rectified by performing sati, whereby the widow throws herself onto her husband's funeral pyre. It is believed that in suicide the wife resolves her shame and as such brings good fortune to herself and her kin (Cheng & Lee, 2000). Although this form of suicide is said to be voluntary, many women commit sati out of fear of their fate as widows, preferring death to life within their community. Additionally, if a widow appears reluctant to commit sati, her kin and neighbors may force her to commit it by going so far as to throw her on top of the funeral pyre. Lack of ability to participate as full citizens within their community perpetuates women's inequality, oppression, and loss of human rights and, as seen in the example of sati, can lead to extreme forms of violence against women.

VIOLENCE AGAINST WOMEN

In recent decades, violence against women has been acknowledged as one of the greatest threats to female health and safety worldwide (Garcia-Moreno, Jansen, Ellsberg, Heise, & Watts, 2005). Twenty years ago, on December

22, 1993, the United Nations General Assembly in New York adopted with unanimous consent the Declaration on the Elimination of Violence Against Women, condemning gender violence within both the private and the public sphere as a violation of human rights (United Nations [UN], 1993). Despite this resolution, women all over the world continue to live with the threat of domestic violence or rape in their own homes and communities, and by people whom they know. Violence against women takes many forms and also includes:

- Honor killings
- Dowry deaths
- Sati
- Female genital mutilation
- War rape
- Private and public beatings

In many countries, it is extremely difficult to protect women from male violence. In fact, in some countries and cultures, much of the gender violence is not considered a violation of rights, as it is embedded in that nation's culture, customs, and/or traditions (Joachim, 2003). Male dominance is so widely accepted in many cultures, that women themselves may not view the violence as an affront to their human rights as this is all they know. Male authority and power plays a huge role in gender violence. Honor killings, for example, are carried out when male kin suspect that women in their family (mothers, daughters, sisters) dishonor the family.

Although reports of honor killings have been widely reported in the Middle East and North Africa (MENA), and South Asia (UN, 2000), more recently honor killings have been documented in North America as well as Europe (Kulczycki & Windle, 2011). In many societies, women are considered the property of their husbands or fathers and are expected to uphold their family's honor. Usually this means conforming to the gender-specific roles of women for a particular culture. Another example of cultural traditions and customs that provoke violence are perceptions of female infidelity.

There are many ways in which women can be seen as dishonoring their family patriarch, most notably via infidelity. Definitions of infidelity differ from culture to culture. In the United States, infidelity is often defined as cheating, adultery, or having an affair. However, in other countries, infidelity may mean women being in the company of

males who are not family members. Fathers also may interpret infidelity as a daughter dressing in a way that he, or her uncle or brother, think is provocative. Thus, the definition is open enough for male family members to define as they see fit. Furthermore, accusations do not have to be confirmed for an honor killing to take place; the mere fact of an accusation is enough to bring shame and punishment to the family. The decision to kill the female in the name of family honor lies solely with the males in the family. According to a United Nations Population Fund (UNFPA) report in 2000 an estimated 5,000 women and girls are murdered each year in so-called honor killings by members of their families (UNFPA, 2000).

Dowry burnings is another form of severe violence against women, albeit not often experienced in the Western world. A dowry is a gift of money, jewelry, animals, or other property that the single woman takes with her as a contribution from her family when she is engaged to be married. It is given to the daughter as her property, but in traditional, male-dominated societies, the dowry actually goes to the husband (Johnson & Johnson, 2001). In these cultures, the wife is seen as property such that whatever she brings to the marriage belongs to her husband. For example, in India, female children are the property of their fathers until they are married, and after marriage they become the property of their husbands (Puri, 1999). In this way women are kept economically dependent, first on their fathers and then on their husbands once they are married.

The lack of a sufficient dowry can be a catalyst for violence against the bride, despite the fact that dowries are prearranged between parents of the bridal couple. Dowry money can reach as high as six times the annual household income in South Asia (Rao, 1993) and four times the annual income in sub-Saharan Africa (Dekker & Hoogeveen, 2002). Regardless of the size of the dowry, the husband's family may find it unacceptable at the last minute and can make demands for more money or other items before the marriage, or they may insist on the family continuing to pay off their daughter's dowry long after marriage occurs. When a bride's family cannot make payments or refuses to invest more in their daughter's dowry, a dowry burning might occur. The demand for a dowry has been outlawed in India since 1961, but strong cultural traditions and patriarchal practices have not diminished the demand for dowries in practice (Johnson & Johnson, 2001).

Female genital mutilation (FGM) is a form of gender-based violence that inflicts severe and lasting harm, both mental and physical, on victims. FGM involves partial or total removal of external female genitalia, most often by a traditional circumciser. Although it is upheld as a cultural practice, in fact the practice of FGM is recognized internationally as a violation of the human rights of girls and women. FGM is most often inflicted upon young girls between the ages of infancy and 15 years and has no health benefits. In some instances, women flee their country and seek refugee status to avoid female excision of their daughters. All too often, however, women do not have the knowledge or resources to protect themselves or their female children from this abuse. In addition to the violation of human rights, FGM can cause health problems, infertility, and difficulty in childbirth.

Another form of gender-specific violence is war rape. Women raped in conflict zones often are regarded as an inevitable consequence of war rather than a crime and a violation of human rights (Brownmiller, 1975; Enloe, 2000). Women frequently are chosen as weapons of war and may be targeted for sexual slavery, gang rape, or individual rape to humiliate the enemy (Farwell, 2004). Because sexual assault of women tends to be viewed as a less significant event, war rape often is not considered to be a war crime and perpetrators are not held accountable (Swiss & Giller, 1993).

War rape has physical and psychological consequences for women and can disrupt entire communities or societies. The list of physical effects is extensive and may include such things as unplanned pregnancies, mortality, unsafe abortions, sexually transmitted diseases, and recurring gynecological problems. The list of long-term psychological effects is long and includes posttraumatic stress, anxiety, depression, and suicide. Children born out of rape often are ostracized or marked as "different." Victims of rape are isolated from their families and communities and, if the rape is widespread and systematic, it can lead to the breakdown of a community. War rape sometimes is perpetuated as an act of cultural genocide, as in the case of Rwanda (Cohen, d'Adesky, & Anastos, 2005).

Seeking help for male-gendered violence is challenging in male-dominated societies. Unfortunately, some women who seek help outside the home are ostracized or shunned by the rest of their family and/or community. For instance in many South Asian cultures, the

sanctity of the family traditionally falls on the shoulders of women, and their culture dictates that what happens in the family stays within the family (Roy, 2012). Because women who pursue social support or professional counseling outside of their family frequently are marked as traitors they may be reluctant to report rape for fear of bringing disgrace to their families. These cultural beliefs are deeply imbedded within the cultural structure of these societies and cannot be ignored by the social work professional. In other words, well-intentioned social workers may actually do more damage if they reach out to victims of the types of violence previously described. It is important to stress here that each person has the right not to receive help and that only she can know what revealing her secret will mean for her. As social workers in this situation, our responsibility lies in being aware of these traditional cultural beliefs, which should guide our professional behavior. When we cannot offer direct services, we may still be able to advocate and educate.

Activists for women's rights are working to change the definition of rape and domestic violence as well as the related judicial treatment of perpetrators and victims to underscore the fact that violence against women is not a "right" of men. An advocacy approach, fighting for women's rights and social justice, allows us to act on behalf of all women without outing individual women and causing them further pain and suffering due to their cultural beliefs. In many male-dominated societies, this may mean persuading males in official roles to adopt decisions that are pro-women, helping those in power to understand that such decisions are key to stopping violence against women. We are not saying that clinical or micro approaches are not important, but rather that the need to address violence against women as a large-scale social problem, due to the systematic discrimination and oppression of women in some patriarchal societies, supersedes the best practice for women who experience such trauma. Only when the violence is seen as an infraction of women's rights will women be able to create services that meet their needs in these societies.

WOMEN'S HEALTH

Women subjected to the horrors described in the previous section often are at higher risk for unwanted pregnancies, sexually transmitted diseases, and further health-related

complications due to restricted health care access. Approximately half a million women die each year from complications related to pregnancy, childbirth, and the postpartum period (Glazier, Gülmezoglu, Schmid, Garcia Moreno, & Van Look, 2006). In developing countries, it is estimated that one-third of all expectant mothers go without health care, 60% of the births take place outside of health facilities, and only 60% of all births have trained staff present at the time of the birth (World Health Organization [WHO], 2005). For women and girls between the ages of 15 and 49 years, complication at time of birth is the leading cause of death and disability in most developing countries (UNFPA, 2000). Women in countries where male dominance exists often face many gendered health problems:

- Maternal mortality
- Lack of family planning information or access to contraceptives
- Unsafe abortion or injuries sustained during an illegal abortion
- Sexually transmitted infections, including HIV
- Persistent gynecological problems
- Psychological problems
- Malnutrition

Maternal mortality rates are highest in Africa, with a lifetime risk of 1 in 16 (WHO, 2005). Many maternal deaths can be attributed to lack of trained professional health care providers and family planning. HIV infection is an ongoing world health issue, particularly for the women of sub-Saharan Africa, where only limited treatment is available (UNAIDS/WHO, 2007). Because they are of lower status, women in these countries lack control over household resources, have less access to information and health services, poorer mental health, and lower self-esteem (Smith, Ramakrishnan, Ndiaye, Haddad, & Martorell, 2003). In many of the poorest of these countries, women often suffer from malnutrition because men and young boys are served first and women eat last and least.

A plethora of articles have been written about our ability to dramatically reduce maternal mortality rates, and about the spread of HIV and female malnutrition on a global level. Understanding why women are not receiving proper care in certain countries involves understanding the position and status of these

women within their respective countries. Most are oppressed due to structural and cultural ideologies that view women as inferior to men. So although an increase in access to maternal care and family planning may help to lower maternal death rates, transformational change needs to start from within countries. Power distribution needs to change, which is no easy task where patriarchal ideologies are systemic in male-dominated cultures. For change to occur, those in power (i.e., men) must see a need to promote women's health issues.

EDUCATION DISCRIMINATION BASED ON GENDER

Once again, in order to truly understand the vast gender inequality in education in patriarchal nations we must have a clear understanding of the local context, politics, history, and cultural beliefs. There are some similarities, however, among countries with the largest disparities. The most profound gender inequalities in education have been noted in countries where women are devalued and traditionally restricted from taking part in the public sphere in any truly meaningful way (Colclough, 2008). Educational discrimination begins at birth. If a female is born into a culture that devalues her gender, she has less chance of survival (Johnson & Johnson 2001). In many East and South Asian countries, a preference for sons has led to lower rates of female infant survival (Westley & Kim Choe, 2007). It has been estimated that nearly two-thirds of the 300 million children around the world without access to education are females, while another two-thirds of the illiterate adult population are women (UNFPA, 2000). The lack of opportunity for an education for many young girls actually is the outcome of a larger issue: the structural and systemic discrimination and oppression due to one's gender status as female. It goes without saying that these inequalities often perpetuate poverty, poor health, and an inability to further oneself within the community.

Female children may not live past birth due to lack of nutrition and health care (Das Gupta, Zhenghua, Bohua, Zhenming, Chung, & Hwa-Ok, 2003). If they do survive, they are usually seen as an economic burden (Johnson & Johnson, 2001). They are often expected to marry early and or perform labor around the house (Das Gupta, Zhenghua, Bohua, Zhenming, Chung, &

Hwa-Ok, 2003). They are susceptible to all forms of abuse due to their female status (Sev'er, 2008). An education is viewed as necessary and appropriate for someone who is expected to join the work force and earn a living for the family, but then again this is not the expectation for many of these women. "Women's work" typically is undervalued and not included in calculating a nation's gross domestic product (Waring, 1999). In many patriarchal societies gender continues to be a source of hate and degradation, thereby determining the types of opportunities available to persons around the world.

ADVOCACY AND EDUCATION

In order to foster change, again, we advocate for a macro level approach. This means we first need to educate ourselves on the complexities of local cultural, political, and historical norms or ways of living outside the United States; a move beyond our often ethnocentric, rose-colored glasses. We need to understand that within the patriarchal society, men benefit from the exploitation of women and, as such, are not willing to give up this benefit. Policies, laws, and traditions are set by men and favor men, meaning that women living in these societies routinely experience oppression and even violence. It also stands to reason that the family, state, and larger society condone such behaviors because these are the norms within those societies. In effect then, we are dealing with both public and private patriarchy whereby women are socialized to believe that their place in their family and the larger society is not equal to a man's (Alabi, Baha, & Alabi, 2014). This may be naturally accepted and not questioned by women due to their cultural and lived experiences.

With this knowledge we can better understand the role of education both for ourselves and in the work that needs to be done to lessen the inequality gap between the genders in patriarchal societies. Education becomes critical to constitutional reform (Wronka, 1994). Once we understand the issues we can then advocate for change that will bring about legislation that will, in turn, enhance human rights on a global level. As Helen Clark, the prime minister of New Zealand from 1999 to 2008, stated on International Women's Day 2014, "Grounded in international human rights, gender equality doesn't just improve the lives of individual women, girls, and their

families, it makes economic sense, strengthens democracy, and enables long-term sustainable progress" (UNDP, 2014).

PART XIII

School Social Work

134 Overview of Evidence-based Practice in School Social Work

Paula Allen-Meares & Katherine L. Montgomery

The primary purpose of this section is to provide social workers and related school-based professionals with current and diverse empirical data on interventions and approaches that address the needs of various pupil groups. Emotional and behavioral problems are among the most predominant and chronic conditions that affect school-aged youth (Pastor, Reuben, & Duran, 2012), and this number is much higher for vulnerable populations (Cooper, Masi, & Vick, 2009). These children are at risk of serious subsequent and interrelated trajectories that include juvenile delinquency, substance use problems, violence, school dropout, and unemployment (e.g., American Psychology Association, 2012). In response, policymakers, practitioners, and researchers have invested enormous efforts over the past several decades to develop and test evidence-based interventions (EBIs) that effectively address these issues in the school setting (Forman et al., 2013). Many school-based EBIs have since been identified that impact several outcomes for at-risk students (e.g., Montgomery, 2014). What is necessary to deliver these services? Where will the future of school-based intervention take us?

In this discussion, we highlight some elements and issues in the future of school social work, a practice field that will be ever more firmly and increasingly rooted in a growing evidence base. In addition, we add a brief summary of issues specific to the selection of evidence-based interventions, methods of getting school social workers to accept and use evidence-based practices, and why schools and communities should create partnerships for mental health services for children and adolescents.

DEFINING EVIDENCE-BASED PRACTICE

The future of school social work may very well rest on the emerging growth and reliance on the evidence-based practice (EBP) approach. Although there is not currently a consensus about the definition of this concept (Hoagwood, 2003; Rubin & Parrish, 2007), many disciplines use the concept, and various definitions may be found within them. Social work, in particular, has embraced the concept as a way to address the perceived gap between research and practice (Brekke, Ell, & Palinkas, 2007; Gould, 2005; Rubin & Parrish, 2007). In this chapter, we attempt to define *evidence-based practice* in a manner that can be commonly understood.

Originally adopted from the medical field, EBP in social work refers to the process of implementing and integrating tested research evidence into practice. The *Social Work Policy Institute* defines EBP as “a process in which the practitioner combines well-researched interventions with clinical expertise and ethics, and client preferences and culture to guide and inform the delivery of treatment services” (2010, para 1). This process is associated with five steps: (1) ask a focused question, (2) find the best evidence, (3) evaluate the evidence, (4) apply information in combination with clinical experience and patient values, and (5) evaluate outcomes (Johnson, 2008). Central to this process is the identification and use of evidence-based treatments (EBTs) in Step Two. Although there are multiple criticisms of EBP (e.g., Straus & McAlister, 2000), scientists assert that when specific EBP steps (c.f., Gibbs & Gambrill, 2002) are followed, most criticisms are

addressed (Rubin & Babbie, 2010) and benefits associated with cost effectiveness, time efficiency, and lasting positive outcomes are made possible. Brekke and colleagues suggest that social work is uniquely situated to play a role in the movement to bridge research to practice, with schools being an opportune and indeed desired setting for direct applicability of EBP. "EBP, by definition, facilitates the very best qualities of social work when a social worker involves clients in a collaborative process to consider available evidence or lack of evidence" (Regehr, Stern, & Shlonsky, 2007). Specifically, practitioners must take into consideration a transactional or person–environment fit in evaluating a child's interactions with family, their educational setting, and their community, as well as how each of those systems interacts with the other (e.g., how the family interacts with the school, how the school fits into its community; Bowen, 2007).

THE SCHOOL

Given the fact that children spend a large portion of their time in school (7 hours a day, 5 days a week, 9 months a year), it makes sense that the educational community plays a strategic role in the lives of children and their families. Indeed, the school has historically been a location in which social workers felt they could assist in children's health and welfare (Allen-Meares & Montgomery, 2014). Jessie Taft, an early leader in the functionalist movement, wrote: "The only practical and effective way to increase the mental health of a nation is through its school system. Homes are too inaccessible. The school has the time of the child and the power to do the job" (Taft, 1923, p. 398). More recently, Dr. S. Hyman, then director of the National Institute of Mental Health, spoke to the importance of the school system as the context for the identification and treatment of school children needing mental health treatment (Rees, 1997). This perspective has been echoed in the No Child Left Behind Act, the Individuals with Disabilities Education Act, and recent federal reports.

For example, the *Report of the Surgeon General's Conference on Children's Mental Health* (U.S. Department of Health and Human Services, 2000), calls attention to the growing numbers of youth (one in five) suffering needlessly because their emotional, behavioral, and developmental needs are not being met.

It strongly suggests that the nation urgently needs to address the emotional, behavioral, and developmental needs of our youth. In a more recent example, the National Research Council (NRC) and Institute of Medicine (IOM) created the *Committee on the Prevention of Mental Disorders and Substance Abuse Among Children, Youth, and Young Adults: Research Advances and Promising Interventions* and received funding from Substance Abuse and Mental Health Services Administration (SAMHSA), the National Institute of Mental Health (NIMH), the National Institute on Drug Abuse (NIDA), and the National Institute on Alcohol Abuse and Alcoholism (NIAAA). The primary aim of the committee was to provide a report with the best evidence and future recommendations associated with prevention among the nation's youth. Specifically, the

report calls on the nation—its leaders, its mental health research and service provision agencies, its schools, its primary care medical systems, its community-based organizations, its child welfare and criminal justice systems—to make prevention of mental, emotional, and behavioral disorders and the promotion of mental health of young people a very high priority. (O'Connell, Boat, & Warner, 2009, p. xiii)

Even when evidence-based interventions are available for use by providers, however, the report highlights that use of evidence-based interventions remains low (O'Connell et al., 2009). It is also imperative to note, especially when discussing the future of school social work and the populations for which social workers provide services, that cultural barriers may often play a role in the assessment, intervention considerations, and actual provision of social work services in schools.

Although ripe for identifying and treating children who exhibit social and mental health needs, the educational system itself is often at the mercy of institutional, local, or federal pressures or demands. As Sipple (2007) states, "The American public educational system is a beleaguered public institution fraught with relentless criticism," adding that "schools are facing ever-challenging and complex educational situations while at the same time an unprecedented inspection and expectation of practice and performance" (pp. 1–2). Services such as special education are underfunded, and state support is either erratic or dwindling depending on the means

of each state. Schools have to involve multiple stakeholders in governance and decision making, and reform and restructure themselves to obtain excellence and relevancy, and do all of this while being cost-efficient and effective. In addition, today's educational system has numerous responsibilities on its doorstep: federal, state, and local standards, desegregation, student diversity, underachieving students, and what to do with overachievers. Add to this the expectation that physical, social, emotional, and behavioral problems will be addressed, and you have an environment that is overwhelmed with multiple agendas and roles. Clearly, the school and its personnel cannot achieve these multiple and important imperatives in isolation from other relevant and interested parties (e.g., community, parents).

Relevant professional providers located in the community, in collaboration with parents and school personnel, will need to become a part of the solution and respond to the mental health and/or health issues that are going undiagnosed among students. We envision unusual and innovative collaborations and partnerships between the school and its community network of service providers in the decades ahead. Two emerging solutions include school-based health centers, which provide mental and physical health services, and arrangements for "linked" services—that is, services provided via community providers in locations other than school (Brener et al., 2007). Furthermore, knowledge from a cross-section of practices and empirical literatures is needed to arm these professionals with new ways to identify, prevent, and treat mental illness among children and adolescents. "No one discipline has a privileged view of either pathogenesis or treatment of mental disorders" (Rees, 1997, p. 8).

SOME CRITERIA FOR THE SELECTION OF EVIDENCE-BASED INTERVENTION

As reflected in this volume, various interventions have different levels of scientific sophistication or rigor undergirding them. It is important to note that (as already mentioned) in social work, the accepted position on EBP is increasingly one that balances scientific rigor with practice knowledge, clinical judgment, client reaction, common sense, and context (Johnson, 2008). When considering what interventions to use in a school setting, or a school/community provider collaboration, the

following criteria should be taken into consideration (note that this list is not exhaustive).

1. Where does the study fall on the continuum of scientific rigor? Although there are a variety of definitions as to how to identify interventions that have been tested with scientific rigor, recent school-based researchers have offered the following gold standard criteria: two or more randomized studies with (1) attention to the specific client population; (2) use of manualized intervention; (3) measurement of multiple outcomes; (4) statistically significant differences between the treatment and control group in favor of the intervention; and (5) replication of the findings, ideally by an additional researcher and team (Kazdin & Weisz, 2010). Other published standards also have specified that scientifically rigorous evidence include "at least one significant long-term follow-up" (Flay et al., 2005).
2. Is the study transportable? One of the challenges of using evidence-based interventions is transportability—that is, will the outcomes of the scientific study that validated this intervention in a laboratory or a clinical setting be consistent when applied in a school setting (Hoagwood et al., 2001)?
3. Is the study generalizable to multiple populations and/or across multiple sites? With few exceptions, "there are no statistical methods for assessing the generalizability of a program's effects" (Flay et al., 2005). Therefore, practitioners should investigate whether the research was conducted with appropriate subgroups with same or similar results.
4. Are there contextual variables required for optimal outcomes? Services to children/youth are delivered in a variety of unique contexts—schools, child and family agencies, family, correctional systems, and community mental health centers. It is, therefore, urgent for the practitioner to know the context in which the research on the intervention was conducted (Hoagwood et al., 2001). Researchers have found that five factors are most likely to influence the successful implementation of interventions in schools: (1) school organizational structures (e.g., a school-based committee designed to oversee implementation of the intervention); (2) program characteristics (e.g.,

- easy-to-understand intervention materials); (3) fit with the school's policies, goals, and other programs; (4) necessary training and technical assistance; and (5) principal and administrator support (Forman & Barakat, 2011).
5. Does the intervention consider co-occurring disorders? Often the intervention focuses on one specific disorder and does not adequately take into account the possibility of other disorders that are present, or the heterogeneity of the mental health problems broadly defined within childhood and adolescence (Hoagwood, 2003).
 6. Is the intervention age-appropriate and/or developmentally sensitive? For example, an intervention found to be effective with preadolescent youth to reduce depression may well be ineffective for adolescent youths (Hoagwood et al., 2001); similarly, effective treatments used with adults may not affect children in the same manner.
 7. Is the intervention culturally sensitive? Was the target group in the experiment/clinical group or single-case design comparable in terms of race/ethnicity, and so on? As the population of the United States continues to become larger and more diverse, this factor has become increasingly important.

IMPLEMENTATION SCIENCE IN SCHOOLS

With the growing focus on evidence-based knowledge to inform practice, how do practitioners integrate what they know with what science proves to be effective? Restructuring how we deliver interventions in the school setting is a difficult, and often daunting, task that requires shifting *both* practice behaviors and organizational climates (Huang, Hepburn, & Espiritu, 2003). How do we make this move to a more effective service delivery?

Over the past decade, substantial efforts have been devoted to closing the gap between research and practice. Although various terms exist (e.g., translational science, implementation science, dissemination and implementation, knowledge translation, diffusion of innovations), researchers across disciplines are beginning to use the term "implementation science" to refer to a field of study that investigates the "uptake of research findings and evidence-based interventions"

(Forman et al., 2013, p. 79). Different from intervention research, the goal of implementation science is not to identify the effectiveness of an intervention. The goal, instead, is to study factors that influence the uptake of an evidence-based intervention in a particular setting. Although not exhaustive, Table 134.1 highlights many specific factors that often influence implementation. It is important to note that successfully addressing all of these factors is not likely possible. Our hope, however, is that the reader will use the questions presented in this chapter to be more thoughtful about the multiple factors that could influence the successful uptake of evidence-based interventions in the school setting.

In addition to acknowledging factors that influence the translation of evidence-based interventions in to practice settings, attention has also recently been given to studying *implementation strategies*. Implementation strategies are designed to increase the likelihood that an evidence-based intervention is implemented in practice settings. Specifically, an implementation strategy is defined as a "systematic intervention process to adopt or integrate evidence-based [interventions] into usual care" (Powell et al., 2012, p. 69). Researchers have recently identified both ineffective and effective strategies that have important implications for school social workers. For example, passive approaches used in isolation (such as continuing education workshops, results published in journal articles, and presentation at national conferences) are ineffective implementation strategies and do not, by themselves, change provider behavior (e.g., Beidas & Kendall, 2010). Conversely, the results of a recent systematic review highlight that multifaceted implementation strategies, such as a combination of ongoing training, access to supervision, regular treatment fidelity monitoring, expert consultation, and peer support, seem to be more effective (Powell, Proctor, & Glass, 2014).

WHERE DO WE GO FROM HERE?

Social work practitioners, both in and out of school settings, are seeing a definite shift from traditionally accepted practices to the cutting-edge best practices. It is important to remember that whether a practitioner is quick to embrace new and better practices or moves slowly and deliberately toward the future, the ultimate goal of prevention and treatment should be concerned

TABLE 134.1 Factors that Impact the Implementation of Evidence-based Interventions

Implementation Factor	Description
Aligning Priority	Do the goals of the intervention align with the priorities and needs of the school?
Collective Action	How many individuals (e.g., school social workers, teachers, principals, policymakers) need to be collectively involved to successfully implement the intervention?
Complexity	Is the intervention easy to explain, understand, and deliver?
Cost	Is there a balance between the costs of implementing the intervention and the perceived benefits? Are there funds available to the schools to support the costs of the evidence-based intervention?
Duration	How much time will it take to implement the intervention? How much time will be needed to change organizational structure to support the uptake of the intervention?
Divisibility	Can the intervention be tested out in a part of the school or in one classroom? Will the intervention be compromised if only parts of it are implemented?
Flexibility/Adaptability	Can the intervention be adapted to meet the needs of the school and/or the specific population being served?
Magnitude/Disruptiveness	To what extent will implementing the intervention require or inadvertently create change at the organizational, structural, financial, or personal level associated with the schools?
Pervasiveness/Scope/Impact	What kind of an impact will the intervention have on both those delivering the intervention and those receiving the intervention? How will receipt of the intervention affect the landscape of the school?
Presentation	How attractive will the intervention be to those in the school setting? Will the length, clarity, and previous research on successful outcomes affect a school's willingness to consider implementing the intervention?
Relative Advantage or Utility	Is the evidence-based intervention better than what is currently being done in the schools?
Risks	What risks are associated with the changes in the school structure to implement the intervention? What are the risks involved if the intervention is not deemed successful?
Trialability/Reversibility	Can the intervention be tried, stopped, or reversed without substantial risk?
Visibility	Can others observe the intended intervention results?

with the health and mental health of the children practitioners are charged with helping.

The importance of evidence in social work and other health and mental health services has been embraced at the highest levels of

administration. The 2003 Surgeon General's Report (U.S. Department of Health and Human Services [USDHHS], 2003) identified several key goals crucial to the treatment of children with mental health issues as social work and

other social sciences move from the tried and true to the tested and approved. These key goals are as follows.

1. The development, dissemination, and implementation of best practices derived from a scientific evidence base must continue.
2. Knowledge on a variety of factors, including social and psychological development, must be researched “to design better screening, assessment, and treatment tools, and to develop prevention programs” (p. 5).
3. Research on contexts (e.g., school, family, culture) must be supported. This research will assist us in identifying opportunities “for promoting mental health services and for providing effective prevention, treatment, and services” (p. 5).
4. Research to develop and test innovative behavioral, pharmacological, and other “mixed” interventions must also be encouraged.
5. Research on proven treatments, practices, and services developed in a laboratory must be increased, particularly the assessment of their effectiveness in “real-world settings” (p. 5).
6. Similarly, the effectiveness of clinical/ community practices must also be studied in context.
7. Development of model programs should be encouraged, particularly those that can be sustained on a community level.
8. Private and public partnerships are key elements in facilitating the dissemination and cross-fertilization of knowledge.
9. The understanding of children’s mental health care needs must increase. Additionally, training to assist practitioners to address the various mental issues among children with special health care needs and their families is necessary and urgent.
10. Research on factors that facilitate or impede the implementation of scientifically proven interventions must take place as part of the evaluation process.

KEY POINTS TO REMEMBER

School-based practitioners, particularly those involved in services for children and adolescents, who want to successfully take a step toward a future practice undergirded by scientific

evidence, must keep the following in the forefront of their minds.

- The EBP approach is built on a scientific foundation. Implementation of evidence-based theories and interventions into real-world applications involving client input, clinical knowledge, and practice experience will ensure that social workers and other mental health professionals are using the best practices for the children they serve.
- The use of these evidence-based interventions may be useful in a school setting if additional criteria, such as scientific rigor, implementation factors, and implementation strategies, are considered.
- School is one area where a large portion of children may be diagnosed and assisted with mental health or other social issues.
- When appropriate to do so, the creation of partnerships with family, community agencies, and other resources may help sustain change.
- Multifaceted implementation strategies are needed to increase the likelihood that practitioners and schools will adopt evidence-based interventions.

135 Evidence-based Violence Prevention Programs and Best Implementation Practices

Ronald O. Pitner, Roxana Marachi,
Ron Avi Astor, & Rami Benbenishty

GETTING STARTED

Social work as a profession has contributed to the national and international dialogue concerning violence prevention programs in schools (e.g., Astor, Benbenishty, & Estrada, 2009; Astor, Benbenishty, Marachi, & Pitner, 2009; Astor, Guerra, & Van Acker, 2010; Benbenishty & Astor, 2005; Benbenishty & Astor, 2012ab; Benbenishty, Astor, & Estrada, 2008; Chen & Astor, 2012; Green, Furlong, Astor, Benbenishty, & Espinoza, 2011; Marachi, Astor, & Benbenishty, 2013; Shiff, Pat-Horenczyk, Benbenishty, Brom, Baum, & Astor, 2010). School social workers play an increasingly important role in shaping and implementing policy, interventions, and procedures that make U.S. schools safer.

In order to use resources to the best advantage and maximize program effectiveness, it is helpful for school mental health professionals not only to know the dynamics and best approaches for assessing and intervening in school violence but also be familiar with available model programs already studied and found to be effective. This chapter reviews several examples of effective violence prevention programs as well as model school safety programs. It should be noted that large-scale reviews of evidence-based programs have not yielded notable changes to the “model” programs described in previous years. Many of the programs of focus here have undergone years of planning and development and are still refining and increasing their processes of implementation and effectiveness.

One great weakness in establishing evidence-based violence prevention programs is that they are often introduced to schools with a “top-down” approach, ignoring variations in local school contexts. Even model programs that have been demonstrated to be effective in large-scale research studies have a better chance for success at a school if the program matches the needs and values of the community, the school, and the school staff. To assist readers in achieving such a match, we offer monitoring and mapping approaches as a guide to developing a bottom-up program and for tracking program interventions and outcomes.

WHAT WE KNOW

In this section of the chapter, we present examples of some of the most widely researched model school safety programs available to schools and practitioners. Table 135.1 includes the names of the programs, websites where the programs can be explored, program components, outcome measures, and results from studies. We include a more extensive list of websites and resources for each program at the end of the chapter. We also include the names and links to other promising programs that could not be elaborated on in this chapter due to length considerations. The programs listed in Table 135.1 have been rated as “effective” by multiple national organizations. Our designation of effective is a composite of ratings from nine independent scientific

Program	Grade	Participants	Program components	Outcome measures	Results
<p><i>Caring School Community Program (formerly Child Development Project)</i> http://devstu.org/caring-school-community (Battistich, Schaps, Watson, & Solomon, 1996)</p>	K–6th Grades	Evaluation studies are based on 4,500+ students ages 6–12 in 24 elementary schools from diverse districts throughout the United States.	<p>This is a comprehensive model focused on creating a cooperative and supportive school environment. Components include:</p> <ol style="list-style-type: none"> 1) Class Meeting Lessons, which provide teachers and students with a forum to get to know one another and make decisions that affect classroom climate; 2) Implementation of a model that fosters cross-grade “buddying” activities 3) Home-side Activities, which foster communication at home and link school learning with home experiences and perspectives; 4) School-wide community-building activities used to promote school bonding and parent involvement activities such as interactive homework assignments that reinforce the family-school partnership. 	<p>Data were collected after 1 year and 2 years of intervention. Teachers were assessed through four, 90-minute observations and annual teacher questionnaires. Student assessments were self-report surveys of drug use and delinquent behavior.</p>	<p>Results showed that students experienced a stronger “sense of community” and more motivation to be helpful, better conflict-resolution skills, greater acceptance of people who are different, higher self-esteem, stronger feelings of social competence, less loneliness in school and fewer delinquent acts.</p> <p>Over a two-year period, a significant 24% decline was found in student discipline referrals in 20 program schools, while referrals increased 42% in four control schools (Marshall & Caldwell, 2007). http://nrepp.samhsa.gov/ViewIntervention.aspx?id=152 * Evaluating Sources 2,4,5,6</p>

Fast Track Project
(Conduct Problems
Prevention Research
Group, 1992)
www
.fasttrackproject
.org

Initial evaluation participants were at-risk kindergartners identified based on combined teacher and parent ratings of behavior (CBCL). Highest 10% recruited for study. N = 445 intervention children N = 446 control group children

Multiple program components. Weekly enrichment program for high-risk children and their parents. Students placed in “friendship groups” of five to six students each. Discussions, modeling stories and films, role-plays. Sessions focused on reviewing and practicing skills in emotional understanding and communication, friendship building, self-control, and social problem solving. Parents met in groups led by Family Coordinators to discuss parenting strategies, then 30-minute parent-child cooperative activity time, Biweekly home visits Academic tutoring provided by trained tutors in 30-min sessions 3X/week

- **Externalizing Scale of CBCL -oppositional, aggressive, and delinquent behaviors—parents.**
- *Parent Daily Report*—degree to which child engaged in aggressive and oppositional behaviors during previous 24 hrs (Given 3x)
- Child Behavior Change
- Teacher assessment of acting out behaviors in school (Teacher Report Form, Achenbach 1991)
- Scale from the TOCA-R (Teacher Observation of Classroom Adaptation- Revised)
- Authority Acceptance Scale
- Peer rating of aggressive and hyperactive-disruptive behaviors.

Intervention group had higher scores on emotion recognition, emotion coping, and social problem solving compared to control group. They also found lower rates of aggressive retaliation compared to control group.

Direct observation results:

- Intervention group spent more time in positive peer interaction than did the control group.
- Intervention group received higher peer social preference scores than control group.

Long term studies indicate variable findings depending on outcomes. Ten-year longitudinal study examined psychiatric diagnoses for conduct disorder, oppositional defiant disorder, attention deficit hyperactivity disorder (ADHD), and externalizing disorders. Findings suggest that the intervention could be effective in preventing externalizing disorders from developing among youth. (Conduct Problems Prevention Research Group, 1999; 2002; 2010; 2011). <http://www.fasttrackproject.org/publications.php>

organizations that evaluated the most popular school violence prevention programs. Criteria considered in designating a program as effective include (1) evidence of effectiveness based on rigorous evaluations with experimental or quasiexperimental designs; (2) the clarity of the program's goals and rationale; (3) the fit between the program content and the characteristics of the intended population and setting; (4) the integration of the program into schools' educational mission; (5) the availability of necessary information and guidance for replication in other settings; and (6) the incorporation of post-treatment and follow-up data collection as part of the program. We describe in detail four programs listed in Table 135.1.

OLWEUS BULLYING PREVENTION PROGRAM

The Olweus Bullying Prevention Program (OBPP) is a comprehensive, school-wide multi-component bullying reduction and prevention program designed for students in Grades 1–9. It was developed during the 1970s by Dan Olweus to reduce bully and victim problems in Norwegian schools. Since then, it has been translated into more than 12 languages and successfully established in schools in more than 15 countries.

Content

As seen in Table 135.1 under Program Components, the OBPP is implemented at three levels of the school environment—the whole school, classroom, and the individual student. At the school-wide level, the program establishes antibullying policies within the school system. To raise awareness and quantify the prevalence of bullying in the school, administrators distribute an anonymous 29-item student questionnaire to all students. A school conference day about bullying is established to talk about the results of the assessment and discuss interventions. Additionally, schools create an OBPP coordination team in which a representative administrator, teacher, counselor, parent, and student come together to lead the program implementation. The school adopts rules against bullying and explains to students the negative consequences for bullying behavior. All staff receive training to learn about the harmful consequences of bullying, to increase supervision in areas on campus

that are prone to violence, and to provide systematic reinforcement of rules applied to all students.

At the classroom level, students have regular workshops about the harmful consequences of bullying. Students have discussions about bullying and violent behaviors, watch video presentations of bullying situations, write about ways to combat the problem, and engage in role-play. Students are encouraged to increase their knowledge and empathy regarding bullying.

The individual student level involves direct consequences for bullying behaviors. There are focused interventions with those identified as bullies and victims, as well as bystanders. The parents of involved students are given help and support to reinforce nonviolence at home. School mental health workers play an essential role in more serious cases of bullying.

The goal of using interventions through all three levels is to ensure that students are given a consistent, coordinated, and strong message that bullying will not be tolerated. The OBPP teaches students that everyone has a responsibility to prevent bullying, either by refusing to support the bullying behavior or by alerting an adult to the problem.

Theoretical Rationale and Conceptual Framework

The Olweus Bullying Prevention Program is based on a systematic restructuring of the school environment that redirects bullying behavior and provides rewards for more prosocial behavior. The conceptual framework is based on research into the development and modification of aggressive behavior, as well as positive child-rearing dimensions (Olweus & Limber, 2010ab). The goal is to create a school environment that (1) is characterized by adults who are engaged and caring, (2) has firm limits to unacceptable behavior, (3) has consistent responses of no rewards and negative consequences for violent behavior, and (4) has adults who act as authorities and positive role models (Olweus & Limber, 2010ab).

Much of the success of the OBPP can be attributed to it being a school-wide program, so that it becomes an integral part of the school environment. Students and adults participate in most of the universal components of the program. Indeed, teachers, parents, and administrators play an important role in the success of the program. School staff and parents are expected

to (1) become aware of the extent of the bullying problem in their school through assessments, (2) gain an understanding of the significance and harmful effects of bullying, and (3) take an active role in enforcing rules against bullying behavior (Olweus & Limber, 2010b).

Evaluation

The first and most comprehensive evaluation study of this program was conducted with 2,500 students in Norway (also see Olweus, 1993). Since then, however, this program has been implemented and positively evaluated in many countries (e.g., Hunter, Boyle, & Warden, 2007; Limber, 2012; Olweus & Limber, 2010ab; Rigby, 2006). Evaluation of this program has demonstrated significant reductions in bully/victim reports across many cultures. General antisocial behaviors, such as vandalism, fighting, theft, and truancy have been reduced in the program schools. Improvements are also found in classroom culture in that students reported improved order and discipline at school, more positive social relationships, and more positive attitudes toward school and schoolwork.

It is also important to keep in mind that the historical success of a program does not necessarily guarantee its effectiveness. Although international data are strong and consistent in documenting reductions of bullying and victimization, evaluations for U.S. schools have not been as consistent. In a 2011 review of the most recent OBPP studies, The Center for Schools and Communities describes challenges in implementation processes and emphasizes the need for careful attention to program fidelity in order to implement the OBPP model effectively. Vreeman and Carroll (2007) also note that although European studies over the past two decades had demonstrated effectiveness of school-wide bullying prevention programs, similar studies in the United States have not replicated these findings.

“CARING SCHOOL COMMUNITY” PROGRAM (FORMERLY KNOWN AS “CHILD DEVELOPMENT PROJECT”)

The Caring School Community Program (CSCP, formerly called the Child Development Project, or CDP) is an ecological approach to intervention that collaboratively involves teachers, parents, and students working to influence all aspects of

the school community (Developmental Studies Center, 1995). Its main objective is to create a cooperative and supportive school environment for children in Grades K–6. Established in 1981, the CDP strives to foster shared commitment to prosocial, democratic values in two specific ways: through adult guidance and through direct participation by children (Battistich, 2008; Battistich, Schaps, & Wilson, 2004). Throughout this process, children are able to develop a sense that the school community cares for them, and they, in turn, begin to care about the school community. Over the years of program refinement, the Child Development Project has separated out into two distinct yet complementary modules: one entitled “Making Meaning” for the reading comprehension emphasis, and the current program of focus, “Caring School Community,” for classroom climate and school community building. Our review of the research focuses on the Caring School Community component of the original Child Development Project.

Teachers are trained to implement most components of the intervention, and ongoing consultation and support are provided by the Developmental Studies Center. Research indicates that schools should make a minimum of a three-year commitment to the Caring School Community Program if it is to be effective (Northwest Regional Educational Laboratory, 1998). The program has been shown to be effective in both ethnically and socioeconomically diverse settings (Battistich, 2008; Chang & Munoz, 2006; Marshall & Caldwell, 2007).

Theoretical Rationale and Conceptual Framework

The Caring School Community Program’s theoretical framework is guided by research on socialization, learning and motivation, and prosocial development (Battistich, 2008). Its overall objective is for schools to be transformed into caring and supportive communities in which everyone works collaboratively in the learning process. Such a focus is expected to foster children’s intellectual and socio-moral development, self-direction, competence, and belonging (Battistich, 2008). Where these qualities are fostered, children become attached to and invested in the school community, which, in turn, leads them to internalize the school norms. School norms typically promote prosocial activity (e.g.,

concern for others) and proscribe antisocial activity (e.g., drug use or gang activity). The program is based on the idea that children's internalization of school norms will solidify their commitment to the school's community values.

Content

There are four interrelated goals on which the components of the CSCP are based: (1) building warm, stable, supportive relationships; (2) attending to social and ethical dimensions of learning; (3) honoring intrinsic motivations; and (4) teaching in ways that support students' active construction of meaning (Battistich, 2008). These goals are interwoven into the five major components of the original CDP (Table 135.1), which were literature-based reading and language arts, collaborative classroom learning, developmental discipline, parent involvement, and school-wide activities, and which are presented in Table 135.1.

The first three components are all designed for the classroom. The literature-based readings component is most directly focused on teaching for understanding. Thus, the selection of books is designed to help teachers foster a deeper and more empathetic understanding of the readings among the students. The component that involves collaborative learning emphasizes the importance of working with others in a fair and cooperative manner. The final classroom component involves building care and respect for everyone in the classroom community (Battistich, 2008). The two other components' foci go beyond the classroom. Parent involvement is designed to develop meaningful conversations between adults and their children; school-wide activities are focused on allowing participation by all and avoiding hierarchies and competition (Battistich, 2008).

Implementation

At least 80% of the school faculty must support their school's adoption of the CDP for it to be established there. Training is conducted by Developmental Studies Center staff and involves initial consultation and planning to identify needs and goals; a three-day summer institute to orient teachers on the CDP components and materials; three half-day follow-up workshops conducted during the school year; three on-site sessions, each lasting 2.5 days, which include consultation, in-class demonstrations, co-teaching, and planning; and professional development

support kits that can be used to train new staff (Developmental Studies Center, 2004).

Evaluation

Caring School Community strengthens students' sense of their school as a community, their ethical and social resources (e.g., conflict-resolution skills, social problem-solving skills, commitment to democratic values, concern for others), academic motivation (e.g., liking for school), and abstention from drug use and other problem behaviors (e.g., gang-related activity) (Battistich et al., 1996, 1997, 2000; Battistich, Schaps, & Wilson, 2004; Northwest Regional Education Laboratory, 1998; Watson & Battistich, 2006). Recent evaluations have also demonstrated improvements in student behavior with the Caring School Community Program. In a single school district evaluation, program schools demonstrated significant reductions in student discipline referrals (Chang & Munoz, 2006). Marshall and Caldwell (2007) also found a significant 24% decline in student discipline referrals over a two-year period in 20 program schools, while referrals increased 42% in four control schools.

FAST TRACK

The Fast Track Project is a long-term comprehensive intervention that encompasses multiple facets of children's social contexts. The intervention is comprehensive in that it has both universal (school-wide) components and targeted components that attempt to provide focused assistance to children at high risk of antisocial behaviors and their social systems. One of the great strengths of this program is its detailed attention to the intersection of the multiple contexts that contribute to children's developmental outcomes. The Fast Track prevention program aims to improve child competences, parent effectiveness, the school context, and school-home communications with the intention of preventing antisocial behavior across the developmental trajectory.

Theoretical Rational and Conceptual Framework

The developmental theory guiding this intervention addresses the interaction of multiple influences on the development of antisocial behavior.

These various elements include socioeconomic factors, family dynamics, peer influences, school factors, and the child's temperament.

Content

There were four Fast Track sites in the United States, with a total of 891 children (and their families) participating (with nearly equal numbers of at-risk children in both intervention and control groups). The initial sample consisted of children identified as "at risk" by a combination of teacher and parent ratings of their behavior. Children in the intervention group were provided with a host of services, including weekly enrichment programs, involvement in "friendship groups," and sessions in which they were taught and had opportunities to practice social skills. The parents of the intervention children were also provided with family coordinators who conducted biweekly home visits in efforts to enhance their parenting behavior management skills, specifically in the areas of praise, time-outs, and self-restraint. Children in the intervention group were also provided with three 30-minute academic tutoring sessions each week.

When the children in the intervention group reached adolescence (Grades 6–10), the group-based interventions were de-emphasized. However, the intervention retained its curriculum-based parent and youth group meetings to support children in their transition into middle school (Grades 5–7). Individual support was provided for participants and their families to strengthen protective factors and reduce risk factors. The targeted intervention at the adolescent phase focused on academic tutoring, mentoring, home visiting and family problem solving, and supporting positive peer group involvement. To address the multiple contexts in the adolescents' lives, the school tried to establish relations with the community agencies that served the participants.

Fast Track also included an important universal component for children in the first through the fifth grades in the target schools. This school-based intervention consisted of teacher-led curricula called "PATHS" (Promoting Alternative Thinking Strategies), designed to provide children with strategies in understanding the development of emotional concepts, social understanding, and self-control. Because PATHS has been evaluated separately and shown to have independent positive effects, we will present it

separately in the next section. Some schools may choose to adopt only sections of the overall program, such as PATHS.

Evaluation

Fast Track is one of the more rigorously evaluated comprehensive violence prevention programs and has become widely known as one of the leading models of an effective approach to prevention of antisocial behaviors in youth. As shown in Table 135.1, evaluation studies of Fast Track have revealed positive outcomes for program participants. The evaluations on the initial cohort of youth selected for the study have spanned over 10 years and have continued to yield positive findings, with over 80% of the original sample remaining (Conduct Problems Prevention Research Group, 2011). In addition to those differences between treatment and control students highlighted in the table, the prevention revealed statistically significant improvements in the targeted children's social-cognitive and academic skills, as well as reductions in their parents' use of harsh discipline. The intervention children also demonstrated considerable behavioral improvements at home, in the classroom, and on the playground during and following their elementary school years. In addition to these behavioral improvements, the intervention children were at a reduced risk of being placed in special education classes than children in the control conditions. The findings generalized across ethnicity, gender, and a host of child and family characteristics.

PROMOTING ALTERNATIVE THINKING STRATEGIES PROGRAM

The Promoting Alternative Thinking Strategies Program (PATHS) is the classroom curriculum component of the Fast Track intervention program. We present it separately because PATHS has been adopted and studied independently of Fast Track. PATHS was designed to promote emotional and social competence and to reduce aggression and other behavior problems in children in Grades K–5 (Conduct Problems Prevention Research Group, 2010a). PATHS focuses on four domains related to school success: (1) prosocial behavior and friendship skills, (2) emotional understanding and self-control, (3) communication and conflict resolution, and (4) problem-solving skills

(Conduct Problems Prevention Research Group, 2010a; 2010b). PATHS provides teachers and counselors with training, lesson modules, and ongoing consultation and support. Additionally, parents receive information and activities to complete with their children.

PATHS can be used with all elementary school-age children, and ideally it should be ongoing, beginning in kindergarten and continuing through fifth grade. It has been field-tested and researched in regular education classroom settings and in settings that serve special needs students, such as the deaf, hearing-impaired, learning disabled, emotionally disturbed, mildly mentally delayed, and gifted (see Greenberg & Kusche, 1998; Greenberg, Kusche, Cook, & Quamma, 1995; Riggs, Greenberg, Kusché, & Pentz, 2006).

Theoretical Rationale/Conceptual Framework

PATHS is based on five conceptual models (Greenberg, Kusché, & Mihalic, 1998). First, the ABCD (affective-behavioral-cognitive-dynamic) model of development promotes skills that are developmentally appropriate. The second model is an eco-behavioral system orientation that focuses on helping the teacher use these skills to build a healthy classroom atmosphere. The third model involves neurobiology and brain organization for cognitive development. The fourth is psychodynamic education that was derived from developmental psychodynamic theory. Finally, the fifth model includes psychological issues related to emotional awareness or emotional intelligence. These conceptual models come together in this curriculum to provide a comprehensive and developmentally based program that addresses students' cognitive processes, emotions, and behaviors.

Content

The PATHS curriculum (Greenberg et al., 1998) is taught three times a week for a minimum of 20–30 minutes a day. The curriculum contains four units with a total of 119 lessons in each unit. They consist of the following: (1) A “Turtle” unit focusing on classroom behavior, emotional literacy, and self-control; (2) “Feeling and Relationship Unit” focusing on building self-esteem and social competence; (3) a “Problem-Solving Unit” with instruction on the 11-step model of social problem solving and positive peer relations; and (4) a

“Supplementary Lessons Unit” containing 30 lessons that delve more deeply into PATHS concepts. The lessons are age-appropriate, and can be seen in Table 135.2. The lessons for third-grade students match developmental stages and cover the conceptual domains of self-control, emotional understanding, self-esteem, peer relations, and problem solving. (Lesson 93, presented in detail in Table 135.2, covers self-control and problem solving.)

The PATHS curriculum includes comprehensive materials, and the Basic PATHS Kit (Grades 1–5) includes an instructor's manual, five curriculum manuals, feelings photographs, feelings face cards, two wall charts, and four full color posters. The Turtle unit (for kindergarten classrooms) includes an instructor's manual, curriculum manual, turtle puppet with pad, turtle stamp, and poster. Teachers receive on-site training and technical assistance to ensure effective implementation of the program.

Evaluation

PATHS has been evaluated in various research studies using randomized control groups and was found to be effective. As seen in Table 135.1, PATHS has been found to be a model or effective program by at least six groups that review violence prevention programs nationwide for effectiveness. An overview of results from all trials reveals a reduction in aggressive behavior, conduct disorder, and violent solutions to social problems. In addition, results found an increase in self-control, vocabulary for emotions, cognitive skills, ability to tolerate frustration, and to effectively use conflict-resolution strategies (SAMHSA Model Programs, 2003). The findings have been consistent across teacher reports, self-reports, and child assessments and interviews. PATHS remains among the highest rated social-emotional learning programs and is nationally and internationally recognized for its strong evidence base, theoretical design, and clarity of implementation. It received a perfect score for program materials and a nearly perfect score for dissemination according to the SAMHSA's National Registry of Evidence-Based Programs and Practices and had the highest possible ratings according to the Center for the Study and Prevention of Violence.

The PATHS program has also been recognized for its effectiveness by the National Institute on Drug Abuse (NIDA) and the Office of Juvenile Justice and Delinquency Prevention (OJJDP).

TABLE 135.3 PATHS Learning Self-Control Volume 5, Lesson 93

Introduction	“Today I’m going to tell you a story about a boy who had problems, but he learned a new way to help himself.”
Story: “Thomas in Control”	This is a story about a boy who did not like to go to school. Thomas felt very upset about going to school. He wanted to run outside and play with his toys or ride his bike or watch television or play a game. Thomas did not like to sit quietly. It was hard for him to pay attention when the teacher or the other kids were talking in class. Instead, Thomas would tease whoever was sitting beside him, by grabbing their pencils and books, by making faces at them, or by whispering to them. The other kids would get angry at Thomas when he bothered them and would yell at him or would do some of the same things back. Then everyone would get caught and would get into trouble. That’s why some of the kids thought that Thomas was a troublemaker. Sometimes when they went out to the playground at recess, the other kids would still be mad at Thomas and they would get into a fight. All of this hate and resentment made Thomas feel very uncomfortable inside. One day when he was feeling his worst, the playground teacher told Thomas that he had to go to the principal’s office because he hadn’t been following the playground rules. “You know,” said the principal in a very calm voice, “you have a very big problem, but I’ll share a secret with you. You already have the answer to your problem with you. You carry it with you everywhere you go. It’s your ability to think. Whenever you feel upset, when you are angry or frustrated, you can use your mind and think. You can stop, take a long, deep breath, and say the problem and how you feel. When you remind yourself to stop and calm down, it’s like taking a rest for a minute. You can rest until you feel calm. That is how you can control yourself. And when you can control yourself, then people will say, “Thomas has good self-control. He thinks before he does something that will cause problems”. The principal showed Thomas the 3 steps for Calming Down. Then the principal reminded Thomas that the next time he felt upset or angry, he could think about the Control Signals and could calm himself down. Thomas liked the idea and wanted to try it himself. He wanted to do well in school, he wanted his teacher to like him, and he especially wanted to make friends....
On board	Begin drawing on the chalk board. Feelings: comfortable and uncomfortable/ Behavior Ok and not Ok.
Discussion	Ask students to name the different feelings and behavior that Thomas felt and list them under the appropriate categories. Ask them to discuss the relationships between these feelings and behaviors if they are able to do so. Ask students to name the kinds of things that bug them in the classroom, playground, lunchroom, etc., and list them in the categories. This will help students become aware of what they do that bothers others. Ask students if using the 3 Steps to Calm Down would help with any of the things they listed on the board overhead.

Tools and Practice Examples

Learning Self-Control, Volume 5—Supplementary Lesson 93, Grade 3

In the PATHS curriculum, each unit builds on the preceding units. Table 135.3 consists of an excerpt from Supplementary Lesson 93 and is intended for third-graders.

The objective of this lesson is to discuss the idea of self-control as an internalized process. It emphasizes the concept of using thinking to

control one’s behavior and distinguish between feelings and behaviors. The teacher reads a story about a boy named Thomas who had problems with self-control, was angry, and would get into fights with other children. Throughout the story, students learn the three steps for calming down to gain control of their behavior. The lesson is followed by the teacher drawing a hierarchy of feelings and behaviors on the board and asking questions to encourage classroom discussion. Students are

encouraged to talk about how they felt when they acted without thinking first, and to say whether things got out of control and how they felt about the outcome. This lesson teaches students anger management and problem-solving skills through a developmentally appropriate story that is easy to relate to and that facilitates discussion.

MONITORING AND EVALUATING VIOLENCE PREVENTION PROGRAMS

A review of the school safety literature strongly suggests that model school safety programs should be developed and implemented in a process that ensures their relevance and applicability to each specific site. These are important assumptions of the programs described in this chapter:

- Fitting a program to a school involves *grassroots* participation.
- Students and teachers in the school need to be *empowered* to deal with the problem.
- *Democracy* is the core of a good school safety program.
- Schools should demonstrate a *proactive vision* surrounding the violence problem in their school.

Implementing interventions or components of any model program is likely to be slightly different for every school. An eye toward the overall assumptions and flexibility should enable each school to adapt the program or general principles to its unique demographic, philosophical, and organizational needs. Several resources are provided at the end of the chapter to support implementation efforts of programs. It is critically important not only to pay attention to the outcome evaluations but also to keep in mind the importance of program fidelity, advocacy, and support from administration, as well as commitment to the program adoption process. Cissner and Farole (2009) highlight lessons learned from process evaluations of program implementation in the field of juvenile justice that can apply just as readily to schools.

DATA AND PROGRAM EVALUATION

Numerous new programs and systems are designed to create data-driven decision-making processes within districts and schools. One of

the more popular programs to address academic learning is Response to Intervention (RTI), whereby students are identified early, provided with intervention, measured for improvement, and referred to special services if there is not adequate “response” to the intervention. Although the programs highlighted in this section were not designed with specific reference to RTI, they do align with the same philosophy of providing early, effective assistance to children who are struggling. Further, each of the programs supports data-driven processes to continually improve the effectiveness of intervention efforts.

An important element of successful school safety programs is the ongoing and interactive use of data. This perspective proposes that the continuous and ongoing analysis and interpretation of data is an essential part of the intervention process. Data are used to create awareness, mobilize various school constituents, assess the extent of the problem, plan and implement interventions, and conduct evaluations. Information is provided on a continuous basis to different groups in each step of the intervention process. Unfortunately, many U.S. schools purchase evidence-based programs but do not collect any data about their own district or school (Benbenishty & Astor, 2012ab; Benbenishty, Astor, & Estrada, 2008).

The process of building and implementing school safety programs is continual and cyclical, always changing to respond to new circumstances and emerging needs. Hence, the evaluation of the program’s progress becomes a reassessment of the situation, leading to a new cycle of awareness building, planning, modifying, and evaluating. A school’s failure to gather site-specific and comparative data could be a significant obstacle in (a) assessing whether that specific school has a violence problem, (b) adapting a school safety program, and (c) evaluating the implementation process and outcomes of the program.

Monitoring can help create a “whole-school response” and help the school identify, create, and/or adapt programs to the site. Monitoring is the ongoing process of collecting and using data to shape, fit, match, and evaluate the intervention. The value of monitoring comes from the two levels of information processing involved: description and comparison. The description of basic frequency of certain behaviors may be quite instructive. For example, it is helpful to know how many weapon-related events or sexual assaults occur at a specific school.

Using Comparisons

In general, comparisons enhance the value of information by putting it into context. In order to adapt a program, it is imperative to ascertain (a) which acts are more problematic than others, (b) which grade levels are victimized more, and (c) how violence levels in a specific school compare over time and for different ethnic, age, and gender groups. For example, if bullying is not a major problem in the school, it does not make sense to adopt an antibullying program. Perhaps bullying is a problem only in one grade level within a large school, whereas other forms of violence are problems in other grades. Though these concerns may sound like common sense, very few schools actually collect systemic information to ascertain the extent of the school safety problem. Currently, many districts and schools across the United States are purchasing expensive violence prevention programs targeting a specific form of violence (e.g., sexual harassment, bullying, weapon use) without data about the extent of the problem in their schools. This creates a chain of difficulties through the implementation process and later in the evaluation of the program. If the problem was never established, it is difficult to know whether the program ever worked. Hence, it is important to examine levels of violence over time.

Using Mapping as a Monitoring Tool

Mapping is a qualitative tool that can help monitor and generate the kind of comparisons just discussed. Mapping does not require extensive training and can provide valuable information that helps implement, monitor, and assess the ongoing health of a program. This procedure is designed to involve school constituents by revealing how forms of violence within a school building interact with locations, patterns of the school day, and social organizational variables (e.g., teacher–student relationships, teachers’ professional roles, and the school’s organizational response to violence; for more detail see Astor, Guerra, & Van Acker, 2010; Astor & Meyer, 1999; Astor, Meyer, & Behre, 1999; Astor, Benbenishty, & Meyer, 2004; Astor, Meyer, & Pitner, 2001; Benbenishty & Astor, 2012ab; Pitner, Astor, & Benbenishty, in press). An important goal of this procedure is to allow students and teachers to convey their personal theories about why specific locations and times in their schools are more dangerous. This process greatly facilitates the implementation and evaluation of the model programs reviewed in the first sections of this chapter.

Step-by-Step Instructions for Mapping

Mapping, interviews, and interventions. The first step in this assessment procedure is obtaining a map of the school. Ideally, the map should contain all internal school territory, including the areas surrounding the school and playground. In communities where the routes to and from school are dangerous, a simple map of the surrounding neighborhood may be added to the assessment process. The focus groups should begin with the facilitator distributing two sets of identical school maps to each individual.

Map A and B: Two photocopied maps of the school are needed for each student and teacher. One map should be used to determine where students and teachers think the most events involving violence occur. Participants should also be asked to identify the locations (on the maps) of up to three of the most violent events that have occurred within the past academic year. Next to each marked event on the map, participants should be asked to write the following information: (1) the general time frame of the event (e.g., before school, after school, morning period, afternoon period, evening sports event, between classes), (2) the grade and gender of those involved in the violence, and (3) their knowledge of any organizational response to the event (e.g., someone was sent to principal’s office, suspended, sent to peer counselor, nothing done). On the second map, members should be asked to circle areas or territories that they perceive to be unsafe or potentially dangerous. This second map provides information about areas within the school that participants avoid or fear even though they may not possess knowledge of a particular event.

Discussion of violent events and areas. The first part of the group discussion should center on the specific events and the areas marked as unsafe or dangerous on these personal maps. We have asked questions such as “Are there times when those places you’ve marked on the maps are less safe?” “Is a particular group of students more likely to get hurt there?” and “Why do you think that area has so many incidents?” The overall purpose of the group interviews is to explore why bullying or victimization occurs at those specific times and in those specific spaces. Consequently, the interviews should also focus on gathering information regarding the organizational response to the event (e.g., “What happened to the two students after the event?” or “Did the hall monitors intervene

when they saw what happened?”), procedures (e.g., “What happens when the students are sent to the office after a fight?” “Did anyone call the parents of the bully or victim?”), follow-up (e.g., “Do the teachers, hall monitors, and/or administrators follow up on any consequences given to the students?” or “Did anyone check on the welfare of the victim?”), and clarity of procedures (e.g., “Does it matter who stops the bullying?” e.g., a volunteer, security guard, teacher, or principal).

Interviewers should also explore participants’ ideas for solutions to the specific violence problems (e.g., “Can you think of ways to avoid bullying or victimization in that place?” or “If you were the principal, what would you do to make that place safer?”). In addition, the interviewer should explore any obstacles that participants foresee with implementation (e.g., “Do you think that type of plan is realistic?” “Has that been tried before? What happened?” or “Do you think that plan would work?”). Such obstacles could range from issues related to roles (e.g., “It’s not my job to monitor students during lunch.”) to discipline policy and issues of personal safety (e.g., “I don’t want to intervene because I may get hurt.”).

In schools that have already started model programs designed to address school violence, specific questions should be asked about the effectiveness of those interventions, why they work or do not work, and what could be done to make the current measures more effective. We recommend that the interviewer ask both subjective questions (e.g., “Do you think the antiviolence program is working?” “Why do you think it works, or why does it not work?”), as well as specific questions related to the reduction of victimization (e.g., “Do you believe the antiviolence program has reduced the number of fights/name calling [or any other type of violence the school is interested in preventing] on the playground?” “Why or why not?”).

Transferring all of the reported events onto one large map of the school enables students and staff to locate specific “hot spots” for violence and dangerous time periods within each individual school. The combined data are presented to all school constituents, and they are asked to once again discuss and interpret the maps. Teachers and students use the maps and interviews to suggest ways to improve the settings and what aspects of the program are working or not working. For example, in one school, events were clustered by time, age, gender, and location. In the case of older students (eleventh- and twelfth-graders), events were clustered in the

parking lot outside of the auxiliary gym immediately after school, whereas for younger students (ninth- and tenth-graders), events were reported in the lunchroom and hallways during transition periods. For this school, the map suggested that interventions be geared specifically toward older students, directly after school, by the main entrance, and in the school parking lot. Students and teachers agreed that increasing the visible presence of school staff in and around the parking lot for the 20 minutes after school had great potential for reducing the number of violent events. Younger students were experiencing violence mainly before, during, and after lunch, near the cafeteria. Many students expressed feelings of being unsafe between classes in the hallways. This school already had an antibullying program, and it was able to incorporate this specific type of intervention into existing activities designed to stem school violence.

Compiling all the interview suggestions into themes is an important second step in adapting context-relevant interventions. Students, teachers, and administrators may have differing viewpoints regarding the organizational response of the school to a violent incident. Relaying the diversity of responses to students, teachers, and administrators can provide an opportunity for reflection and may generate ways to remedy the violence problem in certain situations. When the data are presented to students, teachers, and administrators, they can center their discussions on why those areas are dangerous and what kinds of interventions could make the location safer. Mapping methods provide data-based approaches to gathering information about bullying/victimization in schools. Moreover, they provide site-specific information, which makes it easier for schools to address these problems.

Identifying specific target groups for interventions is another way data can and should be used. A school could use this monitoring system to identify particular problem areas in their school. They could then track progress in reducing violence in these locations over time and by different groups.

In recent years, the Geographical Information Systems (GIS) and Worldwide Web technology provide many more opportunities for mapping violence-related issues both within schools and in the routes to and from schools. For instance, the Los Angeles Unified School district is experimenting with a web-based application used to present students with maps of their school and

of its surrounding neighborhood. Students indicate important information on the map, such as places where they hang out, see violent incidents, or avoid because they fear they would get hurt. These maps are then presented with color codes that highlight information that is important for planning interventions focused on dangerous locations.

KEY POINTS TO REMEMBER

Based on our review of programs, it appears that successful school-wide intervention programs have the following core underlying implementation characteristics.

- They are comprehensive, intensive, ecological, and require buy-in from school and community.
- They raise the awareness and responsibility of students, teachers, and parents regarding the types of violence in their schools (e.g., sexual harassment, fighting, and weapons use).
- They create clear guidelines and rules for all members of the school community.
- They target the various social systems in the school and clearly communicate to the entire school community what procedures should be followed before, during, and after violent events.
- They focus on getting the school staff, students, and parents involved in the program.
- They often fit easily into the normal flow and mission of the school setting.
- They use faculty, staff, and parents in the school setting to plan, implement, and sustain the program.
- They increase monitoring and supervision in nonclassroom areas.
- They include ongoing monitoring and mapping, which provide information that schools can use to tailor a program to their specific needs and increase its chance of success.

136 Solution-focused Brief Therapy Interventions for Students at Risk to Drop Out

Cynthia Franklin, Johnny S. Kim,
Michael S. Kelly, & Stephen J. Tripodi

Solution-focused brief therapy (SFBT) is a popular approach used with students in school settings by school social workers. A review of the literature reveals that solution-focused brief therapy has been increasing over the past decade in school settings and applied to a number of problems including student behavioral and emotional issues, academic problems, social skills, and drop-out prevention (Berg & Shilts, 2005; Franklin, Biever, Moore, Clemons, & Scamardo, 2001; Franklin & Hopson, 2009; Franklin, Streeter, Kim, & Tripodi, 2007; Kral, 1995; Metcalf, 1995; Murphy, 1996; Murphy & Duncan, 2007; Sklare, 1997; Webb, 1999). Because of its brief nature and flexibility in working with diverse problems, SFBT can be a practical intervention approach for school social workers to use (Franklin et al., 2001; Kelly, Kim, & Franklin, 2008; Newsome, 2004). This chapter describes SFBT and the growing research evidence available, and further illustrates the steps and techniques involved in implementing this approach.

SOLUTION-FOCUSED BRIEF THERAPY

Solution-focused Brief Therapy differs in many ways from traditional approaches to treatment by focusing on clients' strengths and previous successes rather than dwelling on the current problem. There is a focus on working from the client's understandings of her/his concern and what the client might want to be different in his/her life. The basic tenets that inform Solution-focused Brief Therapy are as follows:

- It is based on solution-building rather than problem-solving.
- The therapeutic focus should be on the client's desired future rather than on past problems or current conflicts.
- Clients are encouraged to increase the frequency of current useful behaviors.
- No problem happens all the time. There are exceptions—that is, times when the problem could have happened but did not—that

can be used by the client and therapist to co-construct solutions.

- Therapists help clients find alternatives to current undesired patterns of behavior, cognition, and interaction that are within the clients' repertoire or can be co-constructed by therapists and clients as such.
- Differing from skill-building and behavior therapy interventions, the model assumes that solution behaviors already exist for clients.
- It is asserted that small increments of change lead to large increments of change, and this may lead to a solution.
- Clients' solutions are not necessarily *directly* related to any identified problem by either the client or the therapist but are created through the process of setting goals and deciding on specific ways to achieve those goals.
- Therapists use a purposeful conversational approach in building solutions with clients. The conversational skills used in SFBT focus on solution-talk and co-construction of communication, which means social workers ask questions and focus on specific words that clients say in order to shape meanings and interactions toward solutions. Co-construction and other core communication processes used in SFBT are described in detail within a treatment manual that has been developed by international researchers and experts on solution-focused practice. This treatment manual is available at the Solution-focused Brief Therapy Association website (sfbta.org).

The development of SFBT originated in the early 1980s at the Brief Family Therapy Center in Milwaukee with two social work practitioners, Steve de Shazer and Insoo Kim Berg, as well as a group of practitioner/researchers who were studying therapies behind a one-way mirror. Some important researchers were involved in the early study of this approach, such as Wally Gingerich, who also did the first systematic review of SFBT research (Gingerich & Eisengart, 2000). Berg and de Shazer wanted to answer the question, "What works in therapy?" These practitioners were interested not only in the change process but also in how to help clients change efficiently and effectively. SFBT was influenced by the Mental Research Institute Brief Therapy model and the family systems therapy approaches of the day and had

theoretical roots in ecosystems theories. Later, in the 1990s, SFBT became strongly associated with social construction models and social constructivist views within family systems therapies. Readers are referred to other chapters in this volume that review brief therapy, family systems, and constructivist theoretical perspectives and practice approaches in more detail. SFBT became popular and widely used in mental health practice in the 1990s mostly due to the demands for briefer counseling interventions. SFBT has grown exponentially since that time with over 50 books in print on SFBT, SFBT associations in over 10 countries, and several annual national and international conferences devoted to SFBT (Kelly et al., 2008).

Solution-focused Brief Therapy's Emergence in Schools

Practitioners began to use the SFBT techniques in schools during the 1990s with the first publications and small research studies appearing in print around the mid-1990s (e.g., Kral, 1995; LaFountain & Garner, 1996; Metcalf, 1995; Murphy, 1996; Sklare, 1997). Since that time, the SFBT literature for school practitioners across disciplines has been growing (e.g., Berg & Shilts, 2005; Franklin & Gerlach, 2007; Kelly et al., 2008; Metcalf, 2008; Murphy, 2008; Murphy & Duncan, 2007; Webb, 1999) with increasing reports of SFBT interventions and programs being implemented in schools in both the United States and Europe (Kelly et al., 2008).

School-based interventions may be implemented at various levels of the school's programs and with different groups within the school environment. For example, the techniques of SFBT have been used to:

- Help at-risk students in individual, group, and family interventions (Murphy, 2008).
- Coach teachers in using solution-building talk (see the WWOW program, Kelly et al., 2008).
- Change interactions among parents, teachers, and students, such as parent/teacher meetings (Metcalf, 1995, 2008).
- Change the school culture, such as when an entire school adopts the solution-focused change philosophy and trains all staff (including teachers and principals) in SFBT techniques (Franklin & Streeter, 2003, cited in Kelly et al., 2008).

Franklin and Gerlach (2007) summarize reasons why SFBT may be a good match for public school settings. First, public schools frequently serve high-risk populations, such as homeless teens, immigrants, and teen parents. Many students referred for services in the school may also be considered mandated or involuntary clients, and SFBT is an approach to helping that was developed for the purposes of being effective with at-risk populations. Second, schools often face students with multiple challenges, yet have little time or money for therapy and require very practical solutions to the day-to-day issues that may prevent the educational achievement of a student. SFBT focuses on practical goals using active listening and strengths assessment and facilitates collaboration with others involved in the student's life. Finally, SFBT is very flexible and open to the use of techniques from other therapeutic interventions if they are used thoughtfully to accommodate the student's goals (Franklin & Gerlach, 2007).

THE GROWING EMPIRICAL SUPPORT FOR SOLUTION-FOCUSED BRIEF THERAPY IN SCHOOLS

Kim and Franklin (2009) recently reviewed the literature on SFBT in schools within the United States. This systematic review focused on examining the most rigorous studies that used experimental designs, with standardized measures, and met criteria for a solution-focused intervention. Table 136.1 summarizes the results of that review.

Table 136.1 indicates that one experimental design study, six quasiexperimental design studies, and one single-case design study on SFBT in schools have been published since 2000. Most of these studies have arrived within the past two years, perhaps suggesting that more school researchers are conducting outcome studies on SFBT.

Kim and Franklin's (2009) review indicated that SFBT is a promising and useful approach in working with at-risk students in a school setting. Some of the positive findings from the systematic review are as follows:

- Helps students reach goals
- Helps students alleviate their concerns
- Improves academic achievement (e.g., credits earned)

- Helps students reduce the intensity of their negative feelings
- Helps students reduce drug use
- Helps students manage their conduct problems (Franklin et al., 2001; Franklin & Gerlach, 2007; Froeschle, Smith, & Ricard, 2007; Kelly et al., 2008; Newsome, 2004).

The Kim and Franklin (2009) systematic review revealed some mixed results, but enough positive differences were found favoring SFBT to view it as a promising intervention for school settings. The effect sizes calculated by the authors and reported in the individual studies also show SFBT to be promising, with most studies having medium and some large effect sizes.

SOLUTION-BUILDING HELPING PROCESS AND TECHNIQUES

SFBT is a strengths-based approach that helps school social workers build solutions together with their students. The solution-focused helping process, often referred to as solution building, is a purposeful conversation resulting in changes in perceptions and social interactions. The solution-building process or conversation is often contrasted with the problem-solving process. However, Harris and Franklin (2008) have pointed out that it shares values and some similarities with social problem solving and task-centered types of problem solving. The differences, however, are also noteworthy. Approaches to problem solving, for example, focus on the resolution of problems through understanding the problems, enumerating alternatives that can solve the problems, and choosing an alternative. In contrast, solution building changes the way people think about presenting problems and identify future behaviors and tasks that have the potential to accomplish desired goals and outcomes (De Jong & Berg, 2008). SFBT has developed a number of techniques that are used in solution building to guide students in the change process. Box 136.1 defines and illustrates several of the counseling techniques.

SFBT has developed its own structure for social work interviews that is used to guide the change process. The session may be thought of as being a continuous process of elements that are structured in process sequences. De Jong (Chapter 35) defines this structure of the solution-focused interview and the follow-up sessions. Thinking

TABLE 136.1 Solution-focused Brief Therapy Studies in Schools

Study	Design	Outcome Measure	Sample Size	Sample Population	Results
Springer, Lynch, Rubin (2000)	Quasiexperimental	Hare Self-Esteem Scale	10	Hispanic elementary students	SFBT group made significant improvements on the Hare Self-Esteem Scale, whereas the comparison group's scores remained the same. However, no significant differences were found between the SFBT and comparison groups at the end of the study on the self-esteem scale.
Franklin et al. (2001)	Single case	Conners' Teacher Rating Scale	7	Middle school students 10–12 years old	Five of seven (71%) improved per teachers report.
Newsome (2004)	Quasiexperimental	Grades; attendance	52	Middle school students	Statistically significant results with SFBT group increasing mean score of 1.58 to a mean score of 1.69 while grades for the comparison group decreased from a mean score of 1.66 to a score of 1.48. No difference on attendance measure.
Corcoran (2006)	Quasiexperimental	Conners' Parent Rating Scale; Feelings, Attitudes, & Behaviors Scale for Children	86	Students aged 5–17 years	No significant differences between groups, with both improving at post-test. This lack of difference may be because the comparison group received treatment as usual, which had many cognitive-behavior therapy components that have been empirically validated.
Franklin, Moore, & Hopson (2008)	Quasiexperimental	Child Behavior Checklist (CBCL)—Youth Self Report Form—Internalizing, & CBCL Externalizing; Teacher's Report Form—Internalizing & Externalizing Score	67	Middle school students	Internalizing & Externalizing score for the Teacher Report Form showed SFBT group declined below clinical level by post-test and remained there at follow-up while comparison group changed little. Internalizing score for the Youth Self Report Form showed no difference between the groups. Externalizing score showed SFBT group dropped below the clinical level and continued to drop at follow-up.

Franklin, Streeter, Kim, & Tripodi (2007)	Quasiexperimental	Grades; attendance	85	At-risk high school students	SFBT sample had statistically significant higher average proportion of credits earned to credits attempted than the comparison sample. Both groups decreased in the attendance mean per semester; the comparison group, however, showed a higher proportion of school days attended to school days for the semester. Authors suggested that the attendance between groups may not be a fair comparison because the SFBT group worked on a self-paced curriculum and could decrease their attendance when completed.
Froeschle, Smith, & Ricard (2007)	Experimental design	American Drug & Alcohol Survey Substance Abuse; Subtle Screening Inventory Adolescent version 2; Knowledge exam on physical symptoms of drug use; Piers-Harris Children's Self-Concept Scale version 2; Home & Community Social Behavior Scales; School Social Behavior Scales, 2nd ed.; grade point average	65	8th grade females	Statistically significant differences were found favoring SFBT group on drug use, attitudes toward drugs, knowledge of physical symptoms of drug use, and competent behavior scores as observed by both parents and teachers. No group differences were found on self-esteem, negative behaviors as measured by office referrals, and grade point averages.

Box 136.1 Solution-focused Brief Therapy Techniques for Solution-focused Schools

Exception Questions—Questions to explore past experiences in a student’s life when the student’s problem might reasonably have been expected to occur but somehow did not or was less severe.

- *When does the problem not occur?*
- *What was different about those times when things were better between you and your teacher?*
- *Even though this is a very bad time, in my experience, people’s lives do not always stay the same. I will bet that there are times when the problem of being sent to the principal’s office is not happening, or at least is happening less. Please describe those times. What is different? How did you get that to happen?*

Relationship Questions—Relationship questions allow students to discuss their problems from a third person point of view. This sequence of questions makes the problem less threatening and allows the school social worker, counselor, or teacher to assess the student’s viewpoints, and the student to practice thinking about the problem from the viewpoint of others.

- *What would your teacher say about your grades?*
- *What would your mother say?*
- *If you were to do something that made your teacher very happy, what would that be?*

Scaling Questions—Scaling questions are a sequence of questions used to determine where students are in terms of achieving their goals. The school social worker has the option to use scaling questions to quantify and measure the intensity of internal thoughts and feelings along with helping a student anchor reality and move forward from his or her goals (Franklin & Nurius, 1998; Pichot & Dolan, 2003). Numerous variations of this technique can be used, such as asking for percentages of progress, or using smiling and frowning faces for small children.

- *On a scale from one to ten, with one being the lowest and ten being the highest, where would you rate yourself in terms of reaching your goals that you identified last week?*
- *On a scale from one to ten, with one being that you never go to class and ten being that you have perfect attendance, where would you put yourself on that scale? What would it take to move up two numbers on the scale?*
- *On a scale of one to ten with one being that you are getting into trouble every day in the class and ten being that you are doing all your school work and not getting into trouble, where would you be on that scale?*

The Miracle Question—The miracle question strengthens the student’s goals by allowing them to reconstruct their story, imagining a future without the student’s perceived problem (Berg & De Jong, 1996; De Jong & Berg, 2001). Additionally, the school social worker uses the miracle question to help students identify ways that the solution may already be occurring in their lives.

Now, I want to ask you a strange question. This is probably a question no one has asked you before. Suppose that while you are sleeping tonight a miracle happens and the problem that brought you here is solved. However, because you are sleeping, you don’t know that the miracle has happened. So, when you wake up tomorrow morning, what will be the first thing you notice that is different—that will tell you a miracle has happened and the problem that brought you here is solved?

Goal Setting/Goaling—The act of setting goals is used as a verb in SFBT, and is sometimes referred to in the literature as “goaling.” Goals are considered the beginning of behavior change, not the end. The school social worker and the student negotiate small, observable goals, set within a brief time frame, that lead to a new story for the student. A goal should describe what a student is to do instead of describe the problem behavior. The negotiation of goals should start immediately between the school social worker and student.

Break for Reflection—Taken near the end of the session to help formulate a positive ending to the session.

Compliments and a Set of Take-away Tasks—Continuous affirmation of the student’s strengths and character and suggested behavioral tasks that reinforce client solutions.

You did that?

I am amazed.

How did that make you feel?

I bet your mother was pretty proud of you!

That seemed to work! Do you think you could do that again?

Source: from Franklin, Kim, & Tripodi, 2006.

of student interviews in this way may help the school social worker guide the client toward a purposeful solution-building conversation and offer a framework for how to apply the various techniques of the solution-focused approach. See Table 136.2 for a quick guide concerning conversations using the SFBT session structure, including ways to use various solution-focused techniques in the change process.

An SFBT session structure must be flexible enough to adapt to the individual needs of each student but also structured enough to provide guidance to school social workers about the change process.

CASE STUDY

Franklin, Kim, and Tripodi (2006) suggest that most solution-focused interviews occur during the traditional 50-minute session. In schools, however, these interviews may last for shorter periods of time, 20–30 minutes, for example. Regardless of the time, the structure of the SFBT interview may be divided into three parts. The first part usually is spent making small talk with the student to find out a little bit about his or her life. During this first part, the school social worker may be looking to understand the student’s interests, motivations, competencies, and belief systems. The following case example provided by Franklin et al. (2006) illustrates the structure of a solution-focused session in schools and several techniques.

Social Worker: Hello, Charles. I understand your teacher, Mrs. Park, sent you here to see me because you’re at risk of failing out of school. But I’d like to hear from you the reason you are here to see me and how this can help you? [Allows student to state what the problem is.]

Student: I don’t know. I hate this school and I just want to drop out so that people will leave me alone.

SW: So, if I understand you correctly, you’re here to see me because you hate the school, and a lot of people—your teachers and maybe your parents—have been bugging you about your grades and doing homework?

S: Yeah.

SW: So what sorts of things do you like to do when you’re not in school?

S: Ummm, I like to hang out with my friends.

SW: What do you and your friends talk about when you’re hanging out?

S: I don’t know. We talk about basketball and music and stuff. [Social worker will continue to develop rapport and try to find out student’s interests and belief systems.]

The second part of the session, which takes up the bulk of the time—around 40 minutes in traditional sessions but maybe shorter in school interviews—is spent discussing the problem, looking for exceptions, and formulating goals. One of the key components to SFBT that has been emphasized in this chapter is working with the student to identify the problem, look for times when the problem is absent, look for ways the solution is already occurring, and develop attainable goals to help resolve the problem. This second part is usually initiated with questions like, “How can I help you?” or “What is the reason you have come to see me?” or “How will you know when counseling is no longer necessary?” (Sklare, 1997).

SW: OK, so how can I help you or what can you get out of our meeting today so that you know it’s been worth your time to see me?

S: I want my teachers and my parents to stop bugging me about my grades and doing homework. This school is just a waste of my time, and my classes are stupid.

SW: Is there a class that you didn’t think was stupid or a waste of time? [example of looking for exceptions].

TABLE 136.2 Structure of Solution-focused Brief Therapy Interviews

	Begin Session →	Exploring Solutions →	Assessing Progress →	Reflection Break →	End Session
<i>Goals of the Stage</i>	<ul style="list-style-type: none"> • Rapport building; • Shift focus away from problem talk; • Support student. 	<ul style="list-style-type: none"> • School social worker and student build solutions together; • Have student take responsibility for their own solutions; • Discussion is on possible solutions in concrete behavioral details. 	<ul style="list-style-type: none"> • Continue to provide compliments; • Create small, attainable, concrete goals; • Explore steps to achieving the goals. 	<ul style="list-style-type: none"> • Continue supporting student; • Reflect on student's strengths and resources; • Identify future steps. 	<ul style="list-style-type: none"> • Assess whether to schedule another appointment; • Lay groundwork for future sessions.
<i>Questions To Ask</i>	<p><i>How can I help you?</i></p> <p><i>What has to happen while talking with me today that will make it worth your time to come?</i></p>	<p><i>What kinds of things have you done in the past that have worked for you?</i></p> <p><i>What would be different about the problem in your life?</i></p> <p><i>When is the problem better? Even a little bit?</i></p>	<p><i>What would your parents say about your progress?</i></p> <p><i>Who would be the most surprised if you did well on that test?</i></p> <p><i>What would your friends say is the biggest change they've noticed in you?</i></p>	<p><i>I'd like to take a minute to think about what we've discussed. Would that be all right with you?</i></p>	<p><i>Has this been helpful?</i></p> <p><i>What has been helpful for you about our meeting?</i></p> <p><i>Would you like to meet again?</i></p>
<i>Keys Points To Remember and SFBT Techniques</i>	<ul style="list-style-type: none"> • Use student's words and metaphors; • Focus on student's definition of the problem. 	<ul style="list-style-type: none"> • Use exception questions; • Use miracle question to elicit details of student's goals; • Focus on strengths. 	<ul style="list-style-type: none"> • Elicit incidents of small changes students have made; • Use scaling questions; • Use relationship questions. 	<ul style="list-style-type: none"> • Formulate 4–5 genuine compliments for student; • Formulate tasks towards the solution; • Formulate possible homework assignment. 	<ul style="list-style-type: none"> • Client and school social worker both determine whether to meet again.

S: My English class last year was cool because we got to read some interesting books and have good discussions about them.

SW: What made the books interesting and the discussions good?

S: Well, they were books that I could understand and relate to. My teacher also made the time and effort to explain things to us and made sure we all got a turn to speak our thoughts.

SW: You said you hated this school, but yet you haven't dropped out yet. How have you managed to do that? [Allows student to identify possible solutions and possible successes they've already achieved.]

S: Well, I'm still going to some of my classes, but at this point I just don't care anymore.

SW: Charles, for those classes that you do attend, what would your teacher say about your academic work? [example of relationship question].

S: I guess they might say that I don't pay attention in class, that I don't do my homework, and that I'm not trying.

SW: Do you agree with that?

S: I guess, but it's just that the classes are so stupid and boring.

SW: I'd like to ask you an unusual question. It's probably something no one has ever asked you before. Suppose, after we're done and you leave my office, you go to bed tonight and a miracle happens. This miracle solves all the problems that brought you here today but because you were sleeping, you didn't know it occurred. So the next morning you wake up and you sense something is different. What will you notice that is different that lets you know this miracle occurred and your problems are solved? [example of the miracle question].

S: I guess I wouldn't be cutting class and maybe getting better grades.

SW: What will you be doing differently to get better grades?

S: I would probably be better prepared for class.

SW: What does being better prepared for class look like? [Continue to probe and elicit more details and examples.]

S: I'd pay attention in class and take some notes.

SW: What else will you be doing differently when you're getting better grades?

S: Probably doing my homework and not causing trouble in class with the teacher.

SW: So, what will you be doing instead of causing trouble in class?

S: Listen and sit there and take notes, I guess.

SW: So on a scale from 1 to 10, with 1 being "I'm dropping out of school no matter what" and 10 being "the miracle solved my problems and I'm going to graduate," where would you say you are right now? [example of a scaling question].

S: Three.

SW: What sorts of things prevent you from giving it a 2 or a 1?

S: Well, I know I need to get my high school diploma because I always thought I might go study how to be a med tech at college. I like *CSI* and want to work in forensics.

SW: Wow! You want to study forensics. So, you need to finish school for that. So, what would need to happen for you to be a 4 or a 5?

S: I'd need to start coming to classes and doing my work [examples of student identifying goals and solutions]. [Social worker would continue looking for solutions that are already occurring in Charles's life and collaborate on identifying and setting small, attainable goals.]

The final part of the session lasts around 5–10 minutes. It involves giving the student a set of compliments, homework, and determining whether to continue discussing this topic at another time. In school settings, practitioners such as teachers and social workers have separated this last part from the rest of the conversation. The break, for example, might be extended, and the conversation might pick up in different class periods or at a different times of the day (e.g., before and after lunch).

SW: I'd like to take a minute to write down some notes based on what we've talked about. Is there anything else you feel I should know before I take this quick break?

S: No.

SW: [after taking a break] Well, Charles, I'd like to compliment you on your commitment to staying in school despite your frustrations. You seem like a bright student and understand the importance of finishing high school. I'd like to meet with you again to continue our work together. Would that be all right with you?

S: Sure.

SW: So for next week, I'd like you to try and notice when things are going a little bit better in your classes and what you're doing differently during those times.

FUTURE APPLICATIONS

SFBT has been used in schools since the 1990s, and promising empirical support is emerging on this approach. SFBT is a practical, brief intervention for school settings and can help school social workers engage and work with students on diverse problem areas. This approach builds on student strengths and competencies and shows respect for each person. SFBT offers conversational, questioning techniques that help school social workers engage students in a solution-building process that helps students discover goals, tasks, and behaviors that change future outcomes. The future is what SFBT focuses on, and this future focus is perhaps one of its distinguishing characteristics. When applying SFBT, a school social worker must act as a coach and a facilitator who creates an interpersonal context where the solutions emerge from the student. As the case example illustrated, SFBT offers an interview structure and a set of counseling techniques that help social workers successfully facilitate the solution-building process in schools.

137 Treating Children and Adolescents with Attention Deficit Hyperactivity Disorder in the Schools

Steven W. Evans, A. Raisa Petca, & Julie Sarno Owens

Students with Attention Deficit Hyperactivity Disorder (ADHD) are among the students most frequently referred to school mental health professionals. School-based treatments can be the best interventions for helping these students succeed socially, academically, and behaviorally. Descriptions of school-based interventions for children and adolescents with the disorder are included in this chapter. The descriptions and case examples provide important considerations for modifying intervention and assessment approaches based on developmental differences and changes in context between elementary and secondary schools. Intervention plans for both case illustrations include parent involvement in the assessment and treatment procedures.

ADHD is a chronic condition appearing in 3%–10% of school-aged children. The core symptoms of the disorder include problematic inattention, hyperactivity, and impulsivity. Many of the impairments exhibited by children with ADHD manifest at school, including problems completing school assignments, following school and classroom rules, getting along with peers and adults, and keeping their materials and assignments organized. Problems with disorganization are often the most obvious, due to cluttered desks, book bags, binders, and lockers. Although less obvious, disorganization is also evident in poor time management skills, reading and writing difficulties, and poor listening comprehension. In addition, children with ADHD are at high risk for

other problems, including aggression, oppositional behavior, substance use, risky sexual behavior (i.e., conducive to sexually transmitted diseases and/or unwanted pregnancies), school dropout, delinquency, and driving violations and accidents.

School social workers have a unique opportunity to intervene with youth with ADHD and make a positive difference in their lives. They can observe students in socially demanding situations, such as the cafeteria, transitions between classes, and recess, as well as academically challenging situations in the classroom. Based on these observations and other assessments, they can help identify students who may benefit from interventions. School social workers are tasked with various responsibilities such as providing individual or group counseling, conducting prevention and intervention pursuits within the three-tiered model of intervention (e.g., Response to Intervention; RTI; National Center on Response to Intervention, 2010), managing crisis situations and providing teacher consultations with regard to Individualized Education Plans (IEPs), 504 plans, or school-based behavior management plans (Bornstein, Ball, Mellin, Wade-Mdivanian, & Anderson-Butcher, 2011). School social workers may also work in multidisciplinary teams, and act as liaisons between children and community agencies (Leyba, 2009). School social workers are often the primary providers of mental health services for children with challenging mental health issues in the communities they serve, and they are also faced with high caseloads and administrative paperwork demands (Kelly, Berzin, Frey, Alvarez, Shaffer, & O'Brien, 2010). Given the many roles of the school social workers, it is important to maximize the effectiveness of the services provided. One way to maximize positive outcomes is to implement practices that are evidence-based (i.e., have empirical support for their effectiveness for a given problem). Indeed, school social workers who are knowledgeable about evidence-based procedures for the identification and treatment of youth with ADHD and who collaborate with parents and teachers in the implementation of these procedures can have a large, beneficial impact on a child with the disorder, as well as on his parents and the school community.

ELEMENTARY SCHOOL

There are many characteristics of an elementary school classroom that make it well suited for both

the identification and treatment of children with ADHD. Elementary school students typically stay within one or two classrooms for several hours each day, where they encounter both academically and socially challenging situations on a regular basis. School social workers may observe children in these situations in both structured and unstructured activities. The opportunity to regularly observe in these situations allows school social workers to gain a thorough understanding of a child's strengths and weaknesses, the antecedents that may trigger disruptive behavior, and the consequences that may unintentionally serve to maintain disruptive behavior (e.g., attention from peers or adults). Understanding these factors can guide intervention planning and assist with gauging progress in response to interventions. Taking advantage of these opportunities requires that a school social worker understand the manifestations of the disorder in schools.

Some common characteristics of elementary school-aged children with ADHD that can be observed in a classroom are listed below. Not every characteristic is true of all children with the disorder, but they are common of many. Furthermore, these characteristics are not diagnostic criteria for ADHD; rather, they are descriptive of how teachers and other students perceive children with ADHD.

- The materials in the student's desk are very messy, and the child has trouble finding things when asked by the teacher.
- The child is seen by peers as annoying, "hyper," or "different."
- The teacher reports that working with the child can be exhausting.
- The child fails to raise his or her hand, and instead impulsively interrupts the teacher.
- The child raises his or her hand to participate in class discussions and then forgets what he or she was going to say or makes a statement that is irrelevant or redundant.
- During seatwork time in class, the child is frequently off-task. The student may do things to escape extended seatwork periods, such as sharpen pencils, go to the bathroom, or report not feeling well and ask to go to the nurse.
- The child fails to complete work and give it to the teacher on time.

Behavioral interventions that clarify expectations for the child and provide salient and

consistent rewards and consequences for behavior are effective in improving the academic and behavioral functioning of children with ADHD (MTA Cooperative Group, 1999). In other words, providing children with specific expectations for desired behavior and implementing a system by which children gain and lose privileges based on their compliance with these behaviors can correct problem behaviors among children with ADHD. Such interventions require that school social workers consult and collaborate with parents and teachers to implement the interventions in the classroom or home. Rigorous research studies indicate that counseling, play therapy, and self-esteem groups are unlikely to be effective with these children (Pelham & Fabiano, 2008). There is also a lack of evidence that group-based social skills training is effective at increasing social competence among these children (Pelham & Fabiano, 2008). However, there is some evidence that teachers can play a role in improving the child's peer relations by reducing peers' social devaluation of children with ADHD, exclusionary behaviors, and reputational biases (Mikami, Griggs, Lerner, Emeh, Reuland, Jack, & Anthony, 2013). To this end, teachers can employ several strategies: (1) develop positive relationships with children via short, but frequent one-on-one interactions discussing the child's interests, (2) provide behavioral corrections in private communications (rather than public), (3) set explicit classroom rules for social inclusion, (4) identify commonalities among children and arrange brief but collaborative class activities that facilitate small successes for the student with ADHD, and (5) publicly (i.e., in class) recognize the genuine strengths of the student with ADHD unrelated to behavioral compliance. Educating parents and teachers about children with the disorder and training them to consistently provide behavioral interventions over time is a critically important role for school social workers who wish to help children with the disorder.

SECONDARY SCHOOL

One of the biggest changes from elementary school to secondary school for children with ADHD is the increased demand to function independently. In secondary schools, students are expected to bring materials to class without prompting, keep track of assignments without monitoring, and complete work independently.

Many secondary students with ADHD fail to meet these expectations. Attempts to remedy such problems are considerably more complicated at the secondary level for several reasons.

First, the transition to secondary schools typically includes a switch from having one teacher who is with the child all day to the child having a variety of teachers for different subjects. A school social worker attempting to help a child in middle or high school faces the prospect of negotiating with several teachers across a variety of settings.

Second, as children with ADHD progress into the upper grades, they encounter many teachers whose training and focus tends to be more content-driven than child-driven when compared with elementary school teachers. The emphasis on content at the secondary level is encouraged by the testing requirements of the No Child Left Behind Act of 2001 and by related high school graduation requisites.

Third, practitioners in secondary schools appear to rely more heavily on accommodations—as opposed to interventions—compared with practitioners in elementary schools. Accommodations include strategies such as giving students extended time on tests, providing students with class notes, accepting late work without penalty, and other techniques that do more to change the expectations of adults than the competencies of students. Accommodations are frequently used in Individual Education Plan (IEPs) or 504 plans for students with ADHD, and are recommended on many websites and in books written about the topic. Unfortunately, most accommodations are not evidence-based (Harrison, Bunford, Evans, & Owens, 2013) and can be detrimental when they are the primary mode of assistance.

Unlike accommodations, interventions are techniques that train students to meet the expectations of teachers through skill acquisition and enhancement. These techniques include teaching organizational skills, study skills, and behavior management. From a pedagogical standpoint, interventions are consistent with the goal of training children to be educated and competent adults. Interventions tend to take more work and are less likely to provide immediate relief to distressed parents and teachers than accommodations; however, they are more likely to improve the functioning of children with ADHD and facilitate long-term success. Not surprisingly, there is growing evidence for many school-based interventions (see review by DuPaul & Evans, 2008).

CASE ILLUSTRATIONS

The following sections contain two case illustrations that include some assessment and intervention techniques that may be employed by school social workers. The first involves a student with ADHD in an elementary school, and the second involves a student in a secondary school. Additional information about the interventions described in this section is available in other reviews of treatments (e.g., DuPaul & Stoner, 2003; Sadler & Evans, 2011).

Elementary School Case

Andrew is a nine-year-old boy who was referred to the school social worker (Rebecca) by his fourth-grade teacher. The teacher's primary complaints were that he did not stay in his seat and he interrupted the classroom environment by speaking at inappropriate times and being the "class clown." The teacher also reported that Andrew infrequently completed his classwork and homework and, when he did turn it in, his work had many careless mistakes. She stated that Andrew had problems interacting with his peers and provided the example that, during recess, he refused to play by the rules of games that the other children were playing.

Assessment. The first step of the assessment was to identify the questions posed by the teacher's referral. There are many potential questions that could be addressed based on Andrew's referral, including possible eligibility for special education or a 504 plan, determining whether he meets the *DSM-5 (Diagnostic and Statistical Manual of Mental Disorders, fifth edition; APA, 2013)* criteria for a disorder by administering freely available rating scales for ADHD symptoms (e.g., the Disruptive Behavior Disorders (DBD) Scale, Pelham, Gnagy, Greenslade, & Milich, 1992) and associated impairment (e.g., the Impairment Rating Scale (IRS), Fabiano et al., 2006), and gathering information that would help guide the selection of interventions. Rebecca elected to focus her assessment on gathering data that would inform the selection of interventions.

The school social worker began by interviewing the teacher and Andrew's parents. These interviews were used to gather specific information about behavior problems, determine what interventions had already been attempted, and gain a sense of the ability of the parents and teacher to consistently implement interventions over time.

The teacher reported that she allowed Andrew to use the computer during free time at the end of the day if he demonstrated good behavior in class. She reported that this was not very effective, because they often disagreed about whether Andrew had a "good" day, and other children complained that they were well behaved but not allowed to use the computer. She noted that, after trying this for approximately one week, she discontinued it due to the arguments, classmate complaints, and lack of positive outcomes.

When Rebecca interviewed the parents, she learned that they did not have any problems with Andrew. They reported that he came home from school and played video games or "ran around" outside. The parents stated that Andrew had few responsibilities or chores at home. They also mentioned that he did not participate in any clubs, teams, or other organizations. Andrew has an older sister who spends a lot of time with her friends. Because Andrew's sister is very involved in activities in the community, the siblings spend very little time together. The parents were concerned about Andrew's problems at school, but wondered about the teacher's approach because their son did not have problems at home, and problems at school in previous years were minor.

Following the discussion with Andrew's parents, Rebecca decided to interview teachers who had Andrew in their classes in previous years to gather additional information. These teachers reported that Andrew was impulsive and frequently interrupted lessons and completed very little classwork. He also had problems getting along with other children. The teacher from the previous year reported that she did not refer Andrew to the child study team because she was able to work with him individually so that he was able to make adequate progress.

After gathering information from the parents and teachers, having the parents and teachers complete ADHD symptom and impairment ratings scales, and observing Andrew in various activities (e.g., during classroom and recess settings), the school social worker concluded that Andrew likely met diagnostic criteria for ADHD. She determined that the very minimal expectations for him at home may have led to the lack of apparent problems in that setting. Reports from previous teachers confirmed his current teacher's concerns and were consistent with a general trend toward increasing impairment as children with ADHD get older. However, because the parents perceived that there were few problems at home, she focused her

feedback to the parents on implications for home- and school-based interventions. Although she was unsure about the parents' willingness to implement interventions at home consistently, she was confident that the teacher could consistently provide some basic behavioral interventions.

Intervention plan. Based on her assessment of Andrew, Rebecca identified three goals for her involvement in Andrew's intervention plan: (1) raise the parents' and the teacher's awareness about ADHD and associated risks, (2) collaborate with Andrew's parents and teacher to facilitate their implementation of behavior management techniques (e.g., daily report card, contingency management techniques) with Andrew, and (3) facilitate and monitor the implementation and outcomes of these interventions to determine Andrew's response to intervention and/or need for additional interventions.

First, Rebecca conducted a feedback session with Andrew's parents during which she provided information about ADHD and other disruptive behavior disorders, gave them some brochures and directed them to relevant sources for more information (e.g., see resources pages at www.oucirs.org and <http://casgroup.fiu.edu/ccf/>). She emphasized the risks associated with ADHD and the importance of providing effective interventions. Rebecca encouraged the parents to consult with their physician, but neither recommended nor discouraged medication treatment. She told the parents that there were several available interventions for Andrew whether or not he met diagnostic criteria for ADHD.

Second, Rebecca encouraged the parents to participate in a parent training program (e.g., Barkley, 2013; Cunningham, Bremner, & Secord, 1997) that focused on parenting techniques for parents of children with disruptive behavior. Rebecca conducted a 10-week parenting workshop each semester and encouraged the parents to participate in the next group. During the parenting workshops, the school social worker helped parents establish home rules and develop skills in effective behavior management strategies (e.g., developmentally appropriate use of praise, effective instructions, contingent application of consequences). Despite some reservations about whether the parents would consistently implement such an intervention, Rebecca felt that participation in this group was a good first step and, if this was not successful, she planned to work with them individually after the parent training program ended.

Third, Rebecca met with Andrew's teacher and provided information about ADHD, including the chronic nature of the disorder and the need for early and consistent interventions over time. She explained that interventions may take many weeks of consistent implementation to be effective, but that she was willing to meet with the teacher on a bi-weekly basis to help her maximize the effectiveness of her general (Tier 1 intervention) classroom management strategies and to help her implement a daily report card (DRC) intervention that was individualized to Andrew's challenges (Tier 2 intervention). The teacher was willing to implement the DRC with support from Rebecca. Rebecca consulted with the teacher about two key behaviors that the teacher felt were important to address first. They collaboratively decided to initially target task completion and interrupting behaviors. The teacher and the school social worker arrived at clear definitions for these behaviors. Rebecca asked the teacher to track these behaviors for one week without telling Andrew, so that they could obtain a baseline assessment of his current level of functioning. The information obtained from this process would also help Rebecca and the teacher establish initial goals for Andrew that would represent improvement in behavior, but that were also achievable (see Volpe & Fabiano, 2013 for detailed procedures for DRC).

The teacher remembered to track these behaviors for four of five days and she and Rebecca used these data to set a morning and an afternoon goal for each behavior (see Figure 137.1). Each goal he earned translated into small privileges (e.g., free reading time, computer time, line leader) that could be earned just prior to lunch and again prior to the dismissal bell. Andrew also took his report card home each day to share his success with his parents. Rebecca and the teacher continued to meet biweekly to troubleshoot challenges, monitor Andrew's progress, and modify the goals as Andrew's behavior improved. Rebecca told the teacher that it is important to implement the DRC consistently for at least one month before they could determine whether it was effective based on Andrew's response (Owens, Holdaway, Zoromski, Evans, Himawan, Girio-Herrera, & Murphy, 2012). She emphasized the importance of persistence and patience with interventions.

Secondary School Case

Lisa is a 15-year-old girl who was referred to the school social worker (Mike) due to poor academic

Andrew's Daily Report Card		Date: <i>October 17, 2013</i>
Target Behavior	Frequency of Behaviors	Goal Met?
1. Andrew will raise his hand before speaking with 5 or fewer interruptions	# of interruptions 	 
2. Andrew will complete 50% of morning class work.	% Complete 25%	 
Morning Privilege: use magic markers ✖		
1. Andrew will raise his hand before speaking with 5 or fewer interruptions	# of interruptions 	 
2. Andrew will complete 50% of afternoon class work.	% Complete 75%	 
Afternoon Privilege: be a line leader ✔		
Teacher Comments: <i>Andrew had a difficult time staying on task this morning and got distracted frequently. However, after lunch, he was more focused on his class work and put a lot of effort into completing his worksheets.</i>		
Parent Signature: <i>Jane Smith</i>		

Figure 137.1 Sample daily report card.

performance, truancy, and defiant behavior. She moved to the school district at the beginning of the school year, when she enrolled in the ninth grade. Lisa failed three of her classes during the first grading period and teachers reported that she did not seem to care about school and that they could not help her.

Assessment. Mike, the school social worker, began his assessment by interviewing Lisa's teachers and asking them to complete the DBD and IRS rating scales. The information he received from Lisa's teachers was very inconsistent. Some teachers reported that they had no

problems with Lisa and that she was earning a C or D in their classes. Other teachers reported that she was disruptive, never completed any work, was verbally defiant to the teachers, and was failing their classes. The variability across teachers led Mike to review information about Lisa from her previous school. These records were sparse, but revealed that her grades tended to range from D to B. There was no information regarding any behavior problems. Mike called the school social worker from Lisa's previous school and learned that, even though teachers believed that Lisa had a poor attitude and was sometimes irritable and

inappropriate in class, this was not considered a serious problem. Lisa's few friends tended to be younger than she, and she tended to spend more time in isolation than with a group of peers. The previous school social worker remembered that Lisa may have seen a mental health professional in the community, but stated that she was never given details of those services. Lisa had never been referred to the child study team or for an evaluation. The school social worker could not recall any interactions with her parents.

In addition to gathering information about Lisa's behavior from her previous school, Mike observed some of Lisa's current classes. He found that the teachers who reported the most problems with Lisa tended to have moderate-to-high expectations for their students. The teachers who reported that they had few problems operated more informally than the others, had students complete more hands-on activities and, although they gave homework, they also allowed more than enough class time for the students to complete the homework. Lisa's work in these classes was not of high quality, but she did enough to meet minimal expectations. She actively contributed to discussions in these classes with pertinent comments, however, traditional classroom rules (e.g., raising hand before speaking) were not strictly enforced. Mike recognized that the more self-control and independent task completion was expected of Lisa, the more problems she exhibited.

Mike then contacted Lisa's parents and asked them to meet him at the school to discuss Lisa's progress and her transition to the new school. He asked them to bring old school report cards and the results of any previous evaluations that had been completed. Lisa's parents appeared relieved to meet with him and extensively discussed their concerns and frustrations. They spoke of choosing their battles and attempting to monitor and influence Lisa's behavior, but reported little success and substantial worry and concern about the girl's future. They stated that they had long ago abandoned efforts to get Lisa to help with chores at home, because it often led to more arguments rather than positive outcomes. Lisa had seen a counselor in their previous community for a few months, but her parents declared that this had been "a waste of time," as little change in Lisa's behavior was observed. As a result, her parents had concluded that mental health professionals could not help their daughter.

A review of Lisa's report cards revealed that teachers had added comments to her cards since

first grade, indicating that she had trouble completing work and was disorganized. Early report cards also revealed that she had trouble getting along with other children and was easily distracted. The parents reported that they shared these concerns with Lisa's pediatrician, and he mentioned the possibility of prescribing medication for her. They were unsure what medication was considered, but at the time, the parents were opposed to giving her medication for her behavior problems.

Finally, Mike invited Lisa to his office to gather information from her perspective. She reported that she was doing fine both socially and academically. Mike questioned her about some of the teacher reports and low grades. Lisa replied by stating that some teachers do not like her. She acknowledged becoming frustrated with them, but claimed that her statements to the teachers were appropriate in response to the unfair accusations and other mean statements that teachers made to her. Lisa reported having many friends and a happy social life. When asked specifically about the ages of her friends, she acknowledged that some of her friends were younger than she was, but stated that she also had friends in the ninth grade. Mike also asked to look at Lisa's book bag and school binder. The items were very disorganized and drawings, food wrappers, and other items were mixed into her school materials. There was very little information recorded in her assignment notebook, and Lisa stated that she did not use it because she remembers all of her assignments.

Mike synthesized the reports from teachers, parents, Lisa, and the school social worker from the previous school, as well as information from school records and class observation. The results of his comprehensive assessment led Mike to conclude it was likely that Lisa met diagnostic criteria for ADHD.

Intervention plan. Given the complexity of Lisa's problems and the parents' distrust of mental health services, Mike decided that, at this point, the best way of helping Lisa was to meet again with her parents and discuss treatment options. His goals for this meeting included educating her parents about ADHD and evidence-based interventions for ADHD, identifying community resources that could help them, and reviewing school-based or school-linked interventions that were likely to help Lisa, such as an organization intervention and a homework management plan.

In his meeting with Lisa's parents, Mike provided them with reading material (e.g., Zeigler-Dendy & Zeigler, 2003; CHADD fact sheets) and discussed the course of ADHD through childhood and into adolescence. He also shared with them that insight-oriented therapies, like the one they reported was provided to Lisa by the community counselor, are not likely to adequately address the problems associated with ADHD. Mike provided information about evidence-based interventions for ADHD to enable Lisa's parents to make an informed choice of treatment. He also encouraged the parents to speak to Lisa's physician if they were interested in medication treatment. Finally, Mike provided the parents with contact information for the local parent support and advocacy group and encouraged them to consider attending a meeting.

After educating the parents about ADHD and treatment options, Mike talked to them about implementing some interventions at home to help Lisa both academically and with their parent-child relationship. Mike scheduled a standing weekly meeting with Lisa's parents for three weeks to share information about a homework management plan and basic communication and problem-solving procedures. Additional parent meetings could be scheduled on an as-needed basis. He spoke with them about maintaining consistent communication between home and school and offered to be the liaison between Lisa's parents and teachers.

Lastly, Mike discussed the possibility of implementing school-based interventions to target Lisa's academic problems and addressed her parents' queries about the appropriateness of implementing accommodations. He explained that the majority of Lisa's problems were in classes in which the teachers expected students to work independently outside of class, strictly adhere to classroom rules, and had higher expectations regarding behavior. When teachers did not have these expectations, Lisa's irresponsible and disrespectful behaviors were viewed as less of a problem. Mike also told the parents about the extreme disorganization that he discovered in Lisa's binder and book bag and the lack of an effective system for recording assignments. The parents asked about ideas that they heard from other parents, where teachers gave the students longer time on tests, provided them with written notes from the class and a list of the assignments that were due, and did not penalize the students for late assignments. Mike told the parents that

these were accommodations that are sometimes used with students with problems similar to Lisa's, but he discouraged the parents from relying on these techniques. He told them that there is no evidence that these techniques improve the behavior or skills of children with ADHD or related problems. It was his experience that these accommodations do make it easier for students to receive improved grades, but only because adults start expecting less from them and not because the students have learned any skills to cope with their difficulties. He also explained that accommodations may be detrimental to Lisa because they remove the responsibility for her to find the means to be successful and that they should only be used in combination with interventions that help her develop competencies. He stated that it is unlikely that future employers would make such accommodations, and Lisa needed to learn to adjust to age-appropriate expectations. He reviewed a series of interventions designed to improve her ability to succeed in regular education settings such as an organization intervention (Evans, Schultz, White, Brady, Sibley, & Van Eck, 2009), daily report card (Evans & Youngstrom, 2006) and other school-based interventions (see Evans, White, Sibley, & Barlow, 2007) designed to improve Lisa's ability to meet the expectations of regular education teachers. He told the parents that it might take a few weeks or even months for Lisa to show adequate improvement, and he would provide them with updates about her progress. The parents reported feeling a little overwhelmed with this information, but told Mike that they would read the material, discuss the information that had been shared, and return for their next appointment.

CONCLUSION

School social workers are in a position that allows them to have an important impact on the lives of children and adolescents with ADHD. Their training and skills, combined with their position within schools, provide school social workers with a unique opportunity to participate in the assessment of children with ADHD, as well as coordinate effective home- and school-based interventions. In addition, school social workers can be very effective liaisons to community mental health providers to coordinate care. The case illustrations in this chapter were intended to provide information and examples of effective

strategies to help students with ADHD achieve in school. Of course, there are many child and family characteristics that may enhance or compromise response to these interventions. Findings from a large clinical trial of children with ADHD revealed that comorbid anxiety, prior medication use, poverty, severity of symptoms, and maternal depression moderated clinical outcomes (for a complete review, see Hinshaw, 2007). Interestingly, the child's gender and comorbid oppositional defiant disorder or conduct disorder did not significantly alter outcomes.

Many common concerns that practitioners experience when working with youth with ADHD were described in the case illustrations, including the belief by the children that they do not have problems and do not need help, inconsistent reports from teachers about the child's behavior and academic progress, the temptation to rely on accommodations instead of interventions, and the barrier to further care that can result from receiving ineffective interventions. Many additional challenges are inherent in the process of trying to implement interventions such as those described above, including variability in the willingness of teachers and parents to participate in the process. Clearly, excellent consulting and communication skills are a critical prerequisite to working effectively with these youth in schools. It is by no means an easy task, but it is a necessary undertaking that can afford life-changing benefits to youth.

138 Effectively Working with Latino Immigrant Families in Schools

Eden Hernandez Robles, Alan Dettlaff, & Rowena Fong

GETTING STARTED

In 2010 the U.S. Census Bureau (2012a) estimated that 23.2% of all elementary and high school students were classified as Hispanic. Although

Hispanics (both male and female) have experienced a slight decline in the dropout rate, they have continued to drop out at nearly twice the rate of their White and Black counterparts (U.S. Census Bureau, 2012b). In addition, Hispanic males have

higher rates of dropping out when compared with Hispanic females, and also have lower rates of college enrollment when compared with Hispanic females (U.S. Census Bureau, 2012b). Despite being 23.2% of all elementary and high school students, only 6.2% of all college students (both undergraduate and graduate) are Hispanic, and only 13% of all Hispanics age 25 years and older attain a bachelor's degree (U.S. Census Bureau 2012a).

Referred to as Hispanics in census data, the Latino population, particularly those who have migrated from other countries, represents the largest and fastest growing population in the United States. In 2010, the Latino population, consisting of persons from Mexico, Cuba, Dominican Republic, Central America, South America, and other Latin countries, represented 16.3% of the total U.S. population, an increase of 15.2 million people since 2000. Between 2000 and 2010, the Latino population increased by 43%, which was more than four times the growth of the total U.S. population (Ennis, Rios-Vargas, & Albert, 2011). In 2010, Latino children represented nearly one-fourth of all children in the United States, comprising 24% of all children under the age of 18 years (Motel, 2012). Although foreign-born Latino children represent only 8% of Latino children, more than half (52%) of Latino children are U.S.-born children of Latino immigrants (Fry & Passel, 2009). Although children of immigrants reside primarily in six states that have been traditional destination states for immigrants—California, Texas, New York, Florida, Illinois, and New Jersey—the number of children with immigrant parents has more than doubled in most other states, while states including North Carolina, Nevada, Georgia, Arkansas, and Nebraska have experienced growth rates of more than 300% since 1990 (Fortuny, Capps, Simms, & Chaudry, 2009).

Given the rapidly increasing Latino immigrant population, school-based professionals face increasing pressure to assist in the adjustment of children from immigrant families entering school systems. For these children, stressors related to immigration and acculturation may significantly impede the learning process. Upon migration, immigrants are faced with a number of challenges that distinguish them from their native-born counterparts. The migration experience itself can be considerably dangerous, with many immigrants experiencing violence, robbery, and sexual assault (Solis, 2003). Once in the new country, children in immigrant families continue to experience stress resulting from language differences, unfamiliar customs,

loss of routine, and continuing threats of violence and discovery. Additional pressures resulting from acculturation can lead to a variety of strains and difficulties on family systems, as parents and children experience changing cultural contexts along with the loss of previously established support systems (Dettlaff & Rycraft, 2006). Although some foreign-born children overcome these challenges with apparent ease, many others experience very difficult and stressful transitions to their lives in the United States (Goodman, 2004; Tazi, 2004).

Research indicates that the inability to cope or adjust to cultural stressors can result in poor or stagnated academic achievement for children in immigrant families (Moon, Kang, & An, 2009; Padilla & Perez, 2003; Shin, 2004). Thus, the increasing population of immigrant children in school systems necessitates that school-based professionals recognize and respond to the unique needs of this population to facilitate positive academic outcomes. Thomas (1992) contends that the failure to address the adjustment challenges faced by immigrant children within school systems contributes indirectly to their academic failure. Compounding the existing challenges faced by immigrant children, lack of academic achievement can then lead to increased risk of poor self-esteem and drop out (Battin-Pearson et al., 2000; Suh, Suh, & Houston, 2007).

WHAT WE KNOW

The cultural, psychological, and linguistic challenges that stem from experiences with immigration and acculturation make Latino immigrant students a particularly vulnerable population. Among the unique challenges faced by Latino immigrant students in academic achievement is English language acquisition. The experience of many Latino immigrant students is often complicated by a lack of appropriate assessment tools that differentiate between a difficulty in language acquisition and a learning disability (Klingner & Harry, 2006; Lesaux, 2006). Latino students in general continue to be over-represented in Special Education as a result of a misinterpretation of the students' cultural and language barriers as learning disabilities (Artiles, Rueda, Salazar, & Higareda, 2005; Lee, Grigg, & Donahue, 2007; Orosco, 2010; Orosco, Schonewise, de Onis, Klingner, & Hoover, 2008). Latinos are not over-represented in disabilities that require biological verification (educable mental retardation) (National Research Council,

2002). However, research indicates that most schools lack the required resources to support the needs of Latino immigrant students with disabilities (Zehler, Fleischman, Hopstock, Pendzick, & Stephenson, 2003).

Academic Achievement and Dropout Rates

Academic achievement and dropout rates are both areas of major concern for Latino immigrant students. Multiple barriers that the first generation face, including low levels of cultural sensitivity in schools and inadequate academic advisement, affect the ability for subsequent generations to obtain academic success (Hill & Torres, 2010; Nevarez & Rico, 2007; Suarez-Orozco & Suarez-Orozco, 1995). Findings from Tenebaum & Ruck's (2007) study indicated that students are often the subject of repeated discrimination as "teachers praise Latino students less, even for correct answers; behave less favorably toward them; and penalize them for lower levels of English proficiency" (as cited in Hill & Torres, 2010). Although Latino immigrant children face many barriers that may impede their academic success, school-based professionals have the potential to foster academic achievement and completion through culturally sensitive interventions.

It is critical for the school social worker, school mental health professional, or school counselor to be familiar with the cultural belief systems active among Latino families (see Table 138.1) and to be clear on distinguishing characteristics among the Latino immigrant population, which include realizing the difference between immigrant children and children of immigrants and discerning the tremendous variations apparent among different subgroups originating from diverse countries. It is recommended that the school-based professional consider the Latino Dimensions of Family and Personal Identity Model, adapted from Arredondo & Glauner (1992) Dimensions of Personality Identity Model, when working with a Latino immigrant student (Arredondo & Santiago-Rivera, 2000; see Figure 138.1). The Latino Dimensions of Family and Personal Identity Model considers A, B, and C dimensions that include age/generational status, acculturation/citizen status, and personal/familial/historical events before proceeding to work with Latinos (Santiago-Rivera et al., 2002). Using this model as an assessment would help the school-based professional in an early identification of appropriate interventions for the student.

Another determination for the school-based professional to make when working with Latino immigrant students is the appropriate use of the Spanish language. Although the Spanish language is shared among Latino immigrants, the dialect may differ and words may change in meaning depending upon the country of origin (Thorn & Contreras, 2005). Similarly, behavior and body language also differ among the subgroups of Latinos and can be a powerful form of mimesis to forge a therapeutic relationship if applied correctly (Quinones-Mayo & Dempsey, 2005). The bilingual school-based professional should remain alert for these differences in dialect and be prepared to adapt. For example, the word "school bus" translated from the American language would be *el autobus de transporte escolar*. However, depending on the person's country of origin, the word school bus can be translated differently. For persons from Mexico a school bus is *el camion escolar*, while persons from Cuba and Puerto Rico may identify the bus as *la guagua escolar*, and persons from Uruguay or Peru may recognize bus as *el omnibus escolar*. The variations on school bus do not end there. This example simply stresses the importance of recognizing differences in dialect and being able to adapt.

The nonbilingual school-based professional also should remain alert for these differences and use caution if employing translation services. Improper use of the language poses many ethical dilemmas and risks effectively building a therapeutic relationship with the students. Identifying possible bilingual referral sources may be the best choice for nonbilingual school-based professionals; matching the students with language appropriate services is most important in the early stages of intervention when seeking positive outcomes (Carey & Manuppelli, 2000). Nonetheless, the nonbilingual school-based professional's openness to learning these differences, as well as key words of the language, are helpful in building a relationship of trust and mutual respect.

WHAT WE CAN DO

Response to Intervention (RTI) and Positive Behavioral Interventions and Supports (PBIS) are three-tiered models used by school systems to provide instruction and intervention or prevention to students according to their needs (RTI Action Network, 2011). Each tier is structured to identify and then provide tailored support to

TABLE 138.1 Cultural Belief Systems

Principle	Definition	Citation
Los dichos	Cultural sayings that reflect cultural values or lessons. Can be used as a therapeutic tool.	Zuniga, 1992
La educación	Education in mainstream America refers to school. <i>La educación</i> is not a direct translation of education, but refers to the role of the mother for the proper social and moral upbringing of the child and can be a powerful resource.	Goldenberg & Gallimore, 1995; Valdés, 1996
El respeto	Refers to a respect for elders and authority. <i>Respeto</i> is also achieved through empathy in intimate relationships.	Santiago-Rivera et al., 2002 Simoni & Perez, 1995
Familismo	Academic term to define the observed importance of family above self; strong family ties within Latino families. However, the greater a family adapts to the U.S., the weaker <i>familismo</i> becomes.	Santiago-Rivera et al., 2002 Smokowski et al., 2008
Personalismo	Academic term to describe the importance of developing a personal relationship versus institutional relationship. A genuine interest in a person or family, not a professional distance.	Negroni-Rodriguez & Morales, 2001
La confianza	Refers to an established relationship of trust with the families.	Negroni-Rodriguez & Morales, 2001
Simpatía	Refers to the desire to be social, agreeable, sharing, and empathetic. Although this may differ when interacting with persons of a different culture.	Guilamo-Ramos et al., 2007; Simoni & Perez, 1995; Marin, 1993
Dignidad	Refers to the respect and honor given to a person.	Andres-Hyman et al., 2006
Obligación	Refers to a mutual expectation (responsibility) that both those in power and those who are not in power will treat each other with respect.	Padilla, Pedraza, & Rivera, 2005
Ganas	Refers to drive and ambition to achieve goals.	Auerbach, 2006
Marianismo	Academic term that refers to female gender socialization. Girls must grow up to be enduring, nurturing, spiritually strong, and pious women and mothers. This can possibly create conflict within the family.	Lopez-Baez, 1999; Santiago-Rivera et al., 2002
Machismo	Academic term that refers to male gender socialization. Boys must grow up to be responsible, loyal, and protective men and fathers. This term is often confused and used interchangeably with the term machista, which means sexist.	Morales, 1996; Santiago-Rivera et al., 2002

students with learning or behavioral difficulties. Within the tiers, students are continually monitored for progress to determine whether further action is needed to assist students in achieving their goals. The screening process to determine which tier a student will benefit from begins at the classroom level. The classroom level is considered the Tier 1 level and consists of high-quality

classroom instruction using evidence-based educational practices (RTI Action Network, 2011). Students who are identified as having difficulty at this level are provided with supplemental instruction. Students who do not show adequate progress or improvement within the allotted time frame (generally within eight weeks) are moved into the Tier 2 level. Tier 2 supports consist of

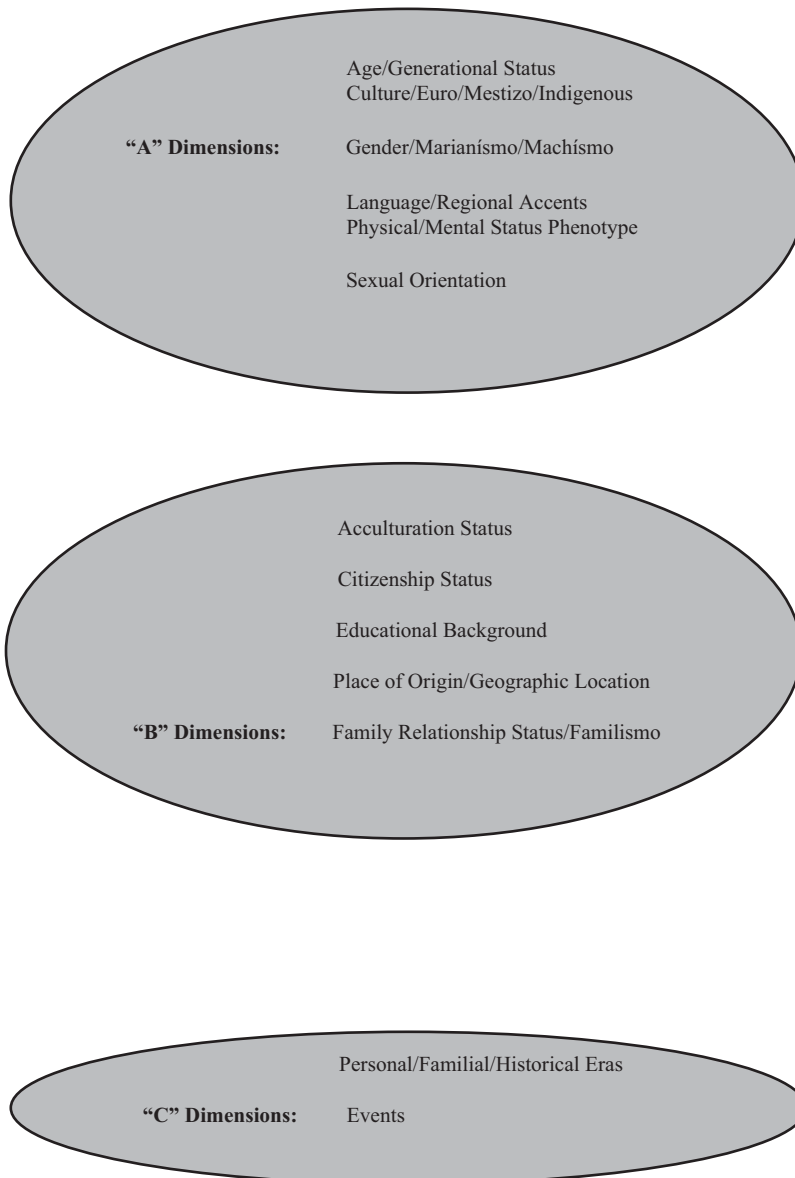

Figure 138.1 Latina/o Dimensions of Family and Personal Identity Model. Source: Adapted from Arredondo & Glauner, 1992.

targeted interventions provided in small-group settings and are a supplement to regular classroom instruction (RTI Action Network, 2011). This level of intervention varies in duration, but does not extend past the grade level. Students who require more support are placed into the intensive Tier 3 interventions that are structured to target the student’s deficits. Students who do not respond to Tier 3 interventions become eligible for a comprehensive evaluation and are considered for special education (Response-to-Intervention [RTI] Action Network, 2011).

Although there are few culturally sensitive evidence-based interventions available for Latino immigrant students, those that have been developed incorporate the students’ traditional culture into instruction while introducing the United States (Orosco, 2007; Orosco, 2010; Klingner & Edwards, 2006; Santiago & Brown, 2004). Culturally sensitive RTI interventions facilitate the transition and adjustment of the students while supporting them in their culture as they work toward academic success (Osher, Cartledge, Oswald, Sutherland, Artiles, & Coutinho, 2004;

Osher & Osher, 2002; Lewis, 2001). The National Task Force on Early Childhood Education for Hispanics (2007) reported that schools that implement culturally relevant classroom interventions from both the traditional and the new culture have a positive impact on the student's cognitive and social development. The following interventions are focused on academic achievement and dropout prevention for Latinos and Latino dual-language learners.

Tier 1 Interventions for Latino Immigrants

Most Tier 1 level interventions focus on English language acquisition as the foundation for successfully aiding the Latino immigrant student in achieving academic progress. Rinaldi and Samson (2008) recommended educators use a prereferral, referral, and assessment approach that focuses on understanding and recording the student's proficiency and development. This would require that educators automatically assess and provide supports to incoming Latino immigrant students instead of waiting to see if they will acquire the language on their own. This Tier 1 strategy would potentially reduce the number of inappropriate disability referrals and unnecessary placements in remedial courses later on in the student's academic career.

Other Tier 1 interventions for Latino immigrants consist of English as a Second Language courses and culturally sensitive classroom instruction. Rolstad, Mahoney, and Glass (2005) meta-analysis of English language learner programs indicated that bilingual education yields greater results for academic achievement when compared with English-only approaches. Furthermore, transitional bilingual education programs were inferior compared with developmental bilingual education programs. These findings support previous meta-analysis findings that dual-language programs have positive effects for students in all academic areas (Willig, 1985; Greene, 1998). Rolstad and colleagues (2005) acknowledged that some state policies and the federal English Acquisition Act serve as barriers to most schools seeking to improve the academic environment for Latino immigrant students. Other researchers on English language learners have indicated that bilingual educational programs, coupled with culturally sensitive classroom instruction are most effective in

maintaining the students at the Tier 1 level (Orosco, 2010; Klingner & Edwards, 2006).

Tier 2 Interventions for Latino Immigrants

Cheung and Slavin (2005) reviewed effective bilingual reading programs and found positive effects for students. Of the programs reviewed, many incorporated group instruction to assist students in achieving academic success. Similar studies also encourage the use of small group tutoring as an effective way to deliver Tier 2 interventions such as *Project Read* (Rinaldi & Samson, 2008; Greene & Enfield, 2006). Although there is still much work to be done in developing evidence-based Tier 2 interventions (Klingner & Edwards, 2006), this review served to identify the benefits of incorporating a cultural component into classroom instruction.

Tier 3 Interventions for Latino Immigrants

Some researchers instead have focused on developing culturally sensitive school programs. For example, *Club Amigas* (Kaplan, Turner, Piotrkowski, & Silber, 2009), an evidence-based mentoring project, concentrated on increasing positive attitudes toward school and motivations to go on to college by pairing teenage Hispanic girls with mentors. The project further incorporated supports to assist the girls in developing their identity as Hispanics in the United States. Pre-test and post-test scores revealed statistically significant improvements in how girls viewed themselves as students. Qualitative results revealed that students experienced benefits of increased learning and aspirations to continue on to college. The actual high school completion rate of the participants was not reported. The findings of this study, however, support current literature that encourages schools to build culturally and linguistically sensitive intervention programs (Nesman, 2007). A similar program, *Project Wings*, an evidence-based school mental health program, was developed with the understanding that poor mental health leads to social issues such as dropping out of school and other deviant behaviors (Garcia, Pintor, Naughton, & Lindgren, 2009). The program focused on improving mental health and incorporated Zumba, sharing circle discussions, and skill-building activities. The skill-building activities addressed such issues as acculturation, self-identity, and healthy relationships, among other life aspects. This program

consisted of 14 two-hour weekly sessions and was used with Latina adolescents. Pre-, mid- and post-assessments reported improved mental health for the participants who completed the program, but did not report on whether the students completed school. Although no longer in existence, the program Achievement for Latinos through Academic Success (ALAS) was an effective evidence-based dropout prevention program for both Latino males and females that incorporated positive supports for cultural identity and encouragement for academic success for students (Fashola & Slavin, 1998). This program also incorporated the use of parent training on how to monitor and guide students in school. The high-risk non-Individualized Educational Plan ALAS participants had a lower dropout rate when compared with non-ALAS participants.

Latino immigrant students stand much to gain within a Response to Intervention framework that ascertains that all children can succeed in the educational system if provided early intervention and careful monitoring of an individualized plan made up of evidence-based practices (NASDSE, 2005). If a culturally sensitive Response to Intervention framework is provided, careful monitoring and evaluation of the data could assist the school-based professional in determining exactly how to proceed in the best interest of the student. In addition to acquiring culturally and linguistically appropriate courses and other academic supports, the school-based professional should seek to direct the student in culturally relevant programs for all other needs.

School-based professionals serving Latino immigrants are often faced with a difficult task that will require careful implementation of programs and services in order to assist the student. Culturally sensitive professionals or consultants could be contacted to assist school-based professionals in identifying culturally relevant programs or resources. Most culturally relevant interventions used within the PBIS framework have been documented as effective, but many still need further evaluation. In addition, because of the complexities of the populations, school-based professionals should be prepared to meet the different sociocultural needs of the students.

TOOLS AND PRACTICE EXAMPLES

The Response to Intervention framework encompasses three caveats that consist of school support, progress monitoring, and diagnostics

or assessment (Capone, 2011). This framework works within a three-tiered model to meet the needs of the students. A Tier 1 response for Latino immigrant students would require culturally and linguistically sensitive ESL classes and regular classroom material (Klingner & Edwards, 2006; Orosco, 2007); Tier 2 would include individualized or group supports for students who needed extra academic support such as peer tutoring or cooperative learning (Osher, Cartledge, Oswald, Sutherland, Artiles, & Coutinho, 2004); and Tier 3 would provide culturally and linguistically appropriate intensive interventions for students at risk for social or behavioral problems (Capone, 2011). The third tier draws upon other supports such as afterschool and in-school programs that should be monitored by the school-based professional on a behavioral action plan to track progress. The culturally sensitive RTI or PBIS progress monitoring would require school-based professionals to evaluate whether the overall model is working; if not, then the model should be changed until it does work (Klingner & Edwards, 2006; Orosco, 2007). By using multiple resources the school-based professional can also effectively build a social support system for both the student and family that they otherwise do not have.

The strategies used in a Response to Intervention framework include (1) Identify; (2) Analyze; (3) Implement; and (4) Monitor and Evaluate.

Identify

Identifying the Latino immigrant student requires a school-based professional to be willing to employ various strategies to locate them. Sending a questionnaire home in Spanish that asks questions such as "Have you recently immigrated to the United States?" can possibly assist in locating these students. Not all immigrants are literate in their native language, however, and as pointed out previously, the Spanish language comes in various dialects (Birman & Chan, 2008). Schools should use culturally sensitive interviewing techniques to screen incoming students for language proficiency (Valdés, 2001). Once the student has been identified and the school-based professional has assessed the unique history of the student using a model, such as the Latino Dimensions of Family and Personal Identity Model, the student can be screened for other educational needs (Arredondo & Santiago-Rivera, 2000).

Analyze

Assuming that most Latino immigrant children are more fluent in Spanish, students will greatly benefit from in-school programs such as ESL. Other afterschool programs that offer one-on-one tutoring or homework assistance also will serve to provide additional support to both the student and the family that may not otherwise be able to assist the child with homework. In order to help identify the psychosocial needs of the child, the Center for Health and Health Care in Schools website offers a great list of diagnostic assessment tools available in various languages, which a school-based professional can use to identify adjustment and mental health issues that may be present in the student (Birman & Chan, 2008). The consent process may prove difficult if the family is not literate and the school-based professional should be prepared to provide alternative forms for consent beyond written consent. The National Center for Youth Law website is a great resource for school-based professionals looking to become familiar with the state laws and school policies regarding mental health services. Once the school-based professional has successfully dealt with these issues, resources can be located or developed and through careful networking these same assessments can be used to monitor progress. Identifying resources for the family, as well, is ideal and strongly encouraged.

Implement

Once the appropriate programs and academic resources have been identified the school-based professional should develop an individualized education plan and an individualized family service plan. The effective school-based professional will coordinate with these programs and academic resources for the good of the student and the family. Efforts to connect the student and family to others in a similar situation will help to create an additional support system that with careful coordination can also be evaluated for effectiveness. Team meetings with all of the student's resources will serve to open lines of communication and assist in the effective implementation of program services.

Monitor and Evaluate

The school-based professional must be diligent in monitoring the individualized education plan. Diagnostic assessments and interviews with key resources should be conducted to ensure fidelity of treatment with the student. If any aspect of the

plan is no longer working or is ineffective as demonstrated by the data collected from the assessment then the plan should be revised and new resources should be introduced. The ultimate goal is for the student to function at his or her highest level, making a successful adjustment to life in the United States while keeping cultural strengths intact.

CASE EXAMPLE

The case example provided illustrates an ideal approach to working with Latino immigrant children and their families. The Montez family has recently enrolled its three children in the school district. David, age 10 years, Veronica, age 7 years, and Ruben, age 5 years, are enrolled at the elementary school. They are recent immigrants from Mexico and are excited to enroll their children in school for a better opportunity.

Tier 1

The school determined that the family was a Latino immigrant family at enrollment. After meeting with the family, a decision was made to place the children in the English as a Second Language (ESL) program. The school-based professional also recognized the need for further supports in the classroom setting and arranged a meeting with the classroom and the ESL teacher. Both the ESL and classroom teacher had completed proper cultural sensitivity training to be able to meet the needs of children like David, Veronica, and Ruben. Regular meetings with the ESL and classroom teacher provided additional support that helped the students in adjusting.

Tier 2

Veronica and Ruben were both very successful at achieving their academic milestones. David, however, had some difficulty with reading and was not making progress. The school team identified a culturally sensitive evidence-based reading program for Latino immigrant children. The necessary supports were put into place in order to provide these same services to David and other children who were also struggling to make progress. The group work and individualized lesson plans aided David in making much improvement.

Tier 3

David, Veronica, and Ruben faced new challenges when they began high school. They worked very

hard to achieve good grades, but did not quite understand the college enrollment process. David wanted to drop out so he could work to help support his family, and Veronica was struggling with the idea of going on to college. In addition, the students often felt alienated by their peers and experienced a great deal of difficulty with their own cultural identity. A school-based professional, who

understood the difficulties unique to the students, identified a culturally sensitive evidence-based academic achievement and dropout prevention program for Latino immigrant students. The students were able to gain both the academic and social support they needed in this program. All three children graduated from high school and were able to successfully enroll in college.

APPENDIX A

Assessment Tools (Available in Spanish)

Type of Measure	Name of Scale	Informant/Reporter	Used with
Acculturation scale for Mexican Americans	Acculturation Scale for Mexican Americans (AR SMA)	Self-report or Semi-structured interview	Mexican and Mexican American population (Cuellar, Harris, & Jasso, 1980)
	Acculturation Scale for Mexican Americans (AR SMAII)	Self-report or Semi-structured interview	Mexican and Mexican American population (Cuellar, Arnold, & Maldonado, 1995)
	Children's Acculturation Scale	Youth Self-report or Semi-structured interview	Mexican children (Franco, 1983)
Acculturation scale for Puerto Ricans	Psychological Acculturation Scale (PAS)	Self-report or Semi-structured interview	Puerto Rican immigrant population (Tropp et al., 1999)
Acculturation scale for Cubans	Behavioral Acculturation Scale	Self-report or Semi-structured interview	Cuban immigrant population (Szapcoznik, Scopetta, Kurtines, & Arnalde, 1978)
Acculturation scale for Latinos	Acculturation Scale	Self-report or Semi-structured interview	Mexicans, Cubans, Puerto Ricans and Central Americans (Marín, Sabogal, Marín, Otero-Sabogal, & Perez-Stable, 1987)
Adaptive and maladaptive behaviors, thoughts and emotions	Behavioral Assessment System for Children (BASC)	Teacher and parent report Youth Self-report	Latino kindergarten children (Flanagan et al., 1996)
Community violence	34-Item Life Events Scale (used as a screener for Cognitive-Behavioral Intervention for Trauma in Schools)	Self-report	Latino immigrants (Stein et al., 2003)
Attitudinal familism	Familism Scale	Self-report	Less acculturated Latinos (Steidel, & Contreras, 2003)
Posttraumatic Stress Disorder (PTSD) symptoms	UCLA PTSD Reaction Index (PTSDRI)	Youth Self-report Parent version also available	Hispanic adolescents (Saltzman, et al., 2001)

139 Online Database of Interventions and Resources for School Social Workers

Natasha K. Bowen

Educational policy of the 2000s, frameworks of school-based practice, the 2012 National Association of Social Workers (NASW) *Standards for School Social Work Services*, and recommendations from school social work researchers all agree on a set of essential practice guidelines for supporting the success of students in American schools. The guidelines include:

- Use assessment data to inform intervention choices.
- Assess and intervene in the social environment, which contributes to student behavior and academic performance at school.
- Use empirically supported practices.
- Categorize interventions into a multi-tiered system based on the two inversely related continua—the number of students needing interventions and the intensity of the interventions.
- Emphasize universal prevention (i.e., targeting all students with low-intensity preventive strategies) to reduce the number of students in need of more intensive intervention.

Educational policies, such as the Individuals with Disabilities Education Act (IDEA) (U.S. Department of Education, 2004) and No Child Left Behind (NCLB, 2001) mandated the use of assessment data and empirically supported interventions in schools. IDEA's language about evaluating students' responses to a series of less-intensive educational strategies before referring them for more intensive (and expensive) services prompted the development of multi-tiered approaches

to school interventions, such as Response to Intervention (RTI, National Center on Response to Intervention, 2010) and Positive Behavioral Interventions and Supports (PBIS or PBS, Office of Special Education Programs, 2011). These frameworks call for the use of ongoing assessment data to evaluate student progress and guide the choice of appropriate empirically supported interventions. See Chapter 84 for more on PBIS.

The 2012 NASW *Standards for School Social Work Services* reflect awareness that the new accountability mandates and models of school-based student supports could affect social workers' roles in schools. The three standards below, for example, include language specifying that assessments and interventions should be ecological, multi-tiered, and that practice decisions should be based on data.

- Standard 3. Assessment (p. 9)
School social workers shall conduct assessments of individuals, families, and systems/organizations (namely, classroom, school, neighborhood, district, state) with the goal of improving student social, emotional, behavioral, and academic outcomes.
- Standard 4. Intervention (p. 9)
School social workers shall understand and use evidence-informed practices in their interventions.
- Standard 5. Decision Making and Practice Evaluation (p. 10)
School social workers shall use data to guide service delivery and to evaluate their practice regularly to improve and expand services.

The literature on school social work has also reflected changes in expectations for school-based practitioners and the perception that school social workers must adapt to frameworks like RTI (Kelly et al., 2010b), or should make use of existing social work training and tools to become leaders in ecological assessment, empirically supported practices, and prevention (N. K. Bowen, 2013; Dupper, 2002; Franklin, Harris, & Allen-Meares, 2013; Powers, Bowen, & Bowen, 2011).

Despite federal legislation, the diffusion of multi-tiered approaches to school-based intervention, and changes to school social work standards to reflect changes in the macro environment for education, it is not clear that social work practices have changed substantially (Kelly et al., 2010a; Kelly et al., 2010b) in recent years. Kelly et al. (2010b), for example, used survey data from school social workers to examine the extent to which their current practices were consistent with major elements of RTI, such as using empirically supported interventions, providing multi-tiered interventions, and employing data-driven decision-making. The researchers found that the practices reported by school social workers came up short in these areas. Similarly, in a manuscript describing social work practices based on 2008 data from a sample of school social workers, Kelly et al. (2010a) concluded that despite the changing climate of school-based practice, school social work had not changed substantially in the previous 10 years. A majority of respondents in the study (60%) indicated they spent all or most of their time providing individual counseling to students; almost one-third (30%) reported that half or more of their case-loads were students with Individual Education Plans (IEP), meaning the students received intensive, targeted exceptional children's services; and a majority wished they could spend more time on prevention (Tier 1) and less on Tier 2 and Tier 3 interventions.

To become leaders in school-based interventions that respond to federal mandates and the needs of students, social workers must equip themselves with appropriate knowledge and tools regarding empirically supported group- and school-level prevention and intervention strategies. An existing publicly available database at the School Success Online website can equip school workers with the information, tools, and resources they need. This chapter describes the School Success Profile (SSP)/Elementary School

Success Profile (ESSP) Best Practices database and demonstrates how it can be navigated. We describe three ways the SSP/ESSP Best Practices Database can equip school social workers to lead or guide efforts at their schools to implement empirically supported, tiered prevention and intervention strategies based on an ecological understanding of student well-being and performance in schools:

1. The "traditional" way—Search by SSP and ESSP social environmental domains (e.g., neighborhood, school) and dimensions (e.g., teen behavior in neighborhood, school safety) to find universal or targeted interventions that address factors with undesirable assessment scores.
2. The "risk and protection profile" way—Use recommendations from SSP and ESSP studies about common profiles of social environmental risk and protection to guide intervention choices.
3. The "freestyle" way—Use the keyword search function in the online database or the Mental Health Database to identify strategies and resources related to the range of referral issues school social workers commonly encounter, including mental health disorders.

By drawing on findings from published SSP and ESSP studies of the relationship of the social environment to student outcomes and published and unpublished information about the best practices database, this chapter provides a comprehensive overview of how the database can serve school social workers in their efforts to support students with the high-quality services they deserve.

OVERVIEW OF SCHOOL SUCCESS PROFILE AND ELEMENTARY SCHOOL SUCCESS PROFILE BEST PRACTICES DATABASE AND ASSESSMENTS

Whether or not they play a direct role in implementing group and individual interventions, the value of school social workers' contribution to school-based efforts to support student success is enhanced when they are familiar with best practices to address the range of barriers to learning encountered by students. The online SSP/ESSP database of best practices and resources (<http://www.schoolsuccessonline.com>)

equips social workers with intervention expertise that can make them indispensable as school team members; as consultants to teachers, other student support professionals, administrators, and parents; and as providers of direct services. Specifically, the database provides social workers with information on empirically supported interventions that address threats to school success revealed in student assessment data (Powers et al., 2011; Powers, Bowen, & Rose, 2005). Entries are listed as “evidence-based programs” or “promising practices” depending on the level of research supporting them. Descriptions of best practices in the database are sufficient to permit decisions about their feasibility and acceptability to school staff. If relevant, contact information for materials and training is also provided in database entries. The database also describes hundreds of books, websites, and other sources of information on problems and disorders, assessments, and interventions relevant to practice in schools in a subsection called “Resources.” The site, therefore, supports the development of expertise in problem areas, the use of published assessments, practice accountability, and the use of empirically supported interventions. In summary, under each social environmental domain and dimension that is important to elementary or secondary students, users of the online database can find:

- Evidence-based programs
- Promising practices
- Resources

Consistent with trends toward tiered responses to student needs, SSP/ESSP evidence-based program entries are organized into three categories based on whom they target: “universal” prevention strategies targeting all students; “selective/indicated” prevention efforts designed for small groups (e.g., Tier 2) or individual students (e.g., Tier 3) for whom universal prevention efforts are not sufficient; and “multicomponent” strategies that include universal and targeted components (Powers et al., 2011). The categorization of entries in the database facilitates the consultative role of social workers serving on school teams focused on school-wide strategies to improve student learning (e.g., school improvement teams), and on teams focused on removing barriers to learning for individual students or small groups of students (e.g., student support teams or exceptional children’s teams). Because Tier 1 and Tier 2 interventions are currently emphasized in school

practice as means to avoid the most expensive and intensive individual-level interventions, including exceptional children’s services, we focus in this chapter on using the Best Practices Database for group- and school-level interventions.

The Traditional Way of Using the Best Practices Database

The online database can be used with or without SSP or ESSP data. It was originally designed, however, to be used in conjunction with group-level reports, or profiles, from the SSP and ESSP. Unlike most assessments used in schools (Bowen, 2013), the SSP for secondary students (G. L. Bowen, Rose, & Bowen, 2005; Richman, Bowen, & Woolley, 2004) and ESSP for third through fifth grade students (N. K. Bowen, Bowen, & Woolley, 2004; N. K. Bowen, 2010) collect data on social environmental factors associated with students’ school success. The SSP for middle and high school students collects self-report data on the neighborhood, school, friend, and family environments of youth. The ESSP collects data from students, their teacher, and a caregiver. Both surveys also collect data about proximal and distal outcomes associated with supportive and problematic social environments—student psychological well-being, behaviors, and academic outcomes. SSP and ESSP data help teachers and school practitioners understand *why* some students may be struggling with social behavior or academic outcomes (N. K. Bowen, 2013), information that is essential to decision-making about strategies to *prevent* undesirable outcomes. Although we describe here the use of SSP or ESSP assessment data in the process of identifying interventions, interventions in the database can be explored by domain and dimension even if other assessments have been used to collect social environmental data on students.

Data from any assessment should provide practitioners with answers to the following questions (N. K. Bowen, Lee, & Weller, 2007; Powers et al., 2011):

- Who should be targeted?
- Which environmental or individual factors should be addressed?
- How much change should be sought?

The answers to these questions will determine which intervention or prevention strategy is appropriate. We describe how SSP and ESSP

results help school social workers answer these questions, but analogous decision-making strategies should apply to other assessments as well.

Who Should be Targeted?

Because group- and individual-level profiles are generated as respondents complete the SSP and ESSP, the question of whom to target is not difficult to answer. If group-level scores in any area are undesirable, school staff may decide school- or grade level-wide strategies are needed. If, according to individual-level profiles, scores are alarming for only a small subset of students, or one student, targeted interventions might be a reasonable strategy. "Group-level" data are often school-level data, but practitioners can request data reports on students with common demographic characteristics (gender, race, age, and grade level) and combinations of those characteristics. With data on subgroups of students at their schools, practitioners can better tailor group-level interventions.

Which Environmental or Individual Factors Should Be Addressed?

The choice of environmental or individual characteristics to be addressed also flows readily from SSP and ESSP assessment data. Group and individual profiles for both the secondary and elementary assessments have embedded interpretation cues. The individual-level SSP profile, for example, uses a stop light format to indicate which dimensions of the social environment and student well-being have scores in the risk (red), cautionary (yellow), and asset (green) categories. The ESSP uses percentage scores with cutoffs to indicate dimensions that have scores in the risk (less than 60%), cautionary (60% to 79%), and protective (80% or higher) range. Dimensions with scores below the cutoff for protective environmental and individual features may be considered as potential intervention targets. Obtained scores on dimensions of the social environment and individual well-being must also be assessed in light of school staff's knowledge of the student body and their own priorities for change.

Using knowledge about which SSP scores are most predictive of proximal (dimensions of personal beliefs and well-being) and distal outcomes (behavior and academic performance) can also help school social workers decide where to devote their intervention efforts. Powers, Bowen, and Rose (2005), for example, demonstrated that of the social environmental dimensions assessed with the SSP, neighborhood safety was most

predictive of school behavior, and school satisfaction was most predictive of school engagement.

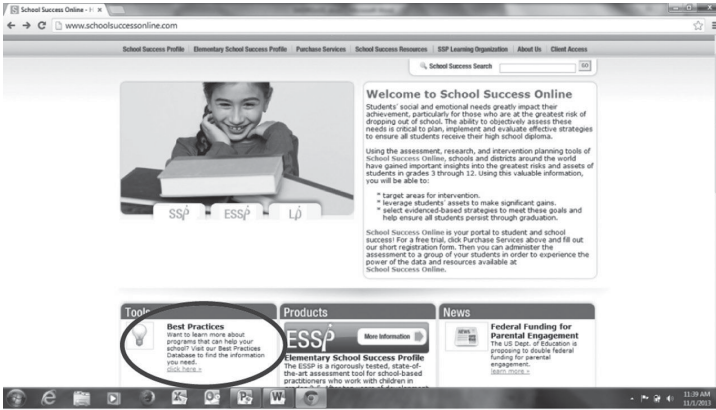

How Much Change Should Be Sought?

The answer to this question is guided by discussion among stakeholders about what scores would be acceptable and how much change is possible in a given time frame. When looking at the Summary Group Profile for the SSP, for example, school staff might be most concerned about what they consider a high percentage of students (e.g., 25%) with scores in the risk range for perceptions of school safety. They might agree that a desirable and feasible goal is to reduce the 25% to 10% in the current school year. One of the ESSP group-level reports provides comparison scores based on a representative sample from a large community sample, which can help school staff evaluate their own scores. Cutoffs for desirable scores on ESSP dimensions are also provided and serve as numeric goals that may be chosen by school social workers. Specifically, scores below 60% (on a scale of 0 to 100) are considered within the risk range; scores from 61% to 79% are considered cautionary; and scores of 80% or higher are considered protective. However, one ESSP study (N. K. Bowen et al., 2007) suggested that scores of 90% or higher are the most beneficial for student outcomes; therefore, school staff might aim to increase scores on dimensions they choose to target up to that level, if feasible.

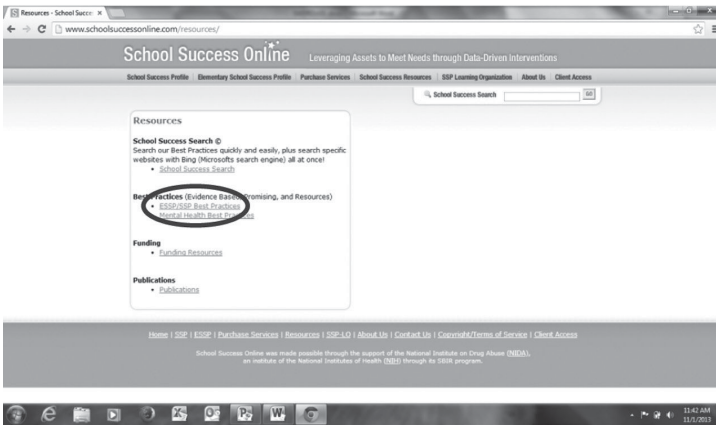

Of course choices about "who," "what," and "how much change" must also take into account resource and time constraints of school staff. Resource constraints, such as lack of discretionary funding for social work interventions, limited staff time, and administrative preferences, will affect decisions about how to proceed from assessment data. Bowen, Lee, and Weller (2007) describe alternatives that may need to be considered in the common circumstance of resource constraints on intervention choices.

How Can We Address the Identified Problem?

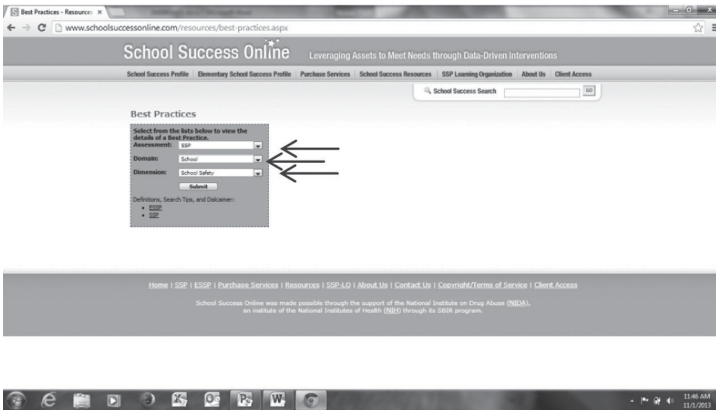

After intervention targets and change goals are identified based on assessment data, the next question is: How do we address the identified problem? Potential answers are provided by the SSP/ESSP online database of best practices and resources. Figure 139.1 illustrates how to navigate from the School Success Online home page to the best practices database. After identifying scores of concern on an SSP or ESSP

Best Practices Link on School Success Online Home Page

ESSP/SSP Best Practices Link

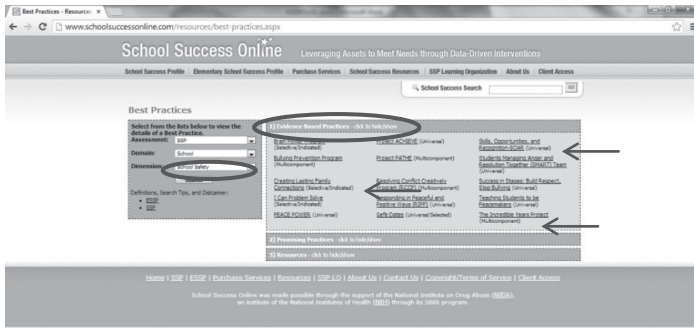

Selecting SSP (Middle and High School Strategies) for School Safety

group-level report, for example, scores indicating low levels of school safety or high levels of bullying, social workers could review the evidence-based and promising practices described in the online database for each of those dimensions. Information on the costs

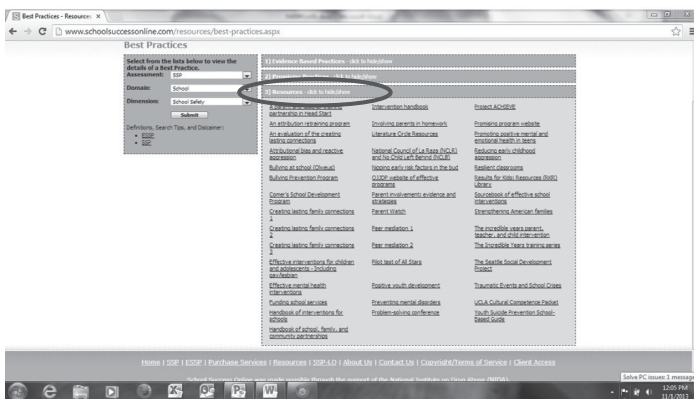

of strategies in the database help school practitioners narrow down intervention options to those they can afford. Depending on cost, material, and personnel resources required, and idiosyncratic preferences of school staff, one or more programs might be selected to

Evidence-Based Program Options for Middle and High School Safety, with Universal, Selective/Indicated, and Multicomponent Labels

Promising Program Options for Middle and High School Safety

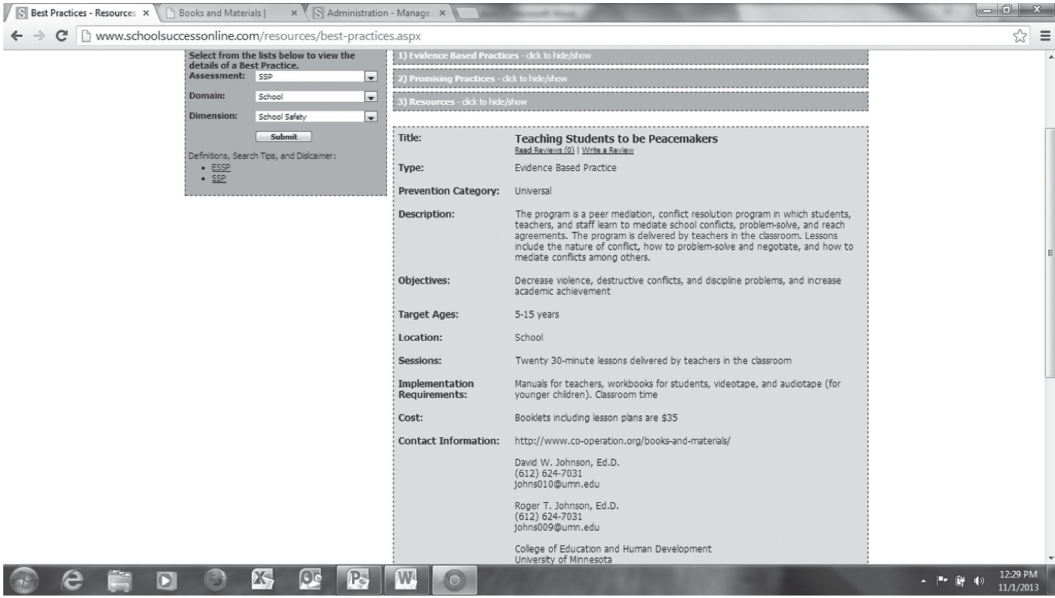

Resource Options for School Safety

Figure 139.2 Illustration of navigation to secondary school interventions for school safety.

address a problem. Additional resources from the database's resource category might also be obtained and consulted. Consideration of protective factors in student profiles could assist in the choice of strategies to use (e.g., if students perceive high amounts of social support in their social environment outside of school, strategies involving adults from outside the school might be feasible).

Example of Traditional Navigation of the SSP/ESSP Best Practices Database

Figure 139.2 illustrates navigation of the Best Practices Database for strategies addressing school safety in a secondary school (starting where Figure 139.1 left off). After selecting the SSP subsection of the database, which contains best practices for middle and high school students, the school domain, and the school

A Promising Practice in the Database

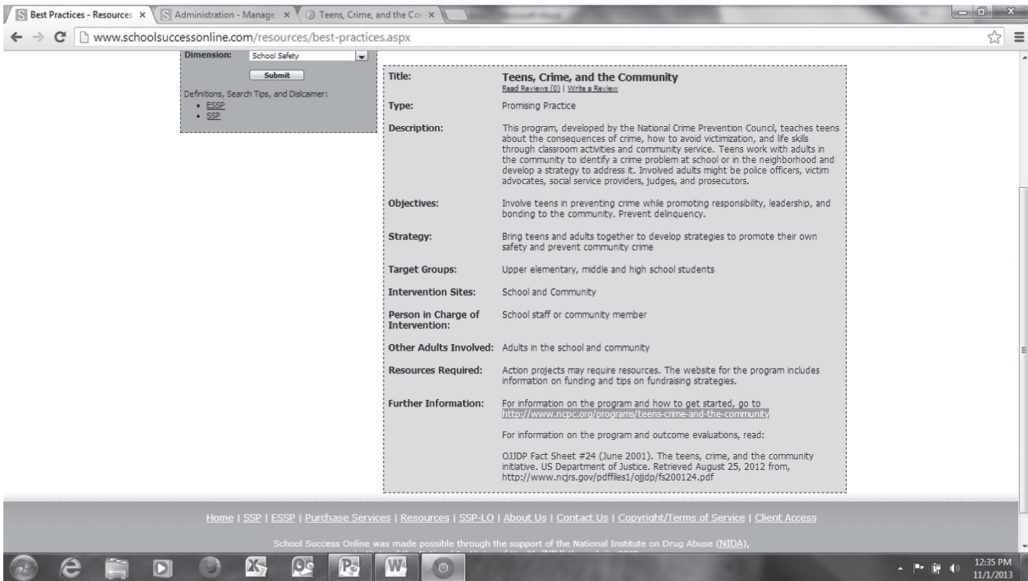

Figure 139.3 Examples of information screens for evidence-based programs and promising practices for school safety.

safety dimension, the school social worker will see a screen with three options on the right. Option 1 provides a list of highly researched evidence-based practices. Option 2 provides a list of promising practices—strategies that have preliminary to promising evidence of utility for addressing the problem area. Option 3 provides a list of print and online resources that provide

background information and/or assessment and intervention information on the problem area. Figure 139.3 provides examples of information screens for evidence-based programs and promising practices for school safety.

Use of the Best Practices Database in this traditional way has been illustrated in previous publications (G. L. Bowen, Richman, & Bowen, 2002;

Powers et al., 2011; Powers et al., 2005). The SSP and ESSP entries on evidence-based practices, promising practices, and resources are the same whether they are accessed the traditional way just described, or through the other approaches described below.

The Risk and Protection Profiles Approach to the Best Practices Database

Three studies using ecological SSP or ESSP data and theoretical approaches have identified combinations of risk and protection that may be common among students. In conjunction with ecological assessment data, knowledge of these common patterns can help social workers decide what social environmental factors should be prioritized and how much change to seek. Findings from the studies also suggest that targeting multiple areas of students' social environments may be important and that building protective factors is a viable prevention strategy. Bowen, Lee, and Weller (2007) looked at patterns of high (protective) and low (risk) scores on eight variables related to neighborhood, school, friends, and family. Adults who care, quality of friendships, treatment by peers, and student perceptions of school as a fun place to learn and be with other children were variables used to create the typology. The authors identified five common profiles of risk and protection that were associated with outcomes of interest to school staff. The study found:

- The best psychological, physical health, behavioral, and academic outcomes were observed for students with high levels of social environmental protection in all areas (90% or higher).
- The worst student outcomes were associated with an accumulation of scores below the moderate protection range (below 80%).
- Students facing risk in only the friend domain had physical health, adjustment, social skills, learning behavior, and academic outcomes similar to students with low scores in multiple domains.

The findings suggest, among other things, that building the number of sources of protection as well as the amount of protection across the neighborhood, school, friend, and family domains is important. In addition, even in the context of protection in other domains, negative peer influences may be a threat to student well-being that should not be ignored. School social workers can be guided

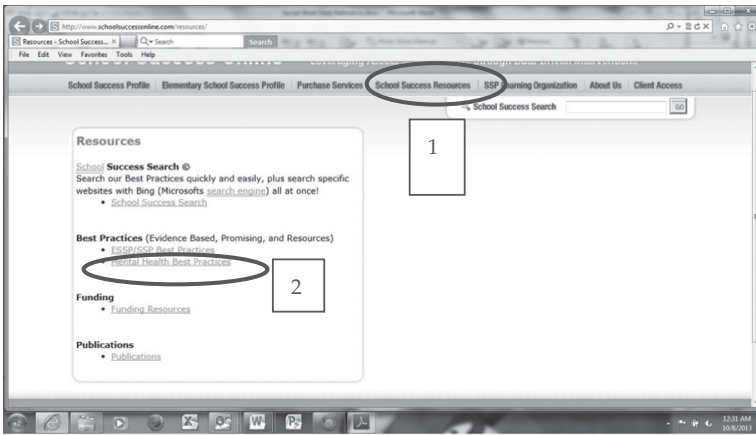

by the findings of this study to search the online database for feasible universal interventions in multiple social environmental domains, but strategies to improve peer relationships schoolwide or for groups of students who are rejected or surrounded by ill-behaved peers might be a priority.

Another study (Weller, Bowen, & Bowen, 2013) using SSP data from middle and high school students examined patterns of witnessing violence in the neighborhood, school, and among friends, and ongoing fear of violence at school and neighborhood. Four patterns of these negative experiences were identified: high exposure and fear, low exposure and fear, high vicarious exposure but low fear, and high fear but low vicarious exposure. The study found:

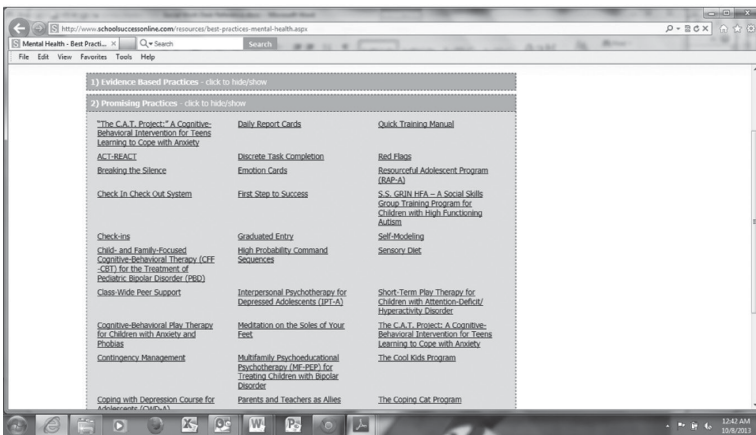

- Witnessing violence was associated with more behavior problems regardless of whether it was accompanied by fear of violence.
- Fear of violence was not associated with behavior problems.
- When witnessing violence or fear of violence occurred in one domain, it also tended to occur in the other domains examined.

The study also examined whether patterns of witnessing violence and fearing violence were associated with gender and racial/ethnic characteristics. White females were the most likely to fear violence at school and in the neighborhood. Black males were the most likely to witness violence in their social environments. Findings from this study highlight the potential negative impact of school and community violence on youth behavior. In addition to using the online database of best practices to identify universal strategies to make the neighborhood and school safer for students, school social workers might discuss with teachers and other school staff the possibility that negative student behaviors are often a consequence of environmental stress—not necessarily student-level deficits.

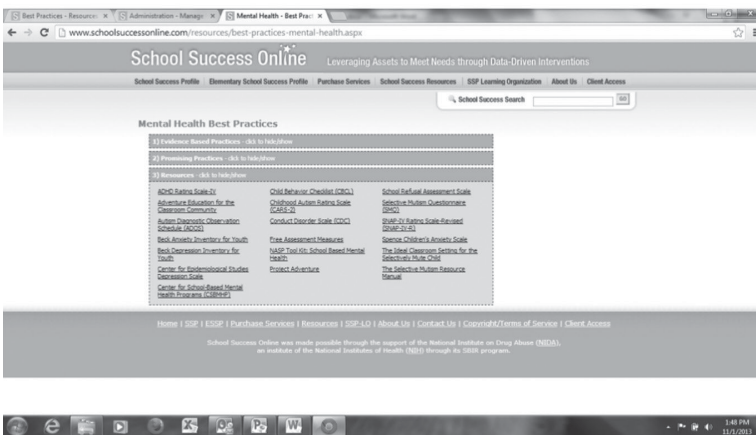

A third study using SSP data from middle school students examined patterns of social capital (defined as supportive relationships) across the neighborhood, school, friend, and family domains (Rose, Woolley, & Bowen, 2013). As in the previous two studies, the authors also examined associations between the patterns, which they called "portfolios" of social capital, and outcomes. The analysis identified eight portfolios characterized by different combinations and levels of social capital. In support of their hypothesis

Navigating from the Website's Banner Links

Promising Practices Currently in the Mental Health Database

Resources Currently in the Mental Health Practices Database

Figure 139.4 Illustration of navigating the mental health subsection of the database.

that the nature or sources of social capital matter, not just the amount, the researchers also found:

- Portfolios containing support from multiple adults were associated with highest levels of school engagement.

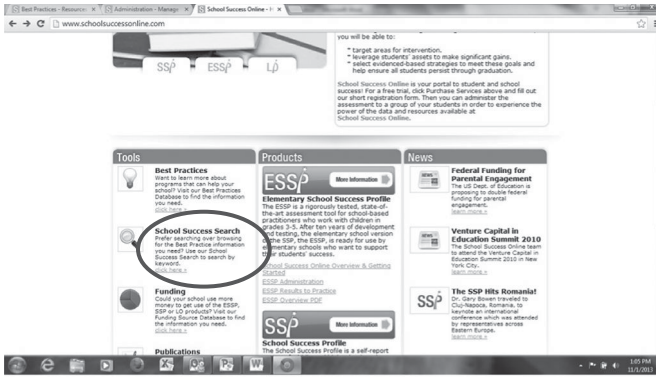

- For some academic outcomes, high levels of teacher support compensated for a lack of support from other adults.

Similar to the first typology study, this study justifies a focus on increasing the number and

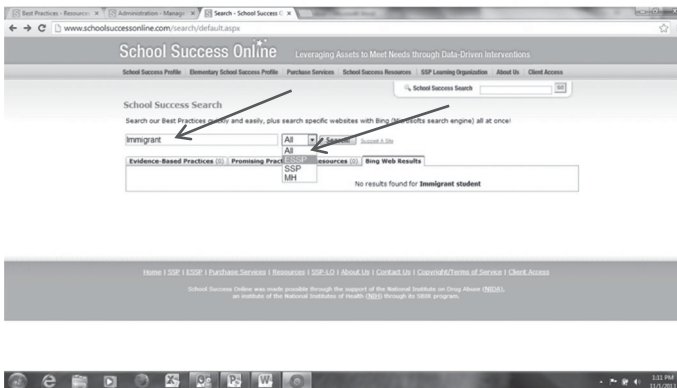

quality of relationships students have with adults and other youth. School social workers can look for evidence-based programs and promising practices related to neighbor, teacher, parent, and friend support. Given common resource

constraints, however, focusing on suggested strategies for improving perceived support from teachers might be a priority.

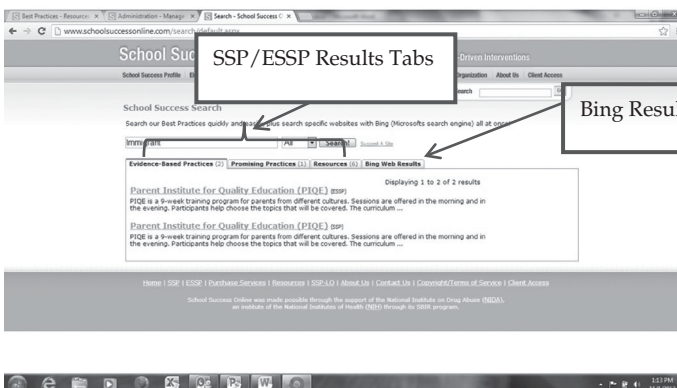

The traditional and risk and protection profile approaches to using the SSP/ESSP Best Practices

Choosing the School Success Search Engine on the Home Page

Entering a Search Term and Selecting Database Subsections

Results Showing SSP/ESSP Database and Bing Tabs

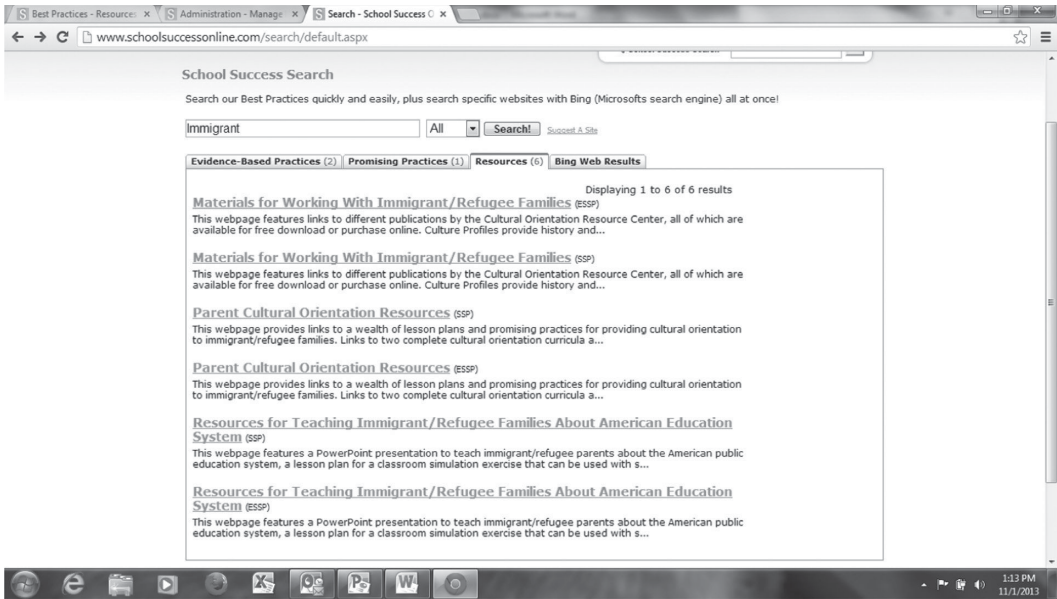

Figure 139.5 Illustration of navigating the keyword search engine.

Database are facilitated by the use of the SSP or ESSP assessment but in no way require it. School social workers who collect ecological data on students with other assessments can easily relate those data to appropriate domains and dimensions listed in the drop down boxes in the database.

The Freestyle Approach to the Best Practices Database

Two other navigation approaches for the best practices database are possible and may be especially convenient for social workers who have not conducted SSP or ESSP assessments. First, a separate subsection of the database focuses on

Results from Resources Subsection of the SSP/ESSP Database

Results from Promising Practices Subsection of the SSP/ESSP Database

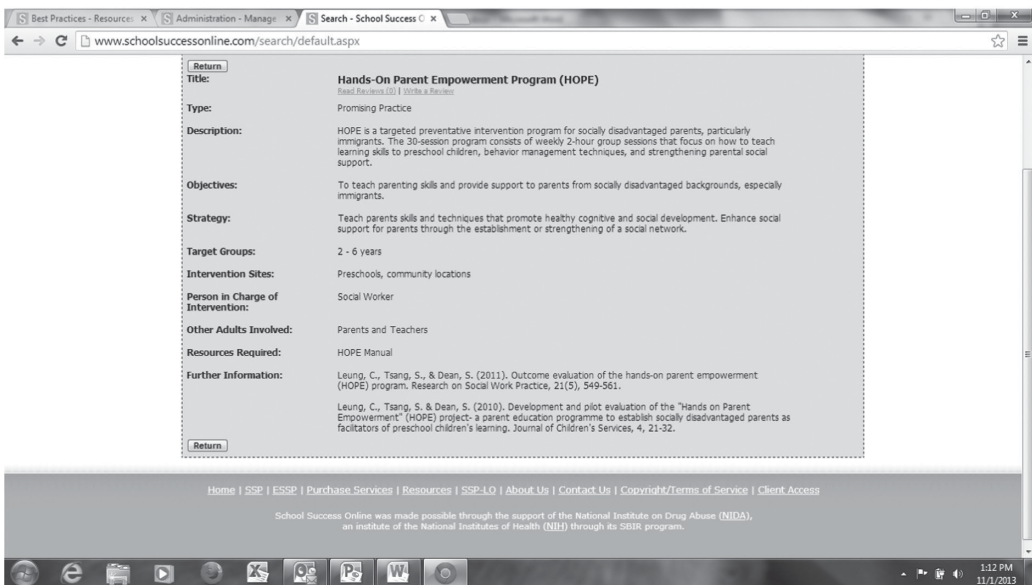

Figure 139.6 Example of results of freestyle search on "immigrant."

mental health interventions (Powers et al., 2012). Evidence-based programs, promising practices, and resources specifically related to mental health issues can be reviewed all in one place in this section of the database. Many of the entries listed under resources relate to mental health assessments. Like the general best practices database, the mental health subsection can be accessed by clicking Best Practices on the School Success Online home page. Figure 139.4 illustrates an alternative way to navigate from the home page to the mental health practices database (and the general database).

Second, the School Success Search feature allows social workers to conduct subject keyword searches. The freestyle approach provides “hits” from the online SSP/ESSP database as well as other carefully selected online sources of information on evidence-based programs, promising practices, and resources on school-based interventions. Figures 139.5 and 139.6 illustrate how to navigate the keyword search engine. Note as well that a School Success Search box and “Go” button are available on most pages of the School Success Online website. They can be seen in the upper right corner of screen shots in Figures 139.1, 139.2, 139.4, and 139.5. Using the School Success Search feature allows school staff to quickly find resources based on terms that they encounter in their everyday practice in schools—for example, attendance, truancy, dropout, pregnancy, disruptive behavior, attention deficit, autism, and school phobia.

CONCLUSION

School social workers, and the school staff with whom they work, are increasingly expected to use ecological assessment data, empirically supported strategies, and group- and school-level approaches to promoting school success and reducing the number of children who need intensive, targeted interventions. Professional standards of school social work practice and the literature on school social work also support these practices. The School Success Online Best Practices Database is a source of extensive information and resources for meeting the demands of school social work. The database, if extensively explored, can also increase school social workers prominence at their schools. School social workers can become intervention and assessment experts on school teams; sources of professional

development on prevention to teachers, school leaders, and other student services personnel; and well-informed advocates for obtaining the most effective strategies to promote the success of students at their schools.

PART XIV

Forensic Social Work

140 The Changing Face of Forensic Social Work Practice

An Overview

José B. Ashford

The National Center for State Courts (NCSC) has a joint project on court statistics with the Conference of Court Administrators and the Bureau of Justice Statistics. The data collected by the Court Statistics Project (CSP) of NCSC documents the caseloads in explicit legal forums where forensic social workers commonly practice: domestic relations, criminal, and juvenile courts. Caseloads in our state courts provide invaluable information about the social significance of our general and limited jurisdiction courts (Willrich, 2003). Caseload data also provide practitioners, policymakers, and academics with the kinds of information that they need in order to develop effective responses for persons involved in legal proceedings (National Center for State Courts, 2012).

The overall caseloads for state courts witnessed a 2% decline in 2010. The most recent data collected by the CSP project shows that the only type of court that witnessed an increase in cases from 2009 to 2010 was the domestic relations court (National Center for State Courts, 2012). Divorce is the central concern that tends to drive domestic relations caseloads. The caseloads for domestic relations courts increased by 7% in 2010 and these domestic relations caseloads have been on the rise since 2007. However, it is unknown whether the observed rise in domestic relations cases since 2007 is connected in any way to the economic downturn that began in that same year (National Center for State Courts, 2012).

Although the number of domestic relations cases increased in 2010, the number of incoming criminal cases to our general and limited

jurisdiction courts was essentially the same in 2010 as in 2009. The adult-criminal courts processed over 20 million individuals in 2010 at an adjusted rate for population size of 6,500 cases per 100,000 population (National Center for State Courts, 2012). This rate is comparable to the benchmark established in 2001 for incoming criminal cases in our state courts. However, this rate is lower than the rate in 2006 when the rate of cases processed by general and limited jurisdiction courts was 7,076 per 100,000 population, which is the highest rate for the years included in CSP's data collection project.

The rates of incoming cases in juvenile courts have also shown declines. The juvenile caseloads declined by 13% from 2007 to 2010. Some of this decline has been attributed to reductions in police and protective service budgets (National Center for State Courts, 2012). Another potential contributing factor is the increased use by many courts of interventions designed to divert juvenile offenders from the justice process. The total number of cases processed in juvenile courts in 2010 was 1,864,345. The rate of incoming cases in 2010 was 2,483 per 100,000 population.

Many of the individuals entering the various doors of our legal system have significant mental health and other related problems. These include:

- Substance-abusing parents in our juvenile courts (at least 80% have substance abuse problems).
- Youths in our juvenile justice system (70.4% meet criteria for at least one mental health disorder).

- Adult offenders (of those detained in local jails, 15% to 16% have serious mental health disorders).
- Guardianship cases (senior citizens incapable of managing their person or property witnessed an 18% increase between 1996 and 2005).

Indeed, the courts have become the societal institution of last resort for many vulnerable individuals who are in need of a diverse array of mental health and other kinds of social services provided by forensic social workers (Ashford, 2013).

Victims of crime and other forms of personal harm are also in need of the services of forensic social workers. Workers can assist victims by providing them with support services while victims' complaints are being processed in the criminal justice system. They can also assist victims with the psychosocial and economic consequences of the crime even if the victims have not filed formal legal complaints. The most recent National Victims Survey results indicate that the overall rates of victimization are on the decline, but the rates at which violent-crimes are reported to the police have remained about the same. That is, the results of the survey continue to show that 50% of the victims of violent crime continue not to report their victimization to the police (National Center for Victims, 2013). Though overall rates of violent crime in the National Victims Survey have shown a decrease, the percentage of individuals reporting physical injury during the same period increased from 24% in 2008 to 29% in 2010 (National Center for Victims of Crime, 2013).

In response to the large numbers of victims and offenders involved in law and law-like systems, we are seeing a corresponding increase of interest in the social work profession in the subspecialty of forensic social work. This subspecialty has undergone significant changes since its initial inception as a distinct area of professional social work practice. This chapter reviews many of these changes, including the prospects and limits of professional practice in this burgeoning area of social work practice.

ORIGINS AND DEVELOPMENT OF FORENSIC SOCIAL WORK PRACTICE

Social workers have long recognized that the law is an important mechanism for achieving many of their professional aims. Most of the early

social workers involved in the establishment of the profession collaborated with lawyers in dealing with many different types of social problems. Harriett Bartlett (1970, p. 19) wrote that the social work profession started in many ways by helping individuals who "fell through the cracks of the medical and legal systems." Indeed numerous social work pioneers, such as Jane Addams, tested many of their theories about crime and other social problems in the newly formed urban courts of Chicago (Willrich, 2003). In particular, Jane Addams played a key role in the establishment of the juvenile court and the modern municipal court system that replaced the traditional justice of the peace courts (Willrich, 2003).

Inasmuch as law and social work interactions were pivotal to the formation of many aspects of social work as a profession, the subspecialty of forensic social work is of much more recent historical origin (Reamer, 2007). Most social work practitioners involved in law and social work interactions never used the term forensic to describe the application of their expertise to legal matters until social workers began practicing as members of forensic psychiatric teams. Psychiatric social workers in a number of states were members of clinical teams that were responsible for performing court ordered evaluations of criminal defendants. Like the psychologists on these teams, social workers carried out their assessment and treatment duties under the supervision of a psychiatrist. This form of medical dominance inhibited the development of forensics as a subspecialty in social work and in psychology for many years (Dix & Poythress, 1981).

CHALLENGES TO THE MEDICAL DOMINANCE OF FORENSIC PRACTICE

Forensics is a term derived from the Latin "forensis" meaning forum. In Roman times, the forum was the public place where issues were debated before a group of citizens. However, this meaning of forensics changed and began to be restricted to legal disputes in courts of law around the 17th century. During this time period, the term forensic began to be applied to legal questions involving the causes of a person's death. Medical practitioners were the first group of professionals (other than clergy, lawyers, and judges) who were involved in assisting the courts with these forensic issues. That is, physicians were initially called to assist the courts as scientific experts in determining the cause

of a person's death. This form of practice led to the development of the field of forensic medicine.

Traditionally, physicians were also the first group of scientific experts called on to identify signs of illness associated with disturbances of a defendant's mind. However, psychiatric and legal historians have written that questions about the mental capabilities of individuals were originally handled by testimony from laypersons who knew the defendant (Gutheil, 2005; Skalevag, 2006). These witnesses would confirm whether the defendant had a "weak mind" from birth or whether they had acquired a derangement of mind that had been observed by individuals who knew the defendant prior to the defendant's involvement in the crime. Prior to the 19th century, priests or other religious authorities also were called to assist the courts in assessing the mental culpability of an offender. However, they were no longer allowed to make these assessments after assumptions about human nature and illnesses began to be influenced by evolving conceptions of illnesses in the medical sciences (Skalevag, 2006).

After scientific assumptions about mental illnesses entered the legal culture, the courts only allowed professionals with medical training to conduct assessments of criminal forensic issues such as competency-to-stand trial or criminal responsibility (Not Guilty by Reason of Insanity, Guilty but Insane, or Diminished Criminal Responsibility). Some early challenges to this medical expertise were raised by philosophers. For instance, the philosopher Immanuel Kant (1770) did not believe that the mental condition of an offender fell under the competence of medicine. "According to Kant, questions concerning the mental faculties are psychological so that answers should come from the faculty of philosophy" (Mooij, 1998, p. 340). Psychology here is not the discipline of psychology we know today because this scientific discipline had not been established when Kant was writing. Kant assumed that philosophers knew much more about human nature and mental faculties than medical practitioners (Mooij, 1998). Nonetheless, most criminal codes deferred to medical professionals for addressing forensic issues involving mental health concerns up until the 1980s.

During the 1970s, psychologists, nurses, and social workers began to challenge psychiatry's claim to ultimate responsibility for treatment of forensic and other patients (Dix & Poythress, 1981). Up until this point in history, practice in most mental health settings was dictated by a 1954 resolution approved by the American

Psychiatric Association, the American Medical Association, and the American Psychoanalytic Association. This resolution contended:

The medical profession fully endorses the appropriate utilization of the skills of psychologists, social workers, and other professional personnel in contributing roles in settings directly supervised by physicians.... [W]hen members of these professions contribute to the diagnosis and treatment of illness, their professional contribution must be coordinated under medical responsibility (see, Dix & Poythress, 1981, p. 962).

Although successful campaigns were launched by social workers and psychologists to achieve independent practice in various areas of mental health, the fight was a bit more difficult for social workers than for psychologists. One presumed drawback for including social workers as independent forensic evaluators was licensure (Dix & Poythress, 1981). When psychologists made their case for inclusion in forensic practice, fewer states licensed social workers than licensed clinical psychologists. However, the licensure problem for social workers has changed dramatically since the initial challenges by psychologists of medical dominance in forensic mental health practice. That is, many states currently license clinical social workers who as mental health professionals can diagnose individuals for the purpose of treating mental disorders. However, this important change in the definition of social work practice did not result in many modifications of criminal codes. Many codes continue to authorize only psychiatrists to conduct competency and insanity assessments. Most criminal statutes still demand either the participation of a physician or limit participation to psychiatrists or psychologists. Although the statutory language in many jurisdictions does not exclude social workers explicitly from performing forensic mental health evaluations, the language in most state statutes demands the participation of either a psychiatrist or a psychologist.

In making psychology's case for independent forensic practice, Dix and Poythress (1981) made a convincing argument about how expertise for forensic assessments should be determined. Donald Langsley, who was a former president of the American Psychiatric Association, had questioned the motives behind psychologists, social workers, and other nonmedical professionals seeking independent practice opportunities. Langsley argued that these requests for opportunities to function as independent practitioners should not be motivated by the pursuit of economic gain

and financial rewards, but instead by dispassionate examination of education and demonstrated competencies in clinical areas of practice. To this end, Dix and Poythress (1981) wrote a law review article that questioned whether medical education justified medical superiority. In this law review article, they also examined the issue of psychology's demonstrated competence in many areas of civil and criminal forensic mental health matters. Social workers also achieved recognition as forensic experts in some jurisdictions by independently demonstrating their competence in forensic areas of practice. This chapter reviews some of the progress that social workers have made in demonstrating their expertise in a variety of legal forums.

RECOGNITION OF SOCIAL WORKERS AS EXPERT WITNESSES

Although many social workers on forensic psychiatric teams developed demonstrated expertise as forensic evaluators, there was still a bias in the legal community against treating social workers as expert witnesses for competency-to-stand-trial and insanity issues. For instance, the court in *People v. Parney* (1977) held that a forensic social worker was not qualified to give expert testimony as to issues of competency to stand trial. However, the nonbinding statements in this decision (dicta) pointed out that this holding was not based on the capabilities of any particular social worker, but based on a court rule that mandated presentation of psychiatric evidence regarding competency. This type of regulatory prohibition that affected the court's assessment of a social worker's expertise is still common in many states. However, there was a landmark decision involving a clinical social worker that challenged psychiatry's dominance in New York in the case of *People v. Gans* (1983). In this case, the New York court held that a clinical social worker with appropriate training and experience was qualified to testify as an expert witness to a defendant's mental condition and their prognosis in competency evaluations.

Today, most states still require that at least one examiner is a psychiatrist, but there is mounting evidence that courts are willing to deem a social worker an expert in making mental health diagnoses in criminal forensic and civil forensic matters by examining the nature and quality of their training and experience (see, *Conely v. Commonwealth of Virginia*, 2007; *America West Airlines v. Tope*, 1996). In addition, some states now allow statutorily for other experts to

perform forensic evaluations in criminal matters besides psychiatrists and psychologists (e.g., Connecticut, Delaware, Iowa, Louisiana, Maine, New Mexico, North Carolina, North Dakota, Nevada, Oklahoma, Tennessee, Texas, Utah, Wisconsin, and Virginia). However, Nevada limits the expertise of social workers to performing these evaluations in misdemeanor offenses; and Virginia limits the scope of social work's expertise as an evaluating expert to cases involving juvenile offenders when psychiatrists and psychologists are not available.

Like psychologists, forensic social workers established an identity in the specialty of forensics by gaining acceptance as experts in performing criminal assessments. However, the specialty is expanding to more general legal issues for a variety of reasons, and now we are observing differences in how to define this burgeoning area of professional social work practice.

DEFINING FORENSIC SOCIAL WORK

As the public's interest in law has increased, the focus of social workers also has shifted to addressing a broader array of legal issues that require the application of professional social work knowledge to achieve legal ends and purposes in a variety of civil and criminal law contexts. The professional practice of forensic social work within, or in consultation with, the civil and criminal legal systems has been defined in many different ways. Forensic social work is narrowly defined as professional practice by social workers who are engaged regularly as experts in the provision of evaluation and treatment services for the judicial system to achieve legal ends or purposes. The National Organization of Forensic Social Work (NOFSW) has described on its website that the application of social work expertise "goes far beyond clinics and psychiatric hospitals for criminal defendants being evaluated and treated on issues of competency and responsibility. A broader definition includes social work practice that in any way is related to legal issues and litigation, both criminal and civil" (National Association of Forensic Social Work [NOFSW], 2013). This broader definition includes practice in child welfare, corrections, law enforcement, victim services, and many other areas of practice that do not involve legal questions that are being litigated in the judicial process or in explicit legal forums. Indeed, social workers play a number of roles in both implicit and explicit legal contexts (Slater & Fink, 2012). The narrow

definition of forensic social work focuses on practice in explicit legal forums (Ashford, 2013).

Today, social workers are using the term, “forensic,” much more than in the past (Neighbors, Faust, & van Beyer, 2002). A number of schools of social work have developed concentrations and courses on forensics. Springer and Roberts (2007) provide a description from a syllabus on forensic social work that captures the complexity of this burgeoning specialty of social work practice. Some of the objectives included in their proposed course were:

1. Understand the purpose, functions, practice roles, and settings relevant to the application of social work expertise to forensic matters.
2. Demonstrate knowledge of the adversary process, including procedural issues of law in civil matters and criminal prosecution.
3. Apply relevant social work values and ethics to ethical dilemmas encountered in forensic social work practice and critically evaluate the relationship between legal and social work ethics.
4. Demonstrate knowledge of methods for determining the competency of an accused to understand rights, waive rights, and participate and assist their attorney in their own defense.
5. Apply biopsychosocial assessment principles in assessing responsibility and culpability, including (a) relevant mental, emotional, and substance abuse disorders; (b) trauma, maltreatment, and other adverse situations and (c) collateral information including records, testing, and medical reports.
6. Apply the knowledge and skills required to present court testimony, including the roles and responsibilities associated with being an expert witness.
7. Identify and evaluate methods of risk assessment and risk management for civil and criminal clients. (Adapted from Springer and Roberts, 2007)

Courses on forensic social work also include specific legal content relevant to practice in child welfare, criminal justice, and other relevant health and human service systems.

CURRENT FORENSIC SOCIAL WORK FUNCTIONS

Forensic social workers are applying their professional expertise to a variety of legal questions

and issues in the civil and criminal justice systems. Some of the roles and functions performed by forensic social workers serving the judiciary and the legal system include:

Testifying in litigation

- Expert witness
- Fact witness
- Education witness

Consultation and training

- Consulting expert to the defense, prosecution, or the judiciary
- Consultant or liaison to parole boards, public defender offices, police departments, prosecution offices, and specialty treatment courts
- Consultants to advocacy groups involved with lobbying the courts through the development of amicus briefs
- Training law enforcement, correctional, judicial, and victim services staff.

Evaluation, assessment, and report writing

- Perform court ordered evaluations of mental capacities, children’s interests, parental competencies, capacities to testify, and mitigating factors.
- Assessments of risks, needs, and strengths for child welfare, mental health, correctional, and victim agencies involved with the legal system
- Perform social and psychosocial investigations.
- Assessments of risk of victimization or dangerousness
- Treatment and service planning for victims, offenders, and participants in family court and other domestic relation courts.

Treatment, crisis intervention services, and case management oversight

- Treating civil and criminal forensic patients
- Treating adult and juvenile offenders
- Case management of civil and criminal individuals under various forms of court jurisdiction
- Assessing and treating victims of domestic violence and crime

Alternative dispute resolution

- Child protective services mediation
- Family mediation
- Victim and offender dialogue/mediation

Research and program evaluation

- Development of risk assessment instruments
- Scientific investigations of principles of socializing and therapeutic jurisprudence
- Scientific investigations of court processes and outcomes
- Evaluating forensic assessment and treatment protocols.

Each of the prior functions and roles require that the forensic social worker is conversant with relevant legal considerations. In order to be effective forensic practitioners, forensic social workers must also understand how their ethical obligations are influenced by participation in litigation and other legally relevant concerns. Some rules of thumb include:

- Offer services only in areas where one has appropriate education, training, and experience.
- Separate therapeutic and supervisory roles from expert witness roles.
- Consultants to legal teams should not serve as expert witnesses in the cases for which they were hired as consulting experts.
- Social workers serving as experts should refrain from giving opinions as to ultimate legal issues.
- Provide appropriate admonitions of a lack of confidentiality and of privilege in court ordered evaluations and forensic treatment contexts.
- Clarify reporting responsibilities and duties with clients.

However, forensic social workers cannot overlook the fact that these rules of thumb will vary depending on the conditions of their employment. If they are hired as an independent expert or as a consultant on a case, then this will differ from a social worker who is employed in an auxiliary role as a member of a legal team or as a provider of treatment and/or supportive services for victims or defendants in implicit or explicit legal contexts.

SUMMARY

This chapter introduces readers to the field of forensic social work practice. It also reviews changes in the subspecialty of forensic social

work since the inception of social work as a profession. Distinctions between narrow and broad definitions of forensic social work are provided to assist in the differentiation of ordinary social work practice from practice in the subspecialty of forensic social work. The extent to which the roles and functions of social workers have evolved over time in areas of forensic social work are reviewed and special attention given to rules of thumb for negotiating potential ethical dilemmas resulting from social work in explicit-legal forums, and in implicit legal contexts involving relevant law and social work interactions. This chapter provided an overview of the subspecialty in social work of forensic social work and serves as an introduction to the principles and practices in selected areas of forensic social work practice that are covered in this section of the *Social Workers' Desk Reference*.

141 Forensic Social Work and Expert Witness Testimony in Child Welfare

Carlton E. Munson

This chapter deals with forensic social work practice in the context of expert witness testimony regarding children and adolescents, but most of the content can be applied to any form of forensic social work. Social workers are increasingly performing forensic child welfare work by providing evaluations of children and families and testifying as experts in relation to court or attorney-requested assessments as well as testifying as fact witnesses in connection with therapeutic intervention (Bullis, 2013). Despite a long tradition of social work involvement in forensic work that can be traced to Jane Addams at Hull House in Chicago (Slater & Finch, 2012), social workers do not generally have training in how to do legal assessments or how to provide effective expert and fact witness testimony. Social work education programs at the baccalaureate,

master's, and doctoral levels do not provide much academic instruction in forensic social work, and there are limited continuing education offerings in this area. A few social work schools have developed forensic specializations, but these do not have a specific focus on child welfare practice. Social work has not been as diligent as psychiatry and psychology in developing forensic specialty professional organizations. The National Organization of Forensic Social Work (NOFSW) was founded in the 1970s and offers training, conferences, and publications. In 1987 the NOFSW approved a revised and updated forensic social work code of ethics. The size of the NOFSW is small compared to the number of social workers providing forensic services.

The social work profession has been slow to develop practice standards for clinical child welfare

practice. At the same time the forensic practice of social work has become highly specialized especially in the area of forensic child welfare practice (Munson, 2011). In addition, the evolution of the Frye standard (*Frye v. United States*, 1923) that expert witness testimony is only admissible if acceptable as recognized in the profession, has led to even more stringent standards imposed by appeals courts in the “Daubert Test” based on a broad ranging four factors review of the nature of the expert testimony (Barsky, 2012; Munson, 2011). The four factors that serve as the basis for expert testimony are: (1) has been scientifically tested, (2) has been subjected to peer review or publication, (3) has a known error rate, and (4) has widespread acceptance in the relevant scientific community (Munson, 2011). Every forensic social worker who offers expert witness testimony should become familiar with the Frye and Daubert “tests.” The following section lists the general areas of training and knowledge the forensic child welfare expert should have to meet the “Frye” and “Daubert” tests for being considered by the courts to be a reliable and acceptable expert.

ENTERING FORENSIC WORK

Training and Knowledge Needed

Forensic assessments and expert witness testimony require highly specialized training and experience. Before entering expert witness practice, the social worker should receive training in forensics and the role of expert witnesses. The primary areas that a child welfare expert witness should have training in include, but are not limited to, the following (key resources are cited):

- Child and adolescent development (Berk, 2012; Bukatko & Daeler (2011); Volkmar, & Martin, 2011)
- Child and adolescent psychopathology (Parritz & Troy, 2013; Saklofske, Reynolds, & Schwean (2013)
- Child and adult assessments (Sadock, Sadock, & Ruiz, 2012; Saklofske, Reynolds, & Schwean, 2013)
- Attachment theory (Cassidy & Shaver, 2010; Oppenheim & Goldsmith, 2011; Solomon & George, 2011)
- Traumatic stress theory (Carlson, 1997; Cohen, Mannaino, & Deblinger, 2012; Nader, Dubrow, & Stamm, 2013; Schiraldi, 2000; Siegel, 2012; Wolchik & Sandler, 2007)
- Basic developmental neuroscience (Applegate & Shapiro, 2006; Cozolino, 2013; Johnson & de Haan, 2011; Montgomery, 2013)
- Basic understanding of psychopharmacology (Bentley & Walsh, 2013; Preston & Johnson, 2011)
- Basic understanding of genetics (Klug, Cummings, Spencer, & Palladino, 2011)
- Basic knowledge of substances and alcohol use/abuse/dependence (Silverman, 2012; Hart, Ksir, & Ray, 2010; Ruiz & Strain, 2011)
- Child welfare clinical practice (Crosson-Tower, 2012, 2013; Lutzker, 2013; Myers, 1998, 2006)
- Ability to administer and interpret standardized measures and instruments (Kaplan & Saccuzzo, 2013; Groth-Marnat, 2009)
- Knowledge of forensic specialization practice (Munson, 2007; Springer & Roberts, 2007)
- Knowledge of local, state, and federal laws relevant to clinical practice specialization and expertise (Dyer, 1999; Myers, 2006; National Association of Social Workers [NASW], 2012)
- General knowledge of forensic practice (Ackerman, 2010; Albert, 2000; English & Sales, 2005; Gudjonsson & Haward, 1998; Heilbrun, Grisso, & Goldstein, 2009; Melton, Petrila, Poythress, & Slobogin, 2007; Saltzman & Furman, 1999; Slater & Finch, 2012)
- Specific knowledge of child and family forensic practice (Myers, 1998; Sparta & Koocher, 2006)
- Specific knowledge of custody evaluation practice standards (Ackerman, 2006; Gould & Martindale, 2009; Stahl, 2011; Tolle & O’Donohue, 2012)
- Specific knowledge of how to provide expert and fact witness testimony (Bernstein & Hartsell, 2005; Brodsky, 2013, 1999; Ceci & Hembrooke, 1998; Gutheil & Dattilio, 2008; NASW, 2013; Tsushima & Anderson, 1996).

Fact and Expert Witnesses

On entering forensic work, the practitioner must understand the difference between expert and fact witnesses. Expert witnesses and fact witnesses are different in most jurisdictions. Fact witnesses are also referred to in some jurisdictions as “treaters.” A treater mental health professional can be called to testify to the treatment

that has been provided to a person. He or she testifies only to the facts of the treatment and does not offer opinions about factors outside the context of the treatment. If the witness is not testifying as an expert, the testimony is in the form of opinions or inferences limited to those rationally based on perception and helpful in clarifying testimony or determination of a contested issue. Expert testimony is admitted, in the form of an opinion, if the court determines that the testimony will assist the trier of fact (judge or jury) in understanding the evidence or to determine a fact in question. In making that determination, the court establishes (1) whether the witness is qualified as an expert by knowledge, skill, experience, training, or education; (2) the appropriateness of the expert testimony on the particular subject; and (3) whether a sufficient factual basis exists to support the expert testimony. An expert opinion is not necessarily inadmissible because it embraces an ultimate issue to be decided by the trier of fact, but an expert witness testifying with respect to the mental state or condition of a defendant in a criminal case may not state an opinion or inference as to whether the defendant had a mental state or condition constituting an element of the offense because that issue is for the trier of fact to decide. This exception does not apply to an ultimate issue of criminal responsibility. Expert witnesses can give opinions and inform the trier of fact for courts to make the best possible decision in cases. For this reason, judges are granted liberal discretion in allowing expert testimony (Mueller & Kirkpatrick, 2013).

It is recognized that a fact or treater witness can be an advocate for the client, and therefore, would be appropriately biased in favor of the client. An expert witness is not to be an advocate and should be objective and impartial. A treater or fact witness should never be an expert in the same case because of the advocacy and impartiality conflict. Some attorneys and judges will attempt to have a fact witness also give expert witness testimony; the fact witness should politely decline the invitation and point out the conflict that is created by performing the two roles simultaneously. If the judge insists the fact witness render an expert opinion, the witness should comply with the judge's directive to avoid being charged with contempt of court (Gutheil & Dattilio, 2008). An expert should not become the treater of the same client after providing expert witness testimony for the client because of the future potential for conflict from having been an expert witness.

Managing Risk

Forensic social work practitioners are at higher risk for lawsuits and regulatory board complaints, and the practitioner should have the maximum professional liability insurance coverage and confirm that the insurance carrier provides coverage for lawsuits and regulatory board complaints. The practitioner should be thoroughly familiar with the National Association of Social Workers (NASW) Code of Ethics (NASW, 1996) and the NOFSW Code of Ethics (NOFSW, 1987). The forensic practitioner should review the state licensing board regulations. Most states do not have specific licensing regulations related to forensic practice, but some have a statutory code of ethics that is used as the criteria for investigation of complaints that is independent of the NASW and NOFSW ethics codes. The forensic practitioner needs to establish what code of ethics applies in the state or states where he/she practices or testifies.

Confidentiality

Confidentiality is of increased complexity in forensic work. Mental health professionals have become much more concerned with confidentiality in the past decades because of confusing state and federal mandates about confidentiality. In the legal arena, the concept of confidentiality is replaced with the concept of "privileged communication." In the law, information the client provides to a professional remains the "property" of the client, and the client owns the right to control the information with respect to disclosure as part of the judicial process (Albert, 2000; Saltzman & Furman, 1999). The forensic practitioner must consult with the client about disclosure of information that may find its way into the legal process, but the concept of confidentiality in the professional sense is an invention of codes of ethics that apply to any disclosure of client information in any context, not just the judicial process. With confidentiality, the professional owns and controls the information and makes the decision as to whether the information will be released with or without the consent of the client. For example, if child maltreatment has been disclosed by the client or the client threatens to harm a person or property, the professional is compelled to disclose the information to the authorities without client consent.

The best protection in this situation is for the forensic practitioner to have an advance written informed consent that details who will be provided information. The traditional abuse reporting and threats of harm or destruction of property reporting should be included, and the disclosure of information to judges and attorneys should be detailed even if the evaluation is court-ordered. The client should be provided a copy of the signed consent.

The 20/20 Rule

An expert witness should organize practice based on the 20/20 rule. The rule refers to the formula that the expert practitioner devote at least 20 hours per week to work in the clinical area of practice in which the expert offers testimony. The practitioner also should not receive more than 20% of total income from expert witness work. The first part of the formula relates to competency and the second part to impartiality, objectivity, and bias. Practitioners who earn more than 20% of total income from expert witness work are subject to allegations of operating from the “hired gun” principle, in which the forensic practitioner relies heavily on income from forensic work and renders opinions based on expectations of the party or attorney who retains the expert rather than objective, unbiased opinions based on scientific evidence.

Bias

Bias is a key feature of forensic work. The practitioner should make special efforts in all aspects of forensic work to guard against allegations of bias. Bias is important because the role of the expert is exclusively to provide objective, scientific information that will educate and assist the trier of fact (judge or jury) in rendering a decision in a case. The following general forensic practice standards can be helpful in avoiding allegations of bias and keeping a pledge of objectivity.

- Request that the court appoint you to do the expert witness work. If the court does not appoint you, maintain independence from the attorney who pays your fee.
- Avoid doing work for an attorney who insists on knowing your opinions before hiring you. Understanding lawyer motivations based on personality functioning has been described by Daicoff (2013).

- Always work on a retainer basis. It is not recommended that an expert testify in a case if the services provided have not been prepaid. Some states require that experts work on a retainer basis.
- Do not have any informal or non–case-related contact with any parties to a case. This would include attorneys for the parents and attorneys for children.
- Never render an opinion about a person you have not interviewed or tested.
- Interview all relevant parties to a case before rendering opinions.
- Base opinions on scientific evidence that is cited in the report to the court or is explained in oral testimony.
- Use standardized measures to support clinical observations. For example, personality testing to support a diagnosis of Antisocial Personality Disorder.
- Submit reports to the court or attorney well in advance of the hearing so all parties can have reasonable time to review the reports before the hearing.
- Never withhold or delay submission of material relevant to the case or opinions offered to the court.

CASE PREPARATION

Preparation for legal system involvement begins the moment the practitioner receives a referral. A thorough and complete record of all activity should be maintained from the time the first contact with a client takes place. The report of an assessment and evaluation is the cornerstone of expert or fact witness testimony. Social workers entering the legal arena to do assessments should be clear about the purpose of the evaluation. In clinical practice with children and adolescents, this can cover a number of areas, but there are basically two types of evaluations performed in forensic child welfare practice. These evaluations should be comprehensive and detailed and should be supported by standardized testing in a number of areas of the evaluation process.

FORENSIC EVALUATIONS

Expert witness testimony does not always involve the expert being directly involved with the parties. In some cases, the expert may only do a records review and testify on the basis of

that review or submit an affidavit that documents the expert's qualifications, the results of the review, and the opinions. In other cases, the expert may only serve as a rebuttal witness after listening to the testimony of other witnesses. In most cases, the expert will do an evaluation that becomes the basis of the expert testimony. A forensic evaluation is significantly different than a traditional psychotherapeutic assessment, which is used exclusively by the therapist for treatment planning. Forensic evaluations are used by lawyers and judges to make a case based on establishing truth through fact-finding, and mental health professionals use scientific probabilities and ranges of prediction in doing evaluations. A fundamental rule of any expert report writing is that the reports should only be written at the request of the judge or retaining attorney. In some situations reports are not discoverable, but all reports should be written based on the assumption they would be discoverable (Melton, Petrila, Poythress, & Slobogin, 2007).

The forensic evaluation should consist of a standard protocol that is routinely used with cases, based on the clinician's specialty practice area. The assessment should include contact with all persons who have relevance to the outcome of the case. Clinical interviews should be conducted with pertinent individuals and standardized measures used when appropriate (e.g., to confirm diagnosis of depression or posttraumatic stress disorder, to determine suitability for custody or level of parenting stress). The evaluator should contact collateral sources that may have information relevant to the issues explored in the evaluation (such as child welfare workers, therapists, medical and psychiatric hospitalization reports, police, school counselors, teachers, employers, and probation officers).

Evaluation reports should be clear, concise, and carefully proofed before submission. Various outlines for submission of reports have been devised (Koocher, Norcross, & Green, 2013; Melton, Petrila, Poythress, & Slobogin, 2007; Nurcombe & Partlett, 2010; Sattler, 1998).

In preparing reports, use language that is familiar to the courts. This language can be derived from written opinions of appeals courts. Do not attempt to make legal statements, but use brief, legal phrases to express concepts. Phraseology can vary by state, but the concepts usually have the same general meaning. For example, phrases that can be helpful are: "best interest of the child," "general well-being of the

child," "substantial risk to the child," "safety of the child," "health of the child," "vulnerability of the child," "special needs child," "preference of the child," "fitness of person seeking custody," "capability or competency to parent," "potential for maintaining natural family relations," "opportunities for the future life of the child," "prior voluntary abandonment or surrender of custody," "parental rights versus performance of parental duties," and "chronic and enduring mental illness."

In preparing the written report the evaluator should indicate source of statements and use qualifier words when direct knowledge of a fact is not available. Use phrases such as, "reported by," "reportedly," and "according to." Professional language should be used, such as, "Appeared to be intoxicated" rather than "He was drunk," and "Indications are she deliberately made inaccurate statements" not "She lied to me," "intellectual disability" not "mentally retarded."

TYPES OF FORENSIC EVALUATIONS

There are basically two types of evaluations performed in forensic child welfare practice. The first type is a child-centered, comprehensive evaluation focused on family history, developmental history, maltreatment history, and trauma exposure/reaction; the second type is a parenting assessment. The forensic evaluation of children places an additional burden on the forensic evaluator because of the developmental focus, the need for special child-oriented communications skills (Sparta & Koocher, 2006), and the inability of children to make decisions independently. The following general sequential outline is recommended for child and adolescent evaluations:

Reason for evaluation. This should be a brief statement of the purpose of the evaluation and the referral source.

Procedures. Identify information sources, persons interviewed, and standardized measures used. A brief statement should be included that describes how suggestive questioning and inducements for participation were avoided (see Ceci & Bruck, 1999).

Abuse history. Identify presence or absence of any individual or family history of neglect, physical abuse, sexual abuse, or domestic violence.

Background. Summarize information relevant to the factors that led to the presenting problem.

Family and individual history. Provide detailed family history data, including information about parents, siblings, education, employment, social functioning, and religious activity.

Developmental history. Include a survey of the mother's use of tobacco, alcohol, substances, and prescription medications during pregnancy. Note if there were any complications during pregnancy or at birth. Review developmental history for premature birth, low birth weight, eating/feeding problems during infancy, problems with toilet training, or problems entering school. There should be a review of the father's role in the child's development with the same relevant factors as reviewed for the mother.

Developmental milestones. Assess and note appropriate developmental milestones of children and adolescents. This can be done with standardized measures or milestone checklists. The most common areas of development are physical, self-help, social, communication, and intellectual (Berk, 2012). Language development can be a crucial indicator of development in combination with maltreatment. Language delays are common (Amster, 1999) and are so prevalent in the child welfare population that they can be used diagnostically for maltreated children (Munson, 2002).

History of out-of-home placements. Include as much information as possible about past and current placements. This applies to children and adults.

Visitation. If the child is not in the care of the parents, give a summary of the visitation schedule and note whether visitation is supervised or unsupervised.

Criminal justice history. Give a history of all arrests, convictions for criminal offenses, and civil litigation the child or parent has experienced.

Substance/alcohol history. Provide a history of substance or alcohol use by child, adolescent, and parents based on the *DSM-5* (APA, 2013) criteria.

Medical history. Report major illnesses, injuries, hospitalizations, and family history of illness for the child and parents. Document date of

last physical examination. If the client has not had a physical examination in the past 30 days, this should be noted and the client referred for medical screening to rule out any medical conditions that could be a source of dysfunction. Children should also be referred for dental, vision, and hearing screenings if there have been no screenings in the last year.

Medications. Note past and current medications, including dosage information. Review for use of herbal medications or culturally bound medications. If the client is taking medication, record the most recent administration prior to the evaluation session.

Mental health treatment. Review past and present inpatient and outpatient mental health treatment. Record diagnoses received and names of therapists, quality of relationship with the therapists, and the outcome of the treatment.

Education. For children, report school functioning academically and behaviorally. For adults, report amount of education and relevant history performance, placement, and behavior.

Clinical interview. Record the identified client's mental status, interview behavior and demeanor, speech, language, somatic complaints, perception, cognition, judgment, memory, intellectual functioning, emotions, interpersonal skills, and access to weapons.

Standardized measures. Describe and summarize any standardized measures administered. Interpret objective measures in clear, concise language. Focus the interpretation on the purpose of the evaluation and the recommendations.

Diagnosis. Provide a thorough *DSM-5* case formulation (see APA, 2013, p. 16).

Summary and conclusions. Give a concise summary of the case and provide an integrated analysis of the significant aspects of the findings. Conclusions should be supported with citations of empirical research and clinical literature that support findings and conclusions. In complex cases, it helps to have subsections of this section. The recommended subheadings are Summary of Facts, Findings, Conclusions and Opinions, and Limitations.

Recommendations. Based on the findings, the diagnostic formulation, conclusions, and opinions, the evaluator should make specific recommendations and justify each recommendation.

Parenting assessments are performed to evaluate the capability of a parent to have a child in his or her care on a permanent basis. These evaluations are usually focused on assisting with reunification planning for the child or are performed as part of a termination of parental rights legal proceeding. These evaluations can be very complex and require a great deal of training, knowledge, and experience to perform. Parenting assessments are not custody evaluations and have a somewhat different outcome focus. The foundational concept in parenting assessments is that the evaluator must not only consider the immediate capabilities of the parent at the time of the assessment, but should also evaluate and render an opinion regarding the long-term capacities of the parent to provide sustained safe, protective, and healthy care for a child (Choate, 2009). Emerging literature on how to perform parenting evaluations (Budd, Connell, & Clark, 2011; Campion, 1995; Choate, 2009; Condie, 2003; Feldman & Aunos, 2010; Ostler, 2008; Pezzot-Pearce & Pearce, 2004; Reder, Duncan, & Lucey, 2003) has been codified in 14 areas by this author:

Family history. The parent's history of being parented and the nature of the parent's family attachment relationships serve as indicators of the parent's parenting capability and should be reviewed and recorded. How people parent is highly correlated with how they were parented.

Motivation to reunify. Motivation to reunify involves the factors of desire, thought, and action, which are key indicators of reunification success. This can involve a range of activities grounded in the parent's quickly and fully taking action to meet whatever conditions are required for reunification that are thoroughly documented as part of the evaluation.

Financial resources. Providing adequate care for a child requires substantial financial resources. An extensive financial assessment should be done and a determination made as to whether the parent has resources sufficient to care for children adequately.

Supportive resources. A critical factor in successful parenting after reunification is supportive networks and supportive resources. The parenting assessment should include a detailed survey of supportive resources.

Substance use history. Alcohol/substance use, abuse, dependence is evaluated with respect to the extent that it impairs the parent's ability to perform parenting tasks and as to whether the alcohol/substance exposure endangers or corrupts the child.

Criminal justice history. Evaluate involvement with the criminal justice system to the extent that it impairs the parent's ability to perform parenting tasks and as to whether the criminal activity endangers or corrupts the child. Information in this area is gathered through standardized screening forms and state judicial case searches available on the Internet.

Medical status. Determine whether any medical conditions are present that would impair the parent's ability to care for, protect, and make the child safe. Information in this area can be gathered through a standardized medical screening form along with a clinical interview.

Psychological/mental illness. A person does not have to have a model personality to provide adequate parenting and everyone has some personality oddities. Screening for capability to parent is an effort to identify areas of concern that need intervention. Standardized personality measures should be used in combination with the clinical interview in this area.

Intellectual functioning. Intellectual disability does not necessarily impair parenting capability, but when intellectual disability severity prevents the person from meeting the physical, psychological, and emotional needs of the child, ability to parent may be temporarily or permanently affected. Standardized measures should be used to determine intellectual level. The Kaufman Functional Academic Skills Test (K-FAST) is a good scale to use in determining whether parents have adequate skills to care for children.

Housing. In order for a parent to care for a child suitably, the care must be provided in an environment that is safe and fit for habitation.

Parenting experience. Parenting experience is indicated by prior successful experience in caring for children through caring for younger siblings, babysitting, employment in a child care setting, or parenting one's own children. When prior experience does not exist, parent training classes or nurturing classes can substitute for direct experience.

Veracity. When a parent withholds information from or provides misleading information to professionals, there arises serious concern about parenting ability as part of a reunification process. Veracity should be assessed through various measures such as collaborative information and collateral contacts.

Diagnosis. Diagnoses the parent has received can be important to capability to parent. Diagnoses often associated with poor parenting skills are schizophrenia, brief psychotic disorder, bipolar disorder, alcohol/substance related disorders, major depressive disorder, conduct disorder, antisocial personality disorder, and dissociative disorder. A formal case diagnostic formulation using the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)* criteria should be performed.

Child status. Status of the child is important to parenting capability and reunification because children with medical, developmental, psychological, and behavioral problems can be demanding of, and create stress for, the parent. Such children require special and intensive care from the parent. If a parent has denial about a child's level of functioning, the denial can be a risk factor for the child. Information about the child's status should be gathered through thorough evaluation of the child or information obtained from social service records, other evaluations that may have been completed on the child, and collateral contacts such as foster parents or kinship care providers. These procedures are consistent with all the models of parenting assessments identified above.

DIAGNOSIS AND EXPERT TESTIMONY

There has been controversy about the legal sanction for clinical social workers to diagnose. A series of appellate legal opinions have confirmed the admissibility as evidence diagnosis performed by clinical social workers where there is legislative sanction. The Maryland Court of Appeals, in a case that involved the author, unanimously affirmed the statutory right of licensed clinical social workers to perform diagnosis, testify as expert witnesses, and testify to the ultimate issue (In Re Adoption/Guardianship no. CCJ14746, 360Md634, 2000). The opinion of the court and the NASW and others amicus briefs

(Brief for NASW et al., 1999) filed in this case can be helpful to forensic social workers in other states who have been legally challenged in the right to diagnose.

A qualification to diagnose mental and emotional disorders is included in most state practice acts. The Association of Social Work Boards publishes a guide titled, *Social Work Laws and Board Regulations: A Comparison Guide* (American Association of State Social Work Boards, 2013), which can be used to find the specific terminology used in a particular state. When performing diagnosis, forensic social workers should review the qualifications for the state in which they practice.

The *DSM-5* (American Psychiatric Association, 2013) uses a "nonaxial documentation of diagnoses" (p. 16). The format requires a "case formulation" that contains these six components: (1) History and concise case summary, (2) Diagnoses, (3) Medical conditions, (4) Notations of related "conditions," (5) Overall "disability" severity statement, and (6) Treatment plan. Before performing or recording a diagnosis for a forensic report, the clinician should carefully read and appropriately apply principles set forth in the *DSM-5* for doing a diagnostic case formulation. When testifying about a diagnosis that has been assigned to a client, it is crucial that forensic social workers make clear to attorneys and the court what edition of the *DSM* was used in formulating opinions about the person. When preparing for court testimony the practitioner should carefully review the criteria of *DSM-5* in making or altering a diagnosis. For more details see my chapter in the diagnosis section of this volume.

The *DSM-5* also contains a section titled, "Cautionary Statement for Forensic Use of *DSM-5*" (p. 25). This brief section should be carefully reviewed by forensic social workers. The section addresses issues of: (1) Legal and clinical definition of a mental illness; (2) Issues of diagnoses and legal determination, for example, civil commitments; (3) Using caution in applying legal and clinical standards of competency, responsibility, and disability, especially in cases where diagnoses of intellectual disability (intellectual developmental disorder), schizophrenia, major neurocognitive disorder, gambling disorder, or pedophilic disorder are present; and (4) The complexity of determining self-control of behavior within a particular disorder.

BEFORE THE HEARING

Expert testimony occurs after the report has been submitted, and the expert's testimony should be based on the procedures and findings contained in the report. A basic rule to remember is that expert witness testimony is only as good as the attorney who offers the professional as an expert. Experts tend to believe that the entire case depends on their testimony and how well they perform. This is not usually the situation. There are often numerous witnesses in a case and many factors that influence and determine the outcome. An expert's testimony is to offer findings and opinions in a truthful, fair, and factual manner, which can assist the trier of fact in making a decision; this should be paramount in expert testimony.

An expert witness should request to meet with the attorney who will be offering the expert to the court. Such a meeting can be helpful in preparing how the expert wants to present testimony and what is to be highlighted. It is important to ask the attorney all questions about the nature of the testimony. The attorney should be provided with written information about your credentials prior to the hearing. If you meet with the attorney, review your written materials, organize them, and highlight key points. Separate from your report, develop an outline of key points you want to testify to, and commit the outline to memory.

AT THE HEARING

The classic advice regarding attire and demeanor continues to be of paramount importance. Dress professionally, act professionally, and arrive in court early. Bring all materials related to the case. Avoid talking with anyone in the waiting room, courtroom, or hall while waiting to testify. This includes colleagues, attorneys, police, strangers, or the parent or child about whom you are testifying. Do not smile, laugh, or joke with anyone in the presence of the judge or jury before, during, or after testifying. For confidentiality reasons, do not leave a briefcase or hearing materials unattended at any time.

ON THE STAND

Before testifying, request the attorney to qualify you as an expert by reviewing your credentials for the court. Sometimes attorneys are conscious

of the need to proceed rapidly and may do a brief review of your credentials, especially if you have testified in the court in the past. If you are easily and quickly qualified as an expert, it is important to include in your testimony responses that call attention to your qualifications. For example, substantive comments can be prefaced with comments such as, "In my 20 years of work with this population, it is my experience that ..." or "As part of my training I became familiar with research that supports ..." Such comments could be crucial if there is an appeal of your testimony.

Procedural qualification of experts focuses on the concepts of knowledge, skill, experience, training, and education because these are the areas identified in the law as basic to being an expert (Mueller & Kirkpatrick, 2013). The process of expert qualification includes review of professional education (degrees and dates received, internships, specialized training, continuing education, honors, awards, licenses, certifications (Tsushima & Anderson, 1996), employment history, number of clients evaluated or treated, research activity, publications, professional paper presentations, and the amount of prior testimony as an expert witness.

The attorney who is challenging your testimony will use the *voir dire* procedure, which is the opposing attorney's opportunity to test and challenge your credentials and competency to testify, as well as to challenge expert testimony in general (e.g., citing research indicating that expert opinions are no more accurate than those of laypersons). There may be attempts to show bias by requesting the expert to provide information about fees received for testimony, your personal history as a victim of abuse or domestic violence to show you are on a mission, promoting a cause, or engaged in advocacy. *Voir dire* is a standard legal procedure that should not be viewed as a personal attack, although it may seem to be. *Voir dire* can be the most difficult phase of expert testimony, because attacks on education, training, and experience can be intense (Tsushima & Anderson, 1996). The key is to remain calm and answer questions directly and honestly. Never become defensive or argumentative during this stage of testimony, especially when feeling attacked personally or professionally. Consider the following example.

Attorney Question (AQ): It is true that the social work profession is on the lowest tier of therapists, with psychiatrists at the top, psychologists next, and social workers at the bottom, correct?

Expert Answer (EA): No, that is not the situation today. It was like that 40 years ago. Clinical practice with children and adolescents today is quite complex and requires multidisciplinary expertise. All recognized mental health professionals are equal members of the evaluation or treatment team. Social workers have the most historical expertise in child welfare, and we often provide leadership in this area. We provide the majority of the mental health services in the United States and have evolved significant research and expertise in the mental health field.

A general rule of testimony is to avoid anticipating what the judge or the attorneys are dealing with or attempting to elicit. Simply answer the questions on the basis of what you did, the reason you did it, and the opinions you formulated. Ask attorneys to repeat unclear questions. Answer only the questions that are asked, and do not attempt to expand on a previously given answer. Focus on the immediate question you are being asked. It is recommended that you look at the judge when giving opinions, look at the attorney when giving facts, and avoid looking at the client when giving difficult testimony. Always look at the judge when giving answers to questions asked by the judge.

If the opposing attorney asks a question directly from your notes or report he or she received as part of the discovery process, ask for the specific page number of the report and answer on the basis of the content of the report. It is also a good policy to make verbal reference to your report. Use statements such as, "In my report summary section, I indicated ..." or "My background information section of the report confirms that ..." and "The results of my testing explained on page 6 of the report indicate ..." This is an effective way to call the judge or jury's attention to your findings. Do not read from the report. Testify from memory and request the court to allow you to review your report or supporting documents if a technical question is asked that requires a precise answer, such as actual test scores.

CROSS-EXAMINATION

Cross-examination is always difficult because it is the opposing attorney's second chance to challenge the expert witness. In the voir dire phase of testimony, there is a general

challenge to qualifications to testify, and in the cross-examination, there are specific challenges of the validity of the expert's procedures and conclusions in the specific case. It is important to remain calm and factual and not alter voice level when such challenges are made. Do not let the attorney make you angry or provoke you. This requires a significant amount of self-control. It is important to remember that you are there to provide facts and opinions related to what you do routinely in conducting assessments. Hesitate when you think you should not answer a question to give the attorney who offered you as an expert an opportunity to object.

During cross-examination, refrain from thinking the case outcome hinges on your testimony, and do not attempt to analyze the effect of your testimony while you are testifying. Focus on the accuracy and scientific basis of your testimony.

Try to avoid answering hypothetical questions, such as the following:

AQ: Hypothetically, if my client had a relative who could provide care for this child, could the child adjust to placement under these circumstances?

EA: It depends. It depends on the home study of the relatives, their parenting skills, the child's bond and attachment with the foster parents, and history of contact with the relatives as well as other factors. So it would be difficult for me to answer that question.

During cross-examination, an expert can use questions to expand on previous answers or to make additional points.

Example 1

AQ: My client was evicted from her apartment because she had no job, could not pay her rent, and DSS [Department of Social Services] would not give her assistance, wasn't she?

EA: My notes indicate that she was evicted because she was having loud parties, and the police were called because of substance use. This was consistent with statements she made to me that she had been using cocaine regularly for the past three years. I have no record that she ever asked for assistance with her rent.

Example 2

AQ: Then all you can testify to is that there were arguments between my client and the mother? There was no real domestic violence in this relationship, was there?

EA: Recurring shouting and belittling are violent acts. In addition, there is increased risk to the child because the father frequently uses alcohol. He has been apprehended for violence in the community. He denies he abused the mother. The child may have special needs and have uneasy temperament. All of these facts increase the risk of violence against the child by the father.

Avoid defensiveness when asked questions that can be viewed as attacks on your ethics. It is best to respond with a simple statement of ethical obligations.

AQ: Isn't it true that you wrote in your report, knowing it would harm her in this TPR [Temporary Protective Rule] hearing, that my client had a history of multiple foster care placements?

EA: No, my professional ethics code would not allow me to do that. I wrote it because generally accepted practice guidelines for parental rights cases require recording all relevant information regarding this case.

AFTER THE HEARING

After a hearing, the best way to prepare for the next time you will testify is to review your testimony and think of ways you could have testified more effectively. Do not obsess about the effect of your testimony; rather, analyze ways you can improve responses in the future. Write down key questions from your testimony that you may be asked in future cases and review them before you testify again.

CONCLUSION

Serving as an expert is difficult under any circumstances. It is a complex aspect of mental health practice that is increasing. Forensic social work is truly one of the artistic and scientific aspects of practice that requires discipline, skill, and preparation. Providing expert witness testimony is

fundamental to the expert role, and the following nine key summary principles should be used as a concise guide before testifying:

1. Determine if you are a fact or expert witness and do not agree to perform both roles in the same case.
2. Only agree to be an expert witness on a retainer basis and never accept a fee for fact witness testimony.
3. Thoroughly document all activity and organize documents for testimony.
4. Commit to memory your credentials and organize them by education, training, skill, knowledge, and experience.
5. While waiting to testify, remain silent and safeguard your documents.
6. Do not become defensive when challenged, and respond in a calm voice using your knowledge base as your guide.
7. Only answer questions asked.
8. If necessary, expand on yes/no questions and qualify hypothetical questions.
9. After testifying, reflect on what you said, but do not obsess about the effectiveness of the testimony. *Remember:* Your testimony is only as good as the attorney who sought you to testify.

142 Mediation and Conflict Resolution

John Allen Lemmon

Mediation is a role that professionals from business, law, social work, and other disciplines may assume. The neutral and impartial mediator works with disputants to help them reach agreement. If they cannot come to an agreement, the mediator's work is finished. No decision is imposed by the mediator. No evaluation or recommendation is made to a court, because these roles would conflict with encouraging clients to speak openly and honestly, as they would to their psychotherapist or their attorney.

THE CONFLICT RESOLUTION CONTINUUM

Persons with conflicts have choices about resolution. Doing nothing is an option. Avoidance may work.

Negotiation

When disputants engage in negotiation, they attempt to reach an agreement. They may converse

directly or communicate with the help of an agent who advocates for their client. This agent may be an attorney or social worker, and informal advocates such as family members may become involved. Clergy or psychotherapists may be asked to help clients with whom they have a current professional relationship to advocate when a dispute arises, or they may be approached for this reason.

Mediation

In mediation, the third party involved does not seek an outcome for a particular client. The mediator is concerned that any agreement reached be understood by and is fair to each of the disputants. Ethical codes for mediators have stated the need to be neutral and impartial while also being an advocate for weaker or absent parties such as children or frail elders, a difficult balance. The essence of mediation is that if agreement cannot be reached by the parties, the mediator does not switch roles and become an evaluator. In the event of an impasse, an evaluation that results in recommending which divorced parent should

have primary responsibility for a minor child is an essential role, but it must be filled by a different person than the mediator if the parties are to speak freely in mediation. Otherwise, there is a sense of betrayal akin to having the client's attorney, clergy, or therapist testify against them in court. The fact that the judge formally makes the decision does not change the role conflict when mediators cross over to become evaluators who write reports and testify in court.

Crossover is a volatile issue in mediation. For example in California, if no agreement is reached, the mediator is barred by the evidence code from testifying. Nothing in writing may be admitted to a subsequent court proceeding. Are there any exceptions? Yes, in the situation of the custody mediation, courts are permitted to adopt a local rule that allows crossover so that the mediator who is a court employee becomes an evaluator in self-described "recommending" counties. This leads clients to say, "When I was in mediation, my mediator testified against me." Such a role conflict leads to ethical dilemmas for professionals from a number of fields. The confidentiality of mediation has been the cause of cases brought against mediators as well as others in the process.

Confidentiality in private mediation continues to be confirmed. The California Supreme Court held in 2011 that it even applies when a mediation participant is subsequently seeking to gather evidence against his own attorney about the mediation process (*Cassel v. Superior Court*, 51 Cal 4th 113). Later that year in a wrongful termination case brought under the state's Whistleblower Act (*Provost v. The Regents of the University of California* [2011] 201 Cal.App.4th 1289) the plaintiff Provost was denied an appeal from a judgment entered pursuant to a stipulation for settlement reached during mediation. Allegations of signing under duress due to coercion from his counsel, defendant's counsel, and the mediator were not deemed admissible. The Indiana Supreme Court held in 2013 that a husband's statements he claimed to make to the mediator must be excluded from evidence in a proceeding in which he sought to terminate his liability for monthly house payments to the wife after her remarriage (*Horner v. Carter*, No. 34S02-1210-DR-582).

Arbitration

Arbitration also brings a third party to help disputants reach an agreement. However, the arbitrator has the power to impose a binding decision

on the parties if they cannot reach an agreement themselves. Arbitration awards are typically final and not subject to appeal, even if the arbitrator does not follow current law. Only in cases where the arbitrator exceeded the scope of what was to be decided or otherwise significantly failed to follow procedures might a judicial review be granted. Arbitration clauses are often written into employment contracts, requiring employees with a dispute to arbitrate rather than file suit in court. Challenges to mandatory arbitration for customers with conflicts have come from consumer groups charging that there may not be a choice in the marketplace or that the notice of changing to mandate arbitration was in fine print on the back of an envelope of a monthly statement. Civil rights groups have stated—and some appellate justices have agreed—that Congress did not intend for allegations of racial or sexual bias to be arbitrated with no recourse to the courts.

Health maintenance organizations requiring arbitration have been criticized by judges for not following their own procedures for a timely process and for having a stable of "the usual suspects" as arbitrators. There is a movement away from arbitration in organizations. One reason is the loss of control by all parties. A single arbitrator taking years to order the break-up of Andersen, the giant accounting and consulting firm, is a cautionary example. Another factor has been an increasing number of sexual harassment cases in the workplace of both *Fortune* 500 companies and small nonprofit organizations. The trend is to offer mediation and permit clients access to the courts if that is their choice.

Adjudication

Adjudication is a decision or verdict rendered by a judge or jury. Filing suit is the most formal conflict resolution procedure. Although "going to court" may appear to be the way most conflicts are resolved, over 95% of civil cases are settled without a verdict. This means that the parties resorted to another option after starting a lawsuit. Why? Sometimes the parties have had as much justice as they can afford. Litigation is expensive, and if the call from the attorney comes to "refresh the retainer" (a request for more fees), many disputants decide to settle or muddle through by continuing to agree to disagree. The passage of time may alter a litigant's perception of the need to continue, as one may discover the strength of the case while preparing for court.

Sometimes a formal decision by the court is desired by one or all parties. Note that unlike mediation, where all parties must agree to the final terms of any agreement, and even in many instances whether to participate, in adjudication, if one party files suit, any named respondents are subject to the court. Just as many combatants prefer arbitration until they receive an adverse award, lawsuits may reflect unwarranted optimism by at least one party.

Unlike arbitration, an unhappy litigant may seek an appeal. Appeals are not automatically granted in most civil cases. Only a small percentage of cases filed for appeal by one of the parties are selected for review by the typical appellate body. Appeals take years and additional funds. A case could wend its way from a state trial court, to an appellate panel, to that state's Supreme Court, and then to the U.S. Supreme Court. Some cases can be slated for fast track to bypass intermediate courts at the request of the trial court judge or one of the parties. Some cases persist because they have been certified as a class action, acting on behalf of both the named parties and others similarly situated. This is a way to resolve a large number of potential as well as present conflicts.

Violence

A conflict resolution continuum must allude to violence or physical aggression, which could be defined as negotiation carried out by other means. From street brawls to international conflicts, aggression is one way, however unsavory, of resolving disputes. To prevent violence, mediation is taught in elementary and secondary schools. Children wearing "Conflict Manager" T-shirts can be found on playgrounds in countries around the world, including those with a history of armed conflict between factions within their own borders. Peace studies programs in universities and groups like the Harvard Program on Negotiation analyze how aggression and negotiation are linked.

BENEFITS OF MEDIATION

The options reviewed, from ignoring or avoiding conflict through mediation, have the advantage of leaving the disputing persons in control of their conflict. No one can impose a settlement on them until they reach the point in the

continuum where they involve an arbitrator or judge or resort to violence. A mediator may prevent or stop the violence. A mediator may help the disputants translate their points of view to each other, doing considerable face-saving in the process. Because the mediator is new to the dispute, he or she can ask clarifying questions that the parties might not tolerate from each other. A partial agreement can be reached, with unresolved issues left for another option on the conflict resolution continuum. If no agreement appears likely, the mediator or any other parties can stop the process, and the entire dispute can be addressed by other procedures on the continuum. Again, unlike arbitration, the parties are free to seek relief from the courts if they are not willing to reach an agreement in mediation.

In *101 Social Work Clinical Techniques*, Turner & Rowe (2013) note that although mediation "initially emerged as a separate methodology in social work practice," the techniques also are used to address conflict that is adversely affecting the therapeutic process. The examples they cite are scheduling a couple's therapy sessions and a teenager's high school class schedule. Although such simple issues are important to resolve by the psychotherapist so that the therapeutic process can proceed, more complex emotional as well as financial conflicts may be addressed by a mediator using advanced techniques such as humor, role-play, storytelling, and other innovative uses of language as well as anger management (Lemmon, 1985).

Comprehensive Guidelines for Child Protection Mediation were approved by the Association of Family and Conciliation Courts in 2012. Mediating cases in which children have allegedly been abused, neglected, or abandoned may include legal, developmental, emotional, and cultural issues. Such cases are among the most complex and important to be mediated, calling for a range of techniques in order to reach an agreement in the best interests of the child.

MEDIATION: FIELD OF PRACTICE OR SKILL-BASED?

For those either seeking a mediator or considering becoming a mediator, a central question is how much the mediator should know about the general area from which the conflict arises. Could a mediator help parents resolve custody issues for their minor children without knowing state

law that would apply if the dispute ends up in court? Could that same mediator help organizations resolve workplace conflicts without awareness of relevant federal, state, and local law?

One point of view is that mediation is foremost a set of skills. A good mediator would recognize universal stages in any conflict and apply techniques to move from anger to agreement. The other position is that virtually all disputants are *Bargaining in the Shadow of the Law*, as Mnookin and Kornhauser (1979) remind us. What would be agreed to in mediation could hinge in great part on what would likely happen in court.

Even established professions hedge this question of general skills versus subject matter expertise. A licensed physician can perform any medical procedure. A licensed attorney can represent a client in court regardless of the nature of the conflict. However, medicine offers voluntary certification—being “board certified”—for certain fields of practice. Similarly, a number of states offer attorneys meeting certain task and experience requirements the opportunity to take a test to become a certified specialist in a field, such as family law or estate planning.

The questions of subject matter expertise and role conflict are important because mediators have a profession or origin, such as law or social work, where they may still be licensed. Are they attorneys or social workers simply acting in a meditative manner? What if a mediator holds both degrees and licenses, and requirements for each license conflict? Such instances involving threats of violence or allegations of abuse are all too common. If a mediator who is not an attorney offers legal advice, does that constitute the unauthorized practice of law? If the mediator is an attorney and provides legal advice to each party, is that a dual representation conflict that violates ethical canons?

Best practice is for the mediator to ask the disputants to sign an agreement to mediate, specifying that only mediation will be provided, even if the mediator holds professional licenses in other fields. This agreement states that if the parties need legal or financial advice, a psychotherapist, or any other professional services, they should seek it elsewhere. Such a document can also serve as a fee agreement, as well as listing relevant state law concerning privileged communication—that nothing said or written in mediation can be introduced into any subsequent court proceeding and any exceptions. Finally, procedures—again

citing any pertinent law—that constitute an agreement, termination, or impasse can be cited.

REGULATING MEDIATION

Ethical codes have been developed by a number of conflict-resolution organizations that provide guidelines for self-regulation by mediators. What is likely in the future? No state licenses mediators yet. Licensing is protection of duties—“You can’t do that,” unless you meet requirements listed in state law—whereas certification is title protection only—“You can’t call yourself that,” unless you meet the requirements under state law. One state that certifies mediators, Florida, takes a field of practice approach by certifying separately by category. Mediators who deal with community conflict, such as barking dogs or blocked driveways, are called county court mediators after taking 20 hours of training and observing, then conducting mediations under observation. Family mediators must hold certain graduate degrees such as social work, or be licensed as a lawyer, a certified public accountant, or a physician who is certified in psychiatry; meet experience requirements; take a 40-hour training and observe; and then conduct relevant mediations under observation.

Some states have required a generic mediation training of 30 or 40 hours. Others have combined such a course with a 20-hour session dedicated to a particular field of practice. Still other jurisdictions require a basic 30-hour family or 40-hour divorce mediation training to be on a panel to receive mediation referrals. Most of these courses have been provided privately by pioneers in the field, as was the case with law and psychotherapy in their early days. However, an increasing number of certificate programs in conflict resolution and the mediation role are being offered by universities, and Model Standards for Mediation Certification Programs were approved by the Board of the Association for Conflict Resolution in 2012.

NEW APPLICATIONS OF MEDIATION

Family Mediation

Family mediation is expanding from custody mediation to financial matters related to divorce. Mediation of conflicts throughout the family life cycle is increasing. Programs offering permanency planning mediation in child welfare as a way to increase open adoptions, mediating

with blended families to address issues of instant intimacy and different rituals, and mediation between adult children and their aging parents concerning problems in living are examples. Dependency mediation programs are addressing issues listed in petitions to the juvenile court.

Organizational Mediation

Organizations are designing conflict-resolution systems that offer a range of the negotiation, mediation, arbitration, or litigation options reviewed above, with mediation as the fastest-growing role. Employee assistance programs often provide mediation, either directly or by referral. Increasingly, federal legislation has a mediation provision. Many disputes that involve the Americans with Disabilities Act have been successfully mediated. The Equal Employment Opportunity Commission has a mediation program. The National Association of Social Workers has built mediation into its policies. Family business members are asking mediators to help them with succession planning and other tasks when family dynamics conflict with standard business practice.

Online Dispute Resolution

Much early online dispute resolution (ODR) involved the application of software to resolve disputes created through online transactions. Disputants enter what they consider to be relevant information online and the software algorithmically proposes a resolution. Software can reflect subsequent offers and counteroffers, estimate what a claim is worth, and what attorney fees might be. Mediators might become involved if resolution cannot be reached through software applications alone.

Modria is a company spun off from eBay and PayPal that leads in ODR. "Now it is branching into disputes over real estate assessments (a county typically pays \$3,000 a month to resolve its valuation cases) and into divorce mediation. Many California counties already ask couples to start with mediation, and it's required by state law in disputes over child custody or visitation—though courts don't charge for it the way commercial providers do. Loic Coutelier, Modria's director of arbitration, hopes that by 2015 ODR platforms will handle 10 percent of mediations arising from the estimated 1.5 million divorce cases nationwide" (Cook, 2013).

Most disputes that originated as a result of an online transaction might be resolved entirely online because they are likely to be primarily financial, at least at first. "For offline disputes, however, the most common goal will be to find tools that can enhance elements in the process rather than managing the whole process. If mediation consists of several processes linked together, e.g. brainstorming, caucusing, prioritizing options, drafting, etc., software can be targeted to a particular process. For example, STORM, software developed at the University of Massachusetts facilitates brainstorming at a distance. It reduces the need for some face to face meetings and has the added benefit of allowing, if the mediator so desires, brainstorming to be conducted anonymously" (Katsh, 2012).

Mediators may have gradually incorporated phone conferencing, then video conferencing with disputants. Documents and proposed agreements are e-mailed and can be reviewed, negotiated, and amended in real time online with tools such as Google Docs. Disputes may be driven by emotions. Feelings are not easily quantifiable, which is necessary if they are to be submitted to software. A hybrid model combining face to face meetings with online processes may be optimal for complex mediations.

There is no dearth of disputes in our personal and professional lives. Conflict resolution is a growth industry. Mediating between parties to help them tailor an agreement to their needs can be rewarding. Whether or not mediation evolves into its own profession, the key is to distinguish the mediation role from others.

143 Child Protection Mediation

An Interest-based Approach

Allan Edward Barsky

The child protection system is designed to safeguard minors from abuse and neglect. When child maltreatment allegations come to the attention of protective services, child protection workers (CPWs) are mandated to assess whether the children are at risk of maltreatment and determine which interventions, if any, are necessary to protect the welfare of the child. Each year, protective services across the United States screen over 3.4 million allegations, and substantiate abuse or neglect in over 2.1 million cases (Children’s Bureau, 2012). Child protection laws require CPWs to use the least intrusive methods required to safeguard children. Accordingly, CPWs strive to offer support and voluntary services in a manner that allows children to remain in the custody and care of their parents. When CPWs are unable to engage families on a voluntary basis, they may petition courts to order family involvement in child welfare services or to order children’s removal from their homes. Protective services remove over 146,000 children from their parents’ homes each year (Children’s Bureau, 2012). Given the magnitude of child maltreatment concerns, child protection agencies and courts have experimented with alternatives to traditional services and judicial processes. One such alternative is child protection mediation.

Child protection mediation (also called dependency mediation) refers to a collaborative conflict

resolution process guided by an impartial third person who facilitates communication among parents, CPWs, and others involved in child protection cases in order to develop an agreement that satisfies the child’s safety and welfare (Hehr, 2007). The child’s voice may be heard directly, or through an attorney or *guardian ad litem* who represents the child. In the early pilot projects of the 1980s, mediation was viewed as a way to divert cases from costly court processes to relatively speedy, informal processes that would reduce legal costs for protective services, families, and the state. Mediation has proven its effectiveness as a cost-saving alternative, as well as a method to empower parents and children, engage extended family members, protect the welfare of children, facilitate planning, and foster satisfaction among various stakeholders in the process (Association of Family and Conciliation Courts, 2012; Giovannucci & Largent, 2009; Madden & Aguiniga, 2013). Although “child protection mediation” sounds like one specific process, there are many different models, including settlement-focused, interest-based, and transformative (Folberg, Milne, & Salem, 2004):

- Settlement-Focused Mediation refers to a task-focused process designed to help parties efficiently resolve their immediate disputes.

Mediators typically meet with parties and their attorneys for one or two sessions (each lasting 30 to 90 minutes). They focus on settling legal issues, rather than underlying emotional and relationship issues. In some cases, attorneys do most of the talking for their clients. By keeping cases out of court, settlement-focused mediation saves money, leads to faster disposition of cases (which may promote permanency planning), and avoids the acrimony that often occurs when cases proceed to an adversarial trial (Barsky, 2014).

- Interest-Based Mediation (IBM) refers to a problem-solving process in which the mediator helps parties resolve their underlying concerns, not just the legal issues (see Table 143.1). IBM typically requires two to eight sessions. Whereas SFM often results in *compromise* solutions: (in which both sides concede some of what they want to reach a middle ground), IBM promotes *win-win* solutions: parties use creative approaches to achieve common ground that satisfies everyone's primary concerns. The purported advantages of an interest-based approach include greater satisfaction with the outcomes, increased likelihood of following through on commitments, and better cooperation between parties (Fisher, Ury, & Patton, 2011).
- Transformative Mediation refers to a process-oriented conflict management process. Mediators provide an environment that allows clients to articulate their concerns, hear one another in a more meaningful way, empathize with one another's concerns, focus on client strengths, and take greater control over how they want to handle their conflict (Barsky, 2014; Folger, Bush, & Della Noce, 2010). Transformative mediation does not have a set time limit, though it typically requires two to ten sessions. The success of transformative mediation does not depend on whether the parties resolve conflict or save money. In fact, transformative mediation may improve how parties interact and manage conflict, even if they do not reach agreement.

Although each model has its benefits, this chapter focuses on IBM given its balance between task and process orientations: IBM helps parties reach agreements and avoid court, while also

TABLE 143.1 Tenets of Interest-Based Mediation

-
- Focus on interests rather than positions.
 - Invent options for mutual gain.
 - Apply objective criteria.
 - Improve communication.
 - Build a positive negotiating relationship.
 - Consider alternatives.
 - Obtain commitments (Fisher, Ury, & Patton, 2011).
-

helping them build better relationships, learn problem-solving skills, and feel greater satisfaction with the outcomes of the process (AFCC, 2012). Building better relationships between family members and child protection workers is particularly important in child protection cases, so the parties can work together on a voluntary basis and for the benefit of the child.

This following section describes child protection situations in which IBM may be appropriate. The balance of this chapter demonstrates IBM skills and strategies by following a case example through the six stages of the IBM process.

WHEN MEDIATION IS APPROPRIATE

Many of the pioneers in child protection mediation came from the field of divorce. Divorce mediators often suggest screening out cases involving alcohol or drug abuse, mental illness, or domestic violence (Holtzworth-Munroe, Beck, & Applegate, 2010). In the case of domestic violence, how could mediation be safe or fair if the abused spouse lives in fear of the perpetrating spouse? In the case of substance abuse or mental illness, how could a party with diminished capacity negotiate fairly and competently within the mediation process? In child protection cases, the vast majority of cases involve domestic violence, substance abuse, and/or mental illness. Thus, screening out cases with domestic violence, substance abuse, or mental illness would mean that mediation could rarely be used. When early mediation proponents asked child protection workers and administrators if they would be willing to try mediation, they also had significant concerns about its safety and fairness. Many were concerned that mediators would pressure CPWs to compromise on children's safety and well-being in order to reach agreements with parents. In practice, however, the presence of CPWs in the mediation process fosters safety and fairness, and distinguishes

this process from divorce mediation. Mediators are supposed to remain neutral and impartial throughout the mediation process. They have no decision-making power over the parties. CPWs, however, are mandated to assess for abuse and neglect and take whatever steps are needed to ensure the child's welfare. Although mediators encourage CPWs to keep an open mind about various ways of ensuring the child's welfare, they do not encourage CPWs to make compromises regarding it (e.g., to tolerate a certain degree of abuse or neglect).

Given that neglect and abuse are not negotiable, the question remains, what is negotiable? The following examples illustrate situations in which mediation may be appropriate:

- Teachers report a student's parents for abusing him by using a strap as a means of corporal punishment. The child's life is not in immediate danger. The parents initially refuse to cooperate with the CPW. During the first court hearing, the judge refers the CPW and parents to mediation to try to establish acceptable forms of punishment for the child's misbehavior.
- Protective services determine a stepfather has been sexually abusing a 10-year-old girl. They place her in an aunt's care, so her immediate safety is assured. The CPW and mother agree to try mediation to develop a plan whereby the girl can be returned safely to her mother's care.
- A 13-year-old boy has been living in foster care for two years due to physical abuse and neglect related to a parent's alcoholism. He refuses to see his parents for scheduled visits. The parents accuse the foster parents of alienating their son from them. The parents, son, and foster parents agree to mediation to sort through their conflicts. Given the parents' ongoing alcohol problems, the mediator establishes a ground rule that they must be sober when they attend mediation.
- Protective services brought a 3-month-old girl into foster care for "failure to thrive" (growth failure due to undernutrition). Her mother died during labor. Her father was unable to take proper care of his daughter due to depression. The father's depression starts to improve following successful use of psychotherapy and antidepressants. The father does not trust the CPW to be fair with him, so he asks for a mediator to help

them negotiate conditions for returning the daughter to his care.

- A court has issued temporary guardianship order for a young girl whose parents live on the streets. An order for permanent guardianship seems likely, given that the parents' lives remain unstable and the CPW wants to make permanent plans for the child. The parents and CPW agree to use mediation to develop an agreement for voluntary surrender of parental rights, so the parents can participate in choosing adoptive parents under an open adoption process.

As these scenarios illustrate, mediation can be used for a broad range of situations, including various forms of abuse or neglect (Hehr, 2007). Although one might assume that mediation is appropriate for mild cases whereas court is required for severe cases, this assumption does not hold true in practice. Parties involved in severe cases may actually have stronger motivation to make things work in mediation because the stakes are so high—particularly for a parent who risks temporary or permanent placement of a child in out-of-home care.

STAGES OF MEDIATION

IBM comprises six stages: intake and preparation, orientation to mediation, issue definition, exploring interests, negotiation and problem solving, and finalizing an agreement. To demonstrate the skills and strategies that mediators use in each stage, consider the following scenario:

Pam has a 16-year-old son, Sandy. One day, Pam discovers a bag of women's clothes in Sandy's closet. When she confronts him, he says his brain is telling him he is female, even though he has male body parts. Pam loses her temper and says that what he is doing goes against God and nature. When Sandy says he plans to dress as a woman in public, Pam throws him out. He moves into a friend's house. The friend's parents call protective services to report Pam for abandoning her child. Chelsey, the CPW assigned to the case, tries to engage Pam but she refuses to cooperate. She says her son is dead to her. Chelsey's supervisor recommends mediation as a way to engage Pam.

1. Intake and Preparation

Mediators receive referrals from court or from the parties themselves. The mediator's primary tasks during this stage are to educate the parties

about the process, assess their readiness to mediate, and prepare them to participate in a constructive manner. Mediators do not assess how the case should be resolved, because this is the parties' responsibility. Mediators do assess the nature of the conflict and how the mediator can improve the way that the parties communicate and negotiate with one another.

In the case example, a private practice mediator named Marsha accepts the referral. During intake, Marsha discovers that Chelsey is a professional social worker who is very familiar with mediation. The first time her supervisor referred her to mediation, she was skeptical because she believed her role was to mediate. She felt like going to mediation was tantamount to admitting she was incompetent. During mediation, she discovered that mediators could engage parties in a manner that was different from CPWs, because mediators were neutral and had no decision-making power. She learned to trust how mediators could empower parents to make decisions and work collaboratively. Chelsey summarizes what she sees as the key issues. She offers to be supportive in any way possible.

Neither Pam nor Sandy knows anything about mediation. Marsha meets separately to explain the mediation process and assess their readiness. Pam says she does not trust CPWs because they are "uncaring and incompetent bureaucrats." Without commenting on protective services, Marsha tries to establish her own caring and competence by demonstrating empathy, unconditional positive regard, genuineness, and knowledge of the mediation process. Marsha explains that one purpose of mediation is to promote effective communication. Pam admits that she was responsible for cutting off communication with her son. She feels ambivalent about trying to make amends. On one hand, she feels embarrassed that her son thinks he is a woman and wonders what she did to make Sandy that way. On the other hand, she loves her son—at least the son that she thought she had. Marsha helps Pam save face by noting that mediation will focus on what to do now, not what happened in the past or who is responsible for what. She helps Pam prepare for mediation by asking her to prepare two lists: a list of things she loved about the "old Sandy" and a list of concerns she has about the "new Sandy."

When Marsha meets Sandy, he asks to be addressed as female. Marsha asks whether he has any concerns about mediation. Sandy says he

does not want to come to mediation if his mother is going to yell or insult him. Marsha discusses how they can use ground rules for communication to make sure that communication is safe and productive. Sandy suggests that mediation may be a waste of time because his mother is too close-minded. Marsha invites Sandy to talk about the possibility that his relationship with his mother could improve. He responds that the chances are less than 10%. They explore the consequences of no improvement versus the consequences of some improvement. Sandy agrees that it is worth trying mediation even if the chances of improvement are limited. Marsha enhances Sandy's hope without imposing ideas or pressure. In preparation for the first joint meeting, Marsha offers Sandy reading material on the coming out processes for transgender children and their families. She suggests this may help him understand his mother's reaction and concerns, as well as how to explain his situation in language she can hear.

2. Orientation to Mediation

During the first joint session, the mediator provides an opening statement, explaining the mediation process, how it differs from court or therapy, the roles of the parties, what happens if the parties reach an agreement, and what happens if they do not (Barsky, 2014). During the orientation, the mediator asserts control over the communication process, while stressing that the parties are responsible for decision-making. The mediator explains her role as an impartial third party, who helps clients resolve conflict, but does not impose decisions or take sides.

As Marsha summarizes the agreement-to-mediate form, Pam asks how she is being paid. Marsha explores this concern, discovering that Pam's underlying question is whether Marsha is impartial. Marsha discloses the government department that funds mediation services and empathizes with Pam's concern that both Marsha and Chelsey receive salaries from the government, even though they work for different departments. Marsha invites the parties to let her know if they ever have concerns that she is demonstrating bias, given her aim is to be neutral and fair to all. By remaining nondefensive and forthright, Marsha enhances Pam's trust.

Marsha invites the parties to set ground rules for a safe and productive conversation. She starts with Sandy, given their discussion about yelling

and insults. Sandy suggests a rule that his mother should not raise her voice or say rude things to him. Pam responds defensively, arguing she is not rude and “how dare you speak to your mother like that.” Marsha separates the person from the problem by suggesting that they both seem interested in using respectful language. She reframes their concerns into a mutual rule, “Everyone will speak to each other calmly and respectfully.” All agree. Chelsey commends Sandy and Pam for reaching their first agreement. They develop additional ground rules and review the rest of the agreement to mediate. Marsha invites questions and ensures they understand the agreement before being asked to sign it. Although Pam and Sandy express doubts about each other’s ability to be reasonable, Marsha expresses optimism in each of their abilities to reach an agreement that satisfies everyone’s interests.

3. Issue Definition

This stage begins with storytelling, as the mediator asks parties to describe concerns they would like to resolve. The mediator allows them to ventilate feelings and review the history of the conflict, demonstrating empathy to build trust and model active listening. The mediator puts appropriate limits on storytelling, refocusing the parties on future-oriented problem solving. As each party shares concerns, the mediator summarizes key points and highlights key issues that they bring to mediation. By identifying common concerns and helping the parties articulate their priorities, the mediator helps them reach an agreement on which issues to focus upon for the rest of the mediation.

Pam seems to be the most distrustful of the mediation process, so Marsha asks her to be the first to “briefly describe the situation that brought you to mediation and what issues you would like to resolve in mediation.” Pam describes the family history, including the challenges of being a single mom and how much she loves Sandy. Marsha paraphrases key points, highlighting the positive relationship Pam had with Sandy. Pam describes the day she discovered Sandy was dressing like a woman. Pam reflects back her feelings, reframing her shock and disgust into uncertainty and parental concern. Pam invites Sandy to summarize what he heard from his mother. Sandy responds, “It’s all about her ... what she wants me to be, not what I am or how I should be treated.” Pam appeals to

Marsha to stop him from being so disrespectful. Marsha reminds everyone of the ground rules. She resumes control over the process by asking Pam what issues she hopes to resolve in mediation. Pam says she wants to discuss “how Sandy’s transgenderism can be cured, so he can be normal again.” Marsha generalizes the concerns to offer an issue that all parties feel comfortable discussing, “So you’d like to talk about what could be done to re-establish a better relationship between you and Sandy.” Pam agrees, so Marsha writes this issue on the flipchart.

Marsha asks Sandy to discuss his concerns. Sandy describes how he felt abandoned by his mother just when he needed her most. Pam interrupts. Marsha gently reminds her to let Sandy finish, offering her a pen to write down her concerns so she can share them later. Sandy goes into a long, detailed discussion of his struggle coming to terms with being transgender. Pam asks what being transgender means. Marsha invites Chelsey to explain. Part of Chelsey’s explanation includes professional jargon, so Marsha reframes it into plain language. Marsha then asks Sandy what issues he would like to resolve. Sandy says he wants to figure out where he is going to live. Marsha lists this issue on the flipchart.

When Marsha asks Chelsey what issues she believes are important to discuss, she says she would like to discuss the possibility of family reunification. If that is not possible, then they need to discuss alternate living arrangements for Sandy. Marsha helps the parties see how they are basically talking about the same issues: the possibility of improving Marsha and Sandy’s relationship so Sandy can move home, and where Sandy should live if moving home is not feasible.

4. Exploring Interests

The primary objective of this stage is to help the parties focus on their underlying interests. The mediator invites parties to look beneath their stated positions and wishes so they can focus on what matters most (Hehr, 2007). By helping the parties focus on their underlying concerns, needs, hopes, and expectations, the mediator helps them disengage from a battle over whose position is right or wrong. When Pam says she is not ready for Sandy to return home, Marsha explores why. Pam says Sandy is obviously sick and needs help, help which she cannot provide. Marsha reframes these concerns, “So you’d like to make sure that Sandy is well and gets the help he needs to be

well." Sandy reacts, "I'm not sick. I just need to be allowed to be who I am." Marsha asks if this means he wants to be treated with respect. Sandy nods. Marsha lists Pam and Sandy's interests, and asks Chelsey if she would like to add any others. Chelsey suggests adding shelter, safety, and parental care. Marsha reviews the interests with the parties and incorporates their suggestions to conclude a list of their common and separate interests.

5. Negotiation and Problem Solving

The mediator encourages the parties to problem-solve based on their underlying interests. Problem-solving strategies include focusing parties on the future, generating a list of creative options that may satisfy their interests, and helping the parties evaluate options using objective criteria (Fisher, Ury, & Patton, 2011). When Marsha initiates brainstorming, Pam suggests that Sandy see a shrink. Sandy retorts that Pam should see a shrink. Marsha does not judge. She simply writes their options on the flipchart and invites them to continue brainstorming. Chelsey suggests other helpful resources: Parents, Friends, and Family of Lesbians and Gay Men (PFLAG) for Pam and a transgender support group for Sandy. All three parties then brainstorm various living arrangements for Sandy: return home immediately or in a few weeks; remain with friends; go into foster care; or stay with a relative.

Marsha helps the parties establish objective criteria for selecting the best options. They agree that the ideal helping resources are ones that are nonjudgmental, private, expert at dealing with transgender concerns, and easily accessible. Marsha then helps them apply these criteria to their options. Although Pam originally thinks PFLAG is just for parents of lesbians and gay men, Chelsey informs her that they also serve parents of transgender or questioning youth. Pam agrees to contact the local PFLAG coordinator for more information, saying she wants to find out how other parents deal with similar issues. Sandy agrees to see a counselor who works with transgender and questioning youth, stating that he feels more comfortable talking privately to one person rather than to a group. Chelsey originally asks Sandy and Pam to sign confidentiality release forms so she can speak with the PFLAG coordinator and counselor. Sandy and Pam stress that privacy is important, so Chelsey agrees to follow-up with Sandy and

Pam after their meetings rather than talk to the others. Marsha congratulates them for agreeing upon support services. They go through a similar problem-solving process to determine where Sandy will live, identifying objective criteria and choosing the best options based on these criteria.

6. Finalizing the Agreement

Once the parties reach a tentative agreement, the mediator helps them decide how to finalize it. If a court case has been initiated, the mediator typically provides the agreement to the parties' attorneys to submit it to court for an order on consent of the parties. If no court case has been initiated (as in the case example) the agreement may be formalized as part of the clients' treatment plan with the protection agency (AFCC, 2012). Marsha reviews the terms of the agreement with the parties to check for potential problems and to ensure they are committed to it. They have agreed that Sandy will stay at his grandmother's house on a temporary basis. Chelsey will facilitate referrals to PFLAG for Pam and to a counselor for Sandy. Chelsey ensures the language of the written agreement is clear, positive, future-focused, and balanced. She includes provisions for follow-up, specifying each party's roles and responsibilities. If the parties experience problems with implementation, they agree to return to mediation to work through these concerns. Marsha concludes the process by reinforcing the progress made by the parties. Even though Sandy is going to live with his grandmother, they have opened communication between Sandy and Pam, and they have developed trust with Chelsey who will help them work towards permanent living arrangements for Sandy. When successful, mediation helps CPWs and family members work together in a collaborative fashion, ensuring the child's safety and welfare in the timeliest and least intrusive means possible.

144 Forensic Social Workers in Offender Diversion

Michael S. Shafer & José B. Ashford

Clients with mental health and/or substance use disorders are at elevated risk for engaging in criminal behavior and becoming involved in the criminal justice system. This involvement may include being arrested (either physically or administratively), facing formal legal court proceedings, being incarcerated in jail or prison, and/or being supervised under conditions of parole or

probation. Depending upon the severity of the criminal offense with which they are charged, their history of criminal behavior, and the policies of the criminal justice system in their community, special need offenders can have opportunities available to them that will allow them to be diverted from protracted criminal proceedings and avoid formal prosecution and incarceration.

Special needs are defined in this context “as any changeable factors associated with disorders of cognition, thought, mood, personality, development, or behavior that are linked to desired outcomes for offenders at any phase of the justice process.” (Ashford, Sales, & Reid, 2001, p. 5.) However, most systems do not allow for the diversion of all types of special need offenders. Offenders diagnosed with serious mental disorders and substance abuse disorders are the most common categories of offenders involved in formalized diversion programs.

The need for effective social work consultation and case management services for individuals with special needs in the criminal justice process is critical, both for those individuals who are diverted from prosecution and incarceration as well as for those individuals who are incarcerated. For this latter group of individuals, the role of social work is particularly critical at the time the individual is released from their period of incarceration (Ashford, Sternbach, & Balaam, 2009). Clearly, the interface of social work with participants in the criminal justice process presents a range of situations and opportunities for professionals with specialized knowledge and skills in forensic social work (Slater & Finck, 2011).

WHAT ARE DIVERSIONARY PROCESSES?

In many communities, formalized systems for diverting individuals with behavioral health and other disabilities and issues (including drug use and possession) who have been charged with a criminal offense have been developed. *Diversion* represents a formalized approach whereby individuals who have engaged in a criminal offense (typically restricted to misdemeanor offenses) can avoid prosecution and incarceration (Perlman & Jaszi, 1976). If the individual volunteers to participate in treatment or in some other relevant social service, then the individual can avoid the logical consequences associated with participation in the criminal justice process. These diversion programs are generally grouped into *Pre-booking Diversion* (e.g., diversion occurs before the individual is booked with a criminal offense charge) or *Post-booking Diversion* (e.g., diversion occurs after the individual is booked, but before sentencing). These programs were designed to ensure that all offenders with these

mental health and substance abuse problems have equal access to diversion opportunities if they meet established eligibility requirements for diversion from the system. Prior to the establishment of formalized diversion programs, some offenders in similar circumstances were not afforded the same benefits of treatment in lieu of incarceration or prosecution (Ashford, 2013).

PRE-BOOKING DIVERSION

Pre-booking diversion identifies individuals prior to being arrested and booked into jail and links these individuals with appropriate treatment *in lieu* of arrest and prosecution. In some communities, local law enforcement may operate specialized outreach teams, comprised of uniformed and civilian personnel who identify and attempt to engage individuals into treatment programming (Deane, Steadman, Borum, Veysey, & Morrissey, 1999). These teams may patrol particular neighborhoods or areas where homeless and other indigent individuals may congregate. Likewise, these teams may respond to requests from other law enforcement officers who are interacting with an individual whom they suspect to be experiencing a behavioral health crisis (either as a result of a mental illness or due to their use of alcohol or drugs). In other communities, these pre-booking diversion teams may be operated directly by a local mental health or social service agency that is called upon by local law enforcement to intervene when it has been determined that an individual is displaying signs of behavioral health distress and the severity of their crime does not warrant prosecution (e.g., nuisance offenses such as urinating in public, public intoxication, loitering, or yelling at persons on the street, leaving a restaurant before paying for a meal).

Social workers can serve a critical role in the provision of pre-booking diversion programming in a number of ways. First, social workers may be called upon to serve on pre-booking diversion teams, either as members of teams constituted by the local law enforcement agency, or as members of teams constituted by a local human service agency that contracts with the courts to provide pre-booking diversion services. Second, social workers may be called upon to provide training and education to local law enforcement officers who are serving on pre-booking diversion teams. Finally, social workers working with local human service agencies (especially homeless shelters

and crisis response centers) can be called upon to facilitate effective reception and referral processing mechanisms for local law enforcement personnel who are transporting or referring individuals to their facilities (Deane et al., 1999).

The types of clinical knowledge and skill sets required of social workers involved in pre-booking diversion programs will include the following:

- Differential diagnosis
- Crisis management and de-escalation skills
- Knowledge of law enforcement processes
- Knowledge of expedited referral and intake procedures

Differential Diagnosis: Although an accurate differential diagnosis may not be possible on initial contact with offenders in the community, social workers need to have the ability to make preliminary assessments of the mental health symptomatology and/or substance use intoxication that individuals are displaying. A fundamental understanding of the behavioral manifestations of the common forms of psychosis and mood disorders (e.g., schizophrenia, bipolar disorder, mania, depression, anxiety disorder) as well as the behavioral symptoms of acute alcohol intoxication and common drug use (heroin, methamphetamine, cocaine, PCP, etc.) is essential. An accurate differential diagnosis may not be possible in the short-term because prolonged use of many illicit drugs (e.g., methamphetamine) will result in behavioral symptoms that mirror psychosis or mood disorders (e.g., paranoia, delusional behavior). Nevertheless, the ability to identify the behavioral manifestations being displayed by an individual and to make a preliminary determination of the basis for these behaviors is an essential skill provided by social workers in pre-booking diversion programs.

Crisis management and de-escalation: Quite frequently, individuals who are diverted through pre-booking diversionary systems are in an elevated state of crisis requiring some form of de-escalation. These individuals may be experiencing an acute anxiety reaction, hyper-manic episode, or severe depression. They may be threatening suicide and/or engaging in suicidal behavior or threats of violence. Social workers involved in pre-booking diversion programs need to have proficiency with the de-escalation of these psychiatric crises.

Knowledge of law enforcement processes: Working within pre-booking diversion

programs requires social workers to have a general familiarity with the procedures and organizational culture of law enforcement systems and to have established and clearly articulated procedures for respective roles, responsibilities, and authorities in managing situations and individuals. Due to the potential for violence in situations wherein pre-booking diversion programming is located, social workers employed in these contexts must recognize that the primary decision-making authority rests with the law enforcement officer.

Knowledge of expedited referral and intake procedures: Creating expedited referral processes and client drop-off procedures is essential for social workers working within treatment or service agencies serving as drop-off or reception facilities for local law enforcement agencies involved with pre-booking diversion programs. One of the great advantages of creating drop-off facilities as part of pre-booking diversion programs is the rapid turnaround that it affords law enforcement officers. If the time required to drop-off an individual at a pre-booking treatment reception facility is as long as or longer than the time required to book the individual into jail, then law enforcement officers are less likely to engage in the pre-booking diversionary service.

Case Study #1

A client who is behaving in a bizarre manner is arrested on a public nuisance offense. The arresting officer recognizes that the individual is either psychotic or intoxicated. The officer contacts a mobile crisis team for a consultation on the case. The social worker on the crisis team reviews the circumstances of the offense with the arresting officer and does a brief assessment of the individual. In addition, the social worker checks a link on a laptop computer to determine whether the individual is in the mental health treatment system. After evaluating the evidence, the worker recommends to the officer that this individual is an appropriate candidate for being brought to a drop-off location for consideration for diversion from the criminal justice system.

POST-BOOKING DIVERSION

Post-booking diversion programs operate by identifying appropriate individuals *after* they have been arrested, booked, and arraigned, but

before they have been sentenced. Individuals who are diverted through post-booking diversion programs can spend a brief period of time in jail, but are typically released to the community to receive treatment in lieu of extended periods of incarceration (Shafer et al., 2004). In some communities, these post-booking diversion programs may operate as formalized specialty courts, such as drug courts or mental health courts; in other communities, these programs will operate less formally. Regardless of the type of post-booking diversion program that is in place, individuals participate in these diversionary programs voluntarily, given that they have the choice to participate in and follow the conditions set forth by the diversionary program (e.g., attend treatment regularly; submit to random urinalysis), or face probable prosecution and possible incarceration. In different communities, post-booking diversion programs will provide diversion opportunities at a variety of points in the criminal justice process, and with varying levels of court sanctioning or involvement:

- Released on own recognizance
- Deferred prosecution and/or deferred sentencing
- Specialty court dockets

Released on own recognizance: Individuals are released after being arrested on the condition that they agree to not re-engage in the criminal behavior and/or that they will engage in treatment or social services. In these situations, there is no ongoing supervision or reporting required by the individual. Their case is dismissed after completing the terms of their diversionary agreement.

Deferred prosecution and/or deferred sentencing: Individuals are released after being arrested on the condition that they agree not to re-engage in the criminal behavior and/or engage in treatment or social services approved by the court. The prosecuting attorney agrees not to prosecute; or, if he or she does prosecute, the judge agrees not to sentence the individual so long as the individual does not reoffend and attends treatment on an agreed upon schedule. Either the individuals, or the service provider from which they receive their treatment or social service, typically submit status reports to the prosecuting attorney.

Specialty court dockets: Specialized treatment courts, drug or mental health courts, also require defendants to participate voluntarily in services

provided by the courts, because these generally have increased levels of supervision and oversight that can increase the defendant's risks for further scrutiny by the courts. Many of these programs also have rules, which if violated can result in jail time for noncompliance that is beyond the sentence for the crime committed. These specialty treatment courts have structures that are similar to the processes employed in deferred prosecution/sentencing programs (Ashford, Wong, & Sternbach, 2008).

Most drug and mental health courts also have a specialized treatment team, consisting of a judge, a prosecuting attorney, a public defender, and a mental health/substance abuse liaison. Members of the team work together to manage the cases that come before that particular court. These various representatives function much like an interdisciplinary team. The members come to the case with a variety of perspectives, and they are allowed to provide their distinct disciplinary input into the management of the case. Additionally, in these forms of specialty courts, the defendants, who participate voluntarily, are required to report to the judge directly on an ongoing basis. With the assistance and input of the rest of the team, the judge serves in the role of a case manager (Berman & Feinblatt, 2005).

Social workers may find themselves engaged in post-booking diversionary programming through variety of venues. Most mental health and drug courts will have a court employee serving in the role of "mental health liaison" or what Hank Steadman and others describe as "boundary spanners" (Steadman et al., 1999). Individuals serving in these roles within criminal justice systems serve as the resident "expert" in mental health and substance use disorders. These boundary spanners also serve as the "bridge" between the court system and the community treatment system, facilitating the referral of clients to treatment providers; obtaining court required status reports; and otherwise enhancing the collaboration and coordination between the treatment and social service systems and the criminal justice system.

Likewise in many communities, local treatment service agencies may employ a "forensic liaison," an individual who maintains a specialty caseload of clients who are actively involved in the criminal justice system. These forensic liaisons serve a centralizing function for treatment and social service agencies by providing continuity and consistency in the communication between the treatment/

social service agency and the criminal justice system. Finally, social workers may find themselves serving clients who are engaged in some form of post-booking diversionary programming wherein the need for specialized case management services or assistance may be warranted.

Case Study #2

Jim is arrested and booked in jail on a charge of assault. A forensic liaison working in the jail screens him for participation in a post-plea diversion program attached to a mental health court. After the assessment, the jail liaison refers the inmate to the probation officer assigned to the mental health court. The probation officer performs a risk assessment, assessment of the instant offense, and gathers information about the jail inmate's criminal history. Results of the liaison's and the probation officer's assessments are referred to the Mental Health Court treatment team. The team screens the offender for his eligibility to be considered for diversion. The social worker on the team evaluates the seriousness of the individual's mental impairments as well as his suitability for release to a Forensic Assertive Community Treatment Team (FACT) team. The prosecutor assesses the offender's risk to the community and concludes that the assault was minor and due to the offender's mental illness. After determining the individual's eligibility for the program, the recommendations are presented to the defendant's attorney for consideration with the defendant. The defendant agrees to plead guilty in lieu of criminal sentencing.

Regardless of the specific type of diversionary program, there are a number of additional factors and skills that social workers need in order to be effective when working in this area of practice:

- Security clearances
- A brokered array of benefits and other services
- Medication management
- Knowledge of distinct court procedures and orders.

Security Clearance: Social workers engaged in diversionary programs need to have regular access to the jail for visiting clients and to the courtrooms for proceedings. In many communities, special access privileges can be established that ease the process of gaining entry to these secured facilities and office locations.

This will typically require a background and fingerprinting check.

Benefits and Other Services: Indigent clients who are receiving Medicaid/Medicare benefits need particular attention if they are incarcerated for any period of time. Federal regulations do not allow for medical or other treatment services to be reimbursed by Medicaid/Medicare during the period of time that an individual in jail or prison. Based upon the state Medicaid agency provisions, Medicaid eligibility for these individuals may be automatically revoked when the individual in jailed or imprisoned; in other states, the individual's Medicaid eligibility is suspended for a period of time. Social workers engaged in diversionary programs should have knowledge of their state's Medicaid regulations. They can obtain this information by either visiting their state's Medicaid agency's website or the website for the Federal Centers for Medicare & Medicaid Services (<http://www.cms.hhs.gov/home/medicaid.asp>).

Medication Management: A common problem confronting individuals involved in post-booking diversion programs is a disruption and/or discontinuity of medications that they were taking prior to their arrest. This issue is particularly problematic for individuals with psychiatric impairments who are jailed. For these individuals, it is critical that the social worker helps ensure the continuity of their psychiatric medication orders for the interim that the individual is in jail. In addition, social workers need to ensure access to medications upon the individual's release from custody. Social workers affiliated with community-based treatment and social service agencies can facilitate the process of medication continuity by developing protocols with local jails and booking facilities that provide timely information about their client's incarceration. These protocols also should call for the presence of liaisons or other personnel at the jail who can identify persons who were taking medications or who appear to be in need of medications.

Knowledge of Distinct Court Procedures and Orders: Case managers engaged in post-booking diversion programs also need to become conversant with existing policies and procedures governing their local courts. These procedures include the various types of release conditions and court orders that their clients may be exposed to as part of a post-booking diversionary process. The type of court that individuals will be remanded to can vary from a justice of the peace to a superior court. Each type of court will have different

methods of operating, different rules, and can issue different types of conditions and orders for diverted offenders. For this reason, social workers engaged in this sort of practice must have knowledge of various types of court “dockets” and the procedures governing each of these dockets in their communities. Likewise, gaining an understanding of the type, frequency, and nature of reporting that clients must engage in as a result of their diversion requirements is critical.

SUMMARY

This chapter examined the various diversion schemas that have evolved over time and that place differential limits and expectations on how forensic social workers bring their professional expertise to the criminal justice process. Individuals involved in the administration of justice have been concerned since the early 1970s about the justice meted out to offenders diagnosed with treatable disorders. For this reason, many communities have attempted to respond to specific questions about the type of justice provided disordered individuals by instituting formalized programs for offender diversion.

This chapter also demonstrated that judges, law enforcement personnel, and other legal authorities would be ill equipped to effectuate appropriate diversion alternatives without the expertise of forensic social workers. Forensic social workers bring their knowledge of mental health assessments, knowledge of community resources, and their case management skills to decisions in the justice process that allow for a select class of offenders to be diverted to treatment in lieu of the traditional criminal justice process. They possess skills for working with clients in crisis and for marshaling evidence for documenting the likelihood of an offender benefiting from a specific type of treatment, as well as an assessment of the offender’s risk to the community. Indeed, the forms of consultation to the justice system provided by forensic social workers are consistent with the profession’s long-standing commitments to combating the social injustices experienced by persons diagnosed with serious mental and substance abuse disorders.

145 Therapeutic Tasks at the Drug Court

Jill L. Littrell

CASES

Frank is a 23-year-old college pre-med student. In high school, he was diagnosed with Attention Deficit Hyperactivity Disorder (ADHD). The first two years of college were relatively easy for Frank and Frank continued taking his medication at its prescribed dose each morning. Once he began taking upper division Biology and Organic Chemistry courses, however, he found the work to be more challenging. Other people in his fraternity told him how their grades improved when they began doubling up on their ADHD meds when studying the night before exams. Frank tried this strategy and found the work was far less exhausting with amphetamines. But then Frank found it hard to sleep, so he began using Valium to sleep. It was hard to wake up the next morning, and fearing he would perform poorly on the exam that he had studied so hard for, he began snorting his “addies” before the exams. After he began this practice, Frank found himself wanting to use more of his medication at higher doses. A friend in his fraternity suggested that he curb his desire for amphetamine by taking OxyContin, which the friend was happy to sell him. Although the OxyContin initially eased his craving for amphetamine, Frank found himself using both OxyContin and amphetamine. His use rapidly escalated into a big expense. In fact, OxyContin was costing about \$50 per pill, which he was now taking on a daily basis. So Frank began selling his medications prescribed for ADHD to others. One of his customers took an overdose of amphetamine and was taken to the emergency room after suffering a seizure. The parents of the hospitalized boy involved the police. The boy revealed Frank’s name. Frank’s lawyer suggested drug court.

Joe is a 23-year-old veteran of the war in Afghanistan. After graduating from high school, he decided to join the army so that he would eventually be eligible for the benefits to pay for college. After being wounded in Afghanistan, Joe was medicated with OxyContin, an opiate medication. Following discharge, he lived with his widowed mother. His

use of OxyContin increased beyond the amounts supplied by his Veterans Administration (VA) doctor. Joe also began drinking heavily. He would fight with his mother, who was insistent that Joe get a job. After a particularly bitter argument, Joe’s mother insisted that he leave. Initially, Joe did rent an apartment and found part-time employment at Walmart as a greeter. Joe’s drug use was escalating, however, and he had switched to street heroin. One day, Joe was found breaking into a car in the Walmart parking lot. This incident resulted in a referral to drug court.

DRUG COURTS AS AN ALTERNATIVE TO THE CRIMINAL JUSTICE SYSTEM

During the 1960s and 1970s, court diversion programs were developed for drug-addicted persons whose addiction resulted in their criminal behavior. In accepting the Drug Court’s adjudication, the individual agrees to participate in treatment for an extended duration of time. The individual does not go to trial and does not have a criminal record, but the judge in the case retains the option of temporary incarceration should the client need a little extra help in staying clean. The judge meets with the client frequently to evaluate progress and suggest additional interventions to promote recovery. The social worker employed by the drug court acts as a consultant to the judge, interviewing the client and, along with the client, developing a plan of action. The defense attorney and the prosecuting attorney also are considered to be members of the drug court team. The 10 key components in the framework of drug courts are the following: integration of addiction treatment with the justice system; a nonadversarial structure; attempts to divert individuals early in the course of their addiction; a continuum of services; regular monitoring including drug testing;

sanctions and adjustments as needed; ongoing interaction with the judge; continued assessment of the court's outcomes; continuing interdisciplinary education; and partnerships with the community (Hora, 2002).

THE INITIAL INTERVIEW

The initial task of drug court personnel, usually the social worker, is to secure an agreement from the client to engage in treatment. Some assessment is also required to promote the initial engagement in the treatment process.

The Therapeutic Alliance

In reviewing the literature on drug courts, Hora advises that drug court involvement is more efficacious when the client feels that he/she has a choice in seeking treatment. The sense of volition is enhanced when clients are involved in creating the treatment plan. Involving the client in plan development is a component of a therapeutic alliance. Numerous meta-analyses of treatment efficacy find that therapeutic modality rarely makes any difference in terms of outcome. However, what always seems to matter a great deal is whether the client and therapist agree on the nature of the problem, the strategy for achieving change, and the goal of treatment (Ilgen et al., 2006). Scott Miller is another researcher who stresses the importance of the therapeutic alliance. When working with involuntary clients, Miller initially aligns with the client to assist the client in achieving his/her goal. At first, clients may not realize the value of sobriety; rather, their goal is to avoid going to jail. Scott Miller enlists the client in assessing what the judge will require to stay out of jail or get a driver's license back. Taking the approach of resource person for the client, Miller helps the client come up with a realistic plan for meeting the terms of the drug court. Later, in the process of treatment, the client frequently can be brought to appreciate the need for a change and to embrace the goal of sobriety.

Using Motivational Interviewing at the Intake Interview

Motivational interviewing (MI, now called enhancement) was developed by William R. Miller at the University of New Mexico for

treating substance abusers. It expands on the technique of reflective listening developed by Carl Rogers. The strategies of MI include expressing empathy, asking about the discrepancy between values and goals and current behavior, reflecting back a client's ambivalence about current behavior, supporting self-efficacy, and asking for permission before providing advice or information. MI avoids arguing, persuading, or confronting a client with examples of negative behavior, or labeling. If the client becomes defensive, then the MI will "roll with resistance" perhaps changing the topic or emphasizing a client's strengths. MI does involve asking questions that tap into the client's concern about his/her drug use. Motivational interviewers amplify the client's concerns and past thoughts, however fleeting, about being sober.

Self-perception theory from social psychology offers rationale for MI approaches. The basic axioms of self-perception theory are:

- People's behavior is consistent with their self perceptions/concepts.
- People learn who they are from the feedback they receive from others.
- People also rely on observing their own behavior to determine their attitudes and preferences.

Self-perception theory predicts that if the client observes himself arguing for the benefits of continued drug use, he will solidify his resistance to treatment. Conversely, if the therapist asks many questions about the details of the client's life, in a nonjudgmental way, the client's ambivalence will emerge. Further questions can amplify the expression of the client's concerns. The important element is what the client sees himself/herself saying, not what the therapist says.

Differences between Motivational Interviewing and Confrontational Strategies: One of the articles of faith in Alcoholics Anonymous is that substance abusers deny that they have a problem. According to the dogma of those embracing Twelve Step points of view, denial fuels the progression of the disease of addiction. Thus, "breaking down denial" is viewed as a necessary component to effective treatment. Theresa Moyers and colleagues (2009) have empirically tested the assumption that confrontation is a useful strategy. Researchers categorized therapist interventions, client status quo or change talk during the session, and subsequent outcomes. In fact,

MI strategies resulted in more change talk from the client. More change talk predicted better outcome during the subsequent year. Morgenstern and colleagues (2003) have also assessed whether embracing the label of alcoholic is required for change. In fact, self-labeling as an alcoholic does not relate to outcome, although a desire for change and self-efficacy regarding change does. The results of these studies call into question whether confronting denial is necessary or useful. MI is also consistent with the transtheoretical model of change (Stages of Change) developed by Prochaska, DiClemente, and Norcross. This model appreciates that people make changes gradually, first contemplating and planning before making a commitment. The social worker should recognize that the client's commitment to a new way of life will require a gradual process.

Agreeing on the Goals of Initial Treatment by the End of the Intake

Although Motivational Enhancement, therapeutic alliance, and Stage of Change frames of reference caution against demanding that a client commit to lifelong abstinence after one session, the exigencies imposed by the judge as a requirement for staying out of jail usually require temporary abstinence at least from the chemical of abuse, if not from all mood and mind altering chemicals. Social workers should assist the client in developing a strategy for staying sober in the short run.

A key component of Drug Courts is involvement in comprehensive treatment. The drug court social worker can act as a resource to identify treatment options. Social workers often work at the agencies to which clients are referred. Possibilities for the treatment vehicle may include inpatient treatment, outpatient treatment, attendance at a Twelve Step meeting, and/or perhaps treatment that the social worker will provide. Treatment is most often provided in groups. The American Society of Addiction Medicine (ASAM) has developed recommendations for level of care. Those who meet criteria for mental health commitment (homicidal or suicidal) should be hospitalized. ASAM also recommends that persons lacking community support be hospitalized. Of course, choices will depend on the particular treatment opportunities available in the community.

Enhancing the Probability that the Client will Follow-through on Initial Commitments: Efforts beyond handing the

client an address are required to ensure that a client gets to initial appointments. Having the client envision himself/herself in the process of going to the AA meeting is often helpful. Through the imagery, any reluctance or apprehension can be identified. Coping mechanisms can be suggested. Further, the availability heuristic (Tversky & Kahneman, 1974) provides that behaviors that can be imagined are more likely to be enacted and has been supported by social psychology research (Littrell & Magel, 1991). Thus, having the client detail the scenario of attending the meeting increases the probability of follow-through. Additionally, signing a contract is another mechanism for increasing compliance through a self-perception mechanism (Goldstein, Martin, & Cialdini, 2008).

If a client voices a desire for change or agrees to attend an AA meeting, handing the client the tools to quickly implement the decision, can help shore up the decision. It is important to have concrete, immediate plans to implement. Frank and Joe must have some Twelve Step meeting or treatment group to attend the very day of the intake. They need to see themselves acting in some observable way that signals their movement to a new stage. A week is too long to wait.

Involving the judge in the planning process for initial and then ongoing treatment is a component of drug court. In the context of team meetings, judges in drug court should be apprised regarding the importance of the therapeutic relationship. Given the philosophy of the therapeutic alliance, the judge and the client should partner in developing a treatment plan. The conditions suggesting when incarceration will be needed to supply additional assistance in staying sober should be agreed upon. In that way, a consequence can be viewed not so much as a sanction, but as a treatment support. Both Frank and Joe agreed that a week's incarceration would be reasonable should they produce a dirty urine.

Additional Issues Requiring Attention during the Initial Interview

Assessing Withdrawal Requirements: Withdrawal from opiates or stimulants is rarely lethal. However, persons who are frail, pregnant, or whose health is compromised for some other reason may require medical support. Barbiturates, benzodiazepines, and alcohol are drugs with potentially lethal withdrawal symptoms. With benzodiazepines (a class that includes Valium),

because of the protracted half-life, symptoms may not be associated with drug cessation. Thus, clients may not seek medical attention.

A social worker may not know whether any particular client is in a medically compromised state. For this reason, it is good practice to have a client who has recently used evaluated by medical personnel. The social worker should inquire about the time of and amount of the client's last use of alcohol and both licit and illicit drugs. If use was recent, the client's withdrawal requirement should be evaluated by a physician. Joe had not used in the week before his first encounter with the drug court; therefore, a physician evaluation was not needed. After securing a release, however, the social worker did call Joe's VA physician regarding a potential referral for methadone.

Dual Diagnoses. Until recently, treatment streams for mental health and substance abuse have been clearly differentiated in this country. In the substance abuse field, practitioners were often suspicious of psychotropic medications. Often, those with major mental disorders were turned away. When mentally ill persons were institutionalized, substance abuse was rarely an issue. With deinstitutionalization, persons with major mental disorders often abused street drugs. Mental health practitioners were unfamiliar with how to treat addictions. SAMHSA The federal government's Substance Abuse and Mental Health Services Administration (SAMHSA) recognized that excluding the dually diagnosed unfairly denied treatment to many. For treatment centers applying for federal money, willingness and ability to treat those with dual diagnoses has become a requirement.

Be alert to the possibility that the client may not be in a great deal of pain. Some substance abusers will not have other diagnoses and may not have deep underlying personality issues (see Minkoff website), although substance abusers have higher rates of mental health diagnoses than the general public. Most alcoholics are primary alcoholics. Substances may have perturbed their biochemistry such that they appear depressed while in withdrawal. Sufficient time should be allowed for the consequences of substance abuse to dissipate prior to diagnosing other *Diagnostic and Statistical Manual of Mental Disorders (DSM)* categories (see Littrell, 1991).

At intake interview, Scott Miller asks clients to complete a form that includes a general assessment of how the client is functioning emotionally,

socially, etc. (The form can be downloaded without cost from the talking-cure website.) A social history might also reveal that a client has a significant history of trauma and abuse. When an abuse history is present, AA recommends that when a particular alcoholic has an extensive background of child abuse and/or adult-child-of-an-alcoholic issues, the first task is staying sober. After the client achieves stable sobriety, should the client wish, background issues can become a focus.

Of course, some clients will be in a great deal of pain because of a co-occurring mental condition, because a family member has severed relationships, because of a job loss, because of guilt over some action, etc. If the client's self-assessment suggests that he/she is distressed, then the distress is an immediate issue for treatment. The most frequent precipitants to relapse are negative moods. Thus, the client's coping mechanism must be developed. Lisa Najavits has fashioned an approach to treating posttraumatic stress disorder (PTSD) in drug abusers. Called Seeking Safety, it entails developing coping skills for defocusing from painful emotions and identifying safe places to be (Najavits, 2007).

Assessing the Therapeutic Alliance at the End of Every Session

Because Scott Miller recognizes the importance of the therapeutic alliance, he makes sure to assess the therapeutic alliance after every session. Short outcome measures requiring 45 seconds to complete invite the client to evaluate the usefulness of the session. (This one-page instrument consisting of five questions can be downloaded without cost from the talking cure website.) If the client is ambivalent about the session, Miller addresses the issue directly, asking the client for feedback about how he could be more helpful.

Summary of What Should Be Accomplished in the First Interview. By the end of the intake the following treatment objectives should be reached:

- The client should have identified short-term goals for abstinence.
- The client should have some strategies and backup plans for staying sober.
- The client and social worker should have identified some form of treatment that the client will attend.

- The client's withdrawal status and need for immediate medical attention should be addressed.
- Imminent mental health needs (suicidality or homicidality) should be addressed.

Both Joe and Frank agreed to investigate the possibilities of methadone maintenance. They both agreed to sample AA meetings in the community to find ones they liked. The judge agreed to their initial plans, and following Joe and Frank's initial investigations of treatment options, the judge listened to their thoughts about their visits to AA meetings and the methadone maintenance clinics.

TASKS FOR TREATMENT PHASE

Evaluating the Role that Drugs Have Played in One's Life

In early treatment, the client is educated about addiction so that he/she can consider how drugs have impacted life. Only with information can the client make decisions about long-term goals. Groups often are the vehicle for treatment. In a group, the client can hear the stories of individuals at various stages of chronic addiction. As the client listens to others, the client evaluates whether he identifies with the stories he/she hears. Usually, early in treatment, the client completes a first step inventory. In this context, the client responds in detail to a series of questions about how drugs have affected the various spheres (work, recreation, family, thinking) of the client's life. This vehicle for reflection informs the client's decisional balance sheet. As a result, the client usually makes a commitment to a behavioral change. The client has moved to the Action Stage. At weekly meetings, the judge discussed with Joe and Frank their plans for "working their programs" for the upcoming months and listened to their thoughts on what they were hearing in their respective treatment centers.

Decisions about Other Drugs

Conflicting viewpoints are found with regard to the imperative of abstinence from all mood and mind altering chemicals. In working with the dually diagnosed, Minkoff encourages therapists to work incrementally toward sobriety. For the dually diagnosed, abstinence from cocaine is a

success, even though the client continues to drink alcohol. For the dually diagnosed with anxiety disorders, psychiatrists may deem benzodiazepines to be appropriate treatment. Stimulants in those with attention deficit/hyperactivity reduce cocaine relapse.

For stimulant addicts in particular, stimulant drug use often escalates rapidly (within a period of several months) from first use to legal problems. Stimulant addicts sometimes have an extended history of nonproblematic alcohol drinking. Such individuals are hard to convince of the necessity of long-term abstinence from alcohol. Empirical research suggests that alcohol consumption increases the probability of cocaine relapse in those who are heavy drinkers, but not for those who drink in moderation (one or two drinks per setting). The risk of cross addiction for heroin addicts to alcohol after they curtail opiate use is particularly high.

Although the treatment community differs on the necessity of abstinence from all mood and mind altering substances, decisions about each particular drug should be addressed during the treatment process. In the course of taking a social history, the social worker should evaluate the role of all illicit drugs, legal recreational drugs (nicotine and alcohol), and psychotropic medications (stimulants for attention deficit hyperactivity; benzodiazepines for anxiety, etc.). Clients who were raised in communities where alcohol abuse was the norm may need education on what constitutes social drinking. Sometimes, drug court judges will make abstinence from all mood and mind altering drugs a requirement of the court, obviating the need for developing drug-specific plans. For the long term, however, clients will need to think through the pros and cons of abstinence from each particular drug. Joe and Frank both agreed to refrain from alcohol and street drugs for the immediate future.

Drugs for Opiate Addiction

Various drug treatments are available for opiate addiction. Naloxone is a drug that will displace an opiate from its receptor while exerting no effect on the neuron. Although naloxone can be helpful in maintaining abstinence, the drawback is that naloxone will generally diminish the motivational systems in the brain, making natural rewards less attractive and diminishing alertness.

Both methadone and buprenorphine are opiate receptor agonists that are legal. Most major

cities offer methadone treatment options. The federal government also has approved buprenorphine, marketed as suboxone, which can be prescribed by doctors in private practice. Information is available at <http://burprenorphine.samhsa.gov>. As yet, there are no widely accepted guidelines as to when in the course of an addiction a client should be offered opiate maintenance treatments. Both Joe and Frank decided upon methadone maintenance programs.

Work by Peter Kalivas has identified a key difference in an addicted brain that magnifies the strength of relapse precipitants. N-acetylcysteine can correct the behavior of the brain, decreasing the strength of craving. It has shown efficacy in reducing craving for cocaine and in gambling addicts (see Littrell, 2011). Frank's VA physician had read the literature on N-acetylcysteine and provided a prescription.

Developing a Plan for Relapse Prevention

After a client makes a decision to abstain from his/her drug of choice, the client is in the Action Stage, which quickly moves to the Maintenance Stage. The client should be thinking about how to get to daily AA meetings. Carrying around reminders of commitment to sobriety (e.g., the Big Book or birthday chips) make sobriety goals salient. These reminders direct thoughts and actions toward new goals displacing cravings and thoughts of drug use. Cues associated with particular goals (pursuit of sobriety) can decrease the salience of cues for incompatible goals (finding drugs). These cues, even when not consciously processed, can activate behavioral programs (Littrell, 2011). For recovery, the strategy is to create triggers for cuing automatic behaviors that support sobriety. For example, the judge always asked Joe and Frank whether they had their chips with them at their weekly meetings with him.

Detailed plans about "working a program" should be made. Adherence to action plans is more likely when plans are highly articulated, diversions from the plans are anticipated, and coping mechanisms for overcoming obstacles are identified. Research also finds that self-efficacy regarding staying sober predicts success (Ilgen et al., 2006). In fact, social psychologists have an equation for motivation that states: motivation = valuing the goal x self-efficacy. Once the client is in the action or maintenance phase, the self-efficacy term requires attention in treatment.

Employing the availability heuristic, that is, having the client imagine successfully performing pro-sobriety behavior, can enhance self-efficacy and increase compliance with specific plans.

Even for individuals who have established a pro-sobriety routine, relapse precipitants can emerge unexpectedly. Years of research examining the conditions under which relapse is most likely to occur can inform about how to avoid relapse. AA's admonition, HALT, (avoid being hungry, angry, lonely, or tired) comports with the list that years of research on conditions predisposing relapse substantiates. The animal and human work suggests that negative moods can trigger relapse. Thus, practicing strategies for extra emersion in AA meetings during times of stress might prove helpful in avoiding relapse. Triggers for relapse need to be identified. Discussion of areas of town to avoid should occur. Identifying individuals who might encourage drug use is helpful. The point is to develop strategies and coping skills.

Sometimes it is impossible to avoid being hungry, angry, lonely, or tired. At such times, self-regulation resources are paramount. Self-regulation is a limited resource. If one is taxed by a lack of sleep, inadequate nutrition, or rigorous demands on one's attention, then it is far less easy to exert self-control. Conversely, positive moods enhance self-regulatory capacity. Brain research suggests that the prefrontal cortex is the area of the brain most heavily involved in self-regulation. One manifestation of the strength of this capacity is heart rate variability (HRV). In fact, experimental work finds that lapses in self-control are presaged by a decrease in HRV. Researchers have identified ways to increase heart rate variability. Relatively cheap biofeedback equipment is available and presently a cheap phone app, called the stress doctor, is marketed by azumio. Exercise and omega-3 fatty acids increase HRV. Meditation, probably through influencing HRV, increases abstinence. Moreover, being with trusted friends increases oxytocin release. Oxytocin will increase heart rate variability. Purposely engaging in behavior to enhance self-regulatory capacity should be part of the treatment plan (Littrell, 2011).

Frank decided to take advantage of the VA benefits for education and enrolled in a community college to earn a degree in heating and air conditioning technology. Frank relapsed consuming alcohol the night before his first exam. The social worker then talked with the VA and

made arrangements for a VA peer counselor at the community college to work directly with Frank in preparing for exams. With extra coaching, Frank became more comfortable with taking tests. The peer-counselor support was added to Frank's diet and exercise regimen as a relapse prevention strategy.

Developing a Plan for Contending with Abstinence Violation Syndrome

Relapses following commitment to abstinence are to be expected. The phenomenon of abstinence violation syndrome, described by Alan Marlatt, refers to the state in which an individual fails to recognize the possibility of reinstating the goal and the difference between a small lapse and a protracted relapse. An additional component is the disappointment and negative mood that also contributes to drug seeking behavior (see Littrell, 1991; 2011). Plans for curtailing drug use and reinstating a recovery environment are critical. Strategies for counteracting abstinence violation syndrome might include preparing a letter to oneself, which should be kept in one's purse or pocket, to be read in the event of relapse. The letter should articulate the sense of hope and personal satisfaction previously experienced after achieving a period of sobriety. The letter can serve as a convincing reminder that significant periods of sobriety can be achieved. Both Joe and Frank read their letters to the judge.

Monitoring Urine

Monitoring of urine is a key component of drug courts. For long-term outcome of opiate users, monitoring of urine is associated with better outcome. Particularly in early sobriety, before the client has established a recovery paradigm, knowing that sanctions result from a dirty urine, can provide an extra incentive. Drug testing should be presented as a mechanism for assessing the efficacy of the treatment plan so that timely adjustments can be made. The social worker monitored Joe and Frank's adherence to treatment, urine analyses, and attendance at Twelve Step meetings and reported to the judge.

Another key component of drug courts is graduated sanctions. Thus, rewards (a reduction in fines, movie tickets, etc.) can be provided for successes. If sanctions are imposed (time in jail) they should be given in the spirit of assisting the client to meet his/her goals. An immediate

negative physical consequence for using can be motivating as well. Antabuse medication will cause nausea given any consumption of alcohol. Involving the judge when sanctions are implemented can be of particular benefit for those with more extensive involvement with the criminal justice system. The judge congratulated both Joe and Frank on their treatment adherence and clean urines.

Length of Treatment

Research on drug courts finds that duration of involvement with the court is a big predictor of success. The alcohol treatment outcome literature suggests that after the initial phase of treatment, when frequent sessions are required, it is the duration of the client's treatment, rather than the frequency of sessions, that bolsters success (Littrell, 1991). Most drug courts require at least a year of engagement (Hora, 2002). However, even after drug court, the client should establish a long-term relationship somewhere in the community.

Case Dispositions

Both Joe and Frank, after listening to stories at AA meetings and in the drug court sessions, decided to refrain from all nonprescription chemicals for the long-term. Joe found a job. Frank returned to school with financing from the VA. In treatment, they both did first steps, developed relapse prevention plans, and developed contingencies for relapse. They both established exercise, diet, and meditation regimens. Anniversary chips from AA remind them of their commitments. They were congratulated by the judge and graduated after one year. Their charges were dropped.

Making a Case for Life

146 *Models of Investigation in Death Penalty Mitigation*

José B. Ashford

INTRODUCTION

The death penalty is authorized in 32 states, the federal government, and the United States Military. There are over 3,000 individuals currently on death row in the United States. The death penalty is intended for the most heinous crimes and the most culpable offenders. In death-penalty cases, “[t]he defense team must conduct an ongoing, exhaustive and independent investigation of every aspect of the client’s character, history, record and any circumstances of the offense, or other factors, which may provide a basis for a sentence less than death” (American Bar Association [ABA] Supplementary guidelines, 2008, p. 689). The United States Supreme Court considered social work a profession that is well-suited to assisting lawyers in the performance of these specialized investigations (*Wiggins v. Smith*, 2003).

The American Bar Association *Guidelines for the Appointment and Performance of Defense Counsel in Death Penalty Cases* states that a capital defense team “should consist of no fewer than two attorneys qualified in accordance with ABA Guideline 5.1, an investigator, and a mitigation specialist.” (ABA, 2003: Guideline 4.1(A) (1)). Mitigation specialists bring special skills to the defense team in making a case for life that differs from other members of the defense team. This chapter reviews some of the skills used and the methods adhered to by forensic social workers in identifying and developing mitigation evidence as members of a capital defense team.

SOCIAL WORKERS AS MITIGATION SPECIALISTS

Current death penalty trials involve a bifurcated process that consists of two distinct phases: a guilt phase and a penalty phase. It is during the penalty phase of a capital trial that jurors are expected to make a reasoned moral decision about the appropriateness of a sentence of death (Ashford, 2013). In making this decision, they have the legal charge of determining whether a defendant is eligible for a death sentence given the presence of relevant aggravators. Following this determination, they are asked to consider and evaluate the moral significance of any proffered mitigation by the defense in the selection of an appropriate punishment. Referencing the ABA Guidelines, Justice Sandra Day O’Connor observed that “investigations into mitigating evidence should comprise efforts to discover all reasonably available mitigating evidence” (*Wiggins*, 2003, p. 2537). The *Wiggins* decision not only clarified what constituted a properly constructed social history investigation for gathering mitigation evidence, but also affirmed the value of social work’s expertise in the area of capital mitigation.

The *Wiggins* postconviction appeal involved a claim that the trial attorneys in the *Wiggins* case failed to conduct a full investigation of his life history. The trial attorneys obtained limited information about *Wiggins*’ background, but they did not use the services of a social historian, described in the opinion as a “forensic social worker,” to prepare a complete social history, despite the availability of funds for that purpose (Ashford, 2013).

Two years after *Wiggins*, the need for a complete and thorough social history investigation was further emphasized in *Rompilla v. Beard* (2005, p. 379). In this case, the defendant's legal counsel made a strategic decision not to investigate Rompilla's history because Rompilla reported that he had an "unexceptional background." This is a frequent occurrence in death penalty cases. Defendants often instruct members of the defense team neither to investigate mitigating evidence nor to present any mitigation during the penalty phase of a capital case. The trial-attorney in the *Rompilla* case performed an investigation into the client's general background and character. This included interviewing a small number of family members who testified about Mr. Rompilla's good character in the penalty trial. The attorneys in this case also consulted with mental health experts in developing affirmative guilt-phase defenses. However, the baseline task in any mitigation investigation of analyzing a client's life-history records was not performed as previously decided in the case of *Williams v. Taylor* (2000). During the post-conviction investigation of Rompilla's case, evidence was uncovered in records, which if presented, may have convinced the jury of his lessened culpability (Ashford, 2013).

The social or the life history investigation is now recognized as a fundamental requirement in case law (*Wiggins v. Smith*, 2003; *Rompilla v. Beard*, 2005) and in professional norms and standards (ABA Supplementary Guidelines 2008) as the cornerstone of practice in death-penalty litigation (Ashford, 2013). That is, the courts now take into account the nature and quality of social history investigations when evaluating the effectiveness of legal counsel in claims of ineffective assistance of counsel in post-conviction appeals of death sentences.

In order to understand the background and circumstances of the defendant's life, the defense team must perform a multigenerational investigation of all the factors that influenced the defendant's criminal history, psychosocial development, character, and condition. An investigation of this nature requires a type of expertise not traditionally possessed by attorneys (Andrews, 1991; Guin, Noble, & Merrill, 2003). In fact, an ABA Advisory Committee found that many post-conviction claims in capital cases were due to defense counsel not properly investigating and uncovering reasonably available mitigation evidence (Ashford, 2013). Robin Maher, Director of

the ABA Death Penalty Representation Project, attributed these failures to lawyers lacking skills "to obtain the sensitive and sometimes embarrassing evidence about a client's life experiences from family members and other sources that are often beyond the abilities of even the most skilled courtroom lawyer" (Maher, 2008, p. 769).

The forensic social worker on a defense team should bring the following skill set to the mitigation investigation process:

- Cultural competency
- An ability to identify the presence of mental health signs and symptoms of specified and unspecified mental disorders
- Techniques for interviewing that can enable them to overcome barriers to disclosure about a variety of human frailties
- Knowledge of how to collect relevant life history records (Ashford, 2013).

These skills and other forms of knowledge required of mitigation specialists are described in greater detail in the American Bar Association's (2008) *Supplementary Guidelines for the Mitigation Function of Defense Teams in Death Penalty Cases*. In addition to these practice guidelines, forensic social workers can encounter different norms and standards for practice depending on whether they are employed in a private or public setting.

PRACTICE EXPECTATIONS: PUBLIC VERSUS PRIVATE PRACTICE SETTINGS

Social workers employed in public defender offices are faced with ethical constraints not encountered in traditional social work practice. Legal decision-making focuses on advocacy, requiring a social worker employed in a legal defense agency to assist the attorney in achieving the defendant's position regardless of community safety and best interest considerations (Ashford, Macht, & Mylym, 1987). Indeed, different models of social work practice have emerged in forensic social work practice based upon the different ethical standards and norms of practice in legal agencies governing social workers employed in defense-oriented settings (Hughes, 2009).

- Social workers employed in offices utilizing an investigative model are treated as part of the defense team. Their function is to

collect and analyze social history information relevant for sentencing. However, because they provide consultation to attorneys in the development and presentation of mitigating evidence, social workers employed in this type of practice setting are not independent experts. Nonetheless, they still engage in a systematic process of document collection, witness identification, witness interviews, and defendant interviews. However, the social worker's analysis of the defendant's life history in this investigatory role is biased, because of the nature of the practice context. Namely, they are considered a consulting expert to the defense team and to the defense team's mitigation strategy. For this reason, the social worker can function only as a fact witness to corroborate witness statements or to authenticate documentary evidence. That is, any testimony or written assessments regarding the social worker's findings would not meet court criteria for an expert witness. Thus, the social worker's findings in this investigatory role are intended to be presented to defense counsel for their use in determining the social history evidence available for presentation at sentencing.

- Other indigent defense agencies employ social workers as disposition specialists assisting the attorney in determining treatment placement, alternatives to incarceration, and brokering appropriate community resources. This model of service provision is typically utilized in practice with lower-felony defendants (i.e., individuals facing minimal prison or community supervision sentences). However, social workers employed as dispositional advocates must be careful not to cross over into a treatment role. Their role in this context is to identify appropriate recommendations for consideration in the case's disposition as part of an attorney memorandum that outlines the defense position to support specific sentencing recommendations appropriate in that case. In this type of support role in the sentencing process, the social worker is not acting as a therapist or as an expert witness. As a consequence, the social worker is bound by the attorney-client relationship and falls under the attorney-client privilege regarding abuse reporting responsibilities. The social worker is not obligated to report suspected abuse or neglect (subject to

locality specific statutory guidelines) and any information obtained from the defendant cannot be disclosed without the defendant's authorization. In other words, the social worker in this type of practice role is not an independent professional, but instead an ancillary staff member who has specific practice responsibilities surrounding the identification of appropriate resources for aiding defense counsel in presenting a case for a desired disposition.

Not all social workers working as mitigation specialists are employed by public defender offices. Some mitigation specialists are also private practitioners who can play various types of professional roles that adhere to a different model of principles for practice. For instance, there are private practitioners who operate under an investigator model: a consulting member of the defense team who is an independent contractor rather than an office-paid employee. The same practice considerations apply for these private practice social workers as social workers who are employed by publicly funded defense agencies. However, many private practice social workers have also adopted an expert model that is described below:

- The social worker/mitigation specialist as an independent expert witness approaches each case initially with the same systematic framework or scientific formulation required to develop the defendant's life history. As an evaluating expert, the social worker in this role is not a consulting member of the defense team. The social worker serving as an expert is expected to inform the trier of fact about the defendant's life history through data interpretation using social science research and theory to explain the defendant's behavior, development, and functioning. Without participation in defense team strategy discussions, the independent social work expert must focus solely on the referral question at hand and provide information to the attorneys within the domains of the professional's expertise, being cautious to operate within social work's specific range of expertise. Testimony and/or written evaluations to the court may be required. Social workers appearing in court as independent expert witnesses must have qualifications and expertise in the specialty

area relevant to the case (Gothard, 1989).

This role is frequently encountered when the defense team has already collected some life history information through investigation, and the social worker as an expert witness is used to analyze and interpret the investigative findings in terms of theory, research, and experience not possessed by laypersons.

Irrespective of practice model, social work has had a longstanding niche in criminal sentencing because of its distinct expertise in the area of social history or life history development. The social history of a criminal defendant is typically complex, with pervasive themes of trauma, mental disability, deprivation, and social exclusion. The investigation requires practitioners to employ a systematic process of document collection and review, before hypotheses can be generated and tested through a process of critical inquiry (Ashford, 2013). The social history assessment also must adhere to accepted social work and social science procedures. To this end, the social worker must establish a chronology of:

- Key life events
- Deviations in thought, mood, and behavior considered signs and symptoms of specified and unspecified mental disorders
- Key developmental transitions
- Psychological and physical traumas
- Adaptive and maladaptive coping strategies
- Recurrent difficulties in relationships
- Disruptions in psychosocial development
- Changes in emotions and cognitions following psychosocial stressors and physical traumas
- Other developmental considerations (see Ashford, 2013).

The social worker must also gather a cross-section of information from key sources in the defendant's social environment (family/significant others, social educational settings, employment, housing, neighborhood, cultural and spiritual environment, service system experiences, accessibility to needed services, income, and legal/crime experiences). After identifying and reviewing the cross section of life events and the longitudinally relevant information gathered in this process, social workers analyze these findings

through various theoretical lenses acquired in their professional training for identifying relevant variables and factors for developing appropriate mitigation themes. This includes reviewing the scientific literature to guide their interpretations of the variables and themes identified in the defendant's life history (Ashford, 2013).

Case Example

- Johnny, a 24-year-old male, is charged with two counts of First Degree Murder and Armed Robbery for killing a clerk and a witness while robbing a convenience store. When interviewed by law enforcement, Johnny confessed to the shooting but could not provide any details about what occurred. Video surveillance from the store documents Johnny wandering around the store confused and stumbling in an aisle for several minutes prior to the beginning of the shooting.
- Johnny was born to a drug-addicted mother who died of an overdose when Johnny was seven years old; he does not know who his father is. After his mother's death, Johnny and two older sisters were sent to live in another state with his maternal grandparents. Maternal grandmother did not work and suffered from Bipolar Disorder. Maternal grandfather worked long hours in a factory and drank alcohol on a daily basis. Each night after returning from the bar, grandfather would return home and physically abuse Johnny, his grandmother, and sisters. At age 10, Johnny began running away from home and was soon placed in foster care. He has several juvenile arrests for property and drug offenses and served several unsuccessful terms of community supervision, eventually being committed to the juvenile corrections department at age 16.

APPLICATION OF A SOCIAL HISTORY FORMULATION

The social worker will need to engage in a systematic process of data collection to obtain objective and reliable information about Johnny's social history. This historical investigation requires the practitioner to adhere to a process of critical inquiry that is separated into various stages, each with separate but cumulative goals in mind (see Ashford, 2013).

1. Identify Key Goals for Social History Investigation

Depending on the type of case, the social worker can be asked to investigate a very narrow portion of the defendant's background. For example, attorneys representing a defendant with known mental health history may only seek the social worker's assistance in the investigation of psychiatric issues. This is common in lower-felony cases where the social worker has a small window of time to prepare a social history before the sentencing hearing. At other times the mitigation investigation already may have been partially completed and the social worker must pick up where the other professional left off, or focus the investigation on areas that require further inquiry.

In most criminal cases, especially death penalty cases, the purpose of collecting historical information is to identify all factors and experiences that have shaped the defendant's background and character. The only reliable method to accomplish this task is to engage in a multi-dimensional, holistic approach to information gathering that is guided by scientific principles and methods of inquiry (Ashford, 2013).

Because a social history can provide insight into pertinent clinical and developmental issues, the goals of the investigation narrow as relevant information is identified. For instance, an initial meeting with Johnny confirms the existence of multiple agencies playing a role in his life. The maternal grandmother received Social Security, which enabled the team to learn about her history of mental illness. She also had contact with many other agencies that collected data on various issues in her home situation, which was referenced in these reports. The information in these reports pointed to other problems, such as the maternal grandfather's alcoholism. This led to the identification of additional documents, which raised concerns about his potential involvement in the criminal justice system.

In essence, each lead can point to a different body of records that can document important phases of Johnny's life. For instance, court records in Johnny's case contained information on the transfer of custody of Johnny and his sisters to the grandparents, as well as information about the criminal history of Johnny's mother prior to her death. Records from Johnny's placement in foster care and subsequent juvenile justice referrals also contained a wealth of life

history information such as mental health evaluations, home studies, educational assessments, and information about potentially relevant behavioral patterns. The collateral documentation contained many investigative leads, such as caseworkers, psychologists, social workers, teachers, neighbors, peers, probation and parole officers, counselors, and law enforcement officers who have knowledge of varying conditions and events in Johnny's life. References in records to individuals who knew Johnny's maternal grandparents were very helpful because they identified professionals who helped corroborate important details about the grandfather's alcoholism and the grandmother's mental health problems.

The goal of the investigation is to provide a picture of the defendant's life, which is illuminated through the testimony of live witnesses and objective historical documentation. This evidence is most credible when it is inherently unbiased, such as the grandfather's ex-employers and employees who never met the defendant. In order to corroborate the data collection process adequately, the investigation must produce multiple individuals with independent recollections of the same historical event or dysfunctional pattern of behavior. The more witnesses or records that can corroborate findings, the more reliable and credible the evidence becomes.

Nonetheless, when evaluating these recollections, mitigation specialists must be aware of potential biases that family members and close acquaintances can have about the defendant. This having been said, even biased information has potential value in the early phases of an investigation, if accounted for, because this information can help support the presence of a fact or theme that will require other kinds of additional corroboration that can be of significant benefit to the investigation process. The early stages of a social history investigation are similar to casting a net for fish. To obtain the most data, the scope of the mitigation investigation must begin as broad and as far reaching as possible. It has to focus initially on data collection before making preliminary hypotheses (Cunningham, 2002). As information is obtained and considered, the goals of the investigation will change and become more focused.

2. Generate Hypotheses

As is common with criminal defendants, Johnny's social history is replete with multiple adverse developmental experiences. In a capital

case, defense counsel is obligated to investigate every aspect of a defendant's life history. Only after a thorough investigation can defense counsel fulfill their ethical obligations for zealous representation.

Within each domain of functioning, there often exist both risk and protective factors acting on a defendant. Throughout the development of a defendant these factors may change as external and internal variables interact separately and cumulatively. For example, consider a number of events during Johnny's adolescence:

- Minimal friendships except other antisocial peers
- No prosocial work history
- Frequent changes in housing
- Unstable and chaotic home environment
- Placement in foster care
- Juvenile justice referrals.

Identifying a cross-section of these events in Johnny's life, and identifying how these events were influenced by other dimensions in his functioning, is critical to understanding the pathway to his instant criminal offense. For example, the detrimental effects of physical abuse on a growing brain have been well documented. However, the experience of repeated head injuries during middle childhood creates different cognitive sequelae than those sustained during adolescence. To be precise, we cannot have a valid understanding of Johnny's adolescent functioning without evaluating the effects of the interactions of biological and psychological influences on each of these events. What were the biological and psychological consequences of these events? Are these consequences evident in the chronology of the events, signs, symptoms, and maladaptive coping strategies documented in the chronology of his life? Do they point to new hypotheses and to other areas of functioning not previously addressed by the defense team?

Triangulation of life history experiences by means of document collection and witness interviews will provide the data to support hypotheses about the timing and effect of adverse developmental experiences. Social workers in the context of mitigation practice use the findings from the application of their scientific formulations to create the overall mitigation themes for use in the penalty phase of the sentencing process.

3. Organize Social History into Themes

The inquiry into Johnny's life history should lead to themes that are confirmed by multiple sources of information. For instance, it is clear that Johnny has suffered repeated losses in his life that are compounded by his chronically chaotic and unstable social environment. This pattern is supported by documentary evidence and third-party witness interviews. From the documentary evidence, we learned about his loss of his biological mother, his lack of any relationship with his biological father, the change in his custody because of his mother's death, his alcoholic and abusive grandfather, his multiple foster placements, and juvenile commitment. The prior information has to be organized into relevant themes. Organizing the information into themes can help the trier of fact understand the breadth and depth of negative experiences that Johnny suffered over the course of his life and how these unfortunate experiences impacted his involvement in the crime for which he was convicted. However, the themes do not have to be directly related to the crime. They also can be used to support other kinds of themes that help to humanize the defendant in ways that speak to why the defendant is not deserving of a sentence of death.

CONCLUSION

The social history information gathered to assess a defendant's degree of moral culpability is not unsupported speculation. Social workers employed as mitigation specialists use systematic procedures of data collection and analysis that are consistent with scientific principles and methods of critical inquiry. Attorneys use the evidence gathered during the social history investigation to develop relevant themes and to obtain additional expert assistance in the presentation and interpretation of this information. Practice in this area of forensic social work can be hampered by agency constraints as well as by how the individual professional characterizes his or her role on the defense team. As a consequence, practitioners in this field of practice must have a strong sense of professional identity and a solid grounding in professional ethics in order to practice effectively in defense oriented contexts as sentencing advocates in the mitigation of a defendant's punishment.

147 Assessing and Treating Adolescent Sex Offenders

Karen S. Knox

Opportunities for clinical and direct practice with adolescent sex offenders have increased for social workers with the development of treatment programs in juvenile justice

settings, community-based outpatient services, residential treatment, inpatient mental health, and incarceration facilities. Services and resources for adolescent sex offenders and

their families are available to meet the various levels of treatment and supervision needed. Treatment protocol and standards of best practice for professionals have been established through empirical research studies and professional organizations, such as the Association for the Treatment of Sexual Abuse (ATSA) and the National Adolescent Perpetration Network (NAPT). These developments have contributed to the knowledge base and growth of expertise in this field of practice. Specialized education and training are necessary to work ethically and effectively with adolescent sex offenders, and professional licensing boards now require additional licensure for clinical professionals working with this client population.

Incidence reports and statistics indicate that juvenile sex offenders commit one-fifth of all sexual assaults and one-half of all child sexual assault/abuse (Cheung & Brandes, 2011). Adolescent sex offenders are typically between the ages of 13 and 17 years, mostly male, with female perpetrators accounting for 8%–12% of reported cases (Brown & Burton, 2010; Cheung & Brandes, 2011; McCartan, Law, Murphy, & Bailey, 2011). Research studies indicate that 30%–60% of adolescent sex offenders have learning disabilities, 80% have a diagnosable mental health diagnosis, with 20%–50% having a history of child physical abuse and 40%–80% being victims of child sexual abuse (Burton, Duty, & Leibowitz, 2011; Cheung & Brandes, 2011). There are higher proportional rates of adolescent Caucasians who are arrested and convicted for sex crimes in comparison with adolescent African Americans, and African American adolescent sex offenders are less likely to have histories of child sexual abuse (Burton & Ginsberg, 2012).

Currently, there are two main perspectives to explain adolescent sex offending: First, the *generalist perspective* suggests that their sexual offenses are only a part of their other antisocial and criminal behaviors, and that this type of adolescent sex offender is similar to other non-sexual adolescent offenders sharing common risk factors such as antisocial attitudes and behaviors, association with delinquent peers, and substance use. Second, the *specialist perspective* suggests that different factors explain adolescent sexual offending, such as trauma histories, early exposure to sexual behavior in the home or on the Internet, and more atypical sexual interests and sexual deviancy arousal that requires

different assessment instruments and treatment approaches (Pullman & Seto, 2012).

CASE ILLUSTRATIONS

John, a 16-year old African American male, is in the 10th grade and lives in a low-income neighborhood. His mother is a single parent with three other younger children, and she works full-time as an administrative assistant. She reports having problems with him following the rules at home, fighting with his siblings, and hanging out with negative peers. He is currently facing a sexual assault charge of fondling a 17-year old classmate on the school bus. John has had incidents of bullying and fighting at school. He is truant frequently and has a learning disability, which has resulted in academic delays and suspensions. This is John's first time appearing in juvenile court. His mother contacted the Public Defenders Office for representation, and he has been placed on probation and community supervision for two years.

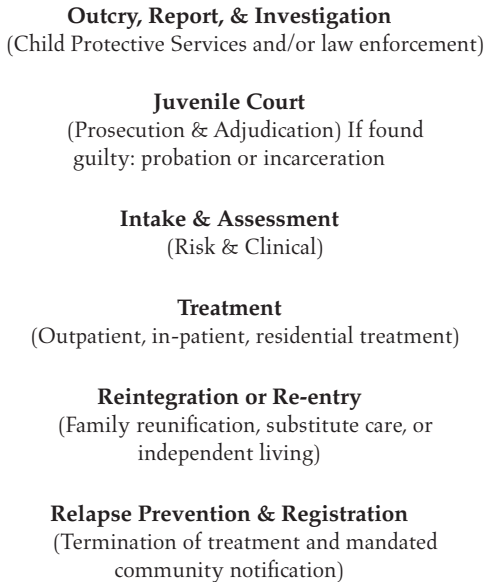

George just turned 13 and lives with his parents and younger brother in an upper middle-class neighborhood. Both of his parents work full-time and report that George has never been in trouble before. They describe him as an excellent student, but he does not have a lot of friends his age. They describe him as immature and a loner who spends a lot of time on his computer. One of his brother's friends disclosed to his parents that George had fondled him and showed him some "nasty pictures" on the computer. The investigation revealed that George had also shown his brother and his other friend some pornography and had exposed himself to them. George's parents hired an attorney who was able to plea bargain for a sentence of probation and community supervision for two years.

Although George's parents have been able to adjust their work schedules and housing arrangements to accommodate his probation supervision guidelines, John's mother has limited resources for supervision after school, so John has been placed on intensive supervision and mandated to perform his community restitution after school to meet his supervision requirements. John was also sent to the alternative learning school, because he can no longer have any contact with his victim. George and his parents have agreed to a strict supervision and safety plan to allow

George to continue to live at home and attend the same school.

Continuum of Treatment

Working with adolescent sex offenders requires the use of a multisystemic approach, given that professionals from various disciplines and settings are involved in a continuum of treatment for these clients and their families. This continuum usually begins with an outcry or report of sexual abuse by the victim, which then involves investigations by child protective services and law enforcement professionals. If charges are filed, the case proceeds through the juvenile court system with prosecution, adjudication, and if found guilty, sentencing of probation or incarceration. The following flow chart shows the typical continuum of treatment:

RISK ASSESSMENT

Sex offender registration and community notification requirements impact risk assessments for adolescent sex offenders on probation or upon release from a penal institution, because an assigned risk level must be indicated on their sex offender registration form. This type of risk assessment is very different from a clinical risk assessment and is usually done by a probation or parole officer. It addresses legal risk factors such as seriousness of the sex offense, offender's age at first referral, and prior adjudications

or referrals for sex offenses or other felonies. Recommendations associated with the various levels of care and supervision are assigned using the following guidelines:

- *Low-Medium Risk:* Youth placed on probation at home/community placement usually for 12–24 months with intensive supervision and outpatient treatment.
- *Medium-High Risk:* Youth placed on probation and placed in a residential treatment or inpatient facility, typically in a secure unit depending on level of psychopathy and other mental health disorders. If successful, the youth may return to home/community and receive additional outpatient treatment. If not successful, the youth may be remanded to a more secure setting or correctional institution.
- *High Risk:* Youth placed in a correctional institution that may have sex offender programs; however, factors such as amenability to treatment, limited services, and waiting lists impact on availability. Many youth may not receive sex offender treatment until released on parole and then referred to outpatient services.

When applying the criteria for the legal risk assessment, both John and George would be assessed as low-medium risk and will be receiving outpatient treatment while on probation. Both will be residing in their homes and receiving intensive supervision. Both will be referred to outpatient counseling and will have to perform 500 hours of community service. However, this is where their similarities end; their clinical assessments will be very different with respect to their clinical issues and family and social histories.

Clinical assessments are often court-ordered to provide recommendations on the type and level of treatment required for the adolescent sex offender. Clinical assessments should not be used as a determination of guilt or innocence and should be made after adjudication and before sentencing to help determine an appropriate treatment plan. This type of assessment can also be conducted as part of the youth's treatment plan when the juvenile has been placed in a therapeutic or correctional setting. Clinical assessments assist in identifying the youth's amenability to treatment, the type and level of care, level of risk for recidivism, developmental

issues, risk and protective factors, and family and community resources to meet the client's needs. Clinical assessments usually include content on the offender's family history, relationship to the victim, age and number of victims, sexual and trauma histories, environmental risks, and psychosocial problems.

Due to the level of expertise and experience required with this client population, it is recommended that clinical assessments be conducted by a licensed sex offender therapist. The clinical assessment should be as comprehensive as possible by addressing other treatment issues or problems, as well as the sexual offending behaviors. The assessment process typically includes a clinical interview(s) with the adolescent and family members, collateral contacts, school records, social services, law enforcement, or mental health providers in the client's history, and standardized instruments that measure treatment issues and psychopathy. Current risk assessment instruments that are widely used include:

- Juvenile Sex Offender Assessment Protocol (J-SOAP-II) (Prentky & Righthand, 2003)
- Juvenile Sexual Offense Recidivism Risk Assessment Tool-II (JSORRAT-II) (Epperson, Ralston, Fowers, & DeWitt, 2009)
- Multiplex Empirically Guided Inventory of Ecological Aggregates for Assessing Sexually Abusive Adolescents and Children (Ages 19 and under) (MEGA) (Miccio-Fonseca, 2010).

Special Clinical Issues

Special clinical issues that are common to adolescent sex offenders include low self-esteem, poor impulse control and emotional regulation, minimal social skills, poor problem-solving and decision-making skills, poor peer relationships, attention problems, disruptive behavior problems, and a lack of appropriate coping skills. Clinical risk assessments and treatment plans need to address issues such as anger management problems, learning and developmental disabilities, trauma history, substance abuse, depression, suicide, anxiety, and other neuropsychological problems.

Specific content on sexual attitudes and history are included in the assessment and intervention plan, along with the level of acknowledgement or denial of responsibility for the sexually offending behaviors. It is typical for these youth and families to evidence denial or minimization of

their sexually offending behaviors and thoughts, even after adjudication of the legal case. Feelings of shame, guilt, and embarrassment contribute to minimizing and denial. Any empathic responses about their victim(s) are assessed as strengths, since deficits in empathy and appropriate affect are a major focus of treatment. Cognitive distortions (thinking errors) associated with the sexual offense contribute to the youth's level of denial or minimization. Other sexually inappropriate behaviors, fantasies, arousal patterns, and resources for sexual materials, such as pornography and the Internet are included in the sexual history section of a clinical assessment.

Case Illustrations

John came into the office for his clinical assessment interview with a wary attitude and was extremely guarded in his responses to the social worker. Copies of the incident report from law enforcement, the probation intake form, and his school records were included in his case files, and the social worker had already identified several areas of concern, including his delinquency history, school problems, substance use, and anger management issues. During the interview, John did acknowledge these issues "get him into trouble," but he had little insight into how to change his behaviors. His primary motivation for change is his probationary status, and he appears to be intelligent and capable of making positive changes. He is, however, reluctant to leave the gang and his friends who have been major influences in his delinquency history. He does take responsibility for the sexual offense, but minimizes the incident as "just bullying and playing around," and denies any other history of inappropriate sexual behaviors. When discussing his family, he states, "I never knew my father." He says his mother does her best but is stressed out and angry with him.

George seemed rather timid and made little eye contact when he first entered the counseling office. His case records indicate he is a loner at school, and he states that his peers think he is "weird and nobody really likes me." George does well academically and has no other school or behavior problems. The standardized assessment instruments indicate that he scored in the clinical range on the sexual offending scales, as well as for anxiety, low self-esteem, lack of communication and social skills, and immaturity. George discloses that an elderly male neighbor had showed

him how to masturbate when he was five years old, and the sexual abuse continued for several years before the neighbor died. George has never told anyone about this because he is scared and ashamed about getting into trouble. He says his family does not really have any problems, but thinks his parents always favored his siblings over him.

Treatment Models

Using a strengths-based approach, the Good Lives Model is a theoretical framework for offender rehabilitation that builds on client capabilities to promote pro-social skills and personal functioning. Recent evaluation research studies indicate positive outcomes for both generalist offenders and sexual offenders (Willis, Gannon, Yates, & Ward, 2013). The model addresses limitations of the traditional risk management approach that emphasizes problems and deficits and uses restriction of activities as the primary means to avoid reoffending. The Good Lives Model promotes social work values of client respect and dignity, so negative labeling and hostile confrontation are inconsistent with this collaborative approach, which is used in conjunction with cognitive behavioral therapy.

The principle treatment model used in sex offender treatment is cognitive-behavioral theory, with group therapy being the primary modality. Cognitive-behavioral therapy (CBT) has been found to reduce sexual recidivism significantly, and research studies provide evidence of its effectiveness in addressing cognitive distortions and atypical sexual arousal and behaviors (Pullman & Seto, 2012). Group treatment is conducive to learning social skills, experiencing appropriate peer interaction, and addressing denial and minimization, given that many adolescents find it easier to disclose and admit responsibility when among others who share similar histories.

Multisystemic therapy (MST) is another model that has been empirically demonstrated to reduce recidivism and out-of-home placements for both generalist offenders and adolescent sex offenders. This model is family-based and targets multiple domains, including family functioning, social skills, problem solving, coping skills, academic problems, negative peers, and substance abuse (Pullman & Seto, 2012). This approach is critical, because most adolescent sex offenders evidence problems across multiple areas in their

social environment, so coordination and collaboration among providers is critical to treatment success.

Individual and adjunct therapies are recommended for other issues such as trauma histories, psychological disorders, substance abuse, and anger management. The length of treatment varies depending on many factors, but most programs range from 12 to 24 months. Youth may remain on probation/parole after completing treatment, which ensures supervision needs, relapse prevention, and follow-up services. Relapse prevention and family reunification should be completed before termination from the treatment program and probation to endure a smooth transition and supervision needs.

Treatment Goals and Plans

Treatment goals focus on reducing antisocial behaviors and recidivism and development of pro-social skills. The treatment plan should include safety rules, supervision guidelines, and specific interventions, specifying the time frame and consequences of not following through with the program. All parties should sign a written treatment contract and intervention plan. It is important to work as a team with other professionals on the case, and to differentiate the roles and responsibilities of those involved in the treatment plan. Specific interventions include positive and negative reinforcement, confrontation, relaxation skills, assertiveness training, and expressive arts techniques such as art therapy, psychodrama, family sculpting, role-play, bibliotherapy, and adventure-based interventions. Adolescent sex offender programs may vary across settings, length, and intensity of therapy, but most follow a standard protocol that includes the following components and goals:

1. *Introduction to Group and the Treatment Process*

- Group rules and supervision guidelines; Laws about sexual behavior; Sexual offense layout or statement

2. *Sexual Abuse Offense and Cycle*

- *Acknowledgement of Responsibility:* Youth who continue to deny or minimize responsibility for any sexually offending behaviors may be required to take a polygraph examination to establish specific areas of deception, and if the polygraph is failed, consequences can

include termination from treatment and possible legal sanctions.

- *Sexual Offense Cycle*: Cognitive distortions (thinking errors), sexual fantasies, arousal patterns, and sex offending behaviors are important issues to confront with the goals of reducing recidivism and learning appropriate sexual attitudes, behaviors, and relationships.
- *Empathy*: Most adolescent sex offenders have a deficit in this area, even those who have prior physical or sexual victimization. Developing empathy for their victims and understanding the consequences of their sexual offenses is critical. The *clarification or apology letter assignment* helps offenders understand the impact of their behavior on their victim(s) and significant others. This assignment is not intended to absolve the offender's guilt or to ask forgiveness. It is typically read only during group for feedback and is not given to the victim(s) unless family reunification is indicated.

3. *Interpersonal and Coping Skills*

Development

- *Clarification of Values*: Adolescent sex offenders either have a deficit in this area or espouse deviant/delinquent values that may impact on recidivism.
- *Self-esteem*: These adolescents experience failure in many aspects of their lives and relationships, so a strengths-based approach is recommended.
- *Social Skills*: The group environment is especially helpful with youth learning and group facilitators modeling appropriate interactions and communication skills.
- *Behavior Problems*: Anger management, impulse control, and conflict resolution are addressed by developing appropriate problem-solving, assertiveness, and coping skills.

4. *Relapse Prevention/Reunification & Termination*

- Adolescent sex offenders develop a relapse prevention plan with strategies to use in at-risk situations. Those who will be reuniting or having approved contact with their families/victims must participate in family therapy and develop a safety plan.

Case Illustrations

John's intervention plan recommended attending adolescent sex offender group therapy once a week and participation in a diversion program through juvenile court for his anger management, delinquency, and substance abuse problems. He was sent to the alternative-learning center where he was doing better academically and with his attendance. However, four months into treatment, he was arrested on a robbery charge with several friends and his probation was revoked. He is currently incarcerated in a juvenile correctional facility where he is receiving treatment services for his generalist offending behaviors.

George's treatment plan also recommended attending sex offender group therapy weekly and individual therapy weekly for his trauma history and psychological issues. His treatment plan addressed his sexual abuse by using the Trauma Outcome Process Assessment Model (TOPA), which provides interventions for his trauma symptoms (Rasmussen, 2012). His family initially wanted him to remain at home, but after participating in a parent support group and family therapy sessions, decided that his level of care and supervision was too much for him to remain at home. He is currently placed at a residential treatment facility in an adolescent sex offender program.

These case illustrations are indicative of the types of issues affecting treatment and probation status for adolescent sex offenders. It is more common that adolescent sex offenders are sanctioned to a higher level of care and supervision for a crime other than a sexual offense, as in John's case. For George, his parents are supportive and able to provide for a more secure setting with specialized treatment for his sex offender behaviors and psychiatric diagnoses.

When both youth are released and return to their homes, the final phase of treatment would involve family reunification services. Clinical issues include earning trust, re-establishing family rules and roles, adjusting to a different level of supervision, reintegrating back into school and the social environment, and maintaining positive changes. Family therapy is recommended for support during this transition period, which can be a high-risk period of time for relapse or recidivism.

Resources for Professionals

Available resources for practitioners, such as workbooks for adolescent sex offenders that have homework assignments and experiential exercises, literature for parents and siblings of offenders, audiovisual materials, and training opportunities can be found at the following websites:

148 Forensic Social Work with Women Who Use Violence in Intimate Relationships

Michelle Mohr Carney

Among the debates in the field of domestic violence, none is more acrimonious than the debate around female initiated violence. Although the prevalence and consequences of male violence directed toward women in intimate relationships has been well established, the research on violent women in intimate relationships is far less developed. Traditional conceptualization of domestic violence is rooted in learned gender roles and considered inherently male. Persistent support for the notion that women are victims and men are perpetrators supports the patriarchal structure of society and reinforces traditional gender roles. The data are widely contested, and researchers argue that a clear depiction of the extent of male victimization is difficult to ascertain, but studies suggest that over 40% of victims of severe physical violence are men (Hoff, 2012). These data, considered to be under-reported and not reflective of the problem, suggest that women are capable of initiating violence in intimate relationships and that a reconceptualization of domestic violence as violence perpetrated by either males or females, and which can be unidirectional, bidirectional, or mutual is warranted.

Johnson (1995, 2000) developed an argument suggesting that feminist scholars, who believe that domestic violence is the result of our patriarchal culture and involves men using violence to subordinate women, and sociological scholars, who believe that domestic violence is a form of conflict resolution used equally by men and women in intimate relationships, are both correct in their conceptualizations of violence and that they are really discussing different phenomena. He contends that there are essentially two distinct forms of family violence, which he refers to

as “patriarchal terrorism” and “common couple violence.” According to Johnson (2000), common couple violence refers to the phenomenon captured in the national family violence surveys, where the violence is not coercive or controlling and is gender balanced. In this model, a couple may engage in physical violence with each other in the context of a specific argument, but the violence is not meant to control the other person and is likely to be bidirectional or mutual (Johnson, 2000). By contrast, patriarchal terrorism refers to the phenomenon seen in shelter populations and criminal courts, where the violence is male initiated and escalating and represents a man’s attempt to dominate and control his partner. In this model, the violence is purposeful and is meant to intimidate and control the female partner. As such, it is not generally confined to physical violence and routinely involves severe emotional abuse, intimidation, and likely will result in severe injury for the woman (Johnson, 2000). Johnson’s conceptualization of domestic violence is helpful because it suggests that both feminist scholars and sociological scholars are correct in their conceptualizations of domestic violence, allowing for movement beyond the perpetrator/victim roles or labels, to address the use of violence and how it can be controlled.

CASE DESCRIPTIONS: FEMALE-INITIATED INTERPERSONAL VIOLENCE

Case 1

Emily and her husband, Scott, had been married for approximately 10 years. Over the course

of the marriage, they had many “domestic disturbance” calls to the police and Scott had been arrested several times for misdemeanor domestic violence offenses. On the most recent occasion, Scott returned from the county jail extremely agitated with Emily for, in his view, causing him to be arrested again. Shortly thereafter, there was a disagreement between the two whereby he held her on the ground while choking her and informed her that he was tired of her. At that time, he indicated to her that he would come home the next day from work and kill her. The following day, she waited for him to return from work and, as he was climbing the stairs to their second floor apartment, dropped a barbecue grill on his head. As a result, Scott was hospitalized and Emily was arrested for domestic violence.

Case 2

Megan was recently divorced with a history of violent behavior and alcohol abuse. Megan and her ex-husband had a history of involvement with the police for “domestic disturbance” calls and on at least two occasions both parties were arrested by the police. After her divorce Megan met Blake, who had a history of repeat arrests for drug possession and pimping. Megan and Blake argued often. After their most recent fight, Megan was arrested for stabbing Blake in an argument about another woman. When asked about interpersonal violence in her relationship with Blake, Megan stated that she has never been a victim of domestic violence because “she would never let a man control her.”

BRIEF ASSESSMENT OF THE CASES

These cases illustrate the complexities of female-initiated domestic violence. First, and perhaps most importantly, there are women who are arrested, prosecuted, and convicted of domestic violence offenses and who occupy dual status as both victims and offenders. This creates serious difficulties for treatment providers as they try to distinguish between women who are both victims and offenders and those women who are only offenders. These cases illustrate the challenges in differentiating between victims and perpetrators, and those who are both victims and perpetrators. In Emily’s case, there was a clear pattern of abuse at the hands of her husband, but on the night of the incident, she was the sole

aggressor. It is possible to see her use of violence against Scott as retaliation for the previously incurred abuse and the fear that resulted from his threat to kill her. Megan’s case is difficult to assess. Although Megan and her ex-husband had a history of bidirectional violence, by her own admission she does not consider herself to be a victim of interpersonal violence. In terms of primary aggressors, it is possible to argue that Megan used violence against Blake, not in retaliation for his violence, but as the sole aggressor in the relationship. Women who are the primary or exclusive aggressors in their intimate relationships appear to be very much like male domestic violence offenders. Second, women who initiate violent acts in their intimate relationships routinely engage in high levels of extreme violence. The conventional wisdom on this topic is that, given the average size and strength differentials between men and women, women must ensure that the violent act incapacitates the man so that he does not retaliate.

Clearly, both Emily and Megan are in need of services and intervention, but are they both victims, both perpetrators, or does that distinction matter? These examples illustrate that women engaged in interpersonal violence can be viewed through a variety of lenses; as women who are victims and use violence in retaliation, women who have a long history of victimization who refuse to be victimized further, and women who are simply violent—not retaliatory. Although the women in all these three cases are being arrested for interpersonal violence and sentenced to treatment, it is critical to match the treatment modality with the motivations for the violence. More important than the perpetrator/victim role or label, is the use of violence and how that can be controlled through taking responsibility for the violence and committing to behavior changes.

Men and women’s motivations for and use of violence differ. Men’s use of violence is often learned and societally reinforced, while women’s use of violence is considered to be a more complex topic. This is not to say that men’s use of violence is simplistic, rather that the societal stigma that prevents abused men from reporting their abuse prevents most people from seeing men in the dual role of victim and perpetrator. Women’s use of violence is not similarly accepted or expected, nor is it often clear whether they occupy dual victim/perpetrator roles and use violence in retaliation or if they are simply violent primary aggressors.

THE RESEARCH

Evidence for the construct of female-initiated violence in intimate relationships is strong. Data from longitudinal studies using large samples presents the strongest evidence of this construct. The Dunedin study including a "complete cohort of births between April 1972 and March 31, 1973 in Dunedin, New Zealand" (population 120,000) was one such study (Magdol et al., 1997, p. 69). This birth cohort of 1,037 subjects has been studied every two years since its inception for a variety of health, development, and behavioral measures. The 425 women and 436 men who were in intimate relationships indicated that both minor and severe physical violence rates were higher for women whether self-reported or partner-reported. The female severe physical violence rate was more than triple that of males (18.6% vs. 5.7%). Perhaps earlier studies of partner violence assumed that men's perpetration rates exceeded those of women, because they relied almost exclusively on clinical samples of women who sought assistance or of men in court-mandated counseling programs (Magdol et al., 1997).

Gender bias in both the reporting of women's use of violence against men, and the handling of the cases by both law enforcement and the courts prevents a clear representation of the magnitude of the problem. Female intimate violence perpetrators are frequently viewed by law enforcement and the criminal justice system as victims rather than actual offenders of violence against men, making access to the necessary treatment for both parties difficult (Kingsnorth & MacIntosh, 2007). However, the increased presence of women, as offenders, in treatment programs for domestic violence offenders is the direct result of legislation mandating the arrest of perpetrators in cases where police respond to a call and determine that domestic violence has occurred. In the late 1980s most states enacted Law Enforcement Protection legislation. This legislation, commonly referred to as "warrantless arrest," allows police who respond to a domestic violence call to arrest the abuser and press charges themselves. Although the arrest of women was clearly an unintended consequence of mandatory arrest statutes, their sudden appearance in court-mandated treatment programs has had a dramatic impact on the national debate regarding female-initiated violence. As a result of women being court-mandated into batterer treatment

programs, it is no longer possible to suggest that women are infrequently the initiators of violence in their intimate relationships. If this were true, there would be very few women arrested, successfully prosecuted, and mandated into treatment as part of a criminal sentence.

Most states, however, do not offer certified intervention programs designed for women, even though the need has been established. Advances in treatment for women who use violence against their partners have been limited by a gendered belief that interpersonal violence is perpetrated exclusively, or mostly, by men. Often, men suffer in silence, and there is a prevailing message to keep quiet when it comes to considering women as perpetrators of partner abuse. As a result, many female perpetrators are not linked with critically necessary services, or in the cases of mandatory arrest, women are often court-mandated into treatment programs designed for men.

Unfortunately, despite the presence of women in court-mandated treatment programs for batterers, very little is known about the role of violence in their lives or the usefulness of treating female offenders in programs designed for men. Specifically, due to the longstanding debate about the existence of female-initiated violence, very little research is available on the topic and women are currently being treated in programs designed for male batterers. Most states offer certified batterers' intervention programming that is guided by certification standards. The goals of this programming are to protect victims and increase accountability for perpetrators. The minimum program duration ranges from 12 to 52 weeks, with the average program lasting 24 to 26 weeks. Most certified programs are linked to systems of accountability and are reviewed regularly by the monitoring agency. Traditional intervention models view the primary cause of male domestic violence as patriarchal ideology and societal sanctioning of men's use of power and control over women. These programs are educational models and are not considered to be therapy. Some of the early educational and intervention programs used as models nationwide included EMERGE in Boston, AMEND in Denver, and the Duluth DAIP Program. These programs were designed for men, with the program focus on the use of violence as an attempt to exert power and control the victim. One of the most prevalent of the educational models is the Duluth model and its use of the "power and control wheel," which illustrates that violence is part of a pattern of behavior that

reflects both the power imbalances in relationships, and in society as a whole, between men and women. In addition to the educational programming, many batterer intervention programs have added cognitive-behavioral programs focused on managing anger and learning signs to recognize escalating violence and techniques for controlling violent outbursts. Batterer intervention programs typically use a group format to promote social accountability and peer reinforcement of nonviolence. In general, key components of the treatment include (1) confrontation; (2) group therapy to help recognize and overcome minimization, denial, and blame as commonly used defense mechanisms; (3) examining batterers' use of anger and identifying ways to change their patterns of interaction with their partners and family; (4) identifying "roadblocks to responsibility" (i.e., minimization, denial, and blame); (5) exploring the concept of partnership in relationships as an alternative to power and control; (6) learning to use "time-out" as a method to avoid the escalation that frequently accompanies arguments that result in violence; (7) providing the batterer with a repertoire of alternate and appropriate behaviors, such as problem solving, assertiveness, and negotiation; (8) adopting the concepts of trust, support, tolerance, and acceptance, with an emphasis on how they relate to successful negotiation; and (9) extensive role-play and group discussion to internalize strategies for incorporating negotiation into their interactions with their partners.

In theory, this is less than ideal, for two reasons. First, the literature on batterer intervention programs for male batterers describes a widespread uniformity in the treatment of male batterers (Bennett & Williams, 2001), an important element of which is a patriarchal analysis of violence against women. Obviously, this focus would have questionable relevance to women who initiate violence in their intimate relationships. Second, there have been very few evaluations of the treatment effect of treating women in intervention programs designed for male batterers (Carney & Buttell, 2006, 2004).

Programs Designed for Violent Women

Intervention programs designed for female primary aggressors are slowly emerging and are modeled largely on the Duluth Model. Consistent in the programs identified for women

who use violence is the premise that violence as problem-solving is not acceptable, and that participants must take responsibility for their violence and be willing to work to change their behavior (Bowen, 2010).

Treatment Goals

Most programs require that the participant make personal goals for the program, in addition to the general program goals, which call for clients to:

- Cease violent behavior.
- Take responsibility for their behavior (without minimization, denial, or blame).
- Identify physical, emotional, and behavioral cues that signal escalating danger.
- Establish safety—physical and emotional—for self, children, and partner.
- Understand the dynamics and effects of partner abuse. Recognize unhealthy interaction patterns compared to healthy ones.
- Learn skills for respectful communication, problem solving, and conflict resolution.
- Learn emotional self-regulation.
- Overcome the effects of childhood and/or adult trauma so that memories are integrated into a survivor's life story.
- Increase capacity for empathy and compassion for self and others.
- Increase autonomy and self-esteem (Bowen, 2010).

Programs such as WAVE in the United Kingdom, which is also based upon the Duluth Model but adapted for use with women, are encouraging steps toward matching treatment to need. Similar to the intent of the program designed for men, the goal was for women to learn about their own use of violence and how to change their violent behavior patterns. Women who have completed the program report the treatment as meaningful and transformative (Walker, 2013). NOVA in Santa Rosa, California uses "a psychotherapeutic approach of cognitive-behavioral strategies grounded in attachment theory, trauma theory, and social learning theory," and adds program elements designed to explore issues in the family of origin (Bowen, 2010, p. 105).

Other innovative program models have begun to incorporate Motivational Interviewing and Stages of Change to encourage client engagement

and motivation. Some are structured to depend on community peers as sponsors who act as advisors and role models for nonviolence for their paired participant. Programs such as the Bennington County Integrated Domestic Violence Docket (IDVD) Project were shown to be effective, comprehensive approaches to responding to interpersonal violence by providing immediate response to domestic violence events by coordinating family and criminal division cases in a “one-stop-shop” model (The Vermont Center for Justice Research, 2011). Some states have had the issue of gender and court-mandated batterer intervention tested through litigation. The laws, and the court-mandated programming that follows them, are designed for men who abuse their female intimate partners. In Maine, the laws that mandated a two-year program for men were challenged as unjust when the required program length for women was only one year.

Given the politicized nature of the debate surrounding female-initiated intimate partner violence, issues surrounding the construct of “dual arrest” in police responses to domestic violence calls, and the probability that there are very real differences between male and female domestic violence offenders, there is much that remains to be discovered about these women. Major issues on the horizon that call for attention include (a) deciding whether and how to develop standards for women mandated to treatment; (b) how to focus on the use of violence and matching violence user with appropriate interventions regardless of gender; and (c) the need for comprehensive evaluation of intervention programs to enable replication of programs that are deemed to be effective. It is probable that evaluation will yield both similarities and differences and that treatment for female offenders will have to begin to be conceptualized as distinct from that intended for male batterers. If the intent is to address and serve client needs effectively, it is critical to recognize that the use of violence as problem solving is counterproductive to healthy relationships in general, and to realize that effective treatment to prevent future violence is more important than who is initiating the abuse. When we focus on the debate over whether women can be violent and the primary aggressors in relationships, we ignore the larger issue of the impact of violence on the family; we impede appropriate service referrals; and we ignore the children, who continue to be damaged by witnessing the

violence regardless of who perpetrates it, and how severe it is.

149 Best Practices for Assessing and Treating Older Adult Victims and Offenders

Tina Maschi, George S. Leibowitz, & Lauren Mizus

INTRODUCTION

Background of the Problem

The case vignettes of Jorge, Mary, and Joseph, illustrated in Table 149.1, represent a tip of the iceberg of the rapidly rising global aging prison population. The mass incarceration of the elderly is international in scope but is particularly problematic in the United States, which has the largest incarceration rate per capita in the world (American Civil Liberties Union [ACLU], 2012). These cases represent only three people out of the 2.3 million people in custody in the United States, of whom 16% ($n = 200,000$) are aged 50 years and older, the age generally designated as elderly in corrections (Guerino, Harrison, & Sabol, 2011). Two major reasons for the rise in the incarcerated elderly population has been attributed to a general increase in the general aging population as well as the stricter sentencing and parole release policies and practices of the 1980s. These punitive criminal justice practices have resulted in individuals serving longer terms, including life prison terms, destining them to grow old and even die in prison (Maschi, Viola, & Sun, 2012). About two out of three of the aging

prison population is incarcerated for committing a violent or sexual offense (ACLU, 2012; Human Rights Watch [HRW], 2012).

The Role of Cumulative Disparities

The diverse backgrounds and differing pathways to prison among the older prison population have implications for culturally responsive assessment and intervention. In the United States, the majority of the aging prison population are men (96%) and are disproportionately racial ethnic minorities (Black = 45%, Latino = 15%, 10% = other racial ethnic minorities) compared with Whites (43%) (Guerino et al., 2011). Maschi and colleagues (2013) typology describes four distinct types of older adults in prison based on time served: (1) incarcerated persons with long-term sentences (a person with 20 or more years served); (2) the lifer (life sentence); (3) persons with histories of acute and chronic recidivism (two or more incarcerations), and (4) persons who first were convicted as older adults (i.e., first convicted in old age). Health status also varies; some individuals have functional capacity while others

TABLE 149.1 Case Vignettes

-
1. Jorge is a 56-year-old male from Puerto Rico and the youngest of nine children. He has a history of trauma and criminal offending that has included the unexpected death of his father at age 5, childhood sexual victimization, poverty, prostitution, drug dealing, substance abuse (heroin addiction), and recidivism (incarcerated two times). At age 17, he reported committing armed robbery to support his heroin addiction and was sentenced to 20 years in prison. During his prison term, he continued to use drugs. He violated parole within 15 months of release after being charged with sexual offense of a minor and possession of controlled dangerous substances, and as a result, is now serving his second and current 45-year sentence. In prison, he has spent eight of the past fifteen years in solitary confinement. He perceives prison as “an overcrowded monster” designed to hold, degrade, and punish people. He views the staff as disinterested and disengaged and is despondent over the limited access to counseling and educational and rehabilitative services. Jorge was diagnosed with cancer six months ago while in prison and is projected to receive parole in 14 years when he is in his late seventies. He has not had any contact with family in over five years and reports feeling depressed.
 2. Mary is a 64-year-old, Caucasian, Catholic woman who is incarcerated in a maximum security facility for women. She identifies herself as a lesbian. As a child, she experienced the divorce of her parents, abandonment by her mother, and sexual, physical, and verbal abuse by her father, whom she described as having serious mental health issues. At age 25, Mary married a man 10 years younger, had two children, and divorced. This is her first criminal conviction, and she is serving a 10-year prison sentence (85% minimum) for conspiracy and the attempted murder of her abusive husband, which she describes as being in self-defense. Mary describes this sentence as unfair and unjust based on mitigating circumstances. She has a medical history of hypertension, vision impairment, and osteoporosis that makes it difficult for her to walk or use a top bunk bed. At age 64, Mary’s extensive dental problems have resulted in a premature need for dentures. She describes her current prison experience as “degrading, especially the way correctional officers treat inmates.” Although she reports feelings of depression and despair, Mary reports that she copes with her prison experience by “finding meaning” in it through spirituality. Despite her ill health, Mary is resistant to using prison health care services. Her projected parole date is in two years, when she will be 66 years old. Because of the distance, Mary has not had any in-person visits with her family members since her incarceration but corresponds monthly by mail, and every three months by phone, with her two adult children and four grandchildren. She says that she misses her family immensely.
 3. Joseph is a 66-year-old Caucasian male of Irish and Polish descent; his family has an intergenerational history of alcoholism. Joseph is a Vietnam war veteran. As a child he experienced “extreme” corporal punishment from his parents and was fearful of communicating with his parents because of it. Joseph was sexually molested for years by his Little League manager. At age 13, he made a conscious decision to “get tough” to protect himself; at age 18 he joined the Marine Corps. After his discharge, Joseph witnessed a man in a bar offering cocaine to several young girls whom he believed would be sexually molested. In a blinding rage, he, together with a peer, took the man outside the bar and murdered him. In prison, Joseph spent time in administrative segregation and solitary confinement. During these periods of isolation he describes engaging in self-reflection. His recent visit to the prison infirmary showed that he had signs of cognitive impairment, suggestive of dementia. He is serving a life sentence in prison.
-

suffer from serious and terminal illnesses such as HIV/AIDS, cancer, and dementia or mental health and substance use problems (36%; James & Glaze, 2006). In addition to criminal offense histories, many have histories of victimization in the community and in prison, which include childhood physical and sexual

assault or witnessing violence (see Maschi et al., 2013). Victimization that has occurred prior to prison often has gone undetected and/or untreated and results in varying levels of adaptive coping responses and access to justice, as well as varying levels of access to social support and service networks (Aday, 2005; Maschi,

Viola, Morgen, 2013; Maschi, Viola, Morgen, & Koskinen, 2013).

As illustrated in the case examples in Table 149.1, the pathway that results in prison for older adults may vary in one or more cumulative disparities related to race, education, socioeconomic status, gender, disability, and legal or immigration status, which can influence access to health and social services, economic resources, and justice (See Figure 149.1). As the international human rights movement is gaining momentum in its efforts to advocate for the rights of older persons, the interdisciplinary practice community is challenged to think creatively and out of the concrete “prison” box on how to respond effectively (United Nations High Commissioner, 2012).

The Trauma of Incarceration: Prison as Elder Abuse

It can be argued that the poor social and environmental conditions of confinement, particularly for older persons, may be classified as elder abuse and neglect. Chronic victimization, medical neglect, lack of rehabilitation services and discharge planning exacerbate physical and mental illnesses and are a violation of human rights to safety protections and multi-holistic well-being (ACLU, 2012; HRW, 2012). The World Health Organization (WHO) (2012) defines elder abuse as a “a single, or repeated act, or lack of appropriate action, occurring within any relationship where there is an expectation of trust which causes harm or distress to an older person” (p. 1). As suggested in the case examples of Jorge, Mary,

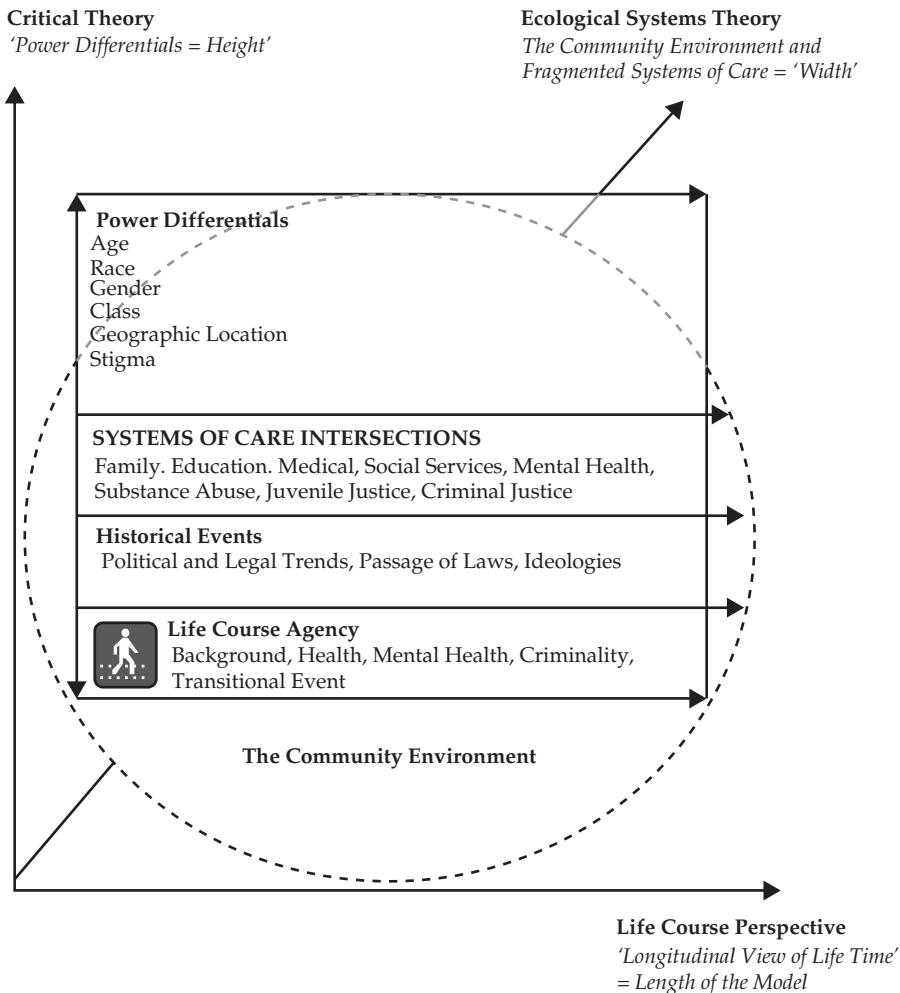

Figure 149.1 A life course system power analysis model for multilevel assessment and intervention.

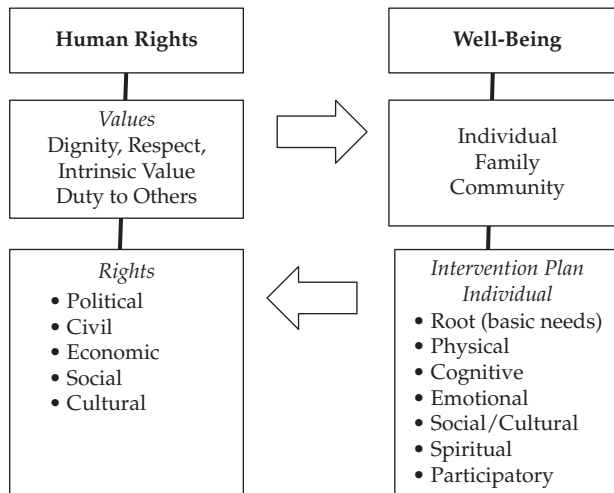

Figure 149.2 A practice model for assessing and treating older adults aging in place in prison.

and Joseph who are incarcerated older adults, prison was described as a source of trauma, abuse, and distress.

Elder abuse may take many forms and consists of physical, sexual, psychological, emotional, financial exploitation, and intentional or unintentional neglect, including medical neglect (WHO, 2012). Older adults in prison often are overlooked as people who are at increased risk of many types of elder abuse. Due to their increasing age-related frailty, older adults in prison are at increased risk of victimization and injury, medical and social care neglect, and exploitation of their resources (Maschi et al., 2013). Yet, despite their vulnerabilities, there is also a growing body of evidence that documents their resilience, such as their use of cognitive, physical, emotional, spiritual, and social coping resources. These multidimensional domains of coping suggest there are avenues for prevention and intervention that promote health and positive human development and rehabilitation (Aday, 2003; Maschi et al., 2013).

Assessment and Intervention Using a Life Course Systems Power Analysis

When considering the important task of assessment and intervention with older adults in the criminal justice system, conducting a holistic assessment of each person, such as Jorge, Mary, and Joseph, in a social environmental context is essential. Given that we are addressing older persons in their social/structural context, a life

course interdisciplinary perspective is integrated with ecological systems and critical theories (See Figure 149.1).

As shown in Figure 149.1, a life course systems power analysis assists in identifying the potential areas in the three case illustrations of Jorge, Mary, and Joseph, that may require an integrated clinical, case management, and/or advocacy response. It allows for an evaluation of the process and current outcomes of older adults in prison and can be used for clinical, organizational, community, and policy level assessment, prevention, and intervention efforts (Maschi, Viola, & Sun, 2012). The model is discussed next, followed by an application of the model to the three case examples and assessment and intervention.

The Life Course (The Length of the Model)

Consistent with a right-based approach, it gives central importance to the whole person, or individual, and his or her inner or subjective experiences and meaning-making, of external life events (e.g., objective event-victim of sexual assault and subjective response-adaptive or maladaptive response) and subjective well-being, are the central focus of the model. Human agency is the core component and commonly used in the life course perspective and social justice capabilities theories (Elder, 2003; Nussbaum, 2004). Human agency is conceptualized as a person's creative life force energy and central driver

through which the individual pursues his or her life's purpose, passion, and goals in connection to and with others, which, in turn, fosters an innate and developing sense of well-being and connectedness (Wahl, Iwarsson, & Oswald, 2012). In the case of Jorge, Mary, and Joseph, earlier life traumas and prison present a barrier for their pursuit of life course human agency.

Well-being is defined consistent with the World Health Organization (1948) definition of health as a state of multidimensional well-being and not just the absence of disease. Specifically, well-being is defined by seven core domains: root (basic needs), physical, cognitive, emotional, social/cultural, spiritual, and participatory (political/legal) well-being. When cumulative determinants or social and environmental conditions are optimal during the life course, individuals express human agency through concern for self and others and sustain high subjective levels of well-being and meaning-making. As older adults in prison describe, domains of well-being include cognitive, physical, emotional, spiritual, and social coping resources. These multidimensional domains of coping suggest there are avenues for prevention and intervention that promote health and positive human development and rehabilitation (Aday, 2003; Maschi et al., 2013).

However, when conditions are suboptimal, such as the experience of personal beliefs or attitudes (e.g., negative worldview) or confronted with social environmental barriers (poverty, low educational attainment; adverse neighborhood conditions, long prison sentences), a person's healthy expression of human agency may diminish his or her subjective well-being and negatively manifest as illness (e.g., somatic symptoms) or offending behavior (Maschi & Baer, 2012; Maschi et al., 2011; 2012). As the three case examples show, Jorge, Mary, and Joseph have had adverse life experiences, including prison placement that they describe as challenging their health and well-being.

Systems (The Width of the Model)

During an individual's life course, the systems, such as family, service, and legal systems, often change over time. This type of dynamic interaction between the person in his or her social environment context also consists of practice and stakeholder contexts. Access to services and justice may facilitate or impede an individual's right to human agency and his or her ability to

achieve life goals. When societal conditions are suboptimal, such as in the case of most U.S. state correctional systems' poor health care services, the health and well-being of older adults may be significantly compromised (United Nations Office on Drugs and Crime [UNODC], 2009). Other social contexts include society's values and ethics, interdisciplinary perspectives, and the use of evidence-based and evidence-informed practices. Values and ethics can be personal, professional, and societal (UN, 1948). As Jorge, Mary, and Joseph describe the lack of access to evidence-based services and justice during the course of their criminal justice system experiences. For example, a central value and ethical principle of human rights philosophy is honoring the dignity and worth of all persons and respect for all persons, including people in prison (United Nations, 1948, 1977, 2012). In many cases, this principle is not honored for older adults in prison, including for the case examples in this chapter.

Power (The Height of the Model)

The history of access to power and privilege throughout the life course also is important to assess, especially for older adults who have experiences of being victimized and who have committed crimes. Power dynamics across the life course may be balanced (equitable) or imbalanced (oppressive). This social environment factor may facilitate or hinder individuals throughout the life course. Characteristics such as age, race/ethnicity, gender, social class, income, immigration, and legal status may serve to open or close doors to advancement in society or result in accumulating disparities across the life course.

According to this model, individuals or groups can be oppressed at the personal (i.e., everyday interactions), structural (e.g., institutional), or cultural levels (e.g., societal attitudes, media). An individual's internalization of negative self-messages influences behavior toward others (Mullaly, 2010). For example, societies across the globe often have social structural barriers that enable the dominant group to subjugate oppressed subgroups as noted above (Mullaly, 2010). Life course cumulative disparities often result in criminalization of oppressed persons, as evidenced in the disproportionate stricter sentencing and confinement of minority populations, and create barriers to parole release (Sampson & Laub, 1997).

Interdisciplinary systems of care intersections (e.g., mental health and criminal justice) are commonly fragmented when addressing aging people in prison, which is another social environmental factor to consider (see Figure 149.1). Given that a social work perspective may vary from a medical perspective that pathologizes, and given that philosophies of practice may change over time, an assessment and intervention should address these varying perspectives. Using a life course systems power analysis, along with using a holistic and integrated theoretical base, is essential to address the process and outcomes of the crisis adequately (Greenfield, 2012). Lastly, the evaluation of evidence-based and evidence-informed practices is needed to best capture the process and outcomes of interventions for older adults in prison (Glasziou, 2005).

Embedding Restorative Justice and Risk, Need, and Responsivity

Embedded in the life course power analysis shown in Figure 149.1 are restorative justice approaches that emphasize strengthening prosocial bonds, community-based management, and systems of care for offenders, and enhancing protective factors against sexual and nonsexual criminal re-offense. The promotion of protective factors in restorative justice approaches (e.g., Circles of Accountability and Support or COSAs; Wilson, Picheca, & Prinzo, 2007) are central in models that focus on offender reintegration and that include fostering interrelationships and community engagement and support, as well as mutual accountability in addressing the needs of older adults in prison. Additionally, principles of risk, need, and responsivity (RNR) (Andrews & Bonta, 2010) coincide with the shift from a punishment/criminalization approach to a rehabilitation model that is more attentive to social and psychological risk and protective factors in designing interventions, which includes substance abuse, trauma, and exposure to violence exemplified in the case vignettes in Table 149.1. RNR underscores respectful and collaborative working relationships between clients and correctional agencies that promote the use of effective assessments and interventions, resulting in lower recidivism rates (Andrews & Bonta, 2010). RNR is based on three therapeutic principles, which focus on matching services to the individual's risk level (risk principle); addressing criminogenic (e.g., sexual drive,

the sequelae of traumatic stress, and social rejection) and noncriminogenic needs (need principle), and tailoring interventions based on an individual's motivation, learning style, agency, identity, and systems context (responsivity principle).

Application of Model to Case Vignettes of Jorge, Mary, and Joseph

What perhaps is most challenging for practitioners who work with older adults with histories of victimization prior to and while in prison, is that there is no cut and dried distinction between being a "victim" and being an "offender." As these case vignettes of Jorge, Mary, and Joseph suggest, older adults with histories of victimization and criminal offending are diverse. Many of the older adults in prison have experienced life challenges related to their marginalized or disadvantaged statuses based on personal or social-structural characteristics and trauma histories. As shown in the case examples, their stories reveal an accumulation or aggravation of life course disadvantages, such as being born in poverty; child, adolescent, and adult trauma or exploitation; and juvenile and criminal involvement. Their high-risk life course trajectories present unique challenges for individuals, families, and communities, including social work and interdisciplinary professionals, to prevent, assess, and intervene as needed. Enhancing social relations compromised by a history of marginalization and victimization, addressing the principles of risks, need, and responsivity (Andrews & Bonta, 2010), and instilling community-based supports attuned to cultural and gender differences in each of these cases can have a stabilizing effect, particularly post-release, and decrease the likelihood of relapse for sexual and/or violent re-offense. Although social workers may work with individuals in the criminal justice system, it is important they acknowledge that interagency cooperation and mutual support is crucial to good outcomes. Consideration of the context of a criminal justice system is required, where the unjust and disproportionate treatment of racial/ethnic minorities, individuals and families living in poverty, persons with mental health or physical disabilities, and a rapidly growing subgroup of older women, are particularly vulnerable (ACLU, 2012). The next section applies the model to assessment and intervention plans, including for the three case vignettes.

Human Rights-Based Assessment and Intervention Plan. In designing intervention plans for Jorge, Mary, and Joseph, a life course systems analysis was conducted. It consisted of a holistic assessment of bio-psychosocial, spiritual, and legal aspects. Table 149.2 highlights the core assessment tools used; instruments that assess traumatic stress (e.g., PTSD Checklist), as well as instruments that specifically estimate the risk for sexual offense (e.g., Static-99; designed only for males), and instruments that can assess a broader range of risk factors for both male and female adults (e.g., Level of Service Inventory; LSI-R) should be administered in order to help determine appropriate interventions.

Jorge. In the case of Jorge, assessing complex life course issues and risk, need and responsivity factors addressing both sexual and nonsexual issues are salient, including history of victimization, loss, and health issues (recent diagnosis of cancer). It is significant that he recidivated on a sexual offense toward a minor (sexual drive and risk for sexual harm considerations; the Static-99 could be used) signaling significant impairments in interrelationships, after a history of nonsexual crimes related to substance abuse/addiction. Interventions in Jorge's case should consider dynamic/protective factors including internal and external coping resources, along with health and mental health factors (e.g., depression) impacting older individuals (see below), and criminogenic needs (attuned to his culture) related to risk management and community safety, such that he can engage in the community upon reentry. Taking into account which competencies and program components should be targeted, which includes re-engagement with his family, and which resources are needed, are crucial in this case (see Table 149.3 and Table 149.4).

Mary. In the case of Mary, there are similar considerations in terms of a history of victimization (domestic violence), coping resource issues, health care concerns, and disengagement with family, with the addition of gender specific considerations and the fact that her only criminal history is related to the attempted murder of her abusive husband. Using risk and needs assessment appropriate for females (e.g., the LSI-R), and gender specific strategies for establishing therapeutic engagement is crucial in this case.

Joseph. In the case of Joseph, a history of coercive parental discipline, abandonment and subsequent impairment in attachment, and sexual victimization led to substance abuse and

traumatic stress symptomatology (hyperarousal as well as dissociative rage), such that he felt compelled to protect potential victims from sexual violence, which led to the murder charge. His current constellation of health issues and isolation are salient factors in the consideration of interventions while he serves his life sentence (e.g., possible dementia).

Intervention Plan. All three individuals were referred to a specialized geriatric unit in the prison, which included geriatric-specific programming. The geriatric specific program highlighted in this chapter is based on the Nevada Department of Corrections, Senior Structured Living Program, or True Grit Program (see Table 149.3; Harrison, Kopera-Frye, & Harrison, 2012). The program is staffed by an interdisciplinary team of doctors, nurses, social workers, chaplains, lawyers, advocates, and volunteers. It infuses principles of human rights and social justice, such as dignity and worth of the person, and incorporates comprehensive structured services that foster bio-psychosocial well-being and accountability among older adults in prison. It has separate programs for men and women. Preliminary analysis of the qualitative data from participants suggests that they view the program as an invaluable part of their lives, helping them cope with daily prison stress while allowing them to offer restitution for their crimes and to plan for community reintegration. Preliminary quantitative analysis suggests that participants who are released from prison have a 0% recidivism rate (Maschi et al., in press). As shown in Table 149.4, the intervention plans to which each of the participants was assigned were selected from program components in Table 149.3.

CONCLUSION

As illustrated in the case study examples of Jorge, Mary, and Joseph, the biggest challenges for interdisciplinary professionals and programs to foster health and well-being among incarcerated older adults are developing competencies in working at the practice intersection of the aging, health/mental health, and criminal justice sectors of care. Although the extent to which some skills are used depends upon where a professional is "positioned" in the system (e.g., clinical social worker in prison, reentry program administrator), this involves having competencies in aging (gerontological practice), physical and mental

TABLE 149.2 Assessment Tools

- **A Life Course Systems Power Analysis.** As shown in Figure 149.1, a life course systems power analysis allows for assessment of an individual's life experiences and subjective response to these events, changing systems (access to services and justice over time), and power dynamics that may result in protective advantages and/or cumulative disparities.
- **Human Rights and Well-being Multilevel Assessment.** As shown in Figure 149.2, the human rights map is a visual assessment tool, similar to an eco-map, which assesses for bio-psychosocial/structural issues in relation to multidimensional well-being (i.e., legal, political, economic, educational, social, physical, mental, spiritual, and cultural well-being) embedded in a human rights framework based on the 30 articles of the Universal Declaration of Human Rights (Maschi et al., 2013).
- **Traumatic and Stressful Life Experiences.** Trauma and stressful life experiences (cumulative objective occurrences and past year subjective distress) were measured using the 31-item Life Stressors Checklist-Revised (LSC-R). The LSC-R estimates the frequency of the objective occurrences of lifetime and current traumatic events (e.g., being a victim of and/or witness to violence). The LSC-R has good psychometric properties, including use with diverse age groups and criminal justice populations (Wolfe et al., 1996).
- **Posttraumatic Stress Symptoms.** Posttraumatic stress symptoms were measured with the PTSD Checklist (PCL) for civilian populations (Weathers, Litz, Herman, Huska, & Keane, 1993).
- **Coping Resources.** Coping resources were measured using the Coping Resources Inventory (CRI) (Marting & Hammer, 2004). The CRI is a valid measure of self-reported coping resources that are available to manage stressors and has been used with samples of older adults and criminal offenders. This 60-item CRI has five subscales that measure cognitive, emotional, spiritual and philosophical, physical, and social coping resources. The CRI has good convergent and discriminant validity and good internal consistency ($\alpha = .80$) across the subscales.
- **Activities of Daily Living.** The Katz Index of Independence in Activities of Daily Living, commonly referred to as the Katz ADL, is the most proper scale to assess functional status as a measurement of an individual's ability to perform activities of daily living independently. Although no formal reliability and validity reports could be found in the literature, the tool is used extensively as a flag signaling functional capabilities of older adults in clinical and home environments.
- **Geriatric Depression Scale.** Geriatric Depression Scale (GDS) is a self-report measure of depression in older adults and had been used with older prison populations (Parmelee, Lawton, & Katz, 1989).
- **Montreal Cognitive Assessment:** The Montreal Cognitive Assessment was used to assess for cognitive impairment.
- **Substance Abuse:** The Addiction Severity Index is a semistructured instrument used in face-to-face interviews conducted by clinicians, researchers, or trained technicians. The ASI covers the following areas: medical, employment/support, drug and alcohol use, legal, family/social, and psychiatric. The ASI obtains lifetime information about problem behaviors, as well as problems within the previous 30 days.
- **Risk and Needs Assessments/Discharge Planning:** (1) The Static-99 is a 10-item actuarial assessment instrument for use with adult sexual offenders who are 18 years or older at the time of community release. (2) Correctional Offender Management and Profiling Alternative Sanctions (COMPAS) assesses needs and risk of recidivism (general recidivism, violent recidivism, noncompliance, and failure to appear). (3) Level of Service Inventory-Revised (Andrews & Bonta, 1995) assesses parole outcome, success in correctional halfway houses, institutional misconducts, and recidivism.

health assessment and intervention, case management, interdisciplinary collaboration, discharge planning, and legal and policy advocacy.

Coupled with society's increased recognition of the elderly as a vulnerable population, as demonstrated by the proposed Convention of the Rights of Older Persons and the growing elder and intergenerational and family justice movements, there is now the potential for older prisoners to achieve access to justice.

Promising comprehensive programs, such as geriatric specific programming, including True Grit prototypes, that bridge prison-to-community services, offer a leap forward toward addressing human rights based best practices for older adults in prison, especially those with histories of being both victims and offenders. Promising practices with older adults in prison honor the dignity and worth of the person, foster human agency and autonomy, and encourage holistic well-being. Program components often include geriatric case management services for medical, mental health, substance abuse, family, social services, housing, education or vocational training, restorative justice (e.g., victim or victim-offender mediation services), spiritual counseling, exercise and creative arts programs, and employment and/or retirement counseling. Program specific aspects include one or more of the following: "age" and "cognitive capacity" sensitive environmental modifications (including segregated units), interdisciplinary staff and volunteers trained in geriatric-specific correctional care, complementary medicine, specialized

case coordination, the use of family and inmate peer supports and volunteers, mentoring, and self-help advocacy group efforts (Davidson & Rowe, 2012).

TABLE 149.3 Program Components

1. **Diversion Activities.** Diversion activities are a major segment of the program. Crocheting, knitting, beading, and latch-hook rug-making provide activity that is not only cognitively stimulating, but affords excellent physical therapy for arthritic hands and fingers
2. **Culturally Responsive Cognitive Interventions.** Cognitive interventions include creative writing, Spanish language study group, ethnodrama, and cultural arts group. The groups produce a newsletter and poetry journal, which are edited by the group members.
3. **Substance Abuse/Addiction Groups.** Weekly meetings of 12-step groups including Alcoholics Anonymous, Narcotics Anonymous, and Sexual Compulsives Anonymous, which are facilitated by volunteer sponsors.
4. **Psycho-education.** Weekly seminars are held that address aging, health and wellness, sexuality, life skills, cooking, menu-planning, and healthy life choices, or other relevant activities.
5. **Animal Assisted Therapy/End-Of-Life Care.** Volunteers provide animal assisted therapy (individually and in group). Animal-assisted therapy targets physical, occupational, speech and psychotherapies, special education, pain management issues, and end of life support.
6. **Physical Exercise.** Program participants are scheduled for daily exercise activities. These include wheelchair softball, basketball, or volleyball; aerobics, tennis, measured-distance walking, weight-lifting, stationary bicycle, billiards, ping-pong, horseshoes, or dancing.
7. **Peer Support Groups/Vet-to-Vet.** Veteran volunteers assist members with writing and producing artwork about their war experiences.
8. **Spiritual Wellness.** Spiritual wellness consists of traditional religious activities by staff or volunteers or peer support members. Bereavement services are provided for when the death of a family member or peer in prison occurs.
9. **Correctional Mental Health Activities.** Formal correctional programs facilitated by both staff and community volunteers are available to program participants. These programs include victim awareness, stress management, anger management, conflict resolution, relationship skills, health-related recovery, commitment to change, trauma and recovery, addiction prevention education, sex offender treatment, parenting and grandparenting classes, and special populations programs.
10. **Prison Legal Services and Victims' Rights Training.** Prison legal services provide program participants access to pro bono lawyers and social workers who are versed in elder and prison rights and law and case management services. Program participants can seek consultation or representation for appeals based on sentencing, parole release, or geriatric, medical, and compassionate release. The prison Ombudsman represents cases of interpersonal victimization and institutional abuse. Community advocates who monitor cases based on the Prison Rape Elimination Act also are available to incarcerated persons at the facility, including program participants.
11. **Family Visiting Programs.** The family visiting program provides extended time with family members, which includes spouses and partners, children, and grandchildren. Families can request transportation services from faith-based volunteers if there is no access to public transportation to get to the facility. An option for televisiting was available for participants, such as Mary, whose family lived at a distance that did not enable them to visit her in person. For participants without family members who can visit, peer visits and volunteer visitors can be arranged based on request.
12. **Restorative Justice/Reconciliation and Forgiveness Groups/Long-termers and Lifers Group.** The program also offers a session for reconciliation and forgiveness. It uses narrative-style writing and group reflection for individuals to process their crime, especially violent or sexual offenses that resulted in the harm or death to another person or persons. For participants with life sentences, a weekly lifers group is offered.
13. **Education and Vocational Training.** Program participants may choose from a range of vocational services to obtain General Educational Development (GED) or high school diplomas, college degrees, and vocational training in occupations, such as the culinary arts and select trades.
14. **Discharge Planning.** Volunteers provide members with information and referrals concerning their eventual release from prison. This includes collaboration with nonprofit organizations, halfway houses, resources for potential employment, and other assistance, such as veterans or disability benefits.

PART XV

Evidence-based Practice

150 Evidence-based Practice, Science, and Social Work

An Overview

Bruce A. Thyer

The process of evidence-based practice (EBP) was introduced to the social work literature over a decade ago (Gambrell, 1999) and represented the extrapolation of the emerging principles of evidence-based medicine to the purposes of our discipline. EBP is fundamentally quite different from precursor perspectives that addressed the potential of applying scientific methods to social work practice: predecessor movements such as psychoanalytic theory and its variants, behavioral social work (BSW) and its cognitive offshoots, and empirical clinical practice (ECP; Jayaratne & Levy, 1979; Siegel, 1984; Reid, 1994). BSW and ECP shared the ideas that social workers should select their choice of interventions from those best supported by empirical research, and also the recommendation that when feasible, social workers should evaluate the outcomes of their clinical practice using single-system research designs (SSRDs). The former idea is difficult to criticize, but it does leave out many important considerations, such as whether the clinician is adequately trained to deliver the empirically supported treatment, the availability of resources required to provide the indicated treatment, the ethical appropriateness of the intervention, an assessment of environmental considerations and client preferences and values, and other factors that bear on the possibility of delivering scientifically supported interventions. The recommendation concerning the use of SSRDs to evaluate outcomes at the level of the individual case has been written about extensively and even successfully applied to a limited extent, but lacking any

external reinforcers to support the efforts, busy social workers have not really adopted SSRDs on a widespread scale.

The process of inquiry known as EBP has received considerable attention within the field of social work over the past decade (see Roberts & Yeager, 2003, 2006; Thyer, 2008; Thyer & Myers, 2011), so much so that this third edition of the *Social Worker's Desk Reference* continues to contain a large section devoted to it. There is some confusion as to what is meant by the term EBP, and this initial descriptive entry will help set the stage for understanding the succeeding chapters. Here are a couple of brief definitions from primary resources in the field of evidence-based medicine, definitions from which most extrapolations to other fields, such as social work, are derived:

"The conscientious, explicit, and judicious use of current best evidence in making decisions about the care of individual patients. The practice of evidence-based medicine requires integration of individual clinical expertise and patient preferences with the best available external clinical evidence from systematic research." (Guyatt & Rennie, 2002, p. 412) *and*

"Evidence-based medicine (EBM) requires the integration of the best research evidence with our clinical expertise and our patient's unique values and circumstances." (Straus, Glasziou, Richardson & Haynes, 2011, p. 1)

By replacing the medically laden term "patients" with the more encompassing word "clients," the

foregoing definitions potentially can be seen to apply readily to all the helping professions, including social work. What is also conspicuous in these definitions is the equal weight given to the core factors of scientific evidence, clinical expertise, patient preferences, and the client's unique values and circumstances. No one factor is implied to be more important than the others—all are important, and each can potentially trump the others. This definitional egalitarianism is important to realize from the outset because some professionals erroneously believe that in EBP research evidence is accorded greater weight than other factors (see Gitterman & Knight, 2013). Straus et al. (2011, p. 3) go on to operationally define what is meant by “best research evidence,” “clinical expertise,” “patient values,” and “patient circumstances” and describe the five steps that comprise the process of EBP.

- *Step 1:* Convert our need for information about the causes of problems, and for possible interventions, into an answerable question.
- *Step 2:* Track down the best evidence with which to answer that question.
- *Step 3:* Critically appraise that evidence for its validity, impact, and applicability.
- *Step 4:* Integrate the critical appraisal with our clinical expertise and the client's unique values and circumstances.
- *Step 5:* Evaluate our effectiveness and efficiency in carrying out Steps 1–4 and seek ways to improve our practice.

The other entries comprising this part of the *Social Worker's Desk Reference* address each of these five steps. Again, EBP does not privilege scientific research findings above other considerations in making practice decisions, but it does insist that such factors be accorded their due weight. It is worth repeating this principle because a common misconception of EBP is that it gives primacy (if not sole attention) to research findings and ignores other crucial elements of practice decision-making.

This valuing of scientific research is not an unfamiliar concept to professional social work and indeed has been a defining characteristic of the formal discipline, something that set it aside from impulsive altruism, the efforts of faith-based social missionaries, or unsystematic secular efforts aimed at helping others. Consider the quotes presented in Table 150.1, selected as

representative of the century-long perspective that science and empirical research must be integrated into social services. Indeed, scientific charity and scientific philanthropy were the original names for the social casework movement in the United States (Bremmer, 1956).

The assertions found in Table 150.1 clearly indicate that the principles of EBP are congruent with central core descriptions of social work as a science-based discipline, dating back to the beginnings of our field. There is much to learn and nothing to fear from a careful appraisal and adoption of the model of EBP. The original phrase “evidence-based medicine” as currently conceived, first appeared in 1992 in an article written by Gordon Guyatt and colleagues (Evidence-Based Medicine Working Group, 1992) and several concurrent developments and issues led to its widespread acceptance within medicine and then rapidly through the other helping professions. Among these developments was the recognition that practitioners really needed valid information about the causes of and possible remedies for the problems clients bring. Another was the recognition that books, traditional journals, conferences, and other usual sources of information were comparatively inefficient ways to acquire this information. Another motivational factor was an increasing awareness that as our clinical expertise is enhanced with years of experience, our knowledge about contemporary developments related to assessment and intervention research often declines. Many practitioners simply do not have much discretionary time to track down clinically useful information through traditional but cumbersome methods, such as reading professional journals or attending continuing education workshops. Though these limiting factors were and are operative in the lives of most social workers, other developments in technology and professional infrastructure pointed to some possible solutions. Among these were the increasing usefulness of the Internet as a means of locating valid information rapidly, the creation of the Cochrane and Campbell Collaborations as international and interdisciplinary organizations devoted to crafting comprehensive systematic reviews for answering commonly asked questions related to practice, and the emergence of journals focused on publishing much more practice-relevant research studies (e.g., *Research on Social Work Practice*). The concatenation of these events and developments set the stage for the emergence of EBP.

TABLE 150.1 Illustrative Quotations Documenting the Supposed Close Linkage Between Science and Social Work

-
- “Charity is a science, the science of social therapeutics, and has laws like all other sciences” (Kellogg, 1880, cited in Germain, 1970, p. 9).
 - “Many of the leaders of the conference [the 1884 meeting of the National Conference on Charities] accepted the implications of a scientific approach to social work problems. They acted on the tacit assumption that human ills—sickness, insanity, crime, poverty—could be subjected to the study and methods of treatment.... This attitude raised these problems out of the realm of mysticism and into that of a science.... As a result of the adoption of this scientific attitude, conference speakers and programs looked forward toward progress.... They believed in the future; that it was possible by patient, careful study and experimentation to create a society much better than the one they lived in” (Bruno, 1964, pp. 26–27).
 - “To make benevolence scientific is the great problem of the present age” (Toynbee, 1912, p. 74).
 - “Social work is not merely a question of enthusiasm, sympathy, self-sacrifice or money, but it is a question of wisdom, discretion, and the scientific interpretation and comparison of facts” (Professor Peabody, c.f., Curtis, 1916, p. 271).
 - “The scientific spirit is necessary to social work whether it is a real profession or only a go-between craft.... The elements of scientific approach and scientific precision must be back of all social reform.... It is almost superfluous to ask why social work should take on the character of science. It is hardly a question of ‘may or may not.’ Rather, should we say, it is a matter of the categorical must” (Todd, 1920, pp. 66, 75).
 - Social work is defined as, “All voluntary efforts to extend benefits which are made in response to a need, are concerned with social relationships, and avail themselves of scientific knowledge and methods” (Cheney, 1926, p. 24).
 - “The faculty and students of a professional school of social work should together be engaged in using the great method of experimental research which we are just beginning to discover in our professional educational programme, and which should be as closely knit into the work of a good school of social work as research has been embodied into the programme of a good medical school ... social workers must be so trained scientifically that they belong in the social science group” (Abbott, 1931, p. 55, 148).
 - “The difference between the social work of the present and of all preceding ages is the assumption that human behavior can be understood and is determined by causes that can be explained ... any scientific approach to behavior supposes that it is not in its nature incomprehensible by sensory perception and inference therefrom” (Bruno, 1936, pp. 192–193).
 - “[In German social work] everywhere the belief in science, in learning and in the scientific spirit is in evidence” (Salomon, 1937, p. 33).
 - “Employment of scientifically approved and tested techniques will ensure the profession the confidence and respect of clients and the public, for increasingly the social casework process will operate more certainly for known and desired ends in the area of social adjustment” (Strode, 1940, p. 142).
 - “The scientific approach to unsolved problems in the only one which contains any hope of learning to deal with the unknown” (Reynolds, 1942, p. 24).
 - “Social work must develop its ‘own science,’ with its ‘own field of knowledge,’ tested in its own research laboratories” (Eaton, 1956, p. 22).
 - “I believe that it is possible to understand scientifically the movement of social and economic forces and to apply our strength in cooperation with them” (Reynolds, 1963/1991, p. 315).
-

There is some concern that EBP is primarily oriented toward clinical practice, but this is a misconception. The Center for Evidence-Based Social Policy is just one of a number of organizations and interest groups interested in applying

the principles of EBP to macro-levels of practice. The empirical literature devoted to EBP and macro-level social work is growing (e.g., Thyer, 2001, 2009), so much so that an entire journal, *Evidence and Policy*, deals with this

topic. A literature search of various social science research databases using key words such as “evidence-based management,” “evidence-based supervision,” “evidence-based administration” will also reveal a burgeoning body of literature.

Another misconception is that EBP is somehow a development unique to the United States. In reality, the major authors in the field of evidence-based medicine were British and Canadian; the Cochrane Collaboration is headquartered in England, and the Campbell Collaboration is based in Norway, with local centers located in the United States and Canada. Thyer and Kazi’s (2004) book describes EBP-related developments not just in the United States, Canada, and Great Britain but also in Israel, Hong Kong, Finland, South Africa, and Australia. The protocols developed by the Cochrane and Campbell Collaborations for the development of systematic reviews explicitly call for using international teams of experts to ensure that relevant non-English literature is not overlooked. EBP is not scientism, nor is it another example of U.S. hegemony in the realm of social work education and practice. It is the natural fruition and maturation of professional tendencies that have existed in our discipline worldwide since its inception in the late 1880s.

Evidence-based practice is not a medical model. It is atheoretical with respect to the causes of problems or conditions, neutral with respect to the types of interventions that are appropriate (e.g., psychosocial treatments vs. medications), and silent as to the disciplinary training required to deliver care (physicians are not assumed to be the service providers). EBP did originate among physicians, but the five-step decision-making model of this approach is a template that is almost universally applicable across the human services and health care disciplines.

Nor does EBP tell social workers what to do with their clients. It does not develop lists of scientifically approved treatments, nor does it prepare practice guidelines. It does lay out a systematic process whereby the social worker seeking information to help him or her make important practice decisions related to choosing assessment and intervention methods can best formulate useful questions capable of being answered. It provides guidance in locating and critically appraising this information. It helps integrate this research-based data into other critical domains, such as one’s clinical skills; the clients values, preferences, and situation; available

resources; and professional ethical guides, to then arrive at a decision. It also guides us in evaluating effectiveness in delivering services. EBP helps us find out what we need to know to arrive at practice decisions. What we choose to do remains the prerogative of the individual social worker, working with the client. It may be that a clinician seeks guidance about possibly effective treatments for someone who is severely depressed. A review of the literature may disclose some interventions shown to generally be quite helpful for depressed persons, such as cognitive-behavioral therapy or interpersonal psychotherapy. But if the client is also intellectually disabled, the social worker may well choose not to provide one of these empirically supported interventions if it is judged that the client lacks the cognitive abilities to be successfully engaged in these treatments. In such a case, the social worker could still be said to be operating within the EBP framework.

Over 85 years ago, John Dewey (1927, p. 179) said, “Men have got used to an experimental method in physical and technical matters. They are still afraid of it in human concerns.” The emergence and adoption of EBP within social work suggests that we are overcoming such fears. We hope the reader finds that the following entries more fully describe what evidence-based practice really is, and we recommend that one consult further primary sources describing this approach in greater detail. Third- and fourth-hand descriptions of EBP commonly found in the social work literature are rife with distortions, incorrect information, and false inferences.

151 Developing Well-structured Questions for Evidence-informed Practice

Eileen Gambrill & Leonard Gibbs

A key step in evidence-based practice (EBP) is translating information needs (knowledge gaps) related to practice and policy decisions into well-structured questions that facilitate a search for related research in relevant databases (e.g., Straus, Glasziou, Richardson, & Haynes, 2011). Reasons include the following.

- Vague questions lead to vague answers; specific questions are needed to gain specific answers to guide decisions.
- It can save time during an electronic search. The better formed the question, the more quickly related literature (or the lack of it) may be revealed.
- If we do not pose clear questions about decisions, we may be less likely to seek and discover helpful research findings and change what we do; we may harm clients or offer clients ineffective methods.
- It is a countermeasure to the arrogance that interferes with learning and with the integration of practice and research; if we seek answers, we will discover how tentative answers are and how much we do not know.
- It is necessary for self-directed, lifelong learning.

The better formed the question, the greater the efficiency of searching should be. Research in medicine suggests that physicians answer only a small percentage of questions that arise by consulting relevant research sources (e.g., Ely et al., 1999). We have no such information in psychology, psychiatry, or social work. There is a tendency to underestimate the difficulty in carrying out this step.

Background questions concern general knowledge about a problem or situation. This may include knowledge of psychological, biological, or sociological factors related to a concern. Such questions include “a question root (such as who, what, when, where, how, why) with a verb” (Straus et al., 2011, p. 15) as well as some aspect of a condition or item of interest. An example is, “What causes hoarding behavior?” Foreground questions concern knowledge to inform decisions. Background knowledge informs foreground knowledge. As Straus et al. (2011) note, as experience in an area increases, need for background knowledge decreases and need for foreground knowledge increases (p. 16).

BEING AWARE OF INFORMATION NEEDS

We are unlikely to search for information if we are not aware of our ignorance. Sources of uncertainty include limitations in current knowledge, lack of familiarity with knowledge available, and difficulties distinguishing among personal ignorance, lack of competence, and actual limitations of knowledge (Fox, 1959). Being aware of our ignorance as well as our knowledge is key to the process and philosophy of EPB. Information needs may concern the following. (See Database of Uncertainties about Effects of Treatments [DUETs] listed under Websites at end of this chapter.)

1. *Description of clients*: how to gather and accurately interpret information concerning client characteristics and circumstances.
2. *Causes*: how to identify causes or risk factors regarding concerns including iatrogenic harms.

3. *Indicators of certain problems*: knowing these and using this knowledge to understand client concerns.
4. *Setting priorities*: when considering possible causes, how to select those that are likely, serious, and responsive to intervention.
5. *Assessment measures*: how to select and interpret assessment measures to understand client concerns based on accuracy, acceptability, safety, expense, and so on.
6. *Prognosis*: how to estimate a client's likely course over time and anticipate likely complications of problems.
7. *Treatment*: how to select services that do more good than harm and that are worth the efforts and costs of using them.
8. *Prevention*: how to reduce the chance of problems by identifying and modifying risk factors, as well as how to identify concerns early on through screening.
9. *Experience and meaning*: how to empathize with clients, appreciate the meaning they find in their experiences, and understand how this meaning influences successful outcomes.
10. *Self-improvement*: how to keep up to date, improve skills, and provide a better, more efficient care system (Adapted from Straus et al., 2005, p. 20).

No matter who initiates the questions, we consider finding relevant answers as one of the ways we serve our [clients], and to indicate this responsibility we call these questions ours. When we can manage to do so, we find it helpful to negotiate explicitly with our [clients] about which questions should be addressed, in what order, and by when. And, increasingly often we're discovering that [clients] want to work on answering some of these questions with us. (Straus et al., 2005, p. 20)

FOUR-PART QUESTIONS

Straus et al. (2005) suggest posing four-part questions (also known as PICO questions) that describe the *population* of clients (P), the *intervention* of concern (I), what it may be *compared to* (including doing nothing) (C), and the *hoped-for outcomes* (O). (See Table 151.1 for examples of four-part questions.) A well-formed question should meet the following criteria: (1) It concerns a problem of concern to clients. (2) It affects a large number of clients. (3) It is probably answerable by searching for related research findings.

Gibbs (2003) refers to well-formed questions as COPES questions. First, they are client-oriented. They are questions clinicians pose in their daily practice that affect clients' welfare. Second, they have practical importance. They concern problems that arise frequently in practice. For example, child protective service workers must assess risk. Asking questions about what types of clients present the greatest immediate risk for child abuse is critical. Third, COPES (PICO) questions guide an electronic search for related research findings. Fourth, hoped-for outcomes are identified. The process of forming a specific question often begins with a vague general question and then is crafted into a well-structured question. Synonyms can be used to facilitate a search. For example, if abused children are of concern, other terms for this may be "maltreated children," "neglected children," "mistreated children." Posing well-formed questions is more the exception than the rule in most professional venues. Initial background reading may be valuable in focusing a question so as to find relevant research rapidly in a major search engine, such as Google.

KINDS OF PRACTICE/POLICY QUESTIONS

Different kinds of practice/policy questions (about diagnosis, prognosis, harm, effectiveness, prevention, risk, assessment, or description) require different research methods to critically test them. A variety of questions may arise with one client or family. Let us say a social worker is employed in a hospice and counsels grieving parents who have lost a child. General *descriptive* questions include, "What are the experiences of parents who lose a young child?" "How long do these last?" "Do they change over time and if so, how?" Both survey data and qualitative research such as focus groups, in-depth interviews, and participant observation can be used to explore such questions. Research may be available that describes experiences of grieving parents based on a large randomly drawn sample of such parents. A research report may use in-depth interviews to describe the experiences of clients who seek bereavement counseling. Questions concerning risk may arise—such as, "In parents who have lost a young child, what is the risk of depression?"—as well as questions about effectiveness. For parents who have lost a young child, is a support group compared to no

TABLE 151.1 Examples of Four-part Questions

Question Type	Client Type and Problem	What You Might Do	Alternate Course of Action	Hoped-for Outcome
	Describe a group of clients of a similar type; be specific	Apply a treatment to prevent a problem; measure to assess a problem; survey clients; screen clients to assess risk	Describe the main alternative	Outcome of intervention or prevention? Valid measure? Accurate risk estimation? Accurate estimation of need?
Effectiveness	Disoriented aged persons who reside in a nursing home	Reality orientation therapy	Compared to validation therapy	Which results in better orientation to time, place, and person?
Prevention	Sexually active highschool students at high risk for pregnancy	Exposure to baby—think-it-over	Compared to didactic material on the proper use of birth control methods	Which group has fewer pregnancies during an academic year and more knowledge of birth control methods?
Assessment	Elderly nursing home residents who may be depressed or have Alzheimer's disease or dementia	Complete a depression screening test	Compared to a short mental examination test	Which measure most efficiently and reliably discriminates between depression and dementia?
Description	Children	Raised with depressed mothers	Compared to mothers who are not depressed	Which group will have the least prevalence of developmental delays?
Prediction/Risk	Preschool children	With antisocial behavior	Compared to children who do not display such behavior	What is the risk of antisocial behavior in adolescence?
Harm	Nonsymptomatic adults	Who participate in depression screening program	Compared with those who do not	Which results in the least harm?
Cost-Benefit	Mothers with poor parenting skills whose children have been removed from their care	Purchase service from another agency	Compared to offering parent training in-house	Which is most effective and cost saving?

Note: The format for all questions is based on Straus et al., 2005.

service more effective in preventing depression? Prevention questions may arise. For parents who have lost a young child, is brief counseling compared to a support group more effective in preventing depression from interfering with care of other children? When selecting key terms to use to search for related research, quality filters relevant to the question type (e.g., effectiveness, risk) are included. For example, if the question is an effectiveness one, relevant quality filters include systematic review, meta-analysis, and study synthesis. If the question concerns risk, relevant methodological filters include sensitivity, specificity, and predictive validity.

Effectiveness Questions

Many questions concern the effectiveness of service methods, such as anger management programs. Consider the terrorist attacks of September 11, 2001, at the World Trade Center in New York. Let us say that an agency administrator wants to find out what methods (if any) may be of value in decreasing related stress reactions. The question may be posed as, "In people recently exposed to a catastrophic event, would brief psychological debriefing, or nothing, decrease the likelihood of posttraumatic stress disorder?" This is an effectiveness question, and ideally we would discover a systematic, high-quality review or meta-analyses of randomized controlled trials related to our question. We may discover the number needed to treat (NNT)—how many clients would have to receive an intervention for one to be helped. (See Bandolier's user-friendly guide describing how to calculate NNT. <http://www.medicine.ox.uk.bandolier/band36/b36.html>.) A search of the Cochrane database would reveal psychological debriefing for preventing posttraumatic stress disorder (PTSD) by Rose, Bisson, Churchill, and Wessely (2001). This critical appraisal showed that there was no benefit of debriefing; one study showed a significantly increased risk of PTSD in those receiving debriefing. Thus, the agency administrator would *not* be inclined to recommend this method because critical tests found it to be either ineffective or harmful.

Prevention Questions

Prevention questions direct attention to the future. These include questions about the effectiveness of early childhood visitation programs in preventing delinquency at later developmental

stages. Examples are, "In young children, do early home visitation programs, compared with no service, influence the frequency of delinquency as adolescents?" "For parents who have lost a young child, is bereavement counseling or a support group most valuable in decreasing prolonged dysfunctional grieving?" Here, too, well-designed randomized controlled trials control for more biases than do other kinds of studies.

Prediction (Risk/Prognosis) Questions

Professionals often attempt to estimate risk, for example, of future child maltreatment. A key question here is: "What is the validity of a risk assessment measure? What is the false positive rate (i.e., clients incorrectly said to have some condition—such as being suicidal)? And what is the false negative rate—clients inaccurately said not to have this characteristic (e.g., not be suicidal)? A four-cell contingency table is of value in reviewing the accuracy of such measures. A well-built risk prognosis question is: "In abused or neglected children placed in foster care, will an actuarial risk assessment measure, compared to a consensus-based model, provide the most accurate predictions regarding re-abuse when children are returned to their biological parents?"

Assessment Questions

Clinicians use a variety of assessment measures. These measures differ in their reliability (for example, consistency of responses over time) and validity (whether they measure what they purport to measure). The sample used to gather data and provide "norms" on a measure (scores of a certain group of individuals) may be quite different than clients of concern, so these norms may not apply. A well-built assessment question is: "In frail elderly people who appear depressed, is the Beck Depression Inventory or the Pleasant Events Schedule most accurate in detecting depression?"

Description Questions

Professionals also seek descriptive information, such as the experiences of caregivers of frail elderly relatives. A description question is: "In those who care for dying relatives, what challenges arise and how are they handled?" Some description questions call for qualitative research.

For example, questions concerning in-depth experiences related to given events, such as loss of an infant or living in a nursing home, call for research methods that can provide accounts such as in-depth interviews and focus groups. In-depth surveys may yield related information. Other kinds of description questions require descriptive data involving large samples regarding problems and their causes. Survey data may provide information about the percentage of grieving parents who continue to grieve in certain ways with certain consequences over years. It may provide information about the percentage of divorces and other consequences and describe how parents cope with them. Here, too, we should consider the quality of related research.

Questions about Harm

Decisions may have to be made about how many people have to receive some assessment measure or service for one to be harmed. This is known as *number needed to harm* (NNH). Important considerations here include: “How many people would we have to screen to identify one person who could benefit from help?” “How many of these who are not at risk would be harmed by simply taking the test?” Any intervention, including assessment methods, may harm as well as help.

Questions about Cost–Benefit

Limited resources highlight the importance of cost–benefit analyses. What is the cost of offering one service compared to another, and how many people benefit from each service? Criteria for reviewing cost–benefit studies can be found in many sources, such as Guyatt et al. (2008).

Questions about How to Encourage Lifelong Learning

Integrating practice and research requires lifelong learning. An example of a question here is: “In newly graduated professionals, will a journal club, compared to a ‘buddy system’ be most effective in maintaining evidence-informed practice skills?”

SELECTING AND SAVING QUESTIONS

Which questions are most important to pose? As Straus et al. (2005) note, there are many more questions than time to answer them. First, they

suggest selecting questions according to the nature of clients’ concerns (i.e., what is most important to client well-being). Other filters include what is most vital to self-learning needs, what is most feasible to answer in the time available, what is most interesting, and what questions are likely to reoccur? Straus et al. (2005) also suggest determining the time frame needed to answer a question. Some questions require immediate answers; others do not. They suggest saving questions as a third strategy, so that answers to recurring questions can be retrieved. They estimate that it takes 15 seconds to record a question. Options they suggest for saving questions include writing questions down on a three- or four-column form (client, intervention, comparison, and outcome), dictating into a pocket-sized recorder, or using a personal digital assistant (PDA) (see PICOMaker). Using a structured approach to posing questions helps practitioners pose more specific questions. As Straus et al. (2005) note, “Good questions are the backbone of both practicing and teaching [EBP], and [clients] serve as the starting point for both” (Straus et al., 2005, p. 24).

Questions and answers can be prepared as critically appraised topics (CATs). These consist of brief (one-page) descriptions of a question, search strategy, related research found, critical appraisal of the research, and clinical bottom line (Straus et al., 2005). A CAT summarizes a process that begins with a practice question, proceeds to a well-built question, describes the search strategy used to locate the current best evidence, critically appraises what is found, and makes a recommendation based on what is found. CATs may be prepared for journal club presentations. The Centre for Evidence-Based Medicine website provides an outline and criteria for preparing a CAT. Content on this site regarding levels of evidence can be drawn on to rate the quality of evidence specific to various types of practice questions. Critical appraisal worksheets are provided to facilitate evaluation of the quality of evidence. Also included is a CATmaker, which:

- Prompts a clinical question, search strategy, and key information about studies found
- Provides online critical appraisal guides for assessing the validity and usefulness of the study
- Automates the calculation of clinically useful measures (and their 95% confidence intervals)

- Facilitates description of the clinical bottom line
- Creates one-page summaries (CATs) that are easy to store, print, retrieve, and share (as both text and HTML files)
- Provides prompts to update CATs
- Facilitates teaching others how to practice EBP.

COMMON ERRORS

Errors that may occur when posing questions include starting with more than one question and trying to answer the question before stating it clearly. Gibbs (2003) notes that students often do not draw a distinction between a practice or policy question (useful to guide a search) and a research question (specific to answering a question by collecting data). Leading or loaded questions may be well built, including all elements of a four-part question, but imply that only a particular answer is acceptable, such as, “For persons who may be at risk for suicide, who receive the Brief Psychiatric Rating Scale or Beck Depression Scale, how much higher will the positive predictive value of the former be for predicting suicide?” (What if it is lower?) Confusing a research question with a well-built search question can restrict the chances of finding useful evidence. A research question specifies a specific time frame, specific location, and may specify a particular outcome measure; for example, “Among interdisciplinary teams functioning during 2007 at Veterans Administration Hospital Psychiatric Units that apply evidence-based practice methods, or apply conventional teamwork methods, will patients served by the former have lower scores on symptom rating scales?” This question is too specific and will prematurely limit a search; better that the question be posed more generally, as follows: “For interdisciplinary, transdisciplinary, or multidisciplinary teams following evidence-based practice procedures or following standard team procedures, will patients of the former fare better?”

Vague questions are so unspecific that they net nothing useful. For example, “What is the most effective treatment for depression?” A better question might be: “For women experiencing depression after giving birth, which psychotropic medications have been used to what effect on symptoms of depression?” Novices may pose different questions

compared with experts in an area who are familiar with practice-related research regarding a concern and the complexity of related factors. A lack of assessment knowledge may result in overlooking important individual differences in a client’s circumstances or characteristics. For example, posing an effectiveness question before discovering factors that contribute to depression (such as, “In adults who are depressed, is cognitive-behavioral therapy, compared to medication, most effective in decreasing depression?”) may overlook the fact that for this client, recent losses in social support are uppermost, which suggests a different question, such as, “In adults who are depressed because of recent losses in social support, is a support group or individual counseling more effective in decreasing depression?”

OBSTACLES

Literature concerning EBP suggests that posing well-structured questions can be difficult. Thus, one obstacle is thinking it is easy and giving up when difficulty occurs. Ely and coauthors (2002) conducted a qualitative study investigating obstacles to answering physicians’ questions about patient care with evidence. Participants included nine academic/generalist doctors, 14 family doctors, and two media librarians. They identified 59 obstacles. Those related to forming clear questions included the following.

- Missing client data, requiring unnecessarily broad search for information. Ely and coauthors note that questions that include demographic or clinical information and information about client preferences may help focus the search. They note that the kind of information that would be of value will vary depending on the question and may not be clear until the search is underway.
- Inability to answer specific questions with general resources. A specific question was, “What is this rash?” and vague cries for help, “I don’t know what to do with this client,” cannot be answered by a general resource.
- Uncertainty about the scope of the question and unspoken ancillary questions. For example, it may not be apparent that the original question should be expanded to include numerous ancillary questions.

Obstacles related to modifying the question include the following.

- Uncertainty about changing specific words in the question
- Unhelpful modifications resulting from flawed communication
- The need for modifications apparent only after the search has begun
- Difficulty modifying questions to fit a four-part question format (client, intervention, comparison, and outcome)
- Trying to solve too many questions at once
- Trying to answer a question while posing it.

Posing clear questions may be viewed as a threat. Questions are not benign, as illustrated by the fate of Socrates. Staff members who pose questions in their agency may create discomfort among other staff, perhaps because they are doing something unfamiliar or because others view such staff as impertinent or disloyal to the agency or profession. Supervisors may not have experience in posing answerable questions and wonder why it is of value; learning to pose well-formed questions has probably not been a part of their education. Other obstacles include lack of training in how to pose well-structured questions, lack of needed tools to follow through on searches, lack of motivation to consider criteria on which decisions are made, and fears that there are more questions than answers.

OPTIONS FOR DECREASING CHALLENGES

Options for addressing challenges include providing repeated guided experience in posing well-structured practice and policy questions during professional education programs and providing effective continuing education opportunities that provide such skills. (See, for example, description of problem-based learning using the process of EBP in Straus et al., 2005.) Learning by doing is emphasized in EBP. The more we use a skill, the more facility we gain with it, if we have access to corrective feedback. Unless we try to perform a certain skill, we cannot determine our competency level. Posing well-structured practice/policy questions may sound easy, but it can be quite difficult. Similarly, searching for related research findings may sound easy until we try to do it and run into obstacles. Well-structured questions related to information needs that

frequently arise could be crafted and shared with colleagues in the form of CATs.

152 Locating Credible Studies for Evidence-based Practice

Allen Rubin & Danielle E. Parrish

EVIDENCE-BASED PRACTICE IN SOCIAL WORK: HARNESSING THE INFORMATION REVOLUTION

Evidence-based practice (EBP) integrates research with practice and relies heavily on the use of technology to access the best available evidence. As Gibbs (2007) suggests, “EBP is genuinely a new response to the information revolution and a philosophical interpretation of how to harness this revolution” (p. 146). Whereas prior efforts to disseminate research findings to practitioners were laden with barriers, a handful of trends born out of this revolution have greatly improved the ease with which busy practitioners can access useful information more quickly to inform their practice. First, the number of empirical studies using true experimental designs has increased steadily within social work and various allied professions, providing a larger pool of information to draw from when making practice decisions (Shlonsky & Gibbs, 2004). Second, a relatively recent survey of National Association of Social Workers (NASW) practitioners reported that 97% of social workers have access to the Internet at work, home, or both, thereby allowing for real-time access to web-based evidence resources (O’Neill, 2003). Third, the widespread access of the helping professionals to the Internet and the EBP movement has led to the sprouting

of myriad web-based resources designed to improve both the access to and dissemination of practice-related research evidence.

Despite these encouraging developments, the success of engaging in the EBP process hinges largely on the ability of practitioners to locate the *best* available evidence both easily and quickly. Because the Web contains a countless number of practice-related resources that vary in their trustworthiness and rigor, practitioners must learn about existing high-quality web-based resources and develop the skills to appraise unfamiliar or new resources critically as they emerge. Practitioners would also benefit by learning specific search strategies that will enable them to search quickly within these resources to find the most relevant information for answering their practice questions. Without this information and these skills, the search for evidence can be fruitless, time consuming, and frustrating.

THE IMPORTANCE OF ASKING A WELL-BUILT EVIDENCE-BASED PRACTICE QUESTION

The success of Step 2 of the EBP process is contingent upon whether the practitioner has identified a well-formulated EBP question. A well-formulated EBP question helps (1) focus our limited time to identifying the most pertinent

evidence to our client's situation, and (2) identify useful search terms to guide our search for the best available research evidence (Straus et al., 2005). Because the development of a clear and specific EBP question is intricately linked to the quality of the evidence we find and the identification of key search terms, it is necessary to briefly visit this topic.

Straus and colleagues (2005; 2011) identify two major categories of EBP questions: background and foreground. Background questions are generally posed when practitioners have limited experience with a particular practice situation or population and are looking for general background information to inform their practice (e.g., a specific practice problem, diagnosis, comorbidity, risk factors, issues related to cultural sensitivity or competence) (Straus et al., 2005). Although background information can be found in single articles, this information is often well summarized in more recent textbooks. For this reason, this chapter focuses less on background questions and more on how to locate evidence to answer foreground questions.

Foreground questions are asked when the practitioner has more experience with the practice situation and population, and wants to locate information to guide practice decisions or actions (Straus et al., 2005). Specifically, these questions ask about the effectiveness of interventions, programs, or policies for specific practice situations. Key elements of a foreground question include some or all of the following: (1) client characteristics and practice situation (always), (2) intervention (if known in advance), (3) comparison intervention (if relevant), and (4) desired outcomes (usually). Practitioners who have conducted a good assessment of the practice situation should be able to identify Items 1 and 4; it is conceivable that if they are not familiar with all of the effective interventions, programs, or policies, they will not know Items 2 or 3 prior to the search.

The most useful EBP questions are posed specifically enough to guide an effective electronic search for the evidence (Gibbs, 2003). This means providing enough descriptive terms within the question to capture the idiosyncratic characteristics of a particular client or target population so that these terms can later be used to search for and locate evidence with the greatest relevance to the client. These descriptive terms might include age or age group, gender, ethnicity or race, income, rural/urban setting, and so on.

The practitioner must use his or her judgment to select the terms that are most important with regard to the treatment setting, client, or target population.

IDENTIFYING USEFUL AND TRUSTWORTHY EVIDENCE RESOURCES

Identifying Useful Resources

After composing a well-built EBP question, the next step is to identify which resources would yield the most trustworthy, current, and best available evidence. Due to the lag time between the publication of research findings and that of textbooks, it is not sufficient to rely on textbooks to provide the *current* best available evidence. It is also not enough to subscribe to one or even a handful of specific journals, as they will only represent a small part of the existing literature to answer an EBP question. For this reason, it is impossible to know whether what little *may* be found is actually the *best* evidence. According to Straus and colleagues (2005), any money that was previously spent on these resources would best be redirected toward purchasing resources (many of which are now web-based) that provide or synthesize a larger and more recent cross-section of the extant literature.

A Model for Accessing Practitioner-friendly Resources

Resources that provide the necessary access to high-quality practice-related research evidence vary greatly in the way they disseminate this information. A model for recognizing the most useful and "evolved" information services for answering practice-related questions has been proposed by Haynes (2007), one of the coauthors of *Evidence-Based Medicine*, and adapted by the authors for use within the social work profession (see Figure 152.1). This model differs from the EBP effectiveness research hierarchy, which is concerned with the kinds of research studies that have a high degree of internal validity, such as systematic reviews, randomized controlled trials, and quasiexperimental designs with a low probability of a selection bias. In contrast, the purpose of this model is to describe the information resources that best disseminate the information generated from these high-quality studies to busy practitioners. According to this model, the

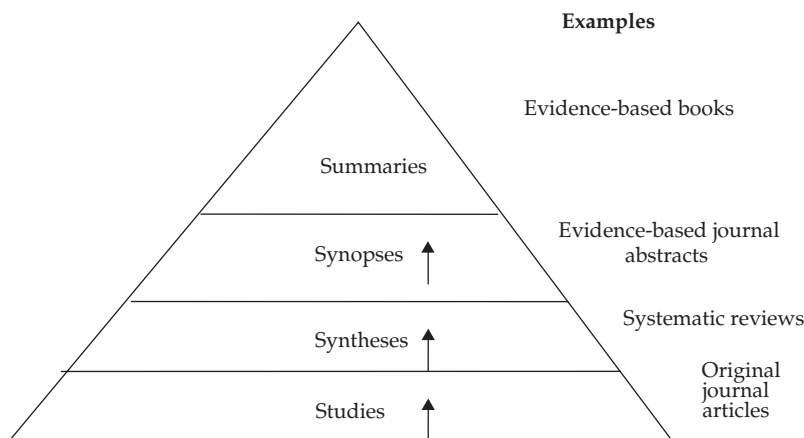

Figure 152.1 Model for recognizing the most useful and “evolved” information services for answering practice related questions. Adapted from Haynes (2007) The “5S” Levels of Organization of Evidence from Healthcare Research.

most user-friendly options for busy practitioners reside toward the top of the pyramid, because these resources summarize the information generated from the bottom two layers, thus sparing practitioners the time required to comb through the results of original research studies. Haynes (2007) emphasizes, “At each level, the standards for evidence generation, retrieval, selection and analysis should be explicit and at the highest evidence standard possible” (p. 6). Therefore, it is essential that evidence-based practitioners critically appraise information resources at all levels within this model, using the skills emphasized in Step 3 of the EBP process.

A *summary*, which resides at the top of the pyramid, draws all of the available high-quality evidence from the three layers below to integrate all of the information within a specific practice area into an up-to-date summary (Haynes, 2007). According to Haynes (2007), a summary “integrate[s] the] best available evidence ... to provide a *full range of evidence* [emphasis added] concerning management options for a given ... problem” (p. 6). A summary then resides at a higher level on this hierarchy than syntheses or systematic reviews because it provides a broader picture of the literature by reporting on all synopses, syntheses, and studies pertaining to a general practice area. For example, a systematic review might report on only one or two interventions for treating a particular disorder, whereas a summary would compile all of the most recent outcome research on all of the known effective

treatments for that disorder, with details about varying levels of support for these disparate interventions in the form of a book or monograph. Although it was mentioned previously that typical textbooks are no longer useful for identifying effective interventions, this type of publication differs in that it usually is updated on a regular basis to capture any new emerging research in the area.

One potentially useful summary is *Clinical Evidence*, an online decision support tool that constantly updates and summarizes high-quality evidence (both articles and reviews) on topics within mental health and medicine. Unfortunately, there are not currently any social work resources that both provide a broad summary of high-quality practice research and frequent updating. The primary author of this chapter, however, has coedited a book series titled, *The Clinician’s Guide to Evidence-Based Practice* (see, for example: Rubin, 2012) that will succinctly summarize the state of evidence within broad mental health and substance abuse treatment areas. In addition, this resource will provide in-depth guidelines on how to carry out the interventions identified as having the most rigorous research evidence. If this resource or any similar broad summary of the literature that is not frequently updated is used, a search for recent resources from other parts of the pyramid should be conducted to ensure access to additional research that may have emerged for a particular practice situation.

The second layer is a *synopsis*, or a brief description of an original article or systematic review (Haynes, 2007). Synopses reside second on the pyramid because the brief description saves time for the practitioner, given that she does not need to access and read the original source. Reputable synopses should reference the original research summarized, report the results quantitatively, and ideally offer an easy way to access these sources if additional information is needed. Synopses can be found in evidence-based journal abstracts, such as *Evidence-Based Mental Health*. This is a multidisciplinary journal whose authors survey a wide range of international journals with strict criteria to identify high-quality outcome studies that are clinically relevant. They synthesize this information in a short, clinically informative summary. The Substance Abuse and Mental Health Services Administration (SAMHSA) also provides a National Registry of Evidence-Based Programs and Practices, which offers a searchable online registry of mental health and substance abuse interventions and programs. The research supporting these interventions has been reviewed and rated by independent reviewers, and this information is available for practitioners to review.

The third layer is comprised of *syntheses* or systematic reviews (Haynes, 2007). Systematic reviews are “based on a rigorous search for evidence, explicit scientific review of the studies uncovered in the search, and systematic assembly of the evidence to provide as clear a signal about the effects of a[n] ... intervention as the evidence will allow” (Haynes, 2007, p. 5). Syntheses are the best resource when there is no current summary that broadly summarizes the evidence, or no synopsis that succinctly describes the results of individual studies or reviews, or if more in-depth information is needed about the existing evidence. Syntheses are third on the pyramid because they can save busy practitioners time from reading all of the original individual studies that may pertain to a particular practice issue. Syntheses are also often a better source than individual studies for practitioners because the authors of such reviews are likely to have more complete access to all of the existing literature and an advanced level of expertise in appraising and synthesizing research studies.

Many useful systematic reviews for social work practice are available on either the Cochrane Collaboration or Campbell Collaboration

websites. Both organizations are nonprofit, independent groups that were created to provide practitioners with up-to-date, accurate practice information. The Cochrane Collaboration primarily provides information for health care professionals, but also has information on topics such as depression, anxiety, schizophrenia, and dementia and cognitive impairment. Access to full-text Cochrane reviews requires a subscription, although abstracts can be read on line free of charge. The Campbell Collaboration offers a searchable database of randomized controlled trials and systematic reviews of social, psychological, educational, and criminological research. Online access to both the reviews and abstracts on this site is free of charge. In addition, Ovid Technology’s Evidence-based Medicine Reviews (OVID EBMR) offers one-stop shopping for both Cochrane and Campbell reviews and those published in other sources (Haynes, 2007). Finally, systematic reviews can be located through typical databases that also retrieve individual studies, such as PsycINFO, which are available with a subscription or may be accessed through a public library or a public university library. Many public libraries are now offering free remote access to the public at large to databases that house full-text articles. If these databases cannot be accessed through a local library, or if these databases are insufficient, public university libraries will allow members of the public to access these databases in person (remote access is usually restricted to students and faculty).

Original studies comprise the bottom layer of the pyramid. If sufficient information cannot be accessed from the three layers above this, high-quality single studies that evaluate the outcome of an intervention provide the next-best source of information to guide practice. Using evidence from individual studies requires that the practitioner obtain a broad sample of the existing literature, and then critically appraise these studies for both their rigor and practice relevance. SUMSearch was developed to assist evidence-based practitioners in identifying a broad sample of the relevant literature by combining meta-searching and contingency searching to search multiple Internet sites and then collating these findings into one summary page. Other high-quality databases include PsycINFO, PubMed (which includes Medline), Social Services Abstracts, and AgeLine.

PsycINFO is updated on a monthly basis, and indexes and abstracts over 1,700 sources,

including international material. There are over 1.8 million individual records dating back to 1887. PubMed provides access to citations in the medical and mental health literature, and is maintained by the U.S. National Institutes of Health (NIH). The Social Service Abstracts contained 137,654 sources dating back to 1979 as of November 2007, and it is updated monthly (averaging 5,500 new sources per year) to provide coverage of current research in the areas of social work and the human services. AgeLine contains detailed summaries of the literature of social gerontology as well as aging-related research from social work and the allied fields. AgeLine contains over 75,000 English-language publication abstracts going back to 1978, and is updated every two months with approximately 800 new citations.

Whereas *Social Work Abstracts* has been described as the “primary source of articles on social work and social welfare, as well as on related fields” by NASW Press, recent reviews of this database found that in comparison with others (PsycINFO, Sociological Abstracts, and Medline), it covered a very small number of social work–related journals, was updated much less frequently, had the fewest number of records, and often omitted important papers relevant to social work (Holden, Barker, Covert-Vail, Rosenberg, & Cohen, 2008; Shek, 2008). *Social Work Abstracts* alone is thus not a sufficient database for obtaining a good cross-section of the existing research literature to guide EBP.

If nothing is found in one of the above databases, or if there is a need to expand the search, Google Scholar or Google can be used. Google Scholar provides access to a broad array of

scholarly literature, while the regular Google search engine searches across a much larger sample of Internet sites beyond scholarly literature. For this reason, it is best to start with Google Scholar to narrow your search to what are more likely to be reputable sources. Both of these sites are best used by engaging the advanced search option, which will assist the user in combining key search terms better.

Practice Guidelines

In addition to the sources already listed, many organizations have begun to provide *practice guidelines*, or a list of recommended treatments or practice techniques that meet a set of predetermined criteria. Criteria for selection vary based on the source, and so it is important to become familiar with the inclusion and exclusion strategy before using these resources to guide practice decisions. Practice guidelines are distinguished from summaries for several reasons. First, they tend to provide a limited picture of the existing research evidence. Division 12 of the American Psychological Association, for example, limits its list of empirically supported treatments to the criteria listed in Table 152.1. This list, though useful for identifying interventions that meet this strict level of rigor, does not include effectiveness studies or other interventions with varying levels of support. For this reason, practice guidelines do not provide the broad picture offered by a summary that may enable the practitioner to consider all variations of the best available evidence when trying to match this evidence with the unique characteristics and preferences of the client system.

TABLE 152.1 American Psychological Association Definition for Empirically Validated Treatments: Well-established Treatments

-
- I. At least two good group design studies, conducted by different investigators, demonstrating efficacy in one or more of the following ways:
 - A. Superior to pill or psychological placebo or to another treatment
 - B. Equivalent to an already established treatment in studies with adequate statistical power (about 30 per group).
 - OR
 - II. A large series of single case design studies demonstrating efficacy. These studies must have:
 - A. Used good experimental designs and
 - B. Compared the intervention to another treatment as in I.A.
- FURTHER CRITERIA FOR BOTH I AND II:
- III. Studies must be conducted with treatment manuals.
 - IV. Characteristics of the client samples must be clearly specified.
-

Second, practice guidelines may not rely solely on the research evidence when identifying the best interventions and may not provide a detailed picture of the research evidence. One example is the American Psychiatric Association's detailed summary of practice guidelines for a variety of DSM disorders, which relies on a combination of the research evidence and clinical consensus, and does not consistently describe the state of the research evidence in detail for the interventions described. Thus, although practice guidelines can be useful, the evidence-based practitioner would need to consult additional sources to ascertain whether excluded interventions with a disparate level of empirical support might better fit the client's unique characteristics, values, and circumstances or to obtain additional information on the research evidence. Practitioners should also be especially vigilant in appraising these resources for potential bias, given that practice guidelines are often developed by work groups whose members may have a vested interest in a certain interventional approach. A number of other practice guideline resources related to social work interventions and programs have been developed, such as the Evidence-Based Program Database, the National Guidelines Clearinghouse, the Office of Juvenile Justice and Delinquency Prevention (OJJSP) Model Programs Guide, and the California Evidence-Based Clearinghouse for Child Welfare.

IDENTIFYING TRUSTWORTHY EVIDENCE RESOURCES

All evidence resources must be critically appraised for their rigor and relevance to practice. For the upper three layers, the retrieval and selection of evidence and the synthesis or analysis procedure should be made explicit and should reflect the following standards. First, the search and inclusion strategy should not be too narrow or restrictive. The best resources will rely on multiple reputable databases, use a well-defined search strategy, and include both published and unpublished sources as well as dissertation research. Second, the authors should present their process for assessing the quality of selected studies, with particular attention to designs that have unbiased measurement and a high level of internal validity, such as randomized controlled trials and quasiexperimental designs that control for or lack an apparent selection bias. Finally, the resource must be critiqued for a potential

bias due to funding or sponsorship, because bias can greatly influence how individual studies are selected, synthesized, and interpreted. When appraising databases that house individual studies, key criteria include (1) having a substantial number of journals and records related to the topic of interest, and (2) frequent updating of records (at least monthly).

DEVELOPING AND EXECUTING A SUCCESSFUL SEARCH STRATEGY

Many of the resources discussed so far require the use of search terms to locate the information that is specific to answering an EBP question. Although some of these sources vary with regard to their general search infrastructure, most follow similar rules and logic. If you are very unfamiliar with a resource, it may be useful to scan its search guidelines to ensure that you are using the right search strategy or to meet with a librarian or information specialist who is familiar with this resource to obtain additional guidance. This section will first present the most common search strategies that apply to the widest number of databases and online resources, which include Boolean operators, truncation, identification of synonyms, quotation marks, and methodological filters. A discussion of these strategies will be followed by a brief presentation on how best to initiate a search using these techniques.

Search Strategies

Boolean operators are connecting words that determine the logic by which two or more terms are searched within an electronic database. The most common Boolean operators are AND, OR, and NOT. The term AND narrows the search by only returning publications that contain both or all of the terms (see Figure 152.2). If searching for "teenagers" AND "pregnancy," the list of articles would be limited to those that contain both of these key words. The term OR as shown in Figure 152.2, expands the search by including all of the publications that include one or both of the search terms. This connector is often used when there are common synonyms for one of the key search terms. For example, a search may require connecting the terms (teenager OR youth OR adolescent) to obtain all of the relevant articles that describe a person between the ages of 12 and 18 years. Notice that the example terms were

Figure 152.2 Use of Boolean operators to narrow or expand a search. These diagrams represent a search of two key words (represented by each circle) using each kind of Boolean operator in a separate search. The shaded area represents what the search will yield when connected with AND, OR, or NOT.

placed in parentheses—this is required for the OR connector to work properly. The term NOT is used to narrow the search by excluding information that is irrelevant. It does this by retrieving records that only retrieve the first search term and reject all that include the second search term (see Figure 152.2). For example, if interested in self-harm behavior but not suicide, the search term might include “self-harm behavior” NOT “suicide.” Keep in mind, however, that NOT may discard useful as well as less useful references. Using the example, the search will only include publications that include “self-harm behavior,” but not any that include both “self-harm behavior” and “suicide,” which may have relevance to answering the EBP question.

Truncation is a way to expand the search by including all variations of characters that follow a word stem by using a symbol, most commonly an asterisk (*) or a dollar sign (\$). For example, “prevent*” will retrieve prevention, preventing, prevented, or prevents. One truncation symbol typically returns one to five characters following a word stem, whereas a double asterisk (**) returns an unlimited amount of characters. A question mark (?) or other form of truncation can also be used to search for variations of characters within a word, for example, “wom?n” would yield both “woman” and “women.” To find the correct truncation symbol for a specific database, consult the help section within the database.

Synonyms expand the search by including all possible terms for a particular keyword or phrase of interest. Although this can be done using simple brainstorming, it is best to consult the database’s thesaurus, if one is available, so that an exhaustive list of the major terms used within that specific database can be generated for the major concept of interest. As mentioned previously, synonyms are connected to one another using the Boolean operator OR, and then this list of terms is linked together with terms of a different concept by the term AND (see Figure 152.3).

Quotation marks limit the search to combinations of words or phrases such as “child welfare.” While searching for both the terms “child” and “welfare” separately will likely yield many relevant hits in child welfare, it will also return records, for example, that discuss the general welfare of children or perhaps public assistance and the effect on children, rather than articles limited just to the child welfare system.

Methodological filters limit the search to the best available research studies specific to answering an EBP question (Gibbs, 2003). Using the terms listed in Figure 152.4, the evidence-based practitioner is able to locate and limit the search more quickly to outcome studies with the most rigorous designs. One way to conduct the search would be to use these terms to drill down through the research hierarchy at each level, starting with the systematic review terms, proceeding to the experimental design terms, and finally to the quasiexperimental design terms (see Figure 152.4). The practitioner would start by combining the key search terms from the EBP question with the systematic review search terms to first identify any such reviews that have been done for the practice problem. If little or nothing is found, the search can be expanded to include the terms that represent experimental designs and quasiexperimental designs. If nothing is yielded using these terms, the search can be expanded further by combining more general terms such as “outcome” and “study” to search for the lower levels of *best available* evidence, keeping in mind that these sources are very tentative in providing evidence of effectiveness. As shown in Figure 152.4, these terms must be connected by OR to obtain all possible combinations of these terms. There are additional methodological search terms for background EBP questions related to assessment and diagnosis, description of experience and meaning, and risk/prognosis (Gibbs, 2003; Straus et al., 2005) provided in Gibbs’s (2003) book.

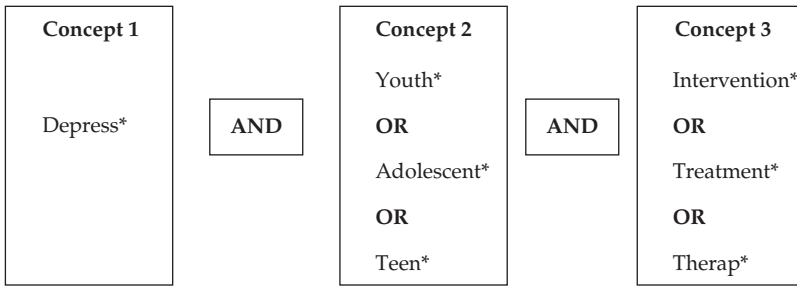

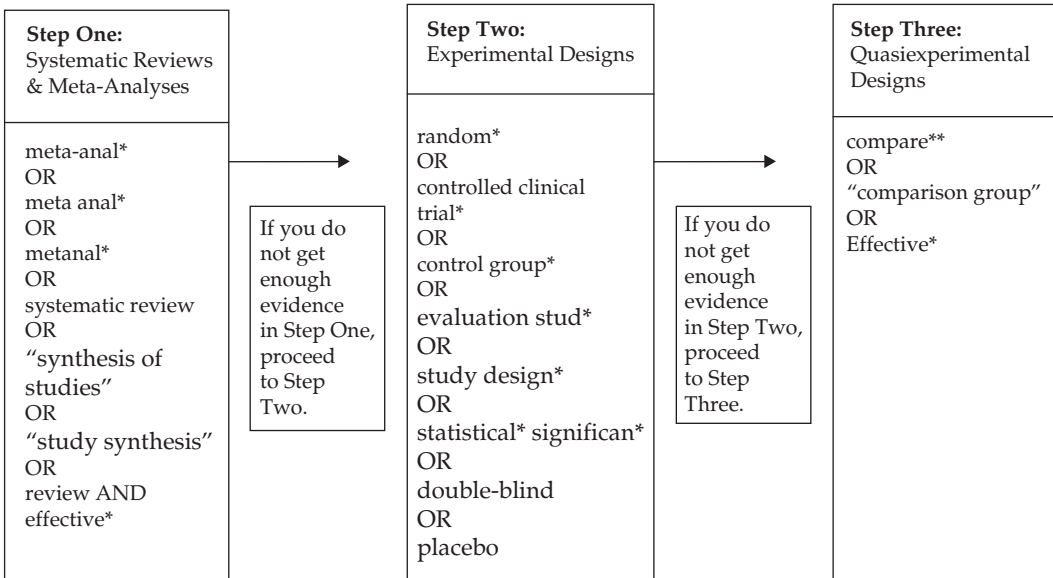

Figure 152.3 Structuring a search using synonyms and Boolean operator.

****If looking for a prevention study: AND prevent*

Figure 152.4 Use of methodological search filters to locate research studies for evidence-based practice. Many of these terms were taken or adapted from Gibbs (2003). Evidence-Based Practice for the Helping Professions. Pacific Grove, CA: Thomson Brooks/Cole.

Starting the Search

Because searching is an iterative process that often requires several attempted combinations of search terms, there is not one way to begin or carry out this process. When engaging in the evidence-based process, however, key search terms should be extracted from the EBP question to narrow the search to the information most relevant to the client’s idiosyncratic characteristics and the issue(s) for which he or she sought help. One way to start the search then would be to extract the most relevant words directly from the question and then create a list of synonyms for each word. Next, this list can be

used to create a search term that begins by connecting each word in the list of synonyms by OR and enclosing them within parentheses. Next, each list enclosed within parentheses would be connected by an AND. This search term would be further altered by identifying word stems that need to be truncated, and phrases should be enclosed in quotation marks. The end result is an initial search term that limits the search to the specific characteristic of the client system and the presenting problem related to the EBP question, while expanding the search to all possible variations of these search terms in the form of synonyms and word stems. An example search term is shown in the case study.

Taking Stock of the Available Evidence

After entering the first search term, the next step is to take stock of what was returned. Two major considerations are the length of the list and the relevance of the items on the list. The first step should be to examine the titles and abstracts to get a sense of what kinds of studies the search term netted. If the list of results is too long and many items seem irrelevant, AND and NOT can be used to limit the search. If the list is small or nothing has been returned, you can do one of the following: (1) try to identify additional or more accurate synonyms or new search terms; (2) reduce the number of keywords used in your search or separate some of your keywords by OR instead of AND (it may be that there is research on the presenting problem but not for a client with the same characteristics); or (3) identify a better database or resource to try the search. If this does not work, it may be that there is currently a lack of research evidence for that particular problem and an opportunity to expose this gap for further research. When this happens, it is all the more important to evaluate practice outcomes to ensure that whatever intervention eventually selected works with that client.

CASE STUDY

Angelica is a 35-year-old Hispanic mother of two who recently settled in a new city after leaving her abusive husband and a supportive women's shelter. She has taken the advice of her counselor at the shelter and decided to enter therapy to deal with her posttraumatic stress disorder (PTSD) symptoms. She is currently most interested in dealing with her difficulty sleeping and nightmares. EBP question: "What is the most effective treatment to alleviate an adult Hispanic female's PTSD symptoms?"

The first step is to identify the best information resource to answer this question. Because *Clinical Evidence* offers a summary on PTSD with adults, this reference would be consulted first, given that it falls at the top of the hierarchy of practitioner-friendly resources. This source is also reputable and regularly updated. If after reading this resource, additional information was needed to inform a clinical decision, a search of the Cochrane Collaboration using a search term would be conducted. In this case, there was a jump from the *summary* layer to the *syntheses* layer, skipping the *synopsis* layer,

because the synopsis layer is not likely to provide any additional in-depth information than the summary, whereas a synthesis or comprehensive systematic review is more likely to do so. Because the EBP question is important for informing the key search terms, practitioner judgment would be used to underline the most important terms within the question for this search, as follows: "What is the most effective treatment to alleviate an adult Hispanic female's PTSD symptoms (with a specific focus on difficulty sleeping and nightmares)?"

Next, a list of synonyms would be created to ensure that all variations of the words are included in the search. Within the Cochrane Collaboration, the MeSH search option offers a thesaurus. The word "treatment" was synonymous within this database with "therapeutics" and combined with terms "treatment effectiveness," "treatment outcome," and "treatment efficacy." The word "adult" was synonymous with "middle aged." The term "women" was not synonymous with any other words, whereas "Hispanic" was linked to "Hispanic Americans." Finally, the term "PTSD" was selected for the search. Because the Cochrane Collaboration library is a collection of systematic reviews and high-quality clinical trials, there is no need to use the methodological search terms to weed out irrelevant publications. The initial search term would be as follows: (treatment* OR therapeutics OR "treatment effectiveness" OR "treatment outcome" OR "treatment efficacy") AND (adult* OR middle aged) AND women AND (Hispanic OR "Hispanic Americans") AND PTSD.

This search term yielded the following two studies:

- Cognitive-behavioural interventions for children who have been sexually abused. G. M. Macdonald, J. P. T. Higgins, P. Ramchandani (2006).
- Behavioural and cognitive behavioural training interventions for assisting foster carers in the management of difficult behaviour. W. Turner, G. M. Macdonald, J. A. Dennis (2007).

Of course, based on the titles, it is obvious that neither of these reviews is relevant to the EBP question. For this reason, the search will be limited to the following term, taking out ethnicity, which may only be discussed in the body of the review: (treatment* OR therapeutics OR

“treatment effectiveness” OR “treatment outcome” OR “treatment efficacy”) AND (adult* OR middle aged) AND women AND PTSD. This change expanded the search to 10 reviews, two of which included the following:

- Psychological treatment of post-traumatic stress disorder (PTSD). J. Bisson, M. Andrew (2007).
- Pharmacotherapy for prevention of post-traumatic stress disorder. J. C. Ipser, S. Seedat, D. J. Stein (2006).

The review on psychological treatment of PTSD examined the evidence for the following PTSD interventions: trauma-focused cognitive-behavioral therapy/exposure therapy (TFCBT), stress management (SM), other therapies (supportive therapy, nondirective counseling, psychodynamic therapy, and hypnotherapy), group cognitive-behavioral therapy (group CBT), eye movement desensitization and reprocessing (EMDR). The results of this analysis were presented in detail, and the authors of this study concluded the following:

There was evidence individual TFCBT, EMDR, stress management and group TFCBT are effective in the treatment of PTSD. Other non-trauma focused psychological treatments did not reduce PTSD symptoms as significantly. There was some evidence that individual TFCBT and EMDR are superior to stress management in the treatment of PTSD at between 2 and 5 months following treatment, and also that TFCBT, EMDR, and stress management were more effective than other therapies (Bisson & Andrew, 2007).

Because both a summary and systematic review of many of the existing PTSD interventions were accessed from reputable sources, these intervention options and the varying levels of empirical support can be presented to the client as a part of an informed consent process.

153 Critically Appraising Studies for Evidence-based Practice

Denise E. Bronson

Adopting an evidence-based approach to practice is predicated upon one's ability to determine which studies or systematic reviews are valid, credible, and relevant to the practice problem one is trying to solve. A *critical appraisal* of the available research is essential for sifting through the plethora of published and unpublished literature to find those studies that employed rigorous methods to minimize potential biases and unwarranted conclusions. There is no single systematic strategy for conducting a critical appraisal but there are numerous guidelines and checklists to help evaluate the quality of the research, the quality of the research report, the relevance of the research, and the presence of potential biases (Harden & Gough, 2012). Using these tools, critical appraisal can be done by anyone with a basic understanding of research methods who also possesses (1) the ability to think critically, (2) a willingness to challenge their own biases and practice preferences, and (3) a systematic strategy to ensure that each study is evaluated according to the same criteria.

All strategies for critically appraising single studies or systematic reviews attempt to identify possible biases that produce conclusions that deviate in some way from the "true" results (Harden & Gough, 2012; Young & Solomon, 2009). Bias can undermine research at many points, beginning with how the research problem is defined to the ways in which the results are reported. Although there is no such thing as a perfect study, a critical appraisal of a study's validity and credibility allows one to assess "the degree to which a study is affected by bias and whether the degree of bias is large enough to render the study unusable" (Petticrew & Roberts, 2006, p. 131).

Critical appraisal strategies focus on identifying possible threats to the validity, credibility, and relevance of the research. Assessing the validity of the research examines whether the research design and methods have eliminated or minimized potential sources of bias (Straus, Glasziou, Richardson, & Haynes, 2011) that could lead to erroneous causal conclusions. A valid study is one that allows us to make causal inferences (also called internal validity) about the effects of an intervention. A study will have good internal validity if the research design and methods allow us to establish a causal relationship between the treatment and the observed outcomes while eliminating other possible explanations. Examining the credibility of the research helps determine whether we have reason to believe the outcomes. A credible study is one that is trustworthy. That is, the study is characterized by transparency, honest reporting of methods and limitations, and a willingness to consider alternative explanations for the observed outcomes. Credibility also includes any possible conflict of interest that might influence the conclusions made by the researcher. Appraising the relevance of the research examines the generalizability of the findings to clinical populations and what outcomes might be expected if an intervention is adopted. The critical appraisal process examines all three areas.

APPRAISING VALIDITY

Critically Appraising the Validity of Single Studies. Several tools are available to help appraise the validity of an individual study. Guidelines for critically appraising validity target the possible

sources of systematic bias in the research methods, which may be introduced by the way in which the study is conducted, how study participants were selected, how data were collected, or through the researchers' analysis or interpretation (Young & Solomon, 2009). Discussions of validity assessments often refer to the "hierarchy of research evidence," which indicates the strength of the evidence produced by various research methods (Howick, Chalmers, Glasziou, Greenhalgh, Heneghan, Liberati, Moschette, Phillips, & Thornton, 2011). Typically the hierarchy of evidence is presented as a pyramid (<http://ebp.lib.uic.edu/nursing/node/12>) with the strongest types of research methods appearing at the top (systematic reviews and meta-analyses) and weaker methods at the base (editorials and expert opinions). Each of the validity appraisal methods presented below rely on this model to assess biases that might be introduced by the type of research methods used.

Gibbs (2003) created the Quality of Study Rating Form (QSRF) to assess the quality of individual effectiveness studies. The QSRF places high value on randomized control trials with outcome data collected by those blinded to the treatment assignments to reduce threats to internal validity. The QSRF also emphasizes the value of random selection and assignment of subjects to treatment conditions, and gives weight to studies using reliable and valid outcome measures. When completed, the QSRF provides an index of the study's validity based on the rigor of the research methods used in the study.

The Social Care Institute for Excellence (SCIE) in England developed the TAPUPAS framework that highlights the dimensions of *transparency*, *accuracy*, *purposivity*, *utility*, *propriety*, *accessibility*, and *specificity* (Harden & Gough, 2012). Critical appraisal of a study using TAPUPAS asks:

- **Transparency**—are the reasons for it clear?
- **Accuracy**—is it honestly based on relevant evidence?
- **Purposivity**—is the method used suitable for the aims of the work?
- **Utility**—does it provide answers to the questions it set?
- **Propriety**—is it legal and ethical?
- **Accessibility**—can one understand it?
- **Specificity**—does it meet the quality standards already used for this type of knowledge? (Pawson, Boaz, Grayson, Long, & Barnes, 2003, p. 40).

This model goes beyond assessing the research methods used by also examining the way in which the findings are reported, possible ethical issues inherent in the research, and the relevance of the research.

Today, the most widely used critical appraisal model is the "Risk of Bias" tool developed by the Cochrane Collaboration, which assesses threats to internal validity by classifying biases into six types—selection bias, performance bias, attrition bias, detection bias, and reporting bias (Higgins & Green, 2011; Higgins, Altman, Gotzsche, Juni, Moher, Oxman, Sovovic, Schulz, Weeks, & Stern, 2011). Each of these potential biases offers an alternative explanation for any changes observed after the introduction of an intervention.

Each of the tools presented uses randomized controlled trials (RCTs) as the benchmark against which to appraise the validity of effectiveness studies. Unfortunately, RCTs are difficult to implement in clinical settings and, as a result, there are relatively few such studies in social work. Some researchers use a variety of strategies to try to create equivalent groups without randomization, but these methods do not remove the possibility of unmeasured systematic errors. These efforts and the use of other less rigorous research designs, such as those relying on nonequivalent comparison groups, case studies, or qualitative research will not address many threats to internal validity or remove potential biases that can distort the conclusions about an intervention's effectiveness. However, qualitative studies may offer information about the efficacy and effectiveness of interventions that cannot be gleaned from quantitative research. The value of less rigorous quantitative research and qualitative research for evidence-based practice has been quite controversial. However, efforts are under way to develop appraisal criteria for these types of studies to minimize issues of bias and to promote their use in evidence-based practice (Bronson & Davis, 2012; Saini, 2007; Saini & Shlonsky, 2012; Noyes, Popay, Pearson, Hannes, & Booth, 2011).

Critically Appraising the Validity of Systematic Reviews. When multiple studies exist on a specific intervention it is possible to strengthen conclusions on the effectiveness of the intervention by synthesizing the results of multiple studies. Both the Cochrane Collaboration and the Campbell Collaboration promote the use of systematic reviews and meta-analyses to summarize a large body of research. Unlike traditional

TABLE 153.1 Cochrane Collaboration Sources of Bias in Clinical Trials (Higgins & Green, 2011)

Selection Bias	Systematic differences between comparison groups at baseline that may impact the results of the study. Random selection and assignment is used to reduce selection bias.
Performance Bias	Systematic differences in how participants in the comparison groups are treated that are not related to the presence or absence of the intervention. Blinding of study participants and personnel used to minimize bias.
Detection Bias	Systematic differences in how outcomes are measured due to knowledge of the subject’s group assignment. Blinding of study participants and personnel used to minimize bias.
Attrition Bias	Systematic differences between groups in withdrawal from the research so that outcome data are unavailable.
Reporting Bias	Systematic differences in which results are reported. Refers to the tendency to report significant results while not reporting nonsignificant findings.

literature reviews, systematic reviews provide a comprehensive synthesis of existing research using transparent and replicable methods. When a sufficient number of studies exist, systematic reviews often include a statistical meta-analysis that calculates an overall effect size based on a synthesis of the statistical results from multiple studies (Cooper, 2010; Littell et al., 2008; Bronson & Davis, 2012).

Assessing the validity and relevance of systematic reviews and meta-analyses requires a different set of evaluative criteria. Each step in the synthesis process presents new validity issues that must be considered in appraising the quality of systematic reviews (Cooper, 2010). Numerous approaches for assessing the quality of systematic reviews have been developed.

The Campbell and Cochrane Collaborations have developed explicit standards to ensure the validity and objectivity of systematic reviews from beginning to end (www.campbellcollaboration.org; Higgins & Green, 2011). Researchers who complete systematic reviews for inclusion in the Campbell or Cochrane Collaboration libraries must adhere to these standards and agree to have all stages of their work reviewed by collaboration members to minimize any potential biases. Although bias can occur at each stage of completing a systematic review, particular attention is given to biases that may occur during the search for relevant research (e.g., publication bias, unreliable coding strategies, or language bias), the extraction of data from the individual studies (e.g., poorly defined methods or missing information), the synthesis of the findings, and the conclusions presented in the final report. Possible

conflicts of interest by the researchers that may bias the final review or the way it is conducted are also carefully assessed. Detailed information on the ways in which the Campbell and Cochrane Collaborations strive to minimize bias and increase the validity of systematic reviews published in their libraries can be found at www.campbellcollaboration.org and <http://handbook.cochrane.org/>.

Not all systematic reviews are conducted under the watchful eyes of the Campbell or Cochrane Collaborations. Two appraisal strategies are available to meet the needs of practitioners with limited time to conduct a critical appraisal of reviews published outside the domains of the Campbell or Cochrane Collaborations. A checklist developed by Bronson & Davis (2012) helps social workers quickly evaluate the transparency, completeness, methodological soundness, credibility, and practice relevance of systematic reviews for practice decision-making. Deficits in any of these areas compromise the overall validity of the review. Similarly, the Centre for Evidence-Based Medicine at Oxford developed a *Systematic Review Appraisal Sheet* (<http://www.cebm.net/>) that asks the following questions:

- *What question did the systematic review address? Was the problem clearly defined?*
- *Is it unlikely that important, relevant studies were missed? That is, how extensive was the search for relevant studies and was it described with enough detail to be replicated? Did it include studies from the major electronic databases, unpublished studies, and non-English studies?*

- *Were the criteria used to select articles for inclusion appropriate?* The inclusion and exclusion criteria should be clearly defined. In addition, the reliability of reviewers' coding should be checked to ensure that the inclusion and exclusion criteria are consistent applied.
- *Were the included studies sufficiently valid for the type of question asked?* This refers to the extent to which the quality of the studies was appraised before including them in the systematic review.
- *Were the results similar from study to study?* The results of a systematic review are more trustworthy if all of the studies have treatment effects going in the same direction (Straus et al., 2011).
- *What were the results and how were they presented?* Was a meta-analysis conducted, were the methods clearly described, and were the results presented using a standard metric and displayed on a forest plot?

These easy-to-use appraisal strategies can help us decide whether the systematic review meets the minimal standards for validity; there are many reviews in the published literature identified as "systematic" that, in fact, do not meet the standards.

APPRAISING CREDIBILITY

The credibility of the research is often overlooked in the appraisal process (Carlson, 1995), and yet the believability and trustworthiness of the study must be considered. If one reads an article in the newspaper reporting on the results of research demonstrating the benefits of chewing gum for stress reduction one might question the credibility of the report if the research was paid for by a company that produces chewing gum. Similarly, studies completed by social work researchers who receive funding from an ideologically driven foundation or researchers who gain financially from the success of an intervention they developed should receive extra scrutiny. There are many factors that contribute to the overall credibility of a study. Appraising the credibility of research is largely a matter of judgment, and one's ability to judge will depend on the completeness and transparency of the report.

A credible report is a readable report. One of the persistent barriers between research and practice has been inability of researchers to

communicate with practitioners in a manner that promotes the transfer of knowledge to practice settings. Research should be reported in a clear, user-friendly manner that facilitates understanding and minimizes jargon. It is impossible to appraise critically the validity or credibility of research that is poorly written (Egger, Smith, & O'Rourke, 2001).

To give us the information we need to adequately judge the credibility of published systematic reviews, standards have been developed to ensure that all pertinent information is presented in the final systematic review report. Campbell and Cochrane reviews also include user abstracts that summarize the findings in language that is usable for policy makers and practitioners. "As with all research, the value of a systematic review depends on what was done, what was found, and the clarity of reporting" (Moher, Liberati, Tetzlaff, Altman, 2009, p. 332). To this end, the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) was created to guide authors in the preparation of the written reports and to provide standards for journals to adopt for publishing systematic reviews. PRISMA consists of a 27-item checklist that indicates what should be included when reporting on a systematic review or meta-analysis. The authors who follow PRISMA in preparing their summary reports are more likely to offer a clear and complete presentation of their methods and findings. This, in turn, will allow one to better assess the believability or credibility of the final report.

Having access to detailed background information about the author of a systematic review will also allow one to evaluate possible personal biases that may have infiltrated the systematic review or meta-analysis. Most journal articles provide information on the author's place of employment and the source of funding for the research. This information may provide some insight into any ideological biases or prejudices that could impact the research. The Campbell and Cochrane Collaborations also have called for researchers to provide information on possible conflicts of interest or previous research activities that might influence the conduct or conclusions of the current project. Finally, in a comprehensive and transparent research report, the author will clearly state the purpose for conducting the research and will honestly report the evidentiary status of the research. Taken together (see Table 153.2), information on the researcher's background, the source of funding, and the

TABLE 153.2 Assessing the Credibility of the Research

-
1. Detailed information is provided about the researcher, including place of employment, previous research, and potential conflicts of interest.
 2. Information is provided about the funding for the research and the funding organization.
 3. Information about possible financial gains for the researcher associated with the outcomes of the research are presented.
 4. The author has clearly presented the purpose of the research.
 5. The research report appears to be transparent and the reporting is honest about the evidentiary status of the research.
-

overall quality of the written report based on the PRISMA standards will help readers appraise the believability and credibility of the research as they consider its applicability to practice.

APPRAISING RELEVANCE

Assessing the relevance of the research allows one to judge whether the changes attributed to the intervention are likely to generalize to other settings when the treatment is implemented with other clients and by different therapists (see Table 153.3). The relevance of a study for social work practice and policy depends on the external validity or generalizability of the results. External validity is especially important when deciding whether an intervention can be adopted in a practice setting. Unfortunately, there is often a trade-off between internal and external validity. For example, research that takes place in a highly controlled setting may achieve good internal validity, but the generalizability of the findings may be reduced. If given the choice, researchers usually will strive for internal validity over external validity (Campbell & Stanley, 1963). This preference has led to the proverbial gap between research and practice and underscores the need for assessing the external validity and relevance of research.

To assess the external validity and relevance of a study, it is important to determine whether the subjects, setting, and therapists in the research are similar (i.e., representative of) the

TABLE 153.3 Assessing the External Validity and Relevance of the Research

-
1. The sample used in the study is representative of people for whom the intervention/treatment will be used.
 2. The results of the study can reasonable be generalized to:
 - A larger population
 - A smaller population (small group or individual)
 - A group of similar size
 3. The study provides detailed information on the following:
 - The subjects of the research
 - The setting in which the treatment was delivered
 - Characteristics of those who provided the intervention
 4. The intervention has been replicated with other populations, in other settings, or with other therapists.
 5. The intervention can be disseminated (i.e., training materials and manuals exist).
-

clients one is serving and the setting in which one is working. Generalizations from research can extend from (1) a small group of subjects to a larger population, (2) a large experimental group to a small group or individual, or (3) one similarly sized group to another (Shadish, Cook, & Campbell, 2002). It is important to consider the type of generalizations that can be made from the research as one appraises its external validity.

Appraising a study's external validity and relevance is largely a matter of subjective judgment. A good research report will describe how subjects were selected for the study and provide detailed information on client demographics, the environment in which services were delivered, and characteristics of the service providers (e.g., training, experience, education, and personal characteristics).

Finally, the generalizability of research findings is more likely if the study has been replicated with other subjects, in other settings, or by other researchers. This requires searching the bibliographic databases for similar studies that evaluate the intervention. The generalizability of the research also will be enhanced by the availability of training materials and manuals to facilitate the dissemination of the intervention. Training materials help ensure that there is treatment

fidelity when the intervention is implemented in diverse settings.

CONCLUSIONS

Critically appraising the validity, credibility, and relevance of research reports and systematic reviews is a fundamental skill in becoming an evidence-based practitioner. Adopting a critical perspective does not end, however, with the appraisal of the research. It is equally important to be aware of any possible biases one might bring to the critical appraisal process. Examining one's own biases or practice preferences will help avoid the "I'll-see-it-when-I-believe-it" syndrome (Gilovich, 1993) characterized by a tendency (1) to identify and remember research that supports one's own preferences, (2) to be less likely to search for disconfirming evidence, (3) to be less critical of research that supports one's biases, and (4) to be highly critical of research that does not (Kahneman, Slovic, & Tversky, 1982). One way to minimize this tendency is to subject all research to the same evaluative criteria, using a systematic approach to critically appraising the studies.

Critically appraising the available evidence for evidence-based practice involves a basic knowledge of research methods, critical thinking, a willingness to challenge one's own biases, and the use of a systematic approach to assess the quality of a study. Although it is not an exact science, carefully examining the validity, credibility, and relevance of a study will reveal the strengths and limitations of the research and enable practitioners to judge the value of the research for clinical practice. These are essential activities for evidence-based practice in social work. Practitioners who routinely apply critical appraisal skills to their reading of the research literature will be prepared to use the best available evidence to guide practice decision-making and will usher in a new era that promotes the integration of social work research and practice.

154 Randomized Controlled Trials and Evidence-based Practice

Paul Montgomery & Evan Mayo-Wilson

Randomized controlled trials (RCTs) are commonly used to determine whether interventions are effective. Simply, RCTs include at least two groups, usually an intervention group and a comparison group. Participants typically have an equal chance of being assigned to either group. Clients are normally allocated individually, but trials might assign multiple individuals (e.g., by classroom, nursing home, or drug treatment center). These are called *cluster randomized* trials (Boruch, 2005). Intervention and comparison groups are usually assessed before and after intervention.

RCTs provide:

- Top-quality evidence of safety and effectiveness
- Limitation of researcher bias
- Identification of causes.

This chapter explains the key features of RCTs, how to critique them, and how to use them in practice. To illustrate the main features and benefits of RCTs, the chapter includes two case studies.

CASE STUDIES

Booklets for Children with Sleep Problems

This study was about the sleep problems of children with learning disabilities (mental retardation) conducted in the community by Montgomery, Stores, and Wiggs (2004). Sleep problems in this population are severe, common, and generally considered difficult to treat. It is known that the best form of intervention is behavioral, but scarce resources limit access to these treatments. This study aimed to investigate a brief behavioral treatment of sleep problems by randomizing children and their parents to receive (1) face-to-face delivered treatment, (2) booklet-delivered treatment, or (3) no treatment. The participants were the parents of 66 severely learning disabled children aged 2–8 years with settling or night waking problems. A composite sleep disturbance score was derived from sleep diaries kept by parents.

The study found that both forms of treatment were almost equally effective compared with wait-list control. Two-thirds of children initially were taking over 30 minutes to settle five or more times per week and waking at night for over 30 minutes four or more times per week. They improved on average to having such settling or night waking problems for only a few minutes or only once or twice per week ($H = 34.174$, $df = 2$, $p < 0.001$). These improvements were maintained after 6 months. It was known before the study began that these behavioral interventions are the most effective treatments available. This study assessed their effectiveness when delivered by booklet. The study used wait-list controls so that participants in the comparison group received an intervention after 6 weeks. This is known as a *crossover* design. In conclusion, it found that booklet-delivered behavioral treatments for sleep problems are likely to be as effective as face-to-face treatment for most children in this population.

In this example, the participants, interventions, key outcome measure, and comparison groups were clear and explicit. Social workers dealing with such children now have a cheap, simple intervention to offer parents. They can be sure that the results were unbiased and that both the booklet and face-to-face behavioral treatment are effective.

Cambridge-Somerville Youth Study

The Cambridge-Somerville Youth Study tested an intervention to reduce childhood delinquency (McCord, 1978). It was based on the theories of Richard Clark Cabot, a professor of clinical medicine and social ethics at Harvard University and president of the National Conference in Social Work. Cabot believed that childhood delinquency was related to poor home environments. He thought social workers could act as a positive force in the lives of children. Therefore, he designed an intervention to target at-risk boys under age 12; to avoid stigma, low-risk boys were included as well. Boys were matched in pairs; one in each pair was assigned to the treatment group on the basis of a coin toss. Recruitment began in 1935 and follow-up of 506 participants began in 1942.

Intervention

- Build close relationships and provide assistance to boys and their families.
- Provide counseling and referrals to specialists.
- Provide academic tutoring, participation in sports, and a woodwork shop operated by the study.
- Summer camp
- Families receive help with problems (e.g., illness and unemployment).

The program lasted until 1945, at which time boys in the intervention group had received about 24 annual visits for more than five years. By 1948, some surprising results had emerged. Court records found that more boys in the *treatment* group had been charged with a crime and had been charged with more offenses (264 vs. 218). In 1979, when the men were 47 years old, 248 men in the treatment group and 246 men in the control group were located. Most participants in the treatment group said the program had helped them by keeping them out of crime and off the streets. However, these participants were more likely to have been convicted of crimes indexed by the Federal Bureau of Investigation. They were more likely to have been diagnosed as alcoholic or to have a severe mental illness. They were more likely to have died. Furthermore, participants who received more of the intervention were more likely

to have adverse outcomes (a *dose-response* relationship).

Several theories may explain why the study had such adverse effects. For example, the intervention may have increased unsupervised time with other delinquent children, increasing the chance that children would brag about delinquent behavior and encourage misbehavior. Though a rigorous evaluation showed the intervention had adverse effects, the Cambridge-Somerville Youth Study was a theoretically sound, well-planned intervention. It was led by experts, delivered by skilled practitioners, and carefully implemented. Although the intervention was well received by participants and their families, it clearly caused long-term harm. An RCT to test the effectiveness of this intervention may have prevented further harm to thousands of boys.

KEY FEATURES OF RANDOMIZED CONTROLLED TRIALS

Well-performed, large randomized trials are the best evidence of intervention effectiveness (Altman, 1991). They are better than any other study design at demonstrating causal relationships. All RCTs are *prospective*, that is, forward-looking, which is necessary for testing causal hypotheses. For A to cause B, A must happen before B. By following a group over time, RCTs can measure change in an outcome that can be attributed to the independent variable, the intervention (Hill, 1965).

Unlike studies using quasiexperimental methods (e.g., a one-group before-and-after comparison), RCTs offer a reliable *counterfactual* scenario. That is, the comparison group shows what would have happened to participants if they had been treated differently. Groups of participants in nonrandomized studies may differ due to *selection bias*. Imagine you want to know whether group therapy is helpful for heroin users. You could compare people in a group therapy program with other heroin users, but they would probably differ in several ways. For example, the people in group therapy might be more committed to change.

Randomization is the best way to eliminate differences between groups on known as well as *unknown* variables. Splitting a small group by chance could result in *unbalanced* groups, but as the number of participants increases,

randomization is increasingly likely to result in similar groups. To further reduce the likelihood of unbalanced groups, you could randomly assign subgroups (e.g., men and women) separately, thereby controlling a known variable while maintaining the benefits of randomization.

Splitting a study population by chance is the best way to eliminate *confounding variables*—variables other than the intervention that may influence the results—and the effects of selection bias. Additionally, randomization makes it difficult to predict which group a person will join if they enroll in the trial. It may not be possible to blind clients and practitioners in social work; however, it is always possible to blind the assessors, the people who analyze the results.

Before they begin enrolling participants, researchers must state who will be included in an RCT. Researchers must specify the *inclusion criteria*, for example, the age and sex of participants and the problems (e.g., insomnia) they must have. Researchers must also specify the *exclusion criteria*, that is, the reasons a person would not be allowed to participate. For example, for ethical reasons a study of Internet-based therapy for depression might exclude participants who are actively suicidal. Ideally, researchers will select participants like those seen in clinical practice so that the results generalize to real-world settings. In summary, well-designed RCTs will possess the following features:

- Prospective, that is, forward-looking
- Minimal selection bias
- No confounding variables
- Control for known and unknown variables
- Explicit inclusion and exclusion criteria
- Allocation that can be concealed
- Researchers and assessors who can be blinded.

ARE RANDOMIZED TRIALS ETHICAL?

Many social workers believe that RCTs are unethical because (1) participants in one group may not receive an intervention, and (2) practitioners may not be able to offer what they think is the most effective intervention for a problem. These valid concerns apply to many types of research. On the other hand, well-intentioned

interventions can have no effect, thereby wasting time and resources. Worse, they can cause harm, as in the Cambridge-Somerville Youth Study. Researchers and practitioners must balance ethical values to determine when RCTs are necessary and appropriate. RCTs may be justified when:

- It is unclear whether an intervention has positive effects.
- It is unknown whether one intervention works better than another.
- An intervention may cause harm (e.g., through unwanted side effects).
- The costs/benefits of an intervention are unknown.

Though we often have good reason to think a particular intervention will have positive effects, questions of treatment effectiveness can only be resolved through empirical investigation. If you developed a new intervention, you would start with a theory and design a strategy to achieve positive impacts for your clients. To be thorough, you would consider reasons the intervention might not work, ways it might harm participants, and whether the benefits would be worth the cost. Based on your knowledge of the problem, the available resources, and your client's characteristics and preferences, you would make a guess about the outcomes of your treatment. But how would you demonstrate that it worked? How would you know what would have happened if you had acted differently, or whether the burden on participants was worth the payoffs? Maybe another intervention would have been more efficient, thereby increasing resources to serve other clients.

Researchers refer to this uncertainty as *equipoise*, not knowing whether one thing is better than another. Randomized trials are the best way of resolving this uncertainty. They can show whether interventions have beneficial effects. Furthermore, RCTs can be designed to overcome many common ethical objections. For example, they can involve multiple treatment arms in which participants in *all* groups receive help. A trial might be designed to compare a new, untested intervention to *treatment-as-usual*, that is, the normal form of care (e.g., a social worker and the client choose an intervention). A wait-list comparison group is a common solution to ethical concerns whereby all participants receive the intervention sooner or

later. However, long-term comparisons between groups are impossible once everyone in the study has received the intervention.

Randomized trials should test interventions that match the goals and values of clients. To be ethically justified, they must resolve an important uncertainty about the effectiveness, safety, or relative benefits of an intervention.

UNDERSTANDING RANDOMIZED CONTROLLED TRIALS

As with any other study design, some RCTs will be better than others. Although there are many strengths to the method, not all RCTs are of high quality. Before using the results of a trial, you will need to assess the study's validity and applicability to your own situation (Fraser et al., 2009). Interventions being investigated should be described precisely. What use is a trial on an intervention if you do not have enough detail to replicate the intervention as it was conducted? This should include details about how the intervention was delivered (e.g., its frequency and duration). Often, study authors publish manuals of their interventions, and this information may be provided in a separate paper.

Interventions should be delivered in a replicable ways. You may think there is little point in having results from a study that cannot be used in everyday social work. With this in mind, the delivery of the intervention, the resources required, and the role of participants should be considered. Did the investigators check that the intention was delivered properly? Did the clients actively participate? For example, if a trial of cognitive-behavioral therapy showed that it does not work for depression, you might ask yourself whether all the therapists performed the same sort of treatment or whether the clients were able to attend all sessions (Montgomery et al., 2013).

The population under study needs to be well described so that the reader knows what sort of clients joined the study and which sort were excluded (Grant et al., 2013). If an intervention worked for people between 18 and 35 years of age, would you use it for an 85-year-old client? A precise description of the population is necessary for you to determine whether you can apply the study's results to your clients. The measures used in the study need to be clear. If meaningful, well-validated instruments are used, then

the trial will be all the more useful. Often, objective measures are better than subjective questionnaires. For example, if you wanted to know whether an intervention for truant children improved school attendance, you would be interested in the number of days children attended school; you might be less interested, when assessing efficacy, in a trial measuring children's attitudes toward school.

Comparison groups should be realistic. If a new intervention is under study, it may be most useful to compare it to the usual form of care rather than to no intervention. Comparing an intervention to something that your clients would never receive does not provide useful information. The method by which study participants are randomized should be described. Even subconsciously, researchers can influence results. Methods of randomization should not be vulnerable to influence by the researcher. To ensure that selection bias does not confound the results of a trial, researchers should assign participants by pulling numbers from a hat, applying a computerized random number generator or some similar process. Assigning people by other means (e.g., alternating assignment) is *not* random and could introduce confounding variables. For instance, if randomization was done by giving participants who attended a social work clinic a particular intervention according to the day of the week, the effect of the intervention might be confused with the impact of different staff with varying levels of skill who work different days of the week. Furthermore, these methods make it difficult to maintain *allocation concealment* because one can predict a participant's assignment before enrolling the participant in the trial. To prevent this, a person unconnected to the trial should control the allocation of participants. For example, a statistician might generate a random number list. After a social worker assesses a potential trial participant, the social worker should call the statistician to find out his group assignment. To prevent bias at later stages, it may be important to blind people involved in the trial.

Finally, there should not be too many outcome measures. If researchers have too many, the chances of finding a positive result by chance will increase. That is to say, at a 5% significance level, 1 in 20 measures will be positive as a result of chance alone. For this reason, studies might have only one primary outcome and perhaps two or three secondary measures.

THE ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

Figure 154.1 is a flow chart showing how the participants moved through the study by Montgomery, Stores, and Wiggs (2004). Note that all the children randomized at the beginning are included in the final analysis.

This is known as an *intention to treat analysis*. Other types of analyses might be called *completers only*, *per protocol*, or *available case*. The method chosen may influence results considerably. For example, if participants found an intervention unacceptable, they might drop out of a study. An analysis of completers would disguise the fact that the intervention was not acceptable for many participants. Therefore, researchers should account for all people randomized, including those who dropped out of the trial. You may observe that some researchers “carry forward” data from baseline (i.e., assume that nothing has changed) or assign mean values to missing cases (which may inflate the apparent benefits of an intervention). If a study does not account for participants who dropped out, you should consider what impact this could have had on the results.

Statistics

Most RCTs use statistical tests that compare two groups. They may also report some trends and correlations. Some of the more frequently used tests are shown in Table 154.1. It is important to think whether the researchers used the correct test to be certain of the results. Table 154.1 describes some statistical methods used to analyze RCTs.

HOW TO RECOGNIZE A GOOD RANDOMIZED CONTROLLED TRIAL

Asking the following questions when considering a randomized trial will help assess its quality.

Was the Study Valid?

Think about the similarity of the groups. Was the intervention the only thing that was different? Aside from the intervention, were the two groups treated in the same way? Were outcomes influenced by biased assessment? Was allocation concealed, and were people blinded as required? Did everyone in the intervention

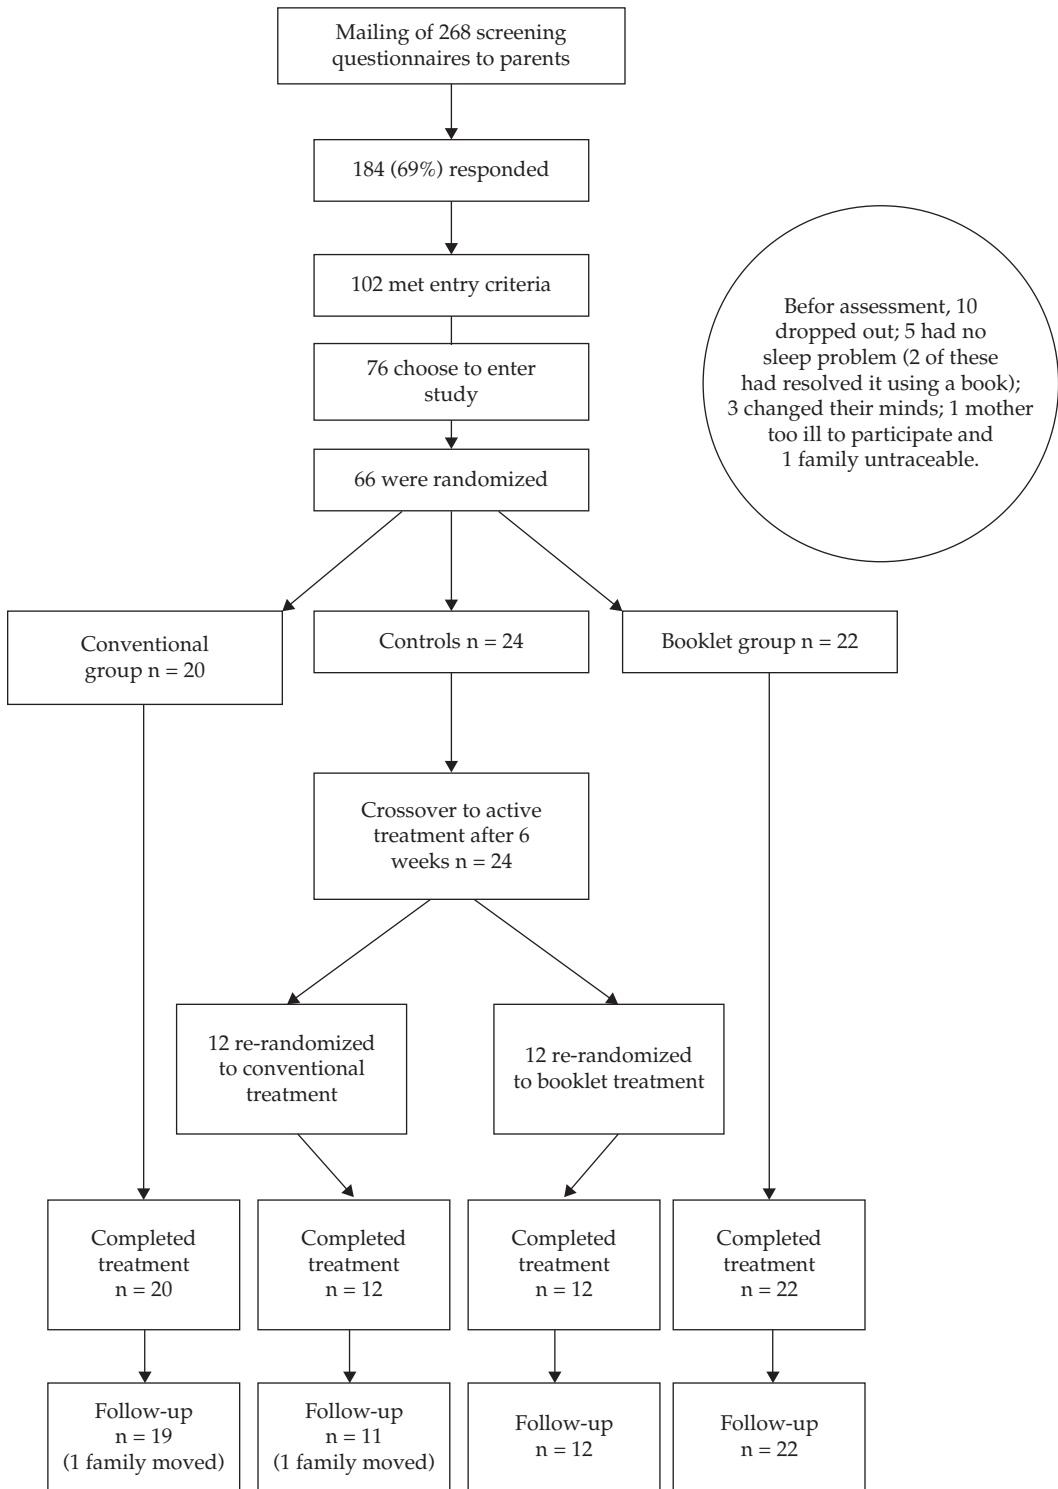

Figure 154.1 Flow of participants through the study.

group receive the intervention, and did anybody in the comparison group receive the intervention (this is sometimes called *contamination*)? Could missing data and dropout have influenced the results? Were the outcomes, measures, and analyses selected in advance and reported completely? Was the trial registered in advance (e.g., with ClinicalTrials.gov) and if so, did the researchers report results as intended (Higgins & Green, 2011)?

What Were the Results?

How large was the effect? Is this *clinically significant* (i.e., would this change be meaningful to one of your clients)? Was it statistically significant, or could it have been the result of chance? Look for statistical tests like standard deviations and confidence intervals. If these are large, which is common in the case of small trials, this may lead you to conclude that individual differences between participants are

TABLE 154.1 Frequently Used Statistical Tests

Parametric Test	Nonparametric Test Version	Purpose of Test	Example
Two-sample (unpaired) <i>t</i> test	Mann-Whitney U test	Compares two independent samples drawn from the same population	To compare the group that received the booklet with those who were in the control group
One-sample (paired) <i>t</i> test	Wilcoxon matched pairs test	Compares two sets of observations on a single sample	To compare sleep duration within one group before and after intervention
One-way analysis of variance (<i>F</i> test) using total sum of squares	Kruskall-Wallis analysis of variance by ranks	Effectively, a generalization of the paired <i>t</i> or Wilcoxon matched pairs test where three or more sets of observations are made on a single sample	To compare more than two observations, for example, booklet versus face-to-face versus control
Two-way analysis of variance	Two-way analysis of variance by ranks	As above, but tests the influence (and interaction) of two different covariates	In the above example, to determine if the results differ in girls versus boys
	Fisher's exact test	Tests the <i>null hypothesis</i> that the distribution of a discontinuous variable is the same in two (or more) independent samples	To assess whether the responders to an intervention were from a particular subgroup, for example, a particular ethnicity
Correlation coefficient (Pearson's <i>r</i>)	Spearman's rank correlation coefficient (r_s)	Assesses the strength of the straight line association between two continuous variables	To assess whether sleep duration correlates with severity of learning disability

substantial, in which case the intervention may not be reliable.

Are the Results of This Trial Useful for My Clients?

To assess the *generalizability* of the study, consider the degree to which your clients are like those in the trial. Did the trial include everyone who might benefit from the intervention? Did it exclude people with the characteristics and problems you see in your practice? Was the setting similar to your setting? Could you perform this intervention or afford this intervention? Consider whether the measures reported are what you are really interested in knowing. Remember RCTs are about groups, and their results may not apply directly to your client (this is called the *ecological fallacy*).

CONCLUSION

RCTs are the strongest form of experimental evidence in intervention studies. They should be preferred over other comparison studies because they minimize bias and eliminate confounding factors of all kinds, known and unknown. Ethical concerns can be addressed in a number of ways (Sheldon & MacDonald, 2006). If more RCTs can be performed in social work, the field will have a much stronger evidence base to ensure that effective interventions are delivered without harming clients and that the benefits of this work outweigh its costs.

155 Meta-analysis and Evidence-based Practice

Jacqueline Corcoran & Julia H. Littell

Evidence-based practice (EBP) is defined as the integration of the best available research evidence with clinical expertise and client values to make informed decisions in individual cases. Systematic reviews and meta-analyses can contribute to the evidence base for social work practice and policy by providing thorough and unbiased summaries of empirical research. (See Littell, Corcoran, & Pillai, 2008, for an elaboration of points made in this chapter.)

Meta-analysis is the quantitative synthesis of data from multiple studies. It uses statistical methods to estimate average effects across studies, identify differences between studies, and suggest possible explanations for those differences.

How does meta-analysis differ from systematic review? A systematic review aims to comprehensively locate and synthesize the research literature that bears on a particular question. If results lend themselves to the synthesis of findings from two or more primary studies, then a systematic review can include meta-analysis, the focus of this chapter.

Meta-analyses offer many advantages over other methods of summarizing results of quantitative studies, including:

- Better estimates of population parameters (more accurate representation of phenomena in the population of interest)
- Ability to assess multiple outcomes (a separate meta-analysis can be conducted for each relevant outcome domain when data are available)
- Systematic accounts for moderators (participant, treatment, or study design characteristics) that influence outcomes

- Tests and adjustments for biases that can be introduced by small samples and publication processes.

Meta-analyses have disadvantages as well.

- They cannot make up for poor quality in the original studies.
- Combining results across different types of studies, treatments, samples, settings, and/or outcomes is not always appropriate.
- Meta-analysis relies on effect sizes, which are not easily understood by many people.

Many of the disadvantages can be eliminated or minimized through correct applications of meta-analytic procedures. These procedures are explained in more detail in Littell et al. (2008), Lipsey and Wilson (2001), and Petticrew and Roberts (2006).

EFFECT SIZES

The ability to synthesize studies is informed by converting the results of original studies to common metrics, called effect sizes, which are then combined across studies. An *effect size* (ES) is a measure of the strength (magnitude) and direction of a relationship between variables. The choice of ES measures is influenced by the purpose and design of a study and the format of the data. Most ES metrics fall into three main categories, related to proportions (univariate proportions or averages can be derived from multiple studies), correlation coefficients (studies that assess relationships between variables without inferring causal directions are likely to report

measures of association), and means. Studies that test intervention effects and other kinds of causal inferences typically report differences (e.g., between treated and untreated groups) in terms of proportions or average scores.

The *standardized mean difference* (SMD) is useful when scores are reported in different ways or different scales are used to assess the same construct. The SMD, also known as Cohen's *d* (Cohen, 1988), is the mean difference divided by the pooled standard deviation of the two groups. The SMD is probably the most well-known ES.

For dichotomous data (received a certain screening or not), the most commonly used ES measures are the *odds ratio* (OR) and the *risk ratio* (RR). *Odds* refer to the chance that something will happen compared to the chance that it will not. *Risks* are probabilities.

Although effect size provides a crucial index of the average effect within and across studies, it is not easily understood by many people. Therefore, an ES can be translated into metrics that have meaning for clinicians and policy makers. For example, dichotomous data can easily be converted from risks to percentages. Cohen (1988) also proposed standards for interpreting OR, SMD, and correlation coefficients.

META-ANALYTIC METHODS IN BRIEF

In meta-analysis, effect sizes from individual studies are presented, along with their confidence intervals, in graphs called Forest plots. The confidence intervals give us a "margin of error" for each ES and tell us whether the ES is statistically significant (if the confidence interval includes the region of no difference, the effect is not significant).

Study effect sizes are then pooled (averaged) together using weighting procedures that allow more precise effect sizes, as well as those from larger studies, to make a greater contribution to the overall average than results that are less precise (including results of smaller studies). These procedures are called inverse variance weighting. There are several ways to do this. Some meta-analyses assume that all studies are estimating the same population effect size; others do not make this assumption. The former use "fixed effect" models, the latter use "random effects."

Meta-analysts can compute effect sizes for subgroups of interest (e.g., separate effects for girls and for boys) and test to see whether

differences between subgroups are significant (using moderator analysis). They can assess the influence of decisions made during the review process (using sensitivity analysis) and can assess and adjust for the influence of publication bias and small sample bias on results.

IMPLICATIONS FOR PRACTITIONERS

Practitioners should be able to locate and understand a publication on meta-analysis because it can summarize a whole body of knowledge on a certain topic of interest. As with systematic reviews, the first places to look for meta-analyses are the online libraries maintained by the non-profit Cochrane Collaboration and Campbell Collaboration. The Cochrane Collaboration synthesizes results of studies on effects of interventions in health care, and the Campbell Collaboration synthesizes results of research on interventions in the fields of social welfare, education, criminal justice, and international development. Both the Cochrane and the Campbell Collaborations produce systematic reviews and meta-analyses (when there are enough studies) to inform decisions about health and social programs and policies. These are usually the best places to search because their meta-analyses tend to be high quality. However, these databases do not have reviews on every possible topic. Therefore, it may be necessary to search library databases, such as PsycINFO and Medline/PubMed, running key words related to the topic with "meta-analysis."

The methodology and the statistics of meta-analysis can become quite complex, so the lay reader should probably look to the "plain language summaries" of the Cochrane Collaboration, the synopsis and the abstract of the Campbell Collaboration, and the abstract and discussion sections of articles on meta-analysis. In order to understand some of the essential elements that comprise meta-analysis, we will provide a summary of two meta-analyses that have relevance to practitioners (see Table 155.1).

CONCLUSION

Meta-analysis can be used to synthesize information on many topics that are important for social work practice and social policy. Because meta-analysis is time-consuming and requires trained discipline, it is not likely to be conducted

Author and Purpose	Inclusion Criteria	Sample	Results
<p>Lipsey, Landenberger, & Wilson (2007). To systematically review the effectiveness of cognitive behavioral therapy (CBT) treatment with criminal offenders in terms of reoffending. A secondary purpose was to examine moderators that influenced variation in effect size.</p>	<p><i>Participants:</i> "criminal offenders, either juveniles or adults, treated while on probation, incarcerated, institutionalized, or during aftercare/parole" (p. 7). <i>Intervention:</i> Cognitive-behavioral treatment. <i>Designs:</i> Randomized or matched nonrandomized group designs that compared CBT to a non-CBT condition. <i>Studies:</i> Published and unpublished studies from any country and written in any language <i>Outcome:</i> Criminal offending after treatment Years included: 1965 to 2005</p>	<p>$N = 58$ studies met inclusion criteria. More adult than juvenile samples; treatment was typically less than 20 weeks; 50% of the studies involved incarcerated participants; predominantly male samples; treatment providers tended to evidence little mental health background and received minimal training.</p>	<p>CBT programs resulted in a 25% decrease in offending recidivism over control conditions. No differences between adult and juveniles in terms of outcomes. Programs that were implemented well and offered critical elements of CBT (anger control and interpersonal problem solving) showed more positive effects. People who are at higher risk to reoffend did better as a result of CBT than low-risk offenders.</p>
<p>Wilson & Lipsey (2006) examined the effectiveness of social information processing programs implemented in the school setting for youth identified with anger and behavior problems. Social information processing programs are a type of cognitive-behavioral treatment.</p>	<p><i>Participants:</i> School-aged children (kindergarten through 12th grade) selected for intervention because of behavioral problems or for risk factors associated with behavioral problems (such as high activity). <i>Interventions:</i> Focus on social information processing. <i>Designs:</i> Randomized and matched nonrandomized designs with a control group (defined as no-treatment, wait-list, or treatment-as-usual, not another treatment). <i>Studies:</i> Any country, both published and unpublished studies. <i>Outcome:</i> Behavior or externalizing problems.</p>	<p>$N = 47$ studies 90% published in United States, mostly male samples, 40% with low socioeconomic status (SES) samples, 45% of studies comprised children 9–11 years, mainly group-based interventions</p>	<p>Participants in social information processing treatment evidenced fewer aggressive/behavioral problems after treatment compared with controls. Moderator analysis: children who were already showing problems did better than those who were at risk for problems; children in special education settings showed less improvement than others; groups were more effective than one-on-one interventions; longer programs and those that were better implemented had better outcomes.</p>

by practitioners or policy makers. However, the information gleaned from meta-analysis can be a tremendous contribution to consumers, practitioners, and policy makers who want to use accurate assessments of current knowledge to inform their choices. Meta-analysis can minimize sampling error and bias in attempts to synthesize the growing body of empirical research relevant to social work. Thus, it has an important role in the development of knowledge for human services.

156 Systematic Reviews and Evidence-based Practice

Julia H. Littell & Jacqueline Corcoran

Systematic reviews can contribute to the evidence base for social work practice and policy by providing thorough and unbiased summaries of empirical research. A systematic review aims to comprehensively locate, critically appraise, and synthesize results of empirical research that bears on a particular question. If results lend themselves to a statistical synthesis, then a systematic review can also include meta-analysis.

Gibbs (2003) and others have shown practitioners how to find, critically appraise, and use empirical evidence to inform practice. "Ideally, practitioners should be able to rely on reviewers to isolate the best evidence for them and to distill it

for its essence to guide practice decision-making. Unfortunately, conventional reviews have fallen far short of such expectations" (Gibbs, 2003, p. 153). Traditional research reviews are often "haphazard" (Petticrew & Roberts, 2006). They tend to rely on convenient samples of published studies and unclear methods of assessment and synthesis; as a result, they are vulnerable to biases of researchers, reviewers, and publication and dissemination processes (Littell, 2008). Unfortunately, many lists of "evidence-based practices" are based on traditional review methods. Because practitioners and policymakers rarely have the time to locate and critically appraise

original studies themselves, unbiased reviews of empirical research are needed to provide reliable summaries of evidence for practice and policy.

Systematic reviews are designed to compensate for the weaknesses of traditional reviews of research. Systematic reviews can provide transparent, comprehensive, and unbiased analyses and summaries of available research on a particular topic that is relevant for social work practice and social policy.

The phrase “systematic review” connotes a scientific approach to every step in the review process, combined with the use of specific methods to minimize bias and error. Unfortunately, this term has been used rather loosely in the social work and social science literature. So-called systematic reviews vary in quality and credibility. Therefore, it is important for practitioners to understand what systematic reviews are and how to evaluate them.

In this chapter, we describe the steps in the systematic review process. We consider different types of systematic reviews and provide examples. Finally, we offer suggestions for finding systematic reviews and guidelines for evaluating them.

STEPS IN A SYSTEMATIC REVIEW

Systematic reviews are observational studies that follow the basic steps of the research process. These steps include problem formulation and planning, sampling, data collection, data analysis, interpretation, and presentation of results (Cooper & Hedges, 1994). In a systematic review, previous studies are identified and analyzed. Specific steps in a systematic review are listed next.

1. Problem formulation and planning
 - Develop a set of clearly formulated objectives and specific, answerable research questions or hypotheses.
 - Form a review team with the necessary substantive, methodological, and technical expertise.
 - Create explicit inclusion and exclusion criteria that specify the problems or conditions, populations, interventions, settings, comparisons, outcomes, and study designs that will and will not be included in the review.
 - Develop a written *protocol* that details in advance the procedures and methods to be used.
2. Sampling: Identification and selection of relevant studies
 - In collaboration with information specialists, identify and implement a comprehensive and reproducible strategy to identify all relevant studies. This includes strategies to find unpublished studies.
 - At least two reviewers screen titles and abstracts to identify potentially relevant studies.
 - Retrieve published and unpublished reports on potentially relevant studies.
 - Determine whether each study meets the review’s eligibility criteria. Two reviewers judge each study, resolve disagreements (sometimes with a third reviewer), and document their decisions.
3. Data collection
 - Reliably extract data from eligible studies onto standardized forms. Assess inter-rater reliability, resolve disagreements, and document decisions.
4. Data analysis
 - Describe key features of included studies (in a narrative, tables, and/or graphs).
 - Systematically and critically appraise the qualities of included studies.
 - When possible, present study results in effect size metrics, with 95% confidence intervals.
 - If a systematic review lends itself to combining quantitative results of two or more primary studies, then it can (and often should) include meta-analysis.
5. Interpretation and presentation of results

Interested readers can find detailed explanations of these steps and the procedures and methods used in systematic review elsewhere (see Cooper & Hedges, 1994; Higgins & Green, 2006; Littell, Corcoran, & Pillai, 2008; Petticrew & Roberts, 2006).

TYPES OF SYSTEMATIC REVIEWS AND EXAMPLES

Any question or topic that can be addressed with empirical research methods can also be the subject of a systematic review of prior studies. To date, most systematic reviews have focused on effects of health care and social interventions. These reviews tend to include randomized

controlled trials (RCTs) when those studies are available, because they usually provide the most credible evidence of intervention effects. The Cochrane Collaboration has produced approximately 3,000 systematic reviews of RCTs on effects of health care interventions, including pharmacological, medical, and psychosocial treatments for HIV/AIDS, mental health, substance abuse, and related medical and social problems.

Some systematic reviews include other types of studies, either in addition to or instead of RCTs. This is because other study designs can sometimes provide credible evidence of effects or because the reviewers may be interested in other kinds of questions. Systematic reviews produced by the Campbell Collaboration focus on effects of interventions in social care (education, crime and justice, and social welfare), and they include RCTS as well as other study designs. Topics that have been covered include effects of interventions aimed at preventing teenage pregnancy, welfare-to-work initiatives, cognitive-behavioral therapies for specific conditions, after-school programs, volunteer tutoring programs, drug treatment programs, parent training, and so forth.

Creative synthesis of qualitative data from naturalistic studies has begun, sometimes in combination with systematic reviews of studies of intervention effects. For example, staff of the Evidence for Policy and Practice Information Centre (EPPI) Centre in London produced a mixed-methods synthesis that includes a systematic review of RCTs on effects of interventions aimed at improving children's healthy eating habits, along with a "views analysis" (content analysis) of themes that emerged from naturalistic studies of children's views of health and eating (Thomas et al., 2004). This approach provides information about intervention effects and the views of those who are the targets of these interventions.

Systematic reviews also have been used to synthesize observational studies and epidemiological data on the incidence and prevalence of various conditions. New methods are being developed to combine results of studies on the diagnostic and prognostic performance of assessment tests. For example, Aron Shlonsky and colleagues at the University of Toronto Faculty of Social Work have embarked on a Campbell review of the predictive validity of instruments that are used to assess the risk of child maltreatment.

Sometimes systematic reviews turn out to be "empty"—that is, reviewers could not find

any studies that met their inclusion criteria. The Cochrane Collaboration published such empty reviews because they provide useful information on current gaps in knowledge. This information has been used to set funding priorities for further research, especially in the United Kingdom.

FINDING SYSTEMATIC REVIEWS

The best systematic reviews can be found in online libraries (or databases) that have been developed and maintained by organizations devoted to the production and dissemination of rigorous, unbiased reviews. These groups provide free access to systematic reviews (or to their abstracts) on the Web. As mentioned, the Cochrane Collaboration produces and disseminates systematic reviews of interventions in health care. The Cochrane Database of Systematic Reviews is available online. The Campbell Collaboration synthesizes results of research on interventions in the fields of social welfare, education, criminal justice, and social development. The Campbell Library is also on the Web. The Centre for Reviews and Dissemination (CRD) at York maintains a large database of systematic reviews on a variety of topics in health and social care. Although the CRD databases include reviews that vary in quality, CRD staff members have provided some appraisal of the quality of most of these reviews.

If these sources do not contain reviews on topics of interest, it may be necessary to search regular bibliographic databases, such as PsycINFO and Medline/PubMed, running keywords related to the topic with "systematic review." These sources will produce reviews of varying quality.

The Cochrane Collaboration and other organizations provide useful plain-language summaries of systematic reviews. When such summaries are not available, readers should find useful information in abstract and discussion sections of reports on systematic reviews.

EVALUATING SYSTEMATIC REVIEWS

Systematic reviews can provide practitioners with useful summaries of large (or small) bodies of research. However, some systematic reviews are more thorough and careful than others. Because there are variations in the quality—and credibility—of systematic reviews, practitioners should know how to appraise systematic reviews critically.

Guidelines and standards for systematic reviews have been developed by the Cochrane Collaboration, the Campbell Collaboration, and others. To the extent possible, these guidelines are based on evidence about features of the research and review processes that minimize bias and error. Building on available guidelines and evidence, Shea and colleagues (2007) developed a

checklist for assessing the qualities of systematic reviews (AMSTAR). An adapted version of this checklist is shown in Table 156.1. This includes questions that readers should ask in evaluating the quality of a systematic review.

As shown in Table 156.1, systematic reviews should follow predetermined protocols. They should be based on independent judgments

TABLE 156.1 Assessing the Quality of Systematic Reviews

1. *Was a protocol developed in advance?*

The research question and inclusion criteria should be established before the conduct of the review.

2. *Was there duplicate study selection and data extraction?*

There should be at least two independent data extractors, and a consensus procedure for disagreements should be in place.

3. *Was a comprehensive literature search performed?*

At least two electronic sources should be searched. The report must include years and databases used. Keywords must be stated, and where feasible the search strategy should be provided. All searches should be supplemented by consulting current contents, reviews, textbooks, specialized registers, or experts in the particular field of study, and by reviewing the references in the studies found.

4. *Was the status of publication (i.e., gray literature) used as an inclusion criterion?*

The authors should state that they searched for reports regardless of their publication type. The authors should state whether they excluded any reports (from the systematic review), based on their publication status, language, etc.

5. *Was a list of studies (included and excluded) provided?*

A list of included and excluded studies should be provided.

6. *Were the characteristics of the included studies provided?*

In an aggregated form such as a table, data from the original studies should be provided on the participants, interventions, and outcomes. The ranges of characteristics in all the studies analyzed (e.g., age, race, sex, relevant socioeconomic data, disease status, duration, severity, or other conditions) should be reported.

7. *Was the scientific quality of the included studies assessed and documented?*

A priori methods of quality assessment should be developed and followed. Multiple questions or items about possible sources and types of bias are preferred to overall quality rating scales.

8. *Was the scientific quality of the included studies used appropriately in formulating conclusions?*

The results of the methodological rigor and scientific quality should be considered in the analysis and the conclusions of the review and explicitly stated in formulating recommendations.

9. *Were appropriate methods used to combine the findings of studies?*

For the pooled results, a test should be done to ensure the studies were combinable, to assess their homogeneity. If heterogeneity exists, a random effects model should be used and/or the clinical appropriateness of combining should be taken into consideration (i.e., is it sensible to combine?).

10. *Was the likelihood of publication bias assessed?*

An assessment of publication bias should include a combination of graphical aids (e.g., funnel plot, other available tests) and/or statistical tests.

11. *Was the conflict of interest stated?*

Potential sources of support should be clearly acknowledged in both the systematic review and the included studies.

Source: Adapted from Shea et al., 2007.

(from multiple raters) on key decisions, such as study eligibility and coding; use comprehensive searches that include efforts to find relevant unpublished studies; identify studies that were included and excluded; describe included studies; assess the scientific quality of included studies and use this assessment in evaluating study results; use appropriate methods for combining results across studies; assess the potential effects of publication bias on results; and report funding sources and conflicts of interest.

CONCLUSION

Systematic reviews can provide comprehensive, unbiased summaries of research on many topics that are important for social work practice and social policy. These reviews aim to minimize error and bias and critically appraise the quality of available studies. They are very labor-intensive, but can produce more reliable information than traditional narrative reviews of research. Social work practitioners and policy makers will find the information from systematic reviews useful for making decisions about how best to help clients with the resources available.

157 Qualitative Research and Evidence-based Practice

Michael Saini & Rory Crath

INTRODUCTION

The evidence-based practice (EBP) decision-making process of integrating the best available evidence with client circumstances and preferences (Sackett et al., 1996; Straus et al., 2011) has gained recognition across professional fields of practice, and specifically within social work (Shlonsky & Gibbs, 2004). Despite the popularity of EBP, however, Thyer (2013) notes that there continues to be frequent misrepresentation and distortion in how EBP is described in the social work literature. There is perhaps no better example than the omission of qualitative studies within widely accepted classification of evidence (Shuval, Harker, Roudsari, Groce, Mills et al., 2011) or the consideration of qualitative studies as the lowest level of evidence, alongside expert opinions (Ebell, Siwek, Weiss, Wolf, Susman et al., 2004).

Misconceptions about the use and application of the evidence-based pyramids and hierarchies of evidence (Sackett, Rosenberg & Gray, 2006; Straus et al., 2011) have led to a limited view of research designs to inform practice by equating the strength of methods based solely on the ability to inform causal pathways of clinical outcomes post interventions (Ramchandani, Joughin, & Zwi, 2001). Indeed, randomized controlled trials (RCTs) and other highly controlled studies are superior for examining the efficacy or effectiveness of interventions because such designs have fewer threats to internal validity, thus providing the best evidence to make causal assertions about the impact of the intervention on selected clinical outcomes (Petticrew & Roberts, 2006). This does not suggest, however, that practice and policy decisions should be based solely on evidence

produced by RCTs. There remains a paucity of RCTs in the social work literature and shortage of evidence to support many widely practiced social work interventions that cannot easily be quantitatively evaluated. There are serious gaps in indiscriminately applying RCTs to answer evidence-based questions that are not directly related to the absolute effect of an intervention (Saini & Shlonsky, 2012), given that many research questions are not amenable to research designs involving RCTs (Lewin, Glenton, & Oxman, 2009).

Despite the immense growth of qualitative studies in social work and related disciplines, findings from qualitative studies have remained largely invisible within the EBP discourse. Consequently, qualitative studies have had little influence on clinical and policy decision-making (Finfgeld-Connett, 2010; Pope & Mays, 2009). Recent shifts, however, have focused on increased attention to the potential benefits of including qualitative research within discussions about EBP. There is also a growing enthusiasm to explore ways in which qualitative research can both complement and expand findings derived from quantitative methods. Case in point, in the newest edition of the evidence-based medicine (EBM) textbook, Straus et al. (2011) not only recognize the unique contribution of qualitative research within evidence-based medicine but further opine that “qualitative research can help us to understand clinical phenomena with emphasis on understanding the experiences and values of our patients” (p. 110). The symbolic departure from targeting qualitative research as the “second class science” (Shuval et al., 2011, pg. 1) helps to move discussion into thinking about

ways that qualitative research can help clinicians apply EBP principles of “integrating individual practice expertise with the *best available external evidence* [emphasis added] from systematic research, as well as considering the values and expectations of clients” (Gambrell, 1999, p. 346). By accepting a broader definition of evidence, other forms of valuable knowledge, such as experiences derived from qualitative studies and practice wisdom, can have equal importance, or even greater relevance, depending on the type of question being asked within the EBP process.

Integrating qualitative studies within EBP is timely for social work, because the development and dissemination of qualitative studies has become widespread in social work journals, and at social work annual conferences, including the Society for Social Work and Research (SSWR) and the Council on Social Work Education (CSWE) (Padgett, 2009). Between 1990 and 2002, the percent of qualitative studies in Social Work Abstracts rose from a mere 0.21% to 4.0%, a 20-fold increase, and similar increases were seen in Social Services Abstracts (Shlonsky & Gibbs, 2004). Attention to qualitative research is also growing across allied professions. Shuval et al. (2011), for example, found a 2.9% absolute increase and 3.4-fold relative increase in qualitative research publications occurring over a 10-year period in 64 journals of general medicine (1.2% in 1998 vs. 4.1% in 2007).

OVERVIEW OF QUALITATIVE RESEARCH

Qualitative research has a long and vibrant tradition in the social sciences that “fundamentally depends on watching people in their own territory and interacting with them in their own language, on their own terms” (Kirk & Miller, 1986, p. 9). There is no “one size fits all” (Padgett, 2008, p. 1) because there is an array of perspectives on the precise focus of, and techniques for, conducting qualitative research. Qualitative research is best described as an umbrella of research methods (Denzin & Lincoln, 1994) with varying epistemologies and philosophical frameworks. There are several types of qualitative methods, including *phenomenology* (an approach to search for the essence or the central underlying meaning of the experience), *ethnography* (a set of strategies for describing and interpreting cultures and cultural phenomena), *grounded theory* (a method

used to generate or discover a theory, an abstract schema that relates to a particular phenomenon), *case study* (an in-depth picture of a “bounded system” or a case by using documents, archival records, interviews, and observations) and participant action research (a self-conscious way of empowering people to take effective action toward improving conditions in their lives). This is far from an exhaustive list, but the intent is to provide a general sense of the various approaches for conducting qualitative research.

Common to most approaches, there is a general tendency to focus on naturalistic inquiry, a reliance on the researcher as the instrument for data collection and interpretation with an emphasis on narratives over numbers (Royse, Thyer, Padgett, & Logan, 2006, p. 88). Qualitative research helps to draw out meanings of particular activities, helps to interpret beliefs within naturalistic and contextualized systems (Padgett, 1998), and assists in exploring the subtleties, complexities, and cultural meanings of activities, events, and singularities being considered to understand subjective perspectives (Valadez & Bamberger, 1994). This practice of research turns the world into a series of representations including field notes, interviews, conversations, photographs, recordings, and memos to the self (Denzin & Lincoln, 2000). In summary, qualitative research seeks to understand constructed meaning and perspectives by seeking to interpret, illuminate, illustrate, and explore meaning, context, unanticipated phenomena, process, opinions, attitudes, and actions (Saini & Shlonsky, 2012).

QUALITATIVE QUESTIONS FOR EVIDENCE-BASED PRACTICE

Qualitative research “enables researchers to ask new questions, answer different kinds of questions, and readdress old questions” (Fetterman, 1988, p. 17). Such questions are useful when traditional quantitative methods are inadequate for understanding the complexity of a problem, or when researchers do not have adequate information about the context and structures related to a given social phenomenon.

Qualitative research is also suitable to answer questions that explore a topic about which little is known; pursues questions that may be too sensitive (emotionally, culturally, etc.); explores the “lived experience” of those in a particular situation; and helps the researcher develop a trusting

TABLE 157.1 Including Qualitative Studies Alongside Randomized Controlled Trials (Lewin et al., 2009)

Steps in Randomized Controlled Trials	Integration of Qualitative Studies
Before a trial	<ul style="list-style-type: none"> • To explore issues related to the question of interest or context of the research • To generate hypotheses for examination in the randomized controlled trial • To develop and refine the intervention • To develop or select appropriate outcome measures
During a trial	<ul style="list-style-type: none"> • To examine whether the intervention was delivered as intended, including describing the intervention as delivered • To “unpack” processes of implementation and change • To explore deliverers’ and recipients’ responses to the intervention
After a trial	<ul style="list-style-type: none"> • To explore reasons for the findings of the trial • To explain variations in effectiveness within the sample • To examine the appropriateness of the underlying theory • To generate further questions or hypotheses

relationship with the participants to gain an inside view of the phenomena (Padgett, 2008).

Questions relevant to qualitative designs also can be integrated with quantitative methods that seek to describe whether interventions “work,” by focusing on “why” interventions work (or do not work) and the influence these interventions may have (or may not have) on clients using the interventions. Adapted from Lewin et al. (2009), Table 157.1 displays the types of questions that qualitative studies can address when integrating qualitative evidence with experimental designs.

Qualitative research can also be the primary source of data to answer questions that do not focus solely on efficacy or effectiveness (Gough & Elbourne, 2002) but, instead, focus on the richly described perceptions of clients, including the perceived needs of clients, their experiences of receiving social work services, and the process that clients go through to access services (Popay, Rogers, & Williams, 1998).

SEARCHING FOR QUALITATIVE STUDIES

One of the major barriers to integrating qualitative research within EBP has been the challenge of locating and retrieving qualitative studies from the electronic databases (Wilczynski & Haynes, 2002). Without clear guidelines for locating and retrieving qualitative studies, there is a risk of

including qualitative studies using haphazard methods rather than careful systematic methods for information retrieval and screening. Some of these challenges include the variability of qualitative methods, the spread of qualitative studies across journals, nonspecific qualitative titles and abstracts, deficiencies in bibliographic indexes, lack of expertise in locating qualitative research, and the lack of evidence about the best ways to locate qualitative research.

The Variability of Qualitative Methods

As stated earlier, qualitative research encompasses a variety of methods and approaches (including ethnography, phenomenology, grounded theory, and discourse analysis), which leads to difficulties in locating qualitative research using common search terms to locate studies based on their methodologies (Evans, 2002). Locating studies across various qualitative methods is further limited based on which database is searched, because not all databases use the same search filters for locating evidence (Evans, 2002; Wilczynski, Marks, & Haynes, 2007).

Qualitative Studies Spread Across Journals

Qualitative studies that may be relevant to a research question may be included in databases

geared toward specific fields of practice, including social work, nursing, medicine, politics, law, psychology, anthropology, and sociology. Although a question may be specific to social work, the question may have been addressed across a multitude of journals spanning many disciplines (McKibbon & Gadd, 2006).

Nonspecific Titles and Abstracts

Qualitative titles and abstracts often focus on the content of the findings and not necessarily the research designs used in the studies (Evans, 2002; McKibbon, Wilczynski, & Haynes, 2006). Again, this causes challenges in retrieving specific qualitative studies to answer the component of EBP questions that require the inclusion of qualitative findings (McKibbon, Wilczynski, & Haynes, 2006).

Deficiencies in Bibliographic Indexes

The development of bibliographic database indexing systems for qualitative designs has not kept pace with the field's indexing of quantitative designs (Evans, 2002). Searching for qualitative studies is, therefore, limited by the deficiencies of electronic database indexing, given that these often do not adequately capture the variability of methods used in qualitative research (Walters, Wilczynski, & Haynes, 2006). Little is known about the sensitivity and specificity of various search strategies across different electronic databases (Shaw et al., 2004). As such, there is a risk that potentially relevant qualitative studies may be missed during the electronic information retrieval process (Evans, 2002).

Limited Ability to Locate Qualitative Research

Although many librarians involved in information retrieval for systematic reviews are proficient at locating RCTs, quasiexperimental designs, and other intervention-based studies (Wade, Turner, Rothstein, & Lavenberg, 2006), less is known about the optimal ways to locate qualitative studies from these same databases (Wilczynski, Marks, & Haynes, 2007). This limited knowledge contributes to making qualitative research a more difficult and challenging enterprise (Dixon-Woods & Fitzpatrick, 2001).

APPRAISING QUALITATIVE STUDIES

Another challenge confronted by integrating qualitative research within EBP is that there remains no standardized method for reporting the design of qualitative studies across journals (Sandelowski & Barroso, 2007), thereby making it difficult to assess the quality of the research designs if pertinent information about the quality and rigor have been omitted or cut at the editorial phase of production. Despite this limitation, several guidelines for assessing the quality and rigor in qualitative research have emerged (Erlandson, Harris, Skipper, & Allen, 1993; Lincoln & Guba, 1985). Traditional methods for assessing the quality of qualitative research have focused on standardization of methods and situations, and emphasized trustworthiness and repeatability of findings (Lincoln & Guba, 1985), but these have been criticized for being too germane to quantitative standards for reliability and validity. Lincoln and Guba (1985) reformulated notions of credibility by introducing techniques to establish quality, including prolonged engagement and persistent observation in the field, triangulation, peer debriefing, the analysis of negative cases, the appropriateness of the terms of reference of interpretations and their assessment and member checking. They also included the dimension of authenticity to include fairness and balance, ontological authenticity, educative authenticity, catalytic authenticity, and tactical authenticity. The additions acknowledge that qualitative research findings are situated with the social, cultural, and political context of the findings and so the appraisal of quality should be completed within this context (Lincoln & Guba, 1985).

There are now over 100 quality appraisal forms to evaluate the quality and rigor in qualitative studies, but there is a lack of attention in many of these tools regarding the epistemological and study design differences of the various types of qualitative designs within the umbrella of qualitative research. One example of these tools is the *Quality Research Checklist (QRC)* (Saini & Shlonsky, 2012), a 25-dimension tool to assess the credibility, dependability, confirmability, transferability, authenticity, and relevance of qualitative studies. The QRC was developed and then pilot tested with four Master of Social Work (MSW) graduate classes to assess the inter-rater agreement of responses after reading a qualitative study. The

underlying assumption of the QRC is that, regardless of the epistemological framework guiding a particular qualitative study, the “story” should be told in a consistent, transparent way and should adhere to the highest standard of methods associated with the philosophical traditions from which the authors purportedly draw. The purpose of the QRC is not to exclude studies from informing EBP based on the lack of quality and rigor, but to provide an understanding of how issues of quality and rigor may inform interpretations of the findings and the potential relevance to the EBP question.

TRANSFERABILITY OVER GENERALIZABILITY

By assessing the quality and rigor of the qualitative studies, consideration is given to the transferability of the knowledge gained. There is a debate, however, about whether knowledge that emerges from qualitative studies should remain locally connected to the context or whether any knowledge can be transferred and integrated within a broader understanding of EBP. Some qualitative researchers argue, for example, that the contextual location of knowledge makes transferability undesirable, while others have argued that some shared meanings can emerge from multiple studies even though these meanings can change over time and remain connected to the context of the original studies (Saini & Shlonsky, 2012). The transferability of qualitative research is, therefore, connected to helping enrich our understanding of the context of EBP, and to helping us connect evidence with our clients by concentrating on the potential barriers, strengths, and considerations that may impact their views and preferences in adopting the EBP process. This helps us shape a broader application of evidence across contexts and locations (Finfgeld-Connett, 2010). Finfgeld-Connett (2009) argues for the transparency of qualitative methods so that consumers of this “new knowledge” are fully informed about the process, context, and situations of the qualitative synthesis in order to make judicious decisions about the transferability of findings (Lincoln & Guba, 1985). This is different than making generalized assertions about the probabilities and/or predictions of how others may experience an intervention. Rather, transferability focuses on bringing some understanding to the context of these interventions and how they may be

perceived by our clients. There is less emphasis on the size of the sample because the purpose is to develop knowledge from tentative suppositions that describe individual cases (Rodwell, 1987). Therefore, gaining a rich and complex understanding of contextual factors takes precedence over generalization and broad assertions. Many qualitative projects employ small samples, principally because the researchers are not concerned with statistical generalizability but rather with conceptual and theoretical development (Baskerville & Wood-Harper, 1996; Pope, Mays, & Popay, 2007).

THE INCLUSION OF QUALITATIVE SYNTHESIS WITHIN SYSTEMATIC REVIEWS

With the increasing attention to developing methods to aggregate, integrate, and interpret qualitative studies, qualitative synthesis methods are providing additional options for integrating qualitative studies with EBP to generate new insights and understandings (Saini & Shlonsky, 2012). Similar to primary qualitative studies, qualitative synthesis can consider the inclusion of only qualitative studies to help answer relevant questions or can complement quantitative reviews (e.g., meta-analysis) by helping to define and refine the question, thus allowing for maximum relevancy.

In 1998, the Cochrane Qualitative Research Methods Group of the Cochrane Collaboration was established to develop methods for the inclusion of findings from qualitative research. In 2008, the group made a major revision to the Cochrane Handbook for Systematic Reviews of Interventions (Version 5.0.0), which included a chapter (Chapter 20) specifically devoted to the development and dissemination of qualitative synthesis reviews. In a similar move, the Campbell Collaboration included a section in their protocol template that specifically deals with the inclusion of qualitative studies by stating that qualitative studies can (a) contribute to the development of a more robust intervention by helping to define an intervention more precisely, (b) assist in the choice of outcome measures and the development of valid research questions, and (c) help to understand heterogeneous results from studies of effect.

Despite the contingent nature of evidence gleaned from synthesis of qualitative studies and

the current lack of consensus about the veracity of some of its aspects, qualitative synthesis is an important technique and, used suitably, can deepen our understanding of the contextual dimensions of complex interventions (Saini & Shlonsky, 2012).

CONCLUSION

As the interest in evidence-based practice continues to grow, there is a move toward integrating the vast and seemingly untapped pool of qualitative studies. Qualitative research can influence social work practice and policy by enhancing our understanding of the contextual considerations that are paramount to the process of EBP decision-making. Linking scientific knowledge with client circumstances, views, and perspectives and the experience and judgement of helping professionals is central to an evidence-informed approach (Saini & Shlonsky, 2012).

Knowledge gleaned from qualitative studies is predicated on finding better ways to integrate qualitative research within the EBP process. Despite the epistemological and methodological challenges of this integration, these efforts can enhance our collective wisdom and make for more relevant social work practice and policy decisions and, ultimately, improve the ways in which we carry out our duties as client-focused and critically informed helping professionals.

158 Integrating Information from Diverse Sources in Evidence-based Practice

Eileen Gambrill

Evidence-based practice “requires the integration of best research evidence with our clinical expertise and our [client’s] unique values and circumstances” (Straus, Glasziou, Richardson, & Haynes, 2011, p. 1). Practitioners must decide what particular characteristics of clients and their contexts to attend to and how to weigh them. They have to decide what information to gather and how to do so. Integrating information and making a decision together with the client as to what to do is often burdened with uncertainties, such as the extent to which external research findings apply to a particular client. Here is where cognitive biases such as tendencies to consider only data that confirm initial assumptions thrive. This step requires integrating information concerning external research findings with circumstances and characteristics of the client, including their values and expectations and available resources, and, together with the client, deciding what to do. The time and effort devoted to making a decision should depend on the potential consequences in relation to making a faulty or good decision and what is needed, based on external research findings and prior experience.

Clinical expertise refers to the ability to use clinical skills and past experience to rapidly identify each client’s unique characteristics and circumstances and their individual risks and benefits of potential interventions (Straus et al., 2011, p. 1).

Increased expertise is reflected in many ways, but especially in more effective and efficient [assessment] and in the more thoughtful identification and compassionate use of individual

[clients’] predicaments, rights and preferences in making clinical decisions about their care.... Without clinical expertise, practice risks becoming tyrannized by external evidence, for even excellent external evidence may be inapplicable to or inappropriate for an individual [client]. Without current best external evidence, practice risks becoming rapidly out of date, to the detriment of [clients]. (Sackett, Richardson, Rosenberg, & Haynes, 1997, p. 2)

Client preferences are considered as well as access to needed resources. Questions include (Glasziou, Del Mar, & Salisbury, 2003) the following: Do research findings apply to my client? That is, is a client similar to clients included in related research? Can I use this practice method in my setting (e.g., are needed resources available?) If not, is there some other access to programs found to be most effective in seeking hoped-for outcomes? What alternatives are available? Will the benefits of service outweigh the harms of service for this client? What does my client think about this method? Is it acceptable to my client? What if I do not find anything? Many application barriers enter at this stage. Gathering information about their frequency and exact nature will be useful in planning how to decrease them. Examples include chaotic work environments, being overwhelmed by problems/issues due to large caseloads, lack of resources, and poor interagency communication and collaboration. Information may be available about certain kinds of clients, but these clients may differ greatly from your clients, so findings may not apply. Resources available will limit options.

DO RESEARCH FINDINGS APPLY TO CLIENTS?

A great deal of practice-related research consists of correlational research (e.g., describing the relationship between certain characteristics of parents and child abuse) and experimental research describing differences among various groups (e.g., experimental and control). In neither case may the findings apply to a particular client. Differences may influence the potential costs and benefits of an intervention to a particular client. Norms on assessment measures may be available, but not for people like your client. (Note, however, that norms should not necessarily be used as a guideline for selecting outcomes for individual clients because outcomes they seek may differ from normative criteria and norms may not be optimal, for example, low rates of positive feedback from teachers to students in classrooms.)

The unique characteristics and circumstances of a client may suggest that a particular method should not be used because negative effects are likely or because such characteristics would render an intervention ineffective if it were applied at a certain time. For example, referring clients who have a substance abuse problem to parent-training programs may not be effective. Other problems, therefore, may influence the effectiveness of a method. In addition, the unique factors associated with a problem such as depression may influence the effectiveness of a given method (e.g., medication, increasing pleasant events, and decreasing negative thoughts). Claims regarding the validity of a practice guideline may not apply to a particular client, agency, or community. Knowledge of behavior, how it is influenced, and what principles of behavior have been found to apply to many individuals may provide helpful guidelines. Questions suggested by Sheldon, Guyatt, and Haines (1998) about whether a particular intervention applies to an individual client are as follows.

1. Is the relative risk reduction that is attributed to the intervention likely to be different in this case because of client characteristics?
2. What is the client's absolute risk of an adverse event without the intervention?
3. Is there some other problem or a contraindication that might reduce the benefit?

4. Are there social or cultural factors that might affect the suitability of a practice or policy or its acceptability?
5. What do the client and the client's family want?

ARE THEY IMPORTANT? THE "SO-WHAT QUESTION"

If external research findings apply to a client, are they important? Would they make a difference in decisions made? Were all important outcomes considered? Were surrogate outcomes relied on—those that are not of direct practical relevance but assumed to reflect vital outcomes? The acronym POEMS refers to patient-oriented evidence that matters. Grandage, Slawson, Barnett, and Shaughnessy (2002) suggest the following for judging usefulness: usefulness = (validity × relevance)/work.

HOW DEFINITIVE ARE THE RESEARCH FINDINGS?

Reviews found may be high-quality systematic reviews or incomplete, unrigorous reviews. In the former, there may be strong evidence not to use a method (e.g., harmful effects have been found) or strong evidence to use one (e.g., critical tests show the effectiveness of a program). Often there will be uncertainty about what is most likely to be effective (See DUETs listed under Websites at end of chapter). Different views of the quality of evidence related to programs abound (e.g., see Littell, 2005).

WHAT IF THE EXPERTS DISAGREE?

Although practitioners and clients may often have to depend on the views of experts, such dependence is not without its risks, as illustrated by studies comparing recommendations of clinical experts to what is suggested based on results of carefully controlled research (Antman, Lau, Kupelnick, Mosteller, & Chalmers, 1992). In some situations, we could seek and review the quality of evidence for ourselves. At other times, this may not be possible due to time constraints. Indicators of honesty among experts include (1) accurate description of controversies, including methodological and conceptual problems with preferred

positions; (2) accurate description of well-argued disliked views; (3) critical appraisal of both preferred and well-argued alternative views; and (4) inclusion of references regarding claims made so readers can examine these for themselves.

WILL POTENTIAL BENEFITS OUTWEIGH POTENTIAL RISKS AND COSTS?

Every intervention, including assessment measures, has potential risks as well as potential benefits—for example, a false positive or negative result. Will the benefits of an intervention outweigh potential risks and costs? We can estimate this in a number of ways: RRR (relative risk reduction), ARR (absolute risk reduction), and NNT (number needed to treat) (see Bandolier worksheet for calculating NNT). A nomogram can be used to calculate the NNT based on absolute risk in the absence of treatment (Guyatt, Rennie, Meade, & Cook, 2008). How many clients have to receive a harm reduction program to help one person? Is there any information about NNH (the number of individuals who would have to receive a service to harm one person)? ARR should always be given; RRR is highly misleading. Accurately communicating risk to clients is much easier using frequencies rather than probabilities (Gigerenzer, 2002; 2014).

HOW CAN PRACTITIONERS HELP CLIENTS TO MAKE DECISIONS?

The lack of correlation between what someone says he or she wants (their preferences) and what he or she does (their actions) is considered such a big issue, with so little related research, that one model of evidence-based practice carves out preferences and actions as a separate area to be considered (Haynes, Devereaux, & Guyatt, 2002). For example, although many people say they want to pursue a certain goal, their actions often do not reflect their stated preferences; that is, they do not do anything. In view of the tendency of some clients to match the goals and values of their therapists and other sources of behavioral confirmation in the helping process, and the role of subtle influences such as question wording and order on the expression of preferences, a variety of methods of inquiry should be used to discover

beliefs and preferences, rather than reliance on one method, which may result in inaccurate accounts.

How decisions are framed (in terms of gains or losses) influences decisions; different surface wordings of identical problems influence judgments (framing effects). Gains or losses that are certain are weighed more heavily than those that are uncertain. Clients differ in how risk-averse they are and in the importance given to particular outcomes. Occasions when discovering client preferences is especially important include those in which (1) options have major differences in outcomes or complications; (2) decisions require trade-offs between short- and long-term outcomes; (3) one choice can result in a small chance of a grave outcome; and (4) there are marginal differences in outcomes between options (Kassirer, 1994). Presentation of risks and benefits by professionals is often quite misleading (e.g., Gigerenzer, 2002). Thus, a key step in helping clients make a decision is for practitioners themselves to be aware of errors they make in estimating risk and presenting options (e.g., framing biases).

Discovering client beliefs and preferences may require involving them in a decision analysis. Decision aids can be used to inform clients about the risks and benefits of various options. Such aids can “personalize” information by allowing clients to ask questions important to them. They can highlight vital information often overlooked, such as absolute risk. Benefits include improving client knowledge about options, feeling more informed about what matters most, increasing accuracy of expectations regarding potential benefits and harms of options, participating more in making decisions, and improving the match between choices and a client’s values (Stacey, Légaré, Col, Bennett, Barry, Eden, Holmes-Rovner, . . . Wu, 2014).

CAN THIS METHOD BE IMPLEMENTED EFFECTIVELY IN MY AGENCY?

Can a plan be carried out in a way that maximizes success? Are needed resources available? Do providers have the skills required to carry out plans? Can necessary resources be created? Differences in provider adherence to practice guidelines may decrease the safety and effectiveness of an intervention. Current service patterns may limit options. Barriers to implementation may be so

extensive that Straus et al. (2005, p. 170–171) refer to them as “the killer B’s:

1. The Burden of Illness (the frequency of a concern may be too low to warrant offering a costly program with high integrity).
2. Beliefs of individual clients and/or communities about the value of services or their outcomes may not be compatible with what is most effective.
3. A Bad Bargain in relation to resources, costs, and outcome
4. Barriers such as geographic, organizational, traditional, authoritarian, or behavioral.

Problems may have to be redefined from helping clients attain needed resources to, instead, helping them bear up under the strain of not having resources or involving clients with similar concerns in advocacy efforts to acquire better services. Questions Sackett et al. (1997) suggest for deciding whether to implement a guideline include the following (p. 182):

1. What barriers exist to its implementation? Can they be overcome?
2. Can the collaboration of key colleagues be obtained?
3. Can the educational, administrative, and economic conditions that are likely to determine the success or failure of implementing the strategy be met?
 - Credible synthesis of the evidence by a respected body.
 - Respected, influential local exemplars already implementing the strategy.
 - Consistent information from all relevant sources.
 - Opportunity for individual discussions about the strategy with an authority.
 - User-friendly format for guidelines.
 - Implementable within target group of clinicians (without the need for extensive outside collaboration).
 - Freedom from conflict with economic and administrative incentives and client and community expectations.

ARE ALTERNATIVE OPTIONS AVAILABLE?

Are other options available, perhaps another agency to which a client could be referred? Self-help programs may be available. Here, too,

familiarity with practice-related research can facilitate decisions.

WHAT IF CLIENTS PREFER UNTESTED, INEFFECTIVE, OR HARMFUL METHODS?

The acceptability of plans must be considered. This will influence adherence to important procedural components associated with success. Most interventions used by professionals in the interpersonal helping professions have not been tested; we do not know if they are effective, ineffective, or harmful. Untested methods are routinely offered in both health and social care. Methods critically tested and found to be ineffective or harmful certainly should not be offered. If an effective method is available, the costs and benefits of using this compared to a preferred ineffective method could be described. Untested methods that continue to be preferred and used should be tested to determine whether they do more good than harm.

WHAT IF A SEARCH REVEALS NO RELATED RESEARCH?

A review of research findings related to important practice questions and related information needs may reveal that little or nothing is known. Ethical obligations to involve clients as informed participants and to consider their preferences provide a guide; that is, the limitations of research findings should be shared with clients, and empirically grounded practice theory, as well as client preferences, can be used to guide work with clients. Evidence-informed practice involves sharing ignorance and uncertainty as well as knowledge in a context of ongoing support (Katz, 2002).

WHAT IF RELATED RESEARCH IS OF POOR QUALITY?

A search will often reveal uncertainty regarding the effectiveness of a method. The phrase “best practice” is used to describe a hierarchy of evidence (e.g., Straus et al., 2005, p. 169). The phrase “best evidence” could refer to a variety of tests that differ greatly in the extent to which claims are critically tested. Available research may be low on this hierarchy in relation to critical

tests of a practice or policy (e.g., a case series). However, this may be the best that is available. For example, if there are no randomized controlled trials regarding an effectiveness question, then we move down the list. This is what must be done in the everyday world because most interventions used in psychiatry, psychology, and social work have not been critically tested. Instead of well-designed randomized controlled trials regarding an intervention, only pre/post studies may be available, which are subject to many rival explanations regarding the cause of change. Some guidelines are described as “well-established” if two well-designed randomized controlled trials show positive outcomes. It is less misleading to say that a claim has been critically tested in two well-controlled trials and has passed both tests. This keeps uncertainty in view. Whatever is found is shared with clients, and practice theory, as well as client preferences, must be used to fill in the gaps.

WHAT IF RESEARCH IS AVAILABLE, BUT IT HAS NOT BEEN CRITICALLY APPRAISED?

One course of action is to appraise this literature critically. The realities of practice, however, may not allow time for this. Perhaps an expert in the area can be contacted. If the question concerns a problem that occurs often, interested others can be involved in critically appraising related research.

BALANCING INDIVIDUAL AND POPULATION PERSPECTIVES

One of the most challenging aspects of practice is considering both individuals and populations. There is only so much money and time. Decisions made about populations often limit options of individuals. Ethical issues regarding the distribution of scarce resources are often overlooked.

COMMON ERRORS

Common errors in integrating information from diverse sources are related to common cognitive biases such as overconfidence, wishful thinking, influence by redundant information, and confirmation biases (Gambrill, 2012). Availability biases such as influence by vivid data are common as are

representative biases (influence by associations that may be misleading rather than informative). Eagerness to help clients and a reluctance to recognize uncertainties may encourage unfounded confidence in methods suggested. Lack of reliability and validity of information is often overlooked, resulting in faulty inferences. Jumping to conclusions may result in oversimplification of causes of a client’s concerns. Or the opposite may occur, as in suggesting obscure complex causes, none of which provide intervention implications. The evidentiary-status of interventions may not be communicated clearly to clients. Lack of evidence may be shared in an unempathetic manner.

ONGOING CHALLENGES AND EVOLVING REMEDIES

Obstacles include both personal and environmental characteristics (see “Can This Method Be Implemented Effectively in My Agency?”). Ongoing challenges include encouraging practitioners to be honest with clients about uncertainties in a supportive manner (Katz, 2002), minimizing common cognitive biases in integrating data, and avoiding influence of inflated claims in the professional literature about “what works” and what accounts for client concerns. Organizational cultures may discourage raising questions regarding services offered and needed tools, such as access to vital databases, may not be available. Biases intrude both on the part of researchers when conducting research and when preparing research reviews (Jadad & Enkin, 2007) as well as at the practitioner level when making decisions. Availability biases, such as a preferred practice theory and preconceptions regarding certain kinds of people, as well as representative biases, including stereotypes, may interfere with sound integration of external research findings with client values, expectations, and unique circumstances and characteristics. Many components of EBP are designed to minimize biases such as jumping to conclusions, for example, using “quality filters” when seeking research related to a question. EBP highlights the play of bias and uncertainty in helping clients and attempts to give helpers and clients the knowledge and skills to handle this honestly and constructively. Consider the attention given to helping both clients and helpers to enhance their skills in critically appraising research.

We can draw on literature concerning judgment, problem solving, and decision-making to discover common biases and how to avoid them, including discussion of organizational obstacles and how to address them (Gambrill, 2012). We can take advantage of literature investigating expertise to help practitioners “educate their intuition” (Hogarth, 2001) and take advantage of guidelines described in the critical thinking literature to minimize biases. Helping professionals to learn from their experience in ways that improve the accuracy of future decisions is a key priority. This will require arranging corrective feedback that permits the development of “informed intuition” (Hogarth, 2001). One problem arises when someone thinks they have expertise but do not and imposes, perhaps by selective attention, an inaccurate view on a situation. They may generalize a decision-making method to a situation in which it is not useful.

Use of handheld computers to guide decisions may be of value in decreasing errors and common biases. Such aids can be used to prompt valuable behaviors, to critique a decision (for example, purchasing services from an agency that does not use evidence-informed practices), to match a client’s unique circumstances and characteristics with a certain service program, to suggest unconsidered options, and to interpret different assessment pictures (Guyatt et al., 2008). Use of clinical pathways and handheld computers with built-in decision aids, such as flow charts, are already in use in the health arena, as are decision aids for clients (see earlier discussion). Just as the narratives of clients may help us understand how we can improve services, the narratives of practitioners may help us identify challenges and opportunities to integrating information from diverse sources (Greenhalgh & Hurwitz, 1998).

RELATED ETHICAL DILEMMAS

Ethical issues that arise in integrating data and making decisions illustrate the close connection between ethical and evidentiary issues. These include ethical obligations of practitioners to inform clients accurately regarding the uncertainties involved in making decisions, including the evidentiary status of recommended methods and their risks and benefits together with the risks and benefits of alternative methods. Should clients be informed regarding effective methods that an agency cannot offer? Should practitioners

continue to offer methods of unknown effectiveness? Is it ethical to offer an intervention in a diluted form of unknown effectiveness? Should practitioners be well informed regarding how to present risks and benefits accurately? Although the answers may clearly be yes, descriptions of everyday practice reveal a different picture. Yet another ethical issue relates to controversies regarding the relative contributions of the person of the helper, common factors such as warmth and empathy, and the particular intervention, to outcome. If it is true that the former contributes more than the latter, this should be considered in deciding what to do (see Wampold, 2006; 2010).

159 Evidence-based Practice in Social Work Education

Aron Shlonsky

The infusion of evidence-based practice (EBP) into social work education has begun in earnest and is still in the initial stages of widespread adoption. This initial stage can be characterized by a growing excitement about the prospect of training students to provide services that are both effective and in line with the core social work value of self-determination. On the other hand, the field is emerging from a long struggle to define EBP and find ways to integrate its philosophy and specific steps into mainstream social work education. This chapter briefly reviews

the current state of implementation of EBP in schools of social work, offers suggestions for shaping individual classes, and provides strategies for the infusion of EBP across the social work curriculum.

CASE EXAMPLE

A school of social work in North America is up for accreditation and is considering infusing EBP into its new Master of Social Work curriculum. As yet,

its faculty and administration are unsure about the extent to which they are willing and able to change the way they have always done things, but there is an acknowledgment that the curriculum is dated and requires substantial revision. There are great methodological (e.g., quantitative vs. qualitative) and epistemological (e.g., postmodern/poststructuralist vs. postpositivist) divides among full-time faculty, adjunct faculty, field liaisons and instructors, and students. The dean is well respected among her faculty and, like any good social worker, she values diversity of opinion and would like to make the transition to EBP an inclusive process. What steps can she take to successfully formulate a new curriculum based on the philosophies and steps of EBP? How should individual faculty members begin to infuse EBP into their classrooms?

THE ADOPTION OF EVIDENCE-BASED PRACTICE IN SOCIAL WORK EDUCATION

The surge of interest in EBP across disciplines over the past decade is reflected in the number and content of peer-reviewed journal articles as well as the appearance of the phrase “evidence-based” in journal titles, both new and old (Figure 159.1). Between 1995 and 2002, the percentage of articles using the phrase “evidence-based” increased exponentially across the disciplines of social work, nursing, medicine, and psychology (Shlonsky & Gibbs, 2004). A number of leading social work journals have recently published

special issues on EBP, including *Research on Social Work Practice* (2003 and 2007), *Brief Treatment and Crises Intervention* (2004), and the *Journal of Social Work Education* (2007). Several books have also appeared, most notably Leonard Gibbs’s (2003) *Evidence-Based Practice for the Helping Professions*, Rosen and Proctor’s (2003) *Developing Practice Guidelines for Social Work Intervention*, and Roberts and Yeager’s (2003) *Evidence-Based Practice Manual*. The two major social work conferences, the Council on Social Work Education’s Annual Program Meeting and the Society for Social Work and Research’s annual conference, have begun to devote considerable presentation slots to researchers and educators presenting on EBP. As well, the first national (U.S.) conference devoted to teaching EBP was convened by Allen Rubin at the University of Texas at Austin in October 2006. In short, EBP has quickly become the new practice archetype, yet definitional issues have arisen in these early stages of adoption.

In keeping with the other chapters in this part, EBP here is defined as it is in medicine as “the conscientious, explicit and judicious use of current evidence in making decisions about the care of individual patients” (Sackett, Richardson, Rosenberg, & Haynes, 1997, p. 71). Though this ideal is difficult to argue with, there has been a great deal of debate with respect to the definition of evidence and how it is gathered and used (Gibbs & Gambrill, 2002), and this is of great import to social work education because we cannot teach what we cannot define. Specifically, there has been confusion about whether EBP entails

Figure 159.1 Percentage of “evidence-based” hits by discipline: 1990–2002.

simply using an empirically validated treatment for a given client problem, and this basic misunderstanding has been one of the major barriers to implementation. However, the original model is quite explicit. EBP at the individual, community, and policy levels must include five steps: (1) posing a practice-relevant, answerable question; (2) systematically searching the extant literature; (3) appraising what is found; (4) combining these findings with what is known about client preferences/actions and clinical state/circumstances to help clients make context-sensitive decisions; and (5) evaluating the outcome. The original EBP approach is inclusive of and even relies on both practice guidelines and empirically supported treatments (ESTs), but is not defined by and goes beyond their use.

Various approaches to teaching EBP have been adopted by schools across North America, each fashioning its curriculum differently, and all attempting to move the philosophy and methods to practice. George Warren Brown University in St. Louis was the first school to reshape its entire curriculum to reflect a practice guidelines approach (Howard, McMillen, & Pollio, 2003), including measures to ensure that students are trained in at least one EST (e.g., cognitive-behavioral therapy for depression). The University of Toronto changed its approach to teaching research, opting to teach the steps of EBP and training students to evaluate research rather than training them to conduct research. Oxford University has gone in yet a different direction and, rather than offering a degree in social care, is now offering a degree in evidence-based social intervention. More recently, other schools have begun to reshape their approach to teaching social work. For instance, Columbia University now offers several courses in EBP and has begun to shape its curriculum accordingly, and the University of Tennessee is now in the process of infusing its entire curriculum with EBP. Of course, there are others and an even larger number of individual academics who are integrating EBP into their courses.

TEACHING EVIDENCE-BASED PRACTICE IN THE CLASSROOM: A GENERAL SET OF GUIDELINES

Creating a Culture of Inquiry

The definition of EBP is best understood when both the guiding philosophy and the

model's accompanying set of systematic steps are clearly explained. The philosophy is the starting point and should include reference to the overall model. Ethical obligations to provide the most effective services to clients, and the integration of evidence with client values/preferences and clinical state/circumstances, should be stressed. Only then do the five steps of EBP begin to make sense. However, this initial understanding must be accompanied by critical thinking (see Table 159.1). That is, search and evaluative tools are necessary but insufficient components of EBP. Every step in the process requires healthy doses of curiosity, skepticism, and a passion for finding the best possible knowledge in the service of helping, and these qualities must be brought out and supported in students. Rather than being mechanical or reductionistic, EBP at its core embraces the complexity of experiences, circumstances, and tendencies of each and every client (Shlonsky & Stern, 2007).

In a very real sense, EBP is a way of putting critical thinking into systematic action, and this requires creating an atmosphere that encourages

TABLE 159.1 Teaching Evidence-based Practice in the Classroom

-
1. Creating a culture of inquiry
 - Critical thinking
 - Socratic questioning
 - Exercises that highlight biases and inconsistencies
 - Exploration of ethical obligations to clients and the profession
 2. Learning to live with uncertainty
 - Model uncertainty
 - Provide tools to dispel ignorance
 3. Using a problem-based learning (PBL) framework
 - Small group format
 - Clinically integrated approach
 4. Anticipating problem areas
 - Provide examples
 - Maintain student interest
 - Model several searches and appraisals
 - Series of small assignments
 5. Expressing probabilities
 - Number Needed to Treat
 - Effect size
 6. Starting with a single client
 7. Build dynamic knowledge over time
-

independent, critical thought. Thus, rather than simply teaching the mechanics of EBP, students must learn how to think critically and conceptually about the systematic information they have gathered and consider ways to apply it to important practice and policy decisions. Questioning the underlying assumptions we make about evidence and about clients is welcome—indeed, it is essential. Socratic questioning, if done in a manner that is not threatening (i.e., curious but demanding speculation), seems to set the tone from the very beginning. Such an approach is interactive and leads by example. Students tend to pick up this approach fairly quickly with one another and the instructor, making for very lively and stimulating discussions. Several exercises and discussions within the Socratic framework can help facilitate this process. These include:

- Exercises that highlight perceptions of evidence (e.g., Gibbs & Gambrill, 1999)
- Exercises that highlight cognitive and other biases in decision making (e.g., Gambrill, 2006)
- An accounting of social interventions that have been harmful
- Discussion of controversial findings from the literature
- Communication of the ethical obligation to inform clients of the risks and benefits of a proposed course of action (Gambrill, 2003), which implies that such information has been systematically gathered and is known by the practitioner.

Learning to Live with Uncertainty

Social work students clearly want to be of service to their clients, and this may engender difficulties in the face of the inevitable uncertainty that arises when working with challenging, multiproblem client situations. There is often no single right path to successful assessment and treatment, and this is sometimes difficult for students to accept. An EBP approach does not shy away from such uncertainty. Rather, it embraces the unknown with curiosity and speculation. Thus, it is crucial that instructors model uncertainty and, rather than stopping with “I don’t know,” find a way to generate the next level of inquiry. In particular, EBP insists on transparency of research findings and

sharing ambiguous or uncertain findings with clients.

Using a Problem-based Learning Framework

Rather than relying solely on lectures, EBP is best taught using a clinically integrated approach. Problem-based learning (PBL), as developed by McMaster University in Canada, uses a small group format (seven or eight students) to present cases (these can be clinical, community, or policy oriented) and employs critical dialogue to identify knowledge gaps. In the interim between meetings, students individually use EBP methods to pose questions and find evidence, bringing information back to the group for further discussion and case plan development. Taking students through several examples, from initial assessment through the search and appraisal of evidence and then back to the client or policy question, provides ample opportunities to become more proficient at this process while maintaining student interest. Sometimes, this can be accomplished using a combination of videos and written assignments (see, for example, Howard et al., 2003) where students are asked to make decisions that rely on their clinical or policy and evaluative skills. By linking instruction with real and/or realistic clients, students are trained to think critically in an applied way, and this process appears to improve knowledge, skills, attitudes, and behavior when compared with more standard forms of pedagogy in medical school (Coomarasamy & Khan, 2004). Hopefully, such educational success translates into a generation of lifelong learners (Gray, 1997; Sackett et al., 1997) who will not be satisfied with knowledge that will soon be obsolete.

Anticipating Problem Areas

Posing questions and developing a search strategy are deceptively difficult, especially the first time. Appraising studies can also be a challenge, especially for students who shy away from numbers or who become easily frustrated by the often technical language contained in scientific papers. Much care and attention must be spent at these crucial junctures. If a student has a bad experience with his or her first attempt at the steps of EBP, he or she loses interest and become dismissive of

the entire process. There is nothing more frustrating for a student than to spend hours on a failed search. Some strategies for avoiding this pitfall include:

- Providing numerous examples of answerable questions
- Relating questions directly to key practicum concerns or, in special circumstances, unique student interests
- Working individually with students to develop questions, especially focusing on clearly specifying their intervention and outcome terms
- Inviting a librarian or other search expert to demonstrate how to conduct EBP searches. This should include:
 - Tours of the various subject-specific databases
 - Developing search terms
 - Using Boolean operators
 - Using wildcards
 - Using methodological filters by question type (see Gibbs, 2003)
- Providing numerous examples of search strategies by question type
- Providing simple methodology appraisal forms and opportunities to practice evaluating study quality
- Encouraging students to first look for systematic reviews at the Campbell and Cochrane Collaborations
- Providing ample opportunity for students to ask for help
- Segmenting larger assignments into smaller pieces to ensure that students are on target at each stage.

Expressing Probabilities

Students and clients often struggle with understanding and presenting findings from their reviews of the literature in real-world terms. One of the more important tools for translating research findings into readily understandable formulations of risk is number-needed-to-treat (NNT). This tool is basically a reworking of absolute risk reduction ($1/ARR$) into a format that almost anyone can understand. NNT gives students the number of people who need to be treated to prevent one bad outcome. The other side of NNT, number needed to harm (NNH), can also be a useful tool. For instance, an intervention might have an absolute risk reduction of

0.2 (e.g., 40% of the treatment group relapsed and 60% of the control group relapsed), translating into an NNT of 5 ($1/ARR = 1/0.2$). Thus, for every five people who receive the treatment, one person who would have relapsed will remain healthy. This number takes into account the fact that some people who do not receive the treatment will remain healthy and some people in the treatment group will relapse, a point many people miss when thinking about treatment interventions. Spending considerable class time on this construct in an introductory course is both necessary and helpful. Although students might find such calculations difficult at first, their intuitive understanding of risk and benefit will be enhanced and, once mastered, NNT can be a powerful tool to use with clients. As well, effect size (measure of the magnitude of difference between groups in an intervention study) is an important construct for students to understand so they can fully appreciate the difference between statistical and real world significance (Shlonsky & Stern, 2007).

Starting with a Single Client

Critics of EBP often point out that social workers do not have the time to go through the five steps—such an approach is unrealistic. Although the techniques cited in this chapter and in this part of the volume substantially decrease time spent, as does repeated application, such criticisms do have merit. In all likelihood, it is unreasonable to follow the EBP process for every decision made. However, students can be encouraged to pick one client facing a problem that often occurs in the field placement setting. Over time and many such clients, a knowledge base can be generated that serves a far greater number.

INFUSING EVIDENCE-BASED PRACTICE ACROSS THE SOCIAL WORK CURRICULUM

EBP is not a single-semester endeavor and should not be presented to students as such. There is far too much information, the process must be practiced to adequate levels of speed and accuracy, and the proper integration of findings with specific clients, programs, and policies is a complex endeavor. Rather, it is a cumulative process that should be woven through all facets of the curriculum. This requires that schools

and departments of social work must somehow become as facile as individual practitioners in adopting new approaches as evidence emerges.

Broad Strategies

There are several steps that should be considered when making such a transition (Table 159.2). Most important, the inclusive philosophy of EBP must be stressed. That is, similar to teaching in the classroom, the basic definition and steps of EBP must be clearly understood and conveyed to faculty. In addition, leaders (both internal and external) should be sought out and engaged to facilitate the adoption of innovation (Rogers, 1995). Incorporating the EBP framework into different curricular areas can also be a challenge, especially areas that are traditionally resistant to empirical approaches. A narrow conceptualization of EBP, perceived or otherwise (e.g., that EBP amounts to using evidence from random clinical trials), may be translated as a thinly veiled attempt at foisting positivism on the entire

faculty (Jenson, 2007). This must be avoided. With respect to distinguishing between ESTs and EBP, faculty must decide on whether to train students in ESTs and practice guidelines, and which ESTs should be chosen.

Finally, decisions must be made about how to involve the field and maintain curricular focus among adjunct professors. An easy approach to involving practicum partners is to evolve a culture whereby students engage with field instructors and placement agencies to pose and begin answering critical questions of import to the field (Gibbs, 2003). For the field, conferences and trainings in EBP, ESTs, and other content areas could help facilitate this process. Mostly, though, the field will need to begin to see how having students using the steps of EBP can actually benefit their agencies through systematic efforts to uncover current best evidence in relevant practice areas. Still, some agencies will not want to have such light shed on their practices, and students will inevitably encounter placements using interventions or supporting policies that have little or no empirical basis (Howard, McMillen, & Pollio, 2003). This brings the student and classroom yet another opportunity to explore controversy and to strategize about how to facilitate change at the agency or policy level. Adjuncts also must be factored into the equation because they teach a large proportion of the classes. One strategy is to create an adjunct liaison position and coordinate instructional content across subject areas (Springer, 2007). Another strategy is to have full-time faculty members coordinate all sections of each class, ensuring that EBP content is infused into courses.

TABLE 159.2 Broad Strategies for Infusing Evidence-based Practice Across the Curriculum

1. Have the discussion—make sure you are all on the same page with respect to definitional issues. Identify and begin to deal with misunderstandings and disagreements, epistemological and otherwise.
2. Identify and marshal internal resources with expertise and/or interest in EBP.
3. Identify external resources. Who can be brought in to lead you objectively through some of this process? An outside resource is sometimes less threatening and may be one way to avoid personal entanglements that are sure to arise.
4. Decide how the EBP framework can be used across curricular areas:
 - a. Research
 - b. Clinical practice
 - c. Policy and management
 - d. Community
 - e. Social justice and diversity
5. Decide whether and how empirically supported treatments (ESTs) will be taught.
6. Decide how to involve the field.
7. Decide how to maintain curricular focus with adjuncts (especially important in large schools).

Establishing an Introductory Evidence-based Practice Course

If EBP is to be woven throughout the curriculum, it must begin with the basics. Rather than the standard research class devoted to teaching students how to conduct research (a class where most students will neither learn enough to conduct good research nor develop a desire to try), why not introduce students to the process of EBP? In other words, change the curriculum to include an EBP class that touches on the various elements of research but is more practically geared toward systematically searching, understanding, appraising, and using the literature. The basics taught in this class can then be expanded and reinforced in subsequent core

and specialization classes, including the basic tenets of research (e.g., basic study design, reliability, validity). Links to specific case examples in this and subsequent classes can help solidify learning. In this way, basic research methodology becomes a part of social work practice (Shlonsky & Stern, 2007).

Building on Courses and Assignments

Replication is the heart of science, and repetition is the heart of EBP. Repeating the process, using different client or policy questions, is essential to achieve a level of speed and proficiency that will enable students to continue the process upon graduation. Moreover, EBP is, at its core, a lifelong learning process (Sackett, Richardson, Rosenberg, & Haynes, 1997). Not only will the questions change as one practices, the evidence base will continue to grow and, in some cases, will change practice. One way to ease the pain of repetition is to envision classes as building on one another, much like general practice courses (i.e., moving from generalist practice in the first year to more specialized classes in the second). Although the basic EBP approach is unchanging in its methods, skills within the framework can be reinforced and expanded in subsequent classes as students begin to acquire greater practice skills. For instance, the first year of an Master of Social Work (MSW) program can focus on the nuts and bolts of posing an answerable question, searching the literature, and appraising what is found. In the second year, content-specific courses include the process but focus more on integrating current best evidence with client preferences/actions and clinical state/circumstances. As well, the second-year classes include a more nuanced consideration of how other factors (e.g., training, organizational resources, political context) enhance or detract from the adoption of EBP, possibly influencing the process of individual and social change (Regehr, Stern, & Shlonsky, 2007).

Encouraging Single-subject Design for Evaluation

For clinical interventions, $N = 1$ studies can be seen as the pinnacle of evaluating personal practice. They are the key to ascertaining whether

interventions are working for clients. Advanced research classes would be well served by paying considerable attention to single-subject designs. Advanced clinical practice courses can also play a role in the fifth step of EBP by requiring students to formulate an evaluation plan as part of their coursework.

Developing Community Partnerships

Good community and agency partnerships are essential to the health of any school of social work, and this is no less the case as faculties move to embrace EBP. Key practice questions should drive research, and these are typically generated when practitioners and administrators notice a gap in knowledge. If research is not relevant to practice, its benefits are limited at best. EBP's bottom-up approach (Gibbs, 2003) requires that community and agency partners help drive the research agenda. To this end, community and agency partners should be encouraged to participate in and commit to the development of EBP at the university through ongoing training/continuing education (e.g., ESTs) and capacity building. As well, processes should be developed whereby community and agency partners are encouraged to generate research questions and join with faculty to carry out new investigations.

Avoiding False Claims and Developing a Long-term Vision

EBP is an emerging approach and it will take considerable time, effort, and resources to make it work. EBP is not a quick fix for all that ails social work and the related helping professions. We must be honest about our current limitations, including the lack of evidence in some content areas, the confines of scarce agency resources and time, and the difficulty of integrating evidence within client context. We have a long way to go. Nonetheless, this wholesale shift in philosophy and practice is promising to the extent that clients will become increasingly well informed; are more likely to be offered high-quality, effective services; and will have greater attention paid to their desires and values.

160 Evaluating Our Effectiveness in Carrying Out Evidence-based Practice

Bruce A. Thyer & Laura L. Myers

From the inception of evidence-based practice (EBP), authorities in this field have advocated that clinicians consider undertaking a type of experimental study they labeled the $N = 1$ randomized controlled trials (RCTs). The primary reference book *Evidence-based Medicine: How to Practice and Teach EBM* (Straus, Glasziou, Richardson, & Haynes, 2011) includes a positive description of this type of design:

The n-of-1 trial applies the principles of rigorous clinical trial methodology to... determine the best treatment for an individual patient. It randomizes time, and assigns the patient... active therapy or placebo at different times, so that the patient undergoes cycles of experimental and control treatment, resulting in multiple crossovers to help both our patient and us to decide on the best therapy. (Straus et al., 2011, p. 131)

The experimental logic of the $N = 1$ RCT can perhaps best be illustrated with an example. Let us say, for example, that a child has been diagnosed with hyperactivity and a physician has prescribed a medication to help calm him down. The parents doubt that drugs will be helpful and are resistant to following this treatment recommendation. However, with the helpful intervention of a social worker, they agree to give it a try for several weeks on an experimental basis. Two identical bottles of pills are prepared, one bottle is labeled A and contains (unknown to the parents or child) the active medicine, whereas bottle B contains similar-looking pills lacking any active ingredient (e.g., a placebo). The social worker arranges for the teacher to rate the child's behavior in school at the end of each day, using a valid behavior rating scale. Flipping a coin, the

social worker assigns the child to receive either pill A (heads) or pill B (tails) each day for a two-week period. The social worker prepares a simple line graph, with behavior ratings scored on the vertical axis, and the days of the week on the horizontal one. The ratings for the days pill A is administered are plotted and connected, and the ratings for pill B are similarly portrayed. If there is no overlap in the two sets of lines, and the ratings during the days the child received the active medication are unambiguously those in which behavior was improved, then clear and compelling evidence of a genuinely experimental nature has demonstrated the superiority of the active drug over placebo.

This type of demonstration has several functions. First, we have empirical proof that the drug is helpful with this individual client, which is, after all, a highly desirable outcome of practicing EBP. Second, the evidence may alleviate the parents' reservations about using medication, and help them decide to continue its use. This example presupposes that the medication has no significant side effects, is not unreasonably expensive, that taking it is not prohibited by the family's religious beliefs, and so on. If the two sets of lines connecting the two different treatment conditions had significant overlap, then the effects of the active drug versus placebo would be less clear. Completely overlapping lines would suggest that the medicine was little better than placebo and need not be used at all. This is also good to know.

Within the field of psychotherapy, this type of design is called the alternating treatments design (ATD; Barlow & Hayes, 1979). In October 2013, we searched the PsycINFO database using

“alternating treatments design” as key words appearing in journal abstracts and found over 370 published examples of its use across a wide array of disciplines, including audiology, medicine, education, and psychology. An ADT was used by social worker Steven Wong to help determine empirically how one’s immediate environmental situation affected the psychotic-like behavior of a person suffering from chronic mental illness (Wong et al., 1987). The client, Tom, was a 37-year-old man with a diagnosis of chronic schizophrenia who was experiencing his fourth hospitalization. Systematic assessments of Tom’s psychotic-like mumblings were tape recorded via a wireless microphone attached to his shirt for five sessions of unstructured free time in the hospital day room where he had access to usual recreational materials (e.g., television, stereo, magazines, books, table games, and cards) but was otherwise left alone. The subsequent experimental phase consisted of randomly alternating between two interventions, a 40-minute session in the day room begun by prompting the client to read articles he found interesting from an assortment of novel magazines offered to him, versus spending 40 minutes in the room without any reading prompting or access to novel magazines (identical to the original baseline condition). These two treatments were randomly alternated for 18 consecutive sessions, and the percentage of

time Tom spent engaged in stereotypic laughter and mumbling, reliably recorded, was the dependent variable (outcome measure). The results are depicted in Figure 160.1. It is very clear that when Tom was given something interesting to do (e.g., reading) his psychotic-like behavior was markedly reduced, relative to having unstructured free time. There is no overlap in the two sets of data, providing compelling evidence that the simple intervention was causally responsible for these behavioral differences. Because a clear causal inference is possible via the intentional manipulation of the intervention and control conditions, this $N = 1$ randomized controlled trial can be legitimately classified as a true experiment. Dr. Wong also used this type of design to demonstrate experimentally that a checklist could be used effectively to help a memory-impaired woman with diabetes successfully undertake regular checking of her own blood sugar levels using a glucometer (Wong, Seroka, & Ogisi, 2000).

Within the field of EBP, randomized $N = 1$ trials are held in such high esteem that it has been claimed that these studies provide a *stronger* foundation for making decisions about the care of individuals than does the evidence derived from systematic reviews, meta-analyses, individual RCTs, and other evidentiary sources (see Guyatt et al., 2002, p. 12)! This certainly turns the usual apex of the evidentiary hierarchy on

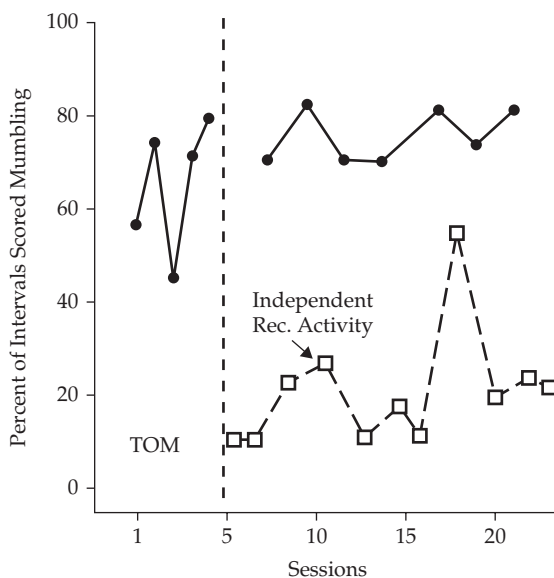

Figure 160.1 Percentage of intervals scored mumbling or solitary laughter in baseline sessions (circles) and in recreation sessions with independent activity (squares). From Wong et al. (1987, p. 80) with permission from the Society for the Experimental Analysis of Behavior.

its head! But note the original definition of EBP: “The conscientious, explicit, and judicious use of current best evidence in making decisions about the care of *individual patients*” (Sackett et al., 1996, p. 71, emphasis added). What better evidence regarding the appropriateness of a given intervention than a clear and compelling demonstration that it really seems to work with *our client*? Large-scale group studies very rarely make use of true probability samples, a prerequisite for generalizing findings, and in any case probability theory only permits inferences upward from sample to population, not downward from a sample (as in an RCT) to an individual.

CAN N = 1 STUDIES REALLY BE CALLED EXPERIMENTS?

Within the social work research literature, the term “experiment” is almost exclusively reserved for nomothetic studies involving relatively large groups of clients who are randomly assigned to receive an experimental psychosocial intervention, to receive no treatment, to treatment-as-usual, or to a placebo-control group. Pretreatment assessments may be used, and post-treatment assessments are essential to make any inferences about possible differential effects of the conditions to which the clients were exposed. Any post-treatment differences may be plausibly ascribed to their assigned condition (e.g., to the active or experimental treatment) as opposed to some rival explanation (e.g., passage of time, regression to the mean, concurrent history). Such designs have the potential to possess

high internal validity in that any conclusions drawn about the relative effects of the experimental conditions can be seen as quite credible, with the random assignment feature controlling for other possibilities. Such designs are called RCTs and can indeed be quite powerful.

However, traditional RCT methodology is often required in social work intervention research only because of the large amount of variance present in our studies. Frequently the independent variable (e.g., treatment) exerts modest effects at best and may be quite labile, readily influenced by client idiosyncrasy or environmental contextual factors. In other words, our interventions are often not robust. Dependent variables (e.g., outcome measures) may lack precision, being subject to various forms of bias, and contain a large amount of noise or unexplained variation as well. These factors essentially *require* the use of sophisticated inferential statistics to separate out the “real” effects of treatment from the noise and also necessitate studies having sufficiently large sample sizes to possess adequate statistical power to accomplish this task. But keep in mind that nomothetic research designs and inferential statistics are just one set of tools to accomplish experimental demonstrations. Extremely powerful treatments do not require such sophisticated controls because their effects are obvious and compelling, swamping the sometimes unwanted variance caused by client and context.

Table 160.1 provides some descriptions of what is meant by the term “experiment” in its broader sense. The crucial factor that distinguishes the true experiment from other forms of research

TABLE 160.1 Some Definitions of the Term “Experiment”

-
- “A study in which an intervention is deliberately introduced to observe its effects” (Shadish, Cook, & Campbell, 2002, p. 12).
 - “One or more independent variables are manipulated to observe their effects on one or more dependent variables” (Shadish et al., 2002, p. 12).
 - “The manipulation of one or more independent variables conducted under controlled conditions to test one or more hypotheses, especially for making inferences of a cause-effect character. Involves the management of one or more dependent variables” (Corsini, 2002, p. 351).
 - “Manipulations of subject and/or intervention is the essence of experimental method.... The demands of science and of practice have led to a whole array of experiments. They include experiments designed... with the subjects serving as controls for themselves” (Wollins, 1960, p. 255).
 - “N of 1 RCT An experiment in which there is only a single participant, designed to determine the effect of an intervention or exposure on that individual” (Guyatt & Rennie, 2002, p. 418).
 - “A research study in which one or more independent variables is systematically varied by the researcher to determine its effects on dependent variables” (Holosko & Thyer, 2011, p. 39).
-

is the deliberate, planned manipulation of an intervention, and the systematic observation of its possible effects. Sample size has no bearing on the validity of this principle. Such an experimental study may involve 1,000 participants, 100, 10, or even only 1. The crucial test is whether clear effects can be observed. If the answer is yes, you have a legitimate demonstration of the value of the treatment, that is, an experiment. If not, one is faced with two possibilities. The first is that the treatment simply does not work. The second is that the treatment “works,” but its effects are so minimal that they could not be detected with the research design and sample size used.

Studies involving small groups of clients (or even only one client) minimize Type I experimental errors (claims that a real effect is present, when it is really not) but are more liable to Type II errors (claiming that an effect is not present, when it really is). Studies with sizable groups minimize Type II errors (they are less likely to miss small but reliable effects of treatments) and are more liable to make Type I errors (claiming that an effect occurs, when it really does not). The use of *p* values derived from inferential tests, absent reporting their associated effect sizes, promotes Type I errors in nomothetic research. We learn more about reliable, albeit trivial, effects. Reporting effect sizes can help reduce this problem. Conversely, *N* = 1 studies are not very good at detecting small effects of our treatments (that is, are prone to Type II errors), and some researchers consider this a good thing, in that we are less liable to claim positive effects for trivially effective interventions, channeling our energies into pursuing treatments with powerful, robust effects. Usually, the data from *N* = 1 studies are graphically depicted and inferences are made on the basis of visual inspection alone. If they cannot be seen by the naked eye, unaided by inferential statistics, then the conservative researcher concludes that any reliable effects are of such small magnitude as to be of little clinical importance. This means that conclusions derived from *N* = 1 research tend to be more robust, in terms of internal validity because confident conclusions are rare, absent visually compelling evidence, such as that displayed in Figure 160.1.

OTHER FORMS OF EXPERIMENTAL N = 1 DESIGNS

The *N*-of-1 RCT or ATD is not the only type of within-client research design that can be applied

to evaluate the effects of interventions with individual clients. Other selected *N* = 1 designs may also permit robust conclusions using the same logic applied with the ATD, namely, repeated demonstrations of an effect, following the introduction or removal of a treatment. In the ATD this introduction or removal of a treatment condition is dictated by the toss of a coin. If the outcome measure reliably fluctuates in a manner closely consistent with the manipulation of the treatment, we have increasing confidence that these outcome fluctuations can be attributed to the treatment itself, or to its removal. The greater the number of such demonstrations, the greater the internal validity.

Similar simple logic is the basis for causal inference in a type of *N* = 1 study called the ABAB design. Here, A refers to a period of time when the client received no formal treatment. The time period could conceivably be hours, days, weeks, or months, depending on the nature of the problem and circumstance surrounding it. During this A or baseline phase, a credible outcome measure is administered a number of times, and the data are plotted on a line graph, with time on the horizontal axis and the outcome measure scaled on the vertical axis. Ideally, the first baseline line is long enough to obtain data that are visually stable, for example, not obviously getting better (it is okay if they are getting worse). Then the treatment is introduced, and the outcome measure continues to be assessed. Ideally, one sees an immediate improvement after the treatment begins during this second, or B, phase. The data continue to be plotted and these improvements themselves stabilize. Thus far, one has completed an AB *N* = 1 study, one that possesses only one apparent demonstration of a functional relationship between the introduction of a treatment and client improvement. Unfortunately, only one such demonstration does not usually qualify a study to be labeled as a true experiment. A number of rival explanations cannot be ruled out with this simple design, for example, concurrent history, regression, placebo, a cyclic nature to the problem, and so on. To help rule out such threats, the intervention, B, is withdrawn or removed, and the baseline condition is reinstated (the second A phase). Ideally, the client relapses—ideally, that is, from the perspective of providing an experimental demonstration. If this happens, then we now enjoy two demonstrations of an apparent functional relationship between the treatment and the problem—one when the

treatment was introduced (the client got better) and the second when the treatment was removed (the client got worse).

The second A phase is then followed by the reintroduction of the treatment for a period of time comprising the second B phase. Ideally, the client improves once again, leaving the social worker with three solid demonstrations of experimental control of outcome by the treatment—twice when the treatment was introduced (the client got better) and once when the treatment was removed (the client got worse). When graphically depicted, with obvious demarcations in the data between the four phases of the study, this is usually a very convincing demonstration of the effects of treatment. The inferential logic remains the same between the ABAB design and the ATD, repeatedly introducing the treatment or its removal. Strong effects are evident to practitioners, clients, and neutral observers alike. Absent strong effects (for example, in the case of only minor changes in the data, or considerable overlap in the range of data between adjacent phases), the same conservative principles suggest that one conclude the intervention is not clinically valuable. Again, Type II error is more likely (you will miss minor but reliable effects) and Type I error minimized (you are very unlikely to conclude that a strong effect is present, when it is really not).

The possible permutations of these simple principles are numerous. A further demonstration may be possible, as in the ABABAB design. One may try to compare the relative efficacy of two interventions, as in the ABAC design. These types of $n = 1$ designs relying on changes in the data coincident with the introduction of the treatment and its *removal* are obviously only possible for interventions with short-lived effects. If a treatment can be expected to produce a durable improvement, then the ABAB design will not be useful, because the relapse anticipated during the second B phase will not be forthcoming. Examples of such interventions may include teaching the client a social or intellectual skill, the attainment of personal insight (perhaps via psychotherapy), personal growth or strengthening of psychological resources, the removal of phobic fears or obsessive-compulsive behaviors, or acquiring a cognitive coping skill (e.g., rational self-talk). Discontinuing such an intervention will not necessarily obliterate any clinical gains made by the client, and thus the ABAB design, or another $N = 1$ study that depends on

client relapse occurring following the removal of a treatment for causal inferences to be made, is not usually a suitable $N = 1$ design in such circumstances.

When one is applying a treatment that is expected to produce not only immediate but also durable effects, another form of $N = 1$ experiment called the multiple baseline (MBL) design may be possible. The MBL also relies on the same logic as other experimental clinical research designs—repeatedly demonstrating that an effect is observed when a treatment is applied. There are various types of MBL designs, and one of the more common is the MBL across clients. This design requires that you have two or more clients seeking treatment at about the same point in time, with a similar problem, for which you believe a particular treatment is appropriate. Let us use as an example two clients who present for help in overcoming a specific phobia. You begin with a baseline phase for both clients, having searched the literature and located one (or more) credible outcome measures. When each client has stability in their baseline data (the A phase), you begin treatment (say, gradual real-life exposure therapy) for Client 1 (transitioning into the B phase) but *not* for Client 2 (who remains in the A phase). The internal validity of this design depends on seeing rapid improvements in Client 1 but *not* in Client 2. Some time passes, Client 1 continues to improve, and you then begin treating Client 2 with a similar program of exposure therapy (the B phase). Imagine two AB designs stacked atop each other, with the lower one having a longer baseline, but each having stable baseline data, and marked improvement only when treatment begins during the B phase. This approach in effect permits two possible demonstrations of experimental control, each time when the treatment was applied to two different clients. Two demonstrations is much better than one (as in a simple AB design), and three such demonstrations, as in an MBL design across three clients, approaches the internal validity of the ABAB design (which also can yield three demonstrations).

A second form of MBL is called the MBL across settings design, and it may be used to determine the effects of one particular therapy on one problem experienced by one client in different contexts. As an example, suppose a child client displayed hyperactive behavior, in the home, and in the school, and this was posing a significant problem for the child. In the MBL across settings

design, baselines would be taken of hyperactive behavior in the two settings, and displayed on two stacked AB-type graphs. When the baseline data are stable in both settings, an intervention (say, a point system to reward in-seat behavior) is initiated in one setting only, say, the school, whereas the baseline condition is maintained in the other setting (the home). Experimentally, one desires to see immediate improvements in the first setting, and stable, problematic conditions continuing in the second one. Then, after some time, the same intervention is applied in the other setting, with, it is hoped, a similar positive effect. This design also constitutes providing two demonstrations of experimental control, an improvement over only one demonstration, and adding a third setting for baselining and intervention enhances internal validity even further.

The third and final form of MBL design is the MBL across problems design. It may be useful in clinical situations wherein one client presents with two or more problems potentially amenable to treatment by the same intervention. Imagine a child doing poorly in two subjects at school, arithmetic and reading. With the cooperation of the teacher, the social worker gets regular reports of the child's grades in each of these two subjects. These grades are baselined separately, and then an intervention, say, tutoring, is provided in *one* subject, but not in the second, which continues to be baselined. Experimentally, one wishes to see that the first academic subject (for which tutoring was provided) displayed immediate and marked improvements in grades, whereas the second subject remained stable (with poor grades). Then the same intervention, tutoring, is provided to the second subject, which then also immediately displays a sharp improvement in grades. Again, the logic is the same, with two or more demonstrations of an effect—the problem is stable, an intervention is applied, and the problem is significantly improved. The MBL across three or more problems is even more convincing than with only two, and in certain circumstances, for example, clear data, a valid outcome measure, and treatments that can be deliberately introduced, the social worker is capable of providing genuinely experimental results, outcomes so compelling that most doubts are removed as to the effectiveness of the intervention.

The logic of $N = 1$ studies follows principles elucidated by John Stuart Mill in his classic book *A System of Logic*. In it he outlines several forms of evidence that can permit causal inferences.

Among these are the so-called Method of Direct Agreement, which states, "If two or more instances of the phenomenon under investigation have only one circumstance in common, the circumstance in which alone all the instances agree, is the cause (or effect) of the given phenomenon" (Mill, 1875, p. 454). Related is the Method of Difference, which reads, "If an instance in which the phenomenon under investigation occurs, and an instance in which it does not occur, have every circumstance save one in common, that one occurring only in the former; the circumstance in which alone the two instances differ, is the effect, or cause, or a necessary part of the cause of phenomenon" (p. 455). And Mill's Method of Concomitant Variations is also pertinent to the logic of $N = 1$ designs: "Whatever phenomenon varies in any manner whenever another phenomenon varies in some particular manner, is either a cause or an effect of that phenomenon, or is connected with it through some fact of causation" (p. 270). These logical principles undergird all experimental investigations, group and single-subject. Keeping other conditions constant, introduce (or remove) a presumptive independent variable (social work treatment). See what happens. Repeat several times. Consistency of apparent effects argues for the influence of the independent variable in a causal sense. Certainly not in terms of ultimate causation, but often with respect to proximal causes, causes that may be useful in social work practice.

In any research design, nomothetic or $N = 1$, poor results mean that experimental control has not been demonstrated, and internal validity is low. But if powerful effects are exerted by the treatment, these can be compellingly disclosed in $N = 1$ studies. The ATD is one $N = 1$ study with the potential to demonstrate internally valid conclusions. $N = 1$ studies using withdrawal designs, such as the ABAB, or the various forms of MBL designs, are also capable of permitting causal inferences. There is no claim that the experimental $N = 1$ studies can be applied in every clinical situation, but certainly their versatility permits far greater use than they have heretofore enjoyed as a method of evaluating clinical outcomes in social work practice. And $N = 1$ designs of lesser internal validity, such as the B, AB, or ABA types (see Thyer & Myers, 2007) are even more readily applicable in everyday practice. The use of $N = 1$ studies within social work is not of hypothetical value. A bibliography on the topic (Thyer & Thyer, 1992) prepared 17 years ago found over

TABLE 160.2 Some Indications for Considering N = 1 Experiments in Evidence-based Practice

- Is there a reliable and valid way to assess the client's problem/condition? For example, is a credible outcome measure available? (The answer should be yes)
- Can the outcome measure be repeatedly assessed over time? (The answer should be yes)
- Are the effects of social work intervention likely to have a rapid onset? (The answer should be yes)
- Is using an N = 1 design ethically acceptable? (The answer should be yes)
- Is participating in an N = 1 design acceptable to the client? (The answer should be yes)
- Is the intervention feasible? (The answer should be yes)
- Will the effects of intervention likely be durable or permanent? If yes, then a multiple baseline design may be indicated. If not, then a withdrawal or alternating treatments design may be most useful.

200 published examples. Wong (2010) is an excellent overview of the use of these designs in social work practice.

EBP has long advocated that practitioners evaluate the effects of their interventions using experimental N = 1 research designs. Thus far the EBP literature in this regard has given limited attention to one type of N = 1 study, the alternating treatments design. However, a more diverse array of N = 1 designs have the potential to yield truly experimental results, and these deserve serious consideration by the social worker seeking to practice within the model known as evidence-based practice. Table 160.2 lists some pragmatic indications for considering using an N = 1 study to evaluate outcomes in evidence-based practice.

The evidence-based model described in this section on evaluating the effects of intervention presents a perspective that has long been present in social work.

"... the social worker can throw light on social causation. It is sometimes said that the sociologist, unlike other scientists, cannot engage in experiments. But that is what the social worker does all the time... he does, and must, experiment... Practical necessity compels the social worker to seek an answer to the questions of causation. (pp. 83–84)... what we want to discover, whether as social scientists or as social workers, is the causes of things, the dependence of one phenomenon on another... The social worker, being always engaged in making experiments, can advance the far too neglected study of social causation. (p. 89)... The question of social causation is so crucial for the social worker that it should determine his whole approach. (p. 93) (McIver, 1931)

Single case experimental designs provide a robust methodology to fulfill these laudable

aspirations of over 80 years ago. When combined with the five-step decision-making process of evidence-based practice, the potential for improvements in the delivery of social work services is immense.

GLOSSARY

Compiled by Mallory Jensen

AB design: A single-system research design for comparing client functioning during treatment (i.e., the intervention or B phase) with client functioning before treatment (i.e., the baseline or A phase). The AB design is used to monitor client change and evaluate treatment outcomes.

ABC model: Originally devised by Albert Ellis, this model inserts cognition as a mediating factor between people's experiences and their emotional/behavioral responses to those experiences. Activating events are followed by *beliefs* that result in consequences of emotions and behaviors.

Abstinence violation syndrome: A concept developed by G. Alan Marlatt describing a phenomenon observed after a slip or relapse. Those who have relapse feel guilty and ashamed. They seek solace in their drug of choice. Further, they fail to draw a distinction between a small lapse deviation from sobriety versus a major relapse from sobriety, which differ in the amount consumed and the duration in the period of use. When the client fails to distinguish between lapses and relapses, there is no incentive to get back on track quickly.

Access to care: The opportunity for consumers to obtain needed services, with attention to such issues as the location of service, hours of operation, and affordable fees.

Accountability: Providing information, in useful form, to others who must make decisions or take action regarding a person, case, situation, agency, or community. A social worker may be accountable to a supervisor, a community, clients, the court, a board of directors, the profession, and other parties. Being accountable means being

responsible for providing services in accordance with high standards.

Actuarial risk assessment: An empirically derived estimation of the likelihood of maltreatment recurrence over time; it has consistently demonstrated higher levels of reliability and validity when compared with consensus-based approaches and clinical judgment in estimating the probability of recurrences.

Adaptedness: A favorable person-in-environment fit that supports human growth and well-being, and preserves and enriches the environment.

Administrative law: The body of law that is focused on rules, policies, procedures and other actions issued by federal, state, and local governmental agencies. It includes agency-created appeal, mediation, and/or hearing processes.

Adverse effect: The physical, psychological, or social effect of an intervention that is unintentional and unrelated to its desired actions.

Advocacy: To speak up in favor of an issue, to plead the case for another, or to champion a cause, often for individuals and groups that cannot speak out on their own behalf. Types of advocacy include self-advocacy, case advocacy (for an individual client), and class advocacy (on behalf of a group or category of individuals in similar circumstances).

Affordable housing: Housing for which the occupant generally pays no more than 30% of gross income for rent.

African-centeredness: Acknowledges African culture, expressions, values, beliefs, and institutions.

African-centered genogram: A cultural visual representation of the African American family that depicts both functional relationships and biological relationships.

Age-specific intervention: An intervention based on empirical studies designed specifically to treat older persons' problems.

Aggressive outreach: Direct and intensive services that occur in the consumer's home and natural community.

Alliances/coalitions: In a family or group, relationships formed between two or more individuals that serve a specific function in influencing interpersonal dynamics.

Allocation concealment: Disguising group assignment, particularly upcoming assignments, in clinical studies. Without it, even properly developed random allocation sequences can be subverted.

Ambiguity: The introduction of therapeutic content that can be interpreted in more than one way by the client.

Ambiguity in therapy: Forms of speech, metaphors, imagery, body movements, and so on, that stimulate a search process in the listeners to find their own relevant meanings.

Anger outburst: Extreme display of emotion characterized by irritability, physical or verbal attack, and rage with negativism that is considered maladaptive when it occurs without an immediate catalyst.

Anorexia nervosa: A disorder characterized by self-induced starvation and severe fear of gaining weight and looking fat, resulting in medical symptoms related to starvation.

Antecedent: An environmental event or stimulus that precedes a response. When the antecedent signals that a response is or is not likely to be followed by a reinforcer, it is referred to as a discriminative stimulus.

Anxiety-management technique: Behavioral processes such as progressive relaxation training, guided self-dialogue, and thought stopping, aimed at teaching clients to reduce and cope with debilitating anxiety.

Anxiolytics: A class of drugs that reduce anxiety; also known as minor tranquilizers.

Arbitration: A conflict resolution process conducted by a neutral third party, who can impose

a legally binding decision if the disputants cannot agree.

Assertive community treatment (ACT): An evidence-based service delivery model in which the same clinical team, using largely outreach methods, provides comprehensive community-based treatment, rehabilitation, and supportive services to persons with severe and persistent mental illness. This model is also known as PACT, or Program of Assertive Community Treatment.

Assessment: The process of systematically collecting data about a client's functioning, and monitoring progress in client functioning, on an ongoing basis. In this way, social workers identify and measure specific problem behaviors as well as protective and resilience factors, and determine whether treatment is necessary. Information is typically gathered from a variety of sources (e.g., individual, family members, case records, observation, rapid assessment tools). Types of assessment include bio-psychosocial history taking, multidimensional crisis assessment, symptom checklists, functional analysis, behavioral measurement, and mental status exams.

Asset development: The process of assisting families or individuals in gaining wealth by building capital through home ownership, savings accounts, retirement accounts, and investment portfolios.

Assimilative integration: Integrative approach to psychosocial intervention drawing on ideas and technical procedures from various schools of thought but guided by a unitary theoretical perspective; practitioners incorporate techniques into the primary conceptual model of intervention.

Assisted suicide: Hastening one's death, in the face of a life-threatening illness or debilitating condition, with aid from another person. This term is generally used to refer to actions taken by a physician, but the assistance (which is illegal in some states) can also be from other health professionals, friends, or family members.

Attention deficit hyperactivity disorder (ADHD): A persistent pattern of inattention, hyperactivity, and impulsivity in two or more settings (e.g., school, work, or home). The *DSM-5* lists three subtypes: combined type, predominantly hyperactive-impulsive type, and predominantly inattentive type (which most closely

resembles what was previously termed attention deficit disorder, or ADD).

Authority theme: Issues having to do with to the relationship between the client (individual, family, or group) and the social worker.

Availability heuristic: First described by Daniel Kahneman and Amos Tversky. The principle holds that whatever a person can imagine will be evaluated as more probable. When applied to one's own behavior, the principle states that if I can envision myself behaving in a particular way, this will change my self-perception. Moreover, I will be more likely to behave consistently with what I have imagined myself doing.

Awareness: A growing consciousness and developing internal knowledge of self through thoughts, sensations, feelings, actions, and memories, and an external attentiveness to others and the environment.

Baseline: The assessment phase of practice, when the frequency of a specific behavior, client functioning, or attitudes are measured over time prior to an intervention.

Batterer Intervention Program (BIP): Batterer intervention programs (BIPs) are treatment programs for men and women who abuse their partners, whether the abuse is physical, verbal, sexual, psychological, or another form of abuse. Most often, those who attend batterer intervention programs have been court-ordered to do so.

Behavioral experiment: Identifying and testing of the validity of a client's thoughts through enactments in actual life experience or through role-plays.

Behavioral family therapy: Family therapies that emphasize reinforcing and punishing family relationships with one another and with the social environment. These therapies are action-oriented and focus on learning new skills that modify behavioral functioning and reframe and alter cognitive perceptions.

Behavioral observation: The process of carefully defining an overt activity or event and tracking the frequency, intensity, or duration of its occurrence. Behaviors should be specified in detail so that others can accurately count the same behavior in the same way.

Behavioral social work: A research-based treatment approach founded on learning theory, which holds that much behavior is learned

through contingencies of reinforcement and/or punishment. Consequently, problematic behavior can possibly be unlearned and prosocial behavior can be learned to replace it. Specific, measurable behaviors are the targets for intervention. A behavioral assessment is first done to identify what environmental changes are needed to modify problematic behavior. A treatment plan is then developed for changing the contingencies of reinforcement and/or punishment. The target behavior is measured in a baseline period and then monitored throughout the treatment process once intervention begins.

Best practice: A technique or methodology that, through empirical research, has proven in the past to lead reliably to a desired result.

Bio-psychosocial model: An attempt to integrate a vision of a client as a person, in situation, not unlike the social work concept of person-environment fit. This model recognizes that biological factors are necessary but not sufficient for understanding a human person in a social world. Although psychosocial factors such as stress, anxiety, and depression may underpin many conditions, some disorders may be understood to be truly bio-psychosocial. There is a known genetic basis to many illnesses, but it is understood that social and environmental triggers must be present to bring about the potential illness. Therefore, this term is applied to phenomena that consist of biological, psychological, and social elements.

Bio-psychosocial-cultural assessment: A comprehensive assessment model that ascertains the influence and interplay of biology, psychology, learnings, social environmental, and cultural factors on a client's mental health. It is the basis of the multiaxial diagnostic system of the *Diagnostic and Statistical Manual of Mental Disorders (DSM)*.

Bipolar I: A level of depression characterized by the presence of episodes of major depressive disorder and at least one documented manic or mixed episode.

Bipolar II: A level of depression characterized by at least one major depressive episode that is accompanied by at least one hypomanic episode.

Blocking: A worker intervention that prevents the execution of undesirable, unethical, or inappropriate behaviors by the group as a whole or individual members.

Borderline personality disorder (BPD): A pervasive pattern of instability of interpersonal relationships, self-image, and affects, along with a marked impulsivity that begins by early adulthood and is present in a variety of contexts. People with BPD have among the highest suicide, attempted suicide, and mental health utilization rates of those with any psychiatric disorder.

Boundaries: The spoken and unspoken rules that case managers and clients observe regarding the physical and emotional limits of their relationship.

Boundary-spanning role: The part played by agency practitioners who have the capability and responsibility of making connections with other organizations and agencies in the community. This promotes coordination and joint effort on behalf of clients.

Brief treatment: An approach to working with clients that acknowledges up front that there is a time limit to treatment. Models vary and may include specific session limits (for example, up to 12 sessions) or time limits (for example, up to three months).

Broad definition of forensic social work: Any form of social work practice that is related in any way to legal issues or litigation in the criminal or civil justice legal systems.

Broker: A case manager who conducts assessment, develops care plans, and makes referrals to provider agencies for services. Brokers cannot authorize or purchase services for their clients.

Bulimia nervosa: A pattern of binge eating combined with attempts to avoid weight gain, such as purging, alternate calorie restriction, laxative use, and/or overexercise.

Bullying: Attacking an individual, often on the basis of a perceived difference or vulnerability; usually associated with school and workplace attacks.

Capacity building: A strengths-based approach to community building that involves preparing and supporting staff, natural helpers, and parents to increase their skills and knowledge for personal, organizational, professional, and family center development. Gaining access to needed resources and services is critical to capacity building.

Capitation: A method of financing health and mental health programs common in many

managed care plans, in which providers agree to offer a specified package of services for a predetermined cost. The payment is most often made on a monthly basis. The provider is responsible for delivering or arranging for the delivery of a designated range of health care services for this predetermined payment, regardless of actual cost of the services. There is concern by social workers that high-risk, high-user, vulnerable populations will be disadvantaged under capitated arrangements.

Caregiver: One who provides services to a client in the home or immediate community environment. This may be a family member, a community member, or a paid provider.

Care planning: A process, involving clients and caregivers, that translates information collected during assessment into a plan of care, identifying services to be delivered, formal and informal providers, frequency of service delivery, and cost. Care planning is a resource-allocation process.

Caring: One element of the construct “working relationship”; the client’s sense that the worker is concerned about him or her and that the worker wishes to help with those concerns the client believes are important.

Case management: A service that links and coordinates assistance from institutions and agencies providing medical, psychosocial, and concrete support for individuals in need of such assistance. It is the process of social work intervention that helps people organize and use the supports, services, and opportunities that enable them to achieve life outcomes that they value. Additionally, it is a direct practice method that involves skills in assessment, counseling, teaching, and advocacy that aims to improve the social functioning of clients served. In this service concept, clients are provided both individualized counseling and are linked to other needed services and supports.

Case record: A written and authenticated compilation of information that describes and documents the client assessment, along with present, past, and prospective services to the consumer.

CAT (Critically Appraised Topic): A brief (one-page) description of a well-structured question, search strategy, related research found, critical appraisal of what is found, and clinical bottom line.

Catharsis: The emotional relief experienced following the process of revealing one's inner anxieties and conflicts. For adults, this can occur through talking about one's problems; for children, this relief can occur through play containing elements of the conflict and anxiety.

Change activist: Someone who acts in an attempt to make a change on another person or community's behalf and may charge a modest fee (e.g., ministers, priests, spiritualists, and folk healers).

Change strategy: The action taken to pursue a desired change based on (1) what is most likely to influence decision makers and allies to make the desired change, and (2) what is possible given the time and resources available.

Change tactics: The actions or events that implement change strategy.

Change target: The person or group that must consent for a change to occur.

Child abuse and neglect: The physical or mental injury, sexual abuse, negligent treatment, or maltreatment of a person under the age of 18 years.

Child protection mediation: A conflict resolution process in which an impartial third party assists parents, children, child protection workers, extended family members, foster parents, or others to resolve conflict in cases involving child abuse or neglect (also called "dependency mediation").

Child support: Provision of financial resources by the parent who does not have primary custody of the child to meet the daily needs of the child.

Circular causality: A repetitive pattern of interaction between two or more individuals that results in an undesirable outcome for one or more of those involved. The term may also refer to a systems perspective that focuses on the mutual influences and interpersonal contexts in which problems develop.

Clarification: Process by which the juvenile with sexual behavior problems clarifies that the responsibility for the assault/abuse resides with the offender and addresses the harm done to the victim and the family.

Class action suit: A court action filed on behalf of named parties as well as a larger number of persons who are said to be "similarly situated" (in comparable circumstances).

Client-monitored behaviors: Actions, thoughts, or feelings that clients track over time. More easily identifiable behaviors tend to be both recognizable by clients and more accurately reported than those they perform automatically or subconsciously.

Clinical algorithm: Schematic diagrams outlining the decision pathways described in a practice guideline. The diagram is usually formatted in a decision-tree format, with yes/no options presented at each decision point.

Clinical case management: An approach to human service delivery that integrates elements of clinical social work and traditional case management practices. The social worker combines the sensitivity and interpersonal skill of the psychotherapist with the creativity and action orientation of the environmental architect.

Clinical expertise: The integration of current best research evidence, client preferences and actions, and clinical state and circumstances.

Clinical social work: This practice area includes case advocacy, case management, psychotherapy, clinical supervision, teamwork, behavior analysis and therapy, and program development. Therefore, clinical social work practice emphasizes direct work with individuals, families, and small groups, but is not limited to psychotherapeutic models and practices.

Clinical syndrome: A cluster of symptoms and behaviors that are defined as a mental disorder. Clinical syndromes are diagnosed on axis I of the *DSM-5* system.

Cluster randomized trial: A trial in which groups or areas are assigned a condition at random. May be used when an intervention can only be administered to the group (e.g., a public education campaign), to avoid contamination (e.g., by assigning schools rather than children or classrooms), or to reduce effort and save money.

Coalition: A cluster of organizations formed for a common purpose or social agenda, while each maintains its own identity. Coalitions have a series of inherent dynamic tensions that need to be balanced: cooperation and conflict, unity and diversity, mixed loyalties, and accountability and autonomy.

Code of ethics: A formal document ratified by a group or organization containing ethical principles, guidelines, and standards. The most

frequently adopted code of ethics for social workers has been approved by the National Association of Social Workers (NASW) and is called the NASW Code of Ethics.

Cognitive bias: An unconscious tendency to distort one's views in a certain direction.

Cognitive distortion: Attitudes, thoughts, or beliefs that are irrational or illogical.

Cognitive distortions & restructuring: Also known as thinking errors; excuses, denial, rationalizations, and minimization of sexual offending behaviors that are identified, examined, and confronted in treatment.

Cognitive elaboration: The generation of alternative conceptualizations of a given event, phenomenon, or stimulus condition. This process is completed in recognition that multiple meanings exist for all human experience.

Cognitive restructuring: The use of logic and evidence to modify cognitions and cognitive processing. Socratic dialogue, guided imagery, and behavioral experiments are typical approaches associated with the cognitive behavior therapy approach.

Cognitive-behavioral therapy: A treatment model emphasizing the primacy of thoughts and beliefs in influencing feelings and subsequent actions. Interventions include social skills training, problem solving, cognitive restructuring, and communication skills training. Also known as a theoretical approach to treatment that stresses the role of thoughts, beliefs, perceptions, and attitudes on feelings and behavior. Techniques include cognitive restructuring; cognitive coping skills such as problem solving, self-reinforcement, and relaxation; and training in social skills, assertiveness, and communication. Behavioral methods, such as rehearsal, modeling, reinforcement, and coaching, are typically employed for the delivery of content.

Cognitive therapy: Therapeutic technique in which dysfunctional cognitions, including automatic thoughts, beliefs, and assumptions are challenged logically and functionally in order to modify them, in turn producing positive changes in related affect and behavioral responses.

Cohesive self: The essential self-structure of a well-adapted, healthily functioning individual whose self-functioning evinces the harmonious interchange of ambitions, ideals, and talents with the events of everyday life.

Common factors perspective: An integrative approach to psychosocial intervention that emphasizes core elements shared by the major systems of psychotherapy rather than specific technical procedures associated with particular schools of thought. Common factors include client characteristics, such as motivation and expectations of change; practitioner characteristics, such as attunement, empathy, and authenticity; provision of rationale for problems in functioning and conceptual framework for intervention; and strategic processes, such as experiential learning, interpretive procedures, modeling, reinforcement, and exposure.

Community-based case management: A model of case management that emphasizes involvement of all community partners in the client's well-being. It benefits from the synergy that occurs when multiple stakeholders work together to deliver client services and has been particularly effective in the child welfare field.

Community-based services: Services that are situated in the home environment of clients and are easily accessible to them. The term is often associated with decentralization of services.

Community capacity: A form of social organization that emanates from the operation and interaction of formal and informal networks of social care in the community that allows community members to demonstrate *shared responsibility* and *collective competence* for addressing community needs and confronting situations that threaten the safety and well-being of the community.

Community organizing: The process of bringing people and groups together to collectively address a need, solve problems, or improve a social condition.

Community partnership: An alliance between citizens and practitioners to bring about planned change for the common good.

Community practice: The generic term for social work intervention at the community level, defined geographically or functionally, including practice in the neighborhood, around a common issue, or around a shared identity. Its components include community building, organizing, development, and planning.

Community results: Aggregate, broad-based outcomes that reflect the collective efforts of individuals and families who live within a specified area.

Comorbidity: When two or more diseases or conditions coexist or co-occur.

Compassion fatigue: Characterized in social workers and counselors by weariness and loss of confidence, often accompanied by self-doubt and loss of conviction in one's knowledge and methods. Results from unrelieved and intense interaction with clients and lack of self-support systems.

Computerized practice management: Computer programs that keep track of basic patient information, appointments, insurance authorizations, and billing and payments. They also may include assessment information and progress notes. Most are designed primarily for individual and small group practices.

Conceptual framework: A guiding set of interrelated assumptions, based on one's worldview, that is used to provide direction for practice methods.

Conduct disorder: A *DSM* diagnosis that involves an entrenched pattern of behavior in which a person violates the basic rights of others or where major age-appropriate societal norms or rules are violated. This pattern involves four categories of behaviors: aggressive conduct either causing or threatening harm to people or animals; nonaggressive conduct leading to property loss or damage; deceitfulness or theft; and serious violations of rules. The person demonstrates at least three such behaviors in the past year, with at least one in the past six months.

Confidentiality: Involves safeguarding personal information from unwarranted disclosure. Under the NASW Code of Ethics, social workers are expected to maintain confidentiality by collecting only essential information about their clients, revealing clients' confidences only for compelling reasons, and disclosing information to third parties only with proper informed consent from clients or others acting on their behalf.

Congruence: A practitioner's display of genuineness and honesty with the client.

Consensus-based safety assessment: List of factors (some of which may come from research) that are thought by a convened group to be related to the likelihood of immediate harm.

Constituency: The group with whom or around which a social worker organizes. Constituents may include clients, consumers, residents, members, parents, students, service recipients, and patients.

Construct: An active processing or organizing experience in an individual's mind. Personal constructs represent personal or shared meanings.

Construct elaboration: The generation of alternative conceptualizations of a given event, phenomenon, or stimulus condition. This process is completed in recognition that multiple meanings exist for all human experience.

Constructivism: A worldview postulating that there is an objective, external reality but a person can never experience it directly and that the structure of the individual human organism and human mind, rather than that of the environment, is the central mechanism in reality construction.

Consumer-directed services: An approach to service delivery for older people and people with disabilities in which consumers have a degree of decision-making authority about their own services.

Consumer-driven case management: A case management model that emphasizes providing the best organized practice for clients in complex and chronic situations.

Contact boundary: The point where self meets other, distinguishing one person from another. The flexibility of this boundary determines the quality of the contact with the other and ultimately the stretching of all boundaries, which from a Gestalt perspective represents growth.

Contact: The psychological process of engaging with the environment and ourselves. Contact refers to the quality of the way one is in touch with and experiences the world.

Contamination: This occurs when members of the control group in an experiment inadvertently receive the intervention. It may be prevented by sampling natural clusters.

Continuing education: Demonstration of continued competency through completion of continuing education hours as part of the re-credentialing process. Traditionally, programs offered for continuing education are for skills that enhance or reaffirm a social worker's professional knowledge and skills.

Continuum of care: A wide range of health and social services, provided in the home, community, and institutional settings designed to serve older adults as their needs change over time. It is more than a collection of service components. It is an organized, coherent, and integrated service system.

Contract: An agreement between parties that defines the relationship between them, the responsibilities of each party, and penalties to each should agreements not be met. To be valid, contracts must be entered into freely and without coercion. There are three kinds of contracts used with clients in social work. The *service* contract describes and defines the relationship between the client and the service provider, agency, or program. The *initial* contract develops the tasks of the initial period, which include gathering information, assessment, and problem definition. The *therapeutic* contract defines worker or client objectives in the change process and the tasks, treatments, and interventions that enable their achievement. The therapeutic contract assigns specific tasks and responsibilities, and develops both a time frame and a system of measurability. The contract is the plan that worker and client will follow in achieving the mutually determined goal.

Contracting process: A worker-initiated effort, usually in the beginning phase of the work, to establish the purpose of the contact, explain the worker's role, gain some sense of the client's issues (feedback), and deal with issues of authority.

Controlled elaboration of ambiguity: Refers to the therapist's responsibility for introducing the sufficient amount of ambiguity during the telling of a therapeutic story to ensure that the client's attention is engaged and resistance is minimal.

Co-occurring services: Where two or more problems exist together (mental illness, domestic violence, substance abuse, developmental disability, etc.), services or programs are provided one after the other (serially), at the same time without information sharing (parallel), at the same with information sharing (coordinated), or at the same time by the same agency (integrated).

Coping question: A form of solution-focused query used when clients seem overwhelmed and discouraged beyond the point of trying. Answers can assist the social worker in moving forward with the client toward solution development.

Core beliefs: Basic beliefs about oneself, others, and the world that are formed early in childhood and are relatively inaccessible to awareness. Overgeneralized, durable beliefs about the self and world may be formed through early life experiences.

Council on Social Work Education (CSWE): Founded in 1952, CSWE is social work's accrediting body for Bachelor's and Master's degree programs in the United States.

Countertransference: Role-responsive complements or counterparts to psychological transference reactions. According to contemporary psychodynamic relational perspectives, the clinician functions as a participant-observer and provides opportunities for creation, recognition, clarification, and revision of maladaptive patterns of interaction.

Crisis assessment: An objective appraisal of a client's perception of present and past situational stressors in terms of personal threat, ability to cope, and barriers to actions, as well as the type of aid needed from the crisis worker.

Coyote: A human smuggler who bring migrants across the border between Mexico and the United States for a fee; often associated with gangs or organized crime rings.

Criminogenic needs: Dynamic risk factors that are empirically linked with recidivism outcomes.

Crisis: A situation that exceeds an individual's coping ability, and leads to severe affective, cognitive, and behavioral malfunctioning. The main cause is an intensely stressful, traumatic, or hazardous event, but two other conditions are also necessary: (1) the individual's perception of the event as the cause of considerable upset and/or disruption; and (2) the individual's inability to resolve the disruption by previously used coping methods. An event or situation that is experienced as distressing and challenging of human adaptive abilities and resources.

Crisis intervention: A therapeutic interaction that seeks to decrease perceived psychological trauma by increasing perceived coping efficacy. It is a timely intervention that focuses on helping mobilize the resources of those differentially affected.

Critical incident stress management (CISM): An integrated, comprehensive, multicomponent crisis intervention system, with interventions for crisis-induced stress symptoms, with efforts beginning in the precrisis phase and lasting through the acute crisis phase into the postcrisis phase.

Critical incident stress: A characteristic set of psychological and physiological reactions or symptoms in response to a stressor event that

can overwhelm the person's capacity to psychologically cope with an incident.

Cultural liaisons: Community-based paraprofessionals, often from the same country or culture or who share a religious or spiritual practice, who can act as trusted intermediaries between immigrants and service providers, facilitating access to services and resources.

Culturagram: This family assessment tool attempts to individualize culturally diverse families and make their needs more approachable for social workers who may be from a very different background. The culturagram examines 10 different areas, from the client's contact with cultural and religious institutions to the amount of time the client has spent in the community, in order to best make his or her issues accessible to the social worker or other practitioner helping her out:

- Reasons for relocation
- Legal status
- Time in community
- Language spoken at home and in the community
- Health beliefs
- Impact of trauma and crisis events
- Contact with cultural and religious institutions, Holidays, Food, and Clothing
- Oppression, Discrimination, Bias, and Racism
- Values about education and work
- Values about family—structure, power, myths, and rules

Culturally competent practice: The ability to recognize similarities and differences in culture; when a social worker comprehends the norms of conduct, beliefs, traditions, values, language, art, skills, and interpersonal relationships within a society, and has the ability to help clients from cultures other than those of the social worker.

Cultural trauma: Chronic, repetitive insults inflicted on individuals who are marginalized based on race, disability, sexual identity, or religion.

Culture-bound syndrome: A pattern of unusual behavior that is specific to a culture or subculture. The behavior may or may not be related to a *DSM-5* diagnostic category.

Culture of care: Provided through norms and values, expressed in communication and action, in ways that shape the character and function of the family center community and the personal identity of parents and staff.

Cumulative trauma: Emotional or psychological wounding that accumulates over time and is caused by repeated exposure to traumatic experiences. This trauma completely overwhelms an individual's psyche and ability to cope.

Debriefing: An organized approach to the management of stress responses, entailing a group meeting using a facilitator who is able to help disclosure of feelings and reactions related to a critical incident.

Deconstruction: Unpacking a concept or issue or showing how it is constructed; finding its limits and gaps.

Deconstructive questioning: Questions designed to challenge one's problem-saturated story as the only truth.

Deep structure: A collection of unedited life experiences from which thoughts, behaviors, and language are composed.

Defense structures: Theoretically, unconscious mental processes by addicted persons, including denial, projection, rationalization, and repression, that present as a result of psychological conflict to protect against loss of self-esteem, or other unacceptable feelings or thoughts.

Defusing: A form of critical incident stress debriefing that may be spontaneous and is usually performed very shortly (within a few hours) after a critical incident.

Deinstitutionalization: Releasing clients from closed institutions, such as state mental hospitals, and providing similar relevant services in a less restrictive environment, preferably a normal residential situation.

Depression: A disturbance of mood marked by inability to enjoy activities and relationships, feelings of hopelessness and worthlessness, problems sleeping and eating, and thoughts of suicide.

Desensitization: Also called *habituation*, this is the process whereby a person experiences decreased levels of anxiety after being exposed to feared stimuli repeatedly and for long periods of time.

Detoxification: The planned withdrawal from use of an addictive substance, usually under professional and/or medical care.

Developmental disability: A severe, chronic disability caused by mental or physical disabilities beginning before the age of 22 years that results in substantial functional limitations in

at least three areas of major life activity, including self-care, receptive and expressive language, learning, mobility, self-direction, and capacity for independent living or self-sufficiency.

Diagnosis: A discrete process of determining through observation, examination, and analysis the nature of a client's illness, disorder, or functional problems.

Diagnosis-related groups (DRGs): A diagnosis-based classification system, used under the prospective payment system for Medicare, in which hospitals are reimbursed for inpatient costs on a per discharge basis, regardless of actual length of stay or cost. DRGs may be thought of as an early form of managed care and a modified version of capitation. Social worker roles in discharge planning were greatly enhanced under this system, begun in 1982, because of the pressures to discharge Medicare patients earlier than in the past (length of stay reduction).

Diagnostic criteria: Detailed descriptions, called diagnostic criteria, are provided in the *Diagnostic and Statistical Manual of Mental Disorders* for each of the specific mental disorders. These specify the rules for inclusion and exclusion symptoms and other features when making each diagnosis.

Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5): The latest edition of the official manual of mental disorders used in the United States and many other countries, published by the American Psychiatric Association. It provides a listing of all of the officially recognized mental disorders and their code numbers, as well as the diagnostic criteria used to identify each disorder.

Dialectical behavior therapy (DBT): A combination of cognitive-behavioral therapy and Zen mindfulness training that was developed as a treatment for self-harming women with borderline personality disorder.

Disasters: Complex interactions between nature, the human-built environment, and social processes that lead to significant harm to people and their sustainable environment and usually overwhelm local emergency resources.

Disequilibrium: An emotional state that may be characterized by confusing emotions, somatic complaints, and erratic behavior. The severe emotional discomfort experienced by the person in crisis propels him or her toward

action that is aimed at reducing the subjective discomfort.

Dissociation: Changes in consciousness or awareness that affect one's ability to access thoughts, feelings, perceptions, and/or memories.

Dissociative disorders: A group of mental disorders characterized by dissociative experiences that often interfere with a person's ability to function normally and cause significant distress and disruption in the sufferer's life. Dissociation also may be a defensive state of consciousness that protects one from traumatic experiences.

Dissociative Identity Disorder: A condition characterized by a subjectively experienced fragmenting of the person's sense of identity.

Domestic violence: Physical and/or sexual violence (use of physical force) or threat of such violence; or psychological/emotional abuse and/or coercive tactics when there has been prior physical and/or sexual violence, between persons who are or were spouses or nonmarital partners (e.g., boyfriend/girlfriend).

Domestic violence perpetrator (DV perpetrator): A person in an intimate relationship who uses a pattern of assaultive and coercive behavior to control his or her partner. The DV perpetrator uses a variety of tactics that result in power and control. (Some of these tactics are criminal or physically violent, while others are neither criminal nor physically violent.)

Due process: A constitutional requirement that governments provide individuals with notice and grievance or appeal options for deprivations of life, liberty, or property.

East Harlem: Largest predominantly Latino community in New York City; bounded by East 96th Street, Fifth Avenue, the East River, and East 142nd Street; often referred to as "Spanish Harlem," it is a neighborhood affected by many social issues.

Ecological theory: Perceives "adaptedness" and adaptation as action-oriented and change-oriented processes. Neither concept avoids issues of power, exploitation, and conflict that exist in the world of nature as well as in the social world of human beings. Adaptedness and adaptation are not to be confused with a passive "adjustment" to the status quo.

Ecosystems perspective: An understanding that individuals and families influence and are

influenced by those in immediate proximity, such as a household, as well as by the surrounding environment of the neighborhood, community, and society.

Educational intervention: The skilled and purposeful application of instructional methods to achieve clinical or programmatic objectives, such as staff development, psycho-educational programs, skill acquisition, health promotion, and public awareness campaigns.

Educational Policy and Accreditation Standards (EPAS): The standards, including curricular content, by which the Council on Social Work Education (CSWE) accredits bachelor's and master's degree social work programs in the United States.

Educator role: In social work, providing clients and other learners with the necessary skills and knowledge to carry out their roles effectively. Social workers acting as educators create an environment conducive to learning and provide relevant information in a useful, comprehensible way.

Effect size: A statistic used to measure the degree of difference between two groups on some variable.

Effectiveness study: An outcome study of social work intervention conducted under naturalistic treatment conditions, with real clients and everyday practitioners.

Efficacy study: Highly controlled experimental outcome studies of social work intervention using protocol-based treatments, well-trained and supervised practitioners, and carefully screened clients.

Egalitarian relationship: A relationship based on the assumption that the client and worker are both resources and that they share in the power base, assessment, goals, plans, and in taking action to make change.

Ego state: The actually experienced reality of one's mental and physical ego at any given moment. It consists of *parent* (borrowed), *adult* (responsive to present reality), and *child* (genetic and archaic). The ego model is derived from the theoretical model called transactional analysis.

Elaborating: The process of helping the client tell his or her story.

Eligibility: The process of determining whether an individual, family, group, or community meets the specific criteria/qualifications needed to receive services.

Emergency: A present or imminent harmful event that requires prompt coordination of actions of persons or property to protect the health, safety, or welfare of people, or to limit damage to property or the environment.

Empathic joining: The shift from blame to a nonjudgmental stance and empathy for one's partner.

Empirically supported treatment: An approach to service delivery that has been carefully evaluated, typically through multiple randomized clinical research trials in various settings, and found to be effective with the population it is designed to serve.

Employment specialist: A vocational worker or rehabilitation worker who provides employment services to the client; employment specialists work with clients to find jobs (job development) and also provide ongoing follow-along support once the job has been obtained.

Empowerment: A process through which people become strong enough to participate within, share in the control of, and influence events and institutions affecting their lives, and in part necessitates that people gain particular skills, knowledge, and power to influence their lives and the lives of those they care about. Empowerment is "a process through which clients obtain resources—personal, organizational, and community—that enable them to gain greater control over their environment and to attain their aspirations" (Hasenfeld, 1987, p. 479).

Empowerment practice: A way of engaging in practice that emphasizes overcoming direct and indirect blocks to action on behalf of oneself and others in the personal, interpersonal, and political spheres. This latter requires action in concert with others. Direct power blocks are oppression and various other kinds of external disempowerment; indirect blocks are internalized attitudes of self-doubt, shame, helplessness, and negative self-valuing.

Empowerment-based social work practice: Intervening with client systems in a way that results in clients developing a greater sense of power over their lives, destinies, and environments, at personal, interpersonal, and contextual (organizational/community) levels.

Enactment: The process through which a family lives out its focal struggle in a therapy session that approximates its experience at home.

End-of-life care: Comprehensive care that addresses the physical and psychosocial needs of persons who have a life-threatening or eventually fatal illness or condition, which can include medical intervention as well as counseling, spiritual support, and other forms of intervention.

Endorsement: The process whereby the regulatory body reviews credentialing requirements a professional has completed under another jurisdiction's regulatory authority. The board may accept, deny, or grant partial credit for requirements completed in a different jurisdiction.

Engagement: Also called *joining*, this is the process of a case manager symbolically entering into the life of an individual or family, establishing a reciprocal, trusting emotional connection to support an individual or family in a process of change.

Environmental specificity: The placement of a support in a specific environment so that it offsets a functional limitation of a person and increases his or her ability to function in the environment and perform a specific role successfully.

Equipoise: The mental state of not knowing which intervention would be best for a client. It is the ethical position required to conduct a randomized controlled trial.

E-therapy (synonymous with online, cyber-, e-mail, or chat therapy): The use of modern remote technologies, rather than traditional face-to-face service.

Ethical decision making: The deliberate use of ethics-related concepts and guidelines to address ethical dilemmas and issues.

Ethical dilemma: A situation in social work practice in which two or more professional duties or obligations conflict.

Ethics complaint: A complaint filed against a social worker with a licensing board, regulatory body, or professional association alleging violation of ethical standards.

Ethnicity: Groupings of people based on shared elements such as physical appearance, culture, religion, and history.

Evaluation: A process used to determine the effectiveness of a particular program or intervention. Effectiveness data may come from a variety of sources (e.g., rapid assessment tools, observation, case records). The results of an evaluation are used to inform agency and system

policies, funding of agencies, and development of programs.

Evidence-based practice: The conscientious, explicit, and judicious use of the current best scientific evidence in making decisions about social work assessment and intervention, also taking into account clinical expertise, client preferences and circumstances, and professional ethics.

Exceptions: Those times in a client's life when the presenting problem is not occurring or is less severe. These exceptional times provide valuable information about what is different when the problem is not actively present, including strengths and coping skills from which to build solutions.

Expectancy: The social worker's confidence and belief in the ability and desire of people to make changes in their lives. When clients sense that the social worker believes that change is possible, they are more likely to begin the process of making changes.

Experience: In this context, experience means perceptual, cognitive, visceral, emotional, and motor behavior.

Experiential exercises: These teaching methods emphasize the use of activities to help learners deepen understanding of issues, practice skills, and develop new insights. Examples include role-plays, simulations, skits, icebreaking exercises, and team projects.

Experiment: The deliberate manipulation of one or more independent variables (treatments) conducted under controlled conditions to test hypotheses, especially for making inferences of a cause and effect nature.

Expert consensus guidelines (ECGs): Derived from a broad-based survey of expert opinion and consist of a compilation of practical treatment recommendations for the treatment of major biological and mental disorders.

Expert witness: A witness qualified as an expert by knowledge, skill, experience, training, or education. The opinion of the expert witness must be based on sufficient facts or data, and be the product of reliable principles and methods.

Exposure therapy: Behavioral technique in which the client is exposed, either through imagery or in vivo, to cues and memories associated with anxiety-provoking events, objects, or experiences for a significant duration allowing for attenuation of anxiety.

Expressed emotion: The quality of communication between people, specifically the presence of hostility, criticism, and emotional overinvolvement. The concept emerged from research on communication between family members and consumers and has more recently been applied to the communication between providers and consumers.

Externalizing problem: (1) Disruptive behavioral or conduct problems that have a primarily negative effect on others (e.g., conduct disorder, oppositional defiant disorder, substance abuse, attention deficit and hyperactivity disorder). (2) In conversation with clients, the problem is externalized, or separated, from the person, whereby the problem and not the person is the target of change.

Extratherapeutic factor: Any aspect of the client's physical, psychological, or social world that influences how services are understood and valued. These factors are viewed as having the greatest single impact on service outcome.

False memory syndrome: A lay term used to describe memories of events that did not happen. Such memories are confabulated or fabricated, usually, but not exclusively, in the course of therapy aimed at retrieving early childhood memories of abuse.

Family assessment tools: Graphic displays of family issues that can be used to understand, empower, and point toward treatment interventions for the family. Three important family assessment tools are the eco-map, which looks at the relationship of the family with the outside environment; the genogram, which examines the intergenerational relationships within the family; and the culturagram, which looks at specific cultural aspects within diverse families.

Family consultation: The process by which a family member seeks the advice or opinion of a professional (the consultant) and works collaboratively with the consultant for the purpose of clarifying a situation, reaching a decision, solving a problem, or accomplishing an objective.

Family intervention: Models for working with families of persons with severe mental illness, such as psycho-education, family education, family support, and family consultation, which help families understand and support their ill relatives. Research indicates that providing these interventions to families improves client outcomes.

Family resilience framework: Practice orientation, key processes, and intervention principles to facilitate family resilience in response to crisis, trauma, or loss; disruptive transitions; and chronic, multi-stress conditions now and in the future.

Family support: An intervention that provides emotional support, empathy, information, and networking for families of persons with severe mental illness.

Family systems therapy: An approach in which all members of a nuclear or extended family are conceptualized as a psychosocial system in need of change and individual problems are viewed as symptoms of interactional sequences in the family. Treatment, therefore, centers on work with the family as a whole, altering the sequences of interactions and examining the functions that symptoms serve for the system.

Father involvement: The activities of fathers aimed at fostering the health, well-being, and development of their children. Such activities include direct engagement with the child, accessibility to the child, and assuming responsibility for the child.

Feminism: (1) A way of viewing and being in the world that evolved from an analysis of women's collective experience with patriarchy. For most feminists, while promoting the interests of women and addressing women's issues, feminism necessarily involves a commitment to ending all forms of oppression and exploitation. (2) A position advocating for the political, social, and economic equality of men and women.

Feminist practice: Can be defined by one's identity as a feminist, by a conceptual framework that is based in strongly held assumptions, or by methods used.

Fidelity: Adherence to the program model, associated with improved outcomes for clients.

Filial therapy: A structured psycho-educational program combining play and family therapy in which parents are trained to be therapeutic change agents for their own children.

First-order change: Change in operation when the attempts to solve the presenting problems are actually maintaining the problem.

Follow-up: A phase of the basic model of single-subject design methodology in which client functioning is measured reliably and validly

over time and compared with the intervention phase to determine whether changes observed immediately after an intervention persist.

Forensic social work: Any form of social work practice that is related in some way to legal issues or litigation in the criminal or civil justice systems.

Full-service community schools: Schools with programs that combine into a concerted effort to integrate health, youth development, family, and other community services to support student learning.

Functional analysis: An assessment procedure that describes the functional relationships between antecedents to a behavior, the behavior, and the consequences that follow the behavior.

Gatekeeper: A person who directs or links a person to informal or formal sources of help.

Geriatric specialized unit: A prison housing facility designated for an incarcerated elderly population. Such units also may offer programming geared toward an aging population.

Generalization: The extent to which learning in treatment transfers to an individual's day-to-day life. Practitioners must always be planning for ways to maximize the generalization of skills learned and promote their continued use after training. Principles involved in generalization include over-learning, varying the stimuli used in training, and encouraging the use of skills in real-life settings.

Generalized anxiety disorder: A *DSM* diagnosis of a subclass of the anxiety disorder where anxiety is experienced in most situations.

Generative fathering: Fathering techniques that meet the needs of the next generation across time and context.

Genogram: A family map, usually of at least three generations. It records information about a person's biological, legal, emotional, and spiritual family members and their relationships over at least three generations. Genograms display family information graphically in a way that provides a quick gestalt of complex family patterns; as such, they are a rich source of hypotheses about how clinical problems evolve in the context of the family over time.

Globalization: The worldwide integration of humanity and the compression of both the temporal and spatial dimensions of planet-wide human interaction.

Goal: A broad, long-term target for a identified problem or desired change that may or may not be reached while the client is in treatment. In treatment planning, the goal is a broadly stated description of what successful outcome is expected. The *goal* of the social work intervention is broad and inclusive, is culturally sensitive, may be achieved through various means, and remains constant throughout the course of the social worker–client relationship.

Goal-attainment scaling: A method of monitoring client progress by identifying the client's problem level at the point of assessment and stating what would constitute "some" and "extensive" improvement and "some" and "extensive" deterioration in progress with a given problem. Problems then are often weighted by how important it is to improve in any of two to four areas. Measurement with goal-attainment scales is usually completed only a few times over the course of an intervention.

Goal-directed metaphor: A type of metaphor constructed to move characters in a manner likely to retrieve targeted and needed experiences in the client but that do not attempt to match the client's problem in content or body of the story.

Grief therapy: Treatment focused on alleviating dysfunctional traumatic or complicated grief reactions.

Grooming: The process of desensitizing and manipulating victim(s) to gain an opportunity to commit a sexually deviant act.

Group: A small collection of individuals among whom there is interaction around some commonality. Such a group may contain a variety of interactional dynamics, including mutual support, goal attainment, acquisition of knowledge and skills, universalization, catharsis, and instillation of hope.

Guided imagery: Therapeutic use of visual imagery as a means of promoting and effecting cognitive, emotional, and behavioral change. Images may be obtained from life events, dreams, or daydreams, and fantasies. Often, relaxation techniques are used in conjunction with the procedure.

Health maintenance organization (HMO): A form of health insurance that only allows clients to visit professionals in a specific network. For behavioral health services, HMOs may offer in-house salaried clinicians or may contract with clinicians who may be salaried, fee-for-service, or capitated.

HMOs often have strict rules limiting services and monitor clinician behaviors for compliance.

Hierarchal construction: Behavioral intervention of creating a list of feared stimuli or situations organized from least-feared to most-feared. The client then uses this hierarchy in exposure therapy, each time moving up the list after having a significant drop in experienced fear at the previous listed item.

HIV/AIDS: HIV (human immunodeficiency virus) is a retrovirus that can cause a breakdown of the body's immune system, leading in many cases to the development of acquired immune deficiency syndrome (AIDS) or related infections or illnesses. AIDS is the name originally given to an array of diseases and malignancies that occur in adults who previously had healthy immune systems. Certain markers (opportunistic infections, cancers, T-cell count) now constitute a diagnosis of AIDS.

Holistic: Describes a practice perspective that takes into account the health, mental health, educational, and spiritual aspects of clients within their environments.

Home-based services: Therapeutic and care management services delivered primarily in the client's home.

Homosexual: A male or female person whose sexual attraction, both physical and affectional, is primarily directed toward persons of the same gender.

Hospital case management: Uses a collaborative process among health care providers to find, assess, plan, intervene, monitor, and evaluate delivery of health care services for hospital-based patients.

Human rights: Those fundamental entitlements considered to be necessary for developing each personality to the fullest. Violations of human rights are any arbitrary and selective actions that interfere with the full exercise of those fundamental entitlements.

Hypervigilance: Constant scanning of the environment, using all senses, for any threats.

Hypnosis: A heightened state of internal concentration that is further characterized by a reduced processing of external perception. An intervention procedure involving the fixation of attention, disruption of normal modes of cognitive functioning, and initiation of change through use of indirect forms of suggestion.

Ideomotor signs: Behaviors exhibited by clients that are the result of private thoughts, images, and sensations.

Immigrant: A person who voluntarily leaves his or her country of origin expecting to live in the host country legally with the option to return to the country of origin. Immigrants may be legally admitted or reside in the new country illegally (in which case they are referred to as undocumented immigrants).

Imminent harm: A situation in which there are predictions of a client's involvement in violence within 24 hours after he or she is seen by the forensic evaluator.

Indirect suggestion: Any number of verbal patterns that are believed to initiate unconscious search processes.

Indirect treatment: Those aspects of a social work intervention that involve persons, resources, and situations of significance in a client's life, the goals of which are to bring about change or benefit to the client.

Individualized education plan (IEP): A written plan developed in schools with interventions and/or accommodations for children who qualify for special education services.

Individualized placement and support model (IPS): An approach to supported employment that has been shown to be an empirically supported treatment in providing services to people with severe mental illness. IPS features an individualized approach with an emphasis on competitive employment, rapid search for a competitive community job, and the integration of mental health and employment services.

Individualized rating scale: A single-item scale developed to measure a client's level on a problem over time. These scales usually are developed in collaboration with the client and use the client's own words to describe differing levels of a problem. These scales can be used repeatedly.

Informal helper: Laypeople in a culture's local community system, such as kinship networks, neighbors, volunteers, and community groups who provide information and advice, along with emotional and social support.

Informed consent: Involving clients in making decisions based on competence, knowledge, and choice. Social workers have an ethical obligation to obtain clients' informed consent for services and prior to releasing information. Clients

can give informed consent if they are mentally competent; are informed of the risks, benefits, and possible consequences of their choices; and are free to make choices. The client's informed consent for services or for release of information should be documented in the record.

Insider strategy: Attempts to influence policy by working through the system and directly approaching legislative and executive branch decision-makers through legislative and political action.

Institutional ethics committee (IEC): An interdisciplinary group of professionals and other parties in a human service organization, whose purpose is to provide a forum for discussion of ethical dilemmas and issues.

Institutional review board (IRB): An interdisciplinary group of professionals and other parties in a human service organization responsible for the protection of human subjects involved in research.

Instructional methods: Refers to an array of techniques typically intended to help learners achieve knowledge, skill, or attitudinal learning objectives. These techniques include lectures, written products, discussions, audio-visual materials, technological resources, and experiential exercises that are selected, sequenced, and paced based on the needs and abilities of the learners and the objectives they are designed to reach.

Integrative gerontological practice: A treatment model based on a bio-psychosocial-cultural framework that incorporates themes from aging and social work, includes a life course perspective, takes into account diversity among older persons, adopts a multi- and interdisciplinary practice approach, and attends to power inequalities among older adults and in their use of services.

Intellectual disability: A disability characterized by significant limitations in intellectual functioning and adaptive behavior as expressed in conceptual, social, and practical adaptive skills. This is the preferred term in the United States for what was once called "mental retardation," and it has growing international currency.

Intensive case management: Case management services marked by low caseloads with an emphasis on aggressive outreach and in-home and community care.

Interdisciplinary: Implies a group of professionals from various disciplines who jointly

bring their particular professional perspectives to bear on solving a problem. This process requires role division based on expertise, communication, interdependence, and coordination.

Interim notes: After a service plan has been developed, the social worker regularly documents changes in the client situation, movement toward achieving goals, and other information in the record. These interim or progress notes serve to inform others who read the record about development of the case over time.

Interdisciplinary teams: A group of people organized to complete a task together. They could include a medical doctor, a social worker, an agency, and a physical therapist all working together to help a client reach his or her goals.

Interest-based mediation: A conflict resolution approach in which an impartial third party helps people involved in a conflict by focusing on underlying interests and ways of collaborating for their mutual benefit (i.e., to develop creative win-win solutions; also called "integrative mediation").

Interests: Underlying needs, concerns, hopes, and expectations.

Intermittent explosive disorder: Several discrete episodes of a client's failure to resist aggressive impulses that result in serious assaultive acts or destruction of property whereby the degree of aggressiveness expressed during the episodes is grossly out of proportion to any precipitating psychosocial stressors.

Intention to treat: A method of analysis that treats participants as members of the groups to which they were assigned, regardless of what happened during the study, including participants who did not receive the intervention and those who dropped out.

International social work: International professional action by social workers and the capacity in the profession for such action. The four dimensions of international action are internationally related domestic practice and advocacy, professional exchange, international practice, and international policy development and advocacy.

Interpersonal empowerment: Acquisition of knowledge, skills, and assertiveness to participate in matters that impact the control and mastery of one's life.

Interpersonal violence: The World Health Organization definition cites any behavior

within an intimate relationship that causes physical, psychological, or sexual harm to those in the relationship.

Intervention: The methods, strategies, tasks, or assignments that a clinician will use to assist the client in achieving the identified goals and objectives. Interventions define the *who* and the *what* that will enable the specific responsibilities and actions to be taken by worker and client during the course of treatment.

Intervention phase: During intervention, when a specified plan is implemented to change client functioning, information is provided about changes in the nature and severity of the client's problem as measured by the same variables employed during baseline, with the results then compared to the baseline results.

Intervention planning: Planning for treatment activity that promotes client problem or symptom reduction or elimination based on a diagnosis and assessment of client problems and/or symptoms.

Introject: An emotionally charged message from parents, siblings, significant others, and institutions that shapes a person's view of the world and feelings about the self.

In vivo service: Service provided at the site where a client uses them in daily living, rather than in a classroom or agency site; for example, when a client is taught to cook on his or her own stove rather than in the kitchen of a day treatment center.

Isomorphism: Refers to any content that corresponds to the client's problem and/or solutions on a one-to-one basis—that is, thing-for-thing and action-for-action.

Job development: The process in which the employment specialist surveys job opportunities in the community and helps clients find jobs matching their preferences. Job development is a key part of supported employment services and has been linked with outcomes in some studies.

Latinos: A diverse group of national origins that currently represent the largest minority group in the United States. Distinct cultural, ethnic, and historical variations mark major within-group differences. Latinos share many commonalities as well, including history and language.

Lay representative: A non-lawyer who is allowed to serve as an advocate and representative

in certain state and federal administrative hearings.

Least restrictive environment: The provision of mental health services in settings that are the closest to everyday life that an individual with a mental disorder can manage.

Legislative advocacy: The activities in the political arena that focus on the promotion of the common welfare or the securing, expansion, or protection of rights and services of a specific population. It can serve as a means to mobilize people, raise political consciousness, and accentuate the contradictions within society.

Level of fit: Measurement of the degree of compatibility between the perceived needs, capacities, behavioral styles, and goals of people, and the characteristics of the environment in which they live.

Licensing: Licensing is required to participate in specific professions. Continuing professional education or training are usually required to maintain licensure.

Life stressor: Life transitions, traumatic events, and environmental and interpersonal pressures that disturb the level of person:environment fit and a prior state of relative adaptedness.

Linking: An intervention in groups in which the worker ties together common elements in the communication pattern of members to assist them in identifying more closely with one another.

Maladaptive belief: A habitual cognition that causes emotional and behavioral distress.

Malpractice: A form of negligence involving a breach of professional duty that causes harm or injury to the client.

Malpractice suits: Civil law suits for negligent, improper, illegal, or unethical professional behaviors.

Managed care: A formal system of health care delivery and financing that attempts to influence or control access, utilization, costs, and quality of services. This system consists of networks of health care providers, third-party funding sources, and other fiscal intermediaries that provide health and mental health services for those participating in the network. It is primarily sponsored by investor-owned, for-profit organizations referred to as managed care organizations (MCOs). Even Medicare and Medicaid managed

care plans tend to be privately owned. Managed care is thus market-driven. There is a large variety of types of plans; the best known is the health maintenance organization (HMO), consisting of a self-contained panel of doctors. A gatekeeping primary care physician controls patient access to all other services (specialists, hospitals, etc.). When managed care is applied to mental health care, it is often referred to as behavioral health.

Manualized curricula:—Sequenced and prescribed content and activities to systematize and standardize interventions. Manualized curricula utilize evidence-based practices and facilitate the adoption and evaluation of interventions.

Manualized treatment: Sequenced and prescribed content and activities to systematize and standardize interventions. Manualized treatments usually use evidence-based practices and facilitate the adoption and evaluation of interventions.

Mediation: A conflict resolution process conducted by an impartial third party, who does not impose a decision or make a recommendation to the court if the disputants cannot reach an agreement.

Medicaid: A jointly funded federal–state health insurance assistance program for people with disabilities, older people, and other people with limited resources. The federal government mandates states to pay for hospital care, home health care, physician services, and nursing home care for eligible people. States can choose to pay for additional services under Medicaid, such as personal assistance services and intermediate care facilities for the mentally retarded. Medicaid is the largest funder of nursing home care and community living costs for people with intellectual and developmental disabilities.

Medicaid waiver: An exception to the usual Medicaid rules, allowing states to use Medicaid funds to provide community-based services to people with disabilities who would otherwise need to be cared for in an institution.

Medical model: A perspective on human behavior that locates the sources of many problems in living within an individual primarily as the result of biological factors, as opposed to cultural or personal background issues.

Mental disorder: A clinically significant, individual functional, behavioral, or psychological

syndrome manifested by distress, disability, or risk of harm that is not a culturally accepted reaction to an event. (See the *DSM-5* for a more detailed definition and explanation.)

Mental health outcome: Any condition that an intervention is intended to affect or change. Common empirically based outcome measures for mental health are functional status, perception of quality of life, benefits of care, problems with care, safety, and client/family satisfaction with mental health services.

Mentalization: The capacity to make sense of self and of others in terms of subjective states and mental processes. This concept makes up the core of mentalization-based treatment, an evidence-based psychodynamic therapy for the treatment of borderline personality disorder.

Meta-analysis: A statistical method used to summarize the effects of several studies in a particular area.

Metacognitions: Thoughts or beliefs about cognitive processes.

Metaphor: An altered framework of presenting ideas, by means of which clients can entertain novel and potentially therapeutic experiences.

Methodological filter: A search term intended to limit a database search to the best available research studies specific to answering an evidence-based practice question.

Middle (or work) phase: The phase of work in which the client and the worker focus on dealing with issues raised in the beginning phase or with new issues that have emerged since then.

Migration narratives: Personal accounts of migration arising out of the use of regular narrative therapy in order to help immigrants examine, understand, and contextualize the migration process for the purposes of healing.

Minor depression: The presence of at least two but fewer than five depressive symptoms including depressed mood or anhedonia during the same two-week period with no history of major depressive episode or dysthymia but with clinically significant impairment.

Minority: Any member of an ethnic group whose population is a numerical minority in a society; minorities sometimes receive unequal and disadvantageous treatment in the society, but may also be part of a privileged upper class.

Miracle question: A question used in solution-focused therapy in which the client is asked to describe what would be different if there were a miracle and the problem went away. The question is useful in helping the client describe a desired future in which the presenting problem no longer exists or is significantly improved.

Mitigating evidence: Evidence that reduces a defendant's moral blameworthiness for a criminal offense.

Mitigation specialist: A professional qualified by education, experience, or training to investigate and interpret information relevant for sentencing determinations.

Mixed mood disorder: Characterized by the simultaneous presence of symptoms of major depression and mania, with depression being predominant in the presence of increased activity.

Mobilization: The organization and application of constituents' resources toward a particular policy goal in a legislative setting. In this context, mobilization is the process of increasing the ability of constituents to act collectively by building their loyalty to a common set of objectives and increasing their ability to influence the course of legislation. Mobilization can take multiple forms—defensive, offensive, and preparatory—depending on the availability of resources, the relative power of advocates, and the particular issues at hand.

Modeling theory: An explanation derived from social learning theory of how new behaviors are acquired. Modeling can be used in treatment programs through stories, plays, and role-plays. Individuals either watch or experience vicariously the behaviors of the person modeling the behaviors to be learned. This process increases the likelihood that in the future the individual will be able to perform a behavior similar to the one modeled.

Monitoring: Keeping abreast of client progress.

Mood stabilizer: A pharmacologic agent such as lithium, valproate, or carbamazepine that may control, delay, or prevent episodes of mania.

Moral culpability: Measure of the degree to which an individual can be held to account for their behavior; degree of blameworthiness for an individual's criminal behavior.

Multisystemic therapy: An empirically supported intervention approach developed for the treatment of youth in the juvenile justice

system. This approach takes an ecological view in that many interlocking systems are seen as involved with individual behavior problems, with treatment targeted at the various systems levels.

Mutual trap: The cycle of interaction that results from partners becoming polarized about an issue following attempts to change one another.

N = 1 experiment: A research design of high internal validity wherein each person serves as his or her own control. Such experiments are characterized by the repeated valid assessment of one or more outcome measures and the repeated introduction or removal of one or more treatments.

Narcissistic personality disorder: One of the personality disorders described in the *DSM-5* distinguished by a stable pattern of grandiosity, sense of entitlement and omnipotence, and fantasies of boundless success and brilliance.

Narrative therapy: A form of therapy based on the assumption that people organize their experience through stories. This approach to therapy stresses the significance of meaning and takes into account the sociocultural context in which people live and the impact this context has on the stories that dominate their lives. Narrative therapy focuses on creating and sustaining therapeutic dialogues in which clients re-story their lives in new and more desirable ways that represent more satisfying and empowering interpretations of their lives. These new stories can be co-created with clinicians, who consult with clients to help them find new possibilities. This approach offers practices to enact a strengths perspective, a collaborative working relationship, and an ethic of respect and accountability.

Narrow definition of forensic social work: A forensic social worker is any professional social worker who is engaged as an expert in the provision of evaluation and treatment services for the judicial system to achieve specific legal aims or purposes.

Natural helper: A nonprofessional, such as a family member, relative, friend, neighborhood advocate, or other volunteer, who provides multifaceted support in the family-centered community.

Naturally occurring resource: A nonsegregated resource that is routinely used by the general population of a given area.

Near problem: A legitimate issue raised by clients, early in the relationship, to establish trust before raising more difficult and often threatening issues.

Negative punishment: A process of intervention derived from social learning theory in which a reinforcing stimulus is removed following a behavior in order to decrease the future frequency of the behavior.

Negotiation: A conflict resolution process in which the disputants attempt to reach an agreement either by communicating directly or through agents.

Neurotransmitter: A chemical substance located near nerve cell synapses that transmits electrical impulses (communication) between nerve cells and along nerve pathways.

Niche: The environmental habitat of people, including the resources they use and the people with whom they associate. Niches can be entrapping or enabling.

Noetic or spiritual dimension: Contains those unique human capacities that make one a human being, such as the will to meaning, creativity, imagination, humor, faith, love, conscience, being responsible for someone or for some ideal, striving toward goals, and learning from past experiences.

Notice of action: In the context of public benefit programs, a written notice that advises a recipient or applicant of an adverse decision and the appeal options they hold.

Noticing: A process of intervening to help a client become more aware of the meaning potentials in their life.

Number needed to harm (NNH): Statistically, the number of people that need to receive a service for one of them to be harmed.

Number needed to treat (NNT): Statistically, the number of people that need to receive a service for one of them to benefit. It is the inverse of the absolute risk reduction.

Object relations psychology: A major paradigm in psychodynamic thought that encompasses overlapping theories of personality development, psychopathology, and psychosocial intervention. In this paradigm, emphasis is given to the motivational force of attachment and relationship in human development; it views

interactive experience as the central organizer of psychic structure and function.

Objective: In treatment planning, the measurable steps that must occur for the change goals to be met in problem solving. The objective is derived from the goal and enables its fulfillment. Objectives define a course of action, a time frame, and a method of measurement to evaluate and assess achievement.

Objective criteria: Impartial standards or measures that people can use to determine which of two or more options is in their mutual best interest.

Offense Specific Treatment: Long-term comprehensive, planned, evidence-based treatment that modifies sexually deviant thoughts, fantasies, and behaviors to promote change and to reduce the chance of re-offending.

Online social work: Involves the use of telecommunications and information technology to provide social work services over the Internet. See also E-THERAPY.

Operant behavior: Behavior that affects the environment to produce consequences and is, in turn, controlled by those consequences. In general, many overt behaviors (including language) are operant behaviors.

Outcome measurement: The use of observable and measurable standardized indicators of intervention effects based on an intervention plan.

Outcome of service: The result achieved because of interventions, as measured against the treatment objectives specified in the service plan; the consequences of service that can be demonstrated in some objective manner.

Outsider strategy: Attempts to influence by indirect means, including litigation and protest using mobilization and community organization. Contrast with insider strategy.

Overarching goal: The broad and inclusive focus of work with an individual client or group, toward which all of the goals and interventions will be directed. The overarching goal should relate to client needs and concerns, strengths, resources, and client choices, which have been explored during the initial contract/assessment phase of the work.

Palliative care: Care for persons at the end of life that focuses on comfort and support instead

of cure for a disease, illness, or condition. One example of palliative care is hospice, a program for persons who are not seeking aggressive medical treatment and have an estimated prognosis for life expectancy of six months or less.

Parallel to the problem (isomorphic): Stories that are designed to heighten the listener's sense of relevance in relation to the listener's problem.

Paraphilia: A group of disorders described in the *DSM-5* that are characterized by recurrent, intense sexual urges, and fantasies.

Parent training: An approach based on the behavioral principle of operant conditioning in which the consequences of a behavior determine its behavior. Parents are taught to set behaviorally specific goals, positively reinforce prosocial behavior, and ignore or punish deviant behavior. Modeling is also used.

Parents as partners: A concept that recognizes parents as the primary focus of a child's life and requires that social workers and other mental health clinicians actively collaborate with parents in addressing the mental health needs of their children.

Partializing: An important part of problem solving, in which problems or concerns are broken down into smaller and more manageable units.

Partner abuse intervention program (PAIP): Community-based programs designed to interrupt and prevent the recurrence of physical and nonphysical aggression against a currently or formerly intimate partner.

Passion statement: An expression of the goal or desire that is most important to a consumer at that time.

Patriarchy: A structural arrangement that privileges the views, interests, and activities of men over women. Because it is structural by nature, all men benefit from it even when they, as individuals, oppose the arrangement. Men as well as women work to end patriarchy as a system that is inimical to the full development of all persons.

Penile plethysmography: Sexual preference testing, also known as phallometry, that involves the measurement of penile volume or circumference when the individual is confronted with a variety of standardized sex-related stimuli.

Perceived self: How a person sees self and how others see them.

Perfect niche: A setting where the requirements and needs of the setting are perfectly matched with the desires, talents, and idiosyncrasies of the consumer.

Personal empowerment: The attitudes, values, and beliefs about self-efficacy, self-esteem, and having rights.

Personal planning: The process for creating a mutual agenda for work between the client and case manager, focused on achieving the goals that the client has set.

Personality disorder: A pervasive, inflexible, and enduring pattern of traits depicted by a persistent pattern of internal experience and outward behavior that diverges notably from cultural expectations, is pervasive and rigid, begins by adolescence or early adulthood, continues over time, and invariably results in significant distress or dysfunction.

Personality states: These recurrently take control of a schizophrenic person's behavior; each state is characterized by its own thoughts, feelings, behavior patterns, likes, dislikes, history, and other characteristics.

Perturbation: A state of system disequilibrium characterized by disorganization and distress resulting in adaptation and emerging complexity and differentiation.

Pharmacodynamics: The effects of a drug on the human body, including such phenomena as the therapeutic index, potency, dose response, lag time, tolerance, and positive and adverse effects.

Pharmacokinetics: The body's response to the presence of a drug, including absorption, distribution, metabolism, and excretion.

Pharmacotherapy: The treatment of a disease or disorder with drugs.

Phase of practice: Practice occurs in a specific sequence of beginnings, middles, and endings, although activities in each phase may be revisited at a later phase, if necessary. With respect to goals, the beginning phase is the one in which assessment and goal specification occur. The middle phase involves work to attain goals. The ending phase includes an evaluation of goal attainment.

Phenomenological: The focusing on the client's experience as it unfolds moment to moment in the therapeutic encounter.

PICO question: Patient-oriented question consisting of description of the population of patients

(P), intervention of concern (I), what it may be compared to (C), and hoped-for outcome (O).

Planned short-term treatment: Social work service that is brief by design, generally fewer than 12 sessions during a three to four month period. It can be contrasted with open-ended service, which may continue indefinitely or may turn out to be brief if the client drops out or if the purpose of the intervention is accomplished quickly.

Pluralism: An orienting approach to understanding, based on the philosophical formulations of William James, that emphasizes the potential value of multiple explanatory systems encompassing scientific and humanistic domains of knowledge; pluralist approaches potentially combine ideas and methods from divergent approaches that would be considered incompatible in purer conceptions of psychosocial intervention.

Podcast/Vodcast: Subscription-based downloadable audio/video files.

Police-based social worker: Practitioners who work in federal, state, and city law enforcement agencies to provide counseling and support services to crime victims, witnesses, and family survivors.

Position: Stated wish or stance on an issue in dispute, as opposed to the underlying interest, need, concern, hope, or expectation that can be used to resolve the dispute.

Positive punishment: A process of intervention in which an aversive stimulus is presented following a behavior to decrease the future frequency of the behavior.

Positive reinforcement: A process of intervention in which a stimulus is presented following a behavior to increase the future frequency of the behavior.

Post-booking diversion: Programs that identify and divert individuals with mental illness or substance abuse disorders to treatment after they have been arrested. These programs may divert individuals very early in the process, such as at first court appearance, or later in the process, including at disposition or sentencing. **Postmodernism:** An approach to knowledge that claims there are many productive methods of knowledge development; that truth and reality, especially in social realms, often have multiple meanings; that universal principles discount cultural (and other) diversities;

and that all ideas and actions inevitably reflect values.

Practice guideline: A set of systematically compiled and organized statements and recommendations regarding efficacy and effectiveness of clinical care usually based on research findings and the consensus of experienced clinicians with expertise in a given practice area. Practice guidelines are often in the form of treatment protocols that provide social work practitioners with explicit, well-defined procedures and instructions on how to conduct psychosocial interventions for specific client problems/disorders.

Pre-booking diversion: Programs that link individuals eligible for diversion to appropriate treatment in lieu of arrest, booking, and/or prosecution.

Pretreatment change: What is different or what has changed from the time the client made the appointment to his or her arrival at the first session? Clients often begin to make changes even before the first encounter with the social worker and what is different provides valuable information about client strengths and problem-solving abilities.

Prevalence: A statistical term referring to the number of cases of a particular disease in a population during a given period of time.

Primary care: Managed care has encouraged the central role of the primary care physician in coordinating patient health needs. The locus of care is shifting from in-patient acute, tertiary, and specialty care to ambulatory and community-based care and to physician offices, group practices, and health maintenance organizations.

Problem-based learning (PBL): An instructional style that engages students in course material through the presentation of a problem or question that they must solve together.

Problem-saturated story: One-dimensional, often negative, stories clients have constructed about themselves in interaction with other people and social cultural forces, which have restricted them from seeing their full potential. These stories are usually only one part of the client's experience but have overshadowed other experiences that contain successes, strengths, resources, and competencies.

Problem-solving therapy: An empirically supported psychosocial intervention for depression that focuses on the identification and

implementation of adaptive solutions to daily problems.

Problem-specific interventions: Interventions created from rigorous studies that treat specific problems, such as anxiety, depression, or substance abuse problems.

Process measures: Measures of patient care that are concerned with activities specific to the provision of patient care. In essence, process measures focus on “what” has been provided to patients and “how.”

Process recording: A form of qualitative evaluation using a condensed and structured outline that fosters reflection and promotes analysis of intervention while providing documentation of progress and assessment of outcome.

Professional negligence: Violation of a professional standard of care, including a breach of professional duty that causes harm or injury and may open the violator to legal action by the clients concerned.

Professional socialization: The process by which members of particular professions are inducted into their profession’s values and ethics, language, preferred roles, methods of problem solving, and establishment of priorities.

Pro se: From the Latin, “for oneself”; refers to an individual who self-represents in a judicial proceeding.

Protocol: A plan for a study or research review that is developed in advance to specify the methods and procedures that will be used.

Provider-consumer-family collaboration: The engagement and involvement by professionals of families in the often lengthy and complicated treatment process of a relative with severe mental illness.

Psychiatric disability: Cognitive, emotional, behavioral, or personality conditions that can reduce functioning and modify conduct and interpersonal interactions in such a way that a person departs from normative expectations. Psychiatric disability is judged by certain diagnostic categories, duration of the illness or symptoms, and severity of impact on role and interpersonal functioning.

Psychiatric medication: Medications in five classes (antidepressants, mood stabilizers, anxiolytics, antipsychotics, and psychostimulants) used in primary care, psychiatry, and other specialties

that are intended to alter mood, thoughts, or behavior.

Psychiatric rehabilitation: An approach to service delivery that focuses on helping people coping with serious mental illness to overcome their psychiatric disabilities through the augmentation of support, the development of skills, the reduction of barriers, and the creation of opportunities to advance their quality of life.

Psychodynamic theory: Those theories of social work practice that put particular stress on the inner life of a client, both as a way of understanding the client’s strengths and limitations and, more important, to seek to effect changes that will enable a client to function in a more satisfying, growth-enhancing manner.

Psychodynamic perspective: Although the pluralist character of psychodynamic thought has generated divergent views of the human condition, problems in living, and therapeutic action, thinkers identify basic domains of concern that shape contemporary understanding and practice, including: conceptions of unconscious emotional and cognitive processes as well as underlying motivational systems; conceptions of conflict and compromise among opposing needs or tendencies; conceptions of defense, coping, and adaptation; propositions about the fundamental role of temperament, attachment, and caretaking experience in the development of personality organization and patterns of interpersonal behavior across the course of life; and conceptions of self, subjectivity, and personal meaning. In the domain of psychosocial intervention, practitioners emphasize the role of the practitioner–client relationship, interpersonal interaction, and experiential learning in efforts to facilitate change and growth.

Psychoeducation: A model of individual, family, or group intervention focused on educating participants about a significant challenge and helping them develop adequate coping skills for managing the challenge.

Psychological flexibility: The capacity to fully experience and embrace necessary pain and to interact flexibly with verbal constructions of the world in order to allow for committed, life-affirming action.

Psychopharmacotherapy: The practice of implementing and monitoring a regimen of psychiatric medication with an individual client.

Psychosocial: A concept used in two ways in social work literature. The first way describes a specific theory and practice in social work from the dual orientation of person, understood in psychodynamic terms, and a person's societal roles and systems. It is also used in a more generic sense to identify or describe social work clinical practice from a diverse theoretical base.

Psychosocial rehabilitation: A humanistic approach to the support of people coping with the causes and consequences of serious mental illness. Recipients obtain support to set a direction and outcome they find meaningful. Rehabilitation facilitates the achievement of this direction through personal change and environmental modification.

Psychotropic medication: Drugs that alter central nervous system functioning.

Punishment: A consequence that serves to weaken or decrease the frequency of a behavior. *Positive punishment* is a process in which an aversive stimulus is presented following a behavior to decrease the future frequency of the behavior. *Negative punishment* is a process in which a reinforcing stimulus is removed following a behavior to decrease the future frequency of the behavior.

Quality assurance (QA): A process or set of activities to maintain and improve the level of care provided to patients (also known as quality improvement, QI). These activities may include review, formal measurements, and corrective actions. The QA/QI function is a standard part of health insurance plans and all institutional health care providers. Managed care often demands that providers present QA/QI findings to the sponsoring plans, especially data on the outcome of care. In the era of managed care, it also has become critical for social workers to be able to demonstrate their effectiveness in measurable terms.

Quality of care: A multidimensional construct that includes patient care *structure*, patient care *process*, and patient care *outcomes*.

Question, well-structured: A practice or policy question consisting of three or four parts that starts with a client/problem and includes an intervention, comparison, and outcome, that facilitates an efficient, effective search for related research. Key terms in the question, together with appropriate quality filters, are used to search for related research.

Radiating impact: The prevalent finding that progress or achievement in one client-set goal leads to unplanned achievements in other areas of life.

Randomized controlled trial (RCT): An outcome study of treatment effectiveness using an experimental design. Such designs usually involve pre- and postassessments of client-system functioning and random assignment of clients to treatment and to alternative conditions such as no-treatment, standard care, or placebo treatment.

Rapid assessment instruments (RAIs): RAIs provide a brief standardized format for gathering information about clients. These instruments are scales, checklists, and questionnaires that are relatively brief, often fewer than 50 items, and easy to score and interpret. RAIs have established psychometrics and can reliably ascertain an individual's traits in terms of their frequency, intensity, or duration.

Rapid cycling: Four or more mood episodes a year of either Bipolar I or Bipolar II.

Recidivism: Recurrence of criminal activity in an offender. "Recidivism rate" refers to the general frequency of re-offense in a particular group of offenders.

Reciprocity: When a professional who is licensed in one jurisdiction is automatically licensed in a separate jurisdiction based on the issuance of the original license.

Reconstructive questioning: Questions designed to open semantic space for new realities. Such questions open the client to new ideas and discoveries—different ways of seeing a reality.

Recovered memory: A memory of a past traumatic event, believed to have been concealed from consciousness by repression or dissociation, but retrieved or recovered intact at a later point in time. See also RECOVERED MEMORY THERAPY and FALSE MEMORY SYNDROME.

Recovered memory therapy: A controversial form of psychotherapy aimed at retrieving traumatic memories that are believed to be repressed or dissociated. Although there is no one method for this, the techniques used most typically include hypnosis, truth serum, guided imagery, dream interpretation, age regression, free association, journaling, psychodrama, primal scream therapy, reflexology, massage and other forms of "body work" to recover "body memories."

Recovery: The process of developing individual potential and realizing life goals while surmounting the trauma and difficulties presented by behavioral, emotional, or physical challenges. For persons with a serious mental disorder, recovery involves a process of personal transformation in which the disorder becomes less central in a person's life as he or she achieves outcomes that increasingly bring personal meaning and life satisfaction.

Reflecting team: A team of members who observe an interview and then have a conversation with each other in which they express their reflections, questions, and ideas while the family or person whose experience is being reflected on observes.

Reframing: A second-order change intervention in which the facts of a situation are given a plausible, alternative definition previously not considered by those involved in the problematic situation. Usually, reframing provides an alternative positive meaning to some aspect of the problem or person with the problem that was previously defined negatively. For a positive reframe to be effective, it must be plausible to those in the problematic situation; the success rate is higher when the reframe is presented tentatively.

Refugee: A person who is outside his or her country of nationality and is unable or unwilling to return to that country because of persecution or a well-founded fear of persecution based on the person's race, religion, nationality, membership in a particular social group, or political opinion.

Reinforcement: A consequence that serves to strengthen or increase the frequency of a behavior. *Positive reinforcement* is a process in which a stimulus is presented following a behavior to increase the future frequency of the behavior. *Negative reinforcement* is a process in which a stimulus is removed following a behavior to increase the future frequency of the behavior.

Relapse prevention plan: Multilevel plan developing strategies to address risk factors or precursors that typically precede sexual offenses.

Reliability: A measurement tool that is reliable to the extent that similar results are consistently obtained on repeated and independent administrations of the tool.

Remarried family: This set of relationships is like those in a stepfamily except that at least one partner has been previously married.

Resilience: Adapting to adversity so as to maintain healthy levels of interactions and functioning. Resilience is demonstrated through our intellectual, emotional, and behavioral responses to adversity. Resilience knowledge and skills are developed through positive nurturing life experiences and adversity with the support of family, friends, and community and societal institutions.

Resistance: The expression of how people hold themselves back. A resistance signals the approach of an emerging contact boundary.

Resource acquisition: The process for acquiring the environmental resources desired by clients to achieve their goals, ensure their rights, and increase each person's assets.

Respondent behavior: Behavior that is reflexive in nature and elicited by preceding stimuli. Often emotional and physiological reactions are respondent behaviors.

Restorative justice: An alternative justice format to the criminal justice system that focuses on victims' rights and offender rehabilitation, as well as the community involved in the incident.

Risk management: Measures designed to prevent negligence lawsuits and ethics complaints.

Role-playing: Setting up an opportunity for someone to practice and rehearse a skill. This usually involves acting out brief real-life situations, with one person practicing the skill and another person responding to or receiving the skill.

Safe passage movement: An effort to bring about fundamental changes in social relationships between schools and community institutions by replacing fragmented, uncoordinated services for youth with integrated, collaborative networks of support.

Satanic ritual abuse: A form of child abuse by widespread, organized, underground satanic cults that engage in horrifying rituals including ritualistic torture, sexual abuse, and human sacrifice. To date, no physical evidence has been found to support the claims of ritual abuse survivors who recovered memories of satanic murder and ritualistic human sacrifice, and neither the FBI nor the police have been able to document even one organized satanic cult murder in the United States.

Scaling question: A versatile technique employed to measure client progress, motivation, and confidence; scales generally run from 0 through 10 with the poles jointly defined by the

practitioner and client. Scaling can also be used to rate a problem, feeling, or situation in terms of severity, frequency, desirability, and so on.

Schemas: "Rules of life" that individuals develop as a result of life experiences. They shape cognitive understanding.

Schema-focused therapy: This approach challenges self-defeating schemas through techniques like imagery and cognitive monitoring so the schemas no longer rule the client's perception of themselves and others.

Screening: Use of observation, records (if available), and standard questions to indicate the likelihood that an individual has a problem or issue other than the one for which he is referred. The screen is used to decide whether an assessment for the problem or issue is warranted. Screening is usually completed in five minutes or less.

Script: Attempts to repeat, in derivative form, a transference drama, which, like theatrical scripts, are primal dramas of childhood. It is a life plan based on decisions made in childhood, reinforced by parents, and justified by subsequent events.

Secondary trauma: Anxiety-related problems experienced by caregivers, first responders, and family members related to their interactions with someone who experiences a traumatic event.

Second-order change: A shift that occurs when an intervention introduces novelty to people stuck in the vicious circle of unsuccessfully trying to solve a problem. Because such interventions are not consistent with what the people involved assume about change, they have to accommodate their assumptions to the novelty of the interventions. Such accommodation results in growth and change of the person(s) stuck in the initial vicious circle involving the problem and, it is hoped, resolution of the problem.

Self-actualization: To fully realize and become one's fullest potential.

Self-care: Efforts by distressed people to alleviate symptoms by applying personal consultation and services to alleviate a health or mental health problem.

Self-psychology: A treatment orientation in psychoanalysis that encourages the growth of an integrated and cohesive intrapsychic structure through empathetic attunement and the internalization of particular functions initially professed by the therapist.

Self-anchored scale: A technique used to request a person to rate a problem or situation using a scale (for example, 1 = not a problem to 5 = a significant problem) to quantify the degree of severity. For example, "Could you please rate, from 1 to 5, your level of anxiety about taking the test?" This crudely quantifies the level of the client's test anxiety.

Self-object: Psychologists use the term *self* to describe individuals who perform one of three functions that sustain and promote healthy development of the self: mirroring (responding to and affirming the child's innate sense of vigor, greatness, and perfection); idealizing (those with whom the child can merge as an image of calmness, infallibility, and omnipotence); and partnering (those with whom the child feels an essential affinity).

Self-report measure: A pencil-and-paper instrument completed by the client to assist in the assessment of certain behaviors, attitudes, feelings, or qualities, and their frequency, duration, and/or magnitude.

Selection bias: Systematic differences between group participants that may result from decisions about care, prognosis, client preference, or responsiveness to treatment.

Serious mental illness: A label used to characterize people who possess a major psychiatric diagnosis, substantial deficits in functioning, and an illness of long duration. Characterizes those individuals who are coping with long-term psychiatric concerns and who require high levels of service and support.

Service management: A model of case management in which the case manager can purchase or authorize services for his or her clients. These case managers are financially accountable for the care plans they develop.

Severe and persistent mental illness: A mental illness that results in serious impairment in functioning in daily community living and persists across time or is so frequently recurrent that such disability is long-term.

Sexual deviancy cycle: Pattern of cognitive and physiological sexual responses and behaviors to inappropriate fantasies, thoughts, animals, and/or persons.

Sexual disorder: A sexual dysfunction, paraphilia, gender identity disorder, or a sexual disorder not otherwise specified. Sexual disorders

involve desired sexual objects, sexual response cycle, or arousal cues.

Sexual dysfunction: A problem characterized by a disturbance in the processes involving the sexual response cycle or by pain associated with sexual intercourse.

Sexual history: A history, usually obtained through a face-to-face interview but sometimes from a pencil-and-paper document, that reveals a person's sexual knowledge and experiences at each stage of development up to the present.

Sexual orientation: The commonly accepted, scientific term for the direction of sexual attraction, emotional and/or physical attraction, and its expression.

Sexual predator: A legal term referring to someone who seeks a relationship with another solely for the purposes of sexual assault.

Sexual response cycle: The stages of this cycle are desire, excitement, orgasm, and resolution. Disorders of sexual response may occur at one or more of these stages.

Shared decision-making: An interactive collaborative process between the health care provider and the consumer that is used to make mental health decisions, where the provider becomes a consultant to the consumer, helping them by providing information and discussing options.

Signs of safety partnership: An approach to child protection that promotes participation, cooperation, and collaboration among the social worker, child, and family.

Single-subject design methodology: The procedures employed in implementing a research design for evaluating the effectiveness of practice with one client unit—that is, individual, couple, family, or group.

Skills-based play therapy: An action-oriented treatment approach using scripted modeling plays, stories that model skills, selected skills from the child's spontaneous play, and plays and stories that are specific to the child's needs.

Social action: A collective endeavor to promote a cause or make a progressive change in the face of opposition.

Social constructivism: An epistemological perspective that takes the view that there is not an objective reality standing independently outside the individual knower, and that both individual

and social processes are involved in the social construction of reality.

Social determinants of health: Social and economic environmental factors that influence an individual's health and vulnerability for disease and/or criminal offending. Often described as risk factors, they can include distribution of wealth, power, resources, or working conditions.

Social diagnosis: The series of judgments about clients and their situations for which the practitioner assumes responsibility made throughout the life of a case, which serve as the basis for intervention.

Social history: A component of the social work record. It includes detailed descriptions of the client and the situation, both current and past. The social history involves both a process (collecting information) and a product (the document). It focuses attention on personal, family, social, and environmental issues, and assists the social worker in developing an understanding of the client-situation in context and over time.

Social justice: The concept of a society in which justice is achieved in every aspect of society, rather than merely the administration of law. As there is no objective, known standard of what is *just*, the term can be amorphous and refer to sometimes self-contradictory values of justice. A just society is generally considered one that affords individuals and groups fair treatment and a just share of benefits.

Social justice clinical practice: An approach to clinical practice that attempts to promote the promotion of social justice in all thinking and action. This newly emerging approach critiques existing theories and practices and develops new ones from the point of view of advancing distributive and relational justice.

Social phobia or social anxiety disorder: A persistent fear of one or more social or performance situations in which the individual experiences unfamiliar people or possible scrutiny. The individual fears that he or she will be humiliated or embarrassed by acting in a certain way or showing anxiety symptoms, and this fear and anxiety interferes with the person's social functioning.

Social planning: The process of defining and documenting a social need (problem analysis), establishing and implementing goals and objectives, and evaluating the effort, effectiveness, and outcomes.

Social skills: These can be defined as a complex set of skills that facilitate successful interactions among peers, parents, teachers, and other adults. The “social” refers to interactions between people; the “skills” refers to making appropriate discriminations—that is, deciding what would be the most effective response and using the verbal and nonverbal behaviors that facilitate interaction.

Social skills training (SST): A well-established form of behavior therapy that involves didactic instruction, role-playing, rehearsal, and reinforced practice of ill-developed social skills. This practice is more effective when conducted in carefully titrated real-life situations, although exposure and practice in imagination may be useful whenever re-creating real-life social situations is not practical.

Social support: Emotional and concrete assistance received from other people. Such assistance involves formal and informal means of aid to clients in the community that allows them to function optimally in a natural setting.

Social work diagnosis: A series of judgments, made by a therapist about the client’s person and his or her social systems, that serves as the therapist’s basis of interventions and for which he or she is prepared to accept professional responsibility. A social work diagnosis may include a *DSM-5* classification.

Social work role: A set of activities and behaviors expected of a social worker within a practice context.

Sociopolitical empowerment: Participation in the sociopolitical process to affect issues and concerns that impact the control and mastery of one’s life.

Socratic dialogue: The dialectic method of exploration using questions and answers to produce conclusions. This questioning procedure is frequently used by cognitive-behavioral therapists in the cognitive restructuring process.

Solution-focused brief therapy (SFBT): A competency-based brief therapy model that respects the client’s capacities to solve his or her own problems and charges the therapist with the job of creating a context by which this can happen. This approach focuses on the future and facilitates changes in language and cognition and coaches clients to take active steps toward solution building.

Spirituality: A search for purpose, meaning, and connection between oneself, other people, the universe, and the ultimate reality, which can be experienced within either a religious or a non-religious framework.

Selective serotonin reuptake inhibitors (SSRIs): A class of antidepressants used to treat anxiety disorders and other conditions. They are said to work by boosting the amount of a neurotransmitter (serotonin) that is linked to mood regulation.

Stages of readiness: The developmental stages (precontemplative, contemplative, preparation, maintenance, and termination) that clients tend to go through when changing their attitudes, beliefs, or behaviors. When a practitioner does not match an intervention to the particular stage of readiness that the client is in, resistance to treatment will result.

Stages of change: The temporal dimension that represents when particular changes occur. Stages also represent a continuum of motivational readiness to take and sustain action. Stages of the transtheoretical model include precontemplation, contemplation, preparation, action, and maintenance.

Stages of migration: A time sequence of the process of international migration that consists of premigration and departure, transit, and resettlement. Each stage entails unique psychosocial stressors that may influence health and mental health.

Standard of care: What an ordinary, prudent practitioner with the same or similar training and education would have done under the same or similar circumstances.

Standardized measure: Paper-and-pencil instruments, completed by the client and/or social worker, that provide a score indicating the extent or severity of a client problem or strength. A measure is standardized when it has been tested (normed) on a relevant group of people, the process of which results in psychometric data, specifically, information about reliability and validity. Also, there are certain procedures for administration, scoring, and interpretation.

Stepfamily: This family type is formed of an adult couple and at least one child from a previous relationship of one of the adults who live in the same household.

Strategic family therapy: A present-focused therapy model that emphasizes the understanding of the client's construction of reality and focuses intervention on altering the dysfunctional interactional patterns that are believed to maintain the client's presenting problems.

Strategic therapy: When the clinician goes into each session with a client with a plan for conducting the session and intervening in the client system based on the clinician's hypotheses about what dynamics are involved in maintaining the problem.

Strategy: A plan for action that links problems and solutions and depends on an ongoing assessment of the actions and sentiments of other actors, including one's own constituency, the target, and the general public.

Strengths: An individual's intellectual, physical, and interpersonal skills, capacities, interests, and motivations.

Strengths assessment: Specialized assessment tools and processes designed to capture the current and past involvement and success of clients in a wide range of life domains including education, employment, housing, health, and use of leisure time. Information is collected on both personal and environmental strengths as a basis for developing a treatment plan that involves building on and amplifying those strengths.

Strengths-based case management: A case management model in which the underlying premise is that the client or family and child have the skills and talents to make changes in their lives. This model provides an opportunity for clients or families to focus on their strengths rather than their deficits.

Stress: Internal (physical or emotional) response to a life stressor that exceeds one's perceived personal and environmental resources to cope with it.

Structural family therapy: A therapy model that defines the family as a system whose structure consists of predictable patterns that govern the family members' interactions. The goal of this therapy is to change the family structure by reinforcing boundaries and helping parents resume parental authority and appropriate roles.

Structured clinical interview for DSM-5 (SCID): A semistructured interview guide for making *DSM-5* diagnoses. It provides diagnostic criteria from *DSM-5*, interview questions for clinicians to determine whether criteria are present, and a place to record ratings.

Structured contextual assessments: Detailed appraisals of individual and family functioning used to develop case plans and treatment goals.

Substance use disorder: A maladaptive pattern of substance use leading to clinically significant impairment or distress.

Substance abuse treatment: State and federally regulated programs for men and women with substance use disorders. Substance abuse treatment may include behavioral therapy, medications, or their combination. Mutual aid groups such as Alcoholics Anonymous (AA) are integral to, but outside of substance abuse treatment.

Supervision: An interaction in which a supervisor is assigned or designated to assist and direct the practice of a supervisee through teaching, administration, and helping.

Support: A resource, the use of which helps an individual to function more effectively in a specific environment.

Supported employment: An approach to helping people with mental illnesses find and keep competitive employment within their communities. Supported employment programs usually occur in an outpatient setting, such as a community mental health center and are staffed by employment specialists who have frequent meetings with treatment providers in order to integrate supported employment with mental health services.

Supported housing: An empowerment and integration model that places consumers in independent housing coupled with flexible individualized services to facilitate community integration.

Surface structure: Behavioral and linguistic responses of edited experience used to convey meaning and pursue desired outcomes.

Switching: The change from one purported personality state to another; usually sudden and often a response to psychosocial stressors.

Synapse: In the brain, the tiny space between cell axons and dendrites filled by neurotransmitters ferrying electrical impulses from one cell to another.

Synergy: When all the parts of the center work together to create the "sum is more than the parts" phenomena that are important to positive program and individual outcomes. The synergy within a center develops the collaboration that results in protective factors to buffer risks for parents and children and promotes transformation and change.

Synopsis: A brief description of an original article or systematic review used to support evidence-based practice.

Synthesizing: A worker intervention that connects specific issues, feelings, or patterns a client is reporting or experiencing.

System of care: A range of programs and services for individuals with mental disorders from the most restrictive locked psychiatric units to the least restrictive community-based outpatient settings.

Systematic review: A comprehensive, unbiased, and reproducible review of prior studies that follows a detailed protocol. This involves a clearly formulated research question, explicit inclusion and exclusion criteria, systematic methods to comprehensively identify relevant studies, agreement on key decisions and coding, critical appraisal of the quality of evidence, and analysis and synthesis of data collected from the studies.

Systems-driven case management: A model of case management emphasizing efficient and effective delivery of organizational services. Efficiency is achieved through rationing of services, enhanced coordination of service delivery, using less expensive alternatives, and controlling clients' behavior.

Tactics: Short-term activities undertaken as part of a strategy for change.

Targets of benefits: The constituents on whose behalf advocacy efforts are undertaken. Sometimes the general public is the intended beneficiary of legislative advocacy.

Targets of influence: Those individuals and groups who are the focus of legislative advocacy efforts. They include the legislators (and their staffs), other political stakeholders, executive department heads (and key staff), the media, and other influential opinion makers and advocates.

Task planning and implementation sequence: In the task-centered model, a systematic sequence of practitioner and client activities designed to help clients develop and carry out problem-solving actions or tasks. Activities include task selection and planning, establishing incentives and a rationale for the task, anticipating obstacles, task rehearsal, task agreement, and summarizing and recording the task. The sequence, or elements of it, can be used in any form of intervention that makes use of between-session tasks or homework assignments.

Task-centered: The name of the model developed by William J. Reid and Laura Epstein in

the early 1970s, in which intervention is focused on helping clients develop and carry out specific problem-solving actions or tasks. The term may be used more generally to refer to any intervention with this focus.

Technical eclecticism: Integrative approach to psychosocial intervention that emphasizes pragmatic application of technical procedures on the basis of clinical efficacy; the aim is to match specific techniques with problems in functioning in light of empirical evidence and clinical expertise; this is the most technically oriented form of integration.

Technique: An observable action or object introduced by the social worker into the treatment process aimed at achieving a particular specific therapeutic outcome. Such action or object is replicable by others, has a level of professional approbation, and is understandable from a relevant theoretical perspective.

Theoretical integration: Integrative approach to psychosocial intervention that emphasizes conceptual synthesis rather than a blend of common elements or technical procedures; unifying frameworks link theories of personality, problems in living, and methods of intervention; generally regarded as the most challenging integrative strategy.

Therapeutic alliance: The collaborative and affective bond between social worker and client. It describes a situation in which the therapist and client agree on what needs to change, the nature of the problem, and the strategy for achieving change. For many types of problems, including substance abuse and major depression, the quality of the therapeutic alliance is more predictive of outcome than is the theoretical orientation of the therapist.

Therapeutic change agents: Term used for parents who are supervised by filial therapists to work directly with their own children to effect therapeutic change in them.

Therapeutic effects: The desired impact of medication on mental, emotional, and behavioral symptoms that are causing difficulty in the lives of clients.

Therapeutic relationship: In the common factors model, the client-clinician relationship is one key source or catalyst of change, not simply a taken-for-granted background for the impact of specific therapeutic techniques. Factors that contribute to the relationship are clinician characteristics, the empathy or warmth shown to the client by the clinician, and how the clinician and

client collaborate together on treatment goals. See also THERAPEUTIC ALLIANCE.

Tolerance building: Reduced sensitivity of a partner to the other partner's unfavorable behavior as a result of exposure to the behavior.

Transaction: A single stimulus and a single response, verbal or nonverbal. It is the unit of social interaction.

Transference: According to psychodynamic theory, the patterns of expectation, established over the course of development and life experience, that influence perceptions of other persons, interpretation of events, and modes of interpersonal behavior. In a therapeutic relationship, transference occurs when the client responds in an unaware manner to the therapist as if the therapist were someone of significance from the client's past. When properly understood, this phenomenon can be a source of growth for the client.

Transgender: A person who identifies as a member of a gender other than that of his or her own body.

Transmuting internalization: The developmental process whereby a function formerly performed by another is taken into the self and becomes the enduring, unique psychological structure of that individual, occurring via optimal frustration and optimal gratification, and characterized by incremental accretion and consolidation.

Transnational life: This theoretical perspective explains the growing trend of close ties between migrants and their home countries. It entails practices, relationships, and identities that maintain a close relationship to the country of origin by immigrants and their children and affects acculturation and assimilation.

Transparency: (1) Clarity of goals and outcomes in terms of organizational operation. The absence of barriers or obstacles to understanding decision making and responsibility. (2) The therapeutic practice of publicly situating ideas in one's experience so as to clarify what they are based on between the worker and clients; intended to help clients clarify the reasons they have sought assistance. (3) As a product, it is a mutual agreement between the worker and the client as to the nature of the problem and the meaning ascribed to the factors influencing the problem.

Transpersonal: A philosophical perspective on human behavior that focuses on human development and potential beyond the development of

rationality and autonomous ego to the possibility of self-transcendence and unity with the ultimate reality.

Transportability: The ease with which the average practitioner can take the ideas and concepts of any therapy model and integrate them into the real world with real clients.

Transtheoretical model: A multidimensional approach to change that includes the advanced integration of change processes and principles derived from the leading theories of behavior change.

Trauma: Experience involving actual or threat of death, serious injury, or loss of physical integrity to which the person responds with fear, helplessness, or horror. These experiences involve distressing physical or psychological incidents outside a person's usual range of experience.

Treatment: A process in which a qualified professional practitioner interacts with a client to alleviate symptoms, produce change in behavior, or improve functioning. Also referred to as *intervention*.

Treatment goal: An aim mutually identified by the social worker and client toward which they will work during the course of treatment. Goals should be clearly defined, observable, measurable, feasible, and realistic; stated in positive terms; stem directly from the assessment; and be set collaboratively by the social worker and the client.

Treatment planning: A formalized process of individualizing and operationalizing clients' treatment goals and specifying measurable outcomes to chart therapeutic progress. A specific plan is mapped out in clear, concise, and measurable terms for the treatment of a client's specific problem and achieving mutually defined treatment goals.

Triangles: The formation of relationships in families and other systems that involves two people functioning in relation to a third, usually reducing tension in the initial dyad. The collusion of the two in relation to the third is the defining characteristic of a triangle. The behavior of one member of a triangle is a function of the behavior of the other two, and behavior is reciprocal.

Tricyclic antidepressants: A class of antidepressants useful with some anxiety disorders. They purportedly work by regulating several neurotransmitters.

Triggers: Events, behaviors, language, and other environmental or emotional stimuli that cause a person's fight/flight/freeze reaction to recur as if the original trauma is occurring.

Tripolar self: According to psychodynamic theory, the mental structure linking particular kinds of self-selfobject relationships with corresponding poles of self experience, consisting of the grandiose-exhibitionistic self, the idealized parent imago, and the alter ego.

Typology: A framework for organizing information into coherent broad categories that contribute to understanding a given phenomenon conceptually.

Undocumented immigrant: A person who comes to live in the host country without legal documentation; this term is preferred to "illegal immigrant."

Ultimate reality (ultimate environment): Conceptualizations of the highest level of reality, understood differently by persons of various spiritual belief systems and/or at different levels of spiritual development or consciousness.

Unconscious process: Any cognitive, affective, motor, and other psychophysiological process that operates beyond a person's conscious control.

Unified detachment: Partners' description of problems in interactions in an emotionally detached and nonjudgmental manner.

Unique outcome: In conversation with clients, any time when a narrative therapist notes that a client has not been overcome by his or her problems—or has successfully challenged them. Such outcomes may represent new truths about themselves, which may be strengths that present clients with new options.

Utilization: Social work practice that uses and values what the client brings, including strengths and inner resources. The social worker not only accepts and values what the client brings but views what is brought as essential to helping the client.

Utilization review: A process in which established criteria are used to evaluate the services provided in terms of cost-effectiveness, necessity, and effective use of resources.

Validation: The social worker's unbiased acknowledgment and confirmation of a client statement or problem. If the social worker does not validate client concerns, he or she may not move forward; if social workers only validate

clients they may not move on; the key is to validate and then move on.

Validity: A measurement tool is valid to the extent that it *accurately* captures or measures the construct for which it is intended.

Values: The preferences, beliefs, traditions, practices, and customs considered desirable by a particular group of people.

Victim blaming: Subtle or blatant assignment of blame and responsibility to the victim of a traumatic event.

Victim services: Crisis and short-term counseling services, community referrals, and legal advocacy provided to crime victims, witnesses, and family survivors through law enforcement and the court systems.

Vitamin: An organic substance essential in small amounts for growth and bodily activity and that may be effective in treating some mental and emotional disorders.

Vulnerable clients: People who have sought assistance with a problem or issue whose disabilities and impediments are serious and long-term and make it difficult for them to meet ordinary personal and social requirements or to fulfill activities of daily living.

Will to meaning: A central human motivational dynamic and reason for human behavior.

Womanism: One form of feminism arising from the African American experience and focusing on the importance of race as well as gender.

Worldview of African Americans: Depicts the perceptions of African Americans in relation to other people, nature, objects, and institutions and is based on the values and ethos of the African American people.

Working alliance: This refers to one aspect of the therapeutic relationship—how the consumer and provider collaborate together to achieve treatment goals. The alliance is measured according to the extent to which the consumer and the provider collaborate on setting goals and completing tasks, and the strength of the bond between them. See also THERAPEUTIC RELATIONSHIP and THERAPEUTIC ALLIANCE.

Z-score: A standardized score that has a mean of zero and a standard deviation of one. A Z-score allows the client's score to be compared relative to another sample. Scores are computed by taking the scale mean from a client raw score and dividing by the standard deviation.
