FOREWORD

For over a century the social work profession has continued to evolve and develop new responses to the issues and challenges of the times. The first and second editions of the *Social Workers' Desk Reference* highlighted and focused attention on the changes occurring in social work practice, education, and research. This third edition continues in that tradition by continuing to identify and put forth responses to the changes occurring in society, especially those that are having an impact on social work practice, education, and research.

On a daily basis people around the world are confronted by issues such as poverty, a lack of access to quality education, unaffordable and/or inadequate housing, and a lack of necessary health and mental services. Now more than ever, we need social workers who have access to the most relevant, timely, and scholarly materials. Multiple social, psychological, and biological factors determine the level of mental health of a person at any point in time. Persistent socioeconomic pressures are recognized risks to mental health for individuals and communities. The clearest evidence is associated with indicators of poverty, including low levels of education. Poor mental health is also associated with rapid social change, stressful work conditions, gender discrimination, social exclusion, unhealthy lifestyles, risks of violence and physical ill-health, and human rights violations.

Specific psychological and personality factors also make people vulnerable to mental disorders. Lastly, there are some biological causes of mental disorders, including genetic factors and chemical imbalances in the brain. (<http://www.who.int/mediacentre/factsheets/fs220/en/index.html>)

The focus and depth of this third edition of the *Social Workers' Desk Reference* indeed contributes

to that effort. It is a useful tool for social work practitioners, educators, and students, as well as other allied professionals who together help to create interdisciplinary, interprofessional education, practice, and research. Throughout its 160 chapters this edition responds and brings attention, in a clear, scholarly, and evidence-informed manner, to some of the most important issues and areas of concern confronting current social work practice.

It is generally known that professionally trained social workers practice and provide services in a variety of settings, including child welfare and foster care agencies, community action centers, hospitals, government offices, mental health centers, homeless shelters, and schools; we also work with persons of diverse ethnic, cultural, racial, economic, sexual orientation, and social backgrounds. As professionals we help people to overcome some of life's most difficult challenges, including poverty, discrimination, abuse, addiction, physical illness, divorce, grief and loss, unemployment, underemployment, educational problems, disability, and mental illness.

Central to social work's primary mission is that of enhancing human well-being and working to ensure that people are able to meet their basic needs, especially the most vulnerable among us. We have done this through our various roles in society and in our varied fields of practice, and now we must work to ensure that those who are the most vulnerable among us are at the front of all of our efforts as we work to put in place a more just economic system.

Paulo Freire (1960) wrote that:

The radical, committed to human liberation, does not become the prisoner of a "circle

of certainty" within which reality is also imprisoned. On the contrary, the more radical the person is, the more fully he or she enters into reality so that, knowing it better, he or she can better transform it. This individual is not afraid to confront, to listen, and to see the world unveiled. This person is not afraid to meet the people or to enter into dialogue with them. This person does not consider himself or herself the proprietor of history or of all people, or the liberator of the oppressed; but he or she does commit himself or herself, within history, to fight at their side. (Freire, 1960)

Freire also said that "those who authentically commit themselves to the people must re-examine themselves constantly" (Freire, 1960, p. 60), and that is just what this new edition helps us to do. This third edition of the *Social Workers' Desk Reference* is not only a major contribution to the field, but its articles focus on the important practice issues of this period. It is an important tool that can and will provide immeasurable benefits to the social work profession. Its chapters are written by some of the field's foremost experts and bring to the reader the most recent conceptual knowledge and empirical evidence to aid in their understanding of the rapidly changing field of social work practice. It offers a guide to social work interventions in a variety of settings: from

the individual clinical level to community-based empowerment and advocacy.

The world is on the move with billions of people yearning to be truly secure—to be free from fear and free from want, and able to live in peace and in dignity. This is a time when global and national issues intersect, calling for a level of coordination and leadership that is essential for all of us. We must show that these concerns really can be dealt with collectively and fairly, with equity and social justice for all. As social work professionals, we cannot do that if we are not working together, and do not have at our fingertips the most relevant and timely information to ensure that our practice is the best informed that it can be! My friends, we have much work before us!

To those who have contributed to this latest edition, thank you all for your hard work.

In solidarity,

Gary Bailey, LHD (h. c.), MSW, ACSW

President, International Federation of Social Workers

Professor of Practice, Simmons College School of Social Work

Professor of Practice, Simmons College School of Nursing and Health Studies

ACKNOWLEDGMENTS

Building on the success of the second edition of *The Social Workers' Desk Reference* and Al Roberts's efforts, we have assembled an esteemed Associate Editor Board, many of whom worked so hard on the first two editions. New Associate Editors were included, however, and here I have intentionally added young talent for the simple reason of succession and the anticipated demand for additional volumes in the future. Al is gone, and by then I will likely be, too, so it is critical to identify who will carry Al's efforts forward. The Associate Editors decided on the scope and content of the sections, with only a few added by me. I am grateful to all the Associate Editors for the seriousness with which they addressed their tasks and for their dedication to producing excellent sections and, in total, an improved third edition.

I know I speak for Al when I express my gratitude to all the staff at Oxford University Press, in particular Joan Bossert, Vice President at OUP, and Dana Bliss, Senior Editor, and the support staff, Brianna Marron, Mallory Jenson and Devi Vaidyanathan. They have been terrific and this book would be the lesser without them.

And finally, this edition would not be possible without the involvement, support, and love from Vikki Vandiver. After 32 years, she is finally getting used to me (I hope).

CONTRIBUTORS

COEDITORS-IN-CHIEF

KEVIN CORCORAN, PHD, JD is Professor of Social Work at the University of Alabama, and has been a college professor for over 35 years. He holds a BA in English literature from Colorado State University, an MA in counseling from the University of Colorado—Colorado Springs, an MSW and PhD from the University of Pittsburgh, and a JD from the University of Houston. He has been involved in research and practice of clinical social work since 1973, and was a commercial and community mediator from 1982 to 2012. He has published over 130 ephemeral journal articles and book chapters, has authored or edited 15 books, including *Measures for Clinical Practice and Research*, the ever-entertaining cookbook, *Food for Thought: A Two-Year Cooking Guide for Social Work Students*, and is co-editor of *Best Practices in Mental Health*. He is the founder of a dotcom called EasyRATs.com (aka Rapid Assessment Tools, RATs) that performs drug, alcohol, and mental health assessments in less than a second; the urls are Do-I-need-therapy.com and Is-therapy-effective.com. He is also the designer or inventor of the “The Electric Seating Chart,” the Internet-based “Sole Mate,” a shoe-powered battery for charging smartphones, and “The Electric Hamster,” which is designed to teach STEM to elementary school girls, and “Little Al” the Alabama cheering glove. His hobbies including gourmet cooking, portrait painting, random study of history, bonsai gardening, creative writing, and a bad golf swing; he is also trying to learn to play the piano.

ALBERT R. ROBERTS, PHD, DACFE. The late Albert R. Roberts was Professor of Social Work and

Criminal Justice, and Director of Faculty and Curriculum Development in the Faculty of Arts and Sciences at Rutgers, the State University of New Jersey in Piscataway. He was a college professor for 35 years. Dr. Roberts received an MA degree in Sociology from the Graduate Faculty of Long Island University in 1967, and a doctorate in social work from the School of Social Work and Community Planning at the University of Maryland in Baltimore in 1978. Dr. Roberts was the founding Editor-in-Chief of the Brief Treatment and Crisis Intervention journal and the Victims and Offenders journal. He was a member of The Board of Scientific and Professional Advisors and a Board-Certified Expert in Traumatic Stress for The American Academy of Experts in Traumatic Stress, and a Diplomate of the American College of Forensic Examiners. Dr. Roberts authored, co-authored, or edited approximately 250 scholarly publications, including numerous peer-reviewed journal articles and book chapters, and 38 books. Among his books were the *Handbook of Domestic Violence Intervention Strategies* (Oxford University Press, 2002), *Crisis Intervention Handbook: Assessment, Treatment and Research*, 3rd edition (Oxford University Press, 2005), *Juvenile Justice Sourcebook* (Oxford University Press, 2004), *Evidence-Based Practice Manual: Research and Outcome Measures in Health and Human Services* (coedited with Kenneth R. Yeager, Oxford University Press, 2004), and *Ending Intimate Abuse* (coauthored with Beverly Schenkman Roberts, Oxford University Press, 2005). Dr. Roberts was also the editor of three book series: the Springer Series on Social Work, the Springer Series on Family Violence, and

the Greenwood/Praeger Series on Social and Psychological Issues. Dr. Roberts was the recipient of many awards for his teaching and his scholarly publications.

Prior to his death in the summer of 2008, Dr. Roberts was in the midst of many projects, including his courses on Crisis Intervention, Domestic Violence, Introduction to Criminal Justice, Research Methods, Program Evaluation, Victimology and Victim Assistance, and Juvenile Justice at Rutgers University; training crisis intervention workers, crisis counselors, and clinical supervisors in crisis assessment and crisis intervention strategies; and training police officers and administrators in domestic violence policies and crisis intervention. He was a lifetime member of the Academy of Criminal Justice Sciences (ACJS), a fellow of the American Orthopsychiatric Association, a member of the Council on Social Work Education and the National Association of Social Workers (NASW) since 1974, and was listed in *Who's Who in America* from 1992 forward.

SECTION EDITORS

PAULA ALLEN-MEARES, PHD, is the Chancellor of the University of Illinois at Chicago. Previously she served as the Dean, Norma Radin Collegiate Professor of Social Work, and Professor of Education at the University of Michigan. Her research interests include the tasks and functions of social workers employed in educational settings; psychopathology in children, adolescents, and families; adolescent sexuality; premature parenthood; and various aspects of social work practice.

JOSÉ B. ASHFORD, MSW, PHD, LCSW is a Professor of Social Work and a member of the Doctoral Faculty in Sociology at Arizona State University. He is also the Director of the Office of Forensic Social Work Research and Training in the School of Social Work and an Affiliate Professor in the Schools of Criminology and Criminal Justice and Justice and Social Inquiry. He is the chief research consultant for the City of Phoenix Prosecutor on matters involving the implementation of principles of community prosecution, offender diversion, and problem-solving justice. He is also involved in research with the Social Intelligence Institute on prevention of

recidivism and continues as a Senior Consultant with Mercer Government Human Services Consulting on issues involving forensic and correctional mental health. Dr. Ashford has published widely on forensic matters, including a coedited book recognized as one of the most influential books on management of violence risk in the forensic literature. His most recent book on death penalty mitigation with Oxford University Press addresses an important gap in forensic literature and is receiving high praise from sentencing advocates, mitigation specialists, and lawyers.

ROWENA FONG, MSW, EDD is the Ruby Lee Piester Centennial Professor in Services to Children and Families at The University of Texas at Austin. Her scholarship and research focus on immigrant and refugee children and families, child welfare, and culturally competent practice. She has over 100 publications, including coauthored books on *Culturally Competent Practice with Immigrant and Refugee Children and Families* and *Culturally Competent Practice: Skills, Interventions, and Evaluations*.

CYNTHIA FRANKLIN, PHD, is Assistant Dean for Doctoral Education and Stiernberg/Spencer Family Professor in Mental Health at The University of Texas at Austin School of Social Work. Dr. Franklin has published widely on topics such as dropout prevention, clinical assessment, the effectiveness of solution-focused therapy in school settings, and adolescent pregnancy prevention. She is the current Editor-in-Chief of the *Encyclopedia of Social Work*.

LAURA M. HOPSON, PHD, MSW is an Associate Professor at the University of Alabama School of Social Work. She has published articles in the areas of school social work practice, school climate, substance abuse prevention, and solution-focused brief therapy, and has coauthored the book, *Research Methods for Evidence-Based Practice*.

KATHERINE L. MONTGOMERY, PHD, MSSW is the School Director at Little Sunshine's Playhouse and Preschool in Saint Louis, Missouri. She graduated with her BSW from Missouri State University and MSSW and PhD in Social Work from The University of Texas at Austin. She has over 18 years of experience working with children and families in a variety of settings, but most of

her recent work focuses on early evidence-based prevention intervention delivery in school settings. She has authored over 30 publications and presented at numerous conferences both nationally and internationally.

LISA RAPP-MCCALL, PHD, MSW is a Professor in Social Work at St. Leo's University in St. Leo, Florida. Her research interests include juvenile crime and violence, at-risk children and adolescents, and prevention.

PHYLLIS SOLOMON, PHD is a Professor in the School of Social Policy & Practice and Professor of Social Work in the School of Medicine at the University of Pennsylvania. She has conducted numerous federally funded randomized clinical trials for adults with severe mental illness and their families. She reviews research grants for U.S. federal agencies, private foundations, and Canadian organizations. She also coedited another book, *The Research Process in the Human Services: Behind the Scenes*.

BRUCE A. THYER, PHD, LCSW is Professor and former Dean with the College of Social Work at Florida State University. Dr. Thyer has authored over 250 articles in refereed journals, written over 60 book chapters, and produced over 28 books. He is the Founding and current Editor of the bimonthly peer-reviewed journal *Research on Social Work Practice*, produced by Sage Publications.

VIKKI L. VANDIVER, MSW, DRPH is Dean and Professor of Social Work at the University of Alabama School of Social Work. She is the author of three books on mental health (*Maneuvering the Maze of Managed Care*, 1996, Free Press; *Integrating Health Promotion and Mental Health*, 2009, Oxford University Press; *Best Practices in Community Mental Health*, 2013, Lyceum Books) and over three dozen chapters and articles on best practices in mental health. She is also coeditor of the peer-reviewed journal, *Best Practices in Mental Health* (Lyceum Books) She has been in the field of community mental health for over 35 years, has taught *Diagnostic and Statistical Manual of Mental Disorders (DSM)* content for the last 21 years, and has recently completed a SAMHSA grant to evaluate equine-assisted therapy with at-risk tribal and nontribal youth.

PART I

*Overview and Introduction to
Social Work*

1 What Changes and What Remains in a Practice Profession

Elizabeth Clark

It has been six years since the second edition of the Desk Reference was released. Since that time, our world has changed in many large and small ways. Our political landscape has become more partisan and more entrenched. The numbers of baby boomers, veterans, prisoners, and the homeless have increased. Global warming and natural disasters are on the rise. Health care reform has moved forward; immigration reform has stalled. The list goes on and on. Against this backdrop of rapid acceleration and social complexity, editors Kevin Corcoran and Albert Roberts and their editorial board had to decide what content to leave in, what to add, and what to revise. This was a formidable task, and they collectively rose to the challenge.

It has been suggested that a profession will not seek new ways or contexts until it feels the “challenge of crisis” (Kuhn, 1970, p. 144). Today, numerous factors are driving social work practice changes. These include globalization, an unending war, an uncertain economy, a fraying of the social safety net, and the speed and impact of technology.

Social work has become a global profession. In the United States, social workers serve in the United Nations, the U.S. Department of State, USAID, the World Bank, Congress, the Peace Corps, the U.S. Department of Agriculture, and many nongovernmental organizations (NGOs) that work abroad. Many schools of social work have established, or are in the process of establishing, schools and programs in countries such as China, India, Cambodia, and Viet Nam. I would contend that the profession now has a moral mandate that crosses geographic boundaries. We must become a visible and active partner

in the search for solutions to the interrelated social challenges around the globe.

Social work principles of human rights and social justice underlie the efforts of our social work colleagues in both developed and developing countries. The over 200 member countries of the International Federation of Social Workers (IFSW), in partnership with the International Association of Schools of Social Work (IASSW) and the International Council on Social Welfare (ICSW), have developed a *Global Agenda for Social Work and Social Development* (<http://cdn.ifsw.org/assets/globalagenda2012.pdf>). The Agenda is committed to “supporting, influencing and enabling structures and systems that allow people to have power over their own lives” (IFSW, 2012). These efforts currently are focused in four areas:

- Promoting social and economic equalities
- Promoting dignity and worth of people
- Working toward environmental sustainability
- Strengthening recognition of the importance of human relationships.

Internationally, social workers are being sought for their ability to resolve human and social problems and for the contributions they can make to the emerging global social, political, and economic landscape. More specifically, social workers can help translate policy into workable projects, help design and evaluate direct services and projects, and work toward community capacity building.

In the United States, social workers work in refugee settlements and in communities with an

influx of immigrants. In clinical practices, they work with victims of torture or those who were imprisoned for their political beliefs and social activism. Social workers volunteer their services and mobilize resources when natural or man-made disasters occur around the globe. At the macro level, social workers are champions of fair immigration laws, the eradication of hunger and infectious diseases such as HIV/AIDS, and the reduction of world violence.

Jane Addams was awarded the Nobel Peace Prize in 1931. Eighty years later, social worker Leymah Gbowee was a 2011 recipient for her peace efforts in Liberia (Gbowee, 2011). Efforts on behalf of peace have always been a part of the fabric of social work practice. On September 14, 2001, Congresswoman and social worker Barbara Lee was the only negative vote for House Joint Resolution 64, the Authorization of Use of Military Force against terrorists involved in the attacks on September 11. Lee said, "We must step back for a minute ... and think through the implications of our actions today so that this does not spiral out of control" (*The Guardian*, 2013).

Twelve years later, the United States seems unable to extricate itself from what has been described as an endless war. The effects of the war are significant. We now have a generation of young people who have grown up against the backdrop of war. The number of American troops who have died fighting in the wars in Iraq and Afghanistan is nearing 7,000 (U.S. Department of Defense, 2013). Depending on sources used, the number physically wounded in battle has surpassed 50,000 (U.S. Department of Defense, 2013), and there have been more than 250,000 brain injuries, the signature wound of this war (American Forces Press Service, 2013).

As a country, we have been slow to recognize the sacrifices and the incredible need for assistance and services for our nation's service members and veterans. In addition to the millions of veterans from past conflicts who still deserve the care and resources that have been promised to them, there have been 2.5 million service members involved in the wars in Iraq and Afghanistan. Many of these young men and women have struggled with mental and behavioral health challenges, unemployment, homelessness, or general difficulties re-acclimating to civilian life. Social workers have been a critical component of the interdisciplinary workforce tasked with ensuring that service members,

veterans, and their families have the support that they have earned.

The United States Department of Veterans Affairs (VA) is now the largest employer of master's level social workers in the country, with over 11,000 professional social workers employed in their many settings and programs (U.S. Department of Veterans Affairs, 2011). Because this practice area continues to grow, standards for best practices and advanced credentials need to be available.

In 2012, the National Association of Social Workers (NASW) worked in partnership with the White House Joining Forces initiative, which was led by First Lady Michelle Obama and Dr. Jill Biden (NASW News, 2012). As part of NASW's commitment to Joining Forces, expert practitioners developed the *Standards for Social Work Practice with Service Members, Veterans, and Their Families* (NASW, 2012). These standards are a resource for clinical social workers providing mental and behavioral health services, direct practitioners in social service agencies, and social work advocates. In addition, NASW created three professional credentials to demonstrate in-depth knowledge, proven work experience, leadership capacity, competence, and dedication in this field of practice at the baccalaureate, advanced, or clinical levels (<http://www.socialworkers.org/military.asp>).

Despite the record numbers of social workers within the VA system and the Department of Defense, veterans today constitute a vulnerable population. They also highlight the inadequacy of the nation's social safety net that generations of social workers have worked to build and maintain.

RECAPTURING THE PAST

In late 2006, I had the honor of attending a "Social Work Pioneer Listening Conference" where six Pioneers talked about the investments in the social work profession from the post-World War II era through the present day. They discussed the social context, major events, and problems social work practitioners faced during that time (Stuart, 2009). They also discussed the successes they achieved.

For example, Delwin Anderson discussed his role at the VA. He joined the VA as a field social worker in Minnesota in 1947. He became the national Director of the Social Work Service in

1964, and served in that position until he retired in 1974. He was responsible for 2,600 social workers employed in 171 hospitals. Together, they revolutionized care for our veterans. They looked at treatment and rehabilitation of the whole patient, and developed ways for patients to receive community care.

Although the clinical accomplishments of Anderson and his co-presenters at the Listening Conference were remarkable, what was most impressive was their community organizing skills and expertise. They saw the need for social work in various agencies and settings and worked from both inside and outside to bring it about.

There are many, many examples of the leadership of social workers in our history. In fact, most of the social safety net we have come to rely upon today was fashioned by social work advocates.

Frances Perkins was the first woman and social worker appointed to a cabinet position. She served as Secretary of Labor from 1933 to 1945, that is, through all of President Franklin Delano Roosevelt's terms. She began her career as a crusader for factory safety. Her agenda as Secretary of Labor included a major unemployment relief program, workers' rights protections, minimum wage, and child labor laws. She also served as Chairwoman of the commission that ultimately crafted the Social Security Act (P.L. 74-271) (Downey, 2009).

Harry Hopkins began his social work career in a New York City settlement house. He was chosen by President Roosevelt to head the first state emergency relief agency during the Great Depression, and later ran the \$500 million federal program (Cohen, 2009).

CRAFTING THE FUTURE

Advocacy had its roots in social work, and advocacy for social supports and increased social services deserves our full attention. In the past decade we have experienced the worst recession since the Great Depression. Salaries have remained static and the minimum wage does not cover minimal family needs. Our schools are in disrepair and their service programs are woefully inadequate.

Despite the advocacy efforts of the 12 social workers in Congress working with tens of thousands of social work activists, recent political successes have been few and far between. The one major exception has been health care reform,

namely, the passage of the Patient Protection and Affordable Care Act of 2010 (ACA) (P.L. 111-148).

The ACA contains many welcome and positive changes including expanding health care coverage to millions of uninsured individuals, eliminating preexisting condition exclusions and lifetime caps, and offering mental health parity (Patient Protection and Affordable Care Act, 2010). With an emphasis on prevention, social determinants of illness, and early intervention, the ACA also offers opportunities for health care and public health social workers.

One downside of the ACA for social workers is role blurring. Over the past few decades, the diversity of practice areas in social work has widened significantly. A consequence of this rapid growth has been an expanding overlap of professional practice fields. At the same time, we have seen a narrowing of what we traditionally have called social work.

New titles and credentials, such as peer counselors (championed by Substance Abuse Mental Health Services Administration), community health workers (Centers for Disease Control and Prevention [CDC] and the Centers for Medicare and Medicaid Services [CMS] offer training grants), and patient navigators (funded by the Patient Protection and Affordable Care Act) have emerged. In many ways, these terms address functions that need to be fulfilled rather than individual professions (SWPI, 2012), but they still present challenges. Add to these the need for service integration to ensure cost-effectiveness, as well as the use of trans-disciplinary teams, and the role blurring and professional competition increase.

Another challenge is the legal regulation of the profession. Social work efforts around licensure began in the 1940s. Now all 50 states have some level of licensure for social workers to seek legal recognition, protection, and reimbursement for services. Because licensing is determined within the states, different definitions of social work and aspects of social work practice vary from state to state. This contributes to confusion about our profession among the public, lawmakers, other providers, and insurers. This lack of clarity, as well as a lack of reciprocity state-to-state, makes it harder to define and defend what we do and are entitled to do as a profession.

In 2010, the major social work organizations came together to hold a national Social Work Congress to reaffirm, revisit, and reimagine the profession. It focused on issues internal

to the profession. The result was consensus around ten “Social Work Imperatives” that needed action in the next decade. They included (NASW, 2010):

1. Business of Social Work: Infuse models of sustainable business and management practice into social work education and practice.
2. Common Objectives: Strengthen collaboration across social work organizations, their leadership, and their membership for shared advocacy goals.
3. Education: Clarify and articulate the unique skills, scope of practice, and “value added” aspects of social work to prospective social work students.
4. Influence: Build a data-driven business case that demonstrates the distinctive expertise and the impact and value of social work to industry, policy makers, and the general public.
5. Influence: Strengthen the ability of national social work organizations to identify and clearly articulate, with a unified voice, issues of importance to the profession.
6. Leadership Development: Integrate leadership training in social work curricula at all levels.
7. Recruitment: Empirically demonstrate to prospective recruits the value of the social work profession in both social and economic terms.
8. Retention: Increase the number of grants, scholarships, and debt forgiveness mechanisms for social work students and graduates.
9. Retention: Ensure the sustainability of the profession through a strong mentoring program, career ladder, and succession program.
10. Technology: Integrate technologies that serve social work practice and education in an ethical, practical, and responsible manner.

In one way or another, progress toward all of these imperatives is included in this comprehensive reference volume. The last imperative, technology, is covered extensively by several authors. This highlights both the importance and the immediacy of the topic.

We are just beginning to understand the potential impact of technology on social work practice. Despite uncertainties around policy, liability,

and licensing concerns, and despite increasing privacy and ethical issues, computer-based or e-therapy is accelerating (Reamer, 2013). We no sooner develop standards and guidelines than a new type of technology enters the horizon and our efforts are outdated. Young social workers are early adapters of such technology. They grew up living online, and they are not only comfortable with it, but find it essential to their lives as well. Schools and educators have struggled to keep up by using technology in the classroom and by offering classes and entire programs online. Supervision is being done electronically, and health care reform requires electronic health records and billing for services.

Technology has contributed positively to social work practice. We can find information quickly and easily. We can keep up with the literature in our fields. This can enhance practice by ensuring that our interventions are evidence based and current. We can find models and best practices, as well as locate colleagues and experts and check resources needed by our clients, our agencies, and our communities. Technology also is an asset for our social advocacy efforts. It is now easy to send an e-mail to a legislator, compose and submit a letter or blog to a news line, or get a requisite number of signatures to make a political point or request an action.

What is needed is an increased sensitivity to the potential negatives of living online, while at the same time incorporating technology into our practices and our lives. Additionally, we need the new generation of social workers, those who are expert in these areas, to take the lead in establishing acceptable parameters and guidelines for use.

CONCLUSION

The questions that remain are (1) Is social work still relevant? (2) Do we have the necessary outcomes data to show our value? (3) Can we ensure a profession appropriate to our times and for the future?

Based on the writings and shared wisdom of the scholars and expert practitioners who have authored the *Social Workers' Desk Reference*, we can answer these questions in the affirmative. They clearly show that the profession of social work continues to grow and expand through practice. They also illustrate how practice informs both research and policy and vice versa.

Forty years ago, Khan, in his preface to the book *Shaping the New Social Work*, asserted that social work practice answers the call of its time (1973, p. vii). We agree that it does. The world is changing rapidly and some things must be surrendered to progress. Yet, there are historical tenets of social work that we deem essential, if not sacred.

The purpose of the profession remains solid and steadfast—to enhance human well-being and meet the human needs of all people; to seek social justice and positive social change; to promote peace; and to practice ethically. Advocacy is our professional cornerstone. Our core values, first adopted as a *Code of Ethics* in 1960, and only amended slightly since that time, remain our guiding principles: service, social justice, dignity and worth of the person, importance of human relationships, integrity, and competence (NASW, 2008).

We have a professional obligation to live up to our founding documents and to honor, support, and advance the teachings upon which the profession of social work has been built. We also need to claim our expertise, and to assume leadership roles in addressing the social problems and issues of today.

Whitney M. Young, Jr., the social worker who transformed the National Urban League during the Civil Rights movement and who was an advisor to three presidents, challenged social workers to be more visible. He said:

There is a lot to tell the public. The important thing is that we can begin saying something as persistently as we can. The media and the government, regardless of their reasons, cannot continue to disregard the findings of current research and the knowledge of thousands of social workers who know as much or more than the so-called experts on the social problems draining the spirit and resources of our nation (Young, 1971).

The authors in the *Social Workers' Desk Reference* have answered that call to action. The content of this third edition will be an indispensable resource for practitioners, educators, researchers, policy makers, and students everywhere.

Professional Socialization

2 *On Becoming and Being a Social Worker*

Shari Miller

Although social work in practice is a "job" (or more accurately a vast range of jobs), and while it is also a career, it can further be understood as a professional culture unto itself, replete with defined values, attitudes, norms, and a sense of identity. Would you be willing to engage in a brief thought experiment? If you like to make things visual, feel free to grab a sheet of paper and draw a picture; if you prefer to think in terms of language use words as your symbols. Now, close your eyes and think "social worker": Who do you see? How do you see her/him? Now close your eyes again and think doctor, or attorney, or nurse, etc. (select one): Now who do you see? How do you see her/him? Were they different? How so? The drawings or narratives you might craft for these respective professionals, and the notable qualitative differences between them can be explained by the idea that professions are cultures. And the differences between the cultures help to shape those narratives.

The questions that began this chapter invite us to look inside the culture of social work.

Research in this area allows us to develop an understanding of key variables, how certain processes unfold over time in particular contexts, and how they all contribute to professional development. A solid understanding of these variables and processes affords the profession of social work a much more informed understanding of its workforce and its capacity, of its educational structures, and of its realms of service provision. And with an understanding of professional socialization, social work students and practitioners are empowered to engage in their own professional development from an informed standpoint, and with agency. This chapter, with its focus on the professional socialization of social workers, invites you to spend time reflecting on the culture of the profession—this context sheds light on the "hows" and "whys" of social work so that practitioners can be best prepared to go out and do the "whats" of practice. This chapter is designed to help you understand what professional socialization is,

how it fits within the historical evolution of social work as a profession, and how it might look in an applied sense.

PROFESSIONAL SOCIALIZATION DEFINED

Socialization in general can be understood as the process through which people gain knowledge, skills, and orientations that organize their membership in a society (Brim & Wheeler, 1966). This process happens over time and contains primary facets that occur during childhood, which tend to be sturdy and hard to change; a worldview becomes situated and serves as a way of making an objective-seeming reality a subjective vehicle for understanding and guiding action (Jarvis, 1983). The secondary facets happen in adulthood as people begin to locate themselves in other spheres in their interaction with the world around them (Jarvis); their functioning in society shifts and so does the emphasis of this secondary socialization. The focus of this phase of socialization is no longer so much on values and establishing a worldview, but instead is on honing and sculpting the ways in which people behave and/or act in those different spheres. Here, in this secondary phase of socialization, professional socialization can occur. Individuals entering a profession adapt “externally, in the requirements of the specific career role, and internally, in the subjective self-conceptualization associated with that role” (McGowen & Hart, 1990, p. 118). They bring their primarily socialized selves into a new cultural space and make shifts in what they think and how they act to adapt and accommodate to the new professional cultural expectations and requirements.

Though adult socialization does not rest on the acquisition of basic values, in professional socialization there is a focus on professional values and norms, which makes it a specialized form of adult socialization that does involve some active grappling with those sturdy worldviews (Shuval, 1980). The process of professional socialization happens before, during, and after formal education (Barretti, 2004; Miller, 2010) and can be understood as linked to both “the intended and unintended consequences of an educational program” (Shuval, 1980, p. 6). Over the course of time, the person entering the culture’s space shifts her/his focus from those reference groups (e.g., parents, extended family, school, community) that informed her/his worldview as s/he was socialized

as a child, to new and specific reference groups that are related to the profession (e.g., classroom instructors, field instructors, peers). These new reference groups serve as her/his “principal anchoring point for values and behavior with respect to the professional role” (Shuval, p. 6). S/he locates these reference groups and makes choices about how s/he fits as s/he enters into the profession’s culture. In order to be professionally socialized there needs to be a professional culture within which to be socialized; what do we know about social work’s professional culture?

THE CULTURE OF SOCIAL WORK

A professional culture is typically characterized by an explicit and/or implicit set of values, preferred attitudes, and norms of behavior; its members have clear professional role identities. In order to understand the culture of a profession and the members who are socialized into it, it is essential to consider context. In this instance, it is particularly important to consider elements of social work’s history, and to clarify its mission and values.

Social Work’s History: Critically Reflective Identity Struggles

The social work profession has a long and storied history of grappling with its self-definition. This history and its related dialogue can be understood as part of social work’s path toward professionalization—the process via which an occupation attains professional status (Abbott, 1988), which has direct implications for professional socialization. Abraham Flexner’s (1915 see Flexner, 2001) “Is Social Work a Profession?” speech is often considered a pivotal moment in social work’s history, and the distinct point in time that marked the beginning of the profession’s ongoing and colorful discourse about its own professionalization. Here we will discuss the history from the point of Flexner’s 1915 speech forward, while all the while acknowledging that the very fact he was invited to speak on this topic suggests social work began questioning its professionalization earlier than 1915.

As the Assistant Secretary of the General Education Board, Flexner was considered eminently influential in the area of professional education, though more specifically, medical education in the United States (Austin, 1983, p. 361). Because of these credentials, he was invited to speak by the

National Conference of Charities and Corrections and to answer the question “Is social work a profession?” Flexner approached the speech with his background expertise, but also with what he said was a lack of familiarity with “social work, with the literature of social work, and with social workers” (Flexner, 2001, p. 152), and warned at the opening of his speech that he doubted his “competency to undertake the discussion” (p. 152). That he was this uninformed about social work, and was invited to speak anyway because he was well informed about medicine, provides us with a window into the social work professionalization discourse at that time. With his caveat in place, Flexner moved forward and applied his set of six criteria that define a profession. There are some who have criticized his criteria as arbitrary because they were based on a subjective set of ideas rather than on detailed comparative study (Austin, 1983). He grounded his six criteria in the example of medicine as the consummate profession and indicated that professions

- (1) Involve essentially intellectual operations with large individual responsibility
- (2) Derive their raw material from science and learning
- (3) This material they work up to a practical and definitive end
- (4) Possess an educationally communicable technique
- (5) Tend to self-organization
- (6) Are becoming increasingly altruistic in motivation (Flexner, 2001, p. 156).

After applying these criteria to his analysis of social work, Flexner determined that social work was not a profession. To this day, you can almost hear the audience gasp at the conclusion, but in that gasp rested confirmation of doubts and impetus for future directions.

Flexner explicated in some detail his reasons for determining social work’s nonprofessional status, but a full discussion of these conclusions is beyond the scope of this chapter (see Flexner, 2001 for complete transcript of speech). It was, however, his assessment that launched social work on its quest to prove its status and define its identity as a profession. Rather than regarding the pivotal Flexner moment as a blow to social work’s sense of professional identity, it is crucial to instead regard it as a moment that concretized one of social work’s essential defining features. The profession itself, though not without

controversy and conflict, dove into the hard work of “self”-reflection and into its intentional, creative self- organization and development.

With this critically self-reflective response to Flexner’s speech, a lively dialogue emerged for social work scholars that was then, and in some ways is still now, characterized by a polarized set of views: those who strive to achieve professionalism as originally defined by Flexner and those who believe that very striving to be antithetical to social work’s mission (Hugman, 1998). Some have suggested that, in fact, “the quest for status and identity has occupied center stage within social work since its inception” (Gibelman, 1999, p. 298). In 2001, a special issue of the journal *Research on Social Work Practice* was published with Flexner’s analysis at its core. The purpose of the special issue was to “examine the perceptions of social workers about the position of social work as a profession at the end of the 20th century against the background of the Flexner statement [made] some 85 years ago” (Austin, 2001, p. 147). The perspectives of the contributing authors unified around the idea that there are significant changes taking place with regard to the organization of human services in our society that will likely continue to be of critical importance to social work. Some suggested that in the face of these changes the profession has stood up well and others suggested that there remain critical issues to be evaluated and challenges to be met with that were as yet not being addressed (Austin, 2001).

Over time, as the profession and its scholars and members worked diligently in these ways to self-identify, while also working to serve the needs of those who seek its services, the agility of social work has been unwavering. What appears to be a never-ending quest for professional identity (Gilbert, 1977) may, in fact, be one of the defining features of social work and its very professional identity—it shifts with the changing societal tides (Gibelman, 1999) and so by its very nature cannot be structured around one static professionalized identity. Social work can be defined as a social movement (Reynolds, 1965) that is a profession (Greenwood, 1957), and as such may have adaptively shifting faces over time. This agility, flexibility, and this orientation to action are very much a part of what defines social work’s culture.

As social work positions itself in the present day to meet the ever-growing demands for social services in the face of shifts in demographics, profound economic changes, global demands, etc.,

it is increasingly clear that it does not have the workforce capacity to meet the predicted level of need (Whitaker, Weismiller, & Clark, 2006). How social workers make their way to the profession and why they choose to remain, or not, as members of the profession is key. In order to build and maintain a professional workforce that is well prepared to meet the profound and growing needs of local and global society, social work must lend resources to understanding its own culture, its educational structure, and its applications in practice. At present, research in the area of professional socialization is limited but growing, and there is a lot of room and opportunity to learn more.

A professional culture is replete with values, attitudes, and norms—all of which rest solidly upon or emanate directly from the profession's unifying mission. These are primarily communicated through the central organizing institution, the collection of accredited schools of social work. With a history characterized by seemingly binary and simultaneous strains of influence, and questions around professionalization, social work has often grappled with whether or not there is one clear mission, and whether or not those educated and practicing as social workers are indeed true to the profession's traditional mission (Specht & Courtney, 1994). Furthering understanding of how practitioners professionally socialize to social work, who plays what roles, how this socialization looks, and what it informs in practice, will enable social work to remain both agile and sturdy in the face of change, and enable its practitioners to be best equipped to meet the critical needs of populations at risk. So, what is the mission of social work?

The Mission and Values of Social Work

In the United States, the National Association of Social Workers (NASW) indicates that the primary mission of social work is "to enhance human wellbeing and help meet the basic human needs of all people, with particular attention to the needs and empowerment of people who are vulnerable, oppressed, and living in poverty" (<http://www.naswdc.org/pubs/code/code.asp>). NASW denotes social work's core values as "service, social justice, dignity and worth of the person, importance of human relationships, integrity, and competence" (<http://www.naswdc.org/pubs/code/code.asp>). Given that the world

and our social community is becoming increasingly globalized, and that with its characteristic agility social work's professional culture is becoming increasingly transnational, it is essential to look beyond the borders of the United States to understand whether the profession's mission is consistent worldwide. According to the International Federation of Social Workers (IFSW), social work's mission is

to enable all people to develop their full potential, enrich their lives, and prevent dysfunction.

Professional social work is focused on problem solving and change. As such, social workers are change agents in society and in the lives of the individuals, families and communities they serve. Social work is an interrelated system of values, theory and practice (<http://ifsw.org/policies/definition-of-social-work/>)

IFSW notes that, with social work's origins in humanistic and democratic ideology, the profession's values "are based on respect for the equality, worth, and dignity of all people ... human rights and social justice serve as the motivation and justification for social work action" (<http://ifsw.org/policies/definition-of-social-work/>). IFSW specifies that "in solidarity with those who are dis-advantaged, the profession strives to alleviate poverty and to liberate vulnerable and oppressed people in order to promote social inclusion" (<http://ifsw.org/policies/definition-of-social-work/>). When taken together, it appears that both the NASW and IFSW statements reflect consistency—social work's mission and values, according to these statements, emphasize working with those at greatest risk, driven by a commitment to human rights, social justice, and change. When considering professional socialization to social work, it is the essence of this mission and associated values that define the standards.

THE PROFESSIONAL SOCIALIZATION LITERATURE

When exploring the scholarly literature related to the professional socialization of social workers, there is both an expansive variety of places to look and also, within that variety, an absence of a clear and systematic body of knowledge in this area. There are rich bodies of literature related to social work values, attitudes, professional identity, the mission of the profession, and to why people become social workers, to name a few. All of this work is of profound value to the profession and

this author would encourage the reader to explore it, but extensive discussion of it here is beyond the scope of this chapter. Aspects of all of this literature are relevant to how we understand professional socialization as a comprehensive process, but because the literature focuses on one of these variables at a time, or is broken up into smaller fragments, taken as a whole what we understand in a systematic way about professional socialization is characterized by more questions than answers (Barretti, 2004; Miller, 2010; Weiss, Gal, & Cnaan, 2004). (For an extensive review of the literature, see Barretti, 2004, and for further review of the literature, see Miller, 2010.)

In the interest of defining at least one common language that would enable the profession to consider questions of professional socialization, this author offered a conceptual framework for the professional socialization of social workers and some research findings designed to provide a systematic foundation for further research in this area (Miller, 2010, 2013). The next section offers an applied synthesis of the conceptual framework (for full discussion of the framework, see Miller, 2010), and highlights elements grounded in the research findings that might be helpful launching points for unraveling the complexity of professional socialization. Aspects of theory suggest that each professional who socializes to social work is going to have a unique set of influences and experiences, although there will also be things common among them, including aspects of the educational structure via which they are formally socialized. Following the applied synthesis of the conceptual framework, a case study is provided to illustrate one hypothetical social worker's (Allison's) experience of professional socialization. The case includes elements of Allison's experience across all three stages of the framework: pre-socialization, formal socialization, and practice after formal socialization. It points to factors that had a potential influence, and also what her professional socialization outcomes look like over time.

**WHAT DO YOU NEED TO KNOW
ABOUT THE PROFESSIONAL
SOCIALIZATION OF SOCIAL
WORKERS RIGHT NOW? CONCEPTUAL
FRAMEWORK SYNTHESIZED**

People are born into an experience and carry with them certain demographic characteristics. Over the years, events in their childhood contribute

to how they view the world, how they engage in relationships, how they see themselves, and to choices they make as they develop into adults. As young adults, they may choose or find an educational path that is meant to relate in some way or another to their entry point into the adult work world. Those people who choose to enter the social work profession do so for a whole host of possible reasons and at various points in their developmental trajectories. As they make the choice to become social workers they carry their primary socialization with them (e.g., demographics, childhood experiences), and in some cases other experiences of secondary socialization (e.g., a prior career); with and through this, they begin to make some anticipatory changes/choices as they approach their formal social work education. These changes/choices are informed by what they think are the cultural expectations of social work—how do they imagine social workers act, talk, believe, think, maybe even dress, etc.? They then begin to try on for size some of these conceptions, and carry those, along with aspects of primary socialization, with them into their social work education.

When they get to their formal social work education they enter into a higher education institution, take classes, have instructors, meet their peers, and often become part of a cohort; they function as interns in typically two different field settings, and meet their field instructors, other professionals, clients, constituents, stakeholders, etc. As they engage in this process they acquire knowledge and skills, a relationship with social work values (e.g., commitment to social justice, service), norms (e.g., social workers are change agents; social workers are overworked; social workers do a lot of self-reflection), and attitudes (e.g., social workers need to hold onto their idealism in the face of great challenges; social workers are compassionate and kind; social workers do not judge), while all the while interacting in idiosyncratic settings, with people and within structures that differ. They have agency and they make choices, they are also potentially influenced via structural mechanisms, power and hierarchy, and role models. When they finish their formal social work education and head out into practice they take all of this with them into that particular context of practice. They call themselves something (e.g., social worker). Based on their practice context and what they bring with them, they adapt situationally, and their role identity and overall professional socialization continue to

evolve. They may keep calling themselves social workers. Or they may identify as something else, such as a clinical social worker, community organizer; or therapist. As this process unfolds for each individual, these individually diverse experiences collectively and reciprocally feed back into the culture of the profession—this informs change and expectations moving forward.

Case Study: Allison’s Professional Socialization to Social Work

Phase I: Pre-socialization. When Allison was a child she spent almost every Saturday morning with her mother and her older brother at the local community food bank packing up bags of food for families in need. Allison remembers seeing the families come into the food bank and observing that there were “kids just like me except they don’t have enough food at home, and sometimes they don’t even have homes.” This always seemed unfair to Allison, and she wanted to do more to make things “more fair.” Allison grew up in a three-bedroom apartment in an urban environment with her older brother and her single-mother. Allison’s mother worked very hard to take care of Allison and her older brother and had a “good paying job” as an account manager for a large corporation. Allison and her brother went to after-school programming and she remembered how tired her mom always was when they got home. Allison and her brother helped with food preparation and other chores at home. No matter how tired her mother was, however, Allison remembers that she always made time to go to the food bank on Saturdays; she was deeply committed to service. She always talked about how she would have loved to have a different job, a job where she could help people and make the world a better place, instead of one where she managed accounts for businesses that “have more than their fair share.” But, she said, she needed to make sure she earned enough money to provide for Allison and her brother and was always grateful to be able to provide in the way that she could. Allison’s father was not often present in her life and rarely, if ever, provided any child support. She and her brother got birthday and holiday cards from him, but that was about it.

When Allison was in high school, she joined a student service organization; when she was a junior, she became the chairperson of that group and remained in that position until she graduated.

She also took part in yearbook and theater activities; she loved to be involved, and she loved to be around people. She did well in her classes, but was not sure what she would major in when she got to college, or what she wanted to do for work. She thought about becoming a teacher or maybe a doctor; she wanted to help people in some way, and she wanted a job that was about “doing something,” not “just sitting in an office.” When she got to college she decided to major in English because she was still not sure “what in the world” she wanted to do for work, and because she liked to read and loved stories about people. When she was in college she continued her civic engagement, serving as a volunteer for a local nonprofit agency focused on providing services to homeless families. This was her first notable exposure to the idea of social work; she realized there was a job you could do that “paid you to help people, to develop relationships with people, to be kind and compassionate, and to take action.” After finishing her undergraduate degree, Allison was hired by the agency to do office management work. During her first year employed there, she decided to return to school and get her Master of Social Work (MSW) degree.

Anticipatory socialization. Allison began spending a lot more time talking to her friends about what needed to change in the world, and she also began paying more attention to the way she listened and how she communicated. She asked the social workers at her agency questions about their jobs, about their social work education, about their lives. She was a little worried because it seemed like they were often really tired, and from what she could tell, it did not look like they got paid that much. They also talked a lot about how the agency just did not have enough resources. But, they also seemed to be so committed to their work, and it was “amazing” to see what they could do to “help these families get back on their feet.”

Allison applied to four MSW programs in her city, two at public institutions and two at private institutions; she was accepted to all four. She was so excited and could feel her future unfolding, but she did not want to take out student loans. Growing up with her mother she had learned a whole lot about managing money and what it was like to live paycheck to paycheck. She was hoping that she might be able to get a scholarship or an assistantship. Allison was offered a scholarship for her first year by one of the smaller private programs and was guaranteed

an assistantship in her second year. She decided to accept this offer, but she did feel a bit uncomfortable. Because tuition to attend this program was high, she was concerned that her classmates would all come from privileged backgrounds, and that she would be out of place. In preparation for school and for her soon-to-start field internship, and with concerns about money, Allison started thinking about how professional social workers act and even dress. She looked through her closet to see if she had anything that would work. She talked to her Mom and her colleagues at the agency and decided to go to Goodwill and buy some professional clothes for her placement. She e-mailed her professors to ask whether they could let her know what she would be reading so she could buy books online, or used books in advance, to save money. She did some reading ahead and was excited to get started—she could understand what she read, but she was ready to be told how to make it all pragmatic, that is, how to actually do it.

Phase II: Formal socialization (academic settings, role models, peers). Allison went to orientation a bit nervous, but also ready and eager to begin this program and her career. She had so many ideas about what she wanted to do when she was done, maybe even start her own community organization! At her orientation she met a whole bunch of other students and realized that she was wrong, they were not all from privileged backgrounds, and even if they were, it did not really matter so much. There were a lot of approachable, friendly, open, “awesome” people. They liked to talk a lot—she thought “it was not like when you walk into a room with a group of people for the first time and everyone’s quiet and awkward; there were a few people in this group who were just so outgoing and they did this amazing job getting everyone comfortable.” Allison felt as though she had found her home.

She did her first-year field placement at an agency that served a formerly homeless older adult population living in a single-room occupancy residential facility. Her supervisor was a woman who had been in the field for over 20 years—she started as a community organizer and then became a licensed clinical social worker, and she functioned in both these roles in her agency. With her broad perspective, she challenged Allison to do work across and around the practice spectrum; Allison formed a meaningful relationship with her supervisor. She also had some good relationships with the other students

placed there (from another university), as well as with one of the staff social workers, and also formed some strong relationships with clients. She enjoyed her classes but sometimes found it hard to figure out how to connect what she was doing in her classes with what she was doing in the field. Her practice teacher was pretty great, but unlike her supervisor, he sometimes seemed cynical to her. He talked a lot about how under-resourced agencies were and how hard it was to function as a social worker in a healthy way. He had been in the field for 10 years before beginning to teach, and he talked a lot about burnout. Allison respected his perspective, but she wondered if he was blowing things out of proportion.

Allison ended up developing a great relationship with the professor of her Human Behavior in the Social Environment (HBSE) course. She initially found this course to be particularly frustrating; she just wanted to know how to do things already. The readings and class content were always so abstract; she told her HBSE professor that she wished they could get past all of this idea stuff and just learn what they were supposed to do. This professor talked to Allison and the rest of the class about how their energy and motivation were wonderful, and about how ready they were to go out there and change the world. She encouraged them not to let go of that, but to take a step to the side. She also encouraged them to recognize that what they were doing in class was pragmatic. Critical thinking and reflection-in-action were essential skills for social workers, she said. If they were going to go out and apply what they learned, they first had to learn it and learn how to think about it. This professor really challenged Allison to think, challenged her to locate her clients in the theories she learned in class or vice versa. This professor was available to meet with students and always had a supportive ear. Allison felt as though this professor was someone she could call a mentor. She also talked a lot about self-care in class and helped the students figure out what it actually was and how to begin to think about it. Allison’s field instructor was also interested in self-care; she helped Allison to think through her own self-care plan, but also allowed Allison to do an assessment of the agency itself and the practices that either supported or inhibited worker well-being. Allison discovered during her placement that she really enjoyed the one-on-one work with clients, as well as some of the program development work. She was not

sure where to concentrate her efforts during her second year of the MSW program.

After talking with her supervisor, her HBSE professor, a social worker at her agency, and some of her MSW student friends, Allison chose a clinical track. Wanting what she thought of as a balanced experience, she advocated for a research assistantship with a faculty member whose work focused on community organizing and community-based participatory research. In this second year of her MSW program, Allison was placed in a community mental health clinic that provided clinical services to a diverse population of individuals, families, and groups; clients spanned the age spectrum and were diverse across the board. Allison was excited to begin this placement; she entered this second year “feeling like a social worker.” She was not concerned as much about her clothing or her relationships; she knew what she needed to do in that sense. She was concerned about whether or not clients would take her seriously; she wanted so badly to help make their lives better, to fix what was broken for them, but was scared that she would fail. Her placement last year had been an “awesome” learning experience, but this just felt different. She remembered how her HBSE professor talked about the thinking process and how powerful and important it is. She felt as though she had learned some useful skills in her classes last year and definitely from her supervisor. She felt pretty confident that she knew how to “know what she doesn’t know,” as her HBSE professor had said. She felt she knew how to reflect back, how to engage empathically, how to locate strengths, but she did not know whether she felt confident in her ability to deliver the best possible services. How evidence-based was her agency’s practice? What did that even mean???

Allison took a deep breath, and called upon the very close friends she had made in her MSW program last year. The group of five friends met up for dinner before the semester began and talked with one another about their fears, apprehensions, and excitement. They discussed how they were planning to manage time, what their agencies were like, and what they would be doing this coming year. They talked about feeling as though they knew they had learned “stuff” last year, and they knew they were ready for this concentration placement, but what if ...? They agreed to remain a support system for one another by getting together at least once a month for this kind of dinner, but for sure more often than

that if they could. They laughed a lot together and felt like they were a wonderful resource for each other. Allison’s mom let her know repeatedly how proud she was of her, the work she was doing, and that she had found her way to this meaningful type of employment. Her Mom did express concerns about Allison’s postgraduation income potential, but she also said she trusted Allison and knew she would “be okay.” Allison’s father had been a bit more present in her life over the past year, and each time she talked with him about school or her internship he said something like, “I don’t know how you spend all your time around people who are so miserable. Don’t you get depressed? Are you going to make any money doing this social work thing? Are you sure you don’t want to go to medical school or something instead?” Allison tolerated her father’s perspective, but tried her best to educate him about what social work really is, and she also tried her best to explain all the ways in which she knew he was wrong.

Allison had a deeply meaningful experience in her second-year field placement and in her research assistantship, and she very much appreciated some of the focused and applied content of her advanced coursework. She particularly enjoyed hearing about the practice experiences of her course instructors, and she engaged in reflective clinical supervision at her placement, learning a lot about herself and her work in the process. She realized she did not do a very good job making space for herself, given that each night she went home and thought about her clients. She stopped making healthy lunches, stopped exercising, and was feeling pretty stressed out and tired. She loved her job and wanted to stay at the agency after graduation, but she knew she would need to make some changes if this work was going to be sustainable. She loved the research assistantship she had and learned a great deal about advocacy and about the community. Though her internship was clinical, she was able to begin to locate some of the research work she was doing in her agency and in the community. She knew she needed to do some more self-care and she knew she needed to keep self-reflecting, but when she graduated she felt ready to call herself a social worker.

Phase III: Practice after formal socialization. After Allison graduated, she was hired on to work for the community mental health clinic. She was very excited to get under way as a practitioner. Once she got assigned her caseload of

28 regular clients and 10 intakes per week, she remembered back to what her practice instructor in her first year said about being under-resourced and over-worked. “Maybe he was not so cynical after all,” she thought. At her agency, Allison worked primarily with other clinicians—some of them called themselves clinical social workers and others called themselves therapists. Her supervisor called herself a therapist so Allison tried that out for a while, but it did not really feel like her. Then she remembered the instructor of her policy analysis class, whom she admired so much. Allison had found her inspiring and always loved to listen to what she said. She remembered that professor (a grant-funded researcher who had written books and was the Director of the MSW program) coming to class on the first day and saying, “Hi, I’m Dr. Jasper and I’m a Social Worker.” When Allison thought about this, she decided that no matter where she worked, or what kind of practice she did, she would always identify herself as a social worker. Over the next five years, Allison continued to practice at this agency and she also continued to do collaborative research with her former professor—she loved how it kept her out in the community. Not only was she a social worker inside this office doing work with her clients, but she was a social worker out there knocking on doors, doing community needs assessment, organizing, and working toward social justice.

CONCLUSION

Having just read about Allison, reflect back to the thought experiment that you engaged in at the beginning of this chapter. Look back at your drawing or narrative. What do you see now that you can identify as an aspect of social work’s professional culture? Who is that social worker? All of this is the stuff of professional socialization; it is powerful and complex, and informs the how, what, and why of practice. Regardless of where you are in your own professional development, theories of professional socialization would suggest that you are not done. Not only is social work about lifelong learning, it is also about career-long professional socialization. Some things will remain consistent, but others may shift to stay current with and, in turn, affect the shifting culture of social work.

Evidence-based Social Work Practice with Children and Adolescents

Alison Salloum & Lisa Rapp-McCall

ASSESSMENT OF CHILDREN AND ADOLESCENTS

Evidence-based Assessment

Building on the growing field of evidence-based practices (EBP), the use of evidence to guide the assessment process is currently evolving. Evidence-based assessment incorporates the use of evidence and theory to select the aspects, conditions, or domains to be assessed; uses evidence-based assessment tools; and uses the best methods for the assessment processes. An evidence-based assessment can help guide the practitioner and client to choose the best available evidence-based intervention for the assessed condition and to monitor progress throughout the intervention (Hunsley & Mash, 2007).

Accessible and practical evidence-based assessment tools and methods are becoming available for practitioners and clients. These brief and easy-to-use tools, commonly referred to as rapid assessment instruments, are available to assess a child's or family's general functioning and competence relative to specific conditions. Assessment tools and processes are being developed to address situations in various settings and contexts. For example, Counts and associates (2010) have developed and tested an easy to administer self-report measure of multiple family-level protective factors against abuse and neglect. Similarly, Edelson et al. (2007) are developing a 46-item tool to assess children's exposure to domestic violence. These types of evidence-based assessment tools and methods are readily available through various websites and books on clinical measures (e.g., Corcoran & Fischer, 2013). In addition, the *Diagnostic and Statistical Manual*

of Mental Disorders (American Psychiatric Association (APA), 2014) includes parent and child and adolescent measures that assess for 12 psychiatric domains and functions. These APA measures can also be used to track clinical progress (the assessment tools for children and adolescents may also be found online at <http://www.psychiatry.org/practice/dsm/dsm5/online-assessment-measures#Level1>

Child-focused Developmental, Ecological, and Cultural Assessment

An evidence-based assessment with children, adolescents, and their families must include a multidimensional assessment that considers development, ecological context, and cultural influences. These three areas of assessment may be considered the foundation for child-focused assessments. With children, evidence-based assessment often includes assessing caregivers, including multiple informants (such as day care providers or teachers) and sources of data (i.e., observation, school records); understanding the variations and effects of development and culture on the situation; and including a broad-based assessment of competencies and challenges (Achenbach, 2007).

Generally, the younger the child, the more involved the parent or caregiver and significant other adults in the child's daily life will be in the assessment process. With older children, especially adolescents, it is important to engage the youth directly in the assessment process. This may be accomplished by using evidence-based self-report assessment instruments with the child and adolescent. When practitioners conduct

the assessment process in a collaborative fashion with the child, the assessment tool can be used to provide education and normalization and elicit specific goals for treatment, as well as to highlight the child's strengths and treatment progress.

Developmental assessments may be used to select the best available treatments for children that take into account the child's developmental status (including emotional, cognitive, biological, social, and behavioral milestones, assets, and delays). As research on EBP continues, we will learn more about which treatments work best with which populations. More specifically, we will learn how development, neurobiology, gender, culture, and context affect treatment outcomes. Developmentally specific assessment can then be used to suggest developmentally specific treatments to the child and parent or caretaker. For example, recent advances have been made in assessment processes for the mental health needs of infants, toddlers, and young children. With this knowledge, specific prevention and treatment strategies grounded in empirical research for this young population are increasing (for more information about early childhood assessment see the Zero to Three website listed at the end of this chapter). Similar advances are being made for middle childhood, early adolescence, adolescence, and late adolescence.

The child-in-environment perspective must be considered during the assessment processes. The influence of the relational processes within the child's ecological context may have a significant impact on the child's functioning and growth. Ecological relational processes may include the child's family; school environment and peers; neighborhood and community; recreational opportunities; religious or spiritual membership or rituals; national and international situations; and systems such as foster care, child welfare, and juvenile justice. Though a beginning point for the practitioner is to assess the strengths within the child and child's family (see Simmons & Lehmann, 2013 for strengths-based assessment measures) a more multidimensional assessment is optimal. This encompasses the child's and family's protective or resilience factors within the cultural context of the child and family (e.g., Cardoso & Thompson, 2010; Jones, Hopson, & Gomes, 2012), and examines the salience of specific and cumulative risk factors, including social conditions such as poverty, discrimination, and limited opportunity. A multidimensional assessment can assist the practitioner, child, and family

in choosing the most appropriate multimodal and multicontextual interventions.

In addition to developmental and ecological assessment processes, evidence-based assessment must be culturally sensitive. Specific assessment tools are being tested with various cultural groups to establish within group norms. In addition to the use of specific culturally relevant assessment tools, an understanding of the cultural context of the child may lead the practitioner and client to decide on a more culturally congruent evidence-based treatment. A cultural assessment may help the practitioner understand the child and family better and identify cultural resources to include in treatment. Discussing culturally competent practice is beyond the scope of this chapter, and practitioners are encouraged to read the National Association of Social Workers' *NASW Standards for Indicators for Cultural Competence in Social Work Practice* that was developed in 2007 (available on the NASW website). Assessments may include areas such as communication patterns, family structure, accepted roles of children, intergenerational conflicts, assimilation of family members, adherence to traditions, spiritual beliefs, values and norms, acceptance of expression of emotions and behaviors, developmental expectations, language preference and proficiency, historical experiences, views of mental health, and help-seeking behaviors.

Client-centered Process

Evidence-based practitioners value the child and family as a collaborative partner in the assessment process and treatment. Indeed, parents' and children's beliefs, values, and preferences are key factors in successfully implementing EBP. Program developers and practitioners can ensure that the child, youth, and family members play an active role in the process of assessment, goal planning, treatment choices, and evaluation. During the assessment process, practitioners should assess the client's (child and participating family members) beliefs about credibility (i.e., believable and logical) and effectiveness of the agreed-upon intervention or treatment prior to implementation. Beliefs about credibility of treatment and expectations of improvements may be associated with motivation for and adherence to treatment, which are important factors for effective outcomes (Nock, Ferriter, & Holmberg, 2007).

A collaborative practitioner–client assessment process begins with the initial meeting and continues throughout the intervention to monitor progress and assess outcome and satisfaction. Eliciting feedback from children and families regarding treatment satisfaction and the service delivery process can be empowering for clients. Valuing systematic approaches to hearing from clients about their experiences can lead to improved treatments and delivery of care (Baker, 2007). A collaborative evidence-based assessment may lead to more objective accountability of satisfaction, effectiveness, and improved services for children and families.

Considerations for Child-focused Evidence-based Assessment

- Use evidence-based assessment tools and processes to guide client and practitioner in choosing EBP.
- Conduct a multidimensional assessment that includes sources of data, including multiple informants (i.e., parents, caretakers, teachers, and other important child–adult relationships), multiple settings (i.e., home, school, peers), and multiple methods (i.e., rapid assessment instruments, interviews, observations).
- Consider using a broad assessment tool followed by a selected specific condition assessment tool.
- Assess the child’s developmental status, including emotional, cognitive, biological, social, and behavioral milestones, assets, and delays and take into account the developmental stage of the child to match appropriate intervention.
- Consider the entire ecological context of child and family.
- Use standardized assessment tools and processes to assess protective factors, competencies, and strengths.
- Use standardized assessment tools or processes to assess risks and emotional, behavioral, and social difficulties.
- Understand the cultural influences on the child, family, and situation and conduct a culturally competent assessment.
- Assess throughout practice to evaluate progress, outcomes, and client satisfaction.
- Practice from a child–family-centered collaborative perspective.

- Assess the child and family’s beliefs, values, preferences, and expectations about evidence-based treatment.

Promotion and Prevention

Current models to guide practices serving children and youth suggest providing promotion programs followed by prevention, treatment, and maintenance services (Frey & Alvarez, 2011; National Center for Mental Health Promotion and Youth Violence Prevention, 2011). Promotion programs focus on improving the overall emotional and social well-being of the child such that self-esteem, coping, social integration, and healthy development are promoted. Some overlap exists between promotion and prevention because both types of efforts try to intervene before the onset of problems. Previously, youth began treatment when they had significantly serious disorders or symptoms that significantly impacted their functioning at home, at school, or in the community. However, research studies have supported what practitioners have observed all along—starting treatment earlier, at the first sign or symptom of difficulty, drastically improves the outcome. This approach is also far more cost-effective than typical interventions, which wait too long and then require more intensive intervention. Thus, promotion and prevention programs have been used to promote well-being, and when needed, intervening early can prevent the disorder completely or lessen its progression. There are many empirically based prevention interventions that are used when youth present no risk factors (universal), exhibit some risk factors (selective), and/or when they evince some symptoms of the problem (indicated). These prevention interventions are now more readily available and used more frequently (e.g., Fagan & Catalano, 2013); however, there is still much work to be done in reframing our thinking to integrate preventive interventions and programs into our current systems. For example, programs need to be sufficiently funded for delivering promotion programs and preventive interventions, not just brief interventions after the problems have grown too serious to change.

Treatment and Maintenance

Treatment and maintenance that involves long-term care to minimize relapse and reoccurrence must be available to children and youth needing this level of care. Many advances have occurred

in the development of EBP for children and adolescents. Currently, many social problems and disorders of childhood and adolescence have treatments that are evidence supported (Kendall & Beidas, 2007). Emerging evidence suggests that children and youth who receive EBP are more likely to improve than when non-evidence based practices are provided (e.g., Kolko, Herschell, Costello, & Kolko, 2009). The contemporary controversy lies not in *whether* to utilize these practices but *how* to consistently facilitate the implementation of these practices with fidelity in real-world community settings.

There are many barriers to implementing EBP in agencies, including limited practitioner time, training and ongoing supervision, practitioner attitudes toward EBP, and lack of adequate resources. Current implementation science, however, has focused on contributing factors to implementing and sustaining EBP in real world settings. Some factors contributing to the successful implementation of EBP include adequate funding and support for implementation, training and ongoing supervision and consultation, treatment fidelity monitoring, and “buy-in” from agency leaders and practitioners (Swain, Whitley, McHugo, & Drake, 2010). Additionally, while earlier concerns included treatment manuals that were too rigid and difficult to apply in real world settings, current manual and treatment protocols are more flexible and are transportable to community-based settings. Another barrier to implementing EBP has been that many of these treatments do not address comorbid or complex client problems that are often presented by children, youth, and families in community settings. Newer approaches to treatment are combining core components of various EBP to address multiple issues and conditions.

Scholars are not only calling for social workers to provide up-to-date EBP that match the child’s and family’s needs, but also to become competent in empirically supported common elements and common factors. Common elements involve using a modular approach in which specific methods common to many EBP, such as psychoeducation, exposure, and rewards, are provided based on the results of an evidence-based assessment. Common factors consist of those ingredients critical to positive outcomes, such as a strong therapeutic alliance, client engagement, motivation, and hope. The implementation of common factors and common elements requires

systematically assessing and tracking progress (Barth et al., 2012).

Multimodal and Multicontextual Interventions

Research suggests that treatments for youth be multimodal and multicontextual, meaning that interventions should be delivered in a variety of formats for learning and change to occur, and that interventions should occur in multiple environments or milieu of the youth. In other words, individual treatment for children alone, without family, school, or community intervention is rarely effective, especially for youth who are having difficulty functioning in various contexts. Likewise, one type of intervention alone, for instance, life skills, may only have a small-to-medium effect as opposed to a multimodal approach that may result in a large effect. Take the following example: a practitioner working with a child experiencing severe difficulty with controlling anger may talk about angry outbursts and their consequences with the child, teach the child anger-control skills, role-play/practice the skills, and read a story about a character who learns to control her anger. In addition, the practitioner may use functional family therapy with the child’s family to intervene with family difficulties, assist the teacher in developing a behavior modification system for the child at school, and work with the child’s soccer coach to help apply the newly learned anger-control skills to replace angry outbursts during soccer practice. The comprehensive nature of these interventions is more likely to produce change than one modality in one context.

Considerations for Child-focused Evidence-based Treatment

- Intervene early with empirically supported and evidence-based prevention interventions.
- Stay abreast of EBP and use with appropriate clients.
- When no known EBP exists for disorders or problems, use common elements and factors that have been associated with treating similar conditions and monitor progress carefully.
- Intervene in multiple contexts (micro, mezzo, and macro).
- Intervene with multiple approaches, when indicated.

FUTURE DIRECTION FOR ASSESSMENT AND INTERVENTION

Understanding the complexities and uniqueness of the child or adolescent by empathetic face-to-face interaction has always been the starting point for the practitioner. Although this will not change, advances in assessment tools and methods will help the practitioner obtain a broader contextual understanding as well as more rapidly ascertain targeted goals. Advances in evidence-based assessment will lead to more research on the influence of development, context, and culture on treatment outcomes and a broader understanding of resilience in childhood. These assessment tools and methods will become standard practices and will be integrated within systems of care for children.

Collaboration with the client will remain central to evidence-based assessment and evidence-based treatment. Once the client and practitioner have collaboratively decided on which evidence-based treatment seems most appropriate, preparation for treatment may be warranted. Treatment readiness or pretreatment sessions help prepare clients for the treatment when it is delivered. The sessions are offered prior to the formal treatment and work to engage and motivate the client. The idea began with mandated adults and has found its way into the child and adolescent arena. Treatment readiness sessions seem to be more common with difficult or mandated young clients (adolescent offenders and substance abusers) but may be promising for use with other client populations. They may also show promise for reducing resistance with other interventions and with brief treatments where change is expected to occur quickly. In addition, practitioners may consider using pretreatment sessions prior to family or group treatments.

Developing and implementing empirically supported and evidence-based social work practices for children requires integration and collaboration: the integration of evidence-based assessment and promotion, prevention, and treatment; the integration of social work research and practice; and collaboration with all concerned parties, including children and families, community residents and leaders, practitioners, researchers, child advocates, child systems (i.e., education, child welfare, juvenile justice), and policy makers. Due to the complex problems

and challenges that children and youth face today, we must advance our knowledge of the programs or methods that work best for particular children. We must also determine the most effective the settings, intensity of delivery, and timing of delivery. Barriers to implementation of child-focused evidence-based assessment and practices can be overcome by such tools as web-based clearinghouses, webinars, videoconferencing to engage in collaborative learning and consultation, and podcasts and apps on implementation of EBP. Although technology and new approaches may assist with dissemination and implementation of evidence-based assessment and EBP, collaboration with all stakeholders—children, adolescents, parents, community leaders, practitioners, researchers, and policy makers—is needed to advance practices to improve the well-being of children, adolescents, and their families.

Overview of Alcohol and Drug Dependence

Identification, Assessment, and Treatment

Kenneth R. Yeager

Alcohol and drug abuse is ubiquitous; it is associated with 2.5 million deaths annually, representative of 4% of all deaths worldwide annually. The National Council on Alcoholism and Drug Dependence (NCADD) reports “The harmful use of alcohol (defined as excessive use to the point that it causes damage to health) has many implications on public health as demonstrated in the following key findings:

- Harmful use of alcohol results in the death of 2.5 million people annually, causes illness and injury to millions more, and increasingly affects younger generations and drinkers in developing countries.
- Nearly 4% of all deaths are related to alcohol. Most deaths caused by alcohol result from injuries, cancer, cardiovascular disease, and cirrhosis of the liver.
- Among males, 6.2% of deaths are related to alcohol, compared with 1.1% of deaths among females.
- Among young people aged 15–29 years, 320,000 die annually from alcohol-related causes, resulting in 9% of all deaths in that age group.
- Almost 50% of men and two thirds of women do not consume alcohol (NCADD, 2013).

The burden of drug and alcohol dependence in the United States is estimated to be \$510 billion, up from \$184.6 billion per year in 2005. The break-out of the impact on children, adults, and communities in the United States is as follows (Substance Abuse and Mental Health Services

Administration (SAMHSA), 2011; Harwood, 2000; Harwood & Bouchery, 2001):

- Alcohol accounts for \$191.6 billion (37.5%) of the \$510.8 billion.
- Tobacco is responsible for \$191.6 billion (32.9%) and drug abuse for \$151.4 billion (29.6%).

The majority of the costs associated with substance abuse in the United States can be related to treatment and prevention of substance abuse, medical care, police, fire department, legal and court-related expenses, property damages, theft, crime, motor vehicle crashes, and fires involving alcohol and drug abuse (Harwood & Bouchery, 2001).

Additionally, productivity costs are closely linked to the cost to society. For example: Smoking contributed to 440,000 deaths in 1999. Alcohol abuse accounted for 42,000 (Harwood, 2000) to 76,000 deaths (Midanik et al., 2004), while drug abuse accounted for an additional 23,000 deaths (Harwood & Bouchery, 2001). This loss in productivity is calculated as estimates of individual lost work time, including impairment, sickness, unemployment, incarceration, disability, and the like.

It is important to note that a significant number of persons with substance use disorders have concurrent mental health disorders. In 2011, there were an estimated 45.6 million adults age 18 years or older in the United States with any mental illness in the past year. This represents 19.6% of all adults in this country. Of this population, SAMSHA (2012) estimates 8 million adults met

the criteria for a substance use disorder (i.e., illicit drug or alcohol dependence or abuse.) Additionally, among the 11.5 million adults with severe mental illness in the past year, 22.6% experienced concurrent substance dependence or abuse. This is significantly higher than the population without a mental illness, which demonstrated only a 5.8% prevalence of substance dependence or abuse, representing 10.9 million adults (SAMHSA, 2012).

When considering risk factors among persons with concurrent mental health and substance abuse, it is important to note the increased risk of self-harm among this population. SAMSHA (2012) reports: Adults aged 18 years or older with a past-year substance use disorder were more likely than those without substance use disorders to have had serious thoughts of suicide within the past year (11.2% vs. 3.0%). Those with a substance use disorder were at greater risk for suicidal ideation, and more likely to make plans for suicide, compared with adults without dependence or abuse (3.6% vs. 0.8%). They also were more likely to attempt suicide when compared with the adult population without dependence or abuse (1.9% vs. 0.4%) (SAMSHA, 2012).

Considerable gaps in the continuum of care exist when considering the need for integrated mental health and substance dependence treatment for persons with concurrent mental illness and substance use disorders. In the population of the 2.6 million adults aged 18 years or older in 2011 with both severe mental illness and substance dependence or abuse in the past year, 65.6% received substance use treatment at a specialty facility or mental health care in that time period. Included in the 65.6% are 12.4% who received both mental health care and specialty substance use treatment, 49.5% who received mental health care only, and 3.6% who received specialty substance use treatment only. Among adults who had a past year substance use disorder, those who also had past year Serious Mentally Ill (SMI) were more likely to have received mental health care or specialty substance use treatment (65.6%), followed by those who had moderate mental illness (41.0%), then by those with low (mild) mental illness (29.7%), then by those who had no mental illness in the past year (15.1%). It is important to recognize that only 12.4% of those with concurrent mental illness and substance use disorders received treatment concurrently for both disorders. This is a fact that continues to contribute to the “revolving door” aspect of persons seeking care for their disorders. Without attention paid to both

diagnoses, the effectiveness of a single approach for mental health or substance abuse is limited in levels or degree of effectiveness.

ADDICTION TREATMENT WITHIN THE HEALTH CARE ENVIRONMENT

Alcohol can be a significant contributing factor to medical conditions such as hepatitis, hypertension, tuberculosis, pneumonia, pancreatitis, and cardiomyopathy (Project CHOICES, 2003). One half of all cases of cirrhosis in the United States are due to alcohol abuse. Excess alcohol consumption also contributes to cancers of the mouth, esophagus, pharynx, larynx, and breast (Emmen, Schippers, Wollersheim, & Bleijenberg, 2005). Alcohol abuse inflicts central nervous system disease (including dementia and stroke) and peripheral nervous system disease (neuropathy and myopathy).

Excessive alcohol consumption is the third leading preventable cause of death in the United States and was estimated to be responsible for approximately 80,000 deaths annually between 2001 and 2005 (Ballesteros, Duffy et al., 2004). This appears to be related in large part to an increased risk of accidental deaths. However, nearly 17,000 traffic fatalities in the United States in 2000 were related to alcohol use, that is, 40% of all traffic deaths. It is also noteworthy that a 3.5 times greater risk for drowning exists within age adjusted populations (Bertholet, Daeppen Wietlisbach et al., 2005).

Growing evidence in the form of systematic reviews and meta-analyses confirms the efficacy of brief intervention for unhealthy alcohol use in primary care patients identified by screening. As an example, a meta-analysis of eight trials of 2,784 patients found that brief intervention decreased the proportion of patients drinking risky amounts one year later when compared to patients who did not receive brief intervention (57% vs. 69%; absolute risk reduction of 12%) (Beich, Thorsen, & Rollnick, 2003). A meta-analysis of nine trials reported consumption outcomes for intention-to-treat participants at 6 or 12 months (Bertholet, Daeppen, & Wietlisbach, 2005). Receiving brief intervention decreased patients’ drinking by an additional three standard drinks per week compared with patients not receiving brief intervention.

Studies have found brief intervention in at-risk substance abusing populations functions to reduce health care utilization, and results in cost savings (Solberg, Maciosek, & Edwards, 2008). In one trial, 774 patients with unhealthy alcohol use identified

by screening for risky drinking amounts were randomized to brief intervention or usual care in 17 primary care practices with a total of 64 physicians (Fleming, Mundt, French et al., 2002). The intervention, consisting of two 10- to 15-minute physician discussions and a follow-up phone call, decreased consumption more than usual care, an effect that persisted at 36 months. Hospital use was lower over the three-year period in patients assigned to the intervention compared with patients receiving usual care (420 vs. 663 days). The intervention was estimated to have saved \$546 per patient in medical costs and \$7,780 per patient in total costs (primarily due to a reduction in motor vehicle crashes).

What is becoming clear is the need to demonstrate multiple levels of competence in brief intervention across populations within a variety of settings to determine potential risk of active substance abuse and dependence, in order to identify, assess, and treat substance use disorders more effectively (Yeager et al., 2013). There exist growing bodies of evidence to suggest that multidisciplinary approaches across a variety of settings (e.g., substance abuse, mental health, and health care settings), focusing on identification, brief intervention, and referral to the most appropriate level of care are both effective and efficient. The goals of a brief intervention for those demonstrating nondependent behaviors should focus on reduction of use, harm reduction, or abstinence, as well as changes in risk behaviors (e.g., avoiding bars and events centered around drinking or drug use). In the population where use has been determined to be detrimental and unhealthy, abstinence is generally the best option. Those defined as being appropriate for abstinence-based intervention include any of the following:

- A diagnosis of dependence
- Failed prior attempts to moderate/control use
- A physical or mental health condition secondary to substance use
- Taking medications that contraindicates any alcohol use
- Pregnant or planning to conceive
- Prior consequences or a family history that suggest remaining abstinent may be indicated.

DIAGNOSIS OF ALCOHOL AND DRUG DEPENDENCE

Substance dependence is defined by the *DSM-IV-TR* as a maladaptive pattern of alcohol and/or drug

use, leading to clinically significant impairment or distress, as manifested by three or more of the following seven criteria, occurring at any time in the same 12-month period, characterized by:

1. Tolerance, as defined:
2. Withdrawal, as defined:
3. The substance is taken in larger amounts or over a longer period than was intended.
4. There is a persistent desire or there are unsuccessful efforts to cut down or control use.
5. A great deal of time is spent in activities necessary to obtain, use, or recover from effects of the substance abused.
6. Important social, occupational, or recreational activities are given up or reduced because of substance use.
7. Substance use is continued despite knowledge of having a persistent or recurrent physical or psychological problem that is likely to have been caused or exacerbated by said substance use.

In the *DSM-5*, the *DSM-IV* criteria for substance abuse and substance dependence have been combined into single substance use disorders specific to each substance of abuse within a new “addictions and related disorders” category. Each substance use disorder has been divided into mild, moderate, and severe subtypes. Whereas *DSM-IV* substance abuse diagnostic criteria required only one symptom, the *DSM-5* now requires at least two. The *DSM-5* revisions are intended to (1) strengthen the reliability of substance use diagnoses by increasing the number of required symptoms and (2) clarify the definition of “dependence,” which is often misinterpreted as implying addiction and has at its core compulsive drug-seeking behaviors. For example, features of physical dependence, such as tolerance and withdrawal, can be normal and expected responses to prescribed medications that affect the central nervous system and that need to be differentiated from addiction. There is a converse example, that is, although marijuana abuse can be functionally very impairing, physical dependence is not part of the clinical picture, even in severe cases. In this sense, the new *DSM-5* criteria are specifically designed to recognize and account for mental and behavioral aspects of substance use disorders (APA, 2013).

Although the new criteria require an increased number of symptoms to qualify for a

substance-related diagnosis, critics of the revision argue that chances of meeting the new criteria are now much greater. They further worry that many individuals who qualify for a substance use disorder diagnosis by the new criteria may have only minor symptoms, making it more difficult for those with more severe symptoms and distress to access already scarce treatment.

What Is Substance Dependence?

Dependence is a chronic *progressive and potentially fatal disease*, with genetic, psychosocial, and environmental factors influencing its development and manifestations. It is characterized by continuous or periodic impaired control over drinking, preoccupation with the drug or alcohol and use of drugs or alcohol despite adverse consequences, and distortions in thinking, most notably denial.

What Does “Progressive and Fatal” Mean?

“Progressive and fatal” means that the disease persists over time and physical, emotional, and social changes are often cumulative and may progress as drinking continues. Substance dependence causes premature death through overdose; organic complications involving the brain, liver, heart, and many other organs; and contributing to suicide, homicide, motor vehicle crashes, and other traumatic events.

What Does “Primary” Mean?

“Primary” refers to the nature of substance dependence as a disease entity in addition to and separate from other pathophysiologic states that may be associated with it. The term suggests that substance dependence is not a symptom of an underlying disease state.

What Does “Disease” Mean?

A disease is an involuntary disability. It represents the sum of the abnormal phenomena displayed by a group of individuals. These phenomena are associated with a specified common set of characteristics by which these individuals differ from the norm and which places them at a disadvantage.

OVERVIEW OF TREATMENT APPROACHES

Treatment of alcohol and drug dependence includes identification of alcohol and drug abuse and dependence, initiating treatment plans, educating the individual and family about the abuse and dependence, conducting clinically based interventions within group settings, and individual approaches. The interventions include referral to Alcoholics Anonymous, Narcotics Anonymous, or Cocaine Anonymous, employee assistance programs, and couple and family counseling. Early intervention is important because it serves to minimize consequences experienced by the individual abusing illicit substances. Social consequences include legal, marital, employment, and financial problems. Additionally, early intervention minimizes the potential for long-term health and mental health consequences. Later intervention includes referral to detoxification services, health and mental health services, legal intervention, and other services necessary to stabilize the individual (Holder & Blose, 1992; Yeager & Gregoire, 2005).

ASSESSING ALCOHOL AND DRUG DEPENDENCE

There are a variety of current best practices for the diagnosis and management of alcohol and drug addiction. The following case study examines the various ways that alcohol and drug addiction can impact an individual. This case represents various symptoms of dependence as well as various treatment needs.

Working with alcohol- and drug-dependent individuals is challenging and rewarding work that requires both skill and tact. Although resistance and active defense structures are hallmarks of alcohol dependence, resistance is less than one might expect. Williams et al. (2006) reported that within a sample of 6,400 patients, a full 75% demonstrated at least minimal levels of willingness to change. When placed within a stages-of-change model, approximately 24% presented in the contemplative stage of change and 51% demonstrated characteristics of taking action to change drinking patterns.

Social workers serve a unique role in assisting persons with alcohol abuse and dependence

issues. Frequently, the task of conducting a complete and thorough assessment of the dependent individual falls to the social worker. Components of a thorough alcohol assessment include, but are not limited to, the following.

Establish the Individual's Perception of the Problem

Begin with the individual's perception of his or her drinking history and the exact nature of the problem. Understanding the individual's perception informs the social worker of where he or she will begin in the treatment process. A willingness to listen openly to the individual's perception of need will also provide an opportunity to begin to gently probe into sensitive areas in a manner that is less intrusive, thus opening channels of communication.

Application of a Disease Frame of Reference

Persons seeking assistance with their drinking frequently feel trapped, guilty, helpless, or hostile. Conducting the initial interview from a disease or illness frame of reference, based in nonjudgmental language, minimizes defensiveness while establishing a working relationship. In many cases, individuals are well aware of the need to become active participants in their health care. Just as persons with diabetes or hypertension are responsible for altering their lifestyle to treat their illness, alcohol-dependent persons should be encouraged to assume a greater level of self-responsibility for their treatment.

Construct a Comprehensive Family History

Alcohol and drug dependence has long been determined to have a strong genetic link, therefore, building a family history will begin to normalize the individual's perception of how he or she came to acquire this illness. A good family history should include examination of maternal and paternal drinking patterns and potential alcohol dependence. Examination of lifestyle, community involvement, reputation, marital, legal, employment, spiritual, and educational history will provide important insight into family responses to and perceptions of alcohol and drug dependence.

Establish a Timeline of Alcohol and Drug Use and Amounts Consumed

As the family history unfolds, it provides a natural segue into the individual's experience with alcohol and drug use. Again using a nonjudgmental, inquisitive approach, begin gathering history surrounding childhood perceptions of drinking and drug use, onset of use, type of substances consumed, and under what circumstances. Make a genuine effort to understand the individual's frame of reference surrounding alcohol and drug consumption (especially over-the-counter drugs). When possible, reinforce the person's self-motivational statements and problem recognition while assessing the level of desire to make positive changes in his or her life.

As accurately as possible, begin to piece together daily, weekly, and monthly drinking or drug use patterns. How do weekdays differ from weekends? What happens on payday, holidays, and vacations? Begin to weave together behavioral and consumption patterns. Discuss the meaning of alcohol and drug withdrawal: what it is, what it looks like, and the risks associated with it. Based on the individual's pattern of use and potential for withdrawal, a determination can be made regarding the most appropriate level of care. In general, the presence of withdrawal symptoms warrants an inpatient detoxification program. This, of course, will depend on the drug of use—some drugs require inpatient detoxification and others do not. Those with lesser withdrawal risk are more appropriately treated in an outpatient program.

Always be on the lookout for red-flag responses, such as arrests, domestic disturbances, accidents, and emergency room visits. Also look for comorbidities commonly associated with alcohol and or drug dependence, such as hypertension, diabetes, liver problems, gastrointestinal problems, injuries sustained through accidents, and sleep difficulties.

Examine Social and Emotional Factors

Once the lines of communication are open, the professional can begin the process of examining sensitive areas of the individual's life. While valuing the previously shared family history and perceptions associated with alcohol and drug use, begin to examine the individual's

day-to-day activities to build understanding of social, emotional, and environmental factors associated with alcohol or drug consumption. Seek to understand how the use of mood-altering substances is integrated into the individual's rituals. When and where does he or she drink or use? With whom do they drink or use? Has this changed over time? If the pattern has changed, question the reason for changes. What are the most common social activities? If there are children, to what extent is the parent involved? How are things in the home? Are family members frequently together, or are there estrangements?

Examine the person's educational, vocational, military, employment, financial, legal, spiritual, and recreational history, as well as current day-to-day activity patterns. It is important to note that many alcohol or drug abusers replace previously enjoyable activities with drinking or drug use. Question whether substance use has any impact on the social aspects of the individual's life and examine what that impact has been. The assessment process is one of exploration and education, so take time to teach and set boundaries. Avoid the tendency to overexamine areas that present with emotionally charged responses. More often than not, this will lead the assessment away from productive interaction into a dead-end of rationalization, blame, and frustration. Remain positive and avoid demoralizing statements and negative attitudes about alcohol or drug problems and treatment programs.

Summarize and Teach

Use the assessment process to reinforce and direct the individual with summary statements. Summary statements are designed to present the individual with nuggets of information you have summarized. The intent is twofold. First, you are checking to be certain you have heard and understood the person's perception. Second, summarizing statements can be used to tie pieces of information together in a way that leads the individual to insights and conclusions previously not examined. Patients need to understand the impact of substance abuse and dependence. Examination of what has worked for them in the past and what has not worked is an important part of the assessment summary. Frequently, individuals will have stopped drinking for periods of time. Examine what did and did not work during those time

periods. Emphasize that resumption of drinking is not a sign of failure but part of a process.

When possible, family members should be involved in the treatment process. Assessment of potential family involvement should begin with the initial assessment and continue throughout the entire treatment process. Establishing family support is a strong positive reinforcement for adopting and maintaining new approaches to establishing and maintaining abstinence. Finally, provide information on risks. Family members and patients should understand that alcohol dependence is a chronic, progressive, and potentially fatal disease. It is important to know what they are up against, what role each person has to play, and how support, openness, and self-responsibility can lead to positive changes. Figure 4.1 describes potential approaches to care and integration of social factors to be addressed by social workers when providing comprehensive addiction treatment.

THERAPEUTIC APPROACHES

Motivational Interviewing and Motivational Enhancement Therapy

Motivational interviewing (MI) is a counseling technique frequently applied in the treatment of alcohol-dependent or -abusing persons. This approach elicits changes in behavior by helping the individual explore and address ambivalence about change. Motivational enhancement therapy (MET) is a nonconfrontational approach that focuses on establishing new and different approaches toward problematic drinking behaviors. Goals of this approach are:

- Seek to understand the individual's frame of reference.
- Elicit and reinforce the individual's personal motivational statements of problem recognition, desire, intent to change, and confidence in ability to change.
- Monitor the individual's readiness to change and maintain a steady and consistent approach to problem resolution.
- Provide support and affirmation of individual choice and potential for self-regulation.

Motivational interviewing is a directive, client-centered counseling style for eliciting behavior change in which patients explore and resolve ambivalence (Miller & Rollnick, 2002).

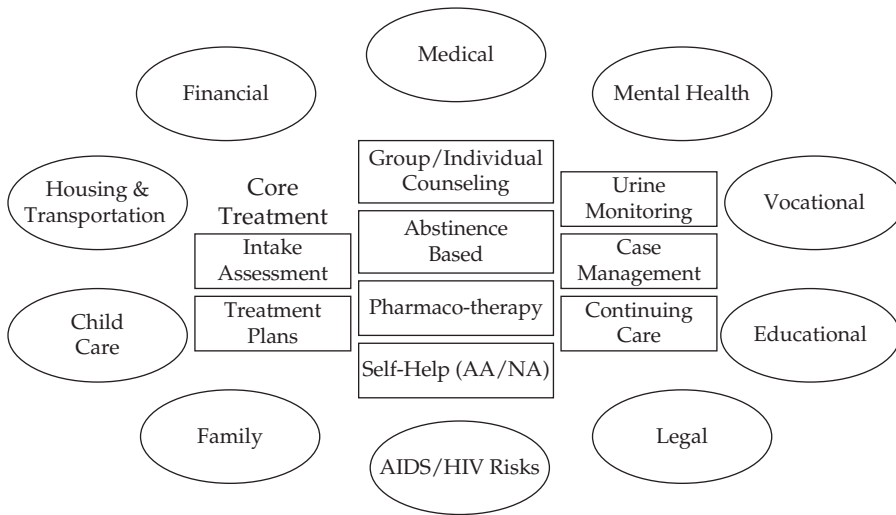

Figure 4.1 Core components of comprehensive services.

Motivational interviewing is less structured than the brief intervention described here, but effective brief interventions have been developed that are adaptations of motivational interviewing or involve similar skills. In motivational interviewing, patients are helped to recognize a discrepancy between their values and goals and their current actions, which can lead them to consider change. Motivational interviewing involves collaboration with the patient, eliciting the patient's thoughts and listening to them, and making it clear that the patient has choices and the autonomy and ability to make them (Miller & Rollnick, 2002).

The individual's perceptions of his/her readiness to change can be used to elicit change talk. For example, if the importance of change is rated as a 3 on a scale of 1 to 10, the clinician can recognize that the score was not zero and ask why. This may lead the individual in question to identify his or her concerns about their substance use. The clinician can then inquire as to what it might take for the score (or identified importance) to increase. The patient's response when examined by the individual and clinician can then be used as a starting point for discussion of how to go about initiating the process of change (Miller & Rollnick, 2002).

As this discussion continues and the individual expresses an increasing interest in change, the clinician should use reflective listening. Doing so permits the patient to hear, in their own words from the clinician, clarifying statements that help them to understand and become comfortable with motivations for change that

might not have previously been clearly understood. In motivational interviewing this concept is considered "change talk" (Miller & Rollnick, 2002).

Change talk—Miller and Rollnick suggest sessions should seek to elicit "change talk" or statements from the patient that are in the direction of change. Examples of change talk include the individual's perceptions of his or her readiness and how their current behavior relates to his or her personal goals. Elements of change talk can be abbreviated with the acronym DARN-C, that is, when the patient expresses:

- **Desire** to change
- **Ability** to change
- **Reasons** for change
- **Need** to change
- Ultimately, **Commitment** to change (Miller & Rollnick, 2002).

Carroll et al. (2006) conducted a randomized trial of MET motivational interviewing in a community-based substance abuse program setting. Findings from this study indicate that exposure to motivational interviewing demonstrated greater levels of program retention when compared to control groups. However, substance abuse outcomes at 84 days did not differ significantly from controls. Despite this disparity, MI continues to emerge as a best practice in treatment of alcohol abuse and dependence. Current literature indicates that there are more than 160 randomized trials,

numerous multisite trials, and recently published meta-analyses of the effectiveness of MI. In these studies, the effectiveness of MI demonstrates wide variability within defined problem areas. In general, positive effects of MI appear early but tend to diminish over time. It is critical to remember that MI effectively captures the individual early in the treatment process, leading to increased participation and potentially increased retention in programming, both of which are key components of successful treatment outcomes.

Cognitive-Behavioral Therapy

Cognitive-behavioral therapy (CBT) is a structured, goal-directed approach designed to help patients learn how thought processes affect their behavior. The social worker helps the individual develop new ways of thinking and behaving through improved cognitive awareness. This leads to an increased ability to adapt to and alter situations within the social environment that present as potential triggers for alcohol consumption.

The evidence for CBT is favorable and indicates it is an effective treatment approach for alcohol dependence and abuse. Current evidence, however, suggests that CBT is most effective when applied as part of a comprehensive treatment plan (Cutler & Fishbain, 2005).

Solution-focused Approach

Solution-focused therapy approaches addiction issues from a prospective approach. Rather than examining problems and past behaviors, solution-focused therapy examines current reality, building on the unique strengths and abilities each individual brings to the therapy process. In the treatment of alcohol abuse and dependence, solution-focused therapy focuses on:

- Envisioning the future without alcohol and the problems that led to treatment
- Discovering effective approaches/solutions to present issues
- Encouraging the individual to build on previous successes, as well as adding new approaches to methods that have demonstrated success previously
- Directing and facilitating self discovery through self-examination

- The individual as the expert in developing effective change and solutions rather than the social worker
- The role of the social worker is to assist in the development of potential solutions.
- Emphasizing the “here and now” rather than the “then and why.”

Steve de Shazer and Insoo Kim Berg of the Brief Family Therapy Center in Milwaukee are the originators of this form of therapy.

HOSPITALIZATION AND REFERRAL OPTIONS

There are times when brief intervention is not useful for patients experiencing severe alcohol abuse or alcohol dependence. If the initial assessment suggests severe alcohol dependence, and the individual indicates a willingness to stop drinking, level-of-care options should be considered. These options consist of the following:

- Inpatient detoxification
- Inpatient treatment
- Residential treatment
- Day treatment or outpatient therapy.

Patients presenting with mild-to-moderate symptoms of alcohol withdrawal have the potential to be managed within an outpatient treatment setting. Outpatient detoxification has become increasingly popular since the emergence of cost-reduction approaches to substance dependence treatment emerged in the late 1980s and early 1990s.

Patients with more severe withdrawal symptoms and susceptibility to environmental cues are better cared for in inpatient treatment environments that are free of relapse triggers. Many providers place their patients in an inpatient treatment setting to initiate detoxification and medical stabilization. This is followed by transition into residential or day-treatment programs.

The third level of step-down approaches to alcohol dependence involves transition into intensive outpatient treatment, which is comprised of education, group, and individual sessions usually three hours in duration occurring three times per week. Following completion of this level of care the individual transitions into a traditional outpatient treatment. Figure 4.2 presents options for individualized treatment

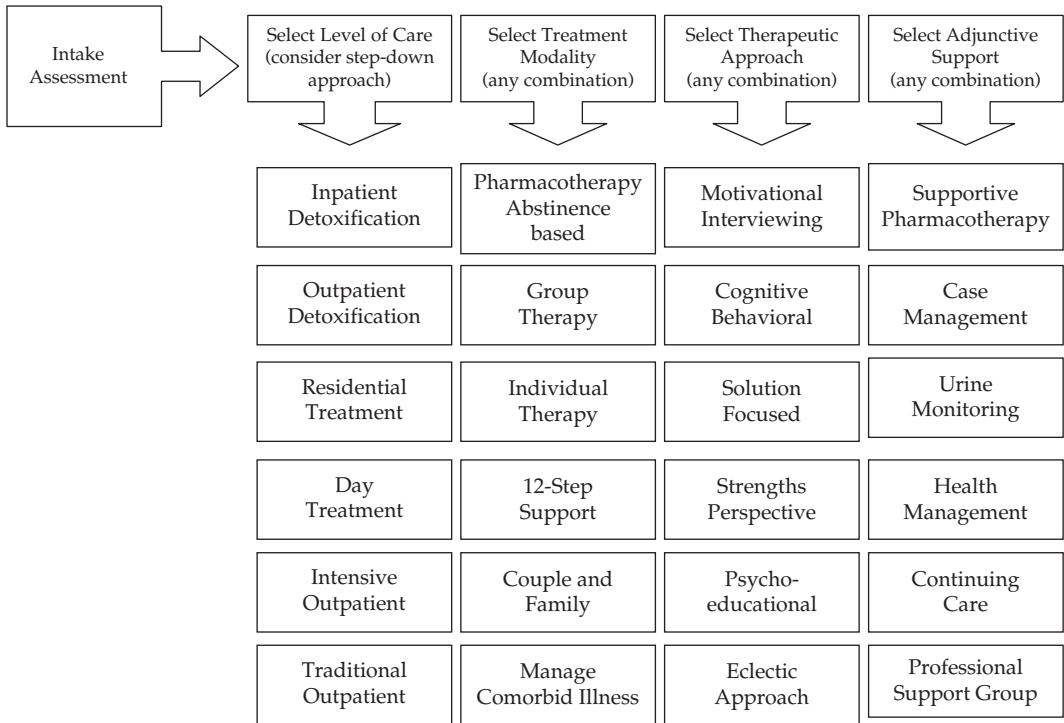

Figure 4.2 Options for individualized treatment approaches with alcohol- and drug-dependent individuals.

approaches when working with alcohol- and drug-dependent individuals.

CASE EXAMPLE

John G. is a 50-year-old self-employed civil engineer who has been extremely successful in developing his own business. John has four regional offices and travels extensively managing each of them, bidding jobs and interacting with various construction companies on business. Seven months ago, while working, John fell while jumping onto a bulldozer to speak with a friend. He injured two vertebrae (L-4 and L-5) in his lower back in this fall. This injury created severe nerve pain that radiates down his leg and causes limited mobility. John is prescribed an opiate-based pain medication. He has always been a drinker, and he enjoys drinking with business associates. His drink of choice is beer, yet there is no stated history of drug or alcohol abuse in his medical record. Initially, John used the pain meds sparingly, but as time progressed, his use increased. Soon he was taking more than the prescribed amount.

On three occasions, his physician increased the strength of his medication. John began to order prescriptions online. He doubled the prescribed dose. He began to miss business appointments and experienced increased marital stress related to his prescription medication use. Finally, John crashed his company car into a school bus when he apparently fell asleep at the wheel in the middle of the afternoon. At the point of entering treatment, John was facing legal problems related to this accident, financial problems related to lack of attention to his business, marital difficulties as a result of the prescription drug abuse, and an emerging single-episode depressive disorder.

John will benefit from a combined approach of MI and CBT. It is best to begin with motivational interviewing to ensure initial connection with treatment processes. Given John's level of cognitive functioning, CBT will be appropriate as treatment progresses. This approach can be helpful in assisting him in developing concrete plans to address issues of chronic pain, as well as establishing a plan for returning to work. An initial focus will elicit information and take advantage of change talk revealed in statements such as "I

am ready to quit” or “I have to quit to get my life back in order.”

Change talk is talk that recognizes a *desire* to change, the *ability* to change, provides *reason* for the change, and describes a *need* to change. Simply remember DARN. However, change does not occur without action or positive steps in the direction of recovery. Action talk requires identification and support of *commitment*; a *willingness*, *intention*, *determination*, or *readiness* for treatment *activation*; and the *willingness* and *preparedness* to take action and actually *take* positive steps toward recovery, which in John’s case requires entering treatment. For action steps, simply remember CAT.

Cognitive-behavioral approaches can be used to frame very specific treatment plans to address underlying issues associated with treatment need and to facilitate continued movement toward established goals. An example of John’s treatment goals might look like the following:

- Goal 1: John will attend physical therapy at 10 a.m. He will work with Joan to complete 30 minutes of stretching and strengthening exercise during each session.
- Goal 2: John will work with Rick (social worker) to address pending legal charges with Mr. Anderson, his attorney. John will complete necessary paperwork to document actions taken to date. This meeting will take place 9

A.M. March 9, in the fifth-floor conference room.

Goal 3: John will write a letter to each of his physicians by noon, March 12, (1) informing them of his entering treatment for substance dependence, (2) specifically describing his program of abstinence, and (3) asking for their assistance in managing his pain without the use of mood-altering substances.

Goal 4: John will continue to build his sober support network by attending three 12-step meetings of his choice on a weekly basis. He will obtain the telephone number of at least one group member per meeting and will make phone contact with at least one person whose number he has collected to discuss the progress he has made in treatment to date.

It is important that treatment goals be specific in nature, measurable, time-limited, and, most important, accomplishable. In this case, John is combining CBT with MI and health care, as well as legal and social support. In doing so, he is addressing many of the components that brought him to treatment, while establishing a firm foundation for ongoing recovery processes. Figure 4.3 outlines multiple options available to care providers when considering treatment and community based support for treatment.

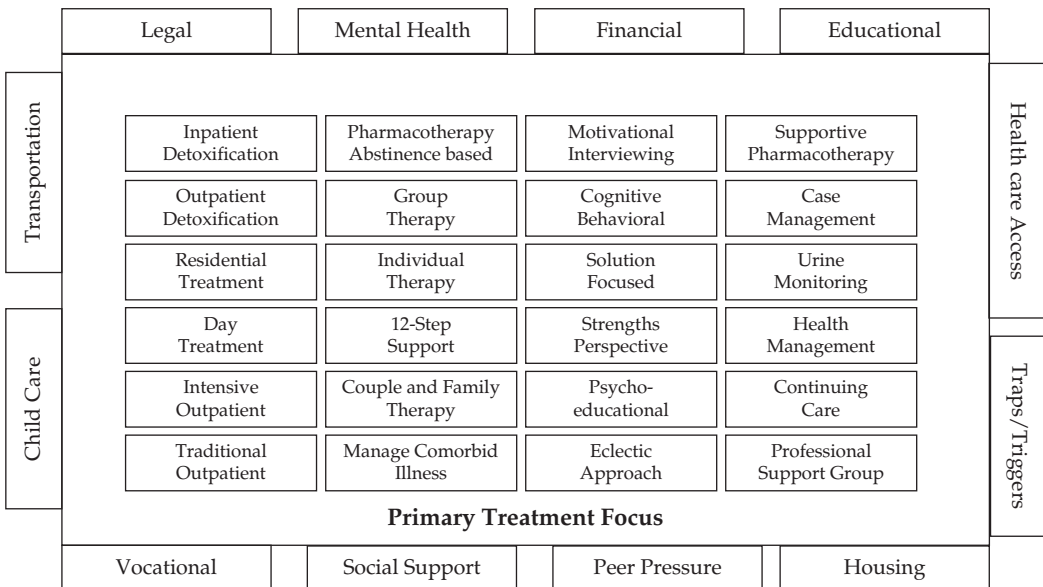

Figure 4.3 Competing social/environmental factors requiring social work intervention.

Case autopsy: John initially was treated on the inpatient unit for detoxification and stabilization. He then transitioned into intensive outpatient treatment, where he remained under the care of a social worker for a total of 16 sessions. John attended psycho-educational, group, individual, and family sessions while in treatment. He successfully resolved his pending legal issues. The DUI charge was resolved with consequences of probation, 90-day license suspension, and requirement to document ongoing treatment for a one-year period of time. John returned to his company and now has established eight years of abstinence.

CONCLUSION

Social workers have a long history of caring for persons with alcohol and drug dependence. Social workers play a key role in the management of persons with alcohol and drug abuse by facilitating acceptance into treatment programming, completing initial assessments to determine the extent and severity of alcohol consumption or substance abuse, conducting initial therapy sessions designed to optimize engagement in treatment, and establishing realistic, measurable, and specific treatment plans. The role of the social worker in addiction continues to expand and transform to meet the ever-increasing needs of those seeking treatment for substance dependence.

Increasingly, this work is being informed by evidence-based approaches to address all aspects of substance abuse and dependence. Today's social worker facilitates treatment processes not only designed to aid in patient care but to serve as an interface between the patient, a variety of caregivers, and critical community-based partners in care. Competent skill sets are required to implement complex, multifaceted approaches to care. Traditional social work skills of communication, organization and facilitation, linkage, brokering, and advocating are intertwined with newer skills of monitoring pharmacotherapy, interacting with managed care and other payer sources, performing utilization review, and dealing with an expanding array of therapeutic approaches to address this complex disease. It is our hope that this chapter serves as a foundation on which each social worker will continue to build a knowledge and skill set that reflects the needs of their individualized treatment setting.

5 School Social Work

Robert Lucio

While the history of school social work over the first 100 years has shown adaptability to the changing social climate, it also reveals a process of specialization (McCullah, 2004). Bartlett (1959) drew a distinction between generic social work theory and specialized social work theory. A generic social work theory was proposed for all social workers with the understanding that each field of social work also needed its own specialization-specific theory. As social workers develop specialized skills and continue working

in specialized environments, there is a clear need for social workers to develop and use effective strategies in practice and research. School social workers are becoming increasingly aware of the need to be accountable for outcomes related to the services provided and are also beginning to understand the need to show decision makers the value of school social work in impacting the lives of students.

Risk and protective factor determinants can be viewed as core components of an ecologically

driven approach to children's issues (Miles, Espiritu, Horen, Sebian, & Waetzig, 2010). It is the process of deciding the *if, what, where, why, and how* of intervening. Having a common understanding that includes assets, competence, and protective processes along with the traditional measures of risk factors, symptoms, problems, and risk-producing processes is critical for student success. As school social workers find themselves in the fight for limited resources within an educational host setting, it is vital that services and outcomes be geared toward academic achievement and success. The social work profession has the ability to influence many areas that will improve students' achievement, behaviors, and other school outcomes, but presently has few empirical ways of showing this to those who are making crucial financial decisions. School districts and school personnel need to be shown that school social workers can help impact student academic and behavioral outcomes.

Beyond understanding the current roles that school social workers play, the future of school social work is being influenced by (1) Response to Intervention (RtI); (2) data informed decisions; (3) evidence-based practices; and (4) the development of a comprehensive school social work model. In addition to these four emerging areas of school social work, the role of social workers in the future will also be discussed. These are critical areas that need to be brought to the attention of school social workers preparing for the next 100 years of practice.

SCHOOL SOCIAL WORKERS' ROLE

School social workers are already asked to do many things and wear many hats throughout the day, including clinician, case manager, advocate, and even policy maker. As the demands on social workers increase, so will the roles they are asked to fill. These range from supporting the mission of the school to serving children on multiple systemic levels in order to promote effective learning through interventions in the school and home environment. Social workers may also be called upon to select appropriate interventions for students, work in small groups or with individuals, or even provide referrals for other services.

Several recent studies of school social workers have looked at how they spend their time

(Bye, Shepard, Partridge, & Alvarez, 2009; Kelly, Berzin, Frey, Alvarez, Shaffer, & O'Brien, 2010; Whittlesey-Jerome, 2013). These researchers looked at the activities that consume their time, what services they are providing, and the broad classification of their services. It was found that almost all school social workers engage in individual counseling, group counseling, and classroom groups. In addition, a majority of school social workers perform psychosocial evaluations and case management services. In fact, school social workers reported that over 60% of their time is spent on secondary and tertiary prevention, while only 30% is spent on primary prevention. The activities are focused on school attendance, discipline problems, school climate, achievement, school violence, drop-out, and teen pregnancy (Bye et al., 2009).

When asked about things they wish they could change about their jobs, school social workers most frequently reported wanting more administrative decision-making ability and a troubling lack of understanding on the part of others regarding their roles and responsibilities (Peckover, Vasquez, Van Housen, Saunders, & Allen, 2013). When roles are not clear, there can be confusion about what school social workers actually do. This can lead to duties being assigned to them that do not fit with their skills and training.

Although school social workers have the ability to focus and direct resources where they are likely to have the greatest impact, and to where there is a high chance of sustainability, the current state of social work practice in schools points to a focus on clinical services for those students already identified as at risk. Currently, school social workers have taken limited roles as leaders in prevention, improvement of school culture, and policy change at the local, state, and national levels (Kelly et al., 2010). Despite the current roles, which often focus on direct services, with the introduction of new approaches to social work practice, namely a Response to Intervention framework, the potential exists for social workers to move beyond providing services to one student at a time. Although there is no doubt this is valuable work, a shift in focus to a prevention model in schools creates an opportunity for school social workers to be at the forefront of this movement and affect both the broader systemic influences (such as the family, teachers, school, and district) and also student level outcomes.

In an effort to expand prevention activities and impact all levels of the schools, it has been suggested that school social workers start by engaging teachers in a collaborative process by offering training and in-service opportunities to empower teachers, providing support for school personnel in dealing with academic and behavior problems, and being advocates for helping children, families, schools, and communities (Bye et al., 2009).

RESPONSE TO INTERVENTION

The *No Child Left Behind Act (NCLB)* of 2001 (P.L. 107–110) and the *Individuals with Disabilities Act (IDEA)* in 2004 (P.L. 108–446) have radically changed the way in which services within education are delivered to students. These laws have introduced evidence-based practices into the realm of schools as one ingredient within the Response to Intervention (RtI) approach to services. RtI is a three-tiered framework for providing high-quality instruction and intervention matched to the student's needs. It provides intervention and educational support to all students with increasing levels of intensity based on individual student needs. The interventions can be based on academic and/or behavioral systems. The key characteristics of this approach are to identify students at risk, closely monitor behavioral or learning outcomes, provide evidence-based interventions, and adjust the intensity of the services provided depending on the student's response to the intervention.

The RtI framework is much like a public health approach to applied education in identifying students who are at risk for academic or behavioral problems and providing instruction and interventions based on the student's needs. The first tier (Tier 1) is focused on primary prevention and intervention efforts for all students at a system-wide level in order to minimize any concerns before they become a problem. For instance, a school-wide anti-bullying program could be implemented in order to reduce the risk of bullying in a specific school. For those students who do not respond to the Tier 1 interventions, small groups of students are engaged in Tier 2 secondary prevention services. These small group interventions can be specialized groups or even systems interventions for those students identified as at risk. Students who are reacting to

bullying or identified as potential bullies could be offered a service if the problem persists despite the system-wide intervention program. Finally, Tier 3 tertiary interventions and services are provided at an individualized level for those students who were provided Tier 1 and Tier 2 services, but did not respond positively to the interventions. Students who continue to have concerns with bullying would be seen by school personnel on a one-to-one basis at the Tier 3 level.

RtI involves the use of data-informed decision-making to modify instruction and implement scientifically based interventions effectively, and is delivered in the following components: multiple tiers of evidence-based instructional service delivery; and problem-solving methods designed to inform decisions at each tier of service delivery. Most importantly, RtI is applicable to all general education students and exceptional student education (ESE). In fact, the nationwide *Response to Intervention* adoption survey found that 71% of school districts were in the process of implementing, piloting, or already fully using RtI district wide (Spectrum K12, 2009).

Some school social work researchers have discussed RtI specifically around the impact on school social work (Kelly et al., 2010). They note four primary principles of RtI where school social workers can have a direct impact. First is the notion that services provided by school social workers should help build the capacity of families, teachers, schools, and districts. In addition to direct services, collaborative endeavors that impact the ability of each of the systems to adopt, implement, and maintain interventions and services should be one focus of school social workers. Although this principle is one of the core building blocks of RtI and school social work, it was found that these critical activities were the least likely to be performed in the current school social worker's job activities. In order to reverse this trend, it is critical that school social workers look for opportunities to expand their role by engaging in strategies and interventions that assist each part of the system; assume leadership roles that influence the broader macro-system; support families, teachers, and administrators in making and sustaining changes; and apply the ecological model to all three tiers. This might take the form of community engagement efforts, teacher trainings, working with families, and working to change the culture of the school to support positive academic and behavioral outcomes.

The second principle relates to the provision of evidence-based practices by school social workers. Schools should use evidence-based practices based on interventions that have proven through empirical research and data to be effective in dealing with the specific academic or behavioral concern. The third principle is the application of the public health prevention framework to education, using a multi-tiered intervention approach. The fourth principle of RtI calls for data to inform decisions about the effect of interventions on student outcomes. School social workers may need to support schools in selecting and implementing interventions, or even collecting, analyzing, and interpreting data in order to ensure students are receiving appropriate services.

The adoption of this framework within the context of schools has broad implications for school social workers. This type of framework requires that school social workers be versed in more than direct clinical services or case management activities. They must also be capable of supporting each of the three tiers in order to improve student outcomes. This might involve learning new skills and taking on new roles, such as directing the implementation of evidence-based practices and assisting in helping schools collect, monitor, and interpret data that helps schools understand whether students are improving.

EVIDENCE-BASED PRACTICES

Another step impacting the future of school social work is to look at which evidence-based interventions can be applied specifically to the identified academic or behavior concerns. This gives social workers a tangible way to impact students, by referring them to or providing the appropriate services. The current research on evidence-based practice can be used as a guide in deciding which interventions to implement, thus allowing the use of best practices with students. Evidence-based practice (EBP) has had a significant impact on school social work and education.

The *No Child Left Behind Act (NCLB) of 2001* requires the use of scientifically based research in schools (Pub. L. No. 107–110). The Colorado Department of Education (2005) addresses the use of evidence-based practices within this framework by stating “evidence-based practice

is the use of practices, interventions, and treatments which have been proven, through data based research, to be effective in improving outcomes for individuals when the practice is implemented with fidelity” (p. 1). The implementation of the RtI approach is centered on evidence-based practice, and using this approach mandates that interventions “must be evidence-based” (Bureau of Exceptional Education and Student Services, 2006, p. 2). With the importance being placed on outcomes in schools, evidence-based practice is certainly moving to the forefront of school social work and has become a strong directive in school social work.

Raines (2004) provides steps in the process of implementing evidence-based practice. The list of the steps is presented as: formulating questions, investigating the evidence, appraising the evidence, applying the evidence, and evaluating progress. Under each process, an example is given so that school social workers can see how this applies to their practices. The author also notes that in order to make evidence-based practice most practical, there must be the creation of relevant knowledge and the dissemination of that knowledge. Of the seven guidelines listed for deciding which interventions to use, two refer to the interaction with theory, namely, whether there is empirical support for a theory or technique and whether the framework recognizes a person-in-the-environment perspective. The tie to theory is a vital key to integrating evidence-based practice into this new framework. Simply reading about best practices does not mean a practitioner has the ability to implement that intervention effectively.

School social workers must understand the context of the schools in which they are providing services in order to successfully implement evidence-based practices. The effective integration of these interventions and services into everyday practice requires knowledge of key organizational and political systems within schools, and knowledge of which interventions promote change, given the characteristics of the current students, teachers, school climate, and school administration (Phillippo & Stone, 2011). This also requires school social workers to have a thorough knowledge base of appropriate interventions, an understanding of how to get information on additional evidence-based practices, the ability to collect and analyze data around effectiveness of services, and an approach that encourages supporting other elements of

the school system through a consultation and collaboration.

DATA INFORMED DECISIONS

The adoption of Rtl as a framework for educational services has created a push toward making data-informed decisions. However, even within this new directive there are few clear guidelines as to who and how services are delivered, which adds to the confusion among student services professions regarding which roles to adopt (Weist, Ambrose, & Lewis, 2006; Weist, Lowie, Flaherty, & Pruitt, 2001). Not only do school social workers have to struggle to define their roles within the schools, but they must do so while attempting to incorporate evidence-based interventions borne from sound social work theory. Using data to inform decisions involves screening at the system and individual levels to help determine needs and the effectiveness of interventions and services in promoting or inhibiting academic and/or behavioral concerns. This might also involve identifying which children are responding to the intervention and which might require more intensive services.

In order for school social workers to engage fully in this process, they should have access to valid and reliable measures, the ability to analyze and interpret the data, and make an effort to engage key stakeholders in conversations around the meaning of the findings (Allen-Meares, Montgomery, & Kim, 2012). Having access to appropriate scales, measures, school data, and any other information will help provide an accurate and useful evaluation of student outcomes (Whittlesey-Jerome, 2013). School social workers should also develop a process to collect and organize data, especially if the data are not part of a regular school data system. Once the data are collected, analysis and interpretation of the data is another essential task that school social workers must have the ability to perform. It is not enough to provide reports if the data presented do not lead to improvements in student outcomes. Taking findings and understanding how to communicate this information to key stakeholders (e.g., community, faculty, or even schools) increases the likelihood that data will be used to inform student services and also increases the visibility of school social workers in the success of students.

SCHOOL SOCIAL WORK FRAMEWORK

The major prevailing framework in school social work is the ecological approach, which serves as a guiding framework for school social work services. This approach enables school social workers to view students, families, schools, communities, and districts within the multiple systems that interact to impact a student's academic and behavioral outcomes. Moving to a more ecological approach recognizes all of the influences on student outcomes. One of the benefits of using this systems view is the ability to be both student and system focused. The ecological model takes into account numerous factors that have an effect on an individual person, including individual, family, peer, school, and community influences. Connecting the person to the environment takes into account multiple levels of interaction and the impact of this network of social and interpersonal influences.

The ecological perspective and school social work practice go hand in hand. School social work practice has four major focus areas: (1) early intervention to reduce or eliminate stress within or between individuals or groups; (2) problem solving services to students, parents, school personnel, or community agencies; (3) early identification of students at risk; and (4) work with various groups to develop coping, social, and decision-making skills. However, because school social workers function within a larger host setting, there is a "need to develop strategies that optimize, enhance, and augment the goals of education" (Atkins, Hoagwood, Kutash, & Seidman, 2010, p. 40). As school social workers operate in a system moving toward outcomes, evidence-based practices, and accountability, it is vital to focus attention on how services ultimately impact students.

Although it is clear the ecological model takes into account numerous factors that have an effect on an individual person, a lack of uniform practice among school social workers exists due to its multiple roles and complexity. School social workers must understand all levels of the system to enact change, requiring social workers to have complete vision of the micro, meso, macro, and chrono systems. However, not having a consistent model can lead to unclear roles and misunderstanding of the capabilities of school social work by faculty and administrators (Dupper, 2003).

A new model for school social work has been called for in order to apply school social work practices consistently in a way that is useful to all parts of the “system.” School social workers should be able to engage in the process of closing the “research to practice gap” and translating research into practice (Ringeisen, Henderson, & Hoagwood, 2003). Kelly and Stone (2009) looked at the contextual characteristics of school social workers and how their environment impacted which interventions were used. Looking at the characteristics of the practitioner, characteristics of the practice setting, and socio-cultural factors, they found little impact on the interventions used. This suggested the need to develop a new school social work model that includes more than individual and group counseling, although predicting the use of more systemic practice factors was more difficult.

Taking this further, Frey et al. (2013) have presented the beginning framework for a model that provides a guide for the types of services that school social workers should be expected to perform. Their goal is to present a broad model that relays school social work roles, skills, and competencies. Specifically they propose the four constructs of social justice, home-school-community linkages, ethical-legal practice, and data-informed decisions in practice as the foundation for the new model. Additionally, they see school social work practice as focused on educationally relevant mental health services, healthy school climate, healthy cultural learning environment, and utilizing access to resources. This new framework serves as a guide to where interventions can be focused to target the greatest chances of impact and success. It also gives school social workers a tool to expand their services to the system level while still embracing their clinical strengths.

CONCLUSION

Recent calls have been made in social work for more scientific and evidence-based research in social work and social work education (Corcoran, 2007; Shaw, 2003; Zlotnik & Solt, 2006). Having a solid knowledge base and clear role expectations, using data to inform student interventions, incorporating evidence-based practices, and using a clear practice model are critical components for the school social work profession to continue moving forward. Although school

social workers are beginning to look at how they impact achievement, the questions about how or why this occurs still need to be examined. These processes and mechanisms for success and failure provide the key to developing and selecting useful interventions. Understanding where to put the effort is important, but it is only the first step in deciphering the complex notion of academic and behavioral success.

The ability to identify students who are at greatest risk allows for the most efficient use of time and resources by school social workers. Targeting interventions to students whose need is greatest enables school social workers to direct services where they are most vital, optimizing resources and allowing for school social workers to differentiate between individual and system concerns. This shift in thinking continues to build on the path that is being paved by evidence-based practice. Understanding which factors help make students successful allows school social workers to partner with families and other systems in addressing those areas that present as risks for academic and behavioral success.

6 Social Work Practice and Leadership

Michael J. Holosko

INTRODUCTION

Social work has a rather long and storied history of not defining core concepts that either direct and inform its practitioners or educate and train its students (Holosko, 2009). Social work leadership is an example of one such core concept. The history of North American social work is characterized by many altruistic leaders who, through their compassion for vulnerable individuals, acted humanely and made a difference in those individuals' lives. William James's (1907) classic essay on pragmatism makes the point more succinctly, as "seeking the difference that makes the difference." These early, turn-of-the-century pioneers led by advocating, reforming, transforming, reflecting, and most importantly—giving names, voice, hope, and inspiration to the clients and communities they served. They included the likes of: Jane Addams, Dorothea Dix, Josephine Shaw Lowell, Mary Richmond, Ellen Gates Starr, Frances Perkins, Florence Kelly, Ida Cannon, Grace Abbott, Lillian Wald, Paul Kellogg, Anita Rose Williams, and Sarah A. Collins—to name just a few.

Our profession's legacy of leaders is much longer than its conceptualization or research about leadership, and this reality is typical of other disciplines that similarly embrace the concept. As Graham (2002) stated:

... research into leadership is a young and still rather shapeless discipline. While leaders and leadership may provide the stuff of bar-room wisdom to glean analytical insights and perspective value at a level approaching normal academic standards. Although some literature exists offering unfalsifiable theories about leadership behavior and personality, there is a dearth of primary empirical information about leaders, the philosophical prisms through which they

perceive reality and the principles by which they conduct themselves. (p. 87)

Despite the fact that leadership was a core concern of the Council of Social Work Education (CSWE) some 15 years ago, as indicated in its *Strategic Plan 1998–2000*, and the NASW, who sponsored the "Leadership Academy" from 1994 to 1997, and conducted an annual meeting on leadership development, Brilliant (1986) referred to leadership as essentially a "missing ingredient" in social work education and training. After reviewing its sporadic attention in our professional literature, she concluded it was essentially a "non-theme" in social work training and education. Later, Reamer (1993) emphatically concluded that we do little to educate for leadership in social work. Then, Stoesz (1997) lamented that social work professionals are often forced to rise to positions of leadership within the profession with little to no mentoring.

Rank and Hutchinson (2000) investigated individuals ($N = 75$) who held leadership positions within the CSWE and the NASW, and concluded that their education and training in this area fell short of both the demands for leadership in the field, and our curricula's ability to teach and educate students about the concept adequately. Their comprehensive analysis made a cogent case for the uniqueness of social work leadership, and they offered a number of constructive suggestions to direct social work in this regard into the twenty-first century. It appears that the profession has had better success in "taking the concept forward," when it responded to the leadership needs expressed by its clients and practicing professionals in its fields of practice (Holosko, 2009). For example, the National Network for Social Work Managers established in the mid-1980s developed

a curriculum focused on core competencies needed to run well-functioning, high-quality health care human service agencies/organizations. Their Academy grants the Certified Social Work Manager (CSWM) credential to social work managers who meet criteria that minimally include education, training, experience, demonstrated competency in 12 core areas, and approval by the Academy (Wimpfheimer, 2004).

Similarly, the John A. Hartford Foundation (www.jhartfound.org) in conjunction with CSWE, has been integral in facilitating and elevating the profession's leadership role in gerontology in the United States. Since about 1996 to 2009, they have spent some \$48 million dollars on a variety of initiatives that have promoted social work to a national leadership position through gerontological education, training, research, collations, collaborations, scholarships, and curriculum development, etc. In this burgeoning worldwide population growth area (www.jhartfound.com), the curious irony is that we routinely tout the importance of leadership within the profession. Social work's enthusiasm for the concept, however, supersedes its meaningful inclusion in education or training. For instance, in CSWE's Educational Policy and Accreditation Standards (EPAS) (2009), among 10 competency standards leadership is only mentioned once. Similarly, a word search count conducted for this chapter of the school mission statements of the top-ranked schools of social work ($N = 50$) cited in *U.S. News and World Report* (2012), and the corresponding titles of courses offered on their respective websites, revealed: (a) 51% of the schools included the word "leadership" in their mission statements; however, (b) only 27% of these same schools used the word "leadership" in any of the titles of their advertised web-listed school courses. In summary, as previously indicated, from a variety of educational perspectives, social workers seem much more enamored with the topic of leadership, and less enamored with developing its educational potential more meaningfully in their schools.

Finally here, for this chapter, a review of social work leadership literature sources only two texts, "*Facilitative Leadership in Social Work Practice*" (2013) by E. Breshars and R. Volker, and "*Social Work Management and Leadership: Managing Complexity with Creativity*" by A. Lawler and J. Bilson (2010), which used the words "social work" and "leadership" together in the same title. Similarly, in a Google search (Google Scholar) of "social work" and "leadership" of scholarly journals

in our field in the past decade, only five articles similarly linked these two terms in their titles.

Where this conceptual fuzziness has potentially a more deleterious effect is in our formal education and training (Nesoff, 2007). However one looks at the issue from this standpoint, we are professionally remiss in this regard, and it appears that we have a rather long and comfortable history of evolving without clearly defining either who we are, or how we should practice (Bartlett, 1970; Boehm, 1958; Flexner, 1915; Gitterman & Germain, 1980; Gordon, 1962; Pincus & Minahan, 1973; Reid & Epstein, 1972). Indeed, educators, accrediting bodies, and legitimizing organizations (e.g., license boards, the NSAW) should take it upon themselves to better define the very concepts we promote and use (Holosko, 2009).

ON BECOMING A SOCIAL WORK LEADER

Leadership versus Management

For a number of years in many academic fields of study, the terms "leadership" and "management" have been: (a) defined in many ways; (b) defined in various ways; (c) used as "garbage can" terms—to describe anything and everything about this content; (d) often overlapped, blurred, and not differentiated from one another; and (e) defined in rather nebulous and unclear ways. In addition: (a) more literature is published about the concept of management as opposed to the concept of leadership; (b) good leaders have a very different skill set than do good managers; (c) very few leaders are effective managers—and vice versa; (d) it appears easier to educate and train social workers and allied professionals to become managers—rather than leaders; and (e) recently, there seems to be more concern about the importance of management in nonprofit and educational settings rather than leadership (Hafford-Letchfield & Lawler, 2010; Holosko, 2009; Holosko & Skinner, 2013; Kamaria & Lewis, 2009; Paton, Mordaunt, & Cornforth, 2007).

Each of these will now be defined in consensual ways: (a) *leadership* is a process whereby an individual influences a group of persons to achieve a common goal, and (b) *management* exercises executive, administrative, and supervisory direction of a group or organization. It requires goal setting, defined objectives and targets, a focus on consistently producing results through planning and budgeting, and organization and staffing, as well as coordination and problem-solving

Figure 6.1 The synergistic conceptual framing components of leadership: The 3 P's of Person, Position, and Process.

(Holosko & Skinner, 2013; Kotter, 1990; Pickett & Kennedy, 2003). This chapter is about the former term, not the latter one.

Core Leadership Attributes

At a simple level, leadership is a synergistic, transformational, and interactive process anchored in the “3 P’s”—the person, the position, and the process (Hartley & Allison, 2002). The “person” refers to the traits or personal characteristics of an individual; the “position” involves the use of authority, governance, and guidance to influence individuals; and the “process” involves how leaders shape events, motivate and influence people, and achieve outcomes (Taylor, 2007).

Holosko (2009) conducted one of the few empirical studies identifying core attributes of leadership in the social work literature. He content-analyzed disciplinary journals ($N = 70$) published in the social and behavioral science databases to sift out its main attributes. Ranked in descending order of importance, their frequencies were:

1. *Vision*
 - a. Having one—To have a description of a desired condition at some point in the future.
 - b. Implementing one—To plan and put in place strategic steps to enact the vision.
2. *Influencing others to act*—To inspire and enable others to take initiative, have a belief in a cause, and perform duties and responsibilities.
3. *Teamwork/collaboration*—To work collectively and in partnership with others toward achieving a goal.

4. *Problem-solving capacity*—To both anticipate problems and act decisively on them when they occur.
5. *Creating positive change*—Moving people in organizations to a better place than where they once were.

Having these attributes certainly is important, but being able to use them effectively in settings to influence change is the real litmus test (Holosko & Skinner, 2013).

Leaders achieve these core attributes through an ongoing interactive transformational application of (a) their personal attributes and (b) their various skill competencies, and (c) by developing a leadership intuition about the attributes indicated in Table 6.1. Thus, there is a process that defines one’s leadership style and imprints one’s operational footprint in moving the organization forward in overtime, by presently using any or all of these five core attributes.

As indicated in Table 6.1, effective leaders use various attributes and competencies in a variety of intuitive ways for different situations as they arise within an organization. As indicated by Snowden and Boone (2007) “truly adept leaders know not only how to identify the context they’re working in, but also how to change their behavior to match” (p. 7). Given this, it becomes easier to understand how learning and imparting management skills that are fairly nonambiguous, straightforward, and less complex is simpler than learning and imparting the many interactive and interrelated social work leadership characteristics noted in Table 6.1.

Using Social Work Attributes to Analyze Leadership Effectiveness

As noted in this chapter, the author has consciously not promoted the notion that leaders are always those in an organization who hold upper level positions of power and/or authority. Although we traditionally think of most leaders as positioned atop the organizational pecking order, social work has clearly promoted the stance that all practicing Bachelor’s in Social Work (BSW) and Master’s in Social Work (MSW) social workers should strive to lead clients, individuals, colleagues and other stakeholders, wherever they practice in the organization’s hierarchy, be it in its upper, middle, or lower ranks. This is reiterated in one of CSWE’s (EPAS, 2009) 10 core competencies. Specifically,

TABLE 6.1 Leadership Necessities: The Synergy of Personal Attributes, Skill Competencies & Leadership Intuition

1. Selective Main Personal Attributes

<p><i>Integrity</i></p> <ul style="list-style-type: none"> • Honesty • Ethics • Transparency 	<p><i>Role Modeling</i></p> <ul style="list-style-type: none"> • Personal • Professional 	<p><i>Charisma</i></p> <ul style="list-style-type: none"> • Promote positive energy
<p><i>Decisive</i></p> <ul style="list-style-type: none"> • Easy decisions • Difficult decisions • Be assertive 	<p><i>Physical Presence</i></p> <p>Have one</p> <p>“What would ... do?”</p> <p>Come to work</p>	<p><i>Self-Confidence</i></p> <p>Exuding not over-bearing</p> <p>Contagion effect</p>

2. Creative Use of Main Skill Competencies

<p><i>Communication</i></p> <ul style="list-style-type: none"> • Oral and written • Sender and receiver • Pleasant • Diplomatic • Appropriate 	<p><i>Knowledge Competence</i></p> <ul style="list-style-type: none"> • Specialized and also broad • Develop “\$ Eyes” • Factual and researched • “I also don’t know” is OK • Thinking smarter
<p><i>Empowering</i></p> <ul style="list-style-type: none"> • Difference between empowering and disempowering • Enabling • Consciousness raising • Believing in others 	<p><i>Inspiring/Influencing/Persuading</i></p> <ul style="list-style-type: none"> • Group vs. individual strategies • Motivating • Timing • Negotiating
<p><i>Managing Others</i></p> <ul style="list-style-type: none"> • Administering • Collaborating • Coordinating • Task orientation • Respecting governance • Focusing on the goal • Personal issues are not as important as organizational ones 	<p><i>Using Power and Authority Judiciously</i></p> <ul style="list-style-type: none"> • Nonauthoritative • Tact and discretion • Devoid of personal agenda • Do not apologize for using power/ authority • Share power and authority

3. Developing One’s Leadership Intuition

<p><i>Know When To</i></p> <ul style="list-style-type: none"> • Pick your spots for expending resources • Defer power and authority • Manage conflicts • Use your strengths • Acknowledge your weaknesses • Deal with troubled employees 	<p><i>Know How To</i></p> <ul style="list-style-type: none"> • Lead vs. manage • Transform vs. transact • Admit you were wrong • Unlearn bad responding habits • Make lemonade from lemons • Provide feedback • Provide positive reinforcement
--	---

in Competency 9—*Respond to Contexts That Shape Practice*, sub-section (b) states: [social workers] “provide leadership in promoting sustainable changes in service delivery and practice to improve the quality of social services”

(<https://www.usi.edu/libarts/socialwork/docs/Ten-Core-Competencies-current.pdf>). Thus, all social workers must strive to achieve leadership in our profession, regardless of where they work in their organizational settings.

TABLE 6.2 The Leadership Attribute Grid (LAG)—Applied at All Organization Levels

Core Leadership Attributes	Various Practice Levels		
	Front Line	Middle Managers	Upper Level Individuals
1. Vision a. Having one b. Implementing one			
2. Problem-solving capacity			
3. Team work/collaboration			
4. Creating positive change			
5. Influencing others to act			
Minor Attributes			
1. Skills 2. Personal characteristics 3. Leadership intuition			

In 2006, while teaching a graduate class at the School of Social Work, University of Windsor, in Canada, the author took this notion—“social work leaders need to lead any level in the organization” seriously, and developed a useful teaching tool interfacing the aforementioned five core social work attributes, across the three main hierarchical levels of an organization as illustrated in the Leadership Analysis Grid (LAG) presented in Table 6.2.

As displayed in Table 6.2, MSW students were asked to identify three person(s) in their places of social service employment who were in front-line, middle, or upper levels, and then identify at least three of the five core attributes (in Table 6.2), and two additional minor attributes (from Table 6.1), and provide examples of how these social workers provided leadership within their organization. Students were taught to explore and think creatively “outside of the management box” while using the LAG. In doing so, they provided rich case examples of how social work leadership is both taught and promoted in our profession.

Concluding Remarks

Although some of our professional associations and bodies, such as the Society for Social Work and Research (www.sswr.org) and the Institute for the Advancement of Social Work Research (www.iasw.soton.ac.uk), have taken proactive

roles in promoting various aspects within the profession, recently the CSWE (www.cswe.org) has identified leadership as a renewed educational priority. In February 2007, CSWE sponsored a two-day conference entitled “Building Leaders in Social Work Education: Pathways to Success” in Mesa, Arizona. This entire conference was devoted to social work leadership in areas of teaching, classroom and field education, training, research, and practice. In 2009, CSWE’s EPAS standard articulating the 10 core competencies that shape accreditation specifically targeted leadership (in competency #9) as an important educational area for BSW & MSW students. Given this reality, it appears that social work is slowly embracing leadership as something that holds legitimate promise for education, training, practice, and professional development. That being the case, the responsibility for defining social work leadership in ways that are simple, clear, timely, and consensually accepted and relevant is not only important, but essential. Hopefully, this chapter has assisted with this concern.

Essentials of Private Practice

Raymond D. Fox

INTRODUCTION

Ups and downs, rewards and challenges, merits and limitations in private practice emanate from its nature—being at the same time a professional endeavor and a business venture. Private practitioners assume total responsibility for every aspect of practice. This includes such diverse constituents as observing ethical standards, setting hours and fees, obtaining insurance, assessing and, most importantly, evaluating their effectiveness. In my view, social workers are particularly well educated as practitioners, but poorly prepared as entrepreneurs. Cox (2009) emphasizes this point.

Consistent with the definition of social work from the International Federation of Social Workers, private practice “bases its methodology on a systematic body of evidence-based knowledge derived from research and practice evaluation, including local and indigenous knowledge specific to its context. It recognizes the complexity of interactions between human beings and their environment, and the capacity of people both to be affected by and to alter the multiple influences upon them including bio-psychosocial factors (2000).

A practitioner for the past 40 years and a teacher, consultant, and supervisor for 35 years, I have come to appreciate the need for a common-sense and down-to-earth approach to private practice. Theoretical frameworks and research findings provide a scientific basis for practice, but little guidance by way of its art and craft. A creative leap is required to bridge abstract theory and concrete reality. Another creative leap is required to close the gap between the professional and the business dimensions of private practice.

THE PROFESSIONAL DIMENSION

Personal Aspect

Only when you are alert to who you are and what you are doing are you sufficiently relaxed, clear, and open-minded to establish and maintain a private practice and better understand clients. It is not possible to be tuned into the feelings of others without first being attuned to your own. Your constant challenge is to understand the interplay between your personal and professional roles and responses. Your personality, values, and sensitivity are the very tools that make you an effective therapeutic instrument. Take time to inventory your unique attributes and skills. Your *personhood*, in other words, is the essential feature in the establishment and maintenance of the therapeutic alliance.

Because you can react only from what is within yourself, you must know yourself so that your capacity for being in relationship is increased, your ability to react consciously is intensified, and you are freer to make deliberate choices about how to respond to clients. Only by knowing yourself are you in a position to make active and creative use of feelings, thoughts, intentions, and motives to optimize the helping process. Only by knowing your assets and shortcomings in terms of a knowledge and skill base, professionally and entrepreneurially, are you in a reasonable position to choose to practice privately.

Awareness leads to more disciplined and clearly directed work as reported in numerous studies. In brief, do what you expect clients to do. Take a hard look at yourself. What is your motivation? Being your own boss? Status? Growing professionally? Earning more money? Minimizing bureaucracy? Maximizing autonomy and independence? Selecting your own client population? Being more creative?

Will you specialize in a method? With a population? With a symptom? Are you fully qualified? Licensed? Do you want a full- or part-time practice? How will you further hone your skills? Advance your knowledge? Do you fully appreciate the consequences in terms of the commitment of time, energy, and money involved in such an enterprise?

Creativity and Fluidity

I encourage a fluid and personal approach to respond differentially and effectively to a wide range of clients with a broad array of problems. As an autonomous practitioner you can enjoy the freedom, within the bounds of accepted ethical and empirical standards, to employ innovative methods for helping clients fathom their lives and gain deeper understanding. I utilize a variety of distinctive strategies more fully described elsewhere (Fox, 2013). One method, however, which I have found indispensable, particularly when working with trauma survivors, is journal keeping. The following sketch of Joan, who used this approach, serves as one illustration.

Joan experienced extraordinary trauma throughout her life. Abandoned by her father at three, his infrequent contact with her was sexually abusive. Her mother suffered a paralyzing automobile accident leaving her disabled and shifting excessive responsibility to Joan and her younger brother. Joan had serious knee problems, which, treated by a family physician, worsened as a result of his injecting it with an unknown substance, causing excruciating pain intended to disguise his having sodomized her at age twelve; as a result she underwent a series of major and painful surgeries for her disabled knee. During our contact she oversaw the nursing home care of her mother, who suffered from Alzheimer's disease. And Joan's mother died at a critical juncture in therapy.

Finding it almost impossible to acknowledge her multiple traumas and articulate their emotional impact, Joan painted. Her's was an art journal (Carey, Fox, & Penney, 2002). An integral facet of her treatment, it contributed significantly her progress. She attributed, as did I, her steady improvement to my serious attention to her vivid entries. In these entries she portrayed unspeakable memories and depicted their emotional residue through the medium of water color. During our face-to-face contact she struggled, and struggled successfully, to translate these artful images into words. The journal served as a source of intense catharsis for her and a source of insight for both of us.

Joan's frightening nightmares dissipated, her neck problems and migraines ceased. Her alcohol use to self medicate when feeling "on edge" desisted. This innovative method promoted her healing.

Evidence Base for Practice

Social work literature promoting evidence-based practice (Pollio, 2006; Proctor, 2003; Rosen, 2003) challenges unexamined and unsystematic clinical interventions. Practitioners are induced to employ empirically validated interventions, whenever possible, linked to clients' goals and objectives and to evaluate outcome effectiveness.

Self-reflection constitutes one form of evaluation. Almost axiomatic is supervision. Case conferences and consultation are additional types of quality control and evaluation. These approaches rely almost exclusively upon subjective assessment and should be part of every practitioner's routine. An array of other means can serve as supplements—practice logs, intensive case studies, and critical incident analysis. Process recording is yet another method for self-reflection (Fox & Gutheil, 2000). All of these enable you to conceptualize all stages of practice interaction through the exercise of reconsidering and analyzing your contact with clients. All enhance your ability to discern efficiency. Especially in urban areas, often having a glut of practitioners, augmented advanced training leading toward a specialization provides an additional welcome edge.

Qualitative methods are refined when combined with objective forms of evaluation. Just as your treatment strategies need to be tailored to meet the unique needs of individual clients, so, too, should your evaluation methods be selected with care. Observations of a client over time constitute a single-subject or single-system design for evaluation. Such a quantitative design requires that client behaviors or events be specified in measurable terms. Goals provide this reference point against which change can be compared. Also emphasized are: (1) specifying target behaviors, (2) identifying a suitable measure, (3) employing it systematically, (4) analyzing observations over time, and (5) charting change. Two discrete methods—Single Subject/System Design and Practice Outcome Inventory stress establishing a clear and quantifiable "before-after" picture of interventions.

Charts or graphs help to track client progress. These make it possible to individualize evaluation

to the unique characteristics, needs, and dilemmas of your clients. They provide ready visual gauges for both you and the client to track change. Decisions can follow as to whether or not there is significant change in a desired direction meeting the expressed purpose of treatment. Corrective adjustments can then be rationally and realistically taken.

Easy-to-use prepackaged standardized scales are also available to incorporate into your practice. From analysis of the information gleaned over a series of time intervals, you can make reasonable assessments about treatment success, discuss options for continuing or discontinuing treatment based on these results, alter interventions, make a referral, or terminate. When such methods are incorporated directly into treatment, they actually propel clinical work. No attempt is made here to detail either Single Subject/System Design or Practice Outcome Inventory, which can encompass sophisticated variations or statistical procedures. Rather, the following illustration is offered, with an appeal to seriously consider incorporating some structured and standardized form of evaluation into your practice.

Cognitive therapy focuses on correcting clients' negatively distorted thoughts and helping them to think more realistically. Already in a depression, Mr. H's sudden loss of employment as a middle manager activated dysfunctional automatic thoughts such as "never being able to do anything right," accompanied by feelings of dejection and devaluation and a sense of paralysis of never being able to work again. Accepting these skewed thoughts as a foregone conclusion, his depression deepened. After I had explained the cognitive approach and we had identified goals for both of us, Mr. H agreed to utilize the Beck Depression Inventory (BDI) within sessions and as homework over a three-month period in order to meet his need for recognizing progress and my need to monitor the success of selected cognitive interventions. Originally intended to be practitioner administered, the BDI is consumer-friendly. I, therefore, encourage clients, and selected others (e.g., family, friends, other involved professionals) to complete it along with the client themselves after obtaining instruction and gaining practice in its application. Mr. H completed one copy of the inventory each day. A weekly composite score of his level of depression was calculated by averaging his daily ratings. Mr. H's wife completed the Inventory weekly for that same time period. Mr. H also kept a mood log each day, which he gave me at our scheduled session.

Perusing his journal, I arrived at a separate third score, a composite weekly score, by averaging the daily entries. Such a procedure provided three independent comparative measures of his depression level over the 12-week course of treatment. These three separate indices were graphed.

Remarkable correspondence was noted among the separate scores—his own, his wife's, and mine. For the first nine weeks of treatment Mr. H's level remained severe; nevertheless, it was steadily declining. The tenth and twelfth weeks marked a sharp decrease in the level of depression. It was evident that Mr. H was recovering and making healthier adaptations in his life. Most importantly, it vividly demonstrated to him that feelings of despair could be overcome even though he initially believed that "nothing could really help." For me it affirmed that selected cognitive interventions, journal-keeping, homework, maintaining the Beck Inventory, had a positive result.

The graph made it immediately evident by charting the three separate indices that Mr. H had made substantial headway over the 12 weeks toward overcoming his depression. Added diagnostic and clinical advantages accrue from using such a visual method for tracking progress. Beyond being a tangible sign for everyone of progress, it became a catalyst for further intensive discussion about other adjustments Mr. H needed to make in his treatment as well as in his life. These discussions, in turn, led to identifying supplementary goals for treatment, including the development of strategies for finding employment.

SIGNIFICANT ADVANCES

Neuroscience and Genetics

The advances in neuroscience (brain structure, function, and chemistry), and genetics have considerable impact on present-day practice. Understanding the brain and the influence of the genome alters the process of therapy (Ilg et al., 2008). We now know that comprehending their impact along with the therapeutic relationship actually serves to create and alter neural circuits. As a consequence, we appreciate more fully what we can and cannot deliver in terms of change (Fox, 2013). It is necessary to stress that even the most sophisticated biologically based therapies will work best when combined with helping clients explore the subjective experience of their behavior and symptoms.

Mindfulness is one powerful method given credence by extant biological research. Its incorporation into practice may alleviate emotional and/or physical suffering, improve the ability to make decisions informed by compassion and kindness, and take responsibility for choices (Sanders, 2010; Turner, 2009; Davis & Hayes, 2011; Ludwig & Kabat-Zinn, 2008; Siegel, D., 2010). The benefits of mindfulness include stress-reduction, improved self-control, affect tolerance and flexibility, enhanced concentration, and mental clarity, as well as fostering kindness, acceptance, and compassion towards others and one's self (Davis & Hayes, 2011). Bruce, Manber, Shapiro, and Constantino (2010) examine the benefits of mindfulness training for mental health clinicians themselves.

DSM 5

The DSM 5 (2014) has met with considerable controversy. Despite its shortcomings, it is central to private practice. Criticized as lacking scientific validity in terms of biological influences, it remains the best tool available to guide you on diagnosing disorders. Moreover, insurance companies, governmental agencies, and the courts rely on it for determining benefits, statistics, evidence, and testimony. Although it fails to point the way to specific effective treatment, it serves as the passport to mental health coverage, and among other things, special educational and behavioral services and disability benefits. It also provides a common language for you to employ when discussing clients with colleagues, supervisors, etc. Get to know it, and get to know it well.

Technology

I would be remiss in not referring to the pervasive and accelerating use of technology. It does not supplant, but instead supplements more conventional clinical tools. Augment your repertoire with the already available and ever evolving electronic resources. The Internet has been instrumental in creating a continually updated and livelier means of contact. It also offers databases that provide highly developed methods tools for searching and analyzing literature and research on recent diagnostic and evidence-based treatment developments. Online platforms such as Skype and texting are constructive adjuncts to real time face-to-face therapy, and promote ongoing connection, communication, and interaction. After much deliberation and encouragement

from colleagues, I have recently acceded to developing a personal website. It promises to provide a beneficial addition to clinical venture. I encourage you to do the same.

Especially because various electronic apparatus is constantly emerging (e.g., the Cloud), and you are bound to face yet unheard of more sophisticated advances, become familiar with the present array of technological enhancements even though by the time you have mastered them, they likely will have been surpassed by more novel ones. I do not advocate becoming technologically dependent. Rather, I recommend that you embark on a pursuit to integrate into your practice those strategies with which you are comfortable and which serve to enhance client interaction.

As ubiquitous, prevalent, and constructive as it might be, technology is not without limitations and reservations. There is a hazard of over-reliance on it, particularly in a practice profession such as ours. Technology is no substitute for face-to-face discourse. I prefer a blend of methods, conventional and novel, distant and proximate, computer-based and personal-based. Technology alone does not make a difference. Employed judiciously and selectively, however, in combination with direct person-to-person contact, a hybrid as it were, it has great advantages.

SELF CARE

By virtue of our being fellow human beings, but more so by virtue of our role as practitioners, we are affected deeply by others' suffering and pain. Such resonance is exacerbated by our own exposure to the same incomprehensible events that affect our clients. Take time for solitude and reflection. Periodically attend to and take care of "self." It has been my experience as a practitioner, supervisor, and consultant that private practice can often be a rather solitary and isolating pursuit. It can make you vulnerable to discouragement, even disillusionment.

Repeatedly dealing with others' stress, anguish, and unexpected crises throughout a career can lead to "compassion fatigue" (Fox, 2003), which has the potential to impact your ability to give fully in your work and extract more from you than is emotionally healthy when listening and absorbing (Figley & Bender, 2012; Newell & MacNeil, 2010). Refuel yourself in healthy ways. Be sure to involve yourself regularly with sources of professional and

personal support, learn to step back and put limits on yourself, make a commitment to seek out supervision and, when needed, counseling, before depletion sets in and compromises your confidence and competence. Consciously endeavor to involve yourself in satisfying experiences outside of work. Avoid the tendency to disengage, not only from clients but from peers and from your “self” as well. Foster associations with colleagues so as to be affirmed, glean support, and create avenues to share experience. **Remember that you cannot fix everything and everyone.**

ENTREPRENEURIAL DIMENSION

General Issues

Practitioners seem ill prepared for the business side of private practice. They rarely receive relevant education in money matters. Many social workers have special difficulty reconciling their backgrounds with a profit motive and with sticking to operating procedures based on management principles. Dealing with a host of financial issues, setting fees, collecting fees, dealing with nonpayment, setting policies for missed appointments, and maintaining financial records, all add to a discomfort level. Issues about having to do with establishing and supporting an office. Options are many—developing a home office, renting shared space in or separate from a group practice, subletting a workplace. Accompanying these concerns are those focusing on how to furnish, lay out, and keep up the office. Beyond rent, routine ordinary expenses include utilities, phone, computer, and cleaning. In addition, other, more remarkable factors need to be considered. Among them are whether to offer your services as an independent provider, as part of a group practice along with social work or interdisciplinary colleagues, or as a professional corporation. Obtaining insurance of all types—disability, accident, dwelling, and malpractice absorbs extra attention.

Valuable assistance in developing preliminary plans and preparing a prospective budget can be obtained by logging onto: www.bplans.com/dp/ and www.socialworker.com.

Especially in these times of a changing and restrictive economy, be cautioned that setting up a practice, as is already evident, is complex and multifaceted. It requires a hefty investment of time and money. Be prepared and deliberate in moving forward. Recognize that diversification

of your personal practice is as critical as diversification of your personal finances.

Marketing

Marketing is a further major consideration. From my observation, social workers are uncomfortable with identity, image management, and public relations. How do you present yourself? As a therapist? A counselor? A social worker?

Exposure is central to boosting a practice and requires comfort in self-promotion and marketing. Steady and reliable referral sources are the life blood of practice. Of paramount importance is networking with colleagues, with like-minded practitioners from allied professions, and with community organizations. Networking is time consuming and costly. Some questions may guide your thinking. Do you offer presentations at a local library? Join a speaker's bureau? Submit an ad to a local newspaper or the “yellow pages”? Do you place flyers and announcements in churches or with community merchants? Do you develop a website? Affiliations of every sort are required to initiate and sustain a private practice and provide ongoing support for your own professional endeavors. Do you connect with clinics, hospitals, employee assistance programs, hotlines, mental health agencies, day care facilities? Do you offer training seminars to a range of professionals? Teaching and writing also increase your exposure. Do you offer workshops to groups such as AARP, PTA, or the Elks? Do you “make the rounds” of doctors, chiropractors, physical therapists, and attorneys to acquaint them with your services? Do you speak publicly in libraries and community meetings?

Over and above being recognized and opening a private practice, you need to build arrangements with other experts with whom to consult about the special predicaments that inevitably arise. Relationships with other experts, those not in the field, are required to assist in the day-to-day operation of your practice. These might include certified public accountants (CPAs), attorneys, and insurance agents. Will you choose to employ support personnel, such as receptionists, secretaries, and office cleaners? What will your business cards look like? What will they say? How will you cover vacations? All of these points are integral to approaching practice as a commercial operation based on business principles, with contractual operations clearly defined and in writing.

Managed Care

A further important factor entails managed care with its attendant benefits and liabilities. Although enrollment in such an organization promises a steady source of referrals, often these are promises only. Frequently, financial remuneration is reduced.

Be cautioned that, increasingly, insurance covers only a minimal number of sessions; prospective clients may not have the necessary out-of-pocket financial resources to proceed. In addition, issues of privacy, confidentiality, and freedom of choice in selecting intervention strategies accompany being on the managed care roster. All these issues can affect, possibly negatively, your client-practitioner relationship. It has been my experience that practitioners are frequently forced into a position of having to adjust client contact to suit the managed care company's conditions. Negotiating the type and extent of treatment, advocating for clients' best interests, obtaining reimbursement for your best efforts constitute major predicaments and often spark ethical dilemmas.

As you think about becoming a managed care provider, become intimately familiar with its regulations about capitation, coinsurance, and copayment. Health maintenance organizations (HMOs), created by insurance companies, provide a package of services for a premium usually paid by employers. They make serious demands on the practitioner. These mostly involve accountability.

Record keeping is fundamental in any manner of practice, but especially so in managed care. More importantly, as an autonomous practitioner you are morally answerable and legally responsible. Documentation of differential diagnosis, medical necessity, treatment plan, explanation of what occurred in contact, under what circumstances, and with what results needs to be in compliance with requirements of regulatory and fiscal bodies to assure accuracy and provision of what is defined as appropriate treatment. Be sure to include in your files referral sources, brief history, medication if indicated, dates, and outcomes. Always keep privileged communication in a completely secure area, under lock and key.

It is a mistake to believe that not keeping notes will protect client confidences and avert subpoena. Do not attempt to out-think or second-guess contractual entities or legal systems. On a different note, if legal action is brought against you,

without up-to-date records it would be impossible for you to construct a case retrospectively and thereby mount a defense.

ETHICAL DIMENSION

Basics

Forcefully stated: *Vigilantly observe the Code of Ethics* www.socialworkers.org/pubs/code
Become intimately acquainted with HIPPA, the Health Insurance Portability and Accountability Act of 1996 (www.hhs.gov/ocr/privacy/).

Malpractice

It is possible, but not probable, that you will be accused of malpractice. It is prudent, however, to keep in mind, the following: To be sued for malpractice, there must first be demonstrable proof that a legal duty existed between you and the client; that you violated that duty by failing to conform to professional standards of care; that evidence exists showing you to be negligent in not conforming to an accepted standard of care, and it can be demonstrated that the client has been harmed or injured in some way and that you were the proximate cause of the injury for which damages are sought. Possible infractions include abandonment of service, mismanagement of the relationship, breach of confidentiality, failure to provide appropriate treatment, and prevention of harm to third parties. Other causes are failure to consult with a specialist, defamation, violation of civil rights, failure to be available when needed, untimely termination of treatment, and inappropriate bill collecting methods. Malpractice insurance is requisite even though being sued is extremely unlikely, especially for social work practitioners.

Fundamentals

Be clear about your specialty niches—those areas of your own expertise as well as those that require involving other experts. Honor your requirement to garner full informed consent from clients. Honor your obligation toward suicidal clients and your duty to warn potential victims of clients who make threats. Acknowledge and follow through with your duty in cases of suspected or actual child or elder abuse and neglect. Grasp requirements

for court testimony and the elements of subpoena. Present danger overrides confidentiality. Protection trumps jeopardy.

Be honest with yourself and with your clients—there are no guarantees and there are no relationships, including practitioner-client relationships, that are totally risk free for either party.

ELEMENTS OF PRIVATE PRACTICE

What works? What should you keep in mind? What are key elements gleaned from my active and deep reflection on 40 years of practice? These interwoven guideposts build upon and enhance each other:

Relating

Research into practice effectiveness across modalities and theories identifies relationship as the foremost ingredient for success and effectiveness.

Hearing Their Story

Accompany clients through their life story. It creates a structure for catharsis of disturbing affects, cleansing of disquieting memories, and discovery of new perspectives.

Naming Things for What They Are

Avoid euphemisms and name the “un-nameable”—abuse, rape, assault, victimization, and trauma because honesty grounds practice and propels the process forward.

Blending Seriousness and Fun

Neither shy away from difficult material nor be too intrusive. Spontaneity, humor, and paradox advance change and provide, simultaneously, caring and challenge.

Educating

Offer practical information, advice, alternative viewpoints. Teach self-soothing techniques. Counter distorted thinking patterns.

Setting Goals

Mutually set goals to give you and your clients impetus to carry on, direction for the future, and

marks of, and satisfaction in, accomplishment as you move forward.

Being Fair

Establish reasonable fees, consider a sliding scale, accommodate to contingencies in clients’ lives such as unemployment, illness, disability.

Believing

Believing in the purposefulness of practice, in yourself, and in clients’ strengths leads to meaningful exploration and examination, as well as recognition of choice.

Creating “Safety”

Meet clients’ basic needs for security and affirmation. This fosters their ability to master their lives, face the challenge of self-discovery and the triumph of ownership.

Taking an Active Stance

Concentrate on clients’ aspirations and resiliency, engaging in active and genuine collaboration toward interrupting dysfunctional patterns and fostering empowerment.

Confrontation

Challenge any discrepancy directly. Even though it is risky, it keeps both of you on track toward advancing true insight.

Balancing

Maintain a dynamic equilibrium between the interdependent features of professional standards of care and entrepreneurial realities.

A FINAL REMARK

Finally, what brings success in private practice is integrity and reputation. Develop referral sources, confer with other professionals from a variety of related disciplines, market your professional attributes, cultivate small business skills, keep abreast of the changing care environment and trends, preserve the nature of your client relationships, obtain medical and psychiatric consultation when relevant, keep accurate

records, and document, document, document. To reiterate, success in private practice arises from integrity and reputation.

Social Work Practice and the Affordable Care Act

Stephen Gorin, Julie S. Darnell, & Christina M. Andrews

BACKGROUND

The call for national health insurance (NHI) was raised as far back as 1912, when Theodore Roosevelt, the presidential candidate of the Progressive Party, called for the introduction of “‘a system of social insurance,’” including the “‘protection of home life against the hazards of sickness’” (cited in Birn et al., 2003). Jane Addams, an NASW Social Work Pioneer, played a leading role in Roosevelt’s unsuccessful campaign.

NHI emerged again as an issue in 1934, when President Franklin D. Roosevelt appointed a Committee on Economic Security, headed by Frances Perkins, the Secretary of Labor, and another NASW Social Work Pioneer (NASW Foundation, n.d.) to address the economic crisis. Their work culminated in the enactment of Social Security. Perkins and others, including Harry Hopkins, also an NASW Social Work Pioneer, had hoped to incorporate health insurance into the bill, but they soon discovered that this would be impossible due to strong opposition from the AMA, whose members “bombed members of Congress with letters, postcards, and phone calls decrying compulsory health insurance” (Quadagno, 2006). Although Roosevelt “pulled the plug” on the NHI component of Social Security, the final legislation did include funds for maternal and child health, public health, and assistance to children with disabilities (Downey, 2010, p. 243).

After the failure of NHI during the 1940s and 1950s, many activists concluded that it was politically unfeasible and began focusing on expanding coverage to older adults. Wilbur Cohen played a central role in the enactment in 1965 of Medicare

and Medicaid. The “architects” of this effort viewed it as a “step toward universal national health insurance” (Ball, 1995, p. 63).

Efforts for NHI emerged again during the late 1980s and early 1990s. In 1993, Bill Clinton introduced his Health Security Act (HSA), which “sought a middle path between a Canadian-style single-payer health care system ... and the largely unregulated approaches advocated by conservatives” (Gorin & Moniz, 2014, p. 412). The HSA provoked strong opposition from both the left and right and the administration pulled it without bringing it to a vote.

During the 2008 presidential campaign, Barack Obama advocated an approach to health care that built “on the current system of mixed private and public group insurance” (Collins, Nicholson, Rustgi, & Davis, 2008). After a year of fierce debate, Congress enacted the Affordable Care Act (ACA), or “Obamacare” as it became known, in March 2010. Although many social workers were disappointed that the final version of the ACA did not include a government-run public insurance option, NASW recognized the ACA as a critical step forward in the century-long struggle for NHI and a victory for social workers (Gorin, 2011).

The ACA is too complex to summarize in a short article; however, broadly speaking, it can be viewed as “a three-legged stool” (Krugman, 2013). The first leg is community rating, which requires insurers to “issue policies without regard to an individual’s medical history” (Krugman, 2013). The second leg is the individual mandate, which requires all citizens to have insurance. Although the mandate is controversial, without it, healthier and younger individuals could avoid buying

coverage, “leaving a relatively bad risk pool, leading to high premiums that drive out even more healthy people” (Krugman, 2013). The third leg consists of subsidies to enable individuals with low incomes to buy coverage. These pieces are interdependent; take away one and the stool collapses.

The ACA is consistent with the “Triple Aim” of expanded coverage, cost control, and improved quality that Berwick, Nolan and Wittington (2008) identified as being critical to health care reform. In terms of coverage, the Congressional Budget Office (CBO) projected that between 2013 and 2023, the share of the nonelderly population (excluding individuals without documentation) with insurance will increase from 82% to 92%. The ACA originally required states to extend Medicaid coverage to individuals with incomes at or below 138% of the federal poverty line (FPL). States refusing to expand coverage would be denied all funding for Medicaid (Gorin & Moniz, 2012). In 2012, the Supreme Court found this section unconstitutional and left it to the states to expand Medicaid without risk of losing all Medicaid funding. This decision places individuals living below the FPL at risk of having no coverage because they are not eligible for assistance to buy insurance in the marketplace. Individuals between 100% and 133% of the FPL will be eligible for subsidies, but they still may not be able to find affordable coverage (Community Catalyst, 2012).

The ACA also addresses the difficult issue of controlling costs. Aaron (2011) noted that the legislation incorporated almost every “rational” approach “analysts have advanced for slowing growth of spending” (p. 2379). The CBO (2013b) and Congress’ Joint Committee on Taxation estimated that the ACA will “reduce deficits over the next 10 years and in the subsequent decade.”

Finally, the ACA addresses the issue of quality (Gorin & Moniz, 2014). Concerns about the quality of health care in the United States have been raised for more than a decade, and it remains a serious issue (Swenson et al., 2010). A central concern here is the fragmented nature of our system, which is “essentially a cottage industry of non-integrated, dedicated artisans who eschew standardization” (Swenson et al., 2010). In an effort to address this, the ACA promotes the introduction into Medicare of Accountable Care Organizations (ACOs), which provide incentives for “doctors, hospitals and other health care providers to form networks to coordinate care better” (Gold, 2013). Although some have heralded ACOs as the wave of the future, their record thus far has been mixed

(Beck, 2012). The ACA also provides incentives for hospitals to reduce readmission rates for chronically ill patients (Gorin & Moniz, 2014).

Understood in its proper context, the ACA is the outcome of a century-long effort to introduce NHI. It realizes Franklin D. Roosevelt’s plan to incorporate NHI into Social Security and, in a real sense, is Social Security’s missing leg.

NEW ROLES AND REALITIES UNDER THE ACA: A CLOSER LOOK

Eligibility and Enrollment

By 2018, the ACA is estimated to nearly halve the number of uninsured individuals, from 55 million to 30 million (Congressional Budget Office, 2013a). Twelve million additional adults and children are expected to obtain coverage through Medicaid and the Children’s Health Insurance Program (CHIP) and 25 million through the new Health Insurance Marketplaces (also known as exchanges) where individuals and small businesses can purchase health insurance coverage from among an array of plans. States have the option to run their own state-based exchange, partner with the federal government, or default into a federally facilitated exchange. Overall, the ACA is anticipated to result in 92% of Americans having insurance coverage.

Achieving the goal of near-universal health insurance coverage will require, however, that millions of people who are eligible for coverage *actually* enroll. Enrolling newly eligible people into health insurance plans will be a difficult task. Previous research estimating the size of the Medicaid eligible-but-not-enrolled population suggests that between 17% and 68% of eligible people do not enroll (B. Sommers et al., 2012; Sommers, Tomasi, Swartz, & Epstein, 2012; U.S. Government Accountability Office, 2005). The reasons for failing to enroll are wide-ranging and include lack of awareness, stigma, and administrative complexity. Among these, the lack of awareness appears to be a particularly acute problem facing the ACA; evidence from public opinion polls, focus groups, and research studies documents that most Americans have little awareness of the ACA, and that what they have heard makes them wary of it (Altman, 2011; Kaiser Family Foundation, 2013b; Perry, Muligan, Artiga, & Stephens, 2012).

Recognizing these key challenges, the ACA contains several provisions intended to improve participation. First, the ACA mandates that

almost everyone purchase insurance or pay a penalty. Second, the law has a “no wrong door” policy in which individuals will be screened jointly for Medicaid, CHIP, and private coverage offered through the marketplace using a single, streamlined application. Third, it creates or expands numerous consumer assistance programs that will help uninsured individuals enroll in new coverage options. They include: (1) navigators, (2) in-person assisters, (3) certified application counselors, and (4) consumer assistance program (CAP) workers.

The ACA requires that all marketplaces establish a navigator program to assist consumers with eligibility, plan selection, and enrollment. Navigators will help consumers determine their eligibility for subsidies or Medicaid. Navigators also will help consumers understand the differences between the platinum, gold, silver, and bronze plans. Navigators may handle grievances and complaints. States have flexibility in designing and operating their navigator programs, but they must conform to the federal minimum standards related to the scope of activities, types of entities allowed to perform navigation tasks, and the competencies and training of navigators.

In-person assisters will play roles similar to navigators. Though conceived of as “non-navigator” assistance, in reality, in-person assisters share many of the same functions as navigators and receive comparable training of about 20–30 hours. This program is state-administered and its availability depends on the type of marketplace: required in partnership exchanges that take on consumer assistance, optional in state-based exchanges, and not available in federally facilitated exchanges.

Beyond navigators and assisters, community-based organizations and providers that have experience providing social services in their communities are eligible to apply to become designated as certified application counselors (CACs). In turn, their staff and volunteers may become certified to help their clients complete applications for coverage. CACs are required to provide information on the full range of coverage options. CACs must comply with privacy and security standards, complete approximately five hours of required online training, and pass a certification exam. Though exchanges must have a CAC program, the marketplaces do not provide funding for it. In addition to the Exchange CACs, states may establish Medicaid CACs to provide

information about, and help individuals enroll in, Medicaid and CHIP.

Finally, the ACA created consumer assistance programs to help consumers enroll in plans and carry out ombudsman-related activities, such as helping consumers file grievances and appeals, tracking and resolving problems, and educating consumers about their rights and responsibilities. Many states established these programs with federal monies, though some have ceased these activities due to reductions in federal funding (Kaiser Family Foundation, 2013a).

What kind of consumer assistance is available, and how much, depends on where one lives, because the responsibilities for consumer assistance functions differ by marketplace. In state-based exchanges, the state takes responsibility for implementing the core marketplace functions. In partnership exchanges, plan management and consumer assistance functions are shared. In federally facilitated exchanges, the U.S. Department of Health and Human Services performs all marketplace functions, including consumer assistance. As of September 2013, just over half of the states ($n = 27$) have defaulted into the federal exchange, 17 states and the District of Columbia have declared a state-based exchange, and seven states have entered into a partnership exchange (see <http://kff.org/health-reform/state-indicator/health-insurance-exchanges/>). All states regardless of type of marketplace must operate a navigator program and a certified application counselor program in the exchange. In-person assistance is required only in partnership exchanges and is not available in federally facilitated marketplaces. Statewide consumer assistance programs and certified application counselors for the Medicaid program are optional. As a result, the amount of consumer assistance resources available to educate uninsured individuals about the new coverage options and enroll them into plans will vary greatly state by state.

Care Coordination The ACA includes two major provisions designed to enhance care coordination and improve integration of primary care and behavioral health services. First, it establishes a new Medicaid option to establish patient-centered medical homes (PCMHs) for enrollees with complex health care needs. The PCMH is an enhanced model of primary care that provides accessible, comprehensive, ongoing, and coordinated patient-centered care

that addresses the needs of the whole person (Patient-Centered Primary Care Collaborative, 2013). PCHMs seek to achieve these ends by organizing physician-led, interprofessional teams that provide continuous and coordinated care, emphasize prevention and effective management of chronic illness, and strive for improved access and communication. To date, the ACA has promoted the establishment of PCMHs in several ways. First, the ACA provides state Medicaid programs with the option to allow providers to create “health homes” based upon the PCMH model for enrollees with certain chronic conditions. States that participate received up to two years of an enhanced matching rate for the services they provided through health homes (Kaiser Family Foundation, 2011). At present, 25 states have implemented health homes within their Medicaid programs. Second, through the ACA-established CMS Innovation Center, new demonstration projects aim to test the effectiveness of PCMH models.

Accountable Care Organizations (ACOs) are the second major model of care coordination promoted by the ACA. Established through the Medicare Shared Savings Program (MSSP), ACOs are defined as organizations of health care providers that are accountable for the quality, cost, and overall care of Medicare beneficiaries (Centers for Medicare and Medicaid Services, 2013c). The ACO model is less structured than the PCMH, encouraging providers to develop creative approaches to providing more cost-effective, quality care that incorporates best practices in improving health care quality and reducing costs through prevention, care coordination, and elimination of unnecessary services. ACOs that meet specified quality performance standards are eligible to receive a percentage of savings incurred if the expenses for care are sufficiently low compared with cost expectations set by MSSP. The program has established five domains in which ACOs must achieve high-quality ratings to earn bonus payments: patient and caregiver experience, care coordination, safety, preventative health, and health of at-risk populations and frail older adults.

Behavioral Health Treatment

The ACA also will expand coverage for mental health and substance abuse treatment services significantly, creating new opportunities for social workers within an expanded behavioral health

services system. Insurance coverage provided through the newly established Health Insurance Exchanges (HIEs) and Medicaid benchmark plans will be subject to the Mental Health Parity and Addiction Equity Act (MHPAEA). When passed in 2008, MHPAEA requirements were restricted to health insurance plans for large employers (i.e., organizations that employed more than 50 employees) that already covered behavioral health services, defined as services to treat mental health and substance abuse disorders. The MHPAEA required that large employers ensure that their limits on behavioral health services were no more restrictive than that of other health services offered by the plan. The ACA extends the MHPAEA by requiring Medicaid benchmark plans and state HIE plans to cover behavioral health services in compliance with the parity guidelines established by the MHPAEA. Consequently, it is projected that approximately 30 million people will gain coverage for behavioral health services through the ACA (Buck, 2011). A significant proportion of these people are already insured, but are covered under programs that do not provide coverage for behavioral health services.

These coverage expansions are expected to trigger significant growth in demand for behavioral health services because the proportion of Americans with behavioral health disorders is high. At present, an estimated 20% of Americans have a mental health disorder, 5% have a serious mental illness, and 12% have a substance use disorder (Substance Abuse and Mental Health Service Administration, 2012). And, the co-occurrence of these disorders/conditions is extraordinarily high. Among adults with substance use disorder, 43%—nearly 9 million—had a co-occurring mental illness. Medicaid enrollment alone is estimated to increase by 82% among states expected to participate in the expansion (Banthin et al., 2012). This is especially important because those newly eligible for coverage through the Medicaid expansion exhibit higher rates of almost every behavioral health disorder than the general population (Garfield, Lave, & Donahue, 2012). There may also be a major spike in help seeking behavioral health disorders as these coverage expansions are implemented due to pent up demand—that is, people who may have wanted to seek out behavioral health services, but have not done so in the past due to lack of health insurance coverage for these services.

Although primary care providers will provide some treatment, the need for staff to provide specialty behavioral health services is expected to grow significantly. These new additions to the workforce will be needed in greater numbers within traditional health care settings, as they strive to provide more comprehensive care, as well as in traditional specialty settings for individuals. The Bureau of Labor Statistics (2013) projects that the health care system increasingly will rely on social workers to provide these services. Their most recent estimates suggest that demand for social workers specializing in the provision of behavioral health services will increase by 31% between 2010 and 2020, faster than psychology (22%), behavioral health paraprofessionals (27%), and even medicine (24%) and nursing (26%). The biggest increases in jobs for the social work profession are expected in health social work, gerontology, and behavioral health; in each of these areas, the Bureau of Labor Statistics is projecting growth rates above 30%.

It remains unclear how the ACA will impact social workers providing behavioral health services in private practice. On the one hand, because insurance coverage for behavioral health treatment will rise, there is expected to be increased demand for behavioral health services. This surge in demand could lead to growth in behavioral health services provided in private practice settings. On the other hand, the ACA is likely to result in a contraction in the specialty behavioral health services treatment sector over time as a result of its drive to integrate behavioral health into primary care and other medical settings. Reducing emphasis on treatment modalities that are separate from primary care settings—including private practices—is an implicit goal of the ACA.

GETTING IN THE GAME

Health Insurance Coverage

Social workers can play an important role in helping to ensure that all uninsured individuals (especially the most vulnerable) get the health insurance coverage for which they are eligible. At a minimum, social workers need to know what consumer assistance programs are available in their state and how to connect their uninsured clients to these resources. Social workers ought to consider, however, a larger and more active role: *becoming* navigators, assisters, certified

application counselors, or consumer assistance program workers. Because of their specialized knowledge, training, and code of ethics, social workers are uniquely qualified to assume any of the new consumer assistance roles created by the ACA (Darnell, 2013, Andrews et al., 2013). The consumer assistance positions merit serious attention from the social work profession; at their core, these new consumer assistance jobs are about linking individuals to resources, a central activity of social work practice. Furthermore, employment opportunities related to helping uninsured people understand, apply for, and enroll in health insurance coverage should be plentiful, given that navigator programs and certified application counselors are required in all 50 states, and other kinds of consumer assistance are available in many states.

The resources targeted to consumer assistance will vary state to state, with some states operating with limited resources and in political climates that are hostile to the ACA (Goodnough, 2013). These conditions likely will have a negative impact on their state's effectiveness in enrolling the uninsured into coverage. Social workers will be needed to step in to serve as "watchdogs" to assess whether the training is adequate and whether the size, composition, and geographic distribution of the consumer assistance workforce is sufficient to serve the state's uninsured population. Social workers who are working with uninsured clients will be in favored positions to judge and report on whether the system is working.

A related watchdog role for social workers is to monitor access to care for the uninsured as well as for the newly insured. There are two reasons why the remaining uninsured may face even greater difficulties in obtaining needed services when they attempt to seek care: primary care providers are expected to be dealing with high levels of pent-up demand from the newly insured and hospitals will have fewer resources than before to serve the uninsured. A portion of the newly insured population might also be unable to get the care they need due to high deductibles or co-pays, limited drug formularies, limited provider networks, and the like.

Coordinated Care Social workers are particularly well equipped to assist in the design and implementation of coordinated care models. They receive in-depth training in identifying and addressing social determinants of health critical to achieving long-term health and well-being

and to do so within the social and environmental contexts in which patients are embedded. Social workers have specialized knowledge of community and social systems and training in case management that is sensitive to cultural beliefs and health literacy (Andrews et al., 2013). Finally, social workers have training in implementing models of behavior change that can help promote effective disease management and prevent illnesses from occurring or reaching stages in which acute medical treatment is needed. Research demonstrates these areas of knowledge and training are particularly effective in meeting the needs of a population referred to as “high utilizers” of health care, which includes individuals with complex health needs, such as co-occurring physical and behavioral health disorders. Social workers have a key role to play in creating the new model of health care to which the ACA aspires, in which prevention, attention to social determinants of health, and well-coordinated care are all central aims. The ACA presents a unique opportunity for social workers to enhance collaborative activities with medicine and allied health professions to maximize the profession’s role in shaping these emerging models of integrative, collaborative, and coordinated care.

Behavioral Health Social workers have a long history in behavioral health and are already the predominant professionals providing these services (U.S. Department of Labor, Bureau of Labor Statistics, 2013). Yet, to expand this role, the profession must be responsive to shifts in decision-making power resulting from ACA-driven insurance expansions. Medicaid is poised to become the primary payer of behavioral health services, and in states that take the expansion option, Medicaid agencies will become the single most powerful decision makers in behavioral health. Concomitantly, state agencies that have administered the majority of public behavioral health funding through state and federal block grants are likely to decline in importance.

These changes in the financing of behavioral health services are likely to result in major changes in the distribution of decision-making power. Although the ACA requires all states to include behavioral health services in their essential benefits packages, state Medicaid agencies and HIEs will have broad discretion in determining which behavioral health services will be covered and who can be reimbursed for providing them—at least among those providers that have

not moved to fully capitated models of financing (Buck, 2011). These decisions will greatly influence the size and scope of the behavioral health workforce expansion resulting from the ACA and the relative role of social workers. It will be critical for social worker advocates and researchers to work together to cultivate strong ties to understand the changing role of Medicaid and the new roles of the HIEs in financing behavioral health treatment, and to be aware of key policy decisions that will or can influence social workers, especially as they relate to the profession’s role in newly emerging models of integrated care. These tasks will need to be carried out on a state-by-state basis.

Advocating for the Most Vulnerable Social workers have a professional responsibility to advocate for social justice. In keeping with this mandate, social workers ought to be advocating for Medicaid expansions in states that have rejected extensions as a result of a 2012 ruling by the Supreme Court on the ACA (*National Federation of Independent Business v. Sebelius and Florida v. United States Department of Health and Human Services*). By October 2013, only 24 states plus the District of Columbia had agreed to expand Medicaid. The CBO (2012) has estimated that 3 million fewer people will gain insurance coverage as a consequence of the Supreme Court decision. Moreover, the states not expanding Medicaid account for 60% of the nation’s “uninsured working poor people” and “68% of poor, uninsured blacks and single mothers” (Tavernise & Gebeloff, 2013).

In addition, an estimated 11 million undocumented immigrants are excluded from the new coverage options. The 5-year ban on Medicaid and CHIP for newly arrived legal immigrants set forth by the Personal Responsibility and Work Opportunity Reconciliation Act of 1996 remains in effect. These disparities in coverage hinder immigrants’ ability to obtain health care. Social workers ought to advocate for health insurance for every individual living in the United States, regardless of immigration status. They must also work to ensure that care is culturally and linguistically appropriate.

CONCLUSION

The enactment of the ACA marked a critical step forward in the century-long effort to achieve

universal health care coverage in the United States. Social workers have long supported, and at times played a leading role, in this effort. The ACA includes “several provisions that will directly benefit” social workers (Malamud, 2010).

Much remains to be done, however. When fully implemented, the ACA will not achieve universal coverage, and whether it will succeed in bringing costs under control remains an open question. It is also unclear how social workers will fare in the transition from a largely fee-for-service system to one based on coordinated care. In a real sense, the ACA is a work-in-progress and is best understood from this perspective.

Social Work Practice in Home-based Services

Martha Morrison Dore & Charlene Zuffante

ANOTHER DAY ON THE JOB

The following reflects a typical day in the life of a social worker delivering home-based services to families and their children.

8:30–9:30 A.M.:	Arrive at office. Hunt for a parking space. Check phone messages, return calls to clients, colleagues, and community partners. Find out from a call to the middle school social worker that Robbie McDonald has skipped school for two days in a row.	Carrie is also entering into adolescence, which requires its own set of developmental adjustments. She also has a very conflicted relationship with her father who has also reacted badly to Anna’s involvement with Ellie and feeds Carrie’s insecurities about her changing relationship with her mom. The focus of treatment at present is on the relationship between mother and daughter, as well as negotiating the role of Ellie in the family, particularly with regard to Carrie.
9:30–9:45 A.M.:	Head off to Dobson family home for treatment session with Anna Dobson, her partner, Ellie, and Anna’s daughter, Carrie Dobson, 13, who has just returned home from two weeks in residential treatment for a suicide attempt.	
9:45–11:30 A.M.:	Home-based session with the Dobson family. The relationship between Anna and Ellie is a relatively new one and Carrie, who has been alone with her mom since her parents’ divorce five years before, is having a great deal of difficulty adjusting to sharing her mom with Ellie.	11:30–12:00
		NOON:
		12:00–1:00 P.M.:
		Travel to ML King elementary school. Attend Individual Education Plan (IEP) meeting at King school for Keisha Harold, age 8, who is experiencing serious attention and behavior problems in second grade. Support Keisha’s mom, who is requesting additional testing by an outside evaluator.

1:00–1:30 P.M.:	Travel back to office. Hunt for parking space.	7:30–8:30 P.M.:	Treatment session with Mr. and Mrs. McDonald and their four children, including 13-year-old Robbie, who has recently been skipping school to hang out with a group of delinquent older teens. The parents suspect he is using drugs and alcohol and may be committing burglaries with the teens. The session focused on bringing Mr. McDonald back into the family system. He travels constantly in his job as a long-distance truck driver and is often gone for days at a time, leaving Mrs. McDonald to manage the household alone, an overwhelming task for a working mother. Robbie, the oldest child, has functioned as the father surrogate, managing the younger children and even disciplining them when his parents are absent. Now that Robbie is becoming a teenager, he is rebelling against these responsibilities by separating himself from the family as much as possible, leading to his involvement with antisocial peers. Reconnecting father and son, who had a very positive relationship when Robbie was younger, removing Robbie from the parenting role, and establishing Mr. and Mrs. McDonald as a couple and as heads of the family are the focus of work with this family.
1:30–2:00 P.M.:	Check messages, return more phone calls, set up next day's home visits.		
2:00–3:00 P.M.:	Write progress notes in Dobson file documenting morning's home-based treatment session. Write up summary of IEP meeting and document next steps in Harold case file.		
3:00–3:30 P.M.:	Travel to el Bassel family home.		
3:30–5:00 P.M.:	Accompany Mr. and Mrs. el Bassel, recent Palestinian immigrants, to the housing office to apply for an emergency transfer because their current neighbors are verbally threatening them because they are Muslims from the Middle East. During travel and waiting time, talk with parents regarding their management of son, age 11, who is having extreme difficulty adjusting to current school placement.		
5:00–5:30 P.M.:	Travel back to office. No problem finding parking.		
5:30–6:00 P.M.:	Work on additional case documentation needed for reimbursement under state contract.		
6:00–7:00 P.M.:	Assist colleague with a domestic violence (DV) crisis unfolding in one of her home-based cases. Her client has called her to report that her boyfriend has beaten her and is threatening to harm her child unless she agrees to move to Tennessee with him. Work phones to obtain help while colleague keeps client talking on phone.	8:30–9:00 P.M.:	Travel to office.
7:00–7:30 P.M.:	Travel to the McDonald family home.	9:00–10:00 P.M.:	Check phone messages, check on colleague with DV crisis, return phone calls, write progress notes on family therapy session with McDonald family, and document next steps with Robbie.

As she thinks about her work in her clients' homes and in the community during this day, the home-based social worker realizes just how much she has learned about her families and their functioning by observing them interacting in their homes and in the school settings. Those fishing poles stacked against the wall near the McDonald's back door led to a discussion of an activity that Robbie and his dad used to enjoy together nearly every weekend and gave her some ideas about how to get them reconnected now. Seeing Carrie's clothes stacked near the pull-out couch in the living room said everything about the girl's

feelings of being a third wheel in her mom's new relationship and gave the family something to talk about in terms of the current apartment's physical space and need for privacy of a teenaged girl. Tasking Anna, Ellie, and Carrie with looking together for a new apartment might be a positive experience that helps to reorganize the family system. The home-based social worker smiled to herself as she thought about how satisfying it was to work with families to help them change their dynamics and move forward in a more positive direction. Whew, what a day!

INTRODUCTION TO HOME-BASED SERVICES

Social work has a long tradition of home-based service delivery, dating back over one hundred years to the friendly visitors of the Charity Organization Society. Although much has changed since that time with regard to knowledge for practice with individuals, families, and children in their own homes, these earliest social workers, like present-day practitioners, recognized that engaging with family members in the context of their daily lives greatly enriched their understanding of the forces that influence current functioning and of the strengths and resources that may be engaged to bring about change.

In the first textbook for training aspiring social workers, *Social Diagnosis*, published in 1917, Mary Richmond presented her arguments in support of working with clients in their own homes: "(a) Its challenge to the case worker at the outset to establish a human relation ... (b) Its avoidance of the need of so many questions, some of which are answered unasked by the communicative hostess and by her surroundings. To the quiet observer, the photographs on the wall ... the household arrangements are all eloquent. And far more revealing than these material items are the apparent relations of the members of the household to one another—the whole atmosphere of

the home; (c) Its provision of natural openings for a frank exchange of experiences (p. 107)."

A review of the current literature on home-based practice reveals that not much has changed since Mary Richmond wrote these words. The value of working with clients in their own homes still emphasizes the importance of establishing a working relationship or "helping alliance" and the greater ease with which the therapeutic relationship develops when the client is in familiar surroundings (Damashek, Doughty, Ware, & Silovsky, 2011; Johnson, Wright, & Ketring, 2002; Thompson, Bender, Windsor, & Flynn, 2009).

Home-based work provides a ready window into the daily lives of clients. Although it may be possible to keep up a pretense that all is well for an hour a week in an out-patient clinic, it is much more difficult to hide evidence of clinical depression or ongoing substance abuse when one's living environment is filthy and in disarray. It is possible for the home-based social worker to understand quickly why a child is failing in school when there is no time or space set aside in a cramped and noisy apartment for homework, where the television blares 18 hours a day, and where no adult takes responsibility for ensuring that homework is done correctly.

The DelBlasio family consisted of Rachel, a 33-year-old mother, and her 10 children ranging in age from 3 months to 14 years. The identified

patient in the family was 9-year-old Billy, who was sexually molested by a 26-year-old cousin. Billy revealed the molestation to a school nurse and Child Protective Services (CPS) was notified. The case was referred by CPS to a home-based family treatment program in an effort to strengthen the family's functioning and prevent an out-of-home placement for Billy.

When the home-based social worker, Susan, arrived at the DelBlasio home, she found a mom, Rachel, who was reluctant to become involved in treatment and a living environment that was chaotic at best. Cockroaches scurried across the trash-strewn floor. At the first family session, it was clear that the older two children, both girls, were carrying a great deal of the responsibility for managing the home and younger children and that Rachel suffered from severe depression, unable to get out of bed to get her children off to school most days. The extreme attention seeking behavior of the younger children with Susan suggested emotional neglect.

Rachel insisted that she could handle the situation with Billy on her own by confronting the perpetrator's mother and not allowing Billy to have any further contact with his cousin. Efforts to help Rachel help Billy with the emotional effects of the abuse were met with stubborn denial. After a few home visits, Billy took matters into his own hands by requesting to meet with Susan alone. He led her into the bedroom he shared with five of his siblings. The six children all slept together on two queen-sized mattresses pushed together on the floor.

Small for his age and rail thin, Billy summoned all of his strength to push a large dresser up against the bedroom door to keep out his brothers and sisters who banged at the door repeatedly, begging to come into the room to see what was going on. Billy motioned for Susan to sit on the floor where cockroaches scurried about. Feeling her commitment to the child was being tested, she joined him in his life at that moment, and the two of them sat together, flicking the bugs away, while Billy talked of his life at home, at school, and of the sexual molestation experience. In a clinic setting, without this opportunity to enter into the child's life as he lived it on a daily basis, it is doubtful that the social worker could have gained such a full and complete understanding of the client in his situation so quickly.

As Mary Richmond noted in 1917, home-based work also provides an essential opportunity to observe the interactions of those living in the home with one another. Very often when a child is referred by a school or medical provider to a

mental health center for assessment and treatment, only the mother and, occasionally, a sibling or two accompany the child to the clinic. Yet, as family social workers have noted for years, it is nearly impossible to understand the functioning of an individual family member, especially a child, without also understanding the dynamics of family interaction. What better way to observe these dynamics firsthand than by providing home-based services? What better way to find out that a family's life together is totally disrupted by the demands of caring for grandpa who is 87 years old and has advanced Alzheimer's disease? What better way to find out that mother's paramour is a violent and abusive man who has punched holes in the apartment wall and kicked the family dog when the children's noisy play awakened him? What better way to discover that the parents of a boy diagnosed with ADHD are uncertain how to manage his frequently disruptive behavior and that their inability to set appropriate limits has allowed the child to "rule the roost?" Although an outpatient clinician may learn of any of these situations in due course, the home-based practitioner witnesses the interaction immediately, and firsthand, and understands implicitly its impact on the family system and on individual family members.

Carlos, a Spanish-speaking social worker in a home-based program, was assigned to a family of Puerto Rican descent, the Rodriquez family, whose 13-year-old son, Jose, had been given the diagnosis of Bi-Polar Disorder. The parents were confused about the meaning of this diagnosis and understandably concerned about its implications for the future of their child. As Carlos met with Mr. and Mrs. Rodriquez, Jose, his older brother, 15, and younger brother, 10, in their own home, a picture began to emerge of loving, well-meaning parents who were frightened by their middle son's frequent rages, which seemed to occur primarily when Jose was asked to carry out a chore such as cleaning his room or completing his homework. During these rages, which Mr. and Mrs. Rodriquez attributed to his Bi-Polar illness, Jose would appear out-of-control, throwing things and breaking up furnishings. Once, when asked to go to his room when he became enraged, Jose refused and proceeded to kick the bedroom door in.

In discussing their parenting styles, his mother readily admitted that she was intimidated by Jose when he was enraged and would retreat to her room until the storm was over. His father, who was a very large man, saw his role as de-escalating Jose's rages through physical intimidation, although

he denied ever using actual physical force with the boy. Neither parent believed in setting limits with their sons, or in having a set structure in the home, such as specific times for homework or family meals. Both felt that this more laissez-faire approach to parenting had worked well with their other two boys and did not understand why Jose could not handle it also, again attributing his behavior problems to his illness.

It was quickly apparent from observing the family in their own home that Jose had learned how to use his illness to control his parents to his own benefit. Helping Mr. and Mrs. Rodriguez examine their ineffective laissez-faire parenting style and identify alternative approaches in which they both could participate was a clear focus of the work with this family. In addition, the importance of structure to a vulnerable child like Jose was part of educating the family about Bi-Polar Disorder. Setting up a schedule for homework and meal-times, as well as for completing chores around the house, would help Jose anticipate in advance what he needed to do rather than always feeling like “things were coming at him out of the blue” as he expressed in one family session. Trying alternative ways of doing things, while receiving the support and encouragement of their home-based worker, helped the Rodriguez family, which had many inherent strengths including their commitment to one another, make positive changes that benefited all members of the family system.

In *Social Diagnosis*, Mary Richmond also noted that home-based practice provides a multitude of opportunities for “frank exchanges.” The home environment is replete with “conversation starters” for clinicians who bring aspects of the environment into the therapeutic process (Macchi & O’Connor, 2010; Reiter, 2006). A picture of mother’s parents on the mantel can initiate a discussion of mother’s childhood, revealing that her father was a longtime alcoholic who was emotionally unavailable and that her mother compensated for his emotional absence by becoming emotionally enmeshed with her only child. This may help the home-based clinician better understand her client’s difficulties in developing healthy intimate partner relationships and her inability to set appropriate limits and expectations for her 11-year-old son. Helping a mother to relate her own childhood experiences to her current parenting practices, using elements available in the home environment such as the picture on the mantel, is a strategy available to home-based clinicians that is seldom accessible to practitioners in clinic settings.

Another important advantage of home-based practice is its ability to deliver services to clients who might otherwise be inaccessible to social work clinicians (Boyd-Franklin & Bry, 2000; Carrasco & Fox, 2012; Chaffin, Hecht, Bard, Silovsky, & Beasley, 2012). One of the first home-based programs described in the contemporary social work literature grew out of a study in the 1950s by social workers in St. Paul, Minnesota, who had observed that a small number of families created a high proportion of the demands on the child welfare system there. These families demonstrated a myriad of difficulties including domestic violence, substance abuse, mental health problems, as well as child abuse and neglect. Engaging these families in efforts to address their difficulties and make substantial changes in their often-chaotic functioning proved frustrating and futile for the St. Paul social workers until it was decided to take services to these families in their own homes rather than wait for them to seek and accept therapeutic services on their own. In this way, many of these families were engaged in treatment and changes in their overall functioning were observed.

The St. Paul Family-Centered Project, as it was called, and others like it that sprang up around the country in the ensuing years, focused on families known to the child welfare system, and worked to ensure family stability and improve family functioning in order to keep children at home and out of foster care. These early home-based programs contributed to the development of what came to be known as family preservation services. Although there were several different models of family preservation services, perhaps the most widely known and utilized was Homebuilders, developed by two psychologists in Tacoma, Washington, in the early 1970s.

The Homebuilders model is a brief, six-week intervention that works with families in crisis who are about to lose their children to foster care (Kinney, Haapala, & Booth, 1991). The work is done almost entirely in the family’s home or in other community locations such as schools or work settings. Homebuilders clinicians carry very small caseloads, are available on call 24 hours a day, and spend as much time as necessary working with the family in the home, especially during the first days or weeks of treatment when the family is in a crisis state. In addition to crisis theory, the model draws heavily on social learning theory to bring about changes in families’ functioning.

Evaluations of the Homebuilders model suggested that it was effective in reducing the number of out-of-home placements of children as compared with usual child welfare services. Homebuilders participation also shortened the length of foster care placement and facilitated children's return to their families (Schwartz, 1995). During the 1980s and 1990s, variations on the Homebuilders model were adopted throughout the United States by state child welfare agencies as a result of federal legislation providing funding to states to strengthen families and prevent out of home placement of children. Home-based services intended to prevent child placement, and to reunify families when placement has occurred, are currently a staple of most state child welfare systems (Macchi & O'Connor, 2010).

Home-based treatment models have been developed to serve families and children involved with the juvenile justice and mental health systems as well as with child welfare. Perhaps the best known home-based model for working with delinquent youth and their families is Multisystemic Therapy, or MST. MST was developed in the early 1990s by Scott Henggeler and his colleagues at the Medical College of the University of South Carolina to address the externalizing behaviors of conduct disordered youth (Borduin, Mann, Cone, et al., 1995). As the name of the model suggests, the focus of treatment is on the multiple systems involved in delinquent behavior: the youth, the family, peers, and community institutions such as the school. MST clinicians work primarily with youth and their families in their own homes and, as in the Homebuilders model, they carry low caseloads, are available 24 hours a day, seven days a week to their clients, and the service is time-limited (3–5 months). Unlike Homebuilders, but similar to many other home-based intervention models, MST draws heavily for its theoretical base and practice approach on family systems theory and its applications in family therapy (Borduin, Mann, Cone, et al., 1995).

The growth of the family therapy movement in the 1960s and 1970s gave social workers working with families in their own homes new tools and strategies with which to approach home-based work. Family systems theory, which underpinned the family therapy movement, guided the interpretation of family dynamics. For example, Murray Bowen, one of the preeminent early theoreticians and family therapy practitioners, gave home-based clinicians working with

families an intergenerational perspective on family functioning, now captured so eloquently by the intergenerational family genogram, a staple in the armamentarium of the home-based practitioner (McGoldrick, Gerson, & Shellenberger, 1999).

From family therapist Salvador Minuchin, working at the Philadelphia Child Guidance Clinic, came the focus on family structure and its importance in understanding and treating families in which the parents had lost control of their children. Minuchin's structural family therapy approach taught home-based practitioners to observe the family's structure and seek to understand the patterns of alliances and coalitions that color a family's daily life (Lindblad-Goldberg, Dore, & Stern, 1998). For instance, in families with a delinquent son or daughter, clinicians often see adults who have given up on authoritative parenting for a variety of reasons, which might include their own substance abuse, clinical depression, marital conflict, or simply being overwhelmed by life stressors. Helping the adults in such families address their own difficulties in order to resume their role as parent is a frequent focus of structural family therapy (Lindblad-Goldberg et al., 1998).

Jay Haley, Chloe Madanes, and other strategic family therapists gave home-based clinicians useful tools such as enactments, or brief playlets, to illuminate a specific sequence of events in the family, such as having the children in the family act out what happens when father gives an order to teenage son that is ignored, or what happens when the family goes on an outing together. These dramatizations of incidents in family life highlight commonly occurring negative interactions among family members as in no other way. They also give the home-based practitioner substantive material with which to initiate an alternative behavioral sequence to bring about change. If a particular sequence of events in a family customarily ends badly for some or all of the participants, illustrating this with the family, then having the family brainstorm and act out an alternative sequence has the potential for meeting the needs of all participants. And, rehearsing the sequence in an in-home session makes it more likely that family members will remember and try it out the next time the opportunity arises.

Family therapy, no matter what the theoretical orientation or school of thought, has given home-based practitioners significant permission to use themselves creatively to bring about

change in a family's problematic ways of functioning. Doing something differently, whether its interacting in a new way with a partner or child, or accessing new community resources together with a parent and observing how the parent interacts with a resource provider in a community setting, differentiates home-based from clinic-based practice. In traditional clinic-based practice, the focus of interaction between the social worker and client is limited to what the client brings into the session, which represents his construction of the reality of his life. Helping the client construct a more accurate interpretation can take many weeks or months of treatment. Home-based work speeds this process greatly by giving the clinician immediate access to alternative perspectives, which he can then use to help the client experience her situation in a different way.

In addition to home-based interventions with families in the child welfare and juvenile justice systems, this approach has been extended to families in the mental health system. Spurred in the early 1980s by the federal Child and Adolescent Service System Program (CASSP) initiative, which funded development of new models of community-based children's mental health services, the state of Pennsylvania invested in developing and implementing a model of home-based services that treated children's mental health needs in the context of their families (Lindblad-Goldberg et al., 1998). The Pennsylvania model was based on an ecological and systemic understanding of factors that contributed to serious emotional and behavioral disturbances in children and drew upon structural family therapy to inform its intervention. All of the treatment was done in the home and community and was intended to prevent psychiatric hospitalization and long-term residential care.

One of the systems concepts that the Pennsylvania home-based model emphasized is that of circular causality. This concept focuses clinicians' attention on the circular feedback loops of communication and behavior among family members. These highlight repetitive patterns of family interaction that illustrate the structural difficulties the family is experiencing. For example, a mother subtly counteracts every request her husband makes of their son by negating his authority with the child, or two siblings enter into a covert alliance to act out behaviorally to draw a response from their mother who is over-involved emotionally with the third child

in the family, who suffers from a chronic illness. This way of understanding family functioning moves away from the practice of blaming specific family members for problems in the family and provides the clinician with a point of intervention and change. Circular feedback loops become apparent very quickly when a clinician spends time with the family in the comfort zone of their own home, and opportunities to challenge these customary ways of behaving are readily available.

Other models of home-based treatment for children and families involved with the mental health system have been developed as well. Beginning in the mid-1990s, clinicians at the Yale Child Study Center have developed and tested a manualized model of in-home psychiatric services called IICAPS (Intensive In-home Child and Adolescent Psychiatric Services) (Woolston, Adnopo, & Berkowitz, 2007). The model provides for home-based assessment and treatment planning, as well as brief family therapy, parent education in child behavior management, social skills development for children, and intervention with environmental resources to build support for the child and family in the community. Each phase of the intervention process is well-defined and is accompanied by a series of measures of its effectiveness. IICAPS is a team-delivered intervention. Clinicians are expected to spend up to five hours per week in the family home and the model calls for a six-month treatment duration. IICAPS is currently a Medicaid-approved treatment for children with DSM Axis I and Axis II diagnoses in the state of Connecticut.

Another home-based intervention designed to support children and adolescents with serious emotional disturbances in their own homes and communities is the Wrap-around model, in which social workers work intensively with families to identify and put in place all of the resources and services needed to maximize the child's psychosocial functioning. In this model, the treatment plan is developed collaboratively by a care planning team that includes social workers from the Wrap-around program, one of whom acts as the primary care coordinator; representatives of community resources such as a school social worker or therapist from the local outpatient mental health clinic; members of the child's current household and others the family may wish to include such as grandparents, close friends or neighbors; and representatives of the referring agency, frequently the juvenile court or state child welfare agency. A primary focus of the

Wrap-around approach is to end the fragmented way services are often provided to children with serious emotional and behavior disturbances and their families.

The Wrap-around model emphasizes honoring the family's voice in care planning. Part of the care coordinator's role is to ensure that team meetings are safe and blame-free for all participants. There is also an emphasis on ensuring that cultural differences are acknowledged and respected in the Wrap-around treatment process. The care planning team is charged with developing the goals and strategies necessary to achieve the outcomes the family seeks with regard to maintaining the child in the home and community. These goals often include helping parents or other family members address their own problems or issues that impact the family's ability to provide the care the child needs.

In recent years, as increased attention has been paid to preventing social and emotional difficulties in young children, particularly as they impact a child's capacity to learn in school, home-based programs for at-risk infants and toddlers have sprung up across the United States. Nationally, programs such as Early Head Start and Healthy Families focus on the functioning of the whole family and may rely on social workers specially trained in early child development to engage, assess, and treat vulnerable families in their own homes (Love, Kisker, Ross, Constantine, Boller et al., 2005; Rodriguez, Dumont, Mitchell-Herzfeld, Walden, & Greene, 2010). A recent national study of Early Head Start found that families and children treated in their own homes, either fully or in combination with center-based treatment, fared significantly better than those who received only center-based care (Love et al., 2005).

Building on growing recognition of the importance of early intervention for very young children already evidencing emotional and behavioral difficulties, home-based programs to treat these youngsters in the context of their homes and families have sprung up across the country. One example of such a program is the Parenting Young Children model, which works with parents to strengthen the child's pro-social behaviors and reduce challenging behaviors in the home through parent education, skill demonstration, and coaching by the home-based clinician (Fox, Mattek, & Gresl, 2013). Studies of this model have found that low-income parents can acquire the necessary skills to help their children

in about eight treatment sessions and that children's problem behaviors can be observed to improve dramatically as a result (Carrasco & Fox, 2012).

As Mary Richmond recognized early in the profession's development, home-based services have historically been a key component of social work practice in a variety of domains. Social workers, with their eco-systemic understanding of human functioning and their trained capacity to interpret person/situation interaction, are ideally suited to be home-based clinicians. Social workers have long appreciated the importance of observing and engaging their clients where they live, in their own homes and community settings. Contemporary home-based programs build on the unique knowledge and skills of social workers developed and refined in over one hundred years of home-based practice to help individuals, families, and children achieve their goals and improve their psychosocial functioning.

10 Social Work Practice in Disasters

Daphne S. Cain

SOCIAL WORK INTERVENTION IN DISASTERS

The History of Social Work Intervention in Disasters

Although interest in traumatic reactions and social support following disaster has been evident in the American literature for decades, social work practices and intervention during and subsequent to disaster did not receive much attention until the 1990s and Hurricane Andrew (August

1992) (Cherry & Cherry, 1996; Sanders, Bowie, & Bowie, 2003); The Great Flood of 1993 (Sundet & Mermelstein, 1996); and the Oklahoma City Bombing (April 1995) (Levine, 1996; North, Tivis, McMillen, Pfefferbaum et al., 2002). Over the past two decades, social work intervention in disaster has become a specialization with intense interest on best practices and evidence-informed intervention. This is evident in the considerable social work literature from the 9/11 Attacks (September 2001) (Adams, Figley, & Boscarino,

2008; Bauwens & Tosone, 2010; Henley, Marshall, & Vetter, 2010; Pulido, 2012), and Hurricane Katrina (August 2005) (Bliss & Meehan, 2008; Cain, Plummer, Fisher, & Bankston, 2010; Coker et al., 2006; Elliott & Pais, 2006; Hoffpauir & Woodruff, 2008; Legerski, Vernberg, & Noland, 2012; Plummer, Cain, Fisher, & Bankston, 2008; Pyles, 2007; Terranova, Boxer, & Morris, 2009). Additionally, there is growing interest in international social work intervention in disaster. Rapid population growth, unplanned urbanization and environmental degradation (especially in disaster-prone and impoverished areas), and climate change have impacted the frequency and severity of natural disasters globally (American Red Cross, 2013). Subsequently, social work has responded to the widespread flooding, earthquakes, tsunamis, and national conflicts and hostilities around the world (Aziz & Aslam, 2012; Bourassa, 2009; Busaspathumrong, 2006; Dominelli, 2013; Goenjian, 1993; Huang, Zhou, & Wei, 2011; Javadian, 2007; Nikku, 2012; Pockett, 2006; Takahashi, Lijima, Kuzuya, Hattori, Yokono, & Morimoto, 2011; Yanay & Benjamin, 2005).

The National Association of Social Workers (NASW) adopted a national disaster policy in 2000, which asserts that, among “all the allied health and human services professionals, social work is uniquely suited to interpret the disaster context, to advocate for effective services, and to provide leadership in essential collaborations among institutions and other organizations” (NASW Press, 2000, p. 4). The social work profession is particularly appropriate for disaster work because of our holistic epistemology at the generalist social work level, our ecological framework and emphasis on the person-in-environment, our values regarding respect for diversity and empowerment and the role of relationships in the delivery of successful interventions, and our strengths-based approach (Bliss & Meehan, 2008; Cronin, Ryan, & Brier, 2007; Rowlands, 2013). More specifically, social workers are trained to apply a community oriented strengths perspective that builds upon existing capacity in a disaster affected area (Dominelli, 2013; Mathbor, 2007; Pyles, 2007; Rowlands, 2013; Tan, 2013).

DISASTER REACTIONS

Although post-disaster reactions and behaviors may appear to be symptoms of psychopathology, in fact, many of these reactions are normal

in a crisis state. These reactions may include symptoms of shock, exhaustion, disorientation, irrationality, racing thoughts, and uncontrollable emotions (Brymer, Jacobs, Layne, Pynoos, Ruzek, Steinberg, Vernberg, & Watson, 2006). Most disaster survivors recover from initial reactions and symptoms with little or no psychological intervention (Norris, Friedman, Watson, Byrne, Diaz, & Kaniasty, 2002). However, some survivors have more acute reactions that may develop into Post Traumatic Stress Disorder (PTSD) or another major psychiatric disorder, including major depressive disorder, dysthymia, agoraphobia, specific phobia, social anxiety disorder, and panic disorder (Aziz & Aslam, 2012; Carroll, Balogh, Morbey, & Araoz, 2010; Hussain, Weisaeth, & Heir, 2011). Individuals who are directly impacted by disaster—those who have lost property or a loved one, or who have been injured or dislocated—are more at risk for developing long-term psychosocial conditions such as PTSD (Kreuger & Stretch, 2003).

TYPES OF DISASTER AND BARRIERS TO DISASTER WORK

Disasters can be defined as “events that disable community social functioning” (Soliman & Rogge, 2002, p. 2). There are natural disasters (tornados, hurricanes, earthquakes, fires, and floods), human-initiated disasters (air disasters, nuclear reactor explosions), and human-initiated disasters that are intentionally caused (war, terrorism, shootings). And, while there is extensive research into natural and human-initiated disasters, there is limited research specific to social work responses to such things as terrorism (Sweifach, LaPorte, & Linzer, 2010).

At the same time, there are many barriers to social work interventions during and subsequent to disasters. These include a lack of disaster/crisis training and preparedness among workers, a lack of adequate training in cultural competence, and contextual challenges including the characteristics and location of the incident(s) and the scale of destruction (Davis, 2013; Legerski, Vernberg, & Noland, 2012).

CULTURE AND DISASTER

Being culturally sensitive is crucial in disaster work. In particular, transnational disaster social

workers need to be highly sensitive to ethical cultural adaptation standards in order to avert cross-cultural errors and/or harm (Bourassa, 2009; Puig & Glynn, 2003; Rowlands, 2013; Shah, 2011; Sommers-Flanagan, 2007). And, research reveals that tailoring social work services to meet the needs of diverse populations effected by disaster is associated with a greater penetration and utilization of services (Rosen, Greene, Young, & Norris, 2010).

VULNERABLE POPULATIONS

Some populations are at greater risk for psychosocial distress following disaster, and it appears that members of vulnerable populations may be less prepared for disaster (Baker, Baker, & Flagg, 2012). Vulnerable populations include children (Brymer et al.; Hayashi & Tomita, 2012), individuals who have been injured or are medically frail, older survivors (Barusch, 2011; Torgusen & Kosberg, 2006), individuals with serious mental illness, individuals with disabilities (Evans, Patt, Giosan, Spielman, & Difede, 2009; Fox, White, Rooney, & Cahill, 2010), those with substance abuse issues, pregnant women and mothers with small children and infants, and disaster response personnel including social workers (Adams, Figley, & Boscarino, 2008; Amaratunga & O'Sullivan, 2006; Brymer et al.). Additionally, marginalized, economically disadvantaged, and minority communities tend to be at greater risk following disaster due in part to the experiences of prior traumatic events and a lack of access to disaster services (Elliott & Pais, 2006; Zakour & Harrell, 2003). Finally, a sense of mistrust, a lack of knowledge about disaster relief services, stigma, and fear may make these most vulnerable populations—these marginalized groups—the least likely to take advantage of resources (Brymer et al.; National Medical Association, 2005; Quinn, 2008).

Children and Adolescents

When working with children it is important to be developmentally appropriate, to be sensitive to cultural differences, and to engage the child's adaptive and positive coping functioning ability (Ager, Stark, Akesson, & Boothby, 2010; Plummer, Cain, Fisher, & Bankston, 2008). Providing counseling services in the school system is an excellent way to reach children and families who have been affected by disaster (Kreuger & Stretch, 2003).

Around the world, disasters have forced children into armed conflict, prostitution, and drug trafficking (Nikku, 2012; Phua, 2008). Immediately after a disaster, attend to children who have been separated from their caregivers because these children are at risk for additional exploitation and psychological harm. Reconnect children with caregivers as quickly as possible, and notify appropriate authorities if caregivers cannot be located. If possible, establish a separate, child-friendly space for unaccompanied children and assign appropriate and trained personnel to staff it. Additionally, provide caregivers with information regarding typical childhood reactions to disaster including fear and anxiety, sleep disturbances, eating problems, irritability, and sadness (Speier, 2000), and refer children and families to more intensive treatment as needed.

Some specific suggestions for working with children include:

- (1) Sit or crouch at the child's eye level
- (2) Help school-aged children verbalize their feelings, concerns, and questions by using simple labels (e.g., mad, sad, scared, worried), but avoid extreme words (e.g., terrified or horrified).
- (3) Use reflective listening skills and check with the child to make sure you understand what they are attempting to communicate.
- (4) Be aware that children may regress developmentally in behavior and/or language.
- (5) Be developmentally appropriate when talking with children—use direct and simple language.
- (6) Talk to adolescents “adult-to-adult” to signify that you respect their feelings, concerns, and questions.
- (7) Reinforce these techniques with parents and caregivers to help them provide appropriate support to their children (Brymer et al., p. 9).

Older Adults

When working with older adults:

- (1) B Respect that they have both strengths and vulnerabilities and realize that many older adults have acquired effective coping skills over their lifetimes and are capable of negotiating adversities.
- (2) Especially for those with hearing difficulties, speak clearly and in a low pitch.

- (3) Do not make assumptions based only on physical appearance or age because some difficulties could be attributed to disaster-related illness (e.g., confusion may be caused by disaster-related disorientation due to changes in the individual's surroundings or environment, poor vision or hearing, dehydration, sleep deprivation, a medical condition or medication effects, or social isolation).
- (4) An older adult with a mental health disability may have increased needs due to confusion and should be referred for a mental health consultation or referral as soon as possible (Brymer et al., p. 9; Takahashi et al., 2011).

Survivors with Disabilities

When working with survivors with disabilities:

- (1) Try to provide assistance in an area with as little distraction (noise or other stimulation) as possible.
- (2) Address the survivor directly rather than the caretaker unless direct communication is too difficult.
- (3) When communication is impaired (hearing, speech, memory) speak simply and slowly.
- (4) If unsure of how to assist, ask, "How can I assist you?" or "What can I do to help?" and trust what the person tells you; focus on strengths and when possible, enable the person to be self-sufficient.
- (5) Be mindful of visually impaired individuals and offer your arm to assist them move about in unfamiliar surroundings.
- (6) Offer to write down information and make arrangements for individuals to receive information in writing.
- (7) Keep essential aids (medications, oxygen tank, respiratory equipment, and wheelchair) with the person (Brymer et al., pp. 9–10).

Missing Family Members

Survivors who have a missing family member, or who have a family member or close friend who has died, may require more intensive attention. Attempt to reconnect missing family members as soon as possible. The American Red Cross can be of assistance when reconnecting family, as well as official radio and

television channels and the local police. What has been learned from previous disasters such as 9/11 and Hurricane Katrina is that social media—including text messaging, Facebook, and Twitter—may be the only means of communication during disaster (Barr, 2011; Cain & Barthelemy, 2008).

When working with survivors who have experienced the death of a loved one:

- (1) Reassure them that what they are experiencing is understandable and expectable.
- (2) Use the deceased person's name.
- (3) Let them know that they will likely continue to experience feelings of sadness, loneliness, and/or anger.
- (4) Refer grieving individuals to more intensive psychological services when requested or as needed (Brymer et al., p. 36).

EVIDENCE-INFORMED DISASTER SOCIAL WORK: PSYCHOLOGICAL FIRST AID

Psychological First Aid (PFA) is an evidence-informed intervention approach designed to assist children, adolescents, adults, and families subsequent to disaster (Brymer et al.; Cain et al., 2010). PFA is supported by disaster mental health experts as the "acute intervention of choice" when responding to the psychosocial needs of children, adults, and families in post-disaster distress (Brymer et al., p. 5), and is listed among the promising practices by the National Child Traumatic Stress Network (n.d.). PFA is designed to reduce the initial distress caused by disaster and to foster both short- and long-term adaptive functioning and coping (Brymer et al.). The principles and techniques of PFA are consistent with evidence-informed research on risk and resilience following trauma, can be implemented in diverse field settings, take a lifespan perspective with regard to theory and technique, and are culturally informed (Brymer et al.). The basic objectives of PFA include:

- (1) Establishing a nonintrusive and compassionate human connection with survivors
- (2) Enhancing safety and providing physical and emotional comfort

- (3) Calming and orienting physically and emotionally overwhelmed or distraught survivors
- (4) Assessing immediate needs and concerns
- (5) Offering practical assistance and information to address immediate needs and concerns
- (6) Connecting survivors with social support networks such as family, friends, and community helping resources as soon as possible
- (7) Supporting adaptive coping—acknowledging coping efforts and strengths, and empowering and encouraging survivors to take an active role in their recovery
- (8) Providing information that can help survivors cope with the psychosocial impact of disasters (Brymer et al., pp. 6–7).

Behaviors to avoid include:

- (1) Do not make assumptions about survivors or what they may be experiencing or have gone through.
- (2) Do not assume that everyone exposed to a disaster will be traumatized.
- (3) Do not patronize survivors or focus on their helplessness, weakness, mistakes, or disability.
- (4) Do not assume that all survivors will want or need to talk; being physically available in a supportive and calm manner may be all that is needed to make survivors feel safe and enhance their abilities to cope.
- (5) Do not “debrief” survivors by asking for details of what happened.
- (6) Do not speculate or offer potentially inaccurate information (Brymer et al., p. 8).

Prior to engaging in PFA, social workers should be trained in disaster mental health, be knowledgeable about the nature of the disaster itself and current circumstances, including the emergency management setting they will be entering, and the types and availability of support services for survivors. Social workers should consider their level of comfort with disaster work, their current health, and their family and work circumstances, as well as be mindful to engage in appropriate self-care (Brymer et al.). Disaster social work and PFA typically take place within the confines of an emergency management setting that is overseen by such agencies as the American Red Cross or the Federal Emergency

Management Agency (FEMA). It is crucial that social workers work within the framework of the emergency management agency authorized to manage the site—all communication and the coordination of services must be coordinated with authorized personnel. This is particularly important for the dissemination of accurate information that is often critical to reducing distress and promoting adaptive coping among survivors (Brymer et al.).

When initially providing disaster assistance, focus your attention on how survivors are reacting and interacting in their environment. Individuals may need immediate assistance when they exhibit signs of acute distress—disorientation; confusion; agitation, irritability, or anger; panic; or apathy (Brymer et al.). It is important when providing assistance to survivors that you as the social worker model appropriate behavior. You should remain calm, focused, mindful, thoughtful, and hopeful. Survivors can take cues from your calm, thoughtful, future-oriented behavior. It is also critical that social workers be sensitive to cultural, ethnic, religious, racial, and language differences in disaster (Brymer et al.). Be aware of your own values and prejudices and how these may influence your ability to serve survivors. Helping to reestablish and maintain customs, traditions, rituals, family structure, gender roles, and social bonds can be very therapeutic in assisting individuals and families to cope with disaster (Brymer et al.).

PFA CORE ACTIONS

Contact and Engagement

“Goal: To respond to contacts initiated by survivors, or to initiate contacts in a non-intrusive, compassionate, and helpful manner” (Brymer et al., p. 23).

The first contact with a survivor is important; be respectful, compassionate, and culturally sensitive. Respond first to those who seek you out. Introduce yourself and describe your role. Ask permission to talk with the survivor and address adult survivors using their last names (e.g., Mr. or Ms. Smith). Try to provide the survivor with as much privacy as possible. Speak softly and calmly and provide the survivor with your undivided attention. Ask the survivor first about immediate needs or problems that need immediate attention. The survivor’s immediate medical condition

should take priority. Prior to communicating with a child or adolescent, seek permission first from a parent or caregiver. As with all social work, client confidentiality is crucial. Mandated reporting laws and the Health Insurance Portability and Accountability Act (HIPAA) remain in effect during disaster relief work. Additionally, there are specific disaster and terrorism provisions within HIPAA (U.S. Department of Health & Human Services Emergency Preparedness Planning and Response, n.d.) with which disaster social workers should be familiar (Brymer et al.).

Safety and Comfort

“Goal: To enhance immediate and ongoing safety, and provide physical and emotional comfort” (Brymer et al., p. 27).

Restoring a sense of safety and promoting comfort are important goals following disaster. Make sure that the physical environment is as safe as possible. When working with survivors, do things that are active (not passive waiting), practical (using available resources), and familiar (draw on the past experiences of survivors) (Brymer et al.). Provide current and accurate information and avoid hearsay information or information that could be inaccurate or excessively upsetting. Inquire about health-related issues and current medication needs, as well as any needs related to tasks of daily living. Contact relatives and caregivers to assist with the immediate needs of survivors, and be alert to signs of suicidal or homicidal ideation and seek immediate medical assistance if these concerns are present (Brymer et al.).

When survivors are ready—when they are able to comprehend what is being stated and are ready to hear the content of messages—begin to reorient them by providing **accurate** information about disaster response activities and services: what to do next; what is being done to assist them; what is currently known about the unfolding event; available services; common stress reactions; and self-care, family care, and coping (Brymer et al.).

Encourage survivors to participate in making their environment comfortable (adaptive coping), and help them to soothe and comfort themselves and those around them (active coping). Promote positive group and social engagement as much as possible (Brymer et al.). Protect survivors from

additional traumatic experiences and trauma reminders including extended media coverage of the event. This is especially true for children who are at high risk for further traumatization from prolonged media exposure (Schuster et al., 2001).

Survivors may turn to their religious beliefs when reflecting on the disaster and their disaster experiences (Cain & Barthelemy, 2008). They may use religious language to discuss what has happened to them and their family, or want to engage in religious practices to cope. Listening and attending to these needs in a nonjudgmental and supportive manner may be necessary. In addition, referring those survivors who practice a religion to clergy members of their faith can be helpful.

Stabilization

“Goal: To calm and orient emotionally overwhelmed or disoriented survivors” (Brymer et al., p. 49).

You may want to enlist the assistance of the survivor’s family members or close friends in orienting them and providing emotional comfort. And, while medication is not recommended as a routine way to cope with acute traumatic stress reactions, medication may be necessary when the survivor is experiencing extreme reactions such as agitation, panic, psychosis, or is a danger to themselves or others. When these reactions are evident, consult with a physician immediately. Additionally, medication may be helpful to treat specific symptoms associated with disaster such as insomnia and panic attacks (Brymer et al.).

Information Gathering

“Goal: To identify immediate needs and concerns, gather additional information, and tailor Psychological First Aid interventions” (Brymer et al., p. 57).

Social work interventions should be adapted to meet the needs of specific survivors. In order to provide tailored intervention, specific information must be gathered. Information that needs to be collected includes:

- The nature and severity of the disaster experience
- Death of a loved one

- Concerns regarding immediate post-disaster circumstances and any ongoing threat
- Separation from or concern about the safety of loved ones
- Physical illness, mental health conditions, need for medications
- Losses (home, school, neighborhood, business, personal property, and pets)
- Extreme feelings of guilt or shame
- Thoughts about causing harm to self or others
- Availability of social support
- Prior alcohol or drug use
- Prior exposure to trauma and death of loved ones
- Specific youth, adult, and family concerns over developmental impact (Brymer et al., pp. 57–62).

This information will allow you to work with the immediate concerns of the survivor and provide you with information that can determine if immediate referral for more intensive services is warranted.

Practical Assistance

“Goal: To offer practical help to survivors in addressing immediate needs and concerns” (Brymer et al., p. 65).

Social work intervention in the immediate aftermath of major incidents is more about orienting survivors and providing practical support, rather than counseling services that may be needed for some survivors later on (Davis, 2013). Indeed, social work case management is frequently neglected while counseling services are more readily available in the immediate aftermath of disaster (Ganesan, 2006). However, immediate attention needs to be paid to the difficulties survivors experience accessing services.

Connection with Social Supports

“Goal: To help establish brief or ongoing contacts with primary support persons and other sources of support, including family members, friends, and community helping resources” (Brymer et al., p. 69).

It is important to connect survivors with primary support persons and community assistance when

needed. Survivors need to feel connected to family and friends, and some may need material or physical assistance that can be found in the community. It can also be helpful for survivors to give back to others and the community so they feel valued, useful, and productive.

Information on Coping

“Goal: To provide information about stress reactions and coping to reduce distress and promote adaptive functioning” (Brymer et al., p. 77).

Many disaster survivors have physical and psychological reactions to the disaster event that cause them alarm and concern, but many of these reactions are normal in a crisis state. Survivors may have intrusive reactions including dreams and flashbacks, avoidance and withdrawal reactions (avoiding reminders of the event, talking about the event, feelings of detachment and numbness), and physical arousal reactions including irritability, angry outbursts, insomnia, and difficulty concentrating (Brymer et al.). It is important to inform survivors that these reactions are normal and that many disaster survivors experience the same things. When reactions and symptoms persist for an extended period of time, however, or begin to interfere with daily life, survivors may need to seek more intensive treatment.

Survivors need to be informed that reminders of the disaster, such as sights, sounds, smells, and specific situations may cause distress. It is also good to discuss anniversary reactions of disaster (Nemeth, Kuriansky, Reeder, Lewis, Marceaux, Whittington, Olivier, May, & Safier, 2012) and how to cope with annual reminders of the disaster event.

Some basic adaptive coping behaviors include talking to another person for support; getting adequate rest, nutrition, and exercise; engaging in positive distracting activities such as sports, hobbies, and reading; maintaining a normal schedule; keeping a journal; and using relaxation methods (Brymer et al.). More maladaptive coping strategies that should be limited include using alcohol or drugs to cope; withdrawal from family, friends, and activities; engaging in risky or dangerous behaviors; excessive working; and overeating (Brymer et al.).

It is very helpful for survivors to reestablish their normal routines as soon as possible, because

this provides structure and can provide comfort, especially for children. Parents may see some regression in behavior and development among children. These regressive behaviors may be a natural reaction to the disaster and should be normalized unless they cause the child significant distress or do not improve over time. Survivors may need to be referred for more intensive treatment should they have substantial anger management issues, highly negative guilt and shame reactions, extended sleep disturbances, or alcohol or substance use issues (Brymer et al.).

Collaborative Services

“Goal: To link survivors with available services needed at the time or in the future” (Brymer et al., p. 93).

Although you may be able to provide for survivors’ immediate needs, many survivors discover that they are in need of additional or more intensive services over time. It is important that survivors know what resources—medical, mental health, social, child welfare, school, drug and alcohol support, senior support, and transportation services—are available for the future.

Worker Self-Care

Secondary Traumatic Stress (STS) is the stress disaster workers may experience as a result of acting as a secondary witness to a traumatic event (Figley, 1995; Naturale, 2007). Figley (1999) defined STS as “the natural, consequent behaviors and emotions resulting from knowledge about a traumatizing event experienced by a significant other. It is the stress resulting from helping or wanting to help a traumatized or suffering person” (p. 10). Symptoms of STS include anxiety, stress, disturbed sleep, anger/rage, fear, social phobia, isolation, perceptual distortions, extreme protectiveness, feeling overwhelmed, feeling depleted, helplessness, and hopelessness, (Arvay & Uhlmann, 1995; Cornille & Myers, 1999; Crothers, 1995; Figley, 1995; Naturale, 2007; Yassen, 1995). General physical conditions associated with STS are increased arousal, sweating, rapid heart rate, breathing difficulties, somatic reactions, dizziness, and an impaired immune system (American Psychiatric Association, 2004; Yassen, 1995). Recognized as an occupational hazard, current research indicates that mental

health professionals working with traumatized individuals are at risk for STS (Boscarino, Figley, & Adams, 2004; Bride, 2007).

Debriefing has been the recommended therapeutic approach to treat STS (Arvay, 2001); however, the scientific community is scrutinizing this widely used method (Naturale, 2007). Indeed, research indicates that debriefing may cause more harm than help (Phipps & Byrne, 2003; Regehr, 2001). Other recommended interventions for STS are preventative in nature, such as discussing the risks of developing STS with individuals working with trauma clients, peer support, and supervision (Naturale, 2007).

Social workers engaged in trauma work are at risk for developing secondary trauma (Adams, Figley, & Boscarino, 2008). “Social workers engaged in direct practice are highly likely to be secondarily exposed to traumatic events through their work with traumatized populations, many social workers are likely to experience at least some symptoms of STS, and a significant minority may meet the diagnostic criteria for PTSD (Bride, 2007, p. 63). Studies reveal that workers who have had previous exposure to traumatic events (such as workers who are survivors of violent crime), who have higher levels of empathy and poor perceived social support, are more susceptible to developing STS (MacRitchie & Leibowitz, 2010). Due to the high levels of susceptibility to STS, worker self-care is as crucial to disaster management as other components (Rowlands, 2013). Engaging in peer support is among the best ways to prevent and/or cope with STS (Pulido, 2012).

The idea of “shared traumatic reality” has been introduced in the literature recently. This occurs when disaster workers are themselves exposed to the same communal disaster as the care recipients. These workers are thus directly exposed to the disaster (they may live in the hurricane affected area or war zone), and then are also called upon to provide care to disaster survivors. These double-exposed workers can find themselves trapped by conflicting needs to protect themselves and their loved ones from the physical and psychological distress associated with the disaster and their professional role to provide direct services to traumatized survivors (Baum, 2011). These conflicting realities can lead to a blurring of boundaries between worker and client, and may also lead to greater emotional distress and exhaustion (Carroll, Balogh, Morbey, & Araoz, 2010; Dekel & Baum, 2010).

Some suggestions to assist double-exposed workers include: ensuring the physical safety of workers; giving priority and legitimacy to workers' personal worries and needs; setting time limits and limiting caseloads for exposed workers; improving worker preparedness; working in pairs to increase peer support; and identifying workers who may be at greater risk for developing adverse traumatic reactions due to situational vulnerability (Dekel & Baum, 2010).

Posttraumatic Growth

The majority of disaster survivors will not develop short- or long-term mental health problems, and, indeed, there is a burgeoning body of research on disaster resiliency and growth (Linley & Joseph, 2006). Evidence suggests that posttraumatic growth can occur even in the case of shared traumatic experiences where workers live and work in the disaster area. For example, Bauwens and Tosone (2010) found that 9/11 clinicians from Manhattan reported that the 9/11 experience was the impetus for improved self-care and the development of new clinical skills. Given the increasingly frequent incidence of natural and human-initiated disasters in the past few years, practitioners with training in disaster social work are and may be needed more than ever. Nevertheless, the possibility that the encounter with disaster can lead to personal and professional growth offers some hope amid often trying and tragic circumstances.

11 Victim Services

Karen S. Knox

INTRODUCTION

In the aftermath of a traumatic incident, crime victims and survivors and their families receive services from social workers and other helping professionals across a range of settings, including advocacy organizations, law enforcement, the court systems, corrections, and probation/parole. As frontline responders on the scene, victim services programs and services that are housed in law enforcement agencies provide unique opportunities

to intervene at a critical time, namely, immediately after the offense and during the investigation. Generally, brief, time-limited, crisis intervention services and referrals for continued mental health, advocacy, assistance, and legal services are provided by victim services social workers.

Victim assistance services at the court level are provided during the court preparation time before hearings, and focus primarily on case notification, preparation for witness testimony, and legal advocacy. Crisis intervention and supportive

counseling services are provided during the court proceedings because survivors, family members, and significant others typically experience a form of re-traumatization as a result of the memories, emotional reactions, and psychological disturbance triggered by their possible court testimony and having to face the offender(s) in court. Victim witness advocates assess and refer clients for Post Traumatic Stress Disorder and grief and loss issues that may indicate the need for continuing longer-term therapy.

Restorative justice programs are found at the corrections and probation/parole levels, and provide services for crime survivors and family members that include release and parole notification, victim impact panels, victim-offender mediation, and restitution programs.

HISTORY

Social workers have a long history of working in law enforcement, beginning in the early 1900s with the establishment of Women's Bureaus in police departments and friendly visitors who worked with women and children in need of protective services (Roberts, 2007). However, it was not until the 1970s, when the battered women's and rape crisis movements became active that the social work presence in law enforcement gained more momentum. Advocacy groups and organizations emerged to fight for victims' rights and compensation programs, with the realization that many crime victims were being victimized twice—once, during the actual crime, and then again by the criminal justice system, which historically had been designed to protect the rights of the criminal/defendant rather than the victim/survivor. The crime victims' movement resulted in federal legislation and funding to establish victim assistance programs in all states through the Federal Law Enforcement Assistance Administration (LEAA) and the Victims of Crime Act (VOCA) of 1984. In 1994, both the Federal Violence Against Women Act (VAWA) and the Federal Law Enforcement and Crime Control Act allocated more funding to state and city police departments to develop crisis intervention and domestic violence counseling programs (Knox & Roberts, 2007).

CASE ILLUSTRATIONS

The victim services crisis team arrives at the scene of a domestic violence incident after being

notified by the police officers that the victim is requesting services. Mary is in her living room so the crisis team leader goes to check with her, while the victim services volunteer talks to the patrol officers to get more information from them about what had happened. Mary states that her boyfriend hit her in the face and stomach while they were arguing about financial problems. She reports that he left in his car and she called 911. After talking with the crisis team leader, Mary decides she would like to be transported to the hospital to get medical treatment.

While at the hospital, the crisis team leader receives a call from dispatch that a sexual assault victim is being transported to the hospital emergency room for a rape exam and the patrol officer is requesting assistance. While Mary is being treated for her physical injuries, the crisis team leader and her volunteer collaborate on how to work both cases at the same time.

TREATMENT MODELS AND PROGRAMS

The primary theoretical models used in victims services programs are crisis intervention, grief and bereavement therapy, cognitive-behavioral approaches, reality therapy, and eye-movement desensitization and reprocessing (EMDR). These provide short-term treatment with a focus on immediate needs and short-term goals, not on past issues or problems requiring long-term treatment, unless those past issues are currently impacting on the current precipitating crisis or incident. Victim services programs in law enforcement offer crisis intervention on the scene or immediately following the crime or traumatic incident, short-term counseling, assistance and referrals for the victim's immediate needs, death notification to family members, and advocacy and assistance during the investigative process. Victim services workers use a team approach with community providers and agencies, such as domestic violence programs/shelters, rape crisis centers, mental health providers and authorities, and other public and social service agencies that can meet the needs of crime victims and survivors.

Victim witness assistance programs in the court systems try to minimize the re-victimization that can occur through involvement with the criminal justice system, defense attorneys, and the court proceedings. Re-victimization can happen when

victims, survivors, and witnesses have negative experiences with attorneys, prosecutors, and others in the legal system that can be perceived as insensitive, unfair, and traumatizing, and which can provoke feelings of being victimized all over again. Reliving the traumatic events and having to testify or confront the offender can trigger posttraumatic stress disorder symptoms that result in the need for continued psychological and supportive counseling services.

The primary roles and objectives for a victim witness advocate in the court system are to inform victims and witnesses of their legal rights, such as victims' compensation and restitution benefits to which they are entitled; to provide information and notification of the court processes; and to offer court and testimony preparation, accompaniment, and crisis intervention during the court proceedings. Victim compensation programs and services are available in all 50 states and the District of Columbia, the U.S. Virgin Islands, Puerto Rico, and Guam (Knox & Roberts, 2007). Victim compensation programs can assist financially with medical expenses, lost wages, and counseling services needed as a result of a crime. However, eligibility criteria can vary across the states and financial awards can be reduced or denied if the victim/survivor has insurance that will pay for such services, and can be dependent upon prosecution and conviction in court. Restitution and criminal fines paid by offenders on probation and parole primarily fund victim compensation programs.

Victim advocacy programs in corrections provide information on offender parole or probation status and release dates, opportunities to impact on parole board and probation hearings, and involvement with victim impact panels where survivors can confront and educate offenders on the effects and consequences of their violent crimes. Restorative justice programs focus on strategies to assist offenders in realizing and understanding the extent of the harm and damages caused by their offenses, and include mediation and restitution services through which social workers advocate for crime victims, survivors, and their families. Other national crime victim advocacy organizations, such as the National Organization for Victims Assistance (NOVA) and the National Center for Victims of Crime, provide volunteer opportunities, educational and training materials for survivors, significant others, and professionals; outreach and referral services; and opportunities for political and advocacy

initiatives that address legal and governmental gaps in policies and services.

EVIDENCED-BASED PRACTICE GUIDELINES AND SPECIAL CLINICAL ISSUES

Evidence-based research in this field guides best practices for training and education of victim services professionals (McCart, Smith, & Sawyer, 2010; Parsons & Bergin, 2010). Research studies have found that providing crisis intervention, financial assistance, referral information, support, and advocacy services have a positive correlation with victim satisfaction with the criminal justice system and increased cooperation with the legal process (Camacho & Alarid, 2008; Larsen, Tax, & Botuck, 2009; Ruback, Cares, & Hoskins, 2008). Standards of practice, national credentialing programs, and other continuing education training are offered by the National Organization of Victim Assistance and the National Victim Assistance Academy, which is sponsored by the Office for Victims of Crime (OVC).

Crisis intervention requires a high level of activity and skill on the part of the social worker, and the time frame for assessment and contracting is brief by necessity. People experiencing trauma and crisis need immediate relief and assistance, and the helping process must be adapted to meet those needs as efficiently and effectively as possible. Therefore, the assessment, contracting, and intervention stages may need to be completed and implemented on the very first client contact. Clients in an active state of crisis are more amenable to the helping process, and are more likely to accept help, so this can facilitate completion of such tasks within a rapid response time frame.

Specialized knowledge about specific types of crime victims and traumatic incidents is necessary for effective intervention planning. For example, working with victims of family violence requires education and training on the dynamics and cycle of battering and abuse, familiarity with the community agencies providing services to this client population, and knowledge about the legal options available to victims. Concrete, basic needs services such as emergency safety, medical needs, food, clothing, and shelter are the first priority in crisis intervention. Mobilizing needed resources may require more direct activity by the social worker in advocating, networking,

and brokering for clients, who may not have the knowledge, skills, or capacity to follow through with referrals and collateral contacts at the time of active crisis.

STEP-BY-STEP TREATMENT MODEL AND GOALS

Roberts' Seven-Stage Crisis Intervention Model is useful in police-based social work because it adapts easily to the various types of crises and to different time frames for intervention (Knox & Roberts, 2008). All of these stages can be completed within one contact if necessary, and in many crisis situations, that may be all the time that is available:

Stage 1: Plan and conduct a psychosocial and lethality assessment: Assessment is ongoing and critical to effective intervention at all stages, but begins with an assessment of the lethality and safety issues for the client. With victims of rape, family violence, child abuse, or assault, it is important to assess whether the client is in any current danger, and to consider future safety concerns in treatment planning. With suicidal clients, it is critical to assess the risk for attempts, plans, or means to harm oneself at the current time, as well as any previous history of suicidal ideations or attempts. The goals of this stage are to obtain sufficient information to determine whether the client is in imminent danger, and to identify and assess critical areas of intervention.

At present, although there is no imminent danger or harm, it is necessary to talk with Mary about a safety plan for when she is released from the hospital. She does not feel safe returning home in case her boyfriend returns. She relates that she recently moved from another city to break off this relationship, and she has no money to relocate again so soon. The victim services volunteer talks with Mary about the local domestic violence shelter and will check on availability of emergency services.

The patrol officer briefs the crisis team leader as Amy, the sexual assault victim, is being brought into the emergency room. While the medical team prepares the room for her rape exam, the crisis team leader introduces herself and explains to Amy that the medical

procedures are done by a specially trained sexual assault nurse examiner, and that the crisis team will stay with her until after the examination, if she wants. The crisis team leader also offers to contact a support person if Amy wants to have a friend or relative come to the hospital.

Stage 2: Make psychological contact and rapidly establish the relationship: The main goals of this stage are to establish rapport and a supportive relationship. Crime victims may question their own safety and vulnerability, and trust may be difficult for them to establish at this time. Therefore, active listening and empathic communication skills are essential to engaging the client. During this stage, clients need support, positive regard, concern, and genuineness.

After Mary's physical exam, she starts going over the details of the night, which is common for crime victims and helps them become more oriented to the time and sequence of events and able to process what happened. It is important to listen and take notes for the incident report, and to let Mary talk without too much questioning.

Amy has already given an initial report to the patrol officers; she will also need to give a statement to the Sex Crimes Unit as soon as possible to further the investigation and possible arrest of a suspect. Amy is concerned that the rapist may return to her apartment and does not feel safe returning home. Empathic communication skills are important at this time to help establish the relationship and encourage her to ventilate and express her emotional reactions.

Stage 3: Identify the major problems: This stage focuses on prioritizing the most important problems or impacts by identifying how each affects the client's current status. The first priority in this stage is meeting the basic needs of emotional and physical health and safety. The focus must clearly be on the present crisis, and any exploration of past problems or issues must be done rapidly and only to aid in intervention planning.

Mary has decided to go to the domestic violence shelter and requests transportation to her apartment to pack a bag and get some personal items. The victim services volunteer arranges for the patrol officer to accompany

them. She explains that the shelter staff will assist her with legal and court procedures for which she can apply to help meet some of her financial, medical, and legal needs.

Amy wants to know what she needs to do to give her statement to the Sex Crimes investigator. She also wants help getting some clothes and her car and calling her employer to explain about missing work tomorrow. She says she can stay with her friend for a few days, and that she does not feel safe returning to her apartment yet.

Stage 4: Deal with feelings and provide support: The primary goal in this stage is dealing with the emotional impacts of the trauma event through ventilation, expression, and exploration of the client's emotions about the crisis event and aftermath. The primary technique used is active listening, which involves listening in an accepting and supportive way, in as private and safe a setting as possible. It is critical that the victim services social worker demonstrate empathy and support. Victims sometimes blame themselves and it is important to help the client acknowledge and accept that being a victim is not one's fault. Validation and reassurance are especially useful in this stage, because survivors may be experiencing confusing and conflicting feelings.

The crisis team leader talks with Amy about support and counseling services at the local rape crisis center. She lets Amy know that a victim services counselor will be available to answer questions or provide other assistance when she goes to the police station to give her statement. The victim services counselor will also inform her about Victim's Compensation and how to apply for benefits, and will make any other necessary community referrals.

The crisis team then calls for the patrol officers to meet Amy and her friend at her apartment so she will be able to get her clothes and car before she goes to her friend's house. The crisis team then leaves with Mary to transport her to the domestic violence shelter. While driving there, the volunteer explains that the Family Violence Unit will be contacting Mary to complete the case investigation, and that she can request further services from the victim services counselor assigned to that unit.

Stage 5: Generate and explore alternatives:

The goal of this stage is to achieve a pre-crisis level of functioning through the client's coping skills and support systems. If the client has unrealistic expectations or inappropriate coping skills and strategies, the victim services social worker may need to be more active and directive in this stage. Clients are still distressed and in disequilibrium at this stage, and professional expertise and guidance could be necessary to produce positive, realistic alternatives for the client.

While at the police station the next day, Mary talks to the victim services counselor about a Protective Order against her boyfriend. She is referred to the County Attorney's Office, where their victim advocate will assist her in completing the forms and provide follow-up services on the court procedures. After Amy gives her statement to the Sex Crimes investigator, she talks to the victim services counselor and is able to ventilate her fear and anger about what happened. She wants to stay with her friend for a couple of more days, because she needs to replace her front door lock and is interested in other security options for her house. Referrals for counseling at the rape crisis center are provided to Amy, and the victim services counselor offers to follow up with her next week to check whether she has any questions about the investigation or needs further services.

Stage 6: Develop and formulate an action plan:

It is important for the client to look at both the short-term and long-range impacts when planning intervention. The main goals are to help the client achieve an appropriate level of functioning and maintain adaptive coping skills and resources. It is important to have a manageable treatment plan, so the client can follow through and be successful. Do not overwhelm the client with too many tasks or strategies, which may set the client up for failure. Ongoing assessment and evaluation are essential to determine whether the intervention plan is appropriate and effective in minimizing or resolving the client's identified problems. During this stage, the client should be processing and reintegrating the crisis impacts to achieve homeostasis and equilibrium in his or her life.

Although both Mary's and Amy's immediate concerns and needs have been

addressed, they will need support and advocacy services through the legal and court procedures that will be provided by the victim witness advocates at the district attorney's office. The police-based victim services counselors provide short-term crisis intervention services, and the local domestic violence and rape crisis centers offer both individual and group counseling services. The agencies also have liaisons who work with the victim witness advocates at the district attorney's office to provide assistance and support when the offender goes to trial. This can be another critical time for crime victims; it may trigger memories of and reactions from their assaults that need to be addressed.

Stage 7: Termination & follow-up measures: Termination begins when the client has achieved the goals of the action plan, or has been referred for additional services through other treatment providers. This last stage should help determine whether these desired results have been maintained or whether further work remains to be done. Typically, follow-up contacts are by phone and should be done within four to six weeks after termination.

The victim services counselors from the police department will follow up with both Mary and Amy to assess whether there are any questions or problems that need to be addressed. Given that cases going through the criminal justice and legal systems often take a very long time, this period is usually when victims may have questions about what is going on with their case or what is happening in the court system. This offers an opportunity to assist with these types of legal issues and concerns. This is also a good time to check whether the victim/survivor has followed up with counseling referrals and treatment, or is still in emotional and psychological distress, and to assist with providing other referrals or treatment options. The victim witness advocates at the courts will also provide continuing services throughout the legal proceedings. Crime victim survivors and their family members also participate in crime victims' rights and advocacy organizations as a way to recover and heal from their own victimization experiences and to help others who share similar experiences.

INTERVENTION SKILLS AND COMPETENCIES

- *Communication Skills:* Social workers in victim services programs need to be attentive to the tone and level of verbal communications to help the client calm down or de-escalate from the initial trauma reactions. Observing the client's physical and facial reactions can provide cues to the client's current emotional state and level of engagement. It is important to remember that delayed reactions or flat affect are common with crime victims, and not to assume that these types of reactions mean that the client is not in crisis. Encouraging the client to ventilate about the precipitating crisis event can assist in problem identification, and clients may have an overwhelming need to talk about the specifics of the trauma situation. Others may be in shock, denial, or unable to verbalize their needs and feelings, so information may need to be obtained from collateral sources or significant others.
- *Intervention Skills:* Intervention begins at first contact when victims and survivors may be experiencing confusing and conflicting feelings. The social worker needs to be knowledgeable about the grief process, which many victims and family survivors follow when expressing and ventilating their emotions. First, clients may be in denial about the extent of their emotional reactions and may try to avoid dealing with them in hopes that they will subside. They may be in shock and not be able to access their feelings immediately. However, significant delays in expression and ventilation of feelings can be harmful to the client in processing and resolving the trauma. Some clients will express anger and rage about the situation and its effects, which can be healthy, as long as the client does not escalate out of control. Helping the client calm down or attending to physiological reactions such as hyperventilation are important interventions in this situation. Other clients may express their grief and sadness by crying, moaning, or fainting (referred to as "falling out" in some cultures), and need time and space to express their reactions, without pressure to move along too quickly.

- *Coping Skills*: Healthy coping skills promote adaptive responses and resolution of the crisis by using support systems, such as people or resources that can be helpful to the client in meeting needs and resolving problems in living that may have resulted from the crisis. Healthy coping skills can increase positive and constructive thinking patterns that reduce the client's levels of anxiety and stress. Victim services professionals can facilitate healthy coping skills by identifying client strengths and resources. Many crisis survivors feel they do not have a lot of choices, and the crisis worker needs to be familiar with both formal and informal community services to provide referrals.
- *Termination & Follow-Up Skills*: It is important to remember that final crisis resolution may take many months or years to achieve (if ever), and that certain events, places, or dates could continue to trigger emotional and physical reactions to the previous trauma. This is a normal part of the recovery process, and clients should be prepared to have contingency plans or supportive help through these difficult periods.
- *Self-Care*: Self-care and safety concerns are critical in this setting. Self-awareness of your own emotional reactions and level of comfort when working with your clients is also critical. It is important to attend to your self-care needs to avoid burnout and emotional fatigue.

12 Social Work in Domestic Violence Services

Brandy Macaluso & Diane L. Green Sherman

A TYPICAL DAY ON THE JOB IN DOMESTIC VIOLENCE SERVICES

Crisis Responder

7 P.M.	Shift Begins: On-Call Phone is Turned On	2 A.M.	Crisis Call from Police to Respond On-Scene to Domestic Violence Call; Victim has Injuries
8 P.M.	Crisis Call from Police Requesting Transport for Domestic Violence Victim to Emergency Shelter	2 A.M.–3 A.M.	Crisis Intervention and Transport with Victim to Local Hospital for Injury Treatment
8:30 P.M.–9 P.M.	Transport Victim to Emergency Shelter and Await Intake with Victim	3 A.M.–6 A.M.	Provide Support to Victim in Hospital for Medical Services, Law Enforcement Reporting, and Discharge
10 P.M.–11 P.M.	Leave Shelter, Return Home, and Document Information for Follow Up by Non-Crisis Staff in the Morning	6 A.M.–7 A.M.	Document Information for Follow Up by Non-Crisis Staff in the Morning
12:30 A.M.–1 A.M.	Crisis Call from Police Requesting Referral Information, No Response Needed On-Scene, Documented Request	7 A.M.	Shift Ends, On-Call Phone is Forwarded to Regular Office Phones with Noted One-Hour Response Time Indicated

Non-Crisis Responder

8 A.M.–8:30 A.M.	Start Shift. Check Voicemail Messages	1 P.M.–3 P.M.	Court: Restraining Order (RO) Hearing
9 A.M.–11 A.M.	New Victim Intakes	3 P.M.–4 P.M.	Case Work: Follow Ups
11 A.M.–NOON	Facilitate Domestic Violence Survivors Support Group	4 P.M.–5 P.M.	Set New Intake Appointments and Make Service Referrals for New Clients
NOON–1 P.M.	Lunch	5 P.M.	End Shift

Shelter Hotline Worker

2:30 P.M.–3 P.M.	Shift Begins; Receive Report of Activity from Prior Shift Worker	9 P.M.–9:30 P.M.	Counsel Victim on the Phone about Available Resources and Shelter Services
3 P.M.–7 P.M.	Receive Calls for Domestic Violence Information and Service Referral Requests	9:30 P.M.–10 P.M.	Receive Call from Police for Phone Intake of Victim
7 P.M.	Receive call from Police for Phone Intake of Victim	10 P.M.–10:30 P.M.	Arrange Victim Pick-Up with Available Shelter Advocate
8:15 P.M.	Receive call from Crisis Advocate for Phone Intake of Victim	10:30 P.M.–11 P.M.	Report of Activity to Hotline Worker on Next Shift
8:30 P.M.–9 P.M.	Arrange Victim Pick-Up with Available Shelter Advocate	11 P.M.	Shift Ends

SERVICE NEEDS OF VICTIMS

- Crisis Intervention
- Safety Planning
- Restraining Order Assistance
- Emergency Safe Shelter/Housing
- Supportive Group Work/Peer Counseling
- Individual Counseling, Therapy, and/or Medications
- Health Care
- Transportation
- Food
- Spiritual Needs
- Legal Services for Divorce/Child Custody, Support, or Visitation
- Pet Care
- Life Skills Training
- Educational Needs
- Long-term Housing
- Vocational Services
- Child Care
- Court Accompaniment/Support for RO and Criminal Case
- Any Other Need Identified by the Victim

EMERGING CONCERNS

New Abusers with Alzheimer’s. In later stages of Alzheimer’s disease, anger and aggression can start to manifest in violent outbursts. These outbursts can be aimed directly at caregivers who are often family or intimate partners of the individual. Unfortunately, there is no known

reason for these outbursts. Doctors indicate that they could be a reaction to stimulus in the environment or they could simply be a symptom of the Alzheimer’s disease itself. The key to averting them is knowing the possible triggers: confusion, overstimulation due to the environment, or discomfort of some kind.

Once caregivers recognize these triggers, taking steps to ease the person with Alzheimer’s disease could be as simple as taking them to a quiet area, minimizing stimulants in the environment, sitting and listening to them talk, asking simple questions about the memories they are recalling at that moment, and/or focusing on the distant past given that the disease affects short-term memory. It may be easier and more pleasant for them to talk about memories from childhood or early adulthood, thus diffusing the aggressive behaviors or abusive outburst.

Service providers assisting victims of abuse by individuals with Alzheimer’s disease should make a referral to the local Alzheimer’s disease center or to programs that provide respite care, day programs, and caregiver supports.

Domestic Homicides. There recently has been a focus on homicides stemming from domestic violence. Perpetrators murder their intimate partners and/or intervening friends, family members, new intimate partners, children, or innocent bystanders. These homicides often spring from jealousy, power, and control over the intimate partner or former intimate partner. According to the *Palm Beach Post*, which has

been tracking Palm Beach County's homicide figures since 2008, there were 11 domestic homicides in the year 2012 and 14 from January 2013 to October 2013 in Palm Beach County.

According to Jane Doe Inc., the Massachusetts Coalition against Sexual Assault and Domestic Violence, these homicides can be predicted and due to their predictability, these homicides are preventable. Further, according to this coalition, three commonalities emerge during case reviews: "First, while systems and services may have failed some victims, the only person ultimately responsible for the abuse, violence and homicide is the perpetrator. Similarly, regardless of what actions these domestic violence victims may or may not have taken, they are not responsible for the abuse and are not to be blamed. Second, our law enforcement, judicial and other systems as well as services have not all adopted current best practices for holding perpetrators accountable and predicting and preventing domestic violence homicides. Third, the lack of connection between the domestic violence victim and a trained domestic violence advocate from a local community (or health-care) based domestic violence program is consistently a missing link in these cases, a practice that research tells us can make the difference between life and death."

Jane Doe Inc. suggests the first step in prevention of domestic homicides is having a victim connect with a domestic violence advocate. The perpetrator of violence relies on the lack of education about services, key resources, or emergency protections as a key to preventing the victim from leaving. Bridging a victim with an advocate to discuss available programs and resources will provide that victim with needed information, adding a safety net for the victim to be able to maneuver away safely from a toxic or abusive relationship. Secondly, use a victim-centered approach which means the victim's safety and welfare is the center of the service provision. By addressing the needs identified by the victim, the success rate increases significantly for the victim to be able to leave the abusive relationship. Third, recognize that best practices exist and establish training and research-based interventions for service providers and individuals in the criminal justice system to use when assisting victims of interpersonal violence (IPV). Fourth, recognize that prevention of domestic homicides is possible, and by

following the preceding steps, these victims can remain on the road to survivorship.

Traumatic Brain Injury. In 2005, 11% of the 1,400,000 Traumatic Brain Injuries were directly caused by assault. In 1999, over 90% of all injuries secondary to domestic violence occur to the head, neck, or face region, which is likely to lead to a traumatic brain injury over time. Among battered women, 30% reported a loss of consciousness at least once, and 67% of battered women reported residual problems that were potentially head-injury related, such as seizures, headaches, and vision problems.

Numerous common physical symptoms appear after a victim acquires a brain injury through violence. Those symptoms include loss of smell or taste, hearing loss, visual difficulties, balance difficulties, problems with motor control or coordination, fatigue, seizures, decreased tolerance for drugs or alcohol, headaches, and sleep disturbances. Cognitive symptoms also can occur. They include short-term memory loss, short attention span, easy loss of concentration, inability to focus, distractibility, decreased verbal fluency or inability to find words previously known to the victim, decreased comprehension, disconnects when processing information, erratic arousal, inability to problem solve, decreased intellectual functioning, inability to conceptualize, and delayed reaction time. Extreme changes in behavior may occur, including impulsivity, emotional fluctuations, irritability, decreased frustration tolerance, impaired judgment, anxiety, depression, aggressiveness, sexual urges, and personality changes.

The above symptoms combined can make safety planning for an individual with a brain injury very difficult. Often these individuals have trouble assessing inflammatory situations or lethality levels. Memory loss precludes them from following their safety plan. Their sometimes erratic behavior can make reporting difficult and in some cases can make police view them as the aggressor in the situation. These brain injuries may also affect their ability to set and maintain goals such as vocational goals, follow shelter schedules, set and keep appointments, and live independently. When it comes to the criminal case, victims with brain injuries may have their disability used against them. For example, their memory loss or inability to recall timelines or provide information in chronological order is used as a way to disregard

their allegations. If they do not present well, their credibility, capacity, or competency may be questioned and they may be subject to evaluations to determine whether they are fit to proceed in the court process. Further, if the victim is on medications to control physical symptoms, mental health diagnoses, or other medical conditions related to the abuse, defense attorneys have been known to use the effects and side effects of those medications as a way to discredit the allegations and recollection of abusive events.

VICTIM PROFILE

Physical Signs of Abuse

- Burns
- Bruises, Cuts, Scars, Abrasions, Scrapes
- Marks Around Mouth from Gagging
- Imprint Injuries
- Missing Teeth
- Spotty Balding from Hair Pulling
- Eye Injuries
- Broken Bones/Sprains
- Vaginal or Rectal Pain, Inflammation, or Infections
- Bleeding from Ears, Nose, Mouth, etc
- Incontinence of someone who was previously potty-trained
- Frequent Sore Throats
- Psychosomatic Complaints (Males—Stomach Upset; Females—Headache)
- Difficulty Walking or Sitting

Nonverbal Signs of Abuse

- Change in the Show of Affection
- Fears Being Touched
- Sudden Onset of Night Terrors
- Changes in Sleep Pattern
- Unwilling to Make Eye Contact
- Timid or Submissive
- Depression/Withdrawal/Mood Swings
- Any Other Sudden Changes in Behavior

ABUSER PROFILE

Characteristics of an Abusive Person

- Low Self-Esteem
- Need to Control
- Confrontational with Anyone Appearing Inferior

- Frustration with Authority
- History of Being Neglected or Abused Themselves
- Lack of Attachment
- Abusive toward Animals
- Lack of Accountability
- Use of Threats, Looks, or Body Language for Intimidation Purposes
- Impulsive
- Devaluing Nature
- Blatant Disregard for Others
- Overly Competitive
- Unwelcoming or Uncooperative Attitude
- Frequently Changes Service Providers, Health Care Providers, and any other “Helping” Service Worker
- Under the Influence of Drugs or Alcohol
- Destroys Others’ Property

INCREASED VULNERABILITY/GAPS IN SERVICE

Elderly. The elderly tend to underreport IPV. The stigma with IPV still exists in their generation and although there are some shifts in the process to address this issue, it is still under-reported. In generations past, it was very common to keep family problems in the family. Violence and relationship issues were not openly discussed outside of the immediate family. Many of the elder generation had been victimized for years before they even realized that they were victims. Some still do not realize they were victims.

Recently, after speaking with an 87-year-old woman, she described her stepfather as a caring person until he started drinking. After drinking, he would come home and tear the house apart, smashing dishes, and hitting her mother. She indicated that unless they went outside, he would come after her and her siblings, too. She stated that they would have to wait in an alley way, sometimes in snow, until he had gone to bed, before coming back into the house to go to bed themselves. After hearing her story, she was asked if she believed she was a victim of domestic violence. Her response was no.

Men. In 2010, a study done by a Campaign group called Parity in the United Kingdom found that over 40% of reported cases of domestic violence indicated that men were victimized by their wives or girlfriends, a number much higher than initially thought. Further, the study showed that violence perpetrated against men is not taken

seriously by police, is “dumbed down” in the media, and there is no real emergency placement or assistance set up for male victims. It also indicated that perpetrators are often freed or given subdued sentencing. Female on male IPV is underreported for these reasons as well as the stigma of being demasculinated by appearing weak, vulnerable, or “unmanly” by being abused by a female partner.

LGBTQ. The lesbian, bisexual, gay, transgender, and queer (LGBTQ) community still has an emerging identity in society. Although much legislation has been passed recently regarding this population, much also has been repealed or delayed for various reasons. “Unfortunately, domestic violence victims in same-sex relationships are not receiving the help they need. This is due to the lack of legal recognition of same-sex relationships, law enforcement’s failure to identify and properly handle domestic violence cases involving people of the same sex, and the shortage of resources available to victims of same-sex partner domestic abuse,” according to the Center on American Progress Report on Domestic Violence in the LGBT Fact Sheet. According to this same fact sheet, the reasons for lack of reporting include fear of the violent partner “outing” their sexual orientation or gender identity to family, friends, police, coworkers, etc. It also indicated that reporting may be seen as endangering solidarity by giving the LGBTQ community a bad name. Other reasons included the fact that children can be used as leverage in cases because most states do not recognize LGBTQ couples or allow same-sex couples to adopt. Lastly, same-sex couples are more likely to fight back against their perpetrator making police believe the abusive behavior may be mutual.

Victims with Disabilities. Individuals with disabilities have historically underreported crimes perpetrated against them. There are two main reasons for this. The first is physical barriers, simply meaning that they are physically unable to report due to their disability or a lack of accommodations made by society in general. This could include lack of Text Telephones (TTY) or Video Phones at local police departments, emergency shelters, or service providers; lack of or too few accessible parking areas; steep terrain or no ramps for wheelchair users; lack of information in alternative formats, such as Braille, for individuals who are blind; and similarly

lacking accommodations required by those with disabilities. The second cause for underreporting is attitudinal barriers, often unintentional, found throughout society. Some individuals are unsure how to make accommodations for people with disabilities and, therefore, simply do not make necessary accommodations, nor do they go out of their way to learn what the law requires. Common attitudinal barriers include giving the person with a disability unfair advantages instead of level standards of opportunity; denial of the disability and, therefore, not making appropriate accommodations; or portraying a person with a disability as special or a hero for overcoming disability. On the other end of the spectrum is inferiority, that is, portraying a person with a disability as helpless or useless; seeing people with disabilities as incapable of managing their own lives or tasks; and, lastly, pitying or patronizing behaviors toward those with disabilities. Often, these physical and attitudinal barriers can lead to discrimination and exclusion from service provision, the court process, and other life activities.

Another issue regarding victims of domestic violence with disabilities is that the perpetrators of violence are often the caregivers for the person with the disability. Perpetrators often cite the stress from caregiving as an excuse for their violent or demeaning behavior and blame the person with the disability for the way they, themselves, act toward them. This abuse does not have to be physical in nature. It can also take the form of threats, intimidation, emotional abuse, isolation, economic abuse, or withholding, misusing, or delaying needed supports including medication, adaptive equipment, and food.

CASE SCENARIOS

Linda Devry, Age 43

Linda contacts the shelter hotline for an intake. The shelter screens her and finds that she fits criteria to enter Domestic Violence Emergency Shelter. Linda makes arrangements to meet the shelter worker. When she shows up to enter the shelter, Linda is apparently drunk. The shelter worker can smell the overwhelming smell of alcohol on her breath. The shelter worker asks the victim if she has been drinking because she can smell alcohol. The victim appears shamed and responds that she had been drinking with her boyfriend and that is what sparked the fight. She drank the last beer in the house. When he

found out, he told her to go to the store, when she refused because she felt she could not drive, he pushed her and started to throw items in the house, including a book, at her. When she pulled out her phone to call police, he grabbed her arm, took the phone, and threw it against the wall, breaking it.

The shelter worker asked Linda if she would like help with alcohol abuse. Linda agreed she wanted to speak to someone. The shelter worker made a referral to the local addictions center and set up an intake for her for the following day. Linda was assigned her sleeping arrangement for shelter and was given a schedule of group and individual sessions required. She was also provided the rules for the emergency shelter.

Linda went to her appointment the next day for the addictions center and was assigned a case manager. She scheduled a follow-up and will attend the outpatient program because she scored low on their addiction screening inventories.

Linda met with the shelter advocate assigned to her later that day. The advocate met with her to get background on her. Linda is currently working a part-time job and receives a widow benefit from her late husband who was killed on active duty. She receives a decent amount of monthly income, with which she will be able to rent a small one bedroom apartment. The advocate sits with her, showing her how to look and apply for apartments. Linda advises that she does not have much family but has a coworker whom she trusts who knows her situation with her boyfriend. The coworker has encouraged her to leave in the past, but cannot assist with housing her because the coworker is in a gated community with homeowner's association rules regarding visitors.

Linda advises that she is scared of her current boyfriend and wants to be protected when he gets out of jail. The advocate explains the restraining order process to Linda and helps her complete the application. She instructs Linda how to file the order on her own at the courthouse. The advocate also tells her about a notification program that will notify her if he is released from jail. Linda is interested in applying. They complete the application.

Linda returns from the courthouse and tells the advocate that she has a court date in two weeks. The advocate refers her to domestic violence legal services to assign her an attorney to represent her during court.

Linda locates an apartment she can afford on her monthly income. She meets the management company and completes an application. Linda is accepted approximately three days later. Linda is excited but apprehensive. She then tells her advocate that she does not have any furniture to put in her apartment. The advocate completes a referral for Linda to the local thrift store for a few items: a dinette set, bed, dresser, and couch. Linda calls a coworker to help her retrieve the furniture.

Linda is given an exit date by the advocate based on the move-in date for her apartment. Linda is also given additional resources to be able to continue counseling services at the shelter outreach department. She is also given information on other community agencies that she can call for additional assistance.

Three months later, Linda completes counseling with the outreach worker and is thriving. Linda has focused on purchasing small furnishings for her apartment. She also disclosed that she bought a kitten so she would not be so lonely.

Naomi Pike, Age 35

You receive a call from the local State Attorney's Office. They are referring a young lady to you for counseling. The victim, Naomi, is having a very difficult time with the criminal court case. Naomi was dating her boyfriend for approximately five months. He had been very controlling from the start. About two months into the relationship, he was physically violent toward her. After five months, she decided to leave despite his threats to kill her. She went back to live with her family and decided to move in with her brother temporarily to get on her feet. Naomi's ex-boyfriend found out she was living at her brother's and started driving by the house, honking the horn a few nights during the week. She contacted police but he fled each time. She applied for a restraining order. The order was granted temporarily and set for a hearing. Because Naomi was unsure of her ex-boyfriend's whereabouts, she called a week after filing to advise that a mutual friend contacted her and gave her the address where he was living. Two days later, while her father was visiting, her ex-boyfriend knocked on the door. Naomi hid in a back room and called police while her brother and father went to answer the door. When they did, her ex-boyfriend pulled out a gun and fired at them killing them instantly. He called out for Naomi but she stayed quiet. She hid in the back bedroom closet and remained on the phone

with 911, silently. He jumped in his car and left. She came out when she heard the car start up to find her father and brother on the floor in front of the front door. Police came within minutes and called a crisis advocate to meet with her. Police found Naomi's ex-boyfriend and arrested him.

Naomi was having a hard time having to face him in court due to the trauma she had endured during the incident. She describes feelings of extreme guilt over the death of her family members. The outreach advocate sets up weekly therapy appointments for Naomi. The advocate also tells her about a local domestic violence support group and traumatic loss group in the community. Naomi is interested in the traumatic loss group but requests that an advocate attend with her for support during her first group meeting.

The group meets monthly and is scheduled for the following Tuesday. The advocate makes arrangements and attends the group with Naomi. The advocate makes connections with group members during the first 15 minutes that are used to network with other members. After networking, the advocate introduces Naomi to group members.

The group meeting commences and Naomi is sitting rigidly next to the advocate. As the group members share their stories, they ask for any new group members who want to share their stories, emphasizing that it was OK for them to simply introduce themselves if they did not want to share right away. Naomi introduced herself and stated that it was her first meeting. She told the group that she did not want to speak about her story but that her brother and father's killer was going to trial soon and she really needed to deal with some of the things she was feeling. The lady next to her waited until Naomi was done and then described her ordeal when her ex-boyfriend came to her house after breaking up thinking that she and her friend were seeing each other. She went on to say how her boyfriend pulled out a box cutter and killed her friend and then came after her, slitting her throat. She pulled her collar back exposing her scar. Naomi started to cry but remained quiet.

After the woman shared her story, a man shared his story about his boyfriend. His boyfriend had been the target of "gay bashing" and was violently assaulted and killed by a group of individuals after leaving work one night. The man explained how guilty he felt because his boyfriend had called him during his break to tell him

that he was a little disturbed by one of the tables he waited on at the restaurant. He described how the group of men asked for another waiter after he took their drink order and continued to stare at him while he waited on other tables in his section. He had also heard the men taunting him by calling him names. His boyfriend wanted him to come down to the restaurant and just hang out to keep an eye on things. When the man explained to his boyfriend that he was too tired to get up and get dressed to go out, his boyfriend seemed annoyed. They argued for a few minutes before hanging up. The man kept describing how guilty he felt for not getting up, getting dressed, and going down there.

The meeting ended and a last call for coffee was announced. After the meeting, the woman next to Naomi leaned over and said that she had seen Naomi's reaction; she hoped Naomi would share her story sometime, and that she knows what it's like to be new. She described the group as being a safe and supportive network of people. She also offered to exchange phone numbers with Naomi. Naomi agreed.

Naomi's appointment fell on the Friday following the loss group. Upon meeting with the therapist, Naomi told her that she sent a text message to the woman who gave her the phone number. The woman texted back and she met her for coffee. Naomi told her story and the woman was really supportive of her. The woman also told Naomi about a domestic violence support group that she attended and offered to attend the group with Naomi when they meet twice a month. Naomi accepted her invitation and is scheduled to go next week. Naomi seemed more empowered with the support of this woman and the group. The therapist worked with her to identify additional supports in her life during the session. She also helped her to start thinking about the types of things she would want to include in her victim impact statement for court. The session ended and Naomi seemed to be coping better than her initial visit. Naomi is scheduled for weekly therapy over the next two months before moving to biweekly appointments, followed by two monthly appointments, and her last follow-up appointment scheduled at six months from her start date.

Over the remaining appointments, the therapist notes that Naomi seems more and more adjusted to the events. She is working through the trauma and has developed a very good support system to help her cope with the incident. She also has individuals to contact if she has a

particularly emotional day. She started attending a church with one of the group participants and is starting to speak out more about her experience with newer members.

At the six-month follow-up appointment, Naomi indicates that she still thinks about the loss daily and still cannot manage to stop being emotional but that she is happy with the new friends she has made and the kindness they have shown her. She is continuing with the groups and is getting involved in some other local groups that promote antiviolence and victims' rights. She is scheduled to share her story during an upcoming event to help other families who are dealing with a loved one being murdered.

13 Traumatic Stress and Emergency Services

Ted Bober

SOCIAL WORK AT AN AIRPORT EMERGENCY: INCIDENT OVERVIEW

An Airbus aircraft is on a flight to a large urban city and scheduled to arrive at 6:00 P.M. local time. There are 280 passengers and 12 crew members on board. Among the other preflight activities, the flight crew members obtained the weather forecast for their arrival, which included the possibility of snowstorms with thunder.

The take-off and flight were uneventful. While preparing for descent, the crew realized that a landing gear was not fully engaged and locked. The airport was notified and emergency operations were initiated on the airport site. According to protocols,

an additional thirty emergency contacts were made in the surrounding city. With the conditions on the ground cold and snowy, a landing was attempted. The rear landing gear failed in the process of landing and the plane slid sideways off the runway. A wing touched ground and a fire broke out.

All passengers and crew were evacuated safely, though many people suffered minor injuries and a few experienced serious but not life-threatening injuries. The fire was extinguished by airport emergency teams. A few minutes of the landing were videoed by motorists on the surrounding highways. Within minutes, the video appeared on local news with the information that there were an unknown number of deaths.

5:30 P.M. The determination to deploy the Airport Crisis Team (Team) will usually be made by the Airport Duty Manager, in consultation with the Administrative Director and/or Clinical Director based on the details of the incident. It is quickly decided the deployment of the Team is appropriate.

5:35 P.M. The clinical director (a social worker) is contacted and is briefed on the unfolding event. The clinical director contacts the on-duty (on-call) crisis team members who include Emergency Professionals and Social Workers and other mental health professionals.

Each team member will be briefed with the available details of the incident.

5:45 P.M. The contacted Team members arrange to meet at a designated airport site. An initial assessment indicates that there are over 75 family members and friends awaiting the arrival of the passengers. Arrangements will be coordinated between the team and the airport emergency manager to have family members and friends taken to a large ballroom at a hotel next to the airport. The room will serve as a family support and information center.

6:15 P.M. The plane lands as described above.

6:30 P.M. Team members are deployed to the hotel ballroom to assist the airport and airlines in supporting family and friends. Initially, the information regarding injuries is not available; soon, however, family members begin to receive text messages and cell phone calls from friends and also see news reports indicating there were several deaths. Rumors and incomplete information heighten the tension in the room.

The social worker and emergency team members coordinate practical assistance such as the provision of water, juice, sandwiches, and blankets. Additional cell phones are arranged with long distance calling cards so relatives may contact other family members. Team members learn there were no deaths and all non-seriously injured passengers first will be taken to a nearby airplane hangar to be assessed medically. Plans are made by the airline to inform the families of the incident, the whereabouts of passengers, and the next steps to be taken. However, details on the full extent of injuries are not available, and the information session feels incomplete for many family members.

On-site triage results in a few passengers being taken directly to hospital. The lead social worker and the Team send two team members to the hangar to assess the practical needs of the passengers. The human resource needs of the Team are reviewed and additional standby social workers and emergency professionals are contacted and requested to assist during the phase of reconnecting families and passengers.

6:45 P.M. The Team, in collaboration with the airline's family assistance team, continues to provide practical information and support. In cooperation with the airline, family members and friends are registered. The administrative director of the team is in the emergency operation center (EOC). The team has a direct link to EOC leadership to exchange information and coordinate resources.

7:15 P.M. At the hangar over 250 passengers are triaged based on medical needs. Additionally, the airport and social workers collect information on contacting relatives and or making arrangements for transportation and accommodation for some passengers.

An increasing number of passengers are contacting family members and friends by cell phone and other handheld devices. The contacted family members are relieved, though many others wait anxiously for additional information. The airlines and airport provide brief details of the incident and report that there were no deaths.

7:30 P.M. Information is received that two airport firefighters are injured on site and taken to the hospital. According to protocol, the team would initiate steps to establish a rest area for emergency professionals during the recovery and investigation period. Given the proximity of the incident to a hangar, the rest area is established at this location.

7:45 P.M. Social workers and emergency team members continually re-evaluate the needs of three groups: the emergency responders, the family and friends, and the passengers. Plans are being established to reunite passengers and families. Practical social-emotional support at this stage focuses on information, practical health and nutrition needs, and facilitating contact with other relatives and friends.

8:30 P.M. Passengers and family members are reunited in a separate larger meeting room. Several other community agencies, such as the Red Cross, are also present to assist the airline and airport crisis team to support passengers requiring additional clothing, transportation, or accommodation. Arrangements have been ongoing to reunite family members with those passengers taken to the hospital. In this community, all hospitals have emergency-based crisis teams staffed by social workers.

8:30 P.M. to 1:00 A.M.	<p>Team members are available and offer support in a nonintrusive manner. A few family members and passengers experience overt signs of distress and are supported in a manner in keeping with evidenced informed psychosocial first aid. Information on practical assistance and health tips is presented verbally, through print material, and on a website.</p>	<p>The airline's family support teams will remain in contact with all passengers. Contact with standby crisis team members has been ongoing and next steps are discussed regarding follow-up. On site, team members stand down knowing which team members will rotate in to follow up. Key activities and potential needs are documented.</p>
2:00 A.M.	<p>All nonhospitalized passengers and family members have returned home or to suitable accommodation. The team members review the evening with a focus on current and potential psychosocial needs and the appropriate follow-up in the coming day.</p>	<p>7:00 A.M. New team members are rotated into the incident. They are briefed and plans are made to make courtesy support calls to the responding airport services and professionals in coordination with the airport management. Print material on the role of the crisis team, professional resilience, and incident stress is made available.</p>

Next 48 Hours

Informal support calls are made to airport services. The Crisis Team includes firefighters from local services and they make an informal outreach to the airport fire department. In this event, no requests are made for ongoing or more intensive disaster mental health service for airport staff. The airline is supported by its own internal support services and an external health provider. A few passengers do contact the crisis team for information and receive telephone support and referral information as indicated. Subsequently, the team reviews its actions and performance, as well as the implications for training, policy, and protocol revision.

SOCIAL WORK AND EMERGENCY SERVICES

For most of our human history, small group communal efforts were the heart of rescue and protection efforts. With increasing complexity and social organization, we began to develop systems to safeguard ourselves from fires, injury, and crime, and in the last century significant developments occurred in our society to move toward professional systems of emergency personnel and management. The "24/7" media coverage often dwells on communities and emergency professionals affected

by large-scale dramatic emergencies and disasters, such as the earthquake and tsunami that struck Japan; severe weather-related events such as hurricanes, floods, and tornadoes; terrorist attacks; and the occurrence or risk of pandemics, such as H1N1. These massive events may distract us from appreciating that each day emergency service professionals face "routine" emergencies with their own challenges; the motor vehicle accidents, fires, shootings, and medical emergencies. These daily challenges occur in the context of government oversight, the hassles of bureaucracy and "office politics," and the increasing scrutiny of the media and public. All of this is unfolding as new and old risks in our changing world merge to create new versions of hazards, such as increasing severe-weather emergencies, pandemics, and biological or cyber terrorism.

Globally, societies have worked to improve the response to mass emergencies and disasters by developing stronger emergency and continuity management programs, moving beyond the all-hazards approach to now include the interconnected parts of emergency management, prevention/mitigation, preparedness, response, and recovery (Gordon, 2002). The first step in an all-hazards approach is to continually identify the natural and human-made hazards that exist, or may develop, in a community. The work of emergency professionals in broad terms is

preventing and preparing for emergencies and their harmful effects, responding effectively and quickly when emergencies do occur, and then helping in the recovery stage.

Canada and the United States developed comprehensive emergency and continuity standards, such as the harmonized standards from the National Fire Protection Association (NFPA-1600) and the Canadian Standards Association (CSA). In the United States, the Federal Emergency Management Agency (FEMA) has incorporated the “whole community” concept to a broadening all-hazard national response strategy. The “whole community” approach seeks to engage and strengthen communities and their partnership with emergency services. The Canadian department, Public Safety Canada (PSC), has recently reissued an updated version of a national Emergency Management Framework. Internationally, the International Standards Organization (ISO) continues to add to a developing series of new standards, under the heading of “Societal security—Guideline for incident preparedness and operational continuity management.” These standards outline the incident command, control, and management of an emergency and disaster. Social Workers interested in working with emergency services need to become familiar with the basics of these emergency structures and processes.

Emergency professionals train extensively and acquire specialized knowledge to deal with a wide range of emergencies and disasters. Nevertheless, there are aspects of emergency response work that may wear down even the most resilient emergency responder or team. The research literature and the popular press have often focused on high profile emergency events and their impact on emergency professionals. Research has overfocused on mass casualty events, such as severe weather-related disasters, rail or plane disasters, and terrorist attacks. Equally significant are the findings from occupational health research showing that persistent workplace stress in an unresponsive, unsupportive organization erodes the well-being of professionals. Without preparation and support, traumatic and/or persistent stress will eventually lead to wear and tear on the emergency professional’s health and disrupt family and work life—even in the most resilient person. The focus of this chapter will be a discussion of the effects of daily occupational stresses, as well

as large-scale events and disasters, on emergency services at the individual, family, and organizational level, followed by an outline of a continuum of supportive actions and interventions, as well as implications for social work practice and education. This chapter on emergency services focuses on the work of professional police, firefighters, paramedics, and/or emergency medical technicians and does not specifically address other valuable emergency responders, such as emergency medical staff in hospitals and specialized disaster responders (e.g., hazardous materials professionals) and volunteers.

A social-ecological framework suggests factors related to the individuals, their workplace, and the emergency event itself combine to affect emergency and disaster-related health outcomes and performance (e.g., situational awareness, cognitive performance, or decision making). Following adversity, the emergency professional’s health outcomes may range from resiliency, as demonstrated by normal stress reactions followed by a healthy adaptation to the adversity. Some professionals may develop problems in work and living (such as family conflicts or loss of productivity or absenteeism). Persistent stress affects cognitive performance and contributes to physical health problems or psychological problems (e.g., depression and/or posttraumatic stress disorder). Individual differences in outcome are the result of life experiences, organizational factors, and event factors. Individual factors include life experiences, such as general health habits, history of trauma, and personal loss. Organizational factors include the presence of effective leadership and support for both the technological and human side of emergencies. Emergency events include adverse, potentially dangerous working conditions, and witnessing the serious injury or death of children and/or colleagues. A discussion of these factors helps further our understanding of emergency services work.

DAILY OCCUPATIONAL STRESSES

Disasters of great magnitude do not happen often in the career of emergency professionals; nevertheless, most experience many gruesome and dramatic events. Most paramedics have been assaulted (almost 70%) and feel that they have been in situations where their lives were at risk (56%). Over 40% of the firefighters in

Canada witness violence against others and multiple casualties. Approximately 30% of firefighters experience the death of a person in their care (Regehr & Bober, 2005). These exposures have the potential to cause emotional and social distress in even the most seasoned responders. Events such as violence against children, dealing with the intense emotions of families, and exposure to multiple gruesome casualties, such as in a disaster, are most likely to lead to more intense reactions or potentially traumatic symptoms. A study of police officers suggested that the death of a partner, the line-of-duty death of another officer, or the suicide of another officer were among the most stressful events on the job. Large-scale events such as disasters have additional factors that lead to stress and distress and these are outlined in Table 13.1.

TABLE 13.1 Emergency Event Conditions that May Increase the Level of Stress

-
- Shift work, long hours and time pressures in situations where events are uncontrolled, happening quickly, and lives are threatened.
 - Making decisions in chaotic situations—at times with incomplete information.
 - Emotional demands of situations where peoples' health is at stake.
 - Witnessing mass casualty incidents, including exposure to grotesque situations.
 - Interactions with disaster survivors and bereaved family members, particularly after the death of a child.
 - Adverse work environments such as cramped or toxic environments, or exposure to adverse weather conditions (cold, rain, snow, high winds).
 - Intense public scrutiny, along with pressure and high expectations to resolve the crisis.
 - Heightened news and social media attention and scrutiny.
 - Worry associated with exposure to chemical, biological, radiological, nuclear and unknown/invisible toxic agents, or infectious diseases.
 - Worry or fear for the safety of one's family.
 - Witnessing the death or serious injury of a colleague.
 - Being unprepared for multi-agency, multi-jurisdictional operations.
-

(ATSDR, 2005; Regehr & Bober, 2005)

ADDITIONAL WORKPLACE SOURCES OF STRESS

Although critical event exposures do carry risk, the nature of the emergency service workplace contributes additional risk factors for distress. One such factor is shift work, which leads to problems of fatigue, sleep disturbances, and workplace accidents, as well as health problems, such as weight gain, cardiovascular problems, and gastrointestinal disturbances. In addition, the work environment is often unpredictable, as high-stress emergency tasks frequently occur between long periods of readiness. One police officer described his work as two hours of boredom followed by two minutes of sheer terror and three hours of report writing (Regehr & Bober, 2005). Organizational changes, along with shifting demands and expectations, are an additional source of stress. A Swedish study examined the physiological reactions of police inspectors during a time of organizational change. Survey questionnaires and blood samples began to be collected shortly after the change and continued at specified time intervals until three years after the change. Significantly, cholesterol levels, cortisol, and testosterone were highly correlated with worry and workload (Grossi, Theorell, Jusisoo, & Setterlind, 1999).

Although considerable evidence exists that these emergencies have an impact on workers, many research studies suggest that it may be the everyday hassles associated with routine administrative, bureaucratic, and organizational structures that create a layer of stress and strain, and form the foundation on which critical events are heaped (Lieberman et al., 2002). Critical events encountered by those who are already experiencing stress and who perceive that they do not have support from their colleagues, managers, and/or unions are more likely to result in traumatic stress reactions than are critical events encountered by individuals at their optimal level of functioning who know they can count on others when they are facing challenges.

Emergency service organizations often have strong attitudes regarding the expression of emotion. Cynicism and pessimism are frequently identified within emergency service organizations, and these factors contribute to higher levels of stress and tension in individual workers. Support from management is one of the primary protective factors in reducing stress and posttraumatic stress reactions in emergency responders. It is gratifying

to note that some workers also perceived a great deal of support from both their immediate supervisors and from management (Regehr et al., 2000). One study examining over 1,700 firefighters and 248 paramedics reported that coworker support had a profound effect on both job satisfaction and work morale, and although the influence of family support was still significant, it had a much smaller influence on these factors (Beaton, Murphy, Pike, & Corneil, 1997). A negative aspect of social support occurs when the group norms lead to a prohibition on expressed emotion and a lack of encouragement to seek help. Seeking help can incur social costs, because the seeker appears incompetent, dependent, and inferior to others.

PUBLIC INQUIRIES

When tragic events occur they rarely end with the tidying of equipment and completion of paperwork. Rather, society has increasingly moved to the process of postmortem inquiries with the goal of identifying errors and avoiding future deaths. Although the goals of public accountability and quality assurance are laudable, these inquiries do not come without cost. There is a profound effect on emergency workers who testify in inquiries. Police, firefighters, and paramedics identify experiences of feeling unprotected, attacked, and presumed guilty of incompetence or negligence when testifying at a postmortem review. Media attention intensifies these feelings, particularly when the news is often sensational and vilifying, with the subsequent public response of suspicion and blame. These feelings intensify further when workers view the organizational response to be unsupportive. As a consequence, emergency workers report symptoms of intrusion, avoidance, arousal, and self-doubt that begin with the tragic event itself and continue throughout the review process. In the end, some responders are able to identify positive outcomes from the review process, such as new learning, some positive recognition, system change, and especially vindication. Nevertheless, a dominant theme is that of betrayal, anger, and reduced commitment.

THE EFFECTS OF STRESS AND TRAUMA

Due to the nature of their work, police officers, paramedics, firefighters, and other emergency

responders face an increased exposure to potentially traumatic events among the public they serve, and at times, witness or personally experience life-threatening situations. Emergency responders will naturally develop some symptoms of stress. Stress in itself can be a positive, motivating force, helping professionals to be energized and focused on a task. Occasionally, however, these symptoms may reach such a level of intensity, lasting for a month or longer, that they develop into posttraumatic stress disorder (PTSD). Although many studies have supported the view that the intensity of the trauma has a bearing on the severity and chronicity of trauma symptoms in rescue workers (Weiss, Marmar, Metzler, & Ronfeldt, 1995), it is becoming increasingly clear that trauma and distress do not have a simple cause-and-effect relationship.

A second set of factors relates to the personal life experiences of the individual responder. Recent reports have highlighted the importance of individual differences in determining the intensity and duration of trauma-related symptoms (Yehuda, 2001; Regehr, Hemsworth, & Hill, 2001). Mediating variables identified by researchers include: a history of trauma before the event, previous mental health problems, and/or a family history of mental health problems (Luce et al., 2002). A cognitive appraisal of an event as manageable and within one's coping ability reduces affective arousal, influences a person's expectations of success, and promotes more adaptive behavior (Bryant & Guthrie, 2007). Thus, a sense of optimism shapes a person's reaction to a crisis and subsequently influences the outcome. Believing in one's self efficacy during a potentially traumatic event, or maintaining a sense of control despite the reactions one feels, may help people to cope more effectively. A final individual characteristic is the individual's ability to develop and sustain interpersonal relationships or relational capacity. This capacity is useful in understanding individual differences in obtaining social support.

A third second set of factors relates to the recovery environment, specifically to social support, which has been identified as one of the more powerful factors affecting the development and course of PTSD. Studies have shown that social support from spouses, family, and friends to be significantly associated with trauma scores (Regehr et al., 2000). Additionally, the public and media responses to the event also validate or strain professional well-being.

When individuals are exposed to events that threaten their lives or cause serious injury to themselves or others, there is a risk of developing PTSD. In the recently revised edition of the *Diagnostic and Statistical Manual of Mental Disorders (DSM-5)*, PTSD was moved into a class of trauma and stressor-related disorders. Relevant to the discussion here is the DSM's recognition that a traumatic stressor may occur in the course of professional duties, such as emergency responders who experience repeated or extreme exposure to trauma-related human suffering as well as gruesome sights and sounds. PTSD symptoms occurring in the aftermath of a traumatic stressor are grouped according to four clusters, namely, intrusion, avoidance, negative alterations in cognition and mood, and alterations in arousal and reactivity.

The criteria for a PTSD diagnosis requires the following: at least one symptom of intrusion, such as recurrent intrusive memories, traumatic nightmares, flashbacks, and marked distress or physiologic reactivity after exposure to trauma-related stimuli; at least one symptom of avoidance, for example, persistent effortful avoidance of distressing trauma-related thoughts, feelings, or external reminders (e.g., people, places, conversations, activities, objects, or situations); at least two symptoms of negative alterations in cognition and mood that include the inability to recall key features of the traumatic event or persistent (and often distorted) negative beliefs and expectations about oneself or the world (e.g., "I am useless" "The world is completely dangerous."). Negative alterations in cognition and mood can also include persistent, excessive self-blame or distorted blaming of others for causing the traumatic event or for resulting consequences; persistent negative emotions (e.g., fear, horror, anger, guilt, or shame); and diminished interest in activities or a sense of detachment or estrangement from others. A diagnosis of PTSD also requires at least two symptoms of trauma-related alterations in arousal and reactivity, such as irritable or aggressive behavior, self-destructive or reckless behavior, hypervigilance, exaggerated startle response, and sleep disturbance or problems in concentration. PTSD symptoms must be present for more than one month and there needs to be evidence of significant distress or functional impairment in domain of life (e.g., social, occupational).

The prevalence of PTSD is expected to be similar to the DSM-IV rates. There is some evidence

to suggest that the prevalence and the course of PTSD for intentional trauma-related events (e.g., assault, war) is higher than for a nonintentional trauma (e.g., a natural disaster). It is best to keep in mind that the trajectory of PTSD is mediated by the severity of exposure, the characteristics of the populations exposed, and the recovery environment, most importantly social support.

Research has found rates for PTSD in emergency professionals ranging from 5% to 32% and higher in the case of police officers involved in a shooting (Kleim & Westphal, 2011). Regehr and Bober (2005) found no significant differences in the scores of police, firefighters, and paramedics; at any given time, 24.6% of emergency responders had high or severe levels of trauma symptoms. A complicating factor of PTSD is that over 80% of PTSD cases are comorbid with other mental disorders or medical illnesses, with more than 50% of those diagnosed with PTSD also having depression (Shah, Shah, & Links, 2012). Other longer-term effects may include a reduced capacity to handle stressful events, substance use, health problems, and a disruption or impairment in functioning in one's work and home life.

THE EFFECTS ON EMERGENCY FAMILIES

Families of responders are also significantly affected by these incidents. One impact is the fact that the exposed worker at times feels disengaged and emotionally distant from family members: "You almost treat your spouse like another call ... there is a [emotional] deficit there." (Regehr & Bober, 2005, p. 77). Another issue is generalized anger and irritability, often vented on family members. Further, responders describe generalized fears for the safety of family members and a tendency to become overprotective. Researchers have demonstrated how job-related stresses, experienced in a variety of working environments, can be transmitted to family members once the individual returns home. In general, findings suggest that job stress dampens the quality of marital interactions and causes the other spouse to feel more negatively toward the relationship (Larson & Almeida, 1999). Another study utilizing physiological measures discovered that on the days officers reported higher levels of stress, both the officers and their wives showed greater levels of autonomic arousal during conversations (Roberts & Levenson, 2001).

SUPPORT AND INTERVENTIONS FOR EMERGENCY RESPONDERS

To provide optimal support, the best approach is a *continuum of interventions*, that is, ongoing and uninterrupted supportive interventions, though the intensity of interventions at any one time must be linked to the health and mental health needs of the emergency responder and the members of responding organizations. Interventions, for our purposes, are planned actions to promote well-being and resilience, while preventing or reducing the harm from adversity or advancing the recovery from adversity. In our experience, no matter how attractive interventions for individuals or groups of individuals may be, they are not likely to be feasible or well-implemented unless politically supported and culturally appropriate for a given organization; all organizations have a direct influence on the health and well-being of their employees. The continuum of interventions generally can be aligned with the phases of emergencies, beginning with psychosocial prevention and preparedness training, such as health promotion programs, organizational and leadership development, family education and support, disaster stress education, and peer support programs. The immediate response and recovery phases may include programs such as emergency psychosocial first aid, consultation and liaison, crisis intervention, risk communication, and posttraumatic stress treatments.

PREVENTION AND PREPAREDNESS TRAINING

There is increasing recognition that promoting resilience to stress and increasing resistance to illness begins with a healthy lifestyle. To that end, one good example of a health promotion program is PHLAME (Promoting Healthy Lifestyles: Alternative Models' Effects). This evidence-based approach is undergoing a multi-year, multisite study with firefighters. It is a very promising approach in promoting physical activity, healthy eating habits, and weight management for firefighters.

Predisaster education and training is another excellent support program. This form of preparedness accomplishes several objectives: it provides information on stressful and potentially traumatic events, normal reactions, and the recovery process; it reviews and expands on healthy and

flexible coping approaches to address stressful demands and promote recovery; it builds social support among coworkers; and it reduces barriers to seeking help, such as isolation, stigma, and embarrassment. Education, for example, on the factors that intensify or mitigate the effects of disaster, prepares people to be less vulnerable to extreme stress by reducing uncertainty and helping people to appraise a situation in a way that supports their sense of competency, confidence, and control. An important component of this education is to train those in leadership positions on how to provide health promoting support to their staff before, during, and after high-stress emergency events. Training programs are also recognizing the challenges of stress on cognitive performance, as well as on mental health. One program incorporating mindfulness as a key component in mental readiness or preparation training is Mindfulness-based Mind Fitness Training (MMFT). MMFT is a course taught over eight weeks, originally designed for the military context to enhance mindfulness skills and stress resilience skills for individuals operating in extreme stress environments. The program is being adapted and considered for use by various police organizations. Research has shown promising results in promoting cognitive resilience by protecting working memory under high-stress conditions (Jha et al., 2010). Another avenue of mental readiness training for occupations in high-stress fields is mental training skills that promote performance excellence. Though there is little research with emergency professionals on the use of mental skills training, such as, enhancing attention, focus, critical curiosity, distraction control, and managing emotions during times of stress, disappointment, or adversity, there is growing evidence of the value of these skills in medicine and with elite athletes (Moulton & Epstein, 2011; Moore, 2009; Orlick, 2007).

Another stressful situation for emergency workers is an encounter with distressed family members of a victim, who possibly has been injured or killed. New efforts are underway to train firefighters in the interpersonal and problem-solving skills needed to assist a distressed family member. An excellent online training program is sponsored by the National Fallen Firefighters Foundation, and the skills presented also may be relevant to other emergency services. The program, Curbside Manner: Stress First Aid for the Street, consists of a series of practical supportive actions to assist distressed

individuals and families. The approach is consistent with the evidence-based Psychosocial First Aid principles discussed below. More information regarding online training and resources is available in the resource section.

Peer support teams have formed the core of trauma-related intervention programs for the past several years. Peer support teams have many advantages, including having indigenous knowledge of the issues faced by the individual workers, and the culture and politics of the organization. Peer support programs provide a means through which to build capacity and sustain knowledge and skills in an organization over time. The challenges in establishing these teams are developing clear roles, boundaries, and ethics, and ensuring the team member's well-being. All this requires effective team selection, training, support, and accountability. Recent international consensus guidelines on peer support team standards and training have been published and social workers can play an important role as mental health clinical resources in the training and support of the teams (Creamer et al., 2012). Social workers' expertise in crisis intervention, effective interpersonal skills, and group dynamics, from a strengths-based perspective, form an excellent foundation for working with and training peer support teams. There are good resources for the development, training, and maintenance of peer support and trauma response teams listed in the resources following this chapter.

FAMILIES OF EMERGENCY PROFESSIONALS

Families are often the forgotten victims of workplace stress and trauma. Family members deal with trauma contagion as they are confronted with attitudes and behaviors of the responder emanating from the exposures on the job, and as they fear for the safety of their loved one. Organizations need to expand their notion of membership to include families and intervention programs that do not incorporate family needs. Table 13.2 outlines several steps to promoting resiliency in the family.

PSYCHOSOCIAL FIRST AID

One of the useful services and skills offered by mental health staff or peers under the supervision of mental health professionals in

TABLE 13.2 Steps to Promote Family Resiliency

-
- Work out family routines systems to accommodate shift work.
 - Establish decompression routines between work and home.
 - Acknowledge your own reactions to events and work to separate them from responses to family situations.
 - Plan responses to questions and comments from children, friends, and neighbors.
 - Establish a support system in both the workplace and personal life.
-

(Regehr & Bober, 2005)

the field is psychosocial first aid, also referred to as Psychological First Aid (PFA), originally described by Raphael (1986) and recently updated with current evidence-based practices through efforts at the National Center for PTSD and the National Child Traumatic Stress Network (Ruzek et al., 2007; Hobfoll et al., 2007; Shultz & Forbes, 2013). The field has debated the best models of support for the emergency services and there is a consensus among researchers, clinicians, the World Health Organization, and the American Firefighter Association recommending PFA as a preferred model of support, though there are emergency services who continue to use a proprietary model of critical incident stress management. The objectives of PFA are, "To establish safety and security, promote connection to social and restorative resources and modulate stress-related reactions and reduce the initial distress caused by traumatic events and foster adaptive short and long-term coping." Three practical ways to support a professional during the rescue and recovery phases are: (1) tangible support, such as food, shelter, tools, equipment, and hands on help; (2) informational support, including regular updates on risk and safety communications; and (3) social-emotional support. Recently, PFA has been modified so that the helping language and process is more culturally relevant for hierarchical emergency service organizations. This model of stress first aid for emergency professionals uses a process of check, coordinate, cover, calm, connect, and competence and confidence. More information is available through the websites listed in the references.

An important part of psychosocial aid is the consultation and liaison function that a social

worker can offer to organizational leaders, peer support teams, and at the Emergency Operation Command Center, particularly during mass emergencies and disasters. Assistance may be provided with the challenging tasks, such as managing work hours, managing rotation among intense and dangerous work, assessing fatigue factors, preparing and staffing rest stations, and assessing potential risk for occupational or traumatic stress reactions. All these involve making critical decisions regarding the safety and well-being of the emergency professionals. A part of this role may include risk communication.

Increasing attention is being paid to risk communication to inform and protect emergency professionals and their families regarding work-related hazards, largely because of high-profile events such as terrorist attacks and pandemic risks. For instance, at Ground Zero, clear evidence indicates that there were health risks at the site that continue to affect emergency responders years later. At the recovery site, some people wore full protective gear, some wore simple paper masks, and some wore no respiratory protection at all. Addressing the current and future risks is a key step to assuring well-being and reducing worry among professionals and their families. The Severe Acute Respiratory Syndrome (SARS) situation in Toronto provides another example where risk communication was vital. Concerns regarding SARS continued to evolve on an hourly basis as information was gathered regarding the nature of the illness, the mechanism for transmission, and its lethality. Many emergency professionals and family members experienced the stress of quarantine, incomplete information, worry, and social isolation.

POSTTRAUMATIC STRESS TREATMENT

As we have discussed, most people recover over time from traumatic stress and yet for a number of reasons, related to their individual characteristics and resources, the nature of the event, and the quality of the psychosocial resources following the trauma, the natural recovery process may be disrupted and some may experience posttraumatic stress disorder. Treatment, or at least a consultation, is indicated when responders experience persistent difficulties in their relationships, changes in their work performance or

productivity, withdrawal from usually pleasurable activities, continual symptoms of anxiety or depression, and/or deteriorating health as noted by fatigue, poor sleep, over- or under-eating, or persistent aches and pains. A physical health examination is a useful starting point. Further, demystifying the process of treatment can be of assistance, given that movies and television generally have not portrayed the therapy process accurately or usefully.

In the many excellent reviews and meta-analyses of research related to treatment efficacy for traumatized individuals, it is generally acknowledged that only cognitive-behavioral treatment (CBT) methods have been subject to rigorous evaluation with controlled trials (Ehlers & Clark, 2003; Solomon & Johnson, 2002). Although the use of Internet-based CBT is currently the focus of a number of research studies, it is not the only treatment that works. There is good evidence for other approaches, including Eye Movement Desensitization and Reprocessing (EMDR) and pharmacological treatment to assist with symptom management for trauma sufferers.

IMPLICATIONS

There are five potentially positive social work practice, policy, and education implications of the above discussion. Firstly, given the increasing risk of large scale emergencies and disasters, Social Work education should include enhancing the knowledge base of social workers to understand the dynamics of emergencies and disasters and how to offer the full range of preparedness and recovery interventions. The strengths of social work in crisis intervention, group work, and community development are excellent foundational building blocks for this education. At a minimum, social work educational programs should offer a primer on emergency and disaster preparedness as a foundation for promoting and modeling self and community efficacy and resilience. Secondly, the academic community can also utilize theory and research-based skills to contribute to the growing knowledge regarding trauma, emergencies, and disasters among specialized populations, such as emergency professionals. Thirdly, social workers can offer the practice skills to assess post-disaster levels of distress, the risk for PTSD, and traumatic grief at the individual, family, and emergency services

organizational level. Social workers can be members of emergency and crisis peer support teams, including providing effective group training and consultation to support the development of peer teams that support emergency and disaster personnel. Social workers may also apply their group and community development skills to understand broader community needs and vulnerability as means to advocate for policy and practice change. Some disasters may have long-term and enduring effects that disrupt social, emotional, and economic well-being and erode the resiliency of the public and emergency professionals. As the population grows, and new and expected hazards and new vulnerabilities evolve, social workers can ready themselves to offer their research and practice skills to provide evidence-based, culturally relevant services to high-risk professional groups, such as emergency professionals, their families, and organizations.

14 Military Social Work

Allen Rubin & James G. Daley

THE DIVERSE NATURE OF MILITARY SOCIAL WORK

Since 1905, social workers, uniformed or civilian, have built a long, rich history of providing services to military personnel, veterans, and their families (Daley, 1999a; Rubin, Weiss, & Coll, 2013). Uniformed social workers have been in the Army, Navy, Air Force, and Public Health Services with ranks from lieutenant to colonel. Civilian military social workers have held diverse positions, including ones in mental health, substance abuse, family advocacy, medical services, and family services, as well as with Wounded Warriors and their families. The scope of their jobs and expected competencies has been recently outlined by the Council on Social Work Education (CSWE) brochure titled “*Advanced Social Work Practice in Military Social Work*” (<http://www.cswe.org/File.aspx?id=42466>). Established in 1926, the social work program in the Veterans Administration has developed into the largest employer of social workers in the United States (<http://www.social-work.va.gov/about.asp>) and offers very diverse programs from medical social work in medical centers to outreach clinics, to residential facilities, to targeted clinics for veterans of Operation Iraqi Freedom (OIF), Operation Enduring Freedom (OEF), and Operation New Dawn (OND) (U.S. Department of Veterans Affairs, 2010).

Social work roles in helping military personnel, veterans, and their families include both micro and macro levels of practice. Social workers performing these roles can be considered to be practicing military social work regardless of whether they are in uniform as commissioned officers in the armed forces or out of uniform working for the Veterans Administration, other departments of the federal government, or in community agencies or private

practice. Nonuniformed military social work can also be provided contractually at military bases.

Their roles span the gamut of social work practice, and might include such services as medical social work for veterans suffering from a traumatic brain injury (TBI) or other ailments; treatment and prevention of sexual abuse, domestic violence, or substance abuse; case management; therapy for posttraumatic stress disorder (PTSD); educating family members about the difficulties they may experience when one of them is deployed overseas; developing programs in the community to help veterans transition to civilian life and alleviate homelessness among them, helping to develop policies and procedures, and many others.

NAVIGATING THE MILITARY CULTURE

The military environment has been called the “Fortress Society,” with a very closed system toward outsiders understanding how the military functions and evolves (Wertsch, 2006). A multitude of rules and regulations, a vision of invulnerability, and a determined passion for mission drive the military as a system and even as an ethnic identity (Daley, 1999b). Rank is worn overtly as a ready recognition of status. Uniforms and shoes are crisp and polished as a symbol of pristine image. Orders are to be accomplished regardless of required effort with no excuses expected or accepted. Deployability is an overarching expectation, and military personnel will minimize personal issues, injuries, or insecurities to be ready to accomplish the mission. A popular saying is, “There are no problems, just opportunities to excel.” Behind the public image can be service members or families who are struggling with PTSD, depression, substance abuse, and more.

To relate to the military, a social worker must be familiar with rank, chain of command, and how to frame interventions in “military-ese.” The language needs to be framed as “help to ensure the client is deployable,” “helping the client build better resilience skills,” and other strengths-focused framing. The social worker should also be familiar with the experiences of combat and how various wars and conflicts are similar or divergent.

THE CHANGING MILITARY CONTEXT

The military has been involved in diverse settings. World War II was the largest war, lasting from 1930 to 1945, with 16 million serving in the U.S. military and 400,000 deaths (<http://www.wwiimemorial.com/>). The enemy was clearly defined, front lines were declared, and the cause was survival at a global level. The U.S. troops were praised as the “greatest generation” (Brokaw, 1998) with portrayed in films such as “Band of Brothers” and “the Pacific” movies. The Korean War from 1950 to 1953 was the first “military action of the Cold War” (<http://www.history.com/topics/korean-war>) and ended with a stalemate that divided Korea into two sections and an ongoing volatile tension that continues today. The Vietnam War escalated slowly from 1954 to a conclusion in 1975 with a peak in 1969 of 500,000 U.S. military deployed (<http://www.history.com/topics/vietnam-war>). The Vietnam War was the first clear defeat of U.S. military power due to political complexities and a primarily guerilla warfare, whereas the Korean War or World War II were primarily uniformed soldiers facing established front lines.

The Vietnam War was very unpopular in the United States, with massive protests held against it. The drafting of young Americans for an unwanted war fueled America’s anger. After Vietnam, there have been no further declared wars, though there have been operations including Operation Restore Hope in Somalia, Operation Noble Anvil in Kosovo, Operation Quiet Resolve in Rwanda (Exum, Coll, & Weiss, 2011). The conflict in Iraq and Afghanistan was never declared a war but rather a series of operations—Operation Iraq Freedom (OIF), Operation Enduring Freedom (OEF), and Operation New Dawn (OND). Further, the Vietnam War was a draft war, whereas the current operations are being conducted by an all-volunteer force. The most recent operations have been deeply intertwined with the “war on terror,” a constantly

evolving effort that blends diplomatic initiatives and military might to reduce the volatility and destructiveness of terrorist organizations. Due to the guerilla warfare dynamic of the recent operations and the consequent civilian casualties and damage to homes, military personnel often have been caught in morally anguishing situations. The complexity of the global war on terrorism defines military missions that send our troops to complex settings where the troops are morally damaged.

THE COMBAT VETERAN AND IMPACT ON FAMILY

Uniformed military social workers are deployed to combat zones as part of a combat stress team. Combat can be stressful and traumatizing, certainly confusing, and hard to contextualize. Combat vets cannot adequately describe to a civilian what they have been through. Traumatic events get submerged, and often there are aspects of the events that they are afraid to allow to emerge. Combat is confusing. Social workers try to offer aid, but combat and the deployment process take a toll on many military members and their families (Kelly, Howe-Barksdale, & Gitelson, 2011; Pryce, Pryce, & Shackelford, 2012). A growing list of books provide self-help guides to coping with the deployment cycle (DeCarvalho & Whealin, 2012; Hart, 2000; Henderson, 2006; Matsakis, 2007; Pavlicin, 2003; Slone & Friedman, 2008; Whealin, DeCarvalho, & Vega, 2008). The family has to cope with predeployment (e.g., getting power of attorney for spouse, preparing children for separation), deployment (e.g., evolving roles when apart, communication while apart via electronic choices of cell phone or video links), and postdeployment (reunion and stress of established new roles) (Franklin, 2013; Pavlicin, 2003; Ponder & Aguirre, 2012).

For military members who are struggling with PTSD or other stressors, the stigma of seeking mental health care continues to be a barrier to effective and timely use of a range of services that military social workers offer (Stotzer, Whealin, & Darden, 2012). Screenings are set up in conjunction with the Veterans Administration (VA) for service members according to a three-month postdeployment time frame to try to reduce stigma and encourage seeking services for PTSD symptoms. The Institute of Medicine has defined PTSD, traumatic brain injury (TBI), and depression as the “signature injuries” for the

OIF/OEF/OND veterans. Therefore, the screenings strive to identify this triad of injuries so treatment can be initiated.

Also, suicide among military members has increased, and efforts to reach out and educate military personnel are top priorities in all the Services. The Department of Defense Suicide Event Report (DODSER) is tracking the prevalence annually, and suicide prevention and outreach programs have ramped up in all the Services and the VA. Legislative efforts have emerged, such as the Joshua Omvig Veterans Suicide Prevention Act of 2007 (Cato, 2013; Pryce, Pryce, & Shackelford, 2012). Joshua Omvig was a military policeman deployed to Iraq who, when he came home on leave, told his family he was “dead inside” and shot himself in front of his mother (<http://joshua-omvig.memory-of.com/legacy.aspx>).

The number of deployments for military personnel is unprecedented, with service members completing as many as five deployments. The National Guard and Reserves have had a higher deployment and combat role than ever in the history of the Guard. Related financial stressors have strained military families. Complex ethical and moral situations in combat settings have produced PTSD symptoms that are hidden from military mental health providers due to the bravado culture of the military and fear that mental health issues might be career damaging.

Women have rapidly increasing opportunities to serve in most combat-related jobs and excel when given the job (Osborne, Gage, & Rolbiecki, 2012). There is growing pressure on the military to prevent and intervene with sexual assault better, particularly in combat settings (Weiss & DeBraber, 2013). Recent military policy changes have enabled gay and lesbian military members to serve openly, although transgender military members’ needs are not currently addressed. Thus, with the military constantly evolving, military social workers need to be involved in policy and practice adaptations to assist military members as they navigate these changes.

The transition from being a military member to being a veteran can be stressful, particularly if the veteran has an identified or hidden service-connected injury. The military culture is focused on mission and deployability, whereas the Veterans Administration is focused on eligibility for service and honoring the veteran’s service. Thus, military members hide their injuries, fearful that they will be nondeployable, whereas

savvy veterans are vocal about the benefits they have earned. Transition programs target military members leaving the service. For example, the Wounded Warrior Program (WW) maintains service members on active duty until they either are eligible to return to the unit or are medically discharged and routed to the VA medical care system. Regardless of the disability, transitioning veterans are eligible for the GI bill for college or technical school and can have priority for some jobs. Student veterans often may find a military and veterans service center at the university they choose (Smith-Osborne, 2013). Advocacy organizations such as the Iraq and Afghanistan Veterans of America (<http://iava.org/>) seek to connect and support veterans transitioning into the civilian world, where only 1% of the population has ever been deployed in OIF/OEF/OND. Because some veterans deteriorate and end up homeless (Carrillo, Costello, & Ra, 2013), funded housing programs and outreach services are targeted specifically for homeless veterans. Some veterans end up in legal conflict, sometimes due to PTSD, TBI, and volatility issues. Veterans Court programs try to route impaired veterans to services rather than prison (Holbrook, 2011).

THE TRANSITION TO A FAMILY-IN-MILITARY CONTEXT

The military population has been shifting from a primarily unmarried force who only served a required brief stay in the military to a predominantly married force with children and a longer and voluntary stay in the military. As the military force changed, the roles and size of its social work staff changed and expanded (Jenkins, 1999; Nelson, 1999; Rubin & Harvie, 2013). Thus, the family-centered programs and needs have increased (Harris, 2013). Family advocacy programs have emerged, which focus on family violence prevention, detection, and interventions; assistance with family member special needs; and educational programs for family resilience building (Wheeler, McGough, & Goldfarb, 2013). Family Support Centers, Family Service Centers, and Army Community Services have developed to offer family life education, financial counseling, relocation assistance, and deployment support groups. Family Readiness Groups have evolved for the National Guard to offer support, especially during deployments (Harnett, 2013). Programs for children (e.g., camps, support

groups during deployments) have been developed (Devoe, Ross, & Paris, 2012; Leskin, Garcia, D'Amico, Mogil, & Lester, 2013). Some unique stressors challenge military families. Single parents are required to have a family care plan indicating that their children will have a caretaker if they are deployed (Blanchard, 2012). Dual-career couples may have the nonmilitary career partner struggle with relocations every three years. Dual military couples can be assigned to separate military installations during their career. Deployed National Guard members can return from deployment to find the company where they worked has gone out of business.

UNIQUE ISSUES THAT MILITARY SOCIAL WORKERS FACE

Military social workers work in many settings. Both the military culture and the VA culture are complex and rule bound. The military is a closed society, and social workers can experience difficulty trying to get access to the information or resources that can help their clients. Getting collateral information to assess a client can be frustrating as well. Uniformed social workers have no confidentiality and must navigate what and how they share client information with great social skill. There is a strong dual loyalty dynamic that creates ethical dilemmas (Daley, 2013). Likewise, the Veterans Administration begins all transactions with eligibility determination. How do we provide needed help to someone dishonorably discharged? They do not get care from the VA. For clients who are eligible, how do we find the right program or resources from the VA? It takes years of gaining knowledge to navigate the programs well. For example, a Purple Heart recipient and World War II veteran who needs to go into a domiciliary in Indiana might not get into the VA home until he has been an Indiana resident for five years. Service is less valued than eligibility. Finally, there are long delays—which are only going to grow longer as more military members transition into veteran status—in processing the disability claims for which eligibility drives all benefits (Reed, 2011).

The possibility of secondary traumatization is another challenge confronting social workers who work with combat veterans and their families. The more effective they are with the client, the more traumatic experiences they will hear about in detail. Although such openness is

an important outcome, it is important for the social worker to have a supervisor or coworker to process those memories with and to strive to prevent developing PTSD themselves (Rubin & Weiss, 2013).

A distinct issue is the social worker's access, depending on their job, to the service member, the spouse, the children, the military unit, and the community. Building resources, gaining clout, and developing holistic interventions are possible. For example, the family advocacy program is an excellent example of military social workers creating comprehensive programs to prevent or reduce family violence. Likewise, some social workers are striving to develop a comprehensive suicide prevention program in the military and in the VA.

CONCLUSION

This chapter has outlined the wide range of issues and programs in which military social workers are involved. The unique dilemmas and resilience of military members, veterans, and their families are discussed. The context of the military culture and the VA culture are highlighted. Military social workers, in uniform or civilian, serve a vital role in providing effective services to their clients. As the military mission shifts, military social workers will be poised to advocate for the best care of our military personnel and veterans, whose service should be honored.

15 Military Social Work in the Community

Anthony Hassan & Sara Kintzle

Social work with service members, veterans, and their families is more critical today than ever before in our profession's history. Since the September 11, 2001 terrorist attacks, the potential threats to national security have caused the United States to respond with increased military presence and action throughout the world. Nearly two million deployments have taken place as part of the wars in Iraq and Afghanistan, with many of these including multiple tours of duty (Belasco, 2009). Ninety-seven percent of those sent to war return home—an unprecedented figure in military history. As the frequency and length of deployments have risen, so have the personal, professional, and familial challenges associated with the conditions of deployment (Hazle, Wilcox, & Hassan, 2012). These challenges require professionals, social workers specifically trained in understanding these experiences within the context of military life (Flynn & Hassan, 2010).

Military social work is defined as “direct practice; policy and administrative activities; and advocacy including providing prevention,

treatment and rehabilitative services to service members, veterans, their families, and their communities” (Council on Social Work Education [CSWE], 2010, p. 2). Military social work serves all branches of the United States Armed Forces, together with veterans of all eras and conflicts served by the Department of Veterans Affairs. The roles of military social workers are expansive and vary by organization. They include providing case management and individual, couple, family, and group therapy, as well as performing community practice and research (CSWE, 2010). Military social work is distinguished from other fields of practice because it is strongly shaped by a workplace perspective and focuses on the holistic consequences of life transitions.

The United States military and associated veterans' programs represent large organized employment structures with organizational values and hierarchies. Perhaps there is no other profession like the military, in which individuals and families are required to make such frequent changes, not only in the form of transfers to other localities, but between statuses. The specialized

nature of military training has created a distinctive culture often poorly understood by civilians (Hall, 2012). Building an understanding of the culture in which military social work exists is essential to working with military populations.

MILITARY CULTURE

The development of a therapeutic alliance between a social worker and service member or veteran client is often dependent on the professional's understanding of the culture in which service members exist (Weiss, Coll, & Metal, 2011). Military culture is a shared system of values, rituals, customary patterns of social relationships, and use of symbols that guides and reinforces group behavior. As one of society's oldest institutions, the traditions and meanings associated with military culture are rich and inspiring. Core military values that honor unit cohesion, teamwork, duty, integrity, service before self, loyalty, and self-sacrifice have been deeply engrained through the generations.

The military is not a one-dimensional entity, but a collection of subcultures and subgroups. The United States Armed Forces has five branches: Army, Navy, Marines Corps, Air Force, and Coast Guard. Each branch of service proudly owns its distinctive history and conventions. Sources of internal diversity include branch of service, rank, and the occupational specialty to which an individual has been assigned. For example, one Army soldier may hold the military occupation of infantryman, while another intelligence. Both soldiers belong to the Army and live together but work apart in much different environments and workplace cultures.

Within each branch of the military are two subgroups that include an active component and a reserve component. The active component includes individuals who are active, full-time, service members stationed throughout the world at combat and noncombat bases. They are considered transient and expected to move every three to five years based on the needs of their respective service. While not in combat, active service members spend their days training to improve their military occupation and combat proficiencies, along with performing their daily duties related to administration, patient care, customer service, and the many other responsibilities of military leadership. Active duty service members and their families live on or near insular military

bases with their own grocery stores, shopping centers, and other conveniences of daily living.

The reserve component includes the Reserves and National Guard. The Reserves is a force that serves part-time and typically trains with units located within its home state. Reserves can be mobilized to an active, full-time, status to meet the needs of the country in times of war or national emergency. The National Guard also serves part-time and is comprised of members who work and live within their local community. The National Guard supports both federal and state missions in times of natural and man-made disaster and is mobilized to active, full-time status when needed. Reservists and National Guard members have played an integral role in recent conflicts and have been deployed to Iraq and Afghanistan at rates not seen in military history.

The power structure within the military is also a component of its cultural identity. Military rank is the mechanism through which members are promoted and assigned responsibility. The military hierarchy is more strictly delineated than hierarchies in civilian society and impinges heavily on the way in which informal and formal communications are carried out. For example, in civilian society an employee might interrupt her boss in a moment of intense discussion; this would be much less acceptable between a military officer and an enlisted service member. To be effective, military social workers must carefully learn the power and authority structure within the military from a workplace and cultural perspective, as well as an appreciation of the impact of this structure on the lives of service members and their families (Hall, 2012; Weiss, Coll, & Metal, 2011).

Also essential to navigating social work intervention within the culture of the military is an understanding of the barriers created by the stigma of seeking mental health services. Military culture has traditionally disdained weakness, and by inference, help-seeking for emotional, marital, or other personal problems. Despite new policies and a public relations campaign aimed at normalizing these issues, a stigma remains, as do the challenges faced by service members and their families, and sometimes continues on into their civilian lives.

REINTEGRATION CHALLENGES

Postdeployment and Postdischarge

Reintegration is characterized by the re-entry into everyday life after military deployment

and may include reunification with family and the return to military or civilian employment (Institute of Medicine, 2011). Although most service members demonstrate exceptional resilience during this time, the reintegration into postdeployment life can create challenges for some. This transition is often met with individual challenges, including issues of physical and emotional health; interpersonal challenges, such as maintaining and improving relationships; and often, the economic challenges that come with securing employment.

The physical impacts of war are obvious in service members returning from deployment. The number of surviving service members with permanent, disabling injuries surpasses that of any previous modern conflict. In World War II, the survival rate for those suffering physical damage was 2:2; it is now 8:1. The physical wounds of the Iraq and Afghanistan wars include loss of limbs and digits, facial wounds, hearing damage, and traumatic brain injury (TBI), principally from encounters with improvised explosive devices.

Less visible are the psychological wounds of war. These include posttraumatic stress, major depressive disorder, generalized anxiety disorder, substance misuse, and suicide risk (Kang & Bullman, 2008; Miller et al., 2009). A study of nearly 300,000 Iraq and Afghanistan veterans found that approximately 20% had been diagnosed with mental health problems, typically depression or posttraumatic stress disorder (PTSD) (Hoge et al., 2006). Service members are also at increased risk for other consequential behavioral health challenges. These include hazardous drinking, drug use, sexual assaults, and misconduct.

Moreover, Schell and Tanielian (2011) have painted a daunting picture of stumbling blocks for service members transitioning to civilian communities where access and utilization of community-based support programs is complicated and fragmented. Veterans are often unaware of available services, unsure of whether a service would be helpful for their specific problems, lack information about service locations, are uncertain of eligibility requirements, and do not know how to apply for services. Although veterans who persist in searching for help or support may find an available service, they are often confronted by well-meaning but uninformed agencies and providers who do not understand the scope of the challenges they face as military-impacted individuals. This is a significant barrier to care when we consider that many service members

and veterans harbor a stigma against seeking help of any kind, especially mental health care, and might become so frustrated by a provider's ignorance of military culture and understanding of reintegration challenges that they discontinue treatment. The lack of coordination among agencies and redundancy of services make it difficult for veterans aiming to access critical resources.

The reintegration back into life after deployment is often a time of financial instability as well. Between 20% and 40% of Iraq and Afghanistan veterans have remained without a job for more than three months postdischarge (Adler et al., 2011; Burnett-Zeigler et al., 2011; Jacobson et al., 2008). Some military specialized occupational classifications do not translate directly into civilian positions (e.g., how can the skills of a combat infantryman be utilized in a civilian career?). In other instances, service members have skills that translate to civilian service well, but they may lack necessary accreditation. For example, a service member who served as a medic within the Army has tremendous medical experience related to trauma, yet may not be qualified for employment in some health care settings due to the lack of specific certifications. These challenges to securing employment, combined with low incomes and inadequate community supports, lead to economic insecurity that has a direct impact on the overall health and well-being of veterans and their families (Little & Alenkin, 2011).

What Providers Need To Know: Diagnosis and Evidence-based Practice

Social workers must acknowledge and understand the barriers to treatment faced by service members and their families. The first is stigma. The contradiction between the culture of the military and the need for supportive mental health services creates a perceived, and sometimes real, shame related to treatment. Stigma can stem from the view of society, as well as the individual, where service members internalize stigmatizing behaviors (Greene-Shortridge et al., 2007). Social workers must acknowledge and address the stigma faced by the military population.

An additional barrier to treatment includes the expectations about treatment. Beliefs about medication and what occurs during treatment often create reluctance to accept services. Some service members also report not being ready to seek

services. They do not feel emotionally prepared to discuss mental health symptoms and will tend to wait until a crisis occurs before seeking help. Concerns about confidentiality and the impact that seeking treatment may have on military career or civilian employment are additional barriers.

Diagnosis and treatment of mental health issues within the military are particularly difficult for a number of reasons. Service members have little incentive to acknowledge symptoms, given that this may mean a delay in transition home or discharge. Some veterans may not manifest the disabling effects of combat experience for a year or more after returning home.

The increased occurrence and awareness of mental health problems has created a push for evidence-based interventions; several of which have emerged as particularly helpful in addressing veterans' issues of mental health. These are identified and described in Table 15.1. Interventions with service members and their families are continually being conceptualized and tested.

Services and support aimed at aiding in the transition of veterans from military to community life, as well as issues related to the aging of service members, will be critical in the years ahead. Community-based groups will play a key role in the adjustment of service members and their families throughout the life course. Military social work has never been more important in promoting positive relationships, improved social policies, and improved well-being among those

who serve our country and those impacted by military presence.

COMMUNITY ENGAGEMENT

The primary purpose of the Department of Defense (DoD) military health system is to ensure that service members are maintained or rapidly restored to readiness for active service. It increasingly has been recognized, however, that combat-related disorders are persistent, may require years of subsequent attention, and may lead to premature discharge and/or retirement for some. By contrast, the Veterans Health Administration (VHA) programs focus on restoring functions impaired by war and military service; protecting those who cannot function, through various forms treatment and community-based care; and assisting veterans with transition to civilian community life. As of July 2013, there were approximately 2.6 million veterans of Iraq, Afghanistan, and other theaters of the global war on terrorism (Carter, 2013). Historically, veterans' mental health care needs have risen sharply over time, with a peak occurring 10 to 20 years after the end of a war. This was true for the Vietnam War cohort and will likely be true for the post 9/11 combat cohort (Carter, 2013).

More veterans seek care outside the VHA, than within it. Therefore, a critical part of the total care network includes the role of civilian community

TABLE 15.1 Evidence-based Practice for Military Populations

Approach	Effective For	Brief Overview
Cognitive Behavioral Therapy (CBT)	Mood disorders, including depression, anxiety disorders including PTSD, substance abuse, sleep disorders, psychotic disorders	Examines the relationship among thoughts, feelings, and behaviors by exploring how thinking leads to self-destructive actions and beliefs.
Prolonged Exposure Therapy (PE)	PTSD, clients with trauma history	Decreases distress related to trauma through education, breathing training, and talking through the trauma. Clients expose themselves to safe situations they have been avoiding since their trauma.
Cognitive Processing Therapy (CPT)	PTSD, depression, clients with trauma history	Assists in handling distressing thoughts and gaining an understanding of traumatic events. Includes education, becoming aware of thoughts and feelings, learning skills to deal with those feelings, and ultimately changing beliefs.

mental health agencies, public and private, independent of those contracting with federal agencies as service providers. In previous and future conflicts, the local mental health clinics, school mental health programs, hospital emergency rooms, and other mental health-affiliated agencies have and will continue to constitute a pillar on which recovery and veterans' support will rest. As many as 40% to 50% of veterans from the current war either do not seek health care through the VHA or discontinue treatment shortly after their first appointment. This means that civilian agencies, especially community mental health programs and primary care clinics, are very likely to become the primary resource. All social workers, not just those in the military specialty, will require an awareness of the needs of this diverse group. Critical to improving the quality of life for veterans will be timely and early mental health intervention. Efforts must be aimed at effectively engaging veterans early in their transition process, instead of at the end of the treatment spectrum.

SUMMARY AND FUTURE CHALLENGES

Military social work involves the mastery of content, skills, and intervention specific to working with service members, veterans, and their families. Today, military social workers work at all levels of practice including direct practice, research, community practice, and policy. These professionals are tasked with not only providing services within a community of distinct culture, but addressing an array of physical, mental, economic, marital, and readjustment issues experienced by this population.

One key aspect of successful community support and engagement is the extent of widespread relatedness and interaction among its citizens. Therefore, military social workers will need to create a coordinated approach to supporting and engaging veterans and their families by bringing together diverse sets of resources and identifying new opportunities across the public and private sectors. It is unlikely that the needs of veterans and their families, as well as the quality of and access to care and qualified providers, will be adequately addressed unless the profession is effective at convincing local, state, and federal agencies to join forces.

Military social workers are uniquely qualified to bring diverse resources together, identify

new opportunities across public and private sectors, and lay the foundation for a coordinated approach to supporting and engaging veterans and their families. Community-based social work initiatives can help guide community practitioners, build community networks, inform policymakers, and identify broadly applicable and scalable translational research with promising real-world prevention interventions. Therefore, the overall goal for military social workers should be to ensure cultural competence, utilization of evidence-based practice, and the building of new opportunities and policies that permit more effective and fiscally sound programs for the reintegration of veterans into our civilian communities across the United States. Ultimately, military social work is the safety net for a civil society that is necessary to support the brave men and women who have served our country (Flynn & Hassan, 2010).

16 Social Work with Military Families

Diane Scotland-Coogan

To date, approximately 1,471,088 Americans have participated in the war on terror. As of March 2010, a reported 5,376 have died in service. There are 23,442,000 living veterans and 17,456,000 living ex-service members in the United States (Library Spot, 2013). The families

of those who died in service are processing the grief of a loss that will change their lives forever. Returning veterans, especially those who have experienced combat, will not come home the same person they were before they left (Coll, Weiss, & Yarvis, 2011). This causes considerable

stress on the family as they seek to welcome home their loved one. Social workers will be called upon more and more to provide professional service to assist these families in the healing process.

As social workers, we understand the importance of cultural diversity in the context of practice and military culture differs greatly from civilian culture (Hall, 2011). Culture may differ somewhat between branches; however, the basic tenets are the same. Each branch of the service has pride in who they are, thus it is important to refer to those in the Air Force as Airman, in the Army as Soldiers, in the Navy as Sailors, in the Marine Corps as Marines, and in the Coast Guard as Coast Guardsmen (recently the term Guardian has been used) (National Association of Social Workers [NASW], 2013). For the purposes of this chapter, these brave men and women will be referred to as veterans, a term that reflects all branches of the service. Further details regarding military culture will be discussed later.

It would be difficult to describe the “typical” day of a social worker working with military families. This type of practice could include home visits, in-office appointments, and support group sessions. Home-based service can be beneficial for many reasons. One consideration would be the client’s ability to attend sessions outside the home; we cannot assume the client has the resources to get to your office. Clients may not have access to a car, do not have a driver’s license, are currently dealing with medical issues that would make driving unsafe, do not have local social support to assist, or access to bus service. If the family is caring for a veteran or family member with disabilities, coming to the office may not be an option for them. Treatment should not result in additional stress to the family; rather, it should assist in relieving some of their stresses. For a social worker, being in the home may have some benefits.

One of the advantages of in-home sessions is getting to know the client system on a more intimate level. In the comfort of their own environment, clients may let down their defenses, providing a plethora of information that may have taken months of in-office sessions to acquire. Observing how the family interacts in their home, what their living conditions may be, and identifying possible barriers to treatment can provide significant information for

determining the most appropriate treatment modality. In-home sessions may also keep treatment occurring on a more regular basis, given that clients are less apt to cancel appointments if you are coming to them. There are, however, some downsides to home visits, especially the likelihood of more distractions for the family. This would need to be addressed on the first visit, as you explain the clinical process and the expectations for sessions when working together.

Office visits have the benefit of having the family’s attention in a more structured environment. They also allow you to see more clients in a day because there is no travel time to consider. As mentioned earlier, the number of missed appointments may increase as clients may not have transportation, they may forget, and obligations in the home may keep them from being able to leave.

Support groups can also be very successful in working with military spouses and their children. When facilitating support groups the social worker assists clients in connecting with others who share their experience, and this can prove very validating. Support groups can include, but not be limited to, other military spouses and children, bereavement groups, domestic violence groups, and substance abuse groups such as Al-Anon. Support groups are available for spouses and children, as well as parents and extended family members. For military families, this can provide insight about their loved one’s behavior. The support of those who understand can make the family members feel less isolated in their situation. The group members will share available resources with each other, which might otherwise not have been identified. Many support groups have online chats available for those who cannot get to a meeting because of lack of resources. Identifying local and online groups to work with families is important resource information to have available, and should be updated regularly to ensure accuracy. Building rapport with a client in the beginning will assist the social worker in creating a therapeutic relationship that fosters trust along with the client’s ability to be more open and honest about situations and needs. Only then can the social worker truly understand what referrals and treatment are warranted. In order to build this rapport with military families, it is essential to develop a basic understanding of military culture.

MILITARY CULTURE

Military culture differs greatly from civilian culture. The veteran is taught from the onset about honor and respect. The military has its own language, acronyms, particular ways to dress, and behave, all of which may be foreign to those in civilian life. To function at optimal level, unit cohesion is promoted over autonomy (Hall, 2011; Harrison, 2006). The military is a world driven by a rigid authoritarian structure. The family must conform to the rigidity of military regimentation, possibly leaving them feeling disconnected from civilian life. They must deal with the effects of rank on social interactions, associating with those of their own rank/status (Hall, 2011). They lack any control over pay and benefits, and must navigate the inflexible system whenever circumstances require help from the military. Spouses must have the consent and participation of their veteran spouse for eligibility of available resources. Some veterans do not want to be viewed as weak or in need, so they will not assist the spouse in obtaining access to these. This can leave families unable to receive the services they may so desperately need. The military life has clearly defined rules, such as little to no tolerance of disagreeing with or questioning authority. Family members may be discouraged from demonstrating behaviors that suggest individualism. The family may experience isolation as a result of frequent moves creating distance from family and friends. Spouses and children may, over time, make limited attempts to engage in a new community with the understanding that it will only be a matter of time until they leave again (Hall, 2011).

There is cultural, religious, and ethnic diversity within the military. This suggests social workers need to practice multicultural skills, including being aware of their own biases, values, and personal limitations, and practicing without judgment. This requires actively developing and implementing appropriate and sensitive practices for working with military families (Hall, 2011; Harrison, 2006). When working with those of a different cultural background, a social worker should ask questions about the culture of the family, engaging a curiosity that seeks not only differences, but similarities in their cultures. Showing interest and acceptance about another's culture to gain an understanding for identifying appropriate treatment also assists in building rapport.

There may be concerns for the military family in working with military mental health services, as well as uneasiness about working with civilian professionals. Veterans may be skeptical about using any mental health services tied to the military, because there is a risk that information may get back to their command, with potential long-term effects on their career. In addition, there is often a stigma associated with mental health issues, for military professionals, which may be seen as a weakness. This may cause them to seek help outside the military with civilian professionals. Other issues may arise in rapport building for the civilian professional; how can someone who has not "lived the life" possibly understand (Coll, Weiss & Yarvis, 2011)? This suggests civilian professionals should seek to understand these clients by gaining a basic knowledge of military culture and how it may affect practice. Practitioners should provide a safe and nonjudgmental atmosphere, which demonstrates respect for veterans and their families, and remain professional, responsive, affirmative, and empathetic. Utilize open-ended questions to garner an understanding about military life experience. Seek to learn about the family as individuals within their family culture and within their family system.

PSYCHOEDUCATION

Psychoeducation is an important aspect of social work with military families. Part of the initial session should include helping the family understand behavioral manifestations of a given diagnosis, as well as how to respond best to these behaviors. A reported 20% of Iraqi war veterans will be diagnosed with posttraumatic stress disorder (PTSD) (National Institutes of Health, 2009). The symptoms of this disorder include a loss of interest in previously enjoyed activities, hypervigilance, heightened startle reflex, insomnia, irritability, and aggression (American Psychiatric Association, 2013). These behaviors can be confusing and anxiety producing for everyone in the family.

Military families are forced to adjust to many separations and reunions, experiencing all the emotions related to predeployment, deployment, and postdeployment. Social workers can assist by educating them about what to expect during the various stages of deployment as far as emotional functioning (Coll, Weiss, & Yarvis, 2011). In the

predeployment stage, all family members begin to experience a feeling of, or an anticipation of loss. The family may find themselves starting to distance themselves from the service member in an attempt to protect their emotions. During deployment, the family must adjust to life without their loved one; it can take months before emotional stability is achieved. Postdeployment requires yet another adjustment for the family. The social worker should psycho-educate about the homecoming process (Coll, Weiss, & Yarvis, 2011; Sneath & Rheem, 2011). Assist the family to understand what their loved one may be experiencing; why they may be distant, unable to share or demonstrate emotions; why they cannot answer certain questions or attend particular functions. Share with the family the importance of not asking for too much from a returning loved one. Suggest they stay away from questions that require the veteran to share emotions, experiences, and expectations. Prepare them for the fact that the veteran may find comfort in the company of other veterans, seemingly more at ease there than when spending time with family. Veterans may feel these are the only people who truly understand them, and share the same intrusive memories that they face constantly in their own minds. These individuals also may share the same shame and guilt for what they may have witnessed or done, which may also add comfort through their shared military experiences and trainings (Hall, 2011).

Veterans have been taught certain skills, which have kept them safe when deployed, such as secretism, relying on their own perception and knowledge for reacting to situations, and being unemotional and hypervigilant. Sadly, the skills that kept them safe overseas can be a disaster for family reconnection. The veteran may shut off psychologically, even toward their spouses and children (Hall, 2011). Encourage the family members to keep things light, wait for the veteran to tell them what they may want to tell, or what they may be able to share. Help them to understand that the loved one's responses are a result of their experiences, and assist the family in developing coping skills to use when the veteran takes some distance and disconnects personally. Set up "safe zones" in the house in which no hard conversations will take place, this could be the dining table, or the couch in the family gathering area, or both. This then becomes a place the veteran can be with the family with the understanding there will be no expectations

except for spending family time together. It is important to note that eliminating stress for the military family is considered an impossible task, and while they may demonstrate resilience, they may still need assistance at times when stressors become overwhelming (Hall, 2012). This is when the social worker is most needed.

CONSIDERATIONS FOR TREATMENT

In sessions with the family, use statements acknowledging you have heard what they say. This does not mean that you necessarily agree with what they said (e.g., "You felt your husband no longer loved you."), but simply means that you are listening. Also, use affirming statements, statements validating that what they are feeling is understandable, or how they may have reacted to a certain situation is understandable. Again, you are not stating that it was appropriate, only that you can understand why. Use Socratic questioning rather than suggesting what they should do; use this form of questioning to get to the family's understanding of the situation. It is important to remember we cannot assume we know what is problematic for them, or what is right for their lives. Make sure to understand the situation from each family member's point of view, and do not allow talking over one another in sessions. Everyone must be able to tell their story. This may be the first time someone has allowed some of them to tell their full story uninterrupted and actually listened to what they had to say. Clients may not have chosen to tell their story; the emotion of what they may be dealing with is so painful they avoid even thinking it. This can include dealing with the grief and loss of the person they used to know, that is, the one who did not come home from deployment. Instead they are living with a stranger, who looks just like their loved one.

Grief and loss is experienced for many reasons. For our military families the most evident and undeniable would be the death of a loved one. Psycho-education about the stages of grief, validation for what they are going through, and a referral to a bereavement group would be the first steps to helping the family move forward (Coll, Weiss, & Yarvis, 2011). Thank them for their loved one's, and their family's, contribution in serving our country. Ask them to share with you stories of their loved one, to tell you about who their loved one was. Engage the family in reflecting on special

memories, responding in an affirmative way about how special this person was.

Social workers must also realize military families experience other types of losses that can have a significant effect on their functioning. This includes the loss of loved ones as they knew them, as a result of physical and/or psychological injuries received while deployed. These losses may also include loss of community and friendships through many moves, loss of physical closeness to family, and shared holidays to name a few. They may have been unable to establish a career because of the many moves. This has financial and self-esteem implications. Seek to understand and explore the losses perceived by the family, and explore and identify possible ways in which some of these may be addressed. This may assist them in bringing a sense of reconciliation to their hopes and dreams. The first step toward building a sense of cohesion for the family adjusting post-deployment may be developing and implementing positive communication skills.

Communication skills may be modeled and demonstrated by the social worker to assist the family in having more positive interactions. Encourage the members to speak to each other (e.g., "Would you share with your mom how you feel?"). Teach "I" statements to assist in sharing emotional information in ways that will not provoke a defensive reaction (e.g., "I feel sad when you call me a name," or "It frightens me when you yell."). Explore the parenting techniques being used, identifying what may and may not be working. Model and demonstrate appropriate positive parenting skills, which may also help to create more cohesion for the family. Children need to have a positive and connected relationship with their parents, especially children in a military family.

Children may deal with the psychological effects of many moves, or with the ambiguous loss of a parent, who is physically there, but not emotionally there. They may be saddened by the military parent missing memorable events and by the constant worry for the parent's safety. Emotional protection for them can be expressed by the family forming a unit that somewhat excludes the deployed parent, making it hard for this parent to reconnect upon arrival home. The military commitment to mission over all can make a child feel insignificant in the eyes of the military parent, furthering the disconnect (Hall, 2011). This may cause children to find friends who may be seen as a negative influence (Sneath

& Rheem, 2011). The social worker can address these perceptions of loss and/or abandonment by assisting the family in developing a stronger bond through improving relational skills. Psycho-educate children about any diagnosis their parent has received; understanding the behavioral manifestations may assist the child in not taking these behaviors personally.

Many of our returning veterans will return home with symptoms of PTSD, including anger, nightmares, anxiety, and hypervigilance. Some will meet the *Diagnostic and Statistical Manual of Mental Disorders* criteria for a diagnosis of PTSD (American Psychiatric Association, 2013). This has been associated with domestic violence in the home. Interpersonal violence is higher among our veterans than among the civilian population. This violence is not just directed at the family, but will be seen at the workplace and in the community (Coll, Weiss, & Yarvis, 2011). Secondary trauma can be experienced by the caregivers of a physically or emotionally disabled veteran. This is usually the direct result of the stress of caring for, and wanting to help, their traumatized loved one. The symptoms will be similar to those of PTSD, including functional impairment; emotional distress; avoidance of thoughts, feelings and/or situations that are reminders of the trauma; and recurrent and involuntary intrusive imagery (Bride & Figley, 2009).

Community-based services should be explored as possible resources for the military family. Continuous updating of available community resources is an important aspect of social work practice. When those in the community, community agencies, and leaders come together they can support the military family in managing stressful events (Hertzog, Boydston, & Whitworth, 2011). Community program funding fluctuates and community needs fluctuate, suggesting the need to identify multiple sources of assistance for clients. Mental health treatment is only a part of what the family may need to achieve optimal functioning. Given the experiences of isolation, military families will benefit from being embraced and supported by their community.

CONSIDERATIONS FOR RISK ASSESSMENT

The military culture's support of cohesion extends to the family and to the military community.

An attitude of protecting those in their unit can cause situations of domestic violence to be overlooked. The reporting spouses may be avoided and ostracized by others if they tell, including their support system of other military spouses (Harrison, 2006). For this reason, the abuse may have never been addressed, and the victims may have difficulty disclosing to the social worker. Types of abuse include physical, sexual, verbal, and emotional (economic or financial abuse is a subtle form of emotional abuse). Signs of abuse include the abuser using dominance, humiliation, isolation, threats, intimidation, denial, and blame. Abusers are able to control their behavior. They choose whom they will abuse, which is usually someone whom they claim to love. Physical abusers will choose places in which the wounds will not be readily seen, and they can stop when it benefits them. If it is clear that the family is being abused the social worker should ask if something is wrong, express concern, listen and validate, offer help, and support the victims' decisions (Smith & Segal, 2013). Help would include shelter information, abuse hotline phone numbers, and creation of a safety plan. Substance abuse has also been found to be a problem for both veterans and their families.

Substance abuse for the veteran and the family must be assessed. Substance abuse has been found to be higher among those diagnosed with PTSD (Hertzog, Boydston, & Whitworth, 2011). Alcohol is a common form of self-medicating for those in the military because it is an acceptable tradition. Such is not the case with prescription medications; the stigma placed on these causes a perception of weakness. The social worker should consider providing a referral to a twelve-step program such as Alcoholics Anonymous, as well as Al-Anon for the rest of the family. With the many reasons why a veteran may self-medicate, such as anxiety, shame, guilt, and depression to name a few, concerns about suicide must also be addressed.

Social workers must complete safety and risk assessment when working with military families. In 2008, the Medical Department of the Army reported that in 26 years of records, the suicide rate of active duty veterans was higher than it had ever been (Coll, Weiss, & Yarvis, 2011). Lower suicide rates have been shown for those Air Force communities that have shown inter-agency collaboration with leadership as a part of their Air Force Suicide Prevention Program (Hertzog, Boydston, & Whitworth, 2011). This

supports the noted importance of community involvement in available resources for military families.

SUMMARY

Best practice for working with the military family comes from a strengths-based perspective. Using a cognitive modality and avoiding long-term approaches would be the most beneficial, concentrating on emotions and feelings experienced by the family members (Hall, 2012). Our military families would best be served by a system that steers away from a disease model, and instead embraces the concept that our returning veterans require a period of adjustment supported by the community as a whole. This would not replace mental health treatment for those in need, but would call on the community to provide employment, respite, and mentoring for those who have served our country. For every five deployed service members, three have a spouse and/or children waiting for them at home. The psychological affects for the family could be eased by the support of a caring community (Straits-Troster, Brancu, Coodale, Pacelli, Wilmer, Simmons, & Kidler, 2011). This model fits with social work because it considers people within their environment. A social worker working with military families would serve these families best through reaching out to the local community to find appropriate resources and support groups and to strive to achieve an appropriate therapeutic relationship built on trust.

Social Work Practice and
Personal Self-care

Jeff Skinner

**THE IMPERATIVE FOR PROFESSIONAL
SELF-CARE**

For a profession that espouses both helping and advocating for those who are marginalized, traumatized, and without resources, one would assume that the social work profession would have given some attention to improving the well-being of the helper, for example, in offering ways to build capacity for resilience and a means to prevent professional distress. Historically, this has not been the case despite numerous studies and descriptions concerning burnout and occupational stress, which were being published in the early 1980s (Gillespie, 1987). In essence, being, and/or practicing as, a social worker does not mean we are experts in exercising self-care in spite of our empowerment strategies for clients to take better care of themselves. Our professional culture now promotes well-being for both good reasons and sometimes for frivolous self-indulgence. In short, a distressed/impaired social worker is an ineffective social worker.

Being self-sacrificial to the altruism mandate of our work is not a professional virtue signifying the utmost of dedication, professionalism, or advocacy. In fact, it often reflects a negative attribute and a symptom of diminished capacity. Listed below are some of the myths, derived from the extant literature surrounding the normal and not so normal hazards of social work practice vis à vis the imperative for professional and personal self-care.

MYTHS

Personal self-care is the same as professional self-care. Although well-being is important for

anyone, the purposes of professional self-care and personal self-care differ. The former is a process of self-awareness and promotes and monitors the use of self in one's professional role. Professional self-care is always connected to the "other self" in social work, namely the client. The latter does not necessarily connect to an occupational role with standards, accountability, and transparency. Personal self-care is aimed at soothing and restoring one's self. Not all personal self-care can be linked to enhancing a benefit for professional role effectiveness.

Being altruistic with our clients will almost always offset any distress felt in the important professional role of social work. Altruism is an attitude and an attribute that serves as motivation to help others foremost, and to place the welfare of others before one's self. Altruism can remind us of our motivation to help others, but unfortunately it does not have any protective properties. Helping others will always produce some distress, simply because we care enough.

Our education and training are sufficient to protect us from distress, burnout, compassion fatigue, etc. If such were the case, then there would never have been any discussion about social work burnout and fatigue, in the first place. Although our Bachelor's in Social Work/Master's in Social Work education and training offers us knowledge, values, and skills, and promotes self-awareness for the purpose of helping others, it does not provide buffers to stress. No person, regardless of education and training, can rise above the realities of day-to-day distress endemic in the nature of social work practice.

Internalizing the causes of distress is the best strategy for self-care. It is rather tempting to

internalize distress as our fault—due to our not trying hard enough, which thereby hides our distress from others. This is not, however a productive strategy; distress is a product derived from the multiple interactions of a social worker, client, and the practice environment. Internalizing distress does not allow for self-examination, and/or problem resolution.

Working in a self-care friendly and facilitative environment is an extra benefit for anyone. Professional self-care by the individual social worker must be practiced alongside of workplace structures, which may also promote professional well-being. If professional self-care is an imperative, then a similar mandate should be applied to our agencies and employers.

PROFESSIONAL AND PERSONAL SELF-CARE

The social work profession, like other helping professions, recently began to give intentional regard to professional self-care in the areas of academia, field education, supervision, direct and indirect practice, research and organizational culture (Cox & Steiner, 2013). Thus, it has taken several decades for our profession to go beyond describing the process and effects of burnout, compassion fatigue, and vicarious traumatization, to requiring the need to practice professional self-care. Discussions about professional self-care occur daily in agencies, in employment interviews, during supervision, in coursework at schools of social work, in field education internships, and in research projects (Moore, Perry, Bledsoe, & Robinson, 2011). Unlike previous generations of social workers, it is universally recognized and now accepted by contemporary social work practitioners and researchers that sometimes—helping others can hurt the helper (Beckett, 2008). Further acknowledged is that such hurting cannot be attributed exclusively to faults or deficits in the character or personality of the social worker helper, but rather to our practice settings (e.g., trauma services, forensic services, military social work).

Contemporary thinking clearly identifies occupational hazards in certain practice settings within social work (e.g., working with trauma victims) and these appear to be accepted by job seekers and employees (National Association of Social Workers [NASW], 2009). The need to practice professional self-care in order to remain effective in practice is endorsed by the NASW (2009) and is

embraced as an ethical imperative and necessary practice behavior. Professions seek to self-regulate (Reamer, 1992) and mandating professional self-care is one manifestation of such regulation. The Council on Social Work Education (CSWE) Educational Policy and Accreditation Standards (EPAS) *Competency Number 1* (CSWE, 2008) and its associated practice behaviors refer specifically to self-awareness, and to conducting one's self professionally. Within this competency, practice behavior (b) calls social workers, "to practice personal reflection and self-correction to assure continual professional development" (CSWE, 2008). Empirical evidence suggests that there is an inverse correlation between stress, burnout, compassion fatigue and professional self-care. In other words, the more a social worker increases professional self-care, the less distress will be experienced, thus decreasing the possibility of deleterious practice with clients (NASW, 2009).

There is also no consensus on the definition of what constitutes professional self-care. Some refer to it as a process (strategies and practices), or as the ability (Lee & Miller, 2013) to increase levels of subjective well-being. Others see it as an outcome that produces resiliency and empowerment, and mitigates against a decline in empathy with the client, thus elevating compassion satisfaction, as contrasted to compassion fatigue (Lee & Miller, 2013). The term "personal self-care" is sometimes used outside of the context of professional practice. Here, a social worker pays attention to stressful aspects of their life outside of work, and seeks ways to address stress when it becomes distress. Although a social worker can make efforts not to have personal distress influence his/her professional performance, it is unrealistic to expect that protracted or acute personal distress outside of work will never influence one's professional effectiveness. Because social workers make frequent "use of self" for professional purposes, the conceptual separation between professional self-care and personal self-care is not always clear and there cannot always be a demarcation line.

Because social workers profess the "use of self" for professional purposes to facilitate client engagement and change, there exists the potential to meet personal needs or to re-enact personal problems with the client. For example, countertransference in its most generic definition often represents responses from the social worker that originate not from the professional voice, but rather from unresolved personal issues that are being played out unknowingly with the client. Often, this displays

itself by the social worker's savior and grandiose fantasies about the client through their sense of a unique, specialized, and exclusive understanding of the client, through contempt, avoidance, and/or an over identification with a client. Sooner or later the social worker will experience some forms of distress when countertransference dominates the working alliance with a client. Inevitably both the client and the social worker will suffer. If self-awareness and self-observation (also termed "the observing ego") are limited and broken, then social work colleagues have an ethical imperative to assist an impaired colleague.

The imperative for professional self-care is associated with the notion of "fitness for duty." The NASW Code of Ethics addresses fitness for duty in subsection 4.05, concerning impairment.

(b) Social workers whose personal problems, psychosocial distress, legal problems, substance abuse, or mental health difficulties interfere with their professional judgment and performance should immediately seek consultation and take appropriate remedial action by seeking professional help, making adjustments in workload, terminating practice, or taking any other steps necessary to protect clients and others (NASW, 2008).

Professional self-care is assumed to be the primary responsibility of the individual social worker and it is implicitly driven by an ethical imperative of fitness for service. Although no consensus exists as to the definition of professional self-care, a definition offered by Lopez, as supported by NASW (NASW, 2009), captures the multiple, inter-related dynamic dimensions of professional self-care.

Professional self-care in social work can be defined as a core essential component of social work practice and reflects a choice and commitment to become actively involved in maintaining one's effectiveness as a social worker. Furthermore, in promoting the practice of self-care, a repertoire of self-care strategies is essential to support the social worker and other mental health professionals in preventing, addressing, and coping with the natural, yet unwanted, consequences of helping (Lopez, 2007).

TYPES OF DISTRESS ASSOCIATED WITH NEGLECTED PROFESSIONAL SELF-CARE

A brief description of the types of distress will illuminate portions, large and small, of the kinds

of distress most social workers will encounter during their careers. When addressing distress and professional self-care the following terms frequently appear: occupational stress and distress, burnout, vicarious trauma (VT), secondary traumatic stress (STS), compassion fatigue (CF), compassion satisfaction (CS), and resilience. Occupational stress refers to either the acute or ongoing negative physical and emotional responses an employee may have in executing job tasks, or as a response to the workplace environment, such as a hostile, racist, sexist, or toxic work environment. Within the social work profession, workplace settings such as child welfare agencies, disaster and trauma-response teams, and forensic settings have higher levels of occupational stress. Over time and when left unchecked, workplace stress can evolve into distress, which results in a decrease in compassion and empathy (Maslach, 2003).

Burnout is "a syndrome of physical and emotional exhaustion, involving the development of negative self-concept, negative job attitudes, and a loss of concern and feelings for clients" (Pines & Maslach, 1978, p. 224). In her seminal work on burnout, Maslach described three distinct areas of concern: emotional exhaustion, depersonalization, and a reduced sense of accomplishment and effectiveness (Maslach, 2003). Emotional exhaustion refers to the fatigue, loss of passion for work, and the overarching sense that the social worker has nothing left to give to clients or the organization. Depersonalization entails the increasing use of cynicism, negativity, and detachment from clients and colleagues. The reduced sense of accomplishment refers to practitioners feeling as though their work with clients is ineffective, unappreciated, and without purpose and meaning. Burning out is more of a process than an event.

Vicarious traumatization (VT) (Bride, 2007) refers to the personal transformation, cognitive changes, and alterations in beliefs and worldviews that a helper may experience when working closely with trauma victims. Often, cognitive shifts center on issues of safety, trust, control, and good versus evil, as a result of empathizing with trauma victims. VT is the result of an indirect experience of the client's trauma whereas posttraumatic stress disorder (PTSD) is a result of a direct experience of trauma. Figley (1995) proposed that symptoms of VT in a social worker can resemble those of PTSD.

Secondary traumatic stress (STS) is closely related to VT, and the two terms are often used

interchangeably (Bride, 2007). STS and VT are limited to those who work with trauma victims, whereas burnout is unrestricted to client populations. In essence, STS occurs as one person experiences the traumatic event through exposure to a client who has undergone a recent traumatic event (Bride, 2007). STS symptoms are similar to those symptoms presented in PTSD. These include intrusion, such as recurrent reflections on the event, distressing dreams, and feeling as though the traumatic event is recurring; arousal, as expressed in difficulty falling asleep, irritability, hypervigilance, and increased startle responses; avoidance, as expressed in detachment, avoidance of talking about the event, avoiding locations associated with the trauma, and exhibiting a limited range of affect; and, finally, distress and impairment.

Compassion fatigue (CF) is a term first used by Figley (1995) as a nonperjorative and more acceptable term for STS. CF is often used to capture a melding of the terms burnout and secondary traumatic stress. Compassion fatigue can be used to denote a momentary state of low empathy and depletion of energy, which can develop into a more chronic persistent state for the helper. Compassion satisfaction (CS) (Stamm, 2002), on the other hand, is a term used to punctuate the preferred ideal state of the positive internal, subjective altruistic sense of helping others effectively, as contrasted with the nonpreferred state of depleted and cynical CF. High workloads, lack of self-efficacy, lack of control, poor external rewards, and toxic institutionally related stress are precipitating factors associated with burnout. Exposure to traumatic material and traumatized clients are the precipitating factors for STS and VT (Bride, 2007). CF is present with all of these conditions.

RISK FACTORS AND VULNERABILITIES

Risk factors unique to social work and its practice settings, combined with any preexisting vulnerabilities in the social worker, and finally, combined with any internal and/or external mediating factors, make up the dynamic interaction of stress evolving into degrees of distress (e.g., CF and burnout). Not all people experience a stressor in the same way or cope with distress in the same way. Identifying risk factors located internally to

the social worker, as well as those located externally to the social worker (i.e., the organization and its supportive/unsupportive culture), will provide perspective later on about strategies for not neglecting professional self-care.

Practice settings and populations served are factors external to the social worker. Social workers practicing with traumatized clients, and/or dying clients, are at higher risk to experience occupational stress, VT, STS, CF, and burnout. Child welfare social workers practicing in child protective services, child forensics, and treatment agencies for physically and sexually abused children and adolescents are also at risk for extreme stress. There is an abundance of empirical research (Siegfried, 2008) discussing the correlation between working in child welfare, and developing vicarious trauma evolving into burnout, and its residual effect on workforce turnover and organizational morale. Social workers practicing in hospices, disaster services, military settings, domestic violence settings, prisons, addiction agencies, and law enforcement settings are at similar high risk for stress. Organizational cultures that are unsupportive and delimiting of professional development and control usually provide little recognition of the stressors placed upon social workers. The most frequently cited organizational culture stressors are an overload of cases, few supportive resources, oppressive policies, and most importantly, a perceived sense that one has little control over the work environment (Lee & Miller, 2013; Loone, 2003).

Risk factors and vulnerabilities unique to social workers involve previous trauma, especially sexual and physical abuse; character disorders; anxiety and depressive disorders; addictions; poor boundary control; and years of practice. Social workers who have at least a decade of practice experience, and are more likely to practice professional self-care, are less likely to describe distress in their job performance (Loone, 2003). Conversely, social workers who are just beginning their professional careers are more likely to experience debilitating stress within their first three years of practice. Such awareness can be attributed to an imbalance between professional and personal life, inadequate support and supervision, and unrealistic expectations for the profession, leading to disillusionment and poorer preparation for practice while in graduate school.

ASSESSMENT AND EVALUATION OF DISTRESS

Most of the measures and instruments developed to assess job satisfaction, job compassion, CF, STS, and VT originated from disciplines other than social work. Social work is beginning, however, to develop its own measures as applied exclusively to the profession to assess for VT and CF (Bride, Radey, & Figley, 2007). The trend among helping professions is to develop instruments that can screen and assess for areas unique to one's profession. Therefore, cross disciplinary assessment tools and measures have limited applicability. Additional resources regarding assessment and screening are available below and on this chapter's website in the subsection, "Resources on the Internet."

The following are some assessment tools commonly used by social workers and other helping professionals. Saakvitne and Pearlman (1996) developed a widely used self-care instrument that assesses the frequency with which a helper may practice personal self-care in the domains of: self-care, psychological self-care, emotional self-care, spiritual self-care, workplace self-care, and overall balance. The Professional Quality of Life Scale, (ProQOL) (Stamm, 2009) was designed primarily to assess positive and negative aspects of helping others, and it is also widely used. It aims primarily at the affective components of working and as such examines both compassion satisfaction and compassion fatigue. It has several helpful subscales: compassion satisfaction, burnout, and STS. The Figley Compassion Fatigue Self-Test (Figley, 1995) developed mainly for those working with trauma victims, has two domains of assessment: (1) areas about the helper; and (2) areas about the working environment. Its aim is to note areas where there is satisfaction, along with areas where there is some CF. The Maslach Burnout Inventory (MBI) (Maslach, Jackson & Leiter, 1996) is the most recognized self-assessment inventory for those working in human services. Having high reliability and validity, it assesses the areas of emotional exhaustion, depersonalization, and feelings of competency across many settings.

Leiter and Maslach's Areas of Worklife Survey (Leiter & Maslach, 2005) provides another assessment of the helper's external environment and contains the following subscales: workload, control over the work, reward, community, and fairness and values. Utilizing both of the MBI

and the Leiter & Maslach assessment measurements can provide a social worker with a fairly accurate picture of multiple internal and external dimensions of burnout and its preceding conditions. Using such self-assessment inventories also increases self-awareness through providing information and knowledge regarding resiliency, coping, areas for self-correction, and areas of personal and professional conflict.

SOCIAL WORK AND CARE STRATEGIES

Unfortunately, there are no magical inoculations or vaccines to prevent the very real feelings of stress, anxiety, organizational uncertainty, and distress in the day-to-day practice of social work. Our responsibilities are to be as healthy as we possibly can be, in identifying and controlling our own physical health, emotional and mental health, spiritual health, and in facilitating healthier work environments. Further, we are responsible for having at hand numerous "what works for me" strategies, techniques, coping mechanisms, and professional supports for use when our professional well-being is threatened or challenged.

Prior to discussing some offsetting strategies to deal with personal and professional stress, it is important to table two issues that are endemic in the DNA of most social work practitioners. The first is personality factors; the other is our motivational reasons for choosing this noble profession. In regard to the former, factors that can mediate between the stress and the response(s) to it have much to do with work-life balance, coping skills, core personality attributes, strength of professional identity, and responsiveness from supervisors and a supportive workplace environment. In a meta-analysis of the relationship between personality and job satisfaction, Judge, Heller, and Mount (2002) related the five-factor model of personality (neuroticism, extraversion, openness to experience, agreeableness, and conscientiousness) to job satisfaction, and maladaptive responses to job stress. These authors concluded that three of these five factors function as mediators, and represent a possible positive correlation to job satisfaction. For example, persons with a negative/cynical nature (neuroticism) who are predisposed to interpreting stressors as more of a problem than a challenge, are inclined to seek job dissatisfaction. Those who are more extroverted than introverted are more disposed to experience

positive emotions and value interpersonal actions as solutions to problems. Those who have higher levels of conscientiousness, demonstrate more effective coping mechanisms. These individuals have a tendency to obtain higher levels of intrinsic rewards, and thus eventually receive equal amounts of external rewards (Judge, Heller, & Mount, 2003).

Second, it has been determined that personality types are tied intimately to one's vocational career selection. This configuration is as such, "... personal traits or personality→one's values and attitudes→his or her interests→personal strengths and skills, all collectively influence→one's motivation to select a certain career; and the cornerstone domino for this chain reaction is personality traits" (Holosko, 2006, p. 428). John Holland's extensive work in the area of occupational choice and personality characteristics describes six main personality trait characteristics: realistic, investigative, artistic, enterprising, conventional, and social—that most of us fit into (Holland, 1992). Social workers almost always fall into the social category. Here, these are individuals who:

... (a) like to do things to help people—teaching, caring, giving first aid, providing information; generally avoid using machines, tools or animals to achieve goals; (b) are good at teaching, counseling, nursing or giving information; (c) value helping people and solving problems; and (d) see themselves as helpful, friendly and trustworthy (Holosko, 2006, p. 428).

This parallels directly the work commissioned in 1957, 1963, and 1988 by the NASW and CSWE in attempting to discover "who enters social work

and why?" Taken together, these studies clearly demonstrated that social workers are "social types" who are attracted to the values that the profession holds most clearly: humanitarianism, service to people, altruism and *caring for others* (Morales & Schaefer, 1989). Thus, social workers are indeed correctly and colloquially referred to as "card carrying members of the altruistic society." Interestingly, and consistent with the message reiterated in this chapter, the attribute of "caring for others," was prominently noted in these studies. However, "caring for self," the focus of this chapter was conspicuously absent.

Each of us is different, with our own unique composition of ourselves and our environment, motivation to practice social work, personality type, tolerance for frustration, affective expressions, etc. Hence, there is no "one size fits all" technique or toolbox for professional self-care that can be prescribed for all. For example, a body massage one person finds soothing another person may experience as intrusive. Care techniques, which are usually person specific, follow the establishment of general strategies. Strategies in one's care are embedded in the professional self first, and constitute one of the many foundational pillars of professional practice behavior. These should address the broader landscape of professional well-being and as such, serve as blueprints for addressing workplace and occupational stressors (Norcross, 2000).

The four domains of professional self-care presented below are physical health, emotional/mental health, spiritual health, and workplace health. Suggested strategies for addressing each of the four areas are also presented below. Figure 17.1 shows the following care strategies are not the providence of either professional

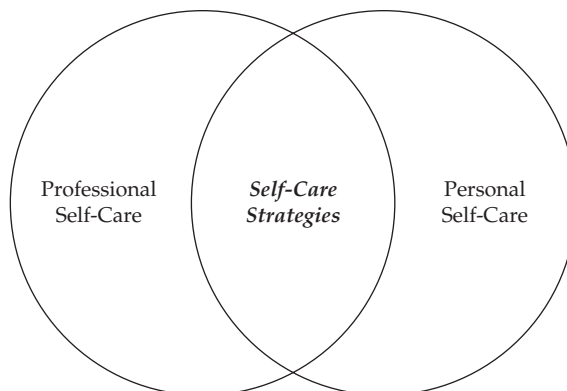

Figure 17.1 Care Strategies

or personal self-care, but rather appear in the eclipsed shaded areas of these overlapping circles. This describes the use of self for professional purposes.

SUGGESTED DOMAINS OF STRATEGIES

1. *Take care of your body and listen to your body's natural signals.* Our minds, hearts, and ability to empathize exist within complex interrelated molecular, neurological, and biological systems, which are vulnerable to dysfunction, but also designed to self-regulate and to self-correct. Developing personal goals to maintain healthy nutrition, adequate sleep, developing a regimen for physical exercise (or sport), scheduling regular medical check-ups, avoiding addictions, and not abusing the body are essential for optimum physical functioning (Rothschild, 2006). It is almost impossible to give ourselves to our clients when we do not have much to give, as a result of feeling acutely or chronically physically depleted. Developing strategies to stay attuned to one's physical health and knowing how your body communicates stress requires us to learn how to respond appropriately.

2. *Developing a sense of mindfulness about your thinking and feeling.* Strategies designed to address the mental and emotional aspects of stress have to do with cognitive and affective dimensions and also with professional identity, including motivation, and compassion satisfaction/dissatisfaction (Skovholt, 2001). We often fluctuate in our careers between the ends of the continuum of compassion satisfaction and compassion dissatisfaction. Our identities as social workers can be challenged based upon our experiences of being helpful; understanding the monetary dimensions of both public and private practices; aligning and realigning our expectations; retooling expectations about changes at the micro, mezzo, and macro levels; enduring early career disenchantment regarding the profession of social work; adjusting to higher case loads; inadequate salaries; and feeling unsupported (Loone, 2003). Effective self-awareness allows the social worker to determine whether any of the above are enduring and disabling enough to require examination, assessment, and change. As indicated, social workers are most vulnerable to distress during their first three years of practice,

which may unfortunately encourage some to leave the profession rather early on.

Understanding the drifts in cognitions that tend toward self-deprecation, extreme negative countertransference, and negative stigmatization of clients (loss of positive regard) require attention and represent "professional acting out." Social workers must understand the basis or essence of their own negative thoughts. Some suggested strategies are to seek consultation and supervision to process their thought patterns, dissect the elements of negative countertransference, and assess the meaning of self-deprecating cognitions. The latter, as a negative thought pattern, could represent frustration with practice abilities, difficulties with a challenging client, ineffective intervention plans, etc. In all such cases, social workers need to seek consultation and learn to practice self-compassion, as a prerequisite to improving themselves as people.

One's mental health is often affected by how much input or control one may have in determining what one's work is about, and how to go about regulating and doing that work. In the professional self-care literature, a common finding noted is that social workers who feel they have some input into how their job is performed and its expectations are more likely to feel job satisfaction and less likely to feel distress, thereby preventing burnout (Newell & MacNeil, 2010). Therefore, when possible, at both the individual and organizational level, strategies should pursue increasing internal loci of control, which can be both a mediating and protective factor.

Benchmark signals of emotional exhaustion and depletion are expressed through enduring feelings of embitterment toward clients and the agency; coping by avoidance; isolation; detachment; somatization; anger; loss of empathy; and loss of passion and pride in being a social worker (Adamson, Beddoe, & Davys, 2012). These enduring affective episodes need to be examined honestly to determine how they came to be such a powerful determining presence over the social worker. Utilizing a therapist or trusted colleague will provide another set of ears and eyes for feedback. A suggested strategy here is to make an oath to yourself, namely, that you will put into words what you are feeling when distressed, and that you then will seek understanding and appropriate change. Additionally, we must recall that an overabundance of empathy in the helping relationship is not the main ingredient necessary

for client change. Other factors and processes, such as strengths, assets, and client resources play a large role in producing change.

3. *We all have spiritual souls: Don't be afraid to bare them.* The importance of spirituality and meaning ground us existentially to our overarching motivation and to sustaining our energy in serving others. Our professional grounding here serves as a protective factor when we experience distress (McGarrigle & Walsh, 2011). We must realize that helping others can hurt, but it does not have to disable and incapacitate individuals. Accepting realistic expectations concerning yourself and your clients will potentially help guard against savior-like thinking and approaches to clients—and against the inevitable let downs in social work practice. Utilizing the strategy of engendering hope in your clients (Snyder, 2002), and practicing from a belief perspective that the human condition can always be improved, refurbishes our purpose, our altruistic drive and motivations, and our resilience in the face of adversities. This feeling of honest humanitarian giving is often our only ultimate reward.

4. *Workplace Health and Stress.* Working in human service organizations with marginalized clients is stressful, as we all know. Agencies push an agenda to do more with less, and to process more clients daily without offering additional resources. Now ubiquitous to all human service agencies is evaluating program outcomes with financial data (Holosko, 2006), whereby a social worker is held accountable for achieving a quota of clients served or units of services billed. This often creates a culture of “people processing” in outsourcing services or in merging agencies, which can undermine the organizational culture. Despite these realities, we must learn to persevere and endure, and not contribute to the toxicity of negative workplace environments. Here are some suggestions: parcel out the good parts of your work, reframe and redirect positive energy, not negative energy; be assertive, not aggressive when you communicate; always understand that the client is the ethical spotlight or validity check for what we do. And, finally, always “take the high ground.”

Formulating clear boundaries between professional responses to clients and personal responses is a *must* for practicing professional self-care. Blurred-boundary violations often trigger the rationale for developing an initial self-care plan, and at the least serve as a wake-up call for greater

self-awareness and more extensive supervision. Reviewing your work with clients each day to assess for boundary violations or boundary blurring allows for self-supervision. Seek consultation when troubled with a client, especially when you are preoccupied with the client. Inklings toward crossing boundaries must be investigated regarding their own internal motivation. Additionally, have some ready-made strategies for when to say “no,” and how to say “no” to constant organizational and agency demands. These ought to be preformulated and rehearsed, because such rather difficult situations often arise unexpectedly.

The kind of pragmatic membership affiliations one has in the social work professional community, and the ways in which the workplace organization endorses and facilitates a culture of self-care will often assist in ameliorating distress. Thus, a social worker should have well-established and functional relationships with colleagues who are deemed helpful and trustworthy. This ensures that a social worker will not practice in isolation or anonymity, or avoid collegial dialogues with other social workers. In addition, talking with other colleagues can help normalize temporary distress as well as offer techniques and support, such as in peer supervision groups. Establish policies and procedures to process and debrief traumatic events. When possible, strategize to practice in a self-care friendly professional organization. If that is not possible, then strategize how to improve the self-care culture of the practice environment and organization. One frequently identified source, as evidenced in the literature, for helping with distress is the supervisory relationship (Skovholt, 2001). Thus, securing a facilitative and well-established on-site or off-site supervisor will serve as a point to address distress. Additionally, when social workers and other professionals feel they have some significant input into their work requirements and expectations, they likely will feel less isolated and estranged.

CONCLUDING REMARKS

Before developing the pragmatics of a self-care plan, which should be unique to each social worker, one must identify one's own preexisting vulnerabilities. If some are identified, then it is necessary to address those (and monitor them for toxic effects) through either supervision or personal psychotherapy. Further, one should be mindful to strive for a balance between

personal and work life. After this, one should take a self-assessment for stress, distress, burn-out, and compassion fatigue through using one of the measures mentioned previously and listed in the following subsection, “Resources on the Internet.” Next, the real work begins—by addressing strategies used as guiding principles in the four cornerstone domains (physical health, mental/emotional health, spiritual health, and workplace health). Here is where previously mentioned techniques are developed. Each domain should also have a place for monitoring the effectiveness of the techniques, as observed. When completed, a social worker can share a plan with a colleague for critique and feedback. And, we must learn to trust and use these perspectives as valuable feedback and advice. Self-care plans are designed for long-term career use, and they should be updated annually, and revised when changing jobs or taking on additional duties. Developing a self-care plan designed to respond to urgent or emergency situations that challenge professional well-being is a wise thing. For example, having in place a network of colleagues to contact will decrease isolation.

An effective and feasible self-care plan is only as good as one is honestly aware of oneself, able to identify one’s vulnerabilities and protective factors, able to assess one’s work environment for professional self-care friendliness, and able and willing to use support and feedback from colleagues. We know that professional self-care plans, when implemented, help to decrease and manage job distress. Essentially, a well developed and implemented self-care plan puts the social worker in better control, rather than the other way around. This is the difference between burnout and an effective social work career and also the difference between helping and harming clients. Indeed, that is why NASW and CSWE regard professional and personal self-care as an imperative and as a required practice behavior.

RESOURCES ON THE INTERNET

The following is a first-rate, comprehensive website for students and practitioners, which contains assessment tools, self care planning, and other resources developed at the School of Social Work at the University of Buffalo. <http://www.socialwork.buffalo.edu/students/self-care/>

18 Ethical Issues in Social Work

Frederic G. Reamer

ETHICAL DILEMMAS

Social workers encounter a wide range of ethical issues. Most such issues in the profession are routine and relatively straightforward. For example, social workers know that ordinarily they must obtain clients' consent before releasing confidential information, respect clients' right to self-determination, and obey the law. Sometimes, however, such common duties conflict with one another; when faced with these ethical dilemmas, social workers must decide which of their conflicting obligations should take precedence (Banks, 2012; Barsky, 2009; Congress, 1999; Dolgoff, Loewenberg, & Harrington, 2012; Reamer, 2013; Strom-Gottfried, 2007). For example, social workers' obligation to respect clients' right to self-determination may conflict with social workers' duty to protect third parties from harm. Social workers' duty to obey the law may conflict with their duty to challenge unjust legal policies and regulations.

Ethical dilemmas in social work take many forms. Some involve direct or clinical practice—that is, the delivery of services to individuals, families, couples, and small groups. Others involve community practice, administration, advocacy, social action, social policy, research and evaluation, relationships with colleagues, and professional education (Reamer, 2001a, 2006, 2009, 2012a). The most common involve actual or potential conflicts among social workers' duties involving the following.

Client Confidentiality and Privileged Communication

Social workers must be clear about the nature of their obligation to respect clients' right to

confidentiality and exceptions to this obligation. Ethical dilemmas occur when social workers must decide whether to disclose confidential information without client consent or against a client's wishes (Dickson, 1998; Reamer, 2003, 2013). This can occur, for example, when a client threatens to seriously harm a third party, seriously injure him- or herself, or abuses or neglects a child or elderly individual. Ethical dilemmas involving privileged communication occur when social workers are asked to disclose confidential information in the context of legal proceedings (for instance, when a client's estranged spouse requests confidential clinical records as part of a child custody dispute).

The emergence of digital and other electronic technology has created new confidentiality challenges for social workers. Practitioners must ensure that their digital, online, and other electronic communications with clients (e.g., e-mail, video conferencing, text messaging communications) protect client confidentiality and adhere to strict ethical and legal standards.

Client Self-determination and Professional Paternalism

It is widely accepted among social workers that clients ordinarily have a fundamental right to self-determination. However, ethical dilemmas arise in exceptional circumstances when, in the social workers' professional judgment, clients' actions or potential actions pose a serious, foreseeable, and imminent risk to themselves or others. In these instances, social workers must decide whether to limit clients' right to self-determination.

Limiting clients' right to self-determination to protect them from harm is called *paternalism*.

Paternalism can occur in several forms, such as withholding information from clients, misleading or lying to clients, or coercing clients. Whether paternalism is morally justifiable in any given situation—for example, misleading a client about her grim medical prognosis or placing a mentally ill homeless person in a psychiatric hospital against his wishes—is often controversial.

Laws, Policies, and Regulations

Ordinarily, social workers should uphold relevant laws, policies, and regulations. Such compliance is important to the smooth functioning of human service organizations and the broader society. Circumstances may arise, however, when ethical obligations conflict with laws, policies, and regulations. In such cases, social workers must take assertive steps to resolve such conflicts, perhaps through consultation, mediation, lobbying, and other forms of advocacy and social action. On occasion, social workers may be faced with difficult decisions of conscience concerning the obligation to comply with what they believe to be unjust laws, policies, and regulations.

Conflicts of Interest and Boundary Issues

Conflicts of interest occur when a social worker's services to or relationship with a client is compromised or might be compromised because of decisions or actions in relation to another client, a colleague, him- or herself, or some other third party. Many conflicts of interest involve boundary issues or dual or multiple relationships. Boundary issues occur when social workers establish and maintain more than one relationship with clients (for example, when a social worker socializes with a client, discloses personal information to clients, or enters into a business partnership with a client). Dual or multiple relationships can occur simultaneously or consecutively (Reamer, 2006, 2012a).

Some dual and multiple relationships are patently unethical—for example, if a social worker maintains a sexual relationship with a client or borrows money from a client. Other dual and multiple relationships are more ambiguous and require careful analysis and consultation. Examples include social workers in rural communities who cannot avoid contact with clients in the supermarket or recreational settings, social

workers who are invited by clients to attend an important life event, social workers' relationships with former clients, and social workers' unanticipated encounters with clients at an Alcoholics Anonymous meeting when both parties are in recovery. Social workers' and clients' use of digital social networking sites—such as Facebook and LinkedIn—has created new boundary-related challenges. Social workers must ensure that their online relationships with clients adhere to strict ethical standards with regard to unprofessional contact and practitioner self-disclosure.

Nontraditional and Unorthodox Services and Interventions

Ethical dilemmas sometimes arise when social workers consider providing nontraditional and unorthodox services and interventions that are not part of customary social work education. On the one hand, services and interventions that are not grounded in sound theory or for which there is little or no empirical evidence of effectiveness can pose significant risks to clients. On the other hand, it is important for social workers to be receptive to innovative forms of practice.

The advent of online, remote, and distance counseling has created new ethical challenges. Some social workers now provide digital and online services to clients they never meet in person. These services expand clients' opportunities to receive help, especially when clients live in remote locations or find travel to an office difficult because of a disability. At the same time, these novel services pose significant risks related to quality control, protection of client confidentiality, and informed consent (Reamer, 2012b, *in press*).

Professional and Personal Values

Social workers sometimes find that their personal values clash with traditional social work values or the official positions of employers or other organizations with which they are affiliated professionally. This can occur, for example, when practitioners object to their employers' political views or positions on important public policy issues, such as reproductive rights, immigration rights, or welfare reform. Social workers may also find that their personal values conflict with those of their clients. This can occur when clients engage in illegal activity or behavior that

seems immoral (for example, engaging in an extramarital affair or drug dealing). Reconciling these values-related conflicts can be difficult.

Scarce and Limited Resources

Social workers often are responsible for distributing resources, such as administrative funds, shelter beds, client stipends, and mental health services. In many instances, they struggle to locate and obtain sufficient resources and must make difficult decisions about how best to allocate available resources. When making these decisions, social workers must choose which allocation criteria to use (for example, whether to distribute resources equally among eligible parties, based on first-come first-served, or based on demonstrated need or affirmative action guidelines).

Managed Care

The pervasive influence of managed care—policies designed to enhance fiscal responsibility and cost containment in health care and human services—has created many difficult ethical dilemmas for social workers (Corcoran & Vandiver, 1996). Strict funding guidelines, reimbursement policies, and utilization review have forced social workers to make difficult ethical judgments about serving clients whose insurance benefits have run out; providing inadequate services to clients with complex problems; and exposing clients to privacy and confidentiality risks as a result of sharing information with managed care staff.

Whistle-blowing

There are times when social workers may be obligated to alert people or organizations in positions of authority to colleagues' unethical behavior or impairment (Bullis, 1995; Jayaratne, Croxton, & Mattison, 1997). Decisions about whether to blow the whistle on a colleague are very difficult. Social workers generally understand that their obligation to protect clients and the public from unethical or impaired colleagues may require such action, but they also understand that whistle-blowing can have serious, harmful repercussions for colleagues whose behavior is reported to state licensing boards, the National Association of Social Workers (NASW), or employers. Whistle-blowing can also pose some risk to the individuals who report collegial

misconduct or impairment; this is also a relevant consideration. See Chapter 22 on the impaired social work professional, and Chapter 19 on whistle-blowers for more detailed information.

Evaluation and Research

Many social service agencies involve clients in evaluation or research activities (such as clinical research, needs assessments, and program evaluations). Ethical issues can arise when, for example, social work researchers decide whether to withhold potentially valuable services from clients who have been assigned to a control group as opposed to an experimental (intervention) group, whether to disclose confidential information revealed in a research interview that suggests the respondent has harmed a third party, whether to interview a respondent whose capacity to sign an informed consent form is questionable, and whether any form of deception is justifiable in social work evaluation and research (for instance, concealing the true purpose of a study to avoid influencing respondents and contaminating the results). The advent of institutional review boards (IRBs) to protect research participants has helped social workers and others address these difficult questions, although simple answers are not always possible.

ETHICAL DECISION MAKING

In the late 1970s, social workers began to explore the ways practitioners make ethical decisions and attempt to resolve ethical dilemmas. This development also occurred in many other professions during this period. Although discussions of ethics and values have taken place since the profession's formal beginning in the late 19th century, deliberate, systematic discussion of ethical decision-making strategies is more recent.

Social work, like most professions, has developed protocols to help practitioners make difficult ethical decisions when they encounter ethical dilemmas (Barsky, 2009; Congress, 1999; Dolgoff, Loewenberg, & Harrington, 2012; Reamer, 1990, 2013; Strom-Gottfried, 2007). Most of these protocols include an outline of steps that practitioners can follow to approach ethical dilemmas systematically, drawing especially on ethical theory; relevant professional literature; codes of ethics; statutes, regulations, public policies, and agency policies; and consultation. For example,

one such model entails seven steps (Reamer, 2013; also see Barsky, 2009; Congress, 1999; and Dolgoff, Loewenberg, & Harrington, 2012):

1. Identify the ethical issues, including the social work values and duties that conflict.
2. Identify the individuals, groups, and organizations who are likely to be affected by the ethical decision.
3. Tentatively identify all possible courses of action and the participants involved in each, along with possible benefits and risks for each.
4. Thoroughly examine the reasons in favor of and opposed to each possible course of action, considering relevant ethical theories, principles, and guidelines; codes of ethics and legal principles; social work practice theory and principles; and personal values (including religious, cultural, and ethnic values and political ideology), particularly those that conflict with one's own.
5. Consult with colleagues and appropriate experts (such as agency staff, supervisors, agency administrators, ethics scholars, ethics committees, and, if there are pertinent legal issues, attorneys).
6. Make the decision and document the decision-making process.
7. Monitor, evaluate, and document the decision.

Some of the elements of this process require specialized knowledge and skill. For example, social workers should be familiar with ethical theories, principles, and guidelines related to professional practice. Most discussions of ethical theory in the profession's literature focus on what are commonly known as theories of normative ethics. Theories of normative ethics are typically divided into two main schools of thought: *deontological* and *teleological* (including *consequentialist* and *utilitarian* theories). Deontological theories (from the Greek *deontos*, "of the obligatory") claim that certain actions are inherently right or wrong as a matter of fundamental principle. From a strict deontological perspective, for example, social workers should always obey the law and regulations, even when they think that violating a law or regulation is in a client's best interest. From this point of view, social workers should always tell the truth and should always keep their promises to their clients, no matter how harmful the consequences may be.

In contrast, teleological (from the Greek *teleios*, "brought to its end or purpose") or consequentialist theories assert that ethical decisions should be based on social workers' assessment of which action will produce the most favorable outcome or consequences. According to the most popular teleological perspective, utilitarianism, ethical choices should be based on thorough assessments of what will produce the greatest good for the greatest number (positive utilitarianism) or the least harm (negative utilitarianism).

More recently, social workers and other professionals have broadened their application of ethical theory to include so-called virtue ethics and the ethics of care. According to virtue ethics, professionals' ethical judgments should be guided by certain core virtues, such as kindness, generosity, courage, integrity, respectfulness, justice, prudence, and compassion (MacIntyre, 2007). The ethics of care, which is related to virtue ethics, was developed mainly by feminist writers (Baier, 1995; Held, 1993, 2007). According to this view, men tend to think in masculine terms, such as justice and autonomy, whereas women think in feminine terms, such as caring. Proponents of the ethics of care argue that professionals should change how they view morality and the virtues, placing more emphasis on virtues exemplified by women, such as taking care of others, patience, the ability to nurture, and self-sacrifice.

These diverse philosophical perspectives are commonly used to analyze ethical dilemmas from different conceptual viewpoints. Thus, a deontologist might argue that social workers should always comply with child abuse and neglect reporting laws—because "the law is the law"—whereas a teleologically oriented practitioner might argue that social workers' compliance with these mandatory reporting laws should be based on their assessment of the likely consequences—that is, whether complying with the law will produce the greatest good or minimize harm to the greatest possible extent. A social worker who embraces virtue theory would be guided by his or her interpretation of the relevance of core virtues, such as autonomy, beneficence, compassion for clients, respect for human dignity, and justice (Beauchamp & Childress, 2012).

Social workers and others disagree about the strengths and limitations of these different philosophical perspectives. Nonetheless, there is general agreement that it is helpful for practitioners to examine ethical dilemmas using these

different vantage points to identify, grapple with, and critically assess all pertinent dimensions of the ethical dilemmas they encounter.

Social workers also need to be familiar with updated and increasingly sophisticated professional codes of ethics, especially the current *NASW Code of Ethics* (Reamer, 2013). This is only the third code in NASW's history and reflects remarkable changes over time in social workers' understanding of and approach to ethical issues.

The first section of the code, the preamble, summarizes the mission and core values of social work. For the first time in NASW's history, the association has adopted and published in the code a formally sanctioned mission statement and an explicit summary of the profession's core values. These help distinguish social work from other helping professions, particularly with respect to social work's enduring commitment to enhancing human well-being and helping meet basic human needs, empowering clients, serving people who are vulnerable and oppressed, addressing individual well-being in a social context, promoting social justice and social change, and strengthening sensitivity to cultural and ethnic diversity.

The second section, "Purpose of the NASW Code of Ethics," provides an overview of the code's main functions, including identifying the core values, summarizing broad ethical principles that reflect these values, and specific ethical standards for the profession, helping social workers identify ethical issues and dilemmas, providing the public with ethical standards it can use to hold the profession accountable, orienting new practitioners, and articulating guidelines that the profession itself can use to enforce ethical standards among its members. This section also highlights resources social workers can use when they face ethical issues and decisions.

The third section, "Ethical Principles," presents six broad principles that inform social work practice, one for each of the six core values cited in the preamble (service, social justice, dignity and worth of the person, importance of human relationships, integrity, and competence).

The final and most detailed section, "Ethical Standards," includes 155 specific ethical standards to guide social workers' conduct and provide a basis for adjudication of ethics complaints filed against social workers. (The code, or portions of it, is also used by many state licensing boards charged with reviewing complaints filed against licensed social workers and by courts

of law that oversee litigation involving alleged social worker negligence or misconduct.) The standards are grouped into six categories concerning ethical responsibilities to clients, to colleagues, in practice settings, as professionals, to the profession, and to the broader society. The code addresses many topics and issues that were not mentioned in the NASW's first two codes (1960 and 1979), including limitations of clients' right to self-determination (e.g., when clients threaten harm to themselves or others), confidentiality issues involving use of electronic media to transmit information, storage and disposal of client records, case recording and documentation, sexual contact with former clients, sexual relationships with clients' relatives and close personal acquaintances, counseling of former sexual partners, physical contact with clients, dual and multiple relationships with supervisees, sexual harassment, use of derogatory language, bartering arrangements with clients, cultural competence, labor-management disputes, and evaluation of practice. Although codes of ethics cannot provide simple, unequivocal solutions to all complex ethical dilemmas, they often provide sound conceptual guidance about important issues to consider when making difficult ethical judgments.

In addition to consulting the code, social workers can access professional ethics consultants, institutional ethics committees, and IRBs. Ethics consultation is now very common in health care settings and is increasingly available in other settings. Typically, ethics consultants are formally educated ethicists (usually moral philosophers who have experience working with professionals or professionals who have obtained formal ethics education) who provide advice on specific ethical issues that arise in practice settings. These consultants can help social workers and other staff identify pertinent ethical issues; assess ethical dilemmas; acquaint staff with relevant ethics concepts, literature, and other resources (such as codes of ethics, policies, statutes, regulations); and make difficult ethical choices.

Institutional ethics committees formally emerged in 1976, when the New Jersey Supreme Court ruled that Karen Ann Quinlan's family and physicians should consult an ethics committee in deciding whether to remove her from life-support technology (a number of hospitals have had panels resembling ethics committees since at least the 1920s). Ethics committees often include social workers as members, along

with representatives from various disciplines found in health care and human service settings, such as nurses, physicians, clergy, allied health professionals, and administrators. Some committees include a lawyer, although the lawyer might not be an employee of the agency to avoid a conflict of interest (Aulisio, Arnold, & Youngner, 2003).

Most ethics committees focus on providing case consultation in the form of nonbinding advice. These committees make themselves available to agency staff, clients, and sometimes family members for consultation about challenging ethical issues. Many ethics committees also take steps to examine, draft, and critique ethics-related policies that affect agencies and their employees and clients. In addition, these committees may sponsor ethics-related educational events, such as in-service training, symposia, workshops, conferences, and what have become known as “ethics grand rounds” (Reamer, 1998, 1999, 2001b).

Social workers employed in settings that conduct research may be involved in IRBs. IRBs (sometimes known as a research ethics board or committee on the use of human participants in research) became popular in the 1970s as a result of increasing national interest in research and evaluation and concern about exploitation of research participants. All organizations and agencies that receive federal funds for research are required to have an IRB review the ethical aspects of proposals for research involving human participants.

Social workers’ understanding of ethical issues has matured greatly. Literature on the subject, professional education, and in-service training have burgeoned. To practice competently, contemporary professionals must have a firm grasp of pertinent issues related to ethical dilemmas and ethical decision making. This knowledge enhances social workers’ ability to protect clients and fulfill social work’s critically important, values-based mission.

19 Risk Management in Social Work

Frederic G. Reamer

Service delivery is also accompanied by risks and consequences, such as litigation. To protect clients and related third parties and minimize risk, social workers need to be informed about prevailing standards to prevent ethics complaints and ethics-related lawsuits. Ethics complaints—filed with social work licensing boards or with professional organizations, such as the National Association of Social Workers (NASW)—typically allege that social workers violated widely accepted ethical standards in their relationships with clients, colleagues, employers, or other parties. Ethics-related lawsuits typically claim that social workers were negligent, in the strict legal sense, by virtue of their mishandling of some ethics-related phenomenon, such as processing confidential information or informed consent, maintenance of professional boundaries, use of controversial treatment techniques, conflicts of interest, or termination of services (Reamer, 2003, 2006, 2013a).

THE NATURE OF RISK MANAGEMENT

Social workers expose themselves to risk when they practice in a manner that is inconsistent with

prevailing professional standards (Houston-Vega, Nuehring, & Daguio, 1997; Reamer, 2003; Strom-Gottfried, 2000, 2003). Some ethics complaints arise out of mistakes and oversights. Examples include social workers who forget to document important clinical information in a client's case record, inadvertently disclose sensitive personal information to a client in a Facebook posting, or fail to protect confidential information transmitted via fax. Other complaints and lawsuits arise from social workers' deliberate ethical decisions—for example, when social workers attempt to manage complex boundaries in their relationships with clients in rural communities, disclose confidential information without clients' consent to law enforcement or child protective services officials, or terminate services to a non-compliant client. In addition, some complaints and lawsuits are the result of practitioners' ethical misconduct, such as sexual relationships with clients or fraudulent billing for services.

Social workers can be held accountable for negligence and ethical violations in several ways. In addition to filing lawsuits, parties can file ethics complaints with the NASW or with state licensing and regulatory boards. In

some instances, social workers are also subject to review by other professional organizations to which they belong, such as the American Board of Examiners in Clinical Social Work, Clinical Social Work Association, and American Association for Marriage and Family Therapy. In exceptional circumstances, criminal charges may be filed (for example, based on allegations of sexual misconduct or fraudulent billing of an insurance company or state funding agency).

Ethics complaints filed against NASW members are processed using a peer review model that includes NASW members and, initially, the National Ethics Committee. If a request for professional review is accepted by the National Ethics Committee, a NASW Chapter Ethics Committee (or the National Ethics Committee in special circumstances) conducts a hearing during which the complainant (the person filing the complaint), the respondent (the person against whom the complaint is filed), and witnesses have an opportunity to testify. After hearing all parties and discussing the testimony, the committee presents a report to elected chapter officers that summarizes its findings and presents recommendations. Recommendations may include sanctions or various forms of corrective action, such as suspension from NASW, mandated supervision or consultation, censure in the form of a letter, or instructions to send the complainant a letter of apology. In some cases, the sanction may be publicized through local and national NASW newsletters or newspapers. NASW also offers mediation in some cases in an effort to avoid formal adjudication, particularly involving matters that do not involve allegations of extreme misconduct. If complainants and respondents agree to mediate the dispute, NASW facilitates the process.

State legislatures also empower social work licensing boards to process ethics complaints filed against social workers who hold a license (in some states the boards are interdisciplinary, including social work and allied helping professions). Ordinarily these boards appoint a panel of colleagues to review the complaint and, when warranted, conduct a formal investigation and hearing (some state boards include public members in addition to professional colleagues).

Negligence claims or lawsuits filed against social workers typically allege that they engaged in malpractice in that they failed to adhere to specific standards of care. The standard of care is based on what ordinary, reasonable, prudent

practitioners with the same or similar training would have done under the same or similar circumstances (Glannon, 2010; Madden, 1998; Woody, 1996). Departures from the profession's standards of care may result from a social worker's acts of commission or acts of omission. Acts of commission can occur as a result of misfeasance (the commission of a proper act in a wrongful or injurious manner or the improper performance of an act that might have been performed lawfully) or malfeasance (the commission of a wrongful or unlawful act). An example of misfeasance is disclosing confidential information improperly; an example of malfeasance is fraudulent billing for services that the social worker did not provide. An act of omission, or nonfeasance, occurs when a social worker fails to perform certain duties that ought to have been performed. An example of nonfeasance is failure to document clinical services or inform clients of exceptions to their confidentiality rights.

Lawsuits and liability claims that allege malpractice are civil suits, in contrast to criminal proceedings. Ordinarily, civil suits are based on tort or contract law, with plaintiffs (the party bringing the lawsuit) seeking some sort of compensation for injuries they claim to have incurred as a result of the practitioner's negligence. These injuries may be economic (for example, lost wages or medical expenses), physical (for example, following a sexual relationship between a practitioner and client), or emotional (for example, depression suffered by a client who did not receive competent care from a practitioner).

As in criminal trials, defendants in civil lawsuits are presumed innocent until proven otherwise. In ordinary civil suits, defendants will be found liable for their actions based on the legal standard of preponderance of the evidence, as opposed to the stricter standard of proof beyond a reasonable doubt used in criminal trials. In some civil cases—for example, those involving contract disputes—the court may expect clear and convincing evidence, a standard of proof that is greater than preponderance of the evidence but less than proof beyond a reasonable doubt.

In general, malpractice occurs when evidence exists that (1) at the time of the alleged malpractice a legal duty existed between the social worker and the client; (2) the social worker was derelict in that duty or breached the duty, either by commission or omission; (3) the client suffered some harm or injury; and (4) the harm

or injury was directly and proximately caused by the social worker's dereliction or breach of duty.

In some cases, prevailing standards of care are relatively easy to establish through citations of the profession's literature and practice standards, expert testimony, statutory or regulatory language, or relevant codes of ethics standards. Examples include standards concerning sexual relationships with current clients, disclosing confidential information to protect children who may have been abused or neglected, fraudulent billing, or falsified clinical records. In other cases, however, social workers disagree about standards of care (Austin, Moline, & Williams, 1990; Haas & Malouf, 2005). This may occur in cases involving controversial treatment methods or ambiguous clinical or administrative circumstances (Reamer, 2013a).

KEY RISKS IN SOCIAL WORK

Social workers' prevention efforts should focus on a number of risk areas (Reamer, 2001b, 2006). These include the following.

Client Rights

Especially since the 1960s, social workers have developed a keen understanding of a wide range of clients' rights, many of which were established by legislation or court ruling. These include rights related to confidentiality and privacy, release of information, informed consent, access to services, use of the least restrictive alternative, refusal of treatment, options for alternative services, access to records, termination of services, and grievance procedures.

Confidentiality, Privileged Communication, and Privacy

Social workers must understand the nature of clients' right to confidentiality and exceptions to these rights. More specifically, social workers should have sound policies and procedures in place related to:

- Release of confidential information pertaining to alcohol and substance abuse assessment or treatment
 - Disclosure of information about deceased clients
 - Release of information to parents and guardians of minor clients
 - Sharing of confidential information among participants in family, couples, and group counseling
 - Disclosure of confidential information to media representatives, law enforcement officials, protective service agencies, other social service organizations, and collection agencies
 - Protection of confidential written and electronic records, information transmitted to other parties through the use of computers, e-mail, fax machines, phones, and other electronic technology
 - Transfer or disposal of clients' records
 - Protection of client confidentiality in the event of a social worker's death, disability, or employment termination
 - Precautions to prevent discussion of confidential information in public or semi-public areas, such as hallways, waiting rooms, elevators, and restaurants
 - Disclosure of confidential information to third-party payers
 - Disclosure of confidential information to consultants
 - Disclosure of confidential information for teaching or training purposes
 - Protection of confidential and privileged information during legal proceedings (e.g., divorce proceedings, custody disputes, paternity cases, criminal trials, and negligence lawsuits).
- To protect clients and minimize risk, social workers should discuss with clients and other interested parties the nature of confidentiality and limitations of clients' right to confidentiality (Dickson, 1998; Fisher, 2013; Polowy & Gorenberg, 1997). Depending on the setting, these topics can include
- The importance of confidentiality in the social worker–client relationship (a brief statement of why the social worker treats the subject of confidentiality so seriously)
 - Laws, ethical standards, and regulations pertaining to confidentiality (relevant federal,

- Solicitation of private information from clients
- Disclosure of confidential information to protect clients from self-harm and protect third parties from harm inflicted by clients

state, and local laws and regulations; ethical standards in social work)

- Measures the social worker will take to protect clients' confidentiality (storing records in a secure location, limiting colleagues' and outside parties' access to records)
- Circumstances in which the social worker would be obligated to disclose confidential information (e.g., to comply with mandatory reporting laws or a court order, to protect a third party from harm or the client from self-injury)
- Procedures that will be used to obtain clients' informed consent for the release of confidential information and any exceptions to this (a summary of the purpose and importance of and the steps involved in informed consent)
- The procedures for sharing information with colleagues for consultation, supervision, and coordination of services (a summary of the roles of consultation and supervision, and coordination of services and why confidential information might be shared)
- Access that third-party payers (insurers) or employers will have to clients' records (policy for sharing information with managed care organizations, insurance companies, insurance company representatives, utilization review personnel, employers, and staff of employee assistance programs)
- Disclosure of confidential information by phone, computer, fax machine, e-mail, and the Internet
- Access to agency facilities and clients by outside parties (e.g., people who come to the agency to attend meetings or participate in a tour)
- Audiotaping and videotaping of clients.

Informed Consent

Informed consent is required in a variety of circumstances, including release of confidential information, program admission, service delivery and treatment, videotaping, and audiotaping (Berg, Appelbaum, Parker, & Lidz, 2001; Miller & Wertheimer, 2010). Although various courts, state legislatures, and agencies have somewhat different interpretations and applications of informed consent standards, there is considerable agreement about the key elements that social workers and agencies should incorporate

into consent procedures (for example, that clients should be given specific details about the purposes of the consent, a verbal explanation, information about their rights to refuse consent and withdraw consent, information about alternative treatment options, and an opportunity to ask questions about the consent process).

Service Delivery

Social workers must provide services and represent themselves as competent only within the boundaries of their education, training, license, certification, consultation received, supervised experience, or other relevant professional experience. They should provide services in substantive areas and use practice approaches and techniques that are new to them only after engaging in appropriate study, training, consultation, and supervision from people who are already competent in those practice approaches, interventions, and techniques. Social workers who use practice approaches and interventions for which there are no generally recognized standards should obtain appropriate education, training, consultation, and supervision.

Digital and Online Technology

Digital, online, and other electronic technology have transformed the nature of social work practice. Contemporary social workers can provide services to clients using online counseling, telephone counseling, video counseling, cybertherapy (avatar therapy), self-guided Web-based interventions, electronic social networks, e-mail, and text messages. The introduction of diverse digital, online, and other forms of electronic social services has created a wide range of complex ethical and related risk-management issues. Compelling ethical issues pertain to practitioner competence; client privacy and confidentiality; informed consent; conflicts of interest; boundaries and dual relationships; consultation and client referral; termination and interruption of services; and documentation (Reamer, 2012, 2013a).

Boundary Issues, Dual Relationships, and Conflicts of Interest

Social workers should establish clear policies, practices, and procedures to ensure proper boundaries related to:

- Sexual relationships with current and former clients
- Counseling former sexual partners
- Sexual relationships with clients' relatives or acquaintances
- Sexual relationships with supervisees, trainees, students, and colleagues
- Physical contact with clients
- Friendships with current and former clients
- Encounters with clients in public settings
- Attending clients' social, religious, or life cycle events
- Gifts to and from clients
- Performing favors for clients
- The delivery of services in clients' homes
- Financial conflicts of interest
- Delivery of services to two or more people who have a relationship with each other (such as couples, family members)
- Bartering with clients for goods and services
- Managing relationships in small or rural communities
- Self-disclosure to clients
- Becoming colleagues with a former client (Reamer, 2001a).

Documentation

Careful documentation and comprehensive records are necessary to assess clients' circumstances; plan and deliver services appropriately; facilitate supervision; provide proper accountability to clients, other service providers, funding agencies, insurers, utilization review staff, and the courts; evaluate services provided; and ensure continuity in the delivery of future services (Kagle & Kopels, 2008; Reamer, 2005; Sidell, 2011; Wiger, 2005). Thorough documentation also helps ensure quality care if a client's primary social worker becomes unavailable because of illness, incapacitation, vacation, or employment termination. In addition, thorough documentation can help social workers who are named in ethics complaints or lawsuits (for example, when evidence is needed to demonstrate that a social worker obtained a client's informed consent before releasing confidential information, assessed for suicide risk properly, consulted with knowledgeable experts about a client's clinical issues, consulted the *NASW Code of Ethics* to make a difficult ethical decision, or referred a client to other service providers when services were terminated).

Social workers should maintain and store records for the number of years required by state statutes or relevant contracts. Practitioners should make special provisions for proper access to their records in the event of their disability, incapacitation, termination of practice, or death. This may include entering into agreements with colleagues who would be willing to assume responsibility for social workers' records if they are unavailable for any reason.

Defamation of Character

Social workers should ensure that their written and oral communications about clients are not defamatory. Libel is the written form of defamation of character; slander is the oral form. Defamation occurs when a social worker says or writes something about a client or another party that is untrue, the social worker knew or should have known that the statement was untrue, and the communication caused some injury to the client or third party (e.g., the client was terminated from a treatment program or lost custody of a child, or a colleague was disciplined by an agency administrator).

Supervision

In principle, social workers can be named in ethics complaints and lawsuits alleging ethical breaches or negligence by those under their supervision. Social work supervisors should ensure that they meet with supervisees regularly, address appropriate issues (e.g., treatment and intervention plans, case recording, correction of errors in all phases of client contact, dual relationships, protection of third parties), and document the supervision provided.

Consultation and Referral

Social workers should be clear about when consultation with colleagues is appropriate and necessary and the procedures they should use to locate competent consultants. Similarly, social workers have a responsibility to refer clients to colleagues when they do not have the expertise or time to assist clients in need. Practitioners should know when to refer clients to other professionals and how to locate competent colleagues.

Fraud

Social workers should have strict procedures in place to prevent fraud related to, for example, documentation in case records, billing, and employment applications.

Termination of Services

Social workers expose themselves to risk when they terminate services improperly—for example, when a social worker leaves an agency suddenly without adequately referring a vulnerable client to another practitioner, or terminates services to a very vulnerable client who has missed appointments or has not paid an outstanding bill. Practitioners should develop thorough and comprehensive termination protocols to prevent client abandonment.

Practitioner Impairment, Misconduct, and Incompetence

A significant percentage of ethics complaints and negligence claims are filed against social workers who meet the definition of impaired professional (impairment that may be due to factors such as substance abuse, mental illness, extraordinary personal stress, or legal difficulties). Social workers should understand the nature of professional impairment and possible causes, be alert to warning signs, and have procedures in place to prevent, identify, and respond appropriately to impairment in their own lives or colleagues' lives (Reamer, 1992; Strom-Gottfried, 2000, 2003).

In addition, social workers sometimes encounter colleagues who have engaged in ethical misconduct or are incompetent. Examples include social workers who learn that a colleague is falsifying travel expense vouchers or client records or providing services outside his or her areas of expertise.

In some instances, social workers can address these situations satisfactorily by approaching the colleague, raising the concerns, and helping the colleague devise an earnest, constructive, and comprehensive plan to stop the unethical behavior, minimize harm to affected parties, seek appropriate supervision and consultation, and develop any necessary competencies. When these measures fail or are not feasible—perhaps because of the seriousness of the ethical misconduct, impairment, or incompetence—one must consider blowing the

whistle on the colleague. Whistle-blowing entails taking action through appropriate channels—such as notifying administrators, supervisors, professional organizations, and licensing and regulatory bodies—in an effort to address the problem. Before deciding to blow the whistle, social workers should carefully consider the severity of the harm and misconduct involved; the quality of the evidence of wrongdoing (one should avoid blowing the whistle without clear and convincing evidence); the effect of the decision on colleagues and one's agency; the whistle-blower's motives (that is, whether the whistle-blowing is motivated primarily by a wish for revenge); and the viability of alternative, intermediate courses of action (whether other, less drastic means might address the problem). Social work administrators need to formulate and enforce agency policies and procedures that support and protect staffers who disclose impairment, misconduct, and incompetence conscientiously and in good faith. See Chapter 22 on the impaired social work professional for more detailed information on impaired social workers and how to remedy the situation.

Management Practices

Periodically, social work administrators should assess the appropriateness or adequacy of the agency's government licenses; the agency's papers of incorporation and bylaws; the state licenses and current registrations of all professional staff; protocols for emergency action; insurance policies; staff evaluation procedures; and financial management practices (Kurzman, 1995).

IMPLEMENTING A COMPREHENSIVE RISK MANAGEMENT STRATEGY

Social workers can prevent ethics complaints and ethics-related lawsuits by conducting a comprehensive ethics audit (Reamer, 2001b, 2013a). An ethics audit entails thorough examination of major risks associated with one's practice setting (whether independent or agency-based practice). The audit involves several steps designed to identify ethics-related risks and minimize harm to clients, social workers, and social service agencies.

1. Appoint a committee or task force of concerned and informed staff or colleagues.

2. Gather the information necessary to assess the level of risk associated with each ethics-related phenomenon (i.e., clients' rights; confidentiality and privacy; informed consent; service delivery; digital and online technology; boundary issues and conflicts of interest; documentation; defamation of character; supervision; staff development and training; consultation; client referral; fraud; termination of services; practitioner impairment, misconduct, or incompetence; management practices) from such sources as agency documents, data gathered from interviews with agency staff, and national accreditation standards.
3. Review all available information.
4. Determine whether there is no risk, minimal risk, moderate risk, or high risk for each risk area.
5. Prepare an action plan to address each risk area that warrants attention, paying particular attention to the steps required to reduce risk, the resources required, the personnel who will oversee implementation of the action plan, the timetable for completion of the plan, the indicators of progress toward reducing risk, and plans to monitor implementation of the action plan.

In recent years, social workers have paid increased attention to the risk of lawsuits and ethics complaints filed against practitioners and agencies. To minimize these risks, and especially to protect clients, social workers need to understand the nature of professional standards of care, malpractice, and negligence. They also need to be familiar with major risk areas and practical steps they can take to prevent complaints.

20 Advocacy in Administrative Forums

Guidelines for Practice in Benefit Appeals

John M. Gallagher

This chapter examines the intersection of administrative law and social work practice. More specifically, it focuses on appeal processes available in public benefit programs and ways that social workers can help their clients utilize them. Although criminal and civil courts may come to mind more readily when considering forensic social work, these administrative forums can be used by clients and their advocates to enforce rights and meet needs. Due to the relative informality of these appeal processes, social workers can play a number of active and supportive roles. The three objectives of this chapter are (1) to explain why it is important for social workers to be aware of these forums; (2) to provide an

overview of administrative appeals and hearings; and (3) to explore ways that social workers can participate in these processes. Throughout the chapter, ethical and practical issues will be raised.

WHY SHOULD SOCIAL WORKERS KNOW ABOUT ADMINISTRATIVE APPEALS?

This question must be addressed in a few different ways. First, the sheer number of individuals enrolled in programs with legally defined appeal processes is compelling. Although the

specific rights and processes vary among programs and states, the material in this chapter applies to individuals receiving Medicaid, Temporary Assistance to Needy Families (TANF), Supplemental Nutrition Assistance Program (formerly called Food Stamps), Medicare, Social Security programs, Veterans Affairs disability programs, many state programs as well as students receiving special education services under the Individuals with Disabilities Education Act. Collectively, there are millions of affected individuals, a great number of whom have routine or episodic interactions with social workers.

Next, the Fifth and Fourteenth Amendments to the Constitution assert that no one shall be “deprived of life, liberty or property without due process of law.” These “due process” provisions apply to both the federal and state governments and have over time been interpreted by the Supreme Court to require appeal processes to challenge denials, reductions, suspensions, and terminations of many programs that make up our social service system. Although the exact level of protection varies across programs, the classic example is *Goldberg v. Kelly* (1970), which established the right to a pre-termination hearing before an impartial decision maker for individuals receiving Aid to Families with Dependent Children (the predecessor to TANF).

Third, despite such important and powerful legal protections, anecdotal reports and the limited available research (Bell & Norvell, 1967–1968; Handler, 1969; Lens & Vorsnager, 2005) indicate that beneficiaries underutilize their appeal options. Interestingly, the same studies suggest that individuals who do file appeals experience relatively high rates of success. Lens (2007) provided further insight through interviews with TANF recipients regarding factors that affected the decision to appeal. One of the findings was that receiving information, encouragement, or support from an individual in the recipient’s social network seemed to increase the utilization of appeal options. Although intended to be accessible to lay individuals, legal scholars have critiqued administrative hearings as inaccessible and intimidating to many recipients (Brodoff, 2010; Kinney, 1990–1991). The types of social, educational, and psychological issues that force many individuals to rely on such programs are often the factors that pose barriers to recognizing, understanding, and utilizing appeal options.

Finally, considering the above, the values, history, and ethical guidelines of our profession call on us to advocate for social justice in administrative as well as other contexts. As the ensuing sections will explore, many social workers are well positioned to help their clients exercise rights they would otherwise experience only in the abstract. To put a human face on this call to advocacy and to help frame the technical discussion that follows, please consider this brief scenario in thinking about the relevant practice principles described in this chapter.

Roberto is a social worker in a federally funded homeless outreach program. Although the program can provide short-term psychiatric services to individuals from its grant, Roberto is charged with helping individuals with a serious mental illness enroll in his state’s mainstream service system for ongoing care. Eligibility for the state’s system requires the establishment of a qualifying diagnosis and a related functional impairment. Mark, a 25-year-old man on Roberto’s caseload, has been diagnosed by the program’s psychiatrist as having schizophrenia. He reports episodic hospitalizations for this condition in five states over the past three years. Roberto has begun requesting records from these hospitals and they have consistent diagnoses of schizophrenia or closely related psychotic disorders. Although offered assistance to enter a shelter, Mark declined due to fear that the staff would poison him. Therefore, he remains on the streets. When referred to the state system he was denied due to a comorbid diagnosis of alcohol abuse in the outreach program’s records. This denial suggests that his functional impairment is likely due to substance use. The state’s program is Medicaid funded and Mark is issued a notice of action which advises him that he may appeal. He informs Roberto that he knew it would not work and mentions moving to another city.

OVERVIEW OF ADMINISTRATIVE APPEALS AND HEARINGS

Having considered why it is often appropriate for social workers to assist in such matters—and before exploring ways to do so—an overview of how these administrative forums function is in order. What follows is of necessity a broad overview. The differences between systems and jurisdictions preclude overarching specifics. However, if the issues and

themes identified here are used as a starting point, program specific details can be found and addressed.

- *Notice rights:* When a government agency—or a provider working under contract—makes a decision to deny, reduce, suspend, or terminate the types of services listed above, they are generally required to provide the client or applicant with written notice. The notice should provide the agency’s reason for the decision, the effective date, and what appeal or review options the individual holds.
- *Appeal initiation:* Upon learning of an adverse decision (even if the agency fails to provide appropriate notice) the client or his/her representative generally has the right to file an appeal of the decision. There are always deadlines within which such appeals must be filed. Although some systems allow oral appeals, written appeals are best. Some agencies have specific forms and in other instances a letter will suffice. Regardless of format, it is prudent to submit the appeal in a way that provides proof of timely filing—for example, certified mail, via fax, or obtaining a signed acknowledgment from agency staff. When a service is already in place and the agency is proposing its termination or reduction, the client often has the option of requesting a service continuation during the appeal process. Although this can be a beneficial option, it is important that the client understand that the system may have the right to receive reimbursement for the service costs if he or she loses the appeal. The notice should cover these details.
- *Pre-hearing steps:* In some systems the appeal process has a level before the dispute is addressed in an administrative hearing. These pre-hearing steps can be either mandatory or an option for the client to exercise. There are two main types of preliminary steps. The first—which is common in clinically oriented systems—is a second review of existing and additional documentation by the agency making the denial. Making sure the agency reviewer has all necessary documentation is essential. For this reason, it is often helpful to request that the reviewer discuss the issue with a physician or other involved clinician who supports the service in question. The other common pre-hearing step is a meeting or conference where the hearing officer or other individual attempts to mediate the disagreement between the parties. If such preliminary steps are undertaken and prove unsuccessful, there may be a need to file an additional request for a hearing.
- *Hearing venue:* Some state agencies/systems, as well as federal agencies, have administrative courts associated with the individual agency to hear appeals. Other states have created independent offices of administrative hearings to adjudicate disputes from a variety of state agencies. Regardless of location, the hearings are typically presided over by an administrative law judge (ALJ) or hearing’s officer. Although significant variation exists among agencies and individual ALJs, these hearings are less formal than criminal or civil courts. Nonetheless, participating clients and social workers should still err on the side of formality in dress and demeanor. For individuals who would have difficulty attending the hearing in person, it is often possible to request a telephonic hearing. Such requests are made by filing a motion with the court. (This need not be a complex process and is discussed below.) Although this can be helpful for individuals who could not otherwise attend, concerns have been raised that appellants who participate by phone are less likely to introduce evidence or call witnesses (Toubman, McArdle, & Rogers-Tomer, 1995–1996).
- *Importance of policy:* Whereas criminal and civil proceedings draw upon statutes and judicial precedents, administrative hearings typically rely on administrative rules and policies issued by federal and state agencies. As these rules (also called administrative codes or regulations) and policies establish the criteria by which agencies are to make eligibility and other decisions, it is essential to consider the relevant sections before and during an appeal. Agencies often provide a citation to the rule or policy they see as supporting their position in the notice of action. In recent years, many agencies have made these guiding documents available on their websites. Legal aid agencies often publish helpful self-advocacy guides, explaining how to use specific appeal processes. It is often advantageous to prepare a short memo for the ALJ listing the policies and/or rules the appellant sees as supporting his or her position.

- *Burden of proof:* There are two issues to be aware of in all judicial hearings. The first is which party “holds the burden.” Depending on a variety of factors, it can be either client or agency that has the obligation to prove the case through evidence. More consistent is the level of proof needed to prevail. Although terms like “beyond a reasonable doubt” and “clear and convincing” are commonly used to describe the level needed to render criminal or civil decisions, administrative processes typically use the lower preponderance of the evidence standard—essentially meaning the party with the burden must simply introduce more credible and relevant evidence than the opposition.
- *Types of evidence:* During hearings, both parties have the opportunity to introduce evidence. There are two basic types of evidence: testimony and documentary evidence. Testimony is provided through the calling of a witness. Although witnesses often appear in person, courts may grant permission for a witness to testify via telephone. This can be particularly helpful if trying to arrange the testimony of a clinician with limited time. As with telephonic hearings, such requests are typically made by filing a motion with the court. Depending on the nature of the appeal, documentary evidence may include clinical, financial, or other documents that demonstrate eligibility for the service or program in question. Although live testimony is generally best, a written statement from an involved clinician is often helpful if testimony is not possible.
- *Requesting a continuance:* There are times where one party needs to request a postponement of the hearing date. These requests are made through motions to the court, should be based on a legitimate reason (e.g., to secure necessary documents or a conflict in the schedule of a witness or the appellant), and the other party has the right to object. The ALJ will issue a response, granting or rejecting the request.
- *Communication during appeals:* Once an appeal has been filed—especially once a hearing has been scheduled—communication between the parties and the court becomes formal. As indicated above, requests for continuances or telephonic hearings/

testimony should be provided to the court via motions. Administrative law judges often accept relatively informal filings—especially from individuals appearing pro se or represented by a lay advocate. Some state agencies and legal aid agencies post templates on their websites. Although there is some informality in style, it is essential that any motion filed with the court is also provided to the opposing party. The failure to do so will usually result in the denial of the request because it prevents the other party from having a fair opportunity to respond. There is also likely to be a deadline by which a motion must be filed—perhaps 14 days before the scheduled hearing. If making a late filing, good cause should be noted. Extending the logic of copying the opposing party on motions, any evidence or policy memos provided to the court must also be provided to the other party.

- *Decision and further appeal:* Following the hearing, the ALJ will issue a written decision. It will generally contain a summary of the evidence introduced at the hearing, how the judge weighed the evidence, and how it related to the relevant policy and code. It often takes a month or more for the decision to be issued. An individual may have options if the decision is unfavorable. In certain instances, a review can be requested by the same administrative court and in others an appeal to a civil court is an option. These possibilities require close research and—especially the appeal to civil court—increase the importance of consulting with an attorney if available. Lay advocates cannot provide representation in civil courts.

ADVOCACY APPROACHES AND CONSIDERATIONS

As with all categories of social work intervention, advocacy with public benefit appeals can take on many forms. The scope of the assistance provided will be influenced by a variety of factors (which will be discussed in the following section).

Before reviewing forms of administrative advocacy, it is important to address a common question: how do practitioners and agencies protect themselves when using these interventions? Although manageable, there are two important issues to consider. First, the potential for

providing unauthorized practice of law exists. As detailed below, when officially serving as a lay representative in a manner consistent with the rules of a system or jurisdiction, an individual is on firm legal ground to perform tasks and give advice that would otherwise constitute the practice of law. Conversely, when state law prevents lay advocacy in administrative hearings the issue is clear and the prohibition must be honored. More individual analysis is required if state direction on lay representation at administrative hearings is lacking or when providing assistance at a lower level of advocacy. There is recognition from the legal community (American Bar Association, 1995, p. 35) that “informal help with legal problems, coming from ... social workers ... who have had experience handling a similar legal problem or are considered to be reliable sources of information, has generally not been considered unauthorized practice.” The ABA further noted that social workers often assist individuals appearing *pro se* in administrative hearings. Although used by the ABA in a slightly different way, the following two questions from their report are useful in evaluating when to assist. First, does the activity pose a serious risk to the client? Specific to this context, does losing an appeal carry a greater consequence than not pursuing it at all? Second, does the client have the ability to understand the social worker is not an attorney and evaluate the potential benefits of the offered assistance? Solid attention to informed consent should address this question.

The second issue is the possibility of a malpractice claim being filed against a social worker or agency due to lay representation or other administrative advocacy. Examples of such claims are not evident in the literature of social work malpractice. Nonetheless, as with any form of direct practice, there is always a possibility of a claim being filed. Although perfect protections against liability do not exist, the issues raised in this chapter and more traditional guidance on preventing social work liability (Reamer, 2003) offer sound advice.

Assisting in Self-representation

Many of the individuals served by social workers are able and willing to utilize their due process protections independently. These protections are, after all, designed to be used by service recipients. The terms *pro se* and *pro per* are often used to describe an individual who represents him or

herself in a legal proceeding. When appropriate, such independent representation has the advantage of supporting client autonomy and empowerment. Nonetheless, there are often barriers to self-representation and ways that social workers can help overcome them. On the most basic level, some individuals may be unaware of the opportunity to file such appeals (despite notice obligations) or aware but skeptical that the process will work for them. Sometimes a little knowledge or encouragement goes a long way. In other instances, clients will need more concrete forms of assistance to successfully self-represent. Such assistance often includes providing computer/Internet access to research relevant law, code, or policy, or to compose and file documents; helping to obtain past treatment records for introduction as evidence; making copies of documents that will be introduced as evidence; serving as a sounding board for approaches to the appeal; or providing transportation to the hearing or related meetings. Individuals representing themselves often encounter difficulties securing witnesses to participate. When the dispute involves a clinical assessment of eligibility for a program or need for an individual service, the service system is usually at a great advantage because it employs clinicians who can testify. Licensed clinical social workers can often fill this need and other social workers can often testify to relevant facts. There are times when a social worker can help a client secure or coordinate the testimony of a psychiatrist or other clinician.

Similar to assisting with self-representation, there may be a family member or other natural support willing and able to serve as a client representative in an appeal. Types of social worker assistance for such advocates are the same as those offered to *pro se* representatives. Ensuring the client authorizes the sharing of information is an important additional step.

Referral to and Coordination with Attorneys

Although resources vary by community and issue type, there may be a local attorney available to represent a client in an appeal. This is most likely if a successful appeal will result in the awarding of a cash settlement for benefits not paid while the appeal was pursued—generally federal disability benefits and workers’ compensation claims. In these instances, private attorneys often will provide representation in

return for a percentage of the retroactive benefit payment if successful. Individual clients must decide whether they are willing to pay for such services. Legal aid and other nonprofit law firms can provide representation in limited instances. Client eligibility for these legal services is often based on being on a very low income, homeless, a domestic violence victim, or an individual with a disability.

At the most basic level, social workers can refer clients to these resources. As with other types of service referral and coordination, it is important to stay abreast of local resources and the types of cases they do and do not accept. It is often helpful to cultivate relationships with legal aid attorneys. There are times when they are seeking clients who present with a certain set of facts in order to use a small number of cases to push for larger system reform. Social workers can remain aware of such issues through both local networking and subscribing to the e-mail lists of national legally based advocacy organizations based on their area of practice.

Driven by individual client need and authorization, social workers can collaborate with attorneys representing common clients in public benefit appeals. Especially for clients whose living situations are unstable or unsafe, social workers can help with communication between attorneys and clients. For clients needing emotional support, transportation, or help understanding information, it is often beneficial to attend appointments with clients. This also helps cultivate networks with the legal services community. Social workers can again serve as witnesses or help arrange the testimony of others. This can be especially helpful with physicians—who may be inclined to assist but reluctant to spend significant time preparing.

Providing Direct Representation

There are times where it is both legally permissible and appropriate for a social worker to represent a client in a public benefits appeal. When assuming the role of a lay advocate, the social worker conducts the appeal for his or her client by filing documents with the agency or court, identifying relevant policy, introducing evidence, and examining and cross-examining witnesses at the hearing. This can be an effective form of advocacy. There are, however, several issues to consider before agreeing to represent a client in this manner.

- *Is it legally permissible?* Although the answer to this is often, “yes,” it varies from program to program and state to state. It is essential to verify this before agreeing to serve as a lay representative for a client, given that some states consider it to be engaging in the unauthorized practice of law. Generally, the answer can be obtained from the involved agency, the administrative court where the hearing is held, or the state’s court system. When allowed, there is often a prohibition against charging a fee for lay representation. Rules issued by the Supreme Court of the State of Arizona (Regulation of the Practice of Law, 2012) provide an example of how one state authorizes lay representation in public benefits. This rule establishes explicit exceptions to the general prohibition against unlicensed practice of law for appeals related to TANF, Medicaid, the free and appropriate public education for a child with a disability, and the public behavioral health system. In these narrow contexts, a non-attorney is allowed to prepare documents, give legal opinions, introduce evidence, and examine witnesses in administrative hearings.
- *Is legal representation available?* Although one objective of this chapter is to increase social workers’ willingness and ability to provide lay representation, this is not intended to replace attorneys. Rather, it is an option that can be offered to clients when a lawyer is not available. In addition to the sources mentioned above, legal assistance may be available through Volunteer Lawyer Programs or free clinics affiliated with law schools.
- *Is your client able to self-represent?* Without pushing someone into undertaking a task for which he or she is unprepared, we must explore this option—including ways to reduce identified barriers. Doing so is consistent with social work’s emphasis on strengths and autonomy. However, perception should also be considered. Although it is unfortunate, some decision makers will view an argument as more credible if it is offered by a professional as opposed to the affected individual.
- *Do you have the competence and confidence required?* Given that these appeal processes are designed to be used by service recipients, lay representation is realistic. Nonetheless,

that does not mean that every social worker will be or feel up to the task. The ethical prohibition against practicing beyond one's competence (NASW, 1996) is as relevant here as it is in more traditional practice realms.

- *How does the representation fit with the primary client relationship?* Social workers are often faced with clients whose needs stretch beyond the purview of their individual positions. Although our practice roles are diverse, an individual practitioner can never meet all needs. Without terming it inappropriate, representing a client in an administrative hearing is less likely to be a good fit for a therapist than it is for a case manager. Beyond individual role, the larger agency or program function should be considered.
- *Does the appeal have merit?* In addition to resources and agency priorities, legal aid agencies consider case merits before agreeing to provide representation. Social workers considering such representation should do the same. These decisions should not be based on what one would like to see happen, but on the likelihood of prevailing. Sometimes an individual desires a service that he or she is simply not eligible to receive. Other times the individual should be eligible but the necessary treatment records, assessment, witnesses, or other forms of evidence are not available. If taking a case would do little more than let your client know you are in his or her corner, your client would be better served by a frank conversation and the development of a realistic plan. Taking the time to develop or obtain the information required for eligibility and reapplying at a later date is often more appropriate than pursuing an appeal.
- *Is your supervisor or agency comfortable with the representation?* You should not be surprised by questions and concerns—especially the first time you propose such an intervention. Be prepared to defend the plan. Thorough internal review can strengthen the case or identify that it lacks merit. If you cannot convince your supervisor of your ability to advocate for your client effectively, perhaps you cannot effectively advocate for your client on the issue in question.
- *Is your client comfortable with you assuming this role?* This may seem obvious; the process will almost certainly require

your client to designate you as his or her representative in writing. Yet, as with other interventions, informed consent is more complicated than obtaining a signature (NASW, 1996). The questions and considerations raised in this chapter should resonate with the essential elements of informed consent: What are the advantages and disadvantages of the intervention? Are there other options available? What are the costs of doing nothing? What is the likelihood of success? How prepared are you? How well does your client understand your level of competence? It is essential to ensure that your client understands that you are not an attorney. The impact on traditional client confidentiality should be clearly discussed and appropriate authorizations obtained before testimony or records are shared with a court or attorneys.

CONCLUSION

Ours is a legally regulated society. Laws, administrative rules, and agency policy shape the rights and responsibilities we all hold. Yet, legal scholars (Felstiner, Abel & Sarat, 1980–1981; Galanter, 1974; Rhode, 2004) and legal aid organizations (Legal Services Corporation, 2009) have consistently noted that low income individuals have fewer resources to identify and enforce the rights they hold. Public benefits advocacy is an area where social workers can help our clients close this justice gap. Although there are questions to answer before providing such assistance and issues to manage while doing so, our discipline's long standing focus on social justice and advocacy suggests we should assist when we can.

21 Social Work Regulation and Licensing

Andrew T. Marks & Karen S. Knox

Social work regulation has been a dynamic, ongoing process of debate and change since the beginnings of the profession in the early 1900s. The many influences and impacts on social work regulation range from political power through appointment to professional boards to financial impacts by third-party reimbursement. Social

work regulation protects and enforces the values, ethics, and professional standards of practice and is the primary means of protecting the public and clients of social services through sanctions for professional and regulatory violations. In addition to providing a foundation for who a social worker is and what a social worker can or cannot

do in a specific jurisdiction, social work regulation has both supported the acceptance of the profession and continued the quandary of what is social work and who is a social worker.

The primary focus of all regulatory bodies, whether voluntary or mandated by government legislation, is protecting the recipients of a professional's service (i.e., consumers), stated most succinctly as "protecting the public." Mandated regulatory bodies are usually created by jurisdiction governance bodies or state legislatures. Their primary goals are to set standards for professional practice, enforce the law, establish rules and regulations that determine minimum qualifications for professional practice, and establish a process to discipline those who do not maintain or continuously meet the established standards. Most regulatory bodies have authority to grant, suspend, and discipline credentials issued by the regulatory body (Biggerstaff, 1995). According to Biggerstaff (1995), social work regulation has four primary purposes:

1. Protect the service consumer
2. Protect the profession
3. Protect the individual professional
4. Aid consumers in the selection of a practitioner in the profession.

Professional regulation through licensing, certification, or registration is a result of the need for government to intervene in activities within the private sector because serious conditions exist in which unqualified practice results in serious threat of harm to public health and safety or economic welfare of the consumer (Biggerstaff, 1995). Additional reasons for social work regulation exist in that the consumer is often unable to evaluate a practitioner's qualifications correctly, and the benefits of credentialing for the consumer clearly prevail over potential harmful effects on the professional (Biggerstaff, 1995).

Another type of social work regulation is through professional organizations and associations that offer voluntary certification as a benefit of membership. Government-sanctioned social worker regulation credentials have proliferated in the United States since the 1980s, so voluntary credentials have become less utilized by practitioners because many jurisdictions have statutes protecting the practice of a profession with credentialing administered by the jurisdictional governing body. This multitude of required governmental and voluntary professional organizational

credentialing is confusing to professionals, not to mention the general public. As a result of the bifurcated credentialing processes, the public has little knowledge or understanding of the difference between mandated or voluntary credentials (Biggerstaff, 1995).

Case Illustration #1

Robert is a Licensed Master Social Worker working as a school social worker. He begins to work with a fifth grade student who is having difficulty with being bullied in class. He contacts the student's mother and explains the reason he was requested to help the student and sets an appointment time with the mother for intake paperwork. As he works with the student to successful resolution, he terminates services with the student. A few days later Robert sees the mother at school, and they strike up a conversation. A few days later the mother calls Robert to ask about a situation with one of her younger children and asks if they could meet for coffee and discuss the situation. Robert agrees and a romance develops. Soon Robert is called in to the school administrator's office because a complaint was filed. Robert reluctantly acknowledges that he is in a romantic relationship with the mother of the student, but that the relationship did not begin until after he terminated his services previously. The administrator files complaints with the School Board and Social Worker Board.

Robert appears before the social work board and explains that he considered his client to be the student and that he did not work directly with his client's mother, except for her to complete and sign the intake forms. The Social Worker Board responds that children do not have the legal right to consent to treatment, therefore, the parent is considered to be the client for minors. The Board revoked his LMSW license. Robert was fired as a result, because he no longer met the required criteria for his position. While the School Board and jurisdiction has laws against sexual activity by teachers and students, there is no school policy about parents and school personnel engaging in sexual relationships.

BRIEF HISTORY OF SOCIAL WORK REGULATION

Social work as a profession is relatively new to regulation, especially as one of the health care

and helping professions. The first attempt at social work regulation dates back to the 1920s in California, and Puerto Rico passed the first credentialing statute for social workers in 1934. California was successful with implementing regulation of social workers by 1945 (Thyer & Biggerstaff, 1989). By 1993, every state and the District of Columbia had some form of social worker regulation (Biggerstaff, 1995).

The first record of a social work organization's action toward legal regulation was in 1947 by the American Association of Social Workers through their delegate assembly (Thyer & Biggerstaff, 1989). The primary purpose for this push for legal regulation was to raise the status of the profession. The National Association of Social Workers (NASW) was created in the mid-1950s with the merger of seven different social work associations and focused on seeking recognition and acceptance for the profession at a legal level in each jurisdiction. During the 1969 delegate assembly, NASW passed a resolution to pursue licensing of social workers in each state (Thyer & Biggerstaff, 1989). Today NASW continues to serve as the largest organization of social workers in the United States. Although the profession has seen a proliferation of specialty associations representing various practice aspects, NASW continues to be viewed as the primary association for the profession, producing the code of ethics which is considered a standard of conduct for social work professionals.

Social worker regulators recognized a need for a separate organization to support the burgeoning proliferation of jurisdictional regulation bodies. Although the call for regulation began within the professional associations, once implemented, the regulatory bodies and professional associations often found themselves on opposite sides of how best to regulate the social work profession. The American Association of State Social Work Boards (AASSWB) was founded in 1979 as a support mechanism for those jurisdictions with regulatory boards and to assist those considering initiating social worker regulation (ASWB, 2004). AASSWB developed the social work examination program currently in use by jurisdictions for required testing for licensure. In 1999, AASSWB was changed to the Association of Social Work Boards (ASWB) to reflect the growing number of memberships from Canadian jurisdictions (ASWB, 2004).

PROTECTING THE PRACTICE OF SOCIAL WORK

At the national level, the Association of Social Work Boards (ASWB) assists the state regulatory boards in carrying out their mandates and is responsible for the social worker licensing examination in the United States. The organization developed the Model Social Work Practice Act for state regulatory boards to use to set minimum competency and practice standards for social work practitioners and implement methods for investigating and addressing consumer complaints (ASWB, 2012). The act also includes definitions for social work practice at the bachelors, masters, and clinical levels of social work regulation. The definition of what social work is and what a social worker does is important to the protection of the profession from unqualified practitioners.

Most social worker credentialing bodies require formal education in social work with a degree from an accredited institution of higher education recognized by either the Council on Social Work Education (CSWE) or other formal accreditation body acceptable to the jurisdiction's higher education coordinating agency. Passage of the national social work licensing exam is required in almost all jurisdictions in the United States. Some have additional examination requirements, such as jurisprudence (covering jurisdictional law and rules) and cultural (covering aspects of working with specific populations). Additionally, for some levels of credentialing, qualified supervised experience may be required prior to approval to sit for the exam.

A challenge in protecting the practice of social work is found when boards grant exemptions to the required credentials for government employees or those with extensive employment experience in social services who can be "grandfathered" in, despite not meeting minimum standards. This can occur when state boards make changes or increase their standards, and it means that someone with a non-social work bachelor's degree could be licensed as a social worker solely because of previous work experience, even though the minimum educational requirement is currently a BSW. Other governmental agencies (such as child protective services and juvenile probation) have exemptions from licensing for employees, but provide services and practices typically requiring licensing in the private or nonprofit sector.

Another challenge in social work regulation is protecting the practice of social work from counseling professionals regulated by other professional boards, educational degrees, and licensing credentials, such as licensed marriage and family therapists (LMFTs), or licensed professional counselors (LPCs). Differentiating social work practice from other helping professions is paramount in defining what social workers can do and what those not regulated as social workers should not do. However, the profession has struggled with this defining activity, because social workers are educated and trained in a variety of different disciplines and therapeutic approaches, so there continues to be a murky definition of professional social work.

PROTECTING THE TITLE OF SOCIAL WORKER

Protecting the title of social worker and defining who is qualified to engage in social work service are important functions for consumer and professional protection. Defining who a social worker is appears easier than defining what a social worker does, and how that definition is displayed in credentialing can be a source of great confusion. A review of credentialing levels and acronyms for the 50 jurisdictions of the United States, 10 Canadian jurisdictions, the District of Columbia, the Virgin Islands, and Puerto Rico, reveals 42 different titles used to describe social worker credentialing (ASWB, 2013). This multilevel use of acronyms that are often interwoven with various meanings, as well as various levels of education and experience, can add a difficult dimension for both consumers and professionals in understanding the social work profession and its regulation.

The development of professional credentials begins with identifying the purpose of the enabling statute. Is the regulation intended to regulate the practice or the title of the practitioner? If the purpose of professional regulation is to ensure that only those individuals who are specifically educated, trained, and most qualified will engage in practice, then more stringent legislation is required. If the purpose is to ensure that only those meeting the highest standards of education and training are permitted to call themselves social workers but not to prevent those not specifically educated or trained in social work to engage in the practice, then legislation to protect the title is all that is required.

Social workers historically agree that those educated at a master's degree or higher and engaging in independent clinical practice need to be regulated due to the potential risk to consumers by the professional. Most jurisdictions support this philosophy by regulating the independent provision of clinical social work practice and title of clinical social worker. However, the profession remains split on the need for regulation of those at the nonclinical and bachelor's level of practice, given that much of this form of social work takes place under the auspices of an agency setting. With more individuals engaging in contract services and independent nonclinical practice, the need to monitor more individuals beyond title protection becomes important.

REGISTRATION, CERTIFICATION, AND LICENSURE

Credentialing is a part of the administrative regulatory function of government in most jurisdictions. Most licensing rules are maintained in the jurisdiction's administrative code. Regulated professionals are afforded due process, and the credential becomes a property right of the individual. The regulatory body issuing the credential may revoke it if the professional commits a violation within the jurisdiction of the regulatory body. Most professional credentialing is divided into three categories—licensing, certification, and registration. At one time, licensing and registration were considered to be government activities.

Licensing is required to participate in specific professions, whereas registration can be voluntary for those who engage in a profession whose title is protected by law. Certification can be voluntary but is not always associated with governing statutes. Certification in practice specializations, such as gerontology or chemical dependency counseling, has been established by various professional associations and organizations. Today, the terms *licensing*, *certification*, and *registration* are used almost interchangeably among jurisdictions and professions.

Licensing carries with it recognition of acceptance at the professional level and authority to practice in a profession. Licensing usually requires continuing professional education or training to maintain licensure. Certification denotes an individual who meets specific criteria

to obtain recognition. In most cases, however, once certified there are no provisions that require maintaining minimum competency, such as mandatory continuing education. Registration symbolizes that one is recognized by a regulatory body as practicing but not necessarily having met specific criteria to engage in the practice of the profession.

Case Illustration #2

Susan is a Licensed Clinical Social Worker (LCSW) who has been in social work practice since 1982. She has maintained her solo private practice after opening her practice specializing in working with children in Child Protective Service (CPS) custody preparing them for return to their family or for termination of parental rights and subsequent adoption opportunities. Prior to her LCSW status, Susan was employed as a caseworker with the CPS system for 12 years, ultimately achieving the status of supervisor. Susan holds a bachelor's degree in psychology and was grandfathered in for social worker licensing based on her work experience when regulation began in her jurisdiction in 1982. She has never had a malpractice complaint or disciplinary action taken against any of her credentials during her professional career. She has successfully maintained her professional credentials through continuing education and prompt renewal of her credentials. After retirement and relocation to a new jurisdiction with a warmer climate, Susan decides she would like to maintain a small practice with geriatric clients. She applies for licensure in her new jurisdiction, but is dismayed to discover she is not eligible based on her not holding a degree in social work.

Susan appeals the board's decision, stating her extensive professional experience, successful credentialing in her previous jurisdiction, and subsequent maintenance of the credential(s) prior to relocation. Susan presents testimony, as well as testimony from her previous clients. The regulatory body upholds the denial and encourages Susan to seek appropriate education to regain her licensure status. The body also reminds her she will need to complete all requirements, which include approved supervision and experience under an approved supervisor to be eligible for the LCSW credential. Susan decides volunteering may be how she will give of her professional expertise.

ROLES AND RESPONSIBILITIES OF THE JURISDICTION REGULATORY BODY

As noted, credentialing is a local (i.e., state) jurisdictional responsibility. The right to issue or remove a credential lies within the enabling statute and structure of the oversight body responsible for implementing and monitoring the regulatory duties. A key question concerns how the regulatory body is comprised. Does it primarily comprise political appointments? Are the appointments derived from both professionals (those regulated by the enabling statute) and nonprofessionals (those having no connection to the regulated profession)? Or is the regulatory process placed within a bureaucratic agency and duties administered by agency employees with the assistance of technical advisors knowledgeable in the profession or perhaps a formal advisory board? Regardless of the regulatory body composition, the following components will need to be resolved: minimum competency and continuing competency.

Minimum Competency

1. Education: What will the minimum level of education be for credentialed individuals? This is easier to answer once the body defines whether it is a single tier (licensing at only one level) or multi-tiered system (credentialing at multiple levels). Credentialing at multiple levels lends itself to defining levels of credentialing according to levels of education. For example, those holding a bachelor's or a master's degree qualify for specific levels of credentialing. Regulatory bodies also define whether the degree must be an accredited degree by a regional or national accrediting body or university accredited by such an accreditation body.

Most schools of social work at universities and colleges in the United States are accredited by the CSWE, and many state jurisdictions specify that degrees in social work must be accredited by CSWE to be eligible for licensure. In Canada, the Canadian Association of Schools of Social Work (CASSW) is the accreditation body. This requirement assists in ensuring public protection by establishing minimum criteria for social work education and granting of social work degrees. A recent challenge in some jurisdictions concerns allowing educational institutions associated with faith-based philosophies to be exempted from

CSWE accreditation and their graduates allowed to sit for credentialing.

2. *Testing:* The profession of social work benefits by having a nationally accepted examination. Currently, California is the only statewide jurisdiction continuing to use a specific state jurisdictional exam. ASWB contracts with the ACT Center Network to administer and maintain the security of the examination process, and exams are currently offered throughout the United States, Puerto Rico, Guam, and the District of Columbia. The local jurisdiction informs candidates which level of examination they qualify to take; although there is some variation, generally the requirements are consistent with the ASWB exam levels. Currently, there are four levels of examination offered:

- Bachelors: BSW degree from a CSWE-accredited program
- Masters: MSW degree from a CSWE-accredited program
- Clinical: MSW degree from a CSWE-accredited program, plus two years postgraduate clinical experience and approved supervision
- Advanced Generalist: MSW degree from a CSWE-accredited program, plus two years postgraduate experience (ASWB, 2013).

3. *Supervision and Experience:* Some jurisdictions require a specific amount and type of work experience to be eligible for social worker credentialing. Generally, this is expected at the advanced or clinical levels of practice credentialing or to compensate for deficits in another area of minimum competency, such as formal education. Most jurisdictions define who can supervise the professional experience that is used to seek social worker credentialing. Some jurisdictions require that the supervisor be approved prior to initiating the supervised experience and many require regular updates or reports during the supervised professional experience. Jurisdictions define the amount of supervised experience and how the supervision is to occur (individual or group session). Additionally, once the professional experience is completed, supervisors must attest to the readiness of the candidate based on the supervised experience. Supervised experience is another method of ensuring the individual possesses the knowledge, skills, and abilities for social worker credentialing.

Continued Competency and Continuing Education

Once a professional has successfully achieved the social work credential, most jurisdictions require credentialed individuals to maintain minimum competency, and most hope for increased professional competency through professional experience and additional formal and informal training. Most jurisdictions require credentialed professionals to demonstrate their continued competency through completion of continuing education hours as part of their re-credentialing process. These hours may be formally acknowledged by jurisdiction rules (i.e., approved continuing education providers) or a nationally recognized accrediting body.

Traditionally, programs offered for continuing education are for skills that enhance or reaffirm a social worker's professional knowledge, not necessarily specific to those skills necessary for the professional's current employment. Therefore, many continuing education opportunities take place outside the employment setting and at a cost to the employer or professional. Many employers attempt to offer continuing education opportunities for their employees as a benefit of employment. Some offer stipends for conference or workshop attendance if it can be demonstrated that the skills garnered will benefit the credentialed person and the employing agency. Continuing education can be earned through attendance at conferences, workshops, or online completion of self-study opportunities. Obtaining continuing education credit is one way regulatory boards can verify that a professional is at least continuing to participate in professional learning and training. Whether continuing education equates continuing competency is of great debate among social work professionals, social work educators, and regulatory board members.

CURRENT ISSUES IN SOCIAL WORKER REGULATION AND LICENSING

Portability: Endorsement versus Reciprocity

Reciprocity describes the custom by which a professional licensed in one jurisdiction is automatically licensed in a separate jurisdiction based on the issuance of the original license. Because licensing is a local function, most jurisdictions do not automatically issue a license based on

licensure in a different area. Most jurisdictions will provide acceptance of those activities used toward credentialing in a separate jurisdiction, as long as the criteria are as rigorous as those in the new jurisdiction. This process is known as *endorsement*. However, very few jurisdictions have exactly the same criteria for licensure.

A review of the Social Work Laws and Regulations Comparison Database shows that jurisdictions vary in the amount of supervised experience, hours of face-to-face supervision, whether the supervision can be in-group or individual sessions, the minimum frequency that supervision must occur, and the qualifications of the person providing the supervision that is acceptable for credentialing (ASWB, 2013). To this end, ASWB has created a concept for a model law and encourages all jurisdictions regulating social workers to consider adopting its criteria as a basis for licensure. ASWB has also begun a Social Work Registry to assist credentialed social workers in maintaining documentation related to their licensure, certification, or registration status. This is particularly helpful if a regulated professional has resided in multiple jurisdictions, achieved specialty recognition in one jurisdiction but not another, or has been employed by a federal institution. The goals of the registry are to make verification of information used toward credentialing easier to access, have one place to call for verification of professional credentials held, and have the criteria used to achieve the credentials in one location.

Recent events, such as the tragedy of September 11, 2001, and Hurricanes Katrina and Rita in 2005, have shown the need for greater portability of social workers to perform disaster relief efforts. Additional issues have arisen in the field of adoption or custody home studies when the guardian or adoptive family may live in one jurisdiction and the child or children live in a separate one. Whether the professional will be required to be credentialed in the jurisdiction where the matter is handled is not only in the hands of the court but in the authority of the enabling statutes for the regulatory boards. Though some areas grant permission for credentialed professionals to perform in their jurisdiction for a specified period of time without formal efforts to be recognized by the jurisdiction, others do not grant such leniency. As such, professionals who regularly work in multiple jurisdictions must achieve and maintain credentialing in each area they serve professionally. This creates greater confusion for

the consumer, especially when credential acronyms are jurisdiction-specific along with the complaint and disciplinary processes. Serving multiple masters, as it were, can also be daunting to the professional, because each jurisdiction may have specific idiosyncratic criteria to its regulatory functions.

Multiple Masters and Dual Credentialing

As market forces drive professionals to find niches to offer greater opportunity for success in providing services, many professionals look to multiple credentials or specialty credentials to boost their marketability. Specialized credentials, certifications, and licenses in play therapy, hypnosis, anger management, mediation, and sex offender therapy are a few examples. One issue is who authorizes and issues the credential. Credentials can be offered by a separate state-governing agency, or can also be sanctioned by a professional association, such as registered play therapist (RPT) and RPT-supervisor, issued by the Association for Play Therapy.

If under the regulation of two government-sanctioned regulatory boards, professionals may face multiple disciplinary processes that could run into large legal expenses. Additionally, because each process is independent of the other, the time frame for resolution will be independent as well. It is not uncommon for one regulatory body to issue a sanction and the other to issue a more severe sanction for the same complaint. Practitioners need to provide contact and complaint filing information to each regulatory body for all credentials they hold. Many jurisdictions require professionals to provide signed written statements from consumers regarding the receipt of this information. Also, some boards require their code of conduct, which contains information on initiating a disciplinary complaint against a regulated professional, to be displayed publicly in the professional's primary place of employment.

Licensing of Social Work Faculty

Thyer and Seidl (2000) debate whether the social work faculty teaching practice courses should be regulated social workers. One argument is that for social work educators to be most effective, they need to be connected to practice, and licensure is one option to ensure faculty maintain

current practice knowledge and technology. However, Seidl argues that there are already adequate academic accountability measures and that requiring licensure does not ensure better teaching of practice by faculty. Marson (2006) argues that licensing of social work faculty is an ethical issue. Whether it is an ethical issue or an issue of competence, regulation of faculty is an issue of public health and safety. Social work as a profession has followed a long historical path toward establishing and maintaining its existence, status, and identity as a professional field. Though much progress has been made, there are many issues left to be resolved regarding professional regulation, including the balance of public protection, professional competence and practice, and addressing the need for consistency and continuity on a national and international scale.

22 The Impaired Social Work Professional

Frederic G. Reamer

All professions are paying increased attention to the problem of *impaired* practitioners. Social work's first national acknowledgment of the problem of *impaired* practitioners was in 1979, when the National Association of Social Workers (NASW) released a public policy

statement on alcoholism and alcohol-related problems (NASW, Commission on Employment and Economic Support, 1987). By 1980, a small nationwide support group for chemically dependent practitioners, Social Workers Helping Social Workers, had formed (NASW, 1987). In 1982,

NASW established the Occupational Social Work Task Force, which was charged with developing a “consistent professional approach for distressed NASW members” (NASW, 1987, p. 7). In 1984, the NASW delegate assembly issued a resolution on impairment, and in 1987, NASW published the *Impaired Social Worker Program Resource Book*, prepared by the National Commission on Employment and Economic Support, to help practitioners design a program for *impaired* social workers. In 1996, NASW completely rewrote its Code of Ethics and included several explicit standards concerning social workers’ responsibility to address their own and colleagues’ impairment. According to the current standards (NASW, 2008):

Social workers who have direct knowledge of a social work colleague’s impairment that is due to personal problems, psychosocial distress, substance abuse, or mental health difficulties and that interferes with practice effectiveness should consult with that colleague when feasible and assist the colleague in taking remedial action. (Standard 2.09[a])

Social workers who believe that a social work colleague’s impairment interferes with practice effectiveness and that the colleague has not taken adequate steps to address the impairment should take action through appropriate channels established by employers, agencies, NASW, licensing and regulatory bodies, and other professional organizations. (Standard 2.09[b])

Social workers should not allow their own personal problems, psychosocial distress, legal problems, substance abuse, or mental health difficulties to interfere with their professional judgment and performance or to jeopardize the best interests of people for whom they have a professional responsibility. (Standard 4.05[a])

Social workers whose personal problems, psychosocial distress, legal problems, substance abuse, or mental health difficulties interfere with their professional judgment and performance should immediately seek consultation and take appropriate remedial action by seeking professional help, making adjustments in workload, terminating practice, or taking any other steps necessary to protect clients and others. (Standard 4.05[b])

Organized efforts to address *impaired* workers have their historical roots in the late 1930s and early 1940s following the emergence of Alcoholics Anonymous and the need during World War II to retain a sound work force (Reamer, 1992, 2013). These early occupational alcoholism programs eventually led, in the early

1970s, to the emergence of employee assistance programs (EAPs) designed to address a broad range of problems experienced by workers. In 1972, the Council on Mental Health of the American Medical Association released a statement that physicians have an ethical responsibility to recognize and report impairment among colleagues. In 1976, a group of attorneys recovering from alcoholism started Lawyers Concerned for Lawyers to address chemical dependence in the profession, and in 1980, a group of recovering psychologists inaugurated a similar group, Psychologists Helping Psychologists (Kilburg, Nathan, & Thoreson, 1986; Knutsen, 1977; Laliotis & Grayson, 1985; McCrady, 1989). In 1981, the American Psychological Association held its first open forum on impairment at its annual meeting (Stadler, Willing, Eberhage, & Ward, 1988).

Strategies for dealing with professionals whose work is affected by problems such as substance abuse, mental illness, and emotional stress have become more prevalent and visible. Professional associations and groups of practitioners have convened to examine impairment among colleagues and organize efforts to address the problem (Bissell & Haberman, 1984; Coombs, 2000; Katsavdakis, Gabbard, & Athey, 2004; Prochaska & Norcross, 1983; Siebert, 2004, 2005). Ironically, however, in contrast to a number of other helping professions, the social work literature contains little discussion of *impaired* professionals (Bissell, Fewell, & Jones, 1980; Fausel, 1988; Reamer, 2003, 2006, 2013; Siebert, 2004, 2005).

EXTENT OF IMPAIRMENT

Both the seriousness of social workers’ impairment and the forms it takes vary (Reamer, 1992, 2013; Siebert, 2004, 2005). Impairment may involve failure to provide competent care or violation of the profession’s ethical standards. It may take such forms as providing flawed or inferior services to a client, sexual involvement with a client, or failure to carry out one’s duties as a result of substance abuse or mental illness. Lamb et al. (1987) provided a widely cited, comprehensive definition of impairment among professionals:

Interference in professional functioning that is reflected in one or more of the following ways: (a) an

inability and/or unwillingness to acquire and integrate professional standards into one's repertoire of professional behavior; (b) an inability to acquire professional skills in order to reach an acceptable level of competency; and (c) an inability to control personal stress, psychological dysfunction, and/or excessive emotional reactions that interfere with professional functioning. (p. 598)

In one of the relatively few studies of impairment among social workers, Siebert (2004) found that 19% of North Carolina social workers reported clinically significant symptoms of depression, 16% had considered suicide at some point in their lives, 20% were taking medication for depression, and 60% self-reported depression currently or at some point in the past. In a prevalence study that included social workers and other professionals, Deutsch (1985) found that more than half her sample of social workers, psychologists, and master's-level counselors reported significant problems with depression. Nearly four-fifths (82%) reported problems with relationships, approximately one-tenth (11%) reported substance abuse problems, and 2% reported past suicide attempts.

Given the distressing absence of empirical data on social workers, it is not possible to estimate the prevalence of impairment within the profession. Therefore, social workers must look primarily to what is known about impairment in professions that are allied with social work, such as psychology and psychiatry. Of course, one cannot infer prevalence rates for social workers on the basis of data from these other professions. However, despite some important differences in their mission, methods, and organizational context, practitioners in these professions offer a number of similar services and face similar forms of occupational stress and strain (Gilroy, Carroll, & Murra, 2002; Smith & Moss, 2009; Williams, et al., 2010).

Prevalence studies conducted among psychologists suggest a significant degree of distress within that profession. For example, in their study of 425 counseling psychologists, Gilroy, Carroll, and Murra (2002) found that more than three-fifths (62%) reported symptoms of depression.

In a study of 749 psychologists, Guy, Poelstra, and Stark (1989) found that 74.3% reported "personal distress" during the previous three years, and 36.7% of this group believed that their distress decreased the quality of care they provided to clients. Pope, Tabachnick, and Keith-Spiegel

(1987) reported that 62.2% of the members of division 29 (psychotherapy) of the American Psychological Association admitted to "working when too distressed to be effective" (p. 993). In their survey of 167 licensed psychologists, Wood, Klein, Cross, Lammers, and Elliott (1985) found that nearly one-third (32.3%) reported experiencing depression or burnout to an extent that interfered with their work. They also found that a significant portion of their sample reported being aware of colleagues whose work was seriously affected by drug or alcohol use, sexual overtures toward clients, or depression and burnout.

In a comprehensive review of a series of empirical studies focused specifically on sexual contact between therapists and clients, Pope (1988) concluded that the aggregate average of reported sexual contact is 8.3% by male therapists and 1.7% by female therapists. Pope reported that one study (Gechtman & Bouhoutsos, 1985) found that 3.8% of male social workers admitted to sexual contact with clients.

CAUSES OF IMPAIRMENT

Several studies report a variety of forms and sources of impairment among mental health professionals (Celenza, 2007; Gabriel, 2005; Zur, 2007). Katsavdakakis, Gabbard, and Athey (2004) found that the three most commonly cited problems leading psychiatrists, other physicians, psychologists, and social workers to seek help were suicidal behavior, marital problems, and work-related problems. Guy et al. (1989) and Thoreson, Miller, and Krauskopf (1989) found diverse sources of reported stress in clinicians' lives, including their jobs, the illness or death of relatives, marital or relationship problems, financial problems, midlife crises, personal physical or mental illness, legal problems, and substance abuse.

Lamb et al. (1987) argued that professional education itself can produce unique forms of stress and impairment, primarily as a result of the close clinical supervision to which students are typically subjected, the disruption in their personal lives often caused by the demands of schoolwork and internships, and the pressures placed on them by academic programs. These authors found that the most common sources of impairment are personality disorders, depression and other emotional problems, marital problems, and physical illness.

This review of research suggests that distress among clinicians generally falls into two categories: environmental stress, which is a function of employment conditions (actual working conditions and the broader culture's lack of support of the human services mission) or professional training, and personal stress, caused by problems with one's marriage, relationships, emotional and physical health, and finances. With respect to psychotherapists in particular, Wood et al. (1985) noted that professionals encounter special problems from the extension of their therapeutic role into the nonwork aspects of their lives (such as relationships with friends and family members), the absence of reciprocity in relationships with clients (therapists are "always giving"), the frequently slow and erratic nature of the therapeutic process, and personal issues that are raised as a result of their work with clients (Kilburg, Kaslow, & VandenBos, 1988; Mahoney, 1997).

RESPONSE TO IMPAIRMENT

Little is known about the extent to which *impaired* professionals voluntarily seek help for their problems (Gutheil & Brodsky, 2008; Olsheski & Leech, 1996; Smith & Moss, 2009). In one of the few empirical studies, Guy et al. (1989) found that 70% of the distressed clinical psychologists they surveyed sought some form of therapeutic assistance. Approximately one-fourth (26.6%) entered individual psychotherapy, while 10.7% entered family therapy. A small portion of this group participated in self-help groups (3.4%) or was hospitalized (2.2%). Some were placed on medication (4.1%). Exactly 10% of this group temporarily suspended their professional practice.

These findings contrast with those of Wood et al. (1985), who found that only 55.2% of clinicians who reported problems that interfered with their work (substance abuse, sexual overtures toward clients, depression, and burnout) sought help. Approximately two-fifths (42%) of all the clinicians surveyed by Wood and colleagues, including *impaired* and nonimpaired professionals, reported having offered help to *impaired* colleagues at some time or having referred them to therapists. Only 7.9% of the sample indicated that they had reported an *impaired* colleague to a local regulatory body. Two-fifths (40.2%) were aware of instances in which they believed no action was taken to help an impaired colleague.

Several phenomena may explain *impaired* professionals' reluctance to seek help and the reluctance of their colleagues to confront them about their problems. Historically, professionals have been hesitant to acknowledge impairment within their ranks because they feared how practitioners would react to confrontation and how such confrontation might affect the future relationships of colleagues who must work together (Bernard & Jara, 1986; Coombs, 2000; McCrady, 1989; Wood et al., 1985). Thoreson, Nathan, Skorina, and Kilburg (1983) also argued that *impaired* professionals sometimes find it difficult to seek help because of their mythological belief in their nearly infinite power and invulnerability. The fact that an increasing number of psychotherapists are involved in private practice exacerbates the problem because of the reduced opportunity for colleagues to observe any unethical or inept practice.

In a valuable study by Deutsch (1985), a diverse group of therapists (including social workers) who admitted to personal problems indicated a variety of reasons for not seeking professional help, including the following: they believed that an acceptable therapist was not available, they sought help from family members or friends, they feared exposure and the disclosure of confidential information, they were concerned about the amount of effort required and the cost, they had a spouse or partner who was unwilling to participate in treatment, they failed to admit the seriousness of the problem, they believed they should be able to work their problems out themselves, and they believed that therapy would not help.

Several organized efforts have been made to identify and address the problems of *impaired* professionals. There is a growing consensus that a model strategy should include several components (Schoener & Gonsiorek, 1988; Smith & Moss, 2009; Sonnenstuhl, 1989). First, there must be adequate means for identifying *impaired* practitioners. Professionals must be willing to assume some responsibility for acknowledging impairment among colleagues. Second, a social worker's initial identification and documentation of a colleague's impairment should be followed by speculation about the possible causes and by what Sonnenstuhl (1989) described as "constructive confrontation." Third, once a social worker decides who shall carry out the confrontation, a decision must be made about whether to help the *impaired* colleague identify ways to seek help

voluntarily or to refer the colleague to a supervisor, professional association, or local regulatory body (such as a NASW ethics committee or a licensing board). Assuming there are sufficient reasons to support a rehabilitation plan, the *impaired* practitioner's colleague, supervisor, or local regulatory body should make specific recommendations. The possibilities include close supervision, personal psychotherapy, and treatment for substance abuse. In some cases, it may be necessary for a licensing board or ethics committee to impose some type of sanction, such as censure, limitations on the professional's social work practice (for example, concerning clientele that can be served), termination of employment, suspension or expulsion from a professional association, or loss of license.

Unfortunately, relatively little research has been conducted on the effectiveness of efforts to rehabilitate *impaired* professionals (Fletcher & Ronis, 2005; Sonnenstuhl, 1989; Trice & Beyer, 1984). Moreover, the few published empirical evaluations—which reported mixed results for various treatment programs—focused primarily on impaired physicians (Herrington, Benzer, Jacobson, & Hawkins, 1982; Katsavdakis et al., 2004; Morse, Martin, Swenson, & Niven, 1984; Pearson, 1982; Shore, 1982).

AN AGENDA FOR SOCIAL WORK

For a profession to be truly self-regulating, it cannot rely entirely on the efforts of dissatisfied or abused clients to file complaints about *impaired* practitioners. The profession must strengthen its efforts to identify *impaired* practitioners and respond to them in a meaningful way. Social workers, like many other professionals, understandably may be reluctant to confront *impaired* colleagues. Nonetheless, it is incumbent on the profession to confront incompetence and unethical behavior and offer humane assistance. Attention should be paid to social workers in solo private practice as well as those who work in group settings, where there may be more opportunity to observe impairment.

Social workers must expand education about the problem of *impaired* practitioners. Relatively few social workers have been trained to identify and confront impairment. The profession's organizations and agencies must sponsor workshops and in-service training on the subject to acquaint social workers with information about the forms

that impairment can take, the signs to look for, and ways to confront the problem.

In addition, social workers should develop collegial-assistance programs to assist *impaired* social workers. Although some cases of impairment must be dealt with through formal adjudication mechanisms (for example, conducted by NASW ethics committees or licensing boards), many cases can be handled primarily by arranging therapeutic or rehabilitative services for distressed practitioners. *Impaired* social workers should have access to competent service providers who are trained to understand professionals' special concerns and needs. For instance, state chapters of NASW can enter into agreements with local EAPs, to which *impaired* members can be referred.

Social workers have a keen understanding of human struggle and impairment. The profession has a tradition of addressing the problems of individuals, along with the environmental stresses that surround them. The same tradition must be extended to *impaired* colleagues.

23 Technology and Social Work Practice *Micro, Mezzo, and Macro Applications*

Jonathan B. Singer & Melanie Sage

Social workers have an ethical responsibility to attend to the environmental forces that create, contribute to, and address problems in living (National Association of Social Workers [NASW], 1999). Developments in Internet and computer technologies (ICT) such as social networks, webcams, texting, virtual reality, and smart phone apps, have significantly changed the way we communicate with one another and interact with our environment (Mishna, Bogo, Root, Sawyer, & Khoury-Kassabri, 2012). Consider the following: Most Americans now get their health-related information from the Internet, instead of from friends, family, and health professionals as

they did a decade ago (Fox & Duggan, 2013). In 2012, nearly a third of Americans reported trying to diagnose themselves or someone else using *only* information found on the Internet (Fox & Duggan, 2013). As people combine new ways of communicating with new ways of seeking health-related information, there has been a natural evolution toward new ways of providing social work services. Just as the Internet evolved from a collection of static Web pages (Web 1.0) to a virtual community called Web 2.0 (O'Reilly, 2005), the integration of social work with ICTs has created a new paradigm for social work, called *Social Work 2.0* (Singer, 2009).

The National Association of Social Workers (NASW) and the Association of Social Work Boards (ASWB) recognize technology as a significant environmental force and have published 16 standards for technology in social work, covering clinical practice, administration, advocacy and community organizing, and research (NASW, 2005). Although these standards provide a foundation for Social Work 2.0, the integration of ICTs and social work services has been limited by micro factors such as the fact that traditional consumers of social work services are the least likely to have access to ICTs (Fox & Duggan, 2013) as well as macro factors such as limited funding for current technology, and training in its possible uses (Wodarski & Frimpong, 2013). The purpose of this chapter is to review existing literature on technology and social services; identify and define key terms and concepts; and describe uses, benefits, and limitations of technology and social service delivery at the micro (clinical practice), mezzo (community practice), and macro (policy) levels. The goal is to promote dialogue and discussion about the role of current and emerging technology in social service delivery.

KEY CONCEPTS

The 15 most important Social Work 2.0 concepts are defined and illustrated in Table 23.1. Some concepts, such as online therapy, e-therapy and telehealth, have overlapping yet distinct meanings (McCarty & Clancy, 2002). For simplicity, the term “online therapy” is used when referring to any mental health service that is provided using ICTs.

USES, BENEFITS, AND LIMITATIONS OF TECHNOLOGY IN SERVICE DELIVERY

The uses, benefits, and limitations of technology in the micro, mezzo, and macro areas of clinical practice, community organizing, and policy issues have been addressed by a number of authors (Barak & Grohol, 2011; Dowling & Rickwood, 2013; Kanani & Regehr, 2003; Mishna et al., 2012; Perron, Taylor, Glass, & Margerum-Leys, 2010; Richards & Viganó, 2013; Singer, 2009; Slone, Reese, & McClellan, 2012; Wodarski & Frimpong, 2013). Whereas the clinical literature is written mostly by psychologists and counselors, with some notable contributions by social

workers (Freddolino & Blaschke, 2008; Langlois, 2011), social workers have contributed extensively to the community organizing and policy literature and have addressed issues such as how to use technology for advocacy of social action (Hick & McNutt, 2002; J. Young, 2012) and how online mental health services are regulated and reimbursed (Reamer, 2013a).

ONLINE MENTAL HEALTH

Since the publication of the previous version of this chapter (Singer, 2009), scholars have written over 500 articles about online mental health services. Meta-analyses and comprehensive reviews of those studies suggest that online mental health services are effective in reducing symptomatology and that they increase functioning for some mental health disorders (e.g., depression, anxiety, eating disorders, posttraumatic stress disorder [PTSD], and substance use disorders), but not for others, such as weight loss (Barak, Hen, Boniel-Nissim, & Shapira, 2008). This body of research has found no significant difference in outcomes between synchronous (e.g., live webcam) and asynchronous (e.g., e-mail) online therapy. While it is possible that certain online environments are better suited for certain problem areas (e.g., virtual reality for treating PTSD or phobias, and text-based reminders for medication compliance), that remains a question for empirical investigation (Pallavicini et al., 2013). Finally, and perhaps most importantly, research comparing face-to-face (F2F) therapies to online therapies has consistently found that client outcomes in online therapy are as good (Barak et al., 2008; Beatty & Lambert, 2013; Champion, Newton, Barrett, & Teesson, 2013; Dowling & Rickwood, 2013; Richards & Viganó, 2013; Slone et al., 2012), and in some cases better (Birgit, Horn, & Andreas, 2013) than F2F therapies.

Research on online and F2F therapies share many similarities: most research is on individual therapy, although interventions exist for couples (Doss, Benson, Georgia, & Christensen, 2013) and groups (van der Zanden, Kramer, Gerrits, & Cuijpers, 2012); most consumers of online mental health services are women; and most empirical studies use cognitive-behavioral and behavioral approaches (Barak et al., 2008). According to a 2008 meta-analysis, the most effective online treatment interventions were

TABLE 23.1 Definitions and Examples of Technology Terms

Term	Definition	Example of Use
Asynchronous communication	Delayed communication; does not occur in real time	Correspondence via letters or e-mail
Chat/messaging	Synchronous web-based communication	Crisis hotline provides real-time text-based services using a program that loads into a browser, allowing the worker and client to communicate instantly
E-supervision	Supervision using e-mail, chat, phone, or webcams—anything but traditional face-to-face supervision	Four clinicians from different states dial in to the same telesupervision group
Online therapy (synonymous with e-, cyber-, e-mail, or chat therapy)	Therapy using technologies, rather than traditional face-to-face services	Client and therapist conduct therapy over e-mail, chat, webcam, or a virtual-world-like Second Life
GIS (Geographical Information Systems)	Computer software that allows social workers to map services and identify where service needs exist	Crisis worker at a nationwide crisis hotline locates local referrals for a suicidal client using GIS software
mHealth	Health care delivered on mobile communication devices such as mobile phones smartphones, and tablets.	Client downloads an app that reminds her to take her medicine, prompts her to rate her mood, and uses the built-in GPS to trigger an alarm when she enters a bar.
Podcast/vodcast	Subscription-based downloadable audio/video files	Client downloads and listens to an audio file created by the therapist on a clinically relevant topic (e.g., relaxation training)
Second Life	An Internet-based virtual world where people can interact with each other and communicate via chat or voice	Services, such as a rape-crisis shelter, are developed and accessed by members of the virtual community
Social Work 2.0	The integration of computer and Internet technologies with traditional social work	Service plans include relevant technology in service provision and goal attainment
Synchronous communication	Communication that occurs in real time	Traditional face-to-face social work, such as a therapy session; e-therapy using real time technology (e.g., chat)
Telehealth	The use of communication technology to provide services to remote locations	Social worker in a rural area uses the phone for assessment and diagnosis
Microblog/micropost	Short posts (usually less than 160 characters) intended to be distributed to “followers.”	Stakeholders use Twitter and Facebook to disseminate information and organize “calls to action.”
VoIP (voice over Internet protocol)	The routing of voice conversations over the Internet	Client uses VoIP to make free phone therapy appointments
Webinar	Internet-based seminar that allows for synchronous communication between people in remote locations and the presenter	Three social workers in different states give an interactive continuing education presentation to social workers from all over the world
Web 2.0	A conception of the Internet as an interactive medium	Consumers and staff co-create the information on an agency Web site using a wiki

cognitive behavioral therapies (CBTs), followed by psycho-educational and behavioral therapies (Barak et al., 2008). Online treatments using narrative therapy or psychodynamic approaches have received a great deal of conceptual attention because of their use of text (narrative) and self-reflection/insight (psychodynamic) (Balick, 2012; Migone, 2013), but have rarely been used in empirical studies (Andersson et al., 2012).

There are a number of notable limitations to online therapy and its existing evidence base. Although online therapies have been evaluated with people of all ages, there is some evidence to suggest that older adults and older therapists are less likely to trust online mental health services (Dowling & Rickwood, 2013; Miller & Bell, 2012). Although this might lend some support to the notion that online therapy is better suited for people who grew up with ICTs (e.g., “digital natives”) than for people who did not (e.g., “digital immigrants”) (Prensky, 2001), there has been no research to support the notion that online therapy is inherently more effective or feasible with younger versus older adults. There are problem areas for which no online treatments have been developed or tested (e.g., online family therapy); problem areas with only a single study (e.g., gambling addiction) (Gainsbury & Blaszczynski, 2011); and problem areas with conflicting evidence (e.g., the evidence for the efficacy of computerized CBT for depression; cf., Andrews, Cuijpers, Craske, McEvoy, & Titov, 2010; So et al., 2013). Even with problem areas for which there is evidence of efficacy, online therapies are susceptible to becoming irrelevant because of the rapid changes in technologies that are being evaluated and used in practice. Finally, in part because of the recency of online therapy, the long-term effectiveness of most online treatments has yet to be established (Dowling & Rickwood, 2013; So et al., 2013).

Types of Online Mental Health Services

Barak and Grohol suggest four distinct categories for online mental health services: (1) online counseling and psychotherapy; (2) online support groups and blogs; (3) interactive, self-guided interventions; and (4) psycho-educational websites (Barak & Grohol, 2011). These categories vary in function, evidence-base, and degree of interpersonal interaction (most = online therapy, least = psycho-educational websites).

1. *Online counseling and psychotherapy* is the provision of mental health services by a mental health professional using ICTs. Online therapy can occur in real time (synchronously) using a webcam, via virtual reality (VR) environment, chat, or other technology; or in delayed time (asynchronously) using e-mail, texting, or video responses. Providers and consumers of online therapy consistently report that one of the most important reasons to use online therapy is “convenience” (K. S. Young, 2005). For providers, it minimizes or eliminates travel time to, and overhead costs for, office space. For consumers, online therapy can reduce structural barriers to treatment, such as transportation and access to providers (McCoyd & Kerson, 2006). For example, people who travel for business, such as truck drivers, or people who stay at work sites for extended periods of time, such as oil rig crew operators or active military, can access mental health services using VoIP programs like Skype, webcams, or even texting. In theory, clients have greater choice of therapists (e.g., characteristics, education), mode of therapy (e.g., chat, webcam), length of session, and time of day. Unlike F2F therapy, clients and providers increasingly have 24/7 online access. Consequently, online therapists are encouraged to establish boundaries regarding frequency and duration of online communications (Kanani & Regehr, 2003; Kolmes, 2010).

Online mental health providers range from those who provide online therapy exclusively (e.g., <http://onlinetherapyinstitute.com/>) to therapists who provide mostly F2F services, but use ICTs to provide services to one or two clients. Social workers who use technology such as e-mail or texting to confirm therapy appointments are not providing online therapy (Mishna et al., 2012). Providers of online mental health services must be aware of security concerns, HIPPA regulations, and other ethical and legal issues that arise when providing therapy online (see Reamer, 2013b for a comprehensive review). Therefore, many providers pay secure, HIPPA-compliant third party online therapy sites to host their online sessions, or join a network of online therapy providers (www.telementalhealthcomparisons.com). One of the earliest selling points of online therapy was that clients could be anonymous and anywhere in the world (Schopler, Abell, & Galinsky, 1998). Today, however, nearly all professional associations (e.g., NASW, APA) recommend verification of identity and emergency contact information prior to providing services. Some third-party sites require

clients to verify their identity prior to connecting them with a provider. Some therapists require at least one F2F meeting for clients who wish to meet online in order to verify the client's identity, get signatures (consent forms, treatment plan), and begin establishing a therapeutic alliance.

How Online Therapy Works: Clients register at the therapist's website with a user name and password, supply a working e-mail address, and perhaps read descriptions of participating therapists. Once the account has been verified, clients can book sessions through an online calendar and decide which type of online therapy they would like: e-mail, chat, phone (either traditional land line or Voice over Internet Protocol [VoIP]), or VR. Third-party therapy sites provide clients with verification of provider credentials, articles on treatment issues, professionally vetted links, and personalized logins where clients can access individualized content such as crisis plans and client-specific podcasts. These sites provide therapists with secure technology, HIPPA-compliant storage of documents, scheduling services, payment management, and confidential modes of communication. McCarty and Clancy (2002) suggested that the most important contribution of online therapy is in revolutionizing recordkeeping. Whereas traditional records (paper or electronic) are essentially a one-sided account of treatment, therapy conducted over e-mail, chat, and even text messaging creates a complete record of communication between client and clinician. Video therapy can be recorded and reviewed by clients either during session or in-between sessions. With either text or video, clients and clinicians can review past sessions to identify treatment progress and clinicians can use the transcripts in consultation. Currently there is no state licensing board that allows social workers to practice across state lines. As a result, clients need to be in-state in order to benefit from the protections afforded by the licensing board. Although getting licensed in all 50 states is impractical, therapists who live near state lines have the option of getting licensed in two states. Some therapists whose in-state clients are hours away develop treatment contracts and/or safety plans that include a local therapist who will be on-call for crises or any time a F2F therapy session is needed. However, given the long history of phone-based crisis intervention services, and more recently chat-based "hotlines," some argue that face-to-face services are not required, even for life and death situations (Barak, 2007).

2. *Online support groups and blogs.* "Online support groups" refers to peer-facilitated mutual aid groups where members meet online either using text-based ICTs such as chat, VR environments such as Second Life, or in webcam-mediated F2F settings with programs like Google Hangouts. Some research has found online support to be as effective in addressing mental health problems as psycho-educational websites and self-guided treatments (Freeman, Barker, & Pistrang, 2008; Griffiths et al., 2012). As with online therapy, the benefits of online support groups are similar to those of offline support groups. Participation leads to an increased sense of self-mastery, satisfaction, and well-being (van Uden-Kraan, Drossaert, Taal, Seydel, & van de Laar, 2009). The benefit of participation increases with interaction (Yalom, 2005). The absence of a professional means that group members can share potentially dangerous or damaging misinformation that will go unchecked. The one type of group that appears to be unique in the online environment are groups that explicitly encourage self-harm, such as "pro-suicide" and "pro-anorexia" groups.

Blogs are written by consumers or providers of mental health services. Bloggers gain social benefits through feedback from people who regularly follow the blog and provide feedback via comments. For consumers, this online community can counteract feelings of isolation, shame, or stigma associated with a mental illness. The act of writing a blog can itself be therapeutic (Pennebaker, J. W. & Chung, C. K., 2011). Therapist blogs can offer insights into the experience of providing mental health services, as well as create resources similar to psycho-education sites for consumers. Ironically, one benefit of blogging for consumers—interaction with other consumers—can become a liability for providers. For instance, if a client follows his therapist's blog or Twitter account and posts a publicly visible comment identifying himself as a client, he has breached his own confidentiality. If that client posts confidential or time-sensitive information, such as thoughts of suicide, with the intention that the provider will respond immediately, it puts the provider in a potentially liable situation if he or she does not. Online therapists are discouraged from engaging with clients in public forums like blogs, Facebook, Twitter, Pinterest, and Tumblr. Dr. Keely Kolmes, a psychotherapist in San Francisco, has developed a social media policy that clarifies her use of technology and social media and sets expectations for clients (Kolmes, 2010).

3. *Interactive, self-guided interventions.* These are typically computer-based, web or mobile app cognitive-behavioral interventions that are intended to be self-paced and self-directed. Although these programs are intended to be used without a therapist, they can be stand-alone or used as an adjunct to other mental health services including online or offline therapy (Carper, McHugh, & Barlow, 2011). They range in complexity from low (e.g., static modules that are offered to every user in the same order) to high (e.g., personalized programs that vary based on users' responses to baseline intake and are continuously modified based on user input).

The best-researched self-guided programs are computerized cognitive behavioral therapy (CCBT) programs, such as MoodGYM (Griffiths, Farrer, & Christensen, 2010; Lintvedt et al., 2013). These programs have been shown to be as effective at reducing depression and anxiety symptoms for people who complete the program as F2F therapy (Griffiths et al., 2010). Although they have been criticized for their high drop-out rates (So et al., 2013), some have argued that the completion rates for self-guided therapy are no lower than for F2F therapy (Andrews et al., 2010). Self-guided therapy programs have been consistently lauded for being cost-effective (Lintvedt et al., 2013; Powell et al., 2013); unlike F2F therapy, self-guided computer-based programs are often free to the user, cost very little to the provider (after recouping the cost of development and hosting), and are easily scaled so that one or one million people could use the program. Proponents of self-guided programs have long argued that the low cost and scalability of the programs could result in widespread adoption of psychotherapy (Bell, 2007). This proposition was recently tested by Powell et al. with the program MoodGYM (Powell et al., 2013). Although MoodGYM was developed to reduce anxiety and depression symptoms, it was hypothesized that the therapy modules would improve the mental health of those without anxiety or depression. Powell et al. recruited members of the general public to complete the modules in MoodGYM. After controlling for baseline depression and anxiety, they found that participants reported an overall improvement in well-being. This study provided the first evidence that computerized self-guided therapies could be used to improve well-being in the general population, and not just within a clinical population (Powell et al., 2013).

Interactive and self-guided interventions are increasingly being delivered over apps designed for mobile devices (e.g., mobile phones, smartphones, and tablets) (Proudfoot, 2013). The delivery of health and mental health services using mobile devices, called mHealth, has a number of advantages over other ICT-based interventions: Mobile devices travel with the client; they can be programmed to send alerts to take medication, call for an appointment, take a deep breath, or record an emotion or thought; or to deliver interventions at set times. GPS-enabled mobile devices can track exercise, or sound an alert when a person is in a pre-established "no-go-zone" such as a bar or casino. Despite their promise, apps are in their infancy, and the most capable developers (e.g., programmers) are not usually the content experts that consumers, providers, or health service organizations would be (HSOs) (Aguirre, McCoy, & Roan, 2013). Apps developed by social workers typically target other social workers, such as the ethics app, *Social Work Social Media* (Cooner, 2013).

4. *Psycho-educational websites* are online sources of information. They are analogous to offline bibliotherapy in that the purpose is to provide information, rather than contact with mental health professionals or personalized referrals. The value of websites has increased as people's access to the Internet through smartphones and tablets has increased. Examples include the *National Institute of Mental Health* (<http://www.nimh.nih.gov>), *Substance Abuse & Mental Health Services Administration* (<http://samhsa.gov/>), and *WebMD* (<http://www.webmd.com/>). Psycho-educational websites are only as good as the information they provide. Providers and consumers should evaluate web resources based on the *authority*, *accuracy*, and *objectivity* of the information (e.g., one person's opinion vs. results of a large-scale study), the comprehensiveness of the *coverage* and whether or not the site meets its stated purpose for its intended audience, how *current* the information is, and whether or not the *design* makes it easier or harder to find information on multiple platforms. Finally, consumers should know that even though they cannot find information on the Internet about a certain topic does not mean that there is no information available.

In sum, online mental health services have a growing evidence base for delivering a variety

of interventions to a variety of consumers using ICTs, including those who were traditionally excluded from treatment based on geographical or other barriers. Advances in self-directed interventions and mHealth point to a future when social workers are no longer providing some mental health and linkage functions. For example, Facebook and the iPhone are programmed to recognize when users make suicidal statements and refer them to the National Suicide Prevention Lifeline or local crisis centers. There continue to be significant limitations to ICTs in social work practice. ICTs do not bridge the “digital divide” by themselves. The benefits of online therapy cannot be realized by those who lack access to technology, the technical skills to participate in therapy online, or the financial resources to pay out of pocket (unlike F2F therapy, online therapy is not covered by insurance). These barriers can be considered economic, social, and electronic justice issues. Therefore, social workers have a professional responsibility to address the mezzo- and macro-level barriers to accessing and using ICT-based services, as well as using technology in mezzo- and macro-level practice and advocacy.

COMMUNITY ORGANIZING

Social work’s community organizing roots emerged in the late 19th century, in part as a response to social problems that developed out of technological advances brought on by the industrial revolution. For much of the 20th century, social workers struggled with the ways that vulnerable and marginalized groups were adversely affected by technology (Hick & McNutt, 2002). In the 21st century, some problems, such as bullying and sex trafficking, have shifted from occurring primarily on the ground to primarily online. For some, lack of access to technology has itself become a social problem. For instance, those with access to Internet-connected computers have educational advantages related to information access, can enhance their marketable computer skills, and are better able to find and apply for jobs online than people without Internet access (Araque et al., 2013). And yet, between 25% and 50% of adults without high school degrees, older adults, and those who identify as a racial/ethnic minority do not have online access (Purcell, Brenner, & Rainie, 2012). Organizing efforts that do not acknowledge or address this “digital divide” may exclude the very groups that would

most benefit from participation in advocacy efforts. And somewhat paradoxically, ICTs in the 21st century have made it possible for people who previously were marginalized because of age, geographical distance, physical or economic limitations, or social stigma, or a combination of all of these, to communicate and organize through virtual communities. Although the early days of the Internet included closed communities (e.g., CompuServ and AOL) and attempts at recreating physical communities online (e.g., Geocities.com), advances in virtual reality and 24/7 access to the Internet via smartphones and tablets has resulted in the creation of truly virtual communities with no offline counterparts. In these early days of the 21st century, social workers have to negotiate a paradox: the very technologies that marginalize and disenfranchise groups can also be used to ameliorate social problems.

In the 21st century social workers need to organize both physical and virtual communities. Technological tools that support community organizing and social work advocacy fall into two primary categories: (1) tools that mediate communication and message delivery, such as e-mail, listservs, social networks (e.g., Twitter, Facebook), and blogs; and (2) tools for data collection and visualization, such as GIS, donor management software, and automated subscription-based alert systems. Community organizers were early adopters of ICTs that mediated communication such as e-mail and listservs. These text-based technologies were inexpensive ways for organizers to communicate with and mobilize key stakeholders. The adoption of high-speed Internet and free video conferencing (via Google Hangouts or FreeVideoConference.com) simplifies and popularizes synchronous webcam-mediated F2F gatherings. Newer ICTs such as Twitter and Facebook combine text with images and videos, can be used synchronously or asynchronously, and, similar to self-guided therapy, have decreased the need for organizing efforts to be facilitated by a trained professional. The Occupy movement and the Arab Spring are examples of social movements that used Twitter and Facebook and were “marked by the absence of a clearly identified leader, a political party or figure, an association, or an organizing capacity” (Marzouki & Oullier, 2012).

Although online tools hold promise for organizing, they are often underutilized by nonprofits, especially in the realm of advocacy (Edwards & Hoefer, 2010). Despite the growing number of

nonprofits that use social media sites, there continues to be a gap between available ICTs and the knowledge and skills necessary to use them to engage stakeholders effectively (J. Young, 2012). Organizers should have a clear goal in mind when adopting a new technology, and consider utilizing multiple strategies (Dunlop & Fawcett, 2008). Social workers who want to increase their proficiency for online community organizing may join online groups such as COMM-ORG (comm-org.wisc.edu/), which offers numerous links to other community organizing resources.

The following is an example of how various ICTs can be used in concert to educate and mobilize key stakeholders around the issue of housing discrimination for same-sex couples:

- A social worker in North Dakota could (1) leverage face-to-face chats in Google Hangouts to organize stakeholders across the state who are interested in housing discrimination issues that affect same-sex couples; (2) use a Facebook group to collect comments about a related nondiscrimination policy proposal and to announce a public hearing; (3) start a statewide nondiscrimination petition on causes.com; and (4) direct people to tweetcongress.org, where they can tweet messages to their elected local representatives to advocate for a policy that bans housing discrimination based on sexual orientation.

Other examples of ICTs in community organizing and advocacy include:

- Geographical Information Systems (GIS) technologies can be used to analyze information about specific geographical regions, such as neighborhoods, zip codes, cities, or counties. Advocacy groups can analyze campaign demographics to improve voter participation on key social service issues. GIS can be used by consumer rights advocates to identify areas of need to improve service delivery.
- A number of websites allow nonprofits to meet a number of community organizing needs, including fundraising, volunteer recruitment, and legislative tracking, as well as collecting signatures, and conducting outreach. For example, anyone can start a petition or fundraising campaign on the

website causes.com, and the site cqrollcall.com offers a paid service by which users can add legislative tracking to their websites.

- E-mail lists and social network sites are low-cost ways of distributing action alerts (e.g., “call your representative now!”), and targeted social media campaigns can be designed specifically to recruit certain disenfranchised groups (Vyas, Landry, Schnider, Rojas, & Wood, 2012). Social media users have higher levels of political participation and civic engagement (Valenzuela, Park, & Kee, 2009); thus, social media can be an ideal facilitator of collective action, political mobilization, and community building (Obar, Zube, & Lampe, 2011). Although a primary reason nonprofits begin using social media is to engage their current audiences (J. Young, 2012), websites like Facebook, YouTube, and Twitter make it easy and economical for agencies to develop an Internet presence, facilitate communication with new and existing stakeholders, and share information about their specific causes (Edwards & Hoefler, 2010).
- Online discussion lists, websites, and blogs, as well as issues-oriented and social change websites can organize people in one neighborhood or from around the world on a specific issue. For issues such as suicide, which has a relatively low base rate (12 per 100,000) and stigma-related silence, geography and social stigma have made it difficult to organize people to promote change. However, the Internet has made it possible for the friends, family, and loved ones of the nearly 38,000 people annually who die by suicide to come together as a community (Mohatt et al., 2013). For example, in July 2013 the advocacy work of American Foundation for Suicide Prevention (AFSP) (afsp.org) provided instrumental support for expanding a bill in the Senate Labor, Health, and Human Services Committee, including a \$15 million budget increase for the National Violent Death Reporting system, which will provide more timely information about national suicide statistics. AFSP used its website to send legislative alerts, raise awareness among politicians, and encourage constituents to call their representatives. They provide tips on what to say when speaking to public officials about suicide.

POLICY ISSUES

Agency Policy

Agency-level policy may inform a social worker's participation in social media and online forums. Although many agencies lack specific social media policy (J. Young, 2012), agency employees who communicate via social media from home or work should understand company policies related to social media use. Additionally, they should know how they can represent their associations with their employers, understand the relative permanence of online postings, and consider how their public online identity might influence their interactions with consumers (Kimball & Kim, 2013). Although it is illegal for employers to limit an employee's private participation in workforce organizing online, online posts that broach professional ethics are not protected (Halpern & Gardner, 2012). Social workers who are government employees should also understand that the technology used at their agency, including web-browsing and e-mail, may be monitored by the agency or subject to public disclosure through freedom of information regulations (Dawes, 2010).

Social workers may be asked to help draft their agency's e-therapy or social media policy. Policy should educate workers, be realistic about the significance of the Internet and social media in the lives of social workers, be specific with examples of justifications and prohibitions for use, include consequences of policy violation, and consider the impacts of social media use, negative and positive, on clients (Reamer, 2013).

Licensing and Regulation of Online Therapy

As with other professions such as law, medicine, and nursing, licensing and regulation of social work occurs at the state level. Online therapy has no geographic boundaries and thus creates complex regulatory issues. For example, if a client resides in Idaho and a therapist works in Georgia and they meet online for therapy, in which state are they conducting therapy? Is the therapist going to the client or is the client coming to the therapist? Which state's consumer protections apply? These questions have yet to be settled by either regulatory or legal precedent. Although groups such as the American Telemedicine Association (ATA) are working toward best practices for telemedicine delivery

across professional disciplines (americantelemed.org), and some state licensing boards offer policy guidance on Internet-mediated practice (Reamer, 2013b) unless explicitly allowed by your state's licensing regulations, interstate online therapy is a violation of your licensure.

Liability and Malpractice in Online Therapy

Social workers are increasingly seen as the primary providers of mental health services and consequently are named in more malpractice lawsuits than ever before. The largest provider of malpractice insurance for social workers, NASW Assurance Services, reports that liability coverage is offered worldwide for services including online therapy unless social workers provide services for which they are not licensed (e.g., practicing social work across state lines) (naswassurance.org). They offer specific caution about the importance of protecting client confidentiality. The onus of responsibility lies with social workers to understand the limits of state licensure. Case law suggests that a professional relationship can be established by responding to an e-mail. Reamer (2013b) notes that social workers are obligated morally and ethically to be familiar with the available research regarding the efficacy of online therapy and be proficient in the use of technology needed to carry out practice; practicing outside of one's scope is an ethical and liability concern. Informed consent requires that consumers are informed of the evidence available to support a course of treatment, and of the provider's qualifications and trainings in the proposed modality. Social work programs only started offering social work and technology courses in 2013 (UB Reporter, 2013). One approach to developing competency in online therapy is for clinicians to use technology in clinical supervision to both increase their comfort level and to receive consultation on online therapy issues (Singer, 2009).

Confidentiality, Security, and Informed Consent

There is currently no case law that clarifies the confidentiality of e-mails, webcam images, or text messages. However, online therapy is bound by specific HIPAA rules that address confidentiality and the security of electronic transmissions (Eack, Singer & Greeno, 2008), and the storage of

any personal health information and telehealth communications. Regulations regarding patient protection mandate the use of privacy safeguards including encryption, security passwords, and intrusion detection software (Scholl et al., 2008). Some states require specific language and signed consents for telemedicine activities (Baker & Bufka, 2011). Social workers should have clear policies related to the storage of online documentation (recordings, chats, e-mails, and records) and ensure that they are not violating any state regulations by practicing across state borders (Reamer, 2013a).

Reimbursement

Insurance reimbursement for clinical services from programs such as Medicaid, Medicare, or private insurance is organized at the state level and, therefore, varies by state. However, insurance companies typically require audio-video equipment to carry out “telemedicine” and exclude services offered via other methods such as e-mail or text (Baker & Bufka, 2011). Some insurance companies authorize e-therapy reimbursement on a case-by-case basis if a special need exists, while others, such as Magellan and Blue Shield, provide regular authorization of online therapy in California (Breakthrough Behavioral Health, n.d.). BlueCross authorizes telemedicine coverage in 21 states but can restrict the types of providers or services that are eligible, and 19 states have specific policies that mandate insurance companies pay for telemedicine services if they would be covered face-to-face (ATA, 2013; Baker & Bufka, 2011).

Online therapy groups require payment at the time of services and do not bill insurance for services. Although this arrangement is adequate for financially independent consumers, the economically disadvantaged consumers who make up social work’s core service recipients will be unable to afford e-therapy. Ideally, social service organizations could develop Social Work 2.0 services, such as text-based technologies like e-mail or chat, telehealth using the phone or VoIP services, or video technologies such as webcams, to address the needs of clients for whom traditional face-to-face services are inadequate or difficult to access. However, this is unlikely until funding is available.

CONCLUSION

Advances in ICT have changed the way social workers think about and provide mental health

services. Some of the advances have reduced the role of social workers in mental health treatment, community practice, and advocacy. Over the coming decades, it is likely that some social work services will be entirely computer-based, whereas others will have only minimal integration with technology. As today’s youth become tomorrow’s consumers, and they see fewer distinctions between their online and offline identity, social workers will have to demonstrate knowledge of and skill with ICTs to provide treatment in any environment. In an effort to address this need, social workers have taken to developing social work education apps (Cooner, 2013). But formal social work education in ICT-mediated social work is lacking; the first social work course to address the use of technology in clinical social work practice was taught as a summer elective in 2013 by Mike Langlois for the University at Buffalo School of Social Work (UB Reporter, 2013).

24 Navigating Complex Boundary Challenges

Kimberly Strom-Gottfried

“Professional boundaries” typically refer to the norms that protect, ground, and guide the helping relationship. They mark a social, physical, and psychological space around the client that is protected from inappropriate intrusion by the social worker. Boundaries help assure the client that actions or expressions by the worker are made in the client’s interest and for the benefit of the services being provided, not for the worker’s social, financial, or sexual needs. Boundaries can be exceedingly complex, with variations in norms across cultures, geographic regions, practice settings, and populations served. Depending on their setting, clientele, and individual disposition, professionals may maintain “thick” or “thin” boundaries. In either instance, the client–worker distinction exists, but the concept acknowledges that some workers prefer to have greater privacy and distance separating their work and personal matters. Boundaries do not imply that clients are inferior to professionals; rather, they assure that the helping relationship is sacrosanct and clients’ needs are accorded the utmost importance.

Boundary violations, such as dual or sexual relationships, are among the most common areas of ethical impropriety in social work and other professions (Boland-Prom, 2009; Daley & Doughty, 2006; Strom-Gottfried, 1999). Although these egregious and exploitive acts are valid areas for attention, subtle conflicts of interest are far more common and have less clear-cut solutions.

- Should a social worker on a home visit accept an offer of food, conduct the meeting with extended family nearby, or take action if illegal activity is observed?

- If a professional in the field of disabilities also has a child receiving services in that field, how should he or she relate to parents who are simultaneously peers and clients?
- A social worker activist in the lesbian, gay, bisexual, and transgender (LGBT) community is often sought for services by members of that community. When do overlapping acquaintances become dual relationships?
- A patient with a life-threatening illness asks the members of the treatment team to be her “supporters” on a Caring Bridge site. Members of the team disagree about the propriety of that role.
- Is the client who “Googles” his new worker, and discovers some unflattering findings from rating and commentary sites, a savvy consumer or a resistant trouble maker?

“Boundary crossings” indicate deviations from standard practices that are typically innocuous, done in the client’s interests and without adverse effects, and are, therefore, not inherently unethical (Reamer, 2001). In the wrong context or with the wrong client, however, even simple boundary crossings may represent problematic conflicts of interest or create the first step in a “slippery slope” toward boundary violations and client exploitation (Epstein & Simon, 1990).

The National Association of Social Workers (NASW) Code of Ethics cautions practitioners to avoid or address potential conflicts of interest by taking “reasonable steps to resolve the issue in a manner that makes the clients’ interests primary and protects clients’ interests to the greatest

extent possible" (NASW, 2008, 1.06a). Certain conflicts of interest, such as sexual relationships with clients, former clients, supervisees and others, are expressly prohibited, and social workers are further cautioned to avoid business, professional, or social relationships with clients and former clients due to the risk of harm or exploitation. Ultimately, the social worker bears the responsibility for "setting clear, appropriate and culturally sensitive boundaries" (NASW, 2008, 1.06c).

INTERSECTING ETHICAL STANDARDS

Although rural practice, in-home services, and online networking can create conflicts of interest and stretch professional boundaries, other ethical standards, including confidentiality, professionalism, and competence are also inextricably bound to these situations.

Confidentiality

Maintaining client privacy is the foundation of the helping relationship. Social workers face significant ethical and legal sanctions for the failure to protect sensitive information or for sharing information for other than professional purposes. Practitioners are expected to use informed consent at the outset of services to alert the client to the limits of privacy, typically in cases with mandatory reporting of child or elder abuse or the risk of harm to the client or someone else. Confidentiality pledges are challenged when clients share information, such as past criminal activity, that is distressing to the worker but is not reportable (Walfish, Barnett, Marlyere, & Zielke, 2010).

Confidentiality also is challenged when personal and professional relationships overlap.

- Professionals in rural areas may observe unhealthy behaviors or activities in the community that are at odds with what clients report in interviews. Should they confront the client on the disparity?
- If a clinician participates in a patient's online caring site and learns that the patient is not following discharge instructions, what is he or she to do with the information?
- During a home visit with an elderly client, the worker observes signs of drug sales out the back door by the client's grandson. Should this be ignored or reported, and if so, reported to whom?

Each of these disparate examples raises similar questions: Where and when does the professional's responsibility end?

The NASW Code of Ethics requires that social workers "... respect clients' right to privacy" and avoid soliciting "private information from clients unless it is essential to providing services or conducting social work evaluation or research" (1.07a); "protect the confidentiality of all information obtained in the course of professional service, except for compelling professional reasons" and "disclose the least amount of confidential information necessary to achieve the desired purpose ..." (1.07c); "inform clients, to the extent possible, about the disclosure of confidential information and the potential consequences, when feasible before the disclosure is made ..." (1.07d); "... protect the confidentiality of clients' written and electronic records and other sensitive information (1.07n); and "... take precautions to ensure and maintain the confidentiality of information transmitted to other parties through the use of computers, electronic mail, facsimile machines, telephones and telephone answering machines, and other electronic or computer technology" (1.07m).

Social workers should not: "... discuss confidential information in any setting unless privacy can be ensured. Social workers should not discuss confidential information in public or semipublic areas such as hallways, waiting rooms, elevators, and restaurants" (NASW, 2008, 1.07i).

Professionalism and Competence

All individuals reveal different dimensions of themselves depending on the social context and the people surrounding them at any given time (Knox & Hill, 2003). Thus, conversations and behaviors with intimate friends and family are likely more frank and unguarded than those with acquaintances or the public. In their interactions with clients and colleagues, social workers are expected to demonstrate professionalism through their integrity, appearance, conduct, and expertise.

Although professionals are urged to be "authentic," they also are cautioned to exercise restraint and be mindful of their "use of self" or the way in which aspects of the worker's own persona are employed to influence the helping relationship (Baldwin, 1987). Social workers may selectively use self-disclosure to reveal information about themselves in the course of their practice with clients and fellow professionals. Some self-disclosures occur in response to queries ("Are

you married?" "How long have you worked here?"). Self-disclosures can also be voluntary and unbidden, as the professional offers information about him or herself that may be beneficial to the client. Such revelations may include coping strategies, interests, personal data, or experiences as a service recipient. The practitioner must consider how the information will be heard and used by the client, the worker's comfort should the client disclose it to others, and the availability of other techniques to assist the client that do not involve personal sharing by the worker (Farber, 2006).

Representative standards for professionalism and competence (NASW, 2008) state that social workers should:

- "... accept responsibility or employment only on the basis of existing competence or the intention to acquire the necessary competence" (4.01a)
- "... treat colleagues with respect and should represent accurately and fairly the qualifications, views, and obligations of colleagues" (2.01a)
- "... relate to both social work colleagues and colleagues from other disciplines with respect, integrity and courtesy and seek to understand differences in viewpoints and practice" (3.1)
- "... make clear distinctions between statements made and actions engaged in as a private individual and as a representative of the social work profession, a professional social work organization, or the social worker's employing agency" (4.06a).

Social workers should not:

- "... allow their own personal problems, psychosocial distress, legal problems, substance abuse, or mental health difficulties to interfere with their professional judgment and performance or to jeopardize the best interests of people for whom they have a professional responsibility" (4.05a)
- "... use derogatory language in their written or verbal communications to or about clients ..." (1.12)
- "... exploit clients in disputes with colleagues or engage clients in any inappropriate discussion of conflicts between social workers and their colleagues" (2.04b)
- "... permit their private conduct to interfere with their ability to fulfill their professional responsibilities" (4.03).

Professionalism is challenged when thin boundaries reveal troubling conduct or new dimensions of the social worker.

- The professional who is bossy and defensive as a member of a peer support group may have trouble undoing that image in interactions with other members as their caseworker. Conversely, the worker may feel she cannot truly be herself in the support group because other members view her in her professional role, not as a parent with the same challenges they have.
- A social worker moonlighting as a bartender or store clerk may worry about his responsibility and legitimacy as a helping professional after encountering clients in the context of his second job.
- The home visitor may note decorations in a client's apartment that indicate common interests or religious affiliations and disclose those similarities in an effort to build rapport.
- Outraged online posts about political events may alienate the clinician's patients, supervisees, or employer. Frivolous party photos that identify or "tag" the worker may come to the attention of clients or administrators who are distressed to see this side of the professional (Decker, 2012). When medical students posed with "their cadavers," for example, or an obstetrician lamented a patient's tardiness and mused about showing up late for the delivery, the posts and derisive responses went viral (Beck, 2013; Heyboer, 2010).

COMPLEX BOUNDARY CHALLENGES

Practice in small, rural, or close-knit communities, in client's homes, and in the era of electronic communications each pose unique challenges for professionals hoping to maintain clear boundaries. They also give rise to dilemmas surrounding confidentiality, professionalism, and competence.

Rural and Close-Knit Communities

In rural and close knit communities, worker self-disclosure is rarely a concern because many people will know the worker through prominence in the community, through connected family and friends, and from activities of daily life

(shopping, the faith community, schools, health care, a barbershop, or car and home repairs). This heightened visibility for the professional is true not only in small geographic communities, but in cultural communities, faith communities, and in groups defined by common interests or attributes (such as the hearing impaired community). These settings are so rife with intersecting relationships that some view dual relationships as a customary factor in service delivery, not an ethical indiscretion (Miller, 1998). The core concern in these situations is the possibility that social workers may be unable to carry out their professional responsibilities if their judgment is clouded by competing loyalties. Additionally, the visibility in these settings can create discomfort for professionals and it can constrain their own help-seeking in times of need (Beskind, Bartels, & Brooks, 1993).

Further challenges imposed by close-knit communities involve the exchange of private information; workers may observe or receive data from multiple sources but must guard against the improper disclosure of information. Worker competence can be tested in small communities when limited referral options exist or when community members prefer to seek help from someone they know instead of from a “stranger,” even if the stranger possesses superior formal credentials (Pugh, 2007).

Home-based Services

Social workers in home-based care must apply recognized ethical principles to novel and, at times, unpredictable circumstances. A clear benefit of home-based care is that it allows the worker to more readily and viscerally envision the client’s reality. These encounters can positively impact rapport, insight, case planning, and other features of the working relationship. Yet immersion into the client’s home requires that the worker use his or her clinical and ethical acumen to decide which of the things that are observed are relevant to the helping process and which are not. For example, a worker who finds an immigrant family using a barbecue grill indoors may intervene to educate the clients about the risks of carbon monoxide poisoning and fire, irrespective of the purposes of the visit. But what if the same worker observes the misuse of disability funds or negligent treatment of a pet? Do clients, in opening their homes to professionals, open

themselves up to all manner of critiques about how they choose to live their lives? Can workers effectively carry out their responsibilities if they selectively attend to troubling data? On what basis should workers act on their observations or choose restraint? Such powerful impressions and experiences may make it difficult for the worker to maintain appropriate boundaries, to focus on professional purposes, and to avoid burnout and vicarious trauma (Naturale, 2007).

In-home work is also characterized by autonomy and isolation. Workers experience less accessible back-up and consultation, and greater risks to health and safety (Allen & Tracy, 2009). In-home employees must be trustworthy in light of their freedom from oversight and office protocols and they must manage the likelihood of role ambiguity for themselves and their clients. Is the worker a friendly visitor, a clinician, an investigator, or a friend? Clients without a history of receiving in-home services may be uncertain about the protocols for hosting such a visit. Unless they are properly informed prior to the visit, this confusion can lead to resentment, apprehension, and heightened anxiety. It can also lead to complications in the session, such as the presence of other guests in the home, offers of food, or lack of preparation for the visit, if, for example, the child client is not home. Workers who are not clear about their roles, responsibilities, and objectives for the session may have difficulty avoiding diversions, structuring the meeting, and setting appropriate boundaries.

Another defining feature of home-based care is that the environment is largely out of the worker’s control. Moving the interaction from the professional’s office to the client’s “turf” has both perceptible and subtle implications. The client’s home may be remote and isolated or teeming with activity. The time allotted to the interview may be punctuated with intrusions from neighbors, family, and pets. Clients may feel more secure in the home environment and engage in behaviors they might not otherwise do in an office setting—slapping a child, opening the door in a nightgown, using the bathroom with the door open, playing video games, preparing a snack. As with the other dynamics in home-based care, a fluid environment and client comfort can enhance the worker’s capacity to understand and engage with the client system. It can also create dilemmas as workers determine where and how to draw limits on requests, behaviors, or activities.

Online Networking

The swift and pervasive rise of online networking (ON) through discussion boards, blogs, and sites such as Facebook and Caring Bridge create unique challenges in the application of familiar ethical concepts such as client privacy, professional boundaries, worker self-disclosure, conflicts of interest, and informed consent. Social workers have long used their colleagues, alumni associations, and social circles to share news and ideas, show photos of vacations and life events, organize around shared interests or causes, and seek assistance with job searches or problem-solving. Yet, ON has taken networking to a broader and potentially more complex level as personal and professional data, opinions, problems, and experiences are spread more rapidly and more widely. Once shared, such information may take on a life of its own, and be difficult if not impossible to erase, even if harmful or untrue (Boyd & Ellison, 2007).

The vastness of online networks has constructive uses for professionals seeking resources or supervision, sharing information on evidence-based practices, marketing new services, or advocating for policy changes. Conversely, ON can create risk and exposure for the professional if a query about a difficult diagnostic issue reveals too much client information or results in sarcastic, unhelpful, or even harmful suggestions.

Online interactions with clients inherently carry a risk of boundary crossings and, ultimately, harmful violations. A social worker who, through Twitter or Facebook, learns unnecessary details of a client's views or activities may have difficulty keeping those details from impinging on the helping relationship. Extraneous information revealed through ON contacts may affect the worker's objectivity, causing him or her to judge the client more favorably (or harshly) than the case, itself, suggests. Innocuous references to shared interests in online profiles may open the door to discussions and activities that are irrelevant to the helping relationship. The challenges extend beyond the client-worker dyad when professionals who serve as instructors, administrators, and supervisors allow the added dimension of ON relationships to affect their ability to carry out their professional responsibilities—the student is upset by a radical blog the professor writes, or the supervisor is disturbed by interest groups with which the employee affiliates online. The NASW Code of Ethics stipulates that

supervisees should be evaluated in “a fair and considerate manner and on the basis of clearly stated criteria (NASW, 2008, 3.03). It can be difficult enough to attain objectivity in appraisals of students or staff without the issues being clouded by inapplicable information.

NAVIGATING COMPLEX BOUNDARY CHALLENGES

Professionals have an array of resources at their disposal to address complex boundary challenges. Each dilemma requires the worker to anticipate the effects of the boundary crossing, consult with ethical standards and other resources, seek supervisory guidance and demonstrate self-restraint.

Anticipation

The practice setting or community type and the information obtained at intake or during the course of treatment will allow the worker to foresee an overlapping relationship and broach the topic with the others involved. For example, “We will probably run into each other at school and other events in the community, but I won't initiate conversations with you in public and I want to assure you that I don't reveal information from work with my family.” Or (to a new supervisee who previously received services at the agency) “I suspect this may be awkward at first, but I want you to know I'm glad you've been hired here and I'm confident we can work through this. If apprehensions or issues arise for either of us, I hope we'll be able to talk about them.”

The prevalence of online activity demands that professionals routinely anticipate requests for electronic communications or networking. The worker's policy should be addressed in writing and verbally at the outset of service, clarifying the worker's electronic availability. (“Text and e-mail messages may be used for scheduling concerns, but we should discuss *in person*, any other information involving your case.” “I do not use social networks.” “It is my policy not to ‘friend’ or otherwise connect with clients, students, or supervisees online.”)

Professionals who are active in ON venues such as Twitter, social networks, blogs, or photo sharing should be alert to the messages they are sending and the ways those messages will be received by various constituents. Tight privacy settings, discretion, and disclaimers (“This blog

represents my personal views, not those of my employer or profession.”) will help put the worker’s posts in context and provide nominal protection, but they are far from perfect. Anticipating how clever comments, frivolous photos, complaints about work, and other posts will appear can help posters decide what to share and what to withhold.

Professionals should anticipate that signing on as a friend or supporter with clients’ or former clients’ networks carry a high risk for difficulties. What is expected of the worker if the client uses it as a method to extend contact with the worker or if he or she posts troubling information? (“I ought to die.” “I’m not supposed to drink with this medication but one beer won’t hurt.”) The ambiguity of roles and responsibilities in this forum suggests that avoiding such contacts sets a proper professional boundary.

Although the social worker may routinely practice in clients’ homes, the experience may be a novel one for the service recipient. Anticipation in these situations requires the worker to learn what he or she can about the client’s locale and related hazards or safety concerns. If possible, the worker should also prepare the client prior to the visit with information about the purpose and length of the meeting, the family members who will be expected to attend, and any questions the client may need to have addressed.

Consultation

The NASW Code of Ethics offers guidance for practice by enumerating social work values, principles, and standards. Licensed professionals may also find guidance in the code of conduct set forth by their state or provincial regulatory board. Professional associations, certifications, and other bodies issue practice standards that may be of help in addressing complex boundaries. Organizational policies will spell out the expectations for employees. Each of these resources will provide important perspectives to the worker struggling with boundary dilemmas. Unfortunately, each may be limited by the use of contextual, vague, or unrealistic provisions. (“Set appropriate boundaries.” “Disclose only in compelling circumstances.” “Assure that your personal conduct does not reflect negatively on the agency.” “Never accept gifts from clients.”) For these reasons, professionals must participate in shaping and articulating these expectations

and engage in dialogue to operationalize them in practice. Continuing education programs, news articles, and staff meetings all provide forums for interpreting standards and developing the accompanying practice norms.

Supervision

Ethical standards encourage professionals to use supervision and peer consultation when faced with ethical dilemmas (Sawyer & Prescott, 2011). Unfortunately, practitioners may be reluctant to raise issues for fear that it will reflect negatively on their competence or impinge on an already overloaded colleague’s schedule (Pope & Spiegel, 2008). Nevertheless, the complexities of practice require education and conversation to assure that client needs are properly addressed.

Professionals must locate resources for ongoing conversations and make use of these resources. Reluctance to raise an issue in supervision should be examined, for it is either a red flag about the lack of trust in the supervisory relationship or the wisdom of the worker’s intentions. The “principle of publicity” serves as a test of worker judgment and the advisability of certain actions (Kidder, 1995). If the worker is reluctant to share information with colleagues, to stand by an action, or even to have others know about it, it is likely that the action is unsound.

Supervisors and peers can help colleagues understand policies and standards, think through the pros and cons of various boundary crossings, prepare for difficult conversations involved in setting boundaries, and evaluate the effects of overlapping relationships on the helping process. The worker must take responsibility for cultivating and using these resources.

Self-regulation

Cautious practice and ethical standards recommend that professionals assess whether a dual relationship is avoidable (Doyle, 1997) and “if the relationship is avoidable, avoid it” (Erickson, 2001, p. 303). What is avoidable? Generally, accepting as a client those with whom the social worker has had significant past or current involvement. This includes friends, neighbors, coworkers, dates, and those with whom the social worker has had substantial business dealings or other connections that might compromise the

ability to serve the client's best interests and preserve confidentiality.

Self-regulation may also include avoiding roles that lead to problematic boundary compromises—for example, declining nomination to a committee whose chair is a client, or abandoning online discussion forums frequented by past or current patients. A professional in recovery may not be able to avoid attending 12-step meetings with clients, but may forego roles (such as sponsor) that compromise his/or her needs and those of the client. Some may say, "Why should I forego this opportunity just because of the possible complications?" In fact, some opportunities may be so rare or special that they cannot be avoided. But for those that can be, or that can be deferred to another time, the advantages are numerous. First, it is the clinician's fundamental obligation "to place the interests of those who are served above his own" (Kitchener, 1988, p. 217). The inability or unwillingness to do so should be cause for some self-examination. And, on a more pragmatic level, the client and the social worker are freed from the level of vigilance required to manage boundaries in overlapping relationships; both may take more pleasure from the activity without the other's presence in it.

Professionals must exercise shrewd self-awareness to identify problematic boundary crossings. By their nature, conflicts of interest require professionals to determine what situations will compromise their objectivity and capacities with a given client. Knowledge of self, fostered by attentive supervision and ongoing education, will help identify situations where overlapping relationships can be reconciled and those where they cannot. If the client gives the in-home worker surplus vegetables from the garden, the worker must determine whether that will affect his or her objectivity in the case, create improper expectations by the client, or simply constitute a normative act of kindness for which the worker should be grateful.

If a patient assigned to the social worker bullied the worker when both were school children, the social worker must appraise his or her capacity to separate the painful past from the patient's current needs. No guideline exists to tell the worker what is right. The decision rests on his or her self-knowledge and willingness to seek the input of others.

When practicing in situations rife with boundary challenges, professionals should develop their own policies and use those to guide routine

choices. Some areas for personal policy development include:

- Whether to accept invitations to client events such as graduations, quinceañeras, bar/bat mitzvahs, or birthday parties
- Whether to accept gifts, homemade objects, bartered services, or refreshments
- Setting limits on home visits around noise, smoke, interruptions, or other distractions
- Establishing understandings with family members when the worker is approached in public by clients or when the worker sets seemingly arbitrary limits on family members' actions ("We cannot hire that service for our roof repair." or "I do not want you to go there for a sleep-over.")

Weighing the Risks of Complex Boundaries

Ultimately, through anticipation, consultation, supervision and self-regulation, the worker must weigh the risks and benefits of complex boundary relationships (Erickson, 2001). One model evaluates, from the consumer's perspective where the relationship falls on the dimensions of power, duration, and clarity of termination. Thus, it asks, "How great is the power differential? How long has the relationship lasted? And has it clearly ended?" (Gottlieb, 1993, p. 45). A traditional psychotherapeutic relationship would rate high on each measure and thus would pose a higher risk if combined with another relationship. If it is not as high on these measures (for example, the social worker was responsible only for discharge planning following a brief hospital stay) then further consideration can be given to the additional relationship. The same dimensions are considered for the new relationship—"Would it involve great power over a long time with uncertain termination?" (Gottlieb, 1993, pp. 45–46). Thus, accepting a former client as an employee would rate high on these dimensions while serving together as classroom parents for the elementary school would not.

Kitchener (1988) borrows from role theory in offering three additional factors on which to evaluate the risk of harm in a dual relationship. Risk is increased when the expectations between roles are incompatible, when obligations diverge, and when there are greater differences in prestige and power. For example, serving as a client's therapist and employer reflects high risk on all variables; the

demands of the roles are incompatible, the obligations of the roles may well lead to divided loyalties or decreased objectivity, and the power differential in both roles is quite vast. Contrast this with the development of a social relationship with a former student or employee where the power differential and role conflicts are minimal, in part because the dual relationships are not concurrent, but also because the differences in power, role expectations, and responsibilities are not as great.

Ebert (1997) offers another, more fully explained model, and suggests attention to additional factors, including where the secondary role relationship occurs (i.e., how public is it?), the purpose of the activity, the extent of contact, the presence of overt or subtle coercion, the likelihood that the behavior will create confusion, how the relationship appears to others, the context in which the conduct takes place, the danger of inhibiting future therapy, threats to clinician objectivity, and the strength of the client. Each of these questions helps the worker to evaluate the potential for conflicts of interest or therapeutic complications and thus determine the relative risk of engaging in the secondary relationship. Buying groceries from a store owned by a client might be construed as lower risk than buying a car at a client's dealership, because the former is a more common, less individualized transaction and one where the prices are fixed and the threat of coercion in negotiating price is not an issue. Attending a soccer party to celebrate the youths' successful season may not raise significant, ongoing discomfort or become intrusive in the helping process, but repeatedly seeing clients at the local health club locker room might (Schank & Skovholt, 1997). A home visit with an old acquaintance is more private, and thus more hazardous than seeing the patient in an office setting.

Many situations and settings create complex boundary questions. Social workers must engage in astute self-evaluation to determine when personal and professional activities can be reconciled and the client's interests upheld. Professional standards, personal policies, and dialogue with colleagues will prepare workers to set boundaries and navigate novel challenges.

25 Integrating Values into Social Work Practice

Juliet Cassuto Rothman

This article will present an overview of values in social work and their impact on our professional functioning. Methods and strategies for working with values will then assist the reader to both become aware of the importance of values and to integrate awareness of values into practice.

UNDERSTANDING VALUES

Values have always been an essential part of human life and human thought, and continue to be central today. Our personal values guide us in decision-making, in our life choices, and in our

relationships. Values are subjective in the sense that each person's values are developed through personal experiences and personal thoughts. Values tend to remain stable throughout our lives, although the actions and the meanings we attach to them may change and evolve.

A part of the human endeavor is reaching out to both determine and achieve that which gives life meaning, on both a personal and a humanitarian level. Meaning is drawn from values. A person who values personal relationships may find meaning in deep friendships, in work that helps others, or in supporting human rights. A person who values nature and natural beauty may find meaning in working in the outdoors, or in becoming involved with environmental issues. A person who values freedom may find meaning in times when she or he is alone, or in working to bring political systems that value freedom to other areas of the world, or in working on equal rights legislation.

Life goals are drawn from that which gives meaning. In our profession, life goals often determine our professional choices—of contexts and fields and populations. Because of the self-awareness that is an essential part of social work practice, we may be aware of our goals, of the things that give meaning to our lives, of our values. However, it is important to recognize that values function similarly in all people, and to integrate this awareness into every aspect of our work.

Because values differ and may conflict, an exploration of values as a part of the social work process can help to increase awareness of potential conflicts, and enable these to be considered and addressed in the development of plans for services (Dolgoft, Harrington, & Loewenberg, 2012).

The theories of Kohlberg and Gilligan often have been used by social workers to understand value formation and moral development. Although their conclusions differ, both understand value development as occurring in childhood over time (Gilligan, 1982; Duska & Whelan, 1975). Values are learned from such varied sources as parents, teachers, coaches, religion, national history, culture and ethnicity, mentors, and friends, but are then filtered through each person's individual experiences.

It is also essential to recognize that the word "value" itself implies something of worth, thus, something that the holder of the value considers to be a good. In addressing behaviors that may be negative, illegal, or destructive of self and others,

it is important to seek the value that may lie hidden beneath the actions and behaviors of others. A few obvious examples:

- A gang member may value friendship, loyalty, and membership in something larger than self
- The pregnant 13-year-old may value loving another, being loved, being independent
- The seller of stolen goods may value comfort and wealth for family and friends.

Clients may be unfamiliar or uncomfortable with using the word "values," and may be able to relate more easily to a different phrasing. One possible way to initiate a discussion of values might be something like, "In order to see how we can work together to help you, we both need to understand what is *important* to you/what you *care* about/what you *want* in life."

In working with values, it is necessary to be aware of three especial challenges we face:

- (1) *Abstract and concrete values:* A common difficulty is related to the terms we use in describing values. We often find agreement when we speak in abstract terms, such as "freedom," "equality," "friendship," "democracy," "God," "the natural environment," etc. This gives us a good "we-feeling" of being united and similar to others. However, it is important to be very cautious here: if we were to ask 20 people who value "freedom" to define it, we would get 20 very different definitions! When the term is abstract, it is easy to have *apparent* agreement; but when we go from this to goal setting and planning, we encounter confusion and differences. Thus, it is important to be aware that in the movement from abstract to concrete values, many differences may become visible and are essential to consider.
- (2) *"Real" and "ideal" values:* In working through the values exercises that will be presented in this article, a consistent challenge is the difference between "real" and "ideal" values. This is most strongly apparent in the consideration of societal values. We value freedom, justice, democracy, religious freedom, human rights—all these lofty and wonderful concepts, which have been a part of our nation since its very formation. However, when we consider how our country operates, we often find

another set of values, such as power, wealth, material possessions, and personal gain. The former set of values encompasses those that we publicly espouse, while the latter are those that often direct actions and personal positions. We strive toward our “ideal” values, we “value” them, but many times our actions support “real” values instead!

- (3) *Cultural value differences*: Our nation is a potpourri of different ethnicities, cultures, religions, and social classes. Because of the way in which values are formed, they are influenced by the context in which people have been raised and in which they live. This often creates real differences in values and priorities. Social workers are as strongly influenced by these factors as clients. Cultural competence requires an awareness of differences, including value differences.

VALUES IN SOCIAL WORK PRACTICE

Consideration of values in social work practice is complex, and often involves seven or more different value systems: (1) the worker’s personal values, (2) values of supervisory and oversight personnel, (3) agency and program values, (4) social work professional values, (5) societal values, (6) client values, and (7) values of the affected system, which may not be involved in receiving direct services. Values from each of these systems have a strong impact on goal setting and achievement, and must be considered both as client services or projects are initiated and as they are evaluated. Strong value dissonances have a negative impact upon goal achievement.

(1) *Personal Values*: Social workers considering personal values often find justice, human well-being, and community among their highest-held values—after all, these values have helped to guide them toward the social work profession!

As with everyone, these and other personal values are shaped by each person’s unique life experiences, and are often so well integrated that there may be little awareness of their presence or of their effect on professional service. Some of our personal values tend to be abstract: when we “fill in” the meanings with concrete terms and examples, we must be conscious of the differences among and between us. In our commitment to being nonjudgmental, and to respecting others, it is vital that we

become aware of our personal values and the ways they impact our professional functioning.

(2) *Professional Values*: Social work’s professional values are defined in the National Association of Social Workers (NASW, 2008) Code of Ethics. Core values of the profession include *service, human relationships, dignity and worth of person, social justice, integrity, and competence* (NASW, 2008). Professional ethical principles and standards are drawn from these values. Each value relates to a separate principle, and a series of standards for professional behavior follow. In examining the Code, the progression from abstract to more concrete values is clear in the transitions from values to principles to standards. The greater the congruence between our personal values and the profession’s values, the better the “fit” between worker and profession, and the fewer value conflicts will be experienced.

Like all groupings of values applied to specific situations, social work’s values may conflict with one another, and may be prioritized differently in different contexts by different practitioners. In addition, it is not possible for the Code to provide specific guidance for every situation workers encounter. To address these and other problems in applying social work values, Stewart suggests that “social justice,” one of the core values, be utilized as an “organizing principle” for the profession (Stewart, 2013).

(3) *Supervisory and Oversight Values*: Because most social workers function within a system that includes supervision and oversight, the personal values of supervisors and others within the agency or program hierarchy also impact on professional services rendered.

(4) *Agency and Program Values*: Agency and program values determine process, methodology, populations, and goals of service, and are generally defined in the mission statement and goals of the organization. Many agencies have come into being through religious, cultural, or governmental organizations, and their missions and policies reflect the values of their founders. In many cases, these values continue to provide meaning and direction and guide services and programs. In others, the context and needs of the population served may have changed, subtly altering the manner in which organizational values are integrated into service. In still others, agency mission and values may

have been reconsidered and redefined to meet the changing needs of the groups and programs served.

It is important to be aware of agency and program values, and to consider these carefully both in seeking and maintaining employment. Value differences between workers and settings may affect the provision of services to clients, and can create stress and discomfort for workers as they choose between responsibility to personal values, and responsibility to those of the employing organization. Some examples of potential value conflicts include: euthanasia and end-of-life issues, abortion and birth control, incarceration and probation, children's rights and parent's rights, and marriage equality.

There may be a special challenge for social workers in a host setting where the values of another profession, or other entity, take precedence in policy, programs, and methods, potentially creating a conflict between social work's professional values and values of the employing organization.

(5) *Societal Values*: We all immediately recognize the challenges inherent in attempting to determine societal values. Who is "society"? Who defines "society"? One common response to this problem is to say that societal values are the values of the "founding fathers." What about the mothers? Slaves? Non-English speakers? More recent arrivals? Can we speak of *national* societal values, or are there many differing societal values, each defined by a community, group, or population? And, how do we resolve the difference between "real" and "ideal" values on a societal level?

Several possible avenues for arriving at an understanding of societal values include determining that (1) societal values may be defined through the Constitution; (2) societal values are embodied in our laws and can be determined by exploring law and policy; (3) because our society is so diverse, it is not possible to arrive at any agreement on what constitutes societal values; (4) our society is made up of many overlapping groups and subgroups whose values may be more or less similar, making it possible to arrive at a number of basic values that can be used to define societal values as used in the social work setting.

The challenge of determining societal values is not easily resolved. However, it is essential to be aware of these values, for social workers are, in a sense, "agents" of society. We are licensed to practice by society, given control of services

and resources that society provides, and given the authority to care for vulnerable members of society. We are charged with supporting laws and policies, while at the same time advocating for changes when these are viewed as unfair.

(6) *Client Values*: Congruence between client values, goals of service, methodologies, and interventions are major factors in the achievement of service objectives. A discussion of values should be initiated early in the relationship, with service plans built upon this foundation.

Where clients appear to have limited self-insight, exploring values may be one of the first objectives to be considered. In situations where clients are unable, or unwilling, to share in a discussion of values, workers can gain insight into value systems by carefully observing clients' behaviors and choices, and/or by learning something of their histories and life experiences. As an example, in helping clients to make end-of-life decisions, Csikai and Chaitin (2006) suggest the development of a "values history" as a useful tool (Csikai & Chaitin, 2006).

It is in one-on-one values discussions with clients that we must be most careful to self-observe and to be self-aware. A word, a gesture, an expression on the part of the social worker can give the client an awareness of value differences, and of the worker's judgment of the client's values. Two other considerations are important in this regard:

(1) Where value differences are clear and easily recognized, we are most aware of the need to respect and consider the client's values. It often feels more comfortable to be working with clients whose values appear similar to our own. However, it is when values *appear* most similar that we should be most vigilant in self-monitoring! Because, as has been noted earlier, abstract words provide a sense of similarity in values, it is easy to focus on these and miss the unique experiences and shades of meaning, that makes client values different from the worker's own (Rothman, 2006).

(2) Cultural differences also affect the way in which values are integrated into the provision of services. In some cultures, the social worker is considered the "expert" whose views, ideas, and plans are easily and unquestioningly accepted by clients. Some cultures may consider objecting to the social worker's ideas and planning as a sign of disrespect for the worker. When applied to values, this may lead to a tendency to accept the worker's values and priorities, even if these differ from the client's own (Rothman, 2006).

(7) *Values of the Affected System*: In planning services and programs, and in working with individual clients, we must also consider the value systems of those who will be affected by the changes service provision will bring. Spouses and partners, children and other family members, friends, employers, community members, and neighbors may all be impacted by changes in individual clients, and client goals and objectives may conflict with their own personal values.

Beyond the individual client, values may affect program funding, service provision, policies, and populations served.

WORKING WITHIN THE VALUES CONTEXT

There are several methodologies and strategies for appropriately integrating a consideration of values into our work with clients at every level of practice from micro to macro, from young children to the elderly, from any ethnicity, religion, culture, and belief system, and in any community. These include developing and working with a values hierarchy, considering the role of real and ideal values, recognizing the importance of personal values, including our own, searching for commonalities, building on commonalities, and utilizing these to develop goals interventions, and relationships. This section will address these practical issues, and suggest methods for addressing them.

Developing a values hierarchy is the first, essential step in the process of integrating values into planning and interventions. Values hierarchies can be developed for each of the seven value systems defined in the previous section. Similar methodology can be used for each, and values hierarchies may be developed specific to different practice methodologies. As an example, in writing about spiritually oriented practice, Dezerotes suggests a practice hierarchy grounded in spiritual values. (Dezerotes, 2006) Values hierarchies can be developed by the worker, by the client, or by worker and client together.

Developing a Personal Values Hierarchy

Because the social worker's personal values hierarchy should be addressed first in order to foster self-awareness and understand the role of personal values in the worker's practice, the process

will be illustrated and presented here using the worker as an example.

Step 1: Consider the things that are of value in your life. Your personal values can range from very abstract, such as "freedom," to very concrete, such as "my home," and everything in between. Do not be concerned about level of abstraction and concreteness—just consider what is important to you, and what gives life meaning. Write your values on a blank sheet of paper, leaving space between each value. Ten values are a good number to work with—but a few less or more are also workable. Writing down too few values restricts reflection and flexibility. Too many may be confusing and overwhelming.

Step 2: Examine your 10 values. You may notice that some concrete values seem to fit under the more abstract values. As an example, "my friend Sarah" and "my classmate Ethan" may both fit under the more abstract value "friendship." The value "women's rights" and "immigration reform" might both be subsumed under the value "social justice." It is your choice to either subsume concrete values under the more abstract values, or to leave them as distinct.

This step in the process will illustrate the way in which similarly stated abstract values are defined differently by different people. Many people would cite the value "social justice," but the concrete meaning of the term may vary individually to include "equal rights," "free enterprise," "quality education for all," "our country," "freedom of speech," or the "rights of the unborn." This is why it is essential for the professional to explore what others mean when they use the term "social justice"; it means very different things to different people!

Step 3: Build a hierarchy. Prioritizing your values involves making painful choices. Is "friendship" more important to you than "social justice"? Is "freedom" or "equal opportunity" more important? "The social work profession" or "my family"? When helping clients to build their own values hierarchy, it is important to remember the challenge of building one's own, and to be supportive and empathic during this process with others.

To create your values hierarchy, you may simply number each value from 1 to 10. Or, you may

tear your list into strips, with one value on each strip, and place the strips into an order. The latter method may appear more cumbersome at first, but actually enables much easier movement, consideration, and changes to values in the hierarchy.

Step 4: When you have completed building your hierarchy, write it out carefully on another sheet of paper to use as a reference. Familiarity with your hierarchy increases your awareness of its impact on your work. It is not usually necessary to formally share your personal values with your clients—they will be obvious to clients from your actions in your work with them, and such sharing would deflect the focus of your work from your clients.

As noted earlier, if you are working with a client who is unable or unwilling to communicate, or with an organization or group that has not developed a formal list, it is still important to consider values. Observation and a review of history also may help you to determine values and build a values hierarchy. Try to consider values early in the professional relationship. You can help clients through this process by using empathy and support.

Values should always be expressed and discussed using the language of the person whose values are being addressed. Rather than trying to use professional, perhaps more abstract, terms for values, help the client to work within his/her own language to support empowerment and to encourage self-expression. Demonstrate acceptance of values and terms used. The process of working with values hierarchies builds trust and relationship, and can serve as an excellent tool upon which to build planning for change.

Considering “Real” and “Ideal” Values

Both “real” and “ideal” values have an important role to play in developing awareness and understanding. In the process of working with their values hierarchy, people often feel a pull between their personal ideal and real values. For example, being available to help someone in crisis is often an important value in a social worker’s values hierarchy, but the social worker also values being available to her/his own children and family. “Real” values such as having a clear period of “down time” and rest may conflict with the “ideal” values of always being available to clients.

Everyone has these kinds of difficulties in trying to reconcile “real” and “ideal” values in a personal values hierarchy. “Family time” versus “career advancement”; “being there for my friends” versus “not being around people on drugs”; “being on time” versus “gathering all the information needed,” are some simple examples of values conflicts. Although this can be stressful, you can learn a great deal about yourself in the process! Personal experiences and history often have great influence, and exploring these can both lead to insights and deepen a trust relationship.

Professional Values, Agency Values, and Societal Values

When you engage with a client, it is important to recognize that, for the client, you represent not only your personal values, but also the values of the social work profession, the agency, and society. This creates certain expectations of worker engagement, methodologies, and values, and is perhaps one of the most important reasons social workers must do their own values work before beginning to work with clients.

The lack of clarity in the consideration of societal values, noted earlier, may leave the worker with some sense of uncertainty. If there is a responsibility to represent society, and societal values are unclear, or conflicting, we may tend to function within the context of personal, professional, and agency values, minimizing the impact of societal values. It is generally helpful to turn for advice to a supervisor, agency director, or ethics committee to address these difficulties.

Client Values and Values of the Affected System

The NASW Code of Ethics clearly states, “Social workers’ primary responsibility is to the well-being of clients” (NASW, 2008). This underscores the importance of exploring client values within the professional relationship. The method presented earlier can easily be used to consider client values, with careful clarification of abstract terms and seemingly ambiguous statements of values. A list of values can be developed, and placed within a hierarchy. Plans for services should be in agreement with client values, although consideration of client values may be more difficult in involuntary settings. Of course, clients also have “real” and “ideal” values, and these differences can offer an opportunity to explore more deeply with the client. Observing

or considering behavior can also serve to illustrate some of the “real” and “ideal” value conflicts.

Clients may also find themselves with conflicting values, and find the process of exploration and the creation of a hierarchy very difficult and stressful. This conflict is most often felt between “real” and “ideal” values, but also may occur during the process of creating a hierarchy. Through careful discussion, social workers can assist their clients with this process.

Where the client is a couple, a family, a group, or other system, exploring commonly held values and value differences is an important aspect of planning. Serious differences in values can limit the success of goals and interventions. A discussion of commonly held values and goals will often reveal not only similarities and differences, but also the power structure within the client group.

If you are working with a client or a family member who is unable or unwilling to communicate, it is important to remember that values are tools for action: observation is an excellent method for determining, or confirming, client values.

You may find that you are unable to work directly to develop a values hierarchy with everyone who will be affected by your work with the client. However, it is important to have as much understanding as possible of these, for they will have an impact on the client, and on the potential achievement of goals. Clients themselves are often aware of the values of others in the client system and can assist you with understanding.

The exploration and understanding of values is often a time-consuming, though essential, process. Exploration of client, client system, and societal values may itself become a major part of the service plan, or can be limited somewhat to accommodate other needs, time constraints, and specific service methodologies.

Preparing an Overview of Values in the Wider System

Congruence between the value systems of worker, client, those potentially affected by services, the social work profession, the agency, and society will encourage and support a positive outcome. Reaching optimal congruence in values requires a clear understanding of the values hierarchy of those involved with, or affected by, the services to be provided.

In order to explore similarities and differences in values, the values hierarchies for affected parties can be prepared, always bearing in mind that the client’s values are primary. A table can be constructed with all of the value hierarchies side by side. This will enable a clear assessment, and may be shared with the client if you believe it would be helpful.

Client	Client	Agency	Community	General
	System			Society

In lieu of this formal structure, the social worker can also discuss values hierarchies and differences with clients verbally, giving opportunity for discussion and reflection.

Seeking Value Congruence, Recognizing Differences

Seeking and supporting value congruence is an essential step in planning for services and setting goals. The greater the value congruence, the greater the chance of success with services rendered to the client.

In considering the values hierarchies listed above, it is important to note

- Differences in the use of language and terminology
- Differences in the levels of abstraction/concreteness
- Cultural issues

Agencies and programs tend to express values using professional terminology—terminology that may be unfamiliar to the client. It is important to remain aware of a possible tendency to attribute greater importance to values stated in such terms than to the perhaps more simply expressed values of the client and the client system. Social workers should also ensure that clients understand agency and program values.

Agency and program values tend to be more abstract and focused toward their client base, community, and society at large, while client values may be focused on self and others in the client system. We can reconcile the two by considering the ways in which the agency’s values can support those of the client.

human relationships // people I care about // the people in my class// my friends// my best friend
Sandy

The client may identify “my best friend Sandy” as a value, while the agency’s program values “human relationships.” Yet, both are identifying similar things: positive, important relationships that support and sustain. Understanding that these are similar values, the social worker can help the client and/or the agency to see the connection between these two values. The movement tends to go from concrete to abstract—it is easier to find value congruence in abstract values, which have some “give” in terms of specifics than to focus on specific, concrete values.

However, the agency’s value of “human relationships” may be irreconcilable with a client value of “independence and privacy.” While acknowledging and respecting this difference, the social worker can continue to explore values hierarchies, seeking other values that may be more congruent.

Cultural differences may impact the congruence-seeking process as well. In some cultures, having a commitment to personal values and goals is a sign of strength, and is greatly valued, while in others, there is a tendency to defer value judgments to the professional, as the “expert” in addressing these issues.

The process of seeking value congruence and recognizing differences should be undertaken prior to any goal setting and specific service planning, as these should be grounded in value systems.

It is also important to remember that clients are very sensitive to approval, disapproval, or questioning, and it is important to carefully self-monitor through this discussion process.

Grounding Goals and Interventions on Common Goals

Once values have been clarified, workers and clients may begin the process of contracting and goal setting, being careful to consider and support client values. Goals that incorporate the client’s basic values have the best chance of success. Goals that also include a consideration of the values of the client system have an even better chance of success. It is our responsibility, however, to ensure that goals and interventions also support the values of the agency and of the community.

Summary

Values are an important element in self-conception, in goal setting, and in how one understands one’s place and role in society. Values are generally learned in childhood, and develop out of each person’s unique life experience process. We tend to keep the same values all of our lives, though the actions that spring from them may change and evolve over time.

Clarifying and understanding values and value systems encountered in professional practice increases self-awareness, and enables a greater chance of success in service delivery. The process must begin with the worker’s exploration of personal values, for these impact clients and client services as well at the relationship between worker and agency or program, the profession, and the broader society. Exploration, definition, and the development of a values hierarchy provide the personal self-awareness that is so necessary in practice.

A similar process will enhance client self-awareness, and the integration of client values into planning, goal setting, and interventions helps to ensure their success, while increasing client self-awareness and building trust in the professional relationships.

Although a consideration of client values is primary to social work practice, it is also important to consider the value systems that underlie supervisory and oversight structures, agencies and programs, the social work profession, and perhaps most challenging, broader society, over whose resources and programs our profession has been given authority. The closer the value congruence among all of the parties affected by the provision of client services, the greater the chance of success in rendering them.

26 Adoption Competency in Social Work Practice

Debra Siegel

Benita Sanchez, an experienced licensed clinical social worker employed at a family service agency, sits in her office with a new client, Jon, a single adoptive father, who called the agency seeking parenting guidance. Jon says, "The state child welfare agency placed my son, Mark, in foster care with me three days after he was born because both Mark and his biological mother tested positive for cocaine, alcohol, methamphetamines, and marijuana. Mark's birth mother told the delivery room staff at the hospital that she was raped and she didn't know who the baby's biological father was. His birth mother did not participate in the state child welfare agency's reunification efforts for two years, so her parental rights were involuntarily terminated and I adopted Mark when he was almost two. We've never had contact with his bio family. Mark is now eleven. He's always been a feisty, spirited youngster, and over the years he's struggled mightily with academic and social issues in school; his behavior for the past two years has become increasingly oppositional at home and school. Lately, he's been crying, kicking me, hitting me, and yelling, "I need to find my birth family NOW, not when I'm eighteen! I can't wait. I can't stand how sad I feel." I can understand

Mark's strong feelings about this, and I'm also concerned for Mark's emotional and physical safety. What do I do? I realize that Mark will soon be able to use Facebook and the Internet to do the search on his own, without my involvement." Benita gulps silently, thinking to herself, "Oh dear! What do I need to know in order to be helpful here?" Like most social workers, extensive education about adoption has not been part of Benita's training. She wonders, "How many of Mark's issues are adoption related? How do I guide Mark's dad? All I know about adoption is from my sister-in-law, who adopted a girl from China."

Most social workers will encounter adoption issues in the course of their careers. Among Americans surveyed, 64% reported having a personal connection to adoption (National Adoption Attitudes Survey, 2002); an estimated one hundred million Americans are touched by adoption (Pertman, 2011); and about 2% of children in the United States under the age of 18 years, approximately 1.8 million children, are adopted (U.S. Department of Health and Human Services [HHS], 2013; U.S. Census Bureau, 2003; U.S. Children's Bureau, 2011). In addition, in 2012 approximately 115,000 U.S. children were

awaiting adoption (U.S. Dept. of HHS, Adoption and Foster Care Reporting System, July 2010).

Families in which a child has been conceived by donor egg or donor sperm, gestated within a surrogate, or adopted by a biological relative or by a step-parent may encounter many of the same issues as families with children who are born to one genetic set of parents and adopted by a person with whom they have no genetic link. In short, significant numbers of people are affected in some way by adoption, perhaps as relatives or friends of adoptive or birth families. Although most people touched by adoption may not seek clinical services, studies indicate that people who have been adopted are disproportionately represented in clinical populations (Harwood & Feng, 2013; U.S. Children's Bureau, 2004; Brand & Brinich, 1999).

Given these facts, social workers engaged in child welfare, clinical practice (i.e., mental health care and individual and family therapy), policy, or administration all need adoption competency. Studies show that adoptive families often struggle to find mental health providers who have the knowledge and skills to help them (Brodzinsky, 2013; New York State Citizen's Coalition for Children, 2010; Riley, 2009; Javier, Baden, Biafora, & Camacho-Gingerich, 2007; Singer, 2004; Casey, 2003; Howard & Livingston-Smith, 1997). A 2010 survey, conducted by the North American Conference on Adoptable Children (Stevens, 2011), with one thousand adoptive parents responding, found that 39% reported having trouble finding mental health providers who understood adoption issues. The NACAC report concluded that adoption competency training for mental health providers is needed, along with greater access to mental health services, parent education and training, and educational advocacy and support.

People contemplating adoption, along with those living with adoption, must grapple with complex issues that professionals who lack adoption competency may misunderstand or leave unaddressed. Professionals' mishandling of these issues leaves clients in distress, without the help they seek and need.

Adoption competency in both child welfare practice and mental health care is not just needed; it is ethically mandated. The National Association of Social Workers (NASW) Code of Ethics (section 1.04 a, b, c; pp. 8–9, NASW, 2008) emphasizes social workers' obligation to acquire the knowledge and skills needed to provide competent services. Although "Many authors have

noted the conceptual vagueness that surrounds competence as a concept" and "one true definition [of competence] does not exist" (Cooper and Menzel, 2013, p. 30), there is agreement that the competent practitioner has specific knowledge, skills, and attitudes (Cooper & Menzel, 2013).

This chapter introduces core areas of values, knowledge, and skills included in adoption competency. Many of the specific areas of knowledge and skill will vary depending upon (1) the type of adoption (e.g., via a public child welfare or private agency; domestic or inter-country; foster, guardianship, or kinship care; older child or infant; transracial or transcultural; sibling group; special educational, medical, or behavioral health needs); (2) the phase of the adoption process (e.g., pre-adoption planning and preparation or postadoption support services); and (3) the identified client (e.g., the child, biological parent, or adoptive parent). Nonetheless, there are cross-cutting issues and themes. Those are the focus of this chapter.

In addition to the above variables, drawing definitive conclusions about what adoption competency consists of remains a challenge, in part because there is no one universally accepted definition. However, the Center for Adoption Support and Education (CASE) has written a definition underpinning a post-master's degree training curriculum for mental health care providers at eight sites (in North Carolina, Minnesota, Ohio, Massachusetts, Indiana, Missouri, Nebraska, and California), with research findings indicating the training's effectiveness (CASE, 2013). Other adoption competency post-master's training programs have been implemented, for example, at Hunter College in New York, Rutgers University in New Jersey, and Portland State University in Oregon. Adoption competency curricula vary, depending on whether their focus is on training child welfare workers (e.g., National Resource Center for Adoption, 2011) or mental health clinicians with master's degrees (e.g., Riley, 2009). Nonetheless, close examination of the programs reveals at least some consensus about adoption competency.

VALUES UNDERPINNING ADOPTION COMPETENCY

Although there may always be differing views, there is widespread agreement about some guiding principles underpinning competent child welfare, clinical, and policy practices in adoption.

- The child's needs and interests are primary. The purpose of adoption is to provide the child with a family, not to provide prospective parents with a child.
- Every child needs and deserves a safe, nurturing, permanent family. Congregate care and impermanent care arrangements are not adequate substitutes for that.
- Generally, a child's interests are best served within the child's biological family, and country and culture of origin. For this reason, adequate family preservation services should be provided so that adoption is not needed. Adoptions across family, national, and ethnic boundaries should occur only when earnest efforts to find an adoptive parent within those boundaries have been unsuccessful.
- The child who is old enough to participate in the adoption decision and choice of family should be permitted to do so, as an essential component of adoption preparation.
- All people have a right to access full information about themselves. The practice of permanently sealing birth certificates should end. Secrecy, lies, and cut-offs in adoption do not serve the adopted person's best interests.
- All information known about the child should be shared with the adoptive parent(s) before they adopt.
- The child should have access to ongoing medical information that emerges in the birth family over the lifespan.
- In most cases, the child also has a right to have access to some sort of contact with the biological family. This access may range from minimal (e.g., infrequent exchange of letters via a post office box) to moderate (e.g., occasional e-mail messages or phone calls) to high (e.g., face-to-face visits in each others' homes), depending on the circumstances.
- Birth parents, including those who have had their parental rights involuntarily terminated because they abused or neglected the child, should be treated with respect.
- Deception, dishonesty, and coercion in adoption are undesirable. Client autonomy and self-determination should be supported.
- It is best to take a nonpathologizing, strengths perspective when working with people whose lives are touched by adoption. Being adopted, a birth parent, or an adoptive parent does not indicate that one is troubled

or trouble. Clients should be viewed as the experts in their own lives.

- Rather than thinking in terms of an adoption triad, comprised of the child, adoptive parent, and birth parent, it is more useful to think in terms of an adoption circle composed of the many adoptive and birth family members, and other systems and players involved in forming and sustaining an adoption. The extended family formed by adoption is best understood in a societal and relational context.
- Adoption is not an event, but a process that unfolds over the lifespan. Thorough preadoption education and preparation for child, biological parents, and prospective adoptive parents is essential. After adoption, access to competent postadoption support services should also be available.

PATHWAYS TO ADOPTION

The child welfare worker or clinician who has adoption competency is able to identify and explore with clients how a child and family's route to adoption may generate issues and themes that need to be addressed both before and after an adoption is finalized. The worker or clinician recognizes that although there are cross-cutting issues that characterize all adoptions regardless of how the adoption occurs (for example, there is no adoption without loss), each adoption is as unique as the people in it, and each pathway to adoption presents different emotional and practical themes. For example, a child may enter adoption via the public child welfare agency; as an infant, older child, or adolescent; alone or as part of a sibling group; with or without special educational, physical, or mental health needs; with or without preadoption trauma. And he or she may or may not differ from the adoptive family in ethnicity, race, religion, class, sexual orientation or gender identity, and other ways. A child might enter adoption via a private agency, from another country, without licensed agency involvement, with or without preadoption counseling and education for the biological and adoptive parents, and with or without having a voice in the adoption plan. A birth parent might choose to terminate parental rights voluntarily or have parental rights involuntarily terminated by the court. An adoptive parent might pursue adoption due to infertility or myriad other reasons. Providing

effective preadoption planning and education requires thorough knowledge of the issues each path to adoption presents, and skills for helping biological and adoptive parents and children plan to manage these issues across the lifespan.

For example, due to federal legislation (Adoption and Safe Families Act of 1997, P.L. 105–89) child welfare practitioners may begin “concurrent planning” for both reunification with the biological family and for adoption as soon as the state becomes involved in a biological family that has abused or neglected its children; the aim is to form a collaborative, cooperative relationship between the biological and foster parents so they can continue to form a circle of shared love around the child regardless of which permanency plan emerges. This approach seeks to build family connections and supportive relationships in the child’s life rather than severing them. The approach also presents unique challenges for child welfare workers, clinicians, and clients both before and after adoption takes place.

KNOWLEDGE AND SKILLS FOR ADOPTION COMPETENT PRACTICE

The many areas of knowledge and skill comprising adoption competency can be viewed in three interwoven conceptual categories: the societal context, interpersonal relations, and intrapsychic dynamics. Although these categories are neither exhaustive nor mutually exclusive, they are useful for organizing the complex array of knowledge and skills that help define adoption competence.

Societal Context

Law. Knowledge of adoption history and law is useful, given that both shape preadoption planning and postadoption issues, not only in child welfare work but in clinical practice as well. Each of the 50 United States and the District of Columbia, and each country across the globe, has its own adoption laws, complicating adoption practice. In addition to state law, there are federal laws and international agreements with which social workers should be familiar in order to provide informed services both before and after an adoption is finalized. For example, one should be familiar with The Multiethnic Placement Act (MEPA) of 1994 as amended by the Interethnic Adoption Provisions (IEP) of 1996; Indian Child

Welfare Act (ICWA) of 1978; Adoption and Safe Families Act (ASFA) of 1997; Safe and Timely Interstate Placement Act of 2006; Child and Family Services Improvement Act of 2006; Fostering Connections to Success and Increasing Adoptions Act of 2008; Hague Convention on Protection of Children in Intercountry Adoption of 1993.

Prevailing Beliefs. Adoption history and law also reflect and perpetuate myths and beliefs that may permeate unhelpful child welfare and clinical practices. Although public attitudes toward adoption have evolved away from viewing the adoptee as a “bastard” who must be protected from the truth by secrecy and total disconnection forever from the biological family (Princeton Research Associates, 1997), many social workers, along with the general public, continue to hold views and use language that unwittingly convey erroneous, pejorative misconceptions and stereotypes about adoption. For example, one hears, “I could never give up my own flesh and blood,” “His real mother gave him away,” or “She decided to keep the baby,” phrases that imply that the adopted child was unwanted, cast away, and that birth parents are reviled. The phrase “blood is thicker than water” implies that adoptive family relationships are not as strong as biological family connections. Practitioners with adoption competency are familiar with these and other terms and phrases that may unintentionally oppress and avoid these terms in favor of “neutral language” to describe the adoption experience. For example, the phrases “The biological mother and father made an adoption plan for their child” or “The birth mother chose to parent,” convey that adoption is a responsible, affirmative choice. Another example of adoption competent language is to avoid calling an expectant biological parent “birth mother” or birth father when she or he is thinking about making an adoption plan, reserving the term “birth parent” only for the biological parent who has finalized an adoption, so as to avoid exerting subtle pressure on the biological parent to choose adoption instead of choosing to parent (Smith, 2006). These and many other nuances of language exert powerful messages that shape not only adoption policy and child welfare practices, but clinical social work practice in mental health and therapy as well.

As the above suggests, adoption talk can reflect or evoke primal emotions, including within the child welfare worker or clinician, who must remain keenly aware of her or his beliefs

and feelings and the ways these shape assessment and intervention. The history of adoption is fraught with examples of how well-intended, confident, but ill-informed social workers have influenced and controlled adoptees and parents, harming them in the process (Carp, 2000). For example, the birth parent who suffers from drug addiction and gives birth to a child who tests positive for cocaine, may be seen as uncaring and willfully dismissive of the child's needs, not as a person struggling with a severe medical and mental health issue; the worker's anger and pejorative judgments about addiction can interfere with effective service delivery. Similarly, the clinician might feel frustrated with the adoptive parent who continues to make condemning statements about the birth parent to a child who feels distraught by divided loyalty, or when an adoptive parent insists that the child has no questions or feelings about adoption even when the child has expressed these in family therapy sessions. Adoption competency includes awareness of and ability to effectively manage such countertransference, including one's own feelings about and experiences with adoption, and the compassion fatigue and vicarious trauma that social workers in adoption may experience.

Racism, Oppression, Discrimination.

Adoption competent practitioners are cautious about "color blindness," the assumption that an adoptive family can raise a child of a different race or ethnicity as if the child comes from the adoptive family's heritage. The practitioner must know how, for example, to offer information gently to parents who adopt a child of a different race or culture, about the importance of weaving the child's racial and cultural identity into the fabric of the family's daily life, perhaps by including books, foods, music, friends, religion, schools, and other activities that reflect the child's ethnic origins. Practitioners can help parents and children anticipate the possibility of, and figure out ways one might respond to, intrusive, insensitive comments, questions, and societal racism so that the responsibility of being a transracial or transcultural family is shared, not borne by the child alone. The adoption competent practitioner is able, in a noninvasive, noncontrolling way, to explore with parents their wish that their loving and accepting the child, alone, will erase the need to do these things. Adoption competency also includes knowledge and skills for preparing and supporting adoptive families with lesbian, gay, bisexual, and transgender parents or youths.

Programs and Services. Although certainly not every adoptive family will need ongoing clinical support, the adoption competent practitioner is able to help families in need access and advocate for adequate adoption subsidy payments, special education services, residential schools and programs for significant behavioral health or learning issues, support groups, and other services (Dore, 2006). A family may benefit from access to an adoption competent clinician with whom they have a good working alliance so, if needed, they can tap into clinical services at points of discomfort for short-term help from time to time (Pavao, 2005), given that it is normal for adoption issues to re-emerge across the lifespan.

Laws, prevailing beliefs, racism, oppression and discrimination, and access, or lack thereof, to needed programs and services, highlight the need for ongoing analysis of ethical issues in adoption. Ethical dilemmas, and decision making, permeate every aspect of social work practice and policy in adoption (Siegel, 2009).

Adoption Ethics. The practitioner must be fully informed of the panoply of ethical issues, dilemmas, and choices embedded in adoption laws, policies, and clinical practices (Freundlich, 2000a, 2000b, 2000c, 2001), especially those related to issues of privacy, autonomy, paternalism and self-determination, confidentiality, informed consent, boundaries, and conflicts of interest. Adoption competency involves the ability to identify these issues, and apply ethical decision-making protocols from the professional ethics literature to address these ethical challenges in child welfare policy and clinical practice (Reamer & Siegel, 2007).

Relational Context

The relational and intrapsychic issues that may need to be addressed, and the skills involved in managing these successfully, vary depending upon the phase of the adoption process. Before a family is formed through adoption, competent preadoption education and planning are essential to enhance the participants' well-being. Once the adoption is finalized, members of the extended family formed by adoption may at times benefit from postadoption education and support.

The adoption journey entails normative, predictable developmental phases and tasks that may emerge throughout the life cycle of the family and of each individual family member. Adoption competent practitioners are aware of

these likely issues. For example, often when a child in foster care is adopted by the foster family with whom he has always lived, grief over having the legal connection to the birth family severed may lead the child to misbehave, even as people are celebrating the adoption as a happy event. An adoptive parent who feels wounded by his infertility, unsure of the child's attachment to him, or not entitled to parent a child born to someone else, might hesitate to discipline the child effectively. An adopted person who moved through childhood with few adoption feelings, may experience intense adoption-related feelings for the first time upon leaving home for college or upon giving birth. A birth parent who feels guilty about terminating her parental rights might not respond to a child's or adoptive parent's request for contact. Adoption competent clinical social workers are able to identify and then address therapeutically the many different ways that living with adoption may affect the participants (Hutchison, 2007). This involves exploring for the issues without insisting on them or denying each family's uniqueness.

Family System Dynamics. All families, whether formed by birth or adoption, have internal family system dynamics; some of these dynamics reflect predictable themes in many families formed by adoption, so clinicians need specific skills to help families navigate these. For example, when a teen says, "You can't tell me what to do. You're not my real mother!" the adoptive parent may need emotional and practical support in figuring out how to assert parental authority while also responding to the teen's adoption feelings.

In some respects, the family system formed by adoption may be best understood as a complex intersecting network of biological and adoptive grandparents, aunts, uncles, cousins, siblings, friends, neighbors, teachers, clergy, physicians, lawyers, adoption professionals, and others who play a role in the adopted person's life and both affect and are affected by the adoption. The adoption competent practitioner recognizes, assesses, and intervenes with the interplay and dynamics generated by these multiple actors. For example, the practitioner anticipates how adoptions through kinship care (i.e., a member of the child's birth family becomes the adoptive parent, shifting biological family roles) present complex issues and is able to help members of the kinship system manage these.

The omnipresence of electronic communication tools and devices has introduced new issues into the child's adoptive and birth families. Where once adoptive and birth parents could reasonably expect to control the child's access to contact with biological relatives, today, social networking sites, cell phones, text and instant messaging, video conferencing, and Twitter accounts create ample opportunities for very young adoptees to communicate with birth-family members with or without a parent's knowledge. For this reason, too, families may find adoption competent guidance helpful in preadoption planning and then in living the adoption adventure that unfolds.

One size does not fit all in adoption competent practice. Hence, although it is essential to recognize that an adoptive family may encounter thematic issues, not every family experiences these issues, or does so in the same ways or at the same times, and the issues may be impossible to tease out from other challenges in the family's experiences and development (e.g., the shifting of family roles and expectations as children reach adolescence, the impact of births, unemployment, illness, divorce, or death). Family systems issues and individual psychological issues are intricately interwoven in all families; assessing for these and intervening with adoptive families requires specific, well-honed assessment and intervention skills.

Open Adoption Issues. Most adoptions in the United States today include some form of openness, in which birth family and adoptive family members, including the child, exchange identifying information and have some degree of ongoing contact with each other (Siegel & Smith, 2012). Effective clinical work with adoptive and birth families requires advanced knowledge and skill about the vast array of open adoption alternatives, the reasons for open adoption, predictable challenges that may arise during the open adoption experience, evidence-based guidelines for successful open adoptions, and skills to help biological and prospective adoptive parents negotiate and maintain workable contact agreements. Adoption competency involves knowing how to work with biological and adoptive family members, helping each clarify for themselves their hopes, needs, fears, and anxieties about contact, and then helping them communicate and negotiate with each other truthfully, respectfully, and compassionately as they develop contact agreements that shift over time as participants' needs change (Siegel, 2013; Siegel, 2012). A clinician

may be helpful when families need to put contact on hold without permanently severing the relationship. In adoptions with no openness, the competent clinician knows how to identify and address the resulting issues.

Search and Reunion Issues. Each member of the extended family of adoption may face decisions about whether, when, and how to reach out to biological relatives and then how to manage the lifelong issues that reunion generates. The adoption competent practitioner is fully informed about these issues, and knows how to help participants navigate them, including how to connect participants with organizations such as the American Adoption Congress for practical and emotional supports.

Child and Family Developmental Issues. The child's biological and adoptive family units experience predictable developmental phases, as does the child and each person within the respective families. The families' and individuals' developmental phases and tasks intersect. The child's understanding of adoption changes as the brain develops. The adoption competent provider is able to identify these phases and the issues each presents, and effectively uses a variety of therapeutic methods, including psycho-education, to help participants address them. The practitioner knows how to help parents find the words to talk helpfully with the children about adoption at each stage of life, sharing difficult adoption-related information truthfully and sensitively in a timely manner. Adoption competency includes knowing how to help parent and child construct an accurate, life-affirming adoption story that acknowledges both the gains and challenges adoption brings. The adoption competent practitioner is able to help families create a birth book or life book and access support groups and Internet resources.

Intrapsychic Context

Silverstein and Roszia (1998) posit core, normative "affective responses" to adoption that birth parents, adoptive parents, and adoptees experience across the lifespan, all in their own ways. These issues include loss, rejection, guilt and shame, grief, identity, intimacy, mastery, and control. Among other core issues identified in the adoption literature are anger, fear of abandonment, trust, loyalty, and self-esteem (Javier et al., 2007). For example, the adopted person, birth parent, and adoptive parent may each fear and

avoid intimacy in different ways and for different reasons, as love and loss are closely connected in adoption. Adoption competency involves the ability to assess for these core issues without insisting on them; validate and normalize them without minimizing or exaggerating them; and use an array of therapeutic methods to support families and individuals in processing and managing them. This alleviates the client's burden of having to educate the clinician about what the issues are and what it means to live with the issues.

Trauma, Attachment, Neurobiology, and Brain Plasticity. Much has been written about the notion that even when an infant is adopted at birth there may be traumatic loss (Verrier, 1993). Certainly, children who were abused or severely neglected prior to adoption have experienced trauma. Trauma affects the child's brain development in ways that may impact attachment, social and relationship skill development, emotional self-regulation, academic performance, problem solving skills, and coping (Szalavitz & Perry, 2010; Cozolino, 2006). The adoption competent practitioner is fully informed on these issues, knows the relevant neurobiological research, and is skilled in using evidence-based methods to address the issues therapeutically with both child and family to foster secure attachments and brain plasticity.

Behavioral Health and Behavior Management. The operant conditioning methods taught in typical parenting classes may not work well with a child who has experienced traumatic loss; a particular child's brain might not be wired to learn from typical parenting tools such as logical consequences, time outs, rewards and punishments, so clinicians must know how to help parents and teachers use collaborative problem solving methods, environmental management, and other coping tools to deal with problematic behaviors, avoiding the inclination to label the child as willfully noncompliant (Greene, 2010). The child's noncompliant, inflexible, explosive, or oppositional behavior may indicate that the child is overwhelmed by internal stimuli or external situational demands. Adoptive parents, too, need strengths-based clinicians who are careful not to assume that the child is misbehaving because the parents lack basic child behavior management skills. Adoption competency involves forming collaborative, supportive alliances with parents as equal members of the treatment team, valuing their unique knowledge of the child, helping

them process their frustrations and fears, and exploring with them parenting strategies that go beyond the kinds of parenting education typically offered.

Genetics. The nature versus nurture debate permeates the world of adoption. Parents who adopt tend to believe in the healing powers of love, structure, and a nurturing environment. They need social workers who both support these beliefs and help parents embrace the reality that genetics and prenatal or childhood trauma may play crucial roles in the human organism's tendency toward a particular mood, social abilities, academic, athletic, mechanical, and other proclivities. Clinicians with adoption competencies use reframing, psychodynamic, cognitive behavioral, psycho-educational, and other psychotherapeutic methods to help adoptive parents avoid blaming themselves or the child for the child's challenges. They help parents take the long view, seeing struggles as opportunities for growth, as parents strive to maintain stable, nurturing, compassionate, family relationships.

EVIDENCE BASE FOR ADOPTION COMPETENCY

It is clear that adoption competency is essential for child welfare workers, clinicians providing mental health care and therapy, administrators and policy makers. A few adoption competence training programs exist. An outcome study measuring changes in knowledge and skill of master's level mental health providers who completed the CASE curriculum demonstrates that program's effectiveness (Atkinson, Gonet, & Riley, 2013). Important next steps include (1) building into Masters of Social Work curricula the values, knowledge, and skills that underpin adoption competence; (2) offering adoption competency training for public- and private-sector child welfare workers and master's degreed clinicians in every state; and (3) completing formative and summative evaluation studies of adoption competency education efforts so that the most evidence-based protocols can be used.

27 Crisis Intervention with Individual and Groups

Frameworks to Guide Social Workers

Yvonne Eaton-Stull

Crises are inevitable in the social work field. No matter where practitioners work, clients will present with a variety of crises: a teenager who experiences her first breakup and is contemplating suicide, a husband who loses his job and is distraught over how he will care for his family, or a child who loses both parents in a tragic motor vehicle accident. All of these scenarios are potential situations that social workers may encounter in their work. Events known to precipitate crises often involve health/mental health issues, financial problems, legal problems, victimization, loss, or natural and other disasters (Roberts & Yeager, 2009). A crisis is individually determined—that is, the individual client lacks the resources or coping skills to handle the stressful situation with which he or she is confronted.

Several different people may experience the same traumatic event, but each responds in a unique way. A practitioner's ability to assist individuals in mobilizing their strengths, protective factors, resilience, and positive coping methods will help to resolve the crisis situation.

An understanding of crisis theory and crisis intervention is essential for competent social work practice. Social workers should be educated and skilled in handling the full range of acute crises episodes because clients frequently present with difficulties and obstacles to crisis resolution and stabilization without intervention (Knox & Roberts, 2008). Crisis intervention consists of the various techniques used to assist individuals in mobilizing resources and developing plans to overcome the temporary situation. It can provide a challenge, opportunity, and turning point (Roberts, 2005).

Unlike typical counseling interventions, crisis work requires a special set of skills and interventions to effectively assist those in need. Greenstone and Leviton (2011) refer to crisis intervention as problem management, not resolution, because it involves quick decision making and the ability to mobilize needed resources. The purpose of this chapter is to provide social workers with practical frameworks to guide individual and group intervention.

FRAMEWORKS FOR INDIVIDUAL CRISIS INTERVENTION

Although social workers have been trained in a variety of theoretical models, very little coursework has provided them with a guide to follow in dealing with crises. Roberts's (2005) seven-stage crisis intervention model and Greenstone and Leviton's (2011) crisis intervention procedures offer two useful frameworks. The subsequent sections will outline each of these models followed by a scenario to illustrate the steps involved.

Roberts Seven-stage Crisis Intervention Model

Stage 1: Plan and Conduct a Crisis Assessment

The first step involves a quick assessment of risk and dangerousness, including suicide and homicide/violence risk assessment, need for medical attention, and current drug or alcohol use (Roberts, 2005). There are a variety of formal assessments for risk of suicide/homicide, but

these tools should always be accompanied by a thorough clinical assessment with information from the individual as well as other relevant sources of information. Key risk assessment questions are outlined in Table 27.1.

Answers to these questions will help the social worker determine the appropriate next steps. Substance use is an important factor to evaluate because it can contribute to impulsively acting on these thoughts. In addition, a substance assessment should include information about drugs used, amount used, last use, and any withdrawal symptoms the client is experiencing (Eaton & Roberts, 2002). If possible, a medical assessment should include a brief summary of the presenting problem, any medical conditions, current medications (including dosages and last dose), and allergies (Eaton & Roberts, 2002). This medical information is essential to relay to medical responders

attempting to treat problems, such as overdoses, if they are in progress.

Stage 2: Rapid Establishment of Rapport This often occurs simultaneously with stage 1. Conveying respect and acceptance are key skills in this stage. Workers must display a non-judgmental attitude as well, ensuring that their personal opinions and values are not apparent or stated (Roberts, 2005). Roberts and Yeager (2009) also note that creativity, flexibility, and a positive attitude are additional strengths in successful crisis workers.

Stage 3: Identify the Major Problems Use of open-ended questions will offer a strategy to hear more from the client’s perspective, such as asking a client what happened to bring them to this point. This provides the crisis worker with valuable insights into the nature of the presenting problem and potential precipitating events.

Stage 4: Deal with Feelings and Emotions Active listening skills are essential during this stage. Clients should be encouraged to share their story as the practitioner listens intently in order to understand their situation better (Roberts & Yeager, 2009).

Stage 5: Generate and Explore Alternatives Ideally, the ability of the worker and the client to work collaboratively during this stage should yield the widest array of potential resources and alternatives (Eaton & Roberts, 2002). According to Roberts (2005), individuals in crisis have untapped resources and coping skills, which can be utilized to help them resolve this crisis. At this point in the intervention the social worker should use solution-focused questions to explore strategies the client has used previously to help them through rough times. These may potentially be useful in formulating the action plan.

Stage 6: Develop an Action Plan The crisis worker should assist the client in the least restrictive manner, enabling them to feel empowered (Eaton & Roberts, 2002). Important steps at this stage include providing coping mechanisms and identifying persons and referral sources to be contacted (Roberts, 2005). According to Jackson-Cherry and Erford (2014), action plans should include (1) information about restricting access, such as removing guns; (2) strategies for self-care/stress management; (3) family supports;

TABLE 27.1 Questions for Assessing Risk

	Suicide & Homicide Risk Assessment
Ideation	1) Are you having thoughts to kill yourself/someone else?
Furtherance	2) Have you done anything already?
Past history	3) Have you ever tried to kill yourself/someone else in the past? If so, how?
Plan/method/ lethality	4) How might you kill yourself/someone else?
Availability of means	5) Do you have access to the methods (cited in Question 4)?
Protective factors/hope	6a) What is stopping you from acting on these thoughts? 6b) Do you feel things can get better?
Supports	7) Can you tell me who in your life might be a support to help you through this?
Substance use	8) What drugs or alcohol have you used today?

(Eaton & Roberts, 2002)

and (4) mental health resources. Writing such a plan on a carbon-copy form allows a quick way for both the social worker and client to agree and document the process.

Stage 7: Follow-up Crisis workers should follow up with the client after the initial intervention to ensure the crisis has been resolved (Roberts & Yeager, 2009). This allows an opportunity to determine whether the client has followed through with recommendations and continued care. If indicated, additional referrals can be made at this time.

Scenario 1 (Application of Roberts Seven-stage Crisis Intervention Model)

The social worker received a call from a concerned parent whose daughter posted a disturbing statement on her Facebook wall, in which she said good-bye to her friends and family because she could not take it anymore. Roberts's (2005) seven-stage crisis intervention model was initiated.

Stage 1: Assess Lethality. The mother had little information about the current mental status of the client and was fearful because she was unable to reach her by phone. The worker responded to the residence hall and found the student crying and curled up in her bed. There were bottles of over-the-counter medication on her desk. A quick assessment revealed that this female was having thoughts to kill herself by overdosing on Tylenol and ibuprofen, which were readily available to her. She had a prior overdose attempt in high school, but was physically stopped from doing so by her best friend. She did not receive any treatment at that time. She reported that the only thing stopping her now was that she hoped her ex-boyfriend, who had broken up with her earlier that day, would see the post and come over. She did not feel she would survive if he did not and was feeling more hopeless with each passing minute that he did not respond. This student had not taken any substances or any of the over-the-counter medication yet.

Stage 2: Establish Rapport. Understanding and support were two essential skills used by the crisis worker to establish a working relationship with the client. Emotional validation was especially helpful in validating how upsetting an unexpected breakup of a two-year relationship could be.

Stage 3: Identify Problems. Luckily, the client had not yet done anything to harm herself, but she was actively contemplating suicide. She had a plan to overdose, but was hoping her ex-boyfriend would see her Facebook post, and they could reconcile. The client expressed that the precipitant was the breakup with her boyfriend.

Stage 4: Deal with Feelings. The worker allowed the client to tell her story about the breakup and her relationship history. The worker was able to validate and identify the client's emotions. Based on the level of intensity of the student's emotions, it was necessary to pursue a higher level of care.

Stage 5: Explore Alternatives. Together, they began to explore more effective ways of coping with her upsetting feelings. Options were discussed, including calling her mother and giving the student the option to obtain a mental health assessment in her home city (with mother's assistance) or the nearby hospital (near the college).

Stage 6: Develop an Action Plan. The client requested that her mother be consulted to help her decide. The mother felt that being near home would allow for more family support. Luckily, the client's home was only about two hours from school, so the mother agreed to come to campus and take her daughter to a hospital near her home. A release of information was obtained for the home hospital, and a phone call was made to the crisis assessment staff to provide referral information.

Stage 7: Follow-up. A follow-up phone call was made to mother the next day. The client was admitted on an inpatient mental health unit at the hospital near her home.

Greenstone and Leviton's Crisis Intervention Procedures

Step 1: Immediacy According to Greenstone and Leviton (2011), this step is critical in assuring that clients do not harm themselves or others. Potential actions such as enlisting the assistance of emergency personnel, police, or other supports may be useful during this step.

Step 2: Control This step is a more directive process. The social worker will attempt to assess the surrounding and individuals present. The

purpose of this step is to help lessen the current chaos as the practitioner maintains a calm, supportive demeanour while attempting to establish structure (Greenstone & Leviton, 2011). One key element during this step often includes separating the client from others who may be fuelling an already intense situation.

Step 3: Assessment During this step, the social worker obtains a lot of helpful information. Unlike typical social work sessions that involve a complete biopsychosocial history, a crisis assessment is more focused on the current struggle and recent precipitants. Greenstone and Leviton (2011) suggest the worker attempt to gain recent information about what happened to the client, why they are having difficulty coping, and what type of intervention is needed. This step also requires a thorough safety risk assessment as previously outlined in Table 27.1. Taking time to hear the client's stressors thoroughly helps the worker determine what areas need immediate attention and as such, what must be included in the disposition.

Step 4: Disposition Greenstone and Leviton (2011) indicate that this step includes the decision about how to handle the crisis situation. Key skills during this step include creative thinking, problem-solving, and considering various options (Greenstone & Leviton, 2011). Based on information gained in the previous step, it is hoped the social worker will have identified existing resources that may be helpful to include in the decision making process.

Step 5: Referral Almost all crises involve making referrals. Often times, this may include referrals to emergency services or hospitals with inpatient mental health care; thus, it is important to have knowledge of local resources. Greenstone and Leviton (2011) suggest that practitioners take steps to build relationships with these crisis providers before being faced with an actual crisis; for example, visiting other agencies, making a resource list, and investigating transportation options.

Step 6: Follow Up Step six is an important step many practitioners fail to complete; however, it can be potentially helpful in preventing another crisis. Greenstone and Leviton (2011) indicated it is important to determine whether the client has connected with the referrals provided or if assistance or re-referrals are needed.

Scenario 2 (Application of Greenstone and Leviton's Crisis Intervention Procedures)

A professional residence life staff member phoned the on-call worker due to a resident assistant's (RA) concern about a student who was cutting herself.

Step 1: Immediacy. In a college setting, it is not uncommon to receive a call from a concerned roommate or residence life professional. It is important to consider the safety of all involved; thus, staff members were directed to call security to assist in securing the knife and support the student until the worker could arrive. It was also suggested that the professional staff evaluate the injuries to determine whether immediate medical attention was needed, and if so, to call an ambulance.

Step 2: Control. Upon arrival, the worker determined that five individuals (security, RA, professional staff, security, and roommate) in addition to the client were present. There were approximately three scratches on the student's arm that had not required medical intervention. The student was cooperative and willing to talk. Following introductions, the student was given some control by asking which one person, if any, she would like to remain as a support. She chose her RA. Others were thanked for their help and informed that they would be contacted if further assistance was needed.

Step 3: Assessment. The student was very open and indicated that she was feeling left out by her hall mates. She admits that she took a nap after class, and therefore, her door was closed and they did not wake her up to go to dinner with them. As a freshman, she was concerned about fitting in and having friends. She denied that her cutting behavior was a suicide attempt, and in fact, denied any suicidal ideation, stating she really liked college and the freedom she had. Her cutting behavior was a past method of coping with upsetting feelings. She interpreted the event as a purposeful way of excluding her from dinner. We explored alternatives, such as the fact they may have thought she was not in her room due to the door being closed. She admitted this was possible. She acknowledged that her RA really attempts to include the floor in various events and is always available to talk to the students on her floor.

Step 4: Disposition. We talked about the need for more effective coping skills, given that her cutting behavior was concerning to others. She acknowledged this and was willing to seek assistance to manage her emotions and coping strategies better. Further, we discussed a simple strategy of writing on the dry erase board on her door that she was napping and to please wake her up for dinner; this way her friends would know she was there and was hoping to go to dinner with them.

Step 5: Referral. A referral was made to the campus counseling center for the next morning.

Step 6: Follow-up. The student kept her scheduled appointment and treatment began. A more detailed crisis plan was developed at this time to assist the student in identifying options for coping with intense emotions, which included supports and other resources.

GROUP CRISIS INTERVENTION

Individual intervention can be guided by the above frameworks, but group intervention requires a different approach. A sudden, traumatic death of a friend may impact a large group of students, or a natural disaster may impact an entire community. The scope and magnitude of a crisis may require social workers to intervene with several individuals simultaneously.

According to expert consensus, psychological first aid (PFA) is the recommended intervention (Kaul & Welzant, 2005; Watson, Brymer, & Bonanno, 2011). PFA is also endorsed by the North Atlantic Treaty Organization (NATO) as the evidence-informed approach to decreasing distress and fostering adaptive functioning and coping (NATO Joint Medical Committee, 2008). PFA includes the following actions—to be provided by the practitioner: (1) making contact and engaging with survivors, (2) enhancing safety and comfort, (3) calming and stabilizing survivors, (4) gathering information, (5) providing practical assistance, (6) connecting with social supports, (7) giving information on coping, and (8) linking with collaborative services (National Child Traumatic Stress Network [NCTSN] & National Center for PTSD [NCPTSD], 2006). Free Web-based training is available for social workers to enhance their knowledge and skills in this area.

Responders must be especially skilled in Steps 1–3 in order to facilitate the other recommended steps of PFA. For example, connecting, comforting, and calming distraught individuals leads to an increased ability to obtain critical information and facilitate appropriate connections. Properly certified crisis response dogs are a great tool to assist practitioners in accomplishing these initial steps of PFA. For more information on animal-assisted social work, readers are encouraged to read the chapter on animal-assisted social work intervention (Chapter 37). Below are three observations of PFA in action, offered by providers following traumatic crises that required group intervention. Each testimonial provides qualitative evidence of how these specially trained and certified HOPE Animal-assisted crisis response dogs engaged with, comforted, and calmed those in crisis, ultimately fostering sharing and connections to facilitate healing from traumatic events.

Example 1: Mercyhurst University, following a homicide of a student, provided intervention to a group of students/friends. Dr. Judy Smith (personal communication, August 15, 2013) offered the following observations: “The appearance of the crisis dogs provided the first felt lifting of moods that we saw in the days after the death of our student. When the teams of dogs and handlers entered the room where a large group of students were meeting, the students immediately went to the animals, petting and hugging them, and asking the handlers many questions. The sense you had as you watched this was that there was an immediate, visceral connection between canine and college student that provided students with a keen sense of comfort and reassurance. There was a clear sense of something important being exchanged as students ran their fingers thorough fur, dodged wagged tails, and buried their faces against another living creature that was willing to simply stand there in the moment with them openly offering its affection and simple presence.”

Example 2: A camp director, Kerri Franks, runs an annual camp, Camp Quality, to support children with cancer, and unfortunately each year children are lost to this devastating illness. Kerri Franks (personal communication, August 13, 2013) offers this testimonial demonstrating PFA in action: “The HOPE AACR dogs have provided tremendous support to our children with cancer, especially during our Remembrance Celebration

(a video slideshow/memorial of campers who have died). Not only have they helped emotionally, we also see the physical benefits of calming down, slower breathing as the children pet the dogs or talk to the dogs and the ability to sit or stay with whatever emotion they are having due to the dog laying or standing beside them. The connection the HOPE dogs make with the kids and the kids with the dogs is truly amazing. The children are captivated by each dog's personality and calmness, which in turn allows the kids to calm themselves."

Example 3: Kathleen Frisina, LPC, a grief specialist/counselor, has witnessed and utilized crisis dogs in her group work with grieving children. Kathleen Frisina (personal communication, August 12, 2013) offers the following professional insights: "When death enters a child's life, nothing is ever the same. It crashes in and changes the present and future. Someone important is missing, often on a daily basis and on those milestone events throughout their lifetime. Often there is a mix of feelings, sadness, anger, or loneliness being among them. Crisis dogs have a presence, a presence that allows the child (or adult) to feel cared for, a presence that allows petting and cuddling to bring a calming effect, and a presence that often opens conversation to a listening therapeutic animal that creates safeness."

Responding to group crises can be overwhelming, even for the experienced practitioners. The utilization of these specially trained and certified crisis response dogs can add an invaluable tool, which assists the practitioner in accomplishing the goals of crisis intervention and PFA. These specially trained animals also offer an added benefit to the practitioner personally by reducing stress caused by their work. HOPE Animal-assisted crisis response (www.hopeaacr.org) is one of two national organizations that offer certified teams to assist practitioners in responding to crises and disasters.

CONCLUSION

Social workers are increasingly being expected to provide brief interventions. Managed care restrictions and concerns of violence are placing pressure on practitioners to be skilled in effectively assessing risks and needs and in providing rapid intervention (Eaton & Roberts, 2002). Roberts's (2005) seven-stage model and Greenstone and

Leviton's (2011) crisis intervention procedures provide social workers with beneficial frameworks. Utilization of one of these models will assist practitioners in effectively resolving individual crises. Additionally, psychological first aid is the recommended strategy for group intervention. Certified crisis response dogs offer a great tool to assist practitioners in effectively meeting the PFA goals.

28 Fundamentals of Brief Treatment

Jan Ligon

As managed care models for behavioral health and other social services have increasingly become the norm (Dziegielewski, 2004), the use of brief intervention models has continued to expand. Even before the advent of managed care, brief services were simply the nature of practice in many settings (schools, hospitals, home health services, and others). Indeed, studies cited by Miller, Hubble, and Duncan (1996) note that clients expected the duration of services to be brief, and the vast majority concluded services in four to eight sessions. Therefore, it is essential for social workers and administrators to be familiar with brief models of practice.

Following an overview of the roots and theory of brief practice, this chapter summarizes the key assumptions, practice components, and approaches to brief social work practice, along with outcome measures, evidence of effectiveness, limitations, and a case example to illustrate an application of the chapter content.

ROOTS AND THEORY

A time-limited perspective has been dated to the work of psychiatrists with World War II veterans in the mid-1940s (Budman & Gurman, 1988), although more contemporary approaches can be traced to the work of Milton Erickson in the 1950s (de Shazer et al., 1986). Many of the theoretical

approaches, assumptions, and techniques of brief work, as it is practiced today, are grounded in the endeavors of two centers—Mental Research Institute’s (MRI) Brief Therapy Center in Palo Alto, California and the Brief Family Therapy Center (BFTC) in Milwaukee, Wisconsin, which provided training and resources for 25 years (1982–2007).

MRI began in 1959 and approached working with clients from a theoretical perspective that differed from the more common approaches of that time in several ways.

1. Problems were viewed as normal occurrences in life; this stance was a radical departure from theories grounded in pathology, deficits, and dysfunction.
2. The purpose of treatment was to make changes, preferably small ones. Insight and meaning, the cornerstone of some treatment, was not the goal of working with clients.
3. The role of the clinician was to be an active and engaged participant who works with what the client brings.
4. The model explicitly limited clients to a maximum of 10 sessions based on the assumption that “a time limit on treatment has some positive influence on both therapists and patients” (Weakland, Fisch, Watzlawick, & Bodin, 1974, p. 144).

Unlike MRI, the BFTC approach did not specify a number of sessions, and the focus was on developing solutions to problems (de Shazer et al., 1986). Both MRI and BFTC note the importance of how the therapist views people, their problems, and solutions.

Milton Erickson, a psychiatrist, was an important influence on those involved in the development of brief approaches to treatment. Although he claimed to not have a theoretical basis for his work (O'Hanlon & Weiner-Davis, 1989), two of his terms are fundamental to brief work. The first is *expectancy*; simply stated, this is the social worker's belief that people and situations can change and the lives of people can be better. This concept is deceptively simple; it is one thing to understand the term and another to embrace the concept to the extent that one's practice connotes this sincere belief. Clients pick up on this very quickly, and the effective social worker truly knows that things can be better; it may not happen, but it can. The object is to set the client up for a positive self-fulfilling prophecy. The second term is *utilization*; the work is conducted with what the client brings (O'Hanlon & Weiner-Davis, 1989). In fact, clients bring vast resources with them, including their past successes, survival skills, life wisdom, and stories that are used extensively in brief treatment models (Saleebey, 2012).

CORE PRACTICE SKILLS AND TECHNIQUES

Numerous authors have published detailed accounts of many techniques and strategies that can be employed in brief practice models (Budman & Gurman, 1988; de Shazer et al., 1986; de Shazer & Dolan, 2007; Dewan, Steenbarger, & Greenberg, 2004; Hudson & O'Hanlon, 1991; Miller et al., 1996; O'Hanlon & Weiner-Davis, 1989; Walter & Peller, 2000; Weakland et al., 1974). There are, however, five core areas of practice that are common to most approaches: (1) the use of time, (2) the approach to problems and solutions, (3) the use of language, (4) the development and measurement of goals, and (5) the use of a strengths perspective.

Use of Time

Obviously, time is a key concern in brief work, and given that most clients complete fewer than eight sessions, the use of time is actually a very manageable task. It is important to not view time

as only that which occurs in the therapy session. Many clients arrive early, and this time can be used to complete not only initial paperwork but also tools that can be helpful in a session, such as rapid assessment instruments to measure problems (Corcoran & Fischer, 2013). Next, clients can be asked about pretreatment change; that is, what has changed since the time the client made the appointment for the first session and the occurrence of the first session? Weiner-Davis found that when asked this, "two-thirds of the clients noticed changes" (de Shazer et al., 1986, p. 215). By inquiring about what is now different and how the client was able to get those pretreatment changes to occur, the social worker can begin to hear information that will help uncover client and family strengths and form solutions for change.

Approach to Problems and Solutions

The therapist's approach to problems is critical. First, it is important to acknowledge and validate clients' problems. If the social worker moves immediately into developing goals and solutions without acknowledging and hearing the clients' problems and issues, the client may not move forward (Hudson & O'Hanlon, 1991). However, to get stuck in a repetitive cycle of only acknowledging the problems will impede forward movement. Next, it is important to ask clients whether they have had a similar problem before and to inquire about how they handled it. This information is essential for use in further identifying client strengths, developing goals, and beginning to view potential solutions. Finally, it is important to not get bogged down in the details of the problem, but rather to find out when the problem does not happen; that is, which are the times noted as the "exceptions to their problems" (de Shazer & Dolan, 2007, p. 4). This is particularly helpful when working with couples; it is easy to find that an entire session's time has been consumed with accusations about the other partner and pleas for understanding about how it really is in the relationship. The brief therapist cannot afford to lose precious time in this manner, and ultimately it is not helpful to the clients. Therefore, it is important to acknowledge, find the exceptions, and move on (Hudson & O'Hanlon, 1991).

Use of Language

The choice of words in brief treatment is critical; language needs to connote movement, openness, the future, and a feeling that is action-oriented.

For example, the early works of MRI (Weakland et al., 1974) noted the importance of discussing *what* is happening or *how* things could be changed. The choice of the word *why*, however, seeks deeper understanding or may imply the need to delve into history; this is not helpful in brief work. O'Hanlon and Weiner-Davis (1989) note that the use of *yet* is helpful; "you haven't found the right job *yet*." Similarly, *when* can keep the dialogue moving forward, which is of key importance in developing solutions; "*when* you are working again" implies hope and a future.

Development and Measurement of Goals

At the core of brief work are the development, implementation, and measurement of goals. De Jong and Miller (1995) note that a well-formed goal is one that is important to the client, framed in the client's language, small, concrete, specific, behavioral, seeks the presence rather than the absence of something, is realistic, worthy, and is a step toward an end (see case example). Clients often do not accomplish goals because they are more of a vision than a goal. For example, "to become independent" or "to live a clean and sober life" are admirable desires for a client, but both are too big. Such goals can be overwhelming and a set-up for failure; both are only attainable through steps leading toward each goal. Therefore, if goals are carefully developed with the client, the likelihood of follow-through is improved, and clients may even accomplish more than the goal once they find that they are able to experience some initial success. Once measurable goals have been developed, it is important to look at outcomes assessment.

Like all service providers, social workers and agencies are increasingly required to document the outcomes of interventions and programs. Two common methods, self-anchored scales and rapid assessment instruments (RAIs), are helpful and simple ways to quantify outcomes. A self-anchored scale is very easy to develop (see case example) by merely asking the client to rate a problem or situation, one at a time, by scoring it from low to high (1 to 5 or 1 to 10). RAIs for use in assessing a wide range of problems are available from a two-volume sourcebook (Fischer & Corcoran, 2007). Such measures can be repeated at the beginning and end of treatment to establish change from pre-test to post-test; measures may also be taken at established increments

with the scores plotted to illustrate change over time. RAIs are particularly helpful during the assessment process to determine the severity of such problems as depression, anxiety, or substance use. Some instruments are also available at no cost from the Internet, including the Zung Self-Rating Depression Scale, which can be used as a screening tool for depression (see websites below for link).

Strengths Perspective

Working from a strengths perspective (Saleebey, 2012) is the antithesis of the approach used by many large human services systems that are based on pathology, dysfunction, symptoms, diseases, and the assignment of diagnoses. Inherent in these approaches, such as the medical model, is an assumption that the service provider is the expert, and the patient is advised what needs to be done by the expert. Social work practice from a strengths perspective recognizes that resources can be tapped within both the social worker and the client, as well as within the community. Therefore, the relationship is approached as collaborative and avoids hierarchy; the intent is to empower the client to collaborate actively in the change process. A strengths perspective acknowledges that the client possesses knowledge, abilities, resilience, coping, and problem-solving skills that are there to be employed. Certainly people get stuck, become overwhelmed, or experience events that render them unable to make full use of their strengths. It is important to identify and amplify strengths so that the client can go back and rediscover what has already worked for him or her in the past. Therefore, the role of the social worker is to facilitate the process, serve as a bridge to the client's own resources, move ahead, and seek solutions.

CASE EXAMPLE

This brief case example is based on an actual client and illustrates some of the fundamental techniques reviewed in this chapter. Katie, age 31, called to make an appointment with the employee assistance program (EAP) offered by her company. The service provided three free visits, although additional sessions could be added if needed. During a brief telephone screening, she stated that she had been feeling particularly down about her job and life and thought maybe it would help to talk to a

professional because things were not getting better. She was seen for her first appointment three days after the initial call.

Katie completed a self-reported instrument for depression (Radloff, 1977) as well as an initial information form in the lobby prior to her appointment. After brief introductions and an overview of the EAP services, Katie discussed that she feels very stuck in her life; she has been in the same job, with a modest salary, for six years. She has a high school education and realizes that this has held her back; she wants to move on in her life but finds herself in a rut. The dialogue continues.

Client: It seems lately that I'm not only feeling stuck, but I'm cranky; I cry easier lately.

Worker: You seem to feel trapped, but you want to move on in your life. [Acknowledge] You mentioned feeling down, crying more; how would you rate just how down you've been feeling from 1 to 10 with 1 being really down and 10 feeling on top of the world? [Measurement]

Client: Oh, I think like a 4 lately.

Worker: A 4, and the rating scale you completed for me shows about the same, a moderate level of feeling down. Have you had thoughts of wanting to hurt yourself? [Acknowledgment]

Client: No, never, and I don't drink or do drugs, thank goodness. [Strength]

Worker: That's good to know. Are you taking any medications right now for any reason?

Client: No, I don't take anything, I'm lucky; I'm in good health. And it's not like I'm clueless about my situation; I know that getting a college education would help. I need to do that.

Worker: So I'm hearing that you are a determined woman; you want more. [Validate, strengths] Can you tell me *what* I would *see* you doing *when* you have the college degree? [Language]

Client: Oh that's an easy one; I'd be teaching first grade. That's exactly what I want to do.

Worker: That's great; maybe you've already thought some about the process of getting from here to there. What *will* you do first *when* you begin the process? [Validate, language, goals]

Client: Oh I've thought a lot! I guess it's pretty straightforward—enroll and start classes.

Worker: Do you know which school or program you might pursue?

Client: Oh yes, the college is near my house; I think they have a program, I need to check.

Worker: Would it be possible to pick up some information and bring it next time? [Goals]

Client: Sure, I'll do that. I can stop by after work one day this week. [Goals]

When Katie returned for the next appointment, she had not only brought the catalog but had made an appointment to meet with the admissions counselor for the elementary education program the next week. This exemplifies the importance of goals that are realistic, small, seek the presence of something (the information), and take a step toward an end (a college education).

CAVEATS AND CAUTIONS

Brief interventions have been found to be useful in working with inpatient mental health clients (Durrant, Clark, Tolland, & Wilson, 2007; Lamprecht et al., 2007), for the prevention and treatment of substance abuse (Substance Abuse and Mental Health Services Administration, 2012), with couples (Davidson & Horvath, 1997), with children and adolescents (Monroe & Kraus, 2005; Newsome, 2005; Tripodi, Springer, & Corcoran, 2007; Valdez, Cepeda, & Parrish, 2013), for gambling problems (Larimer et al., 2011), in suicide prevention (Lamprecht et al., 2007; Petrakis & Joubert, 2013), and with families who have been affected by substance abuse (Ligon, 2004; Velleman et al., 2011). Indeed, clients have been found to be satisfied with only one, two, or three sessions (Ligon, 1996).

However, no single model is universal (Stalker, Levene, & Coady, 1999), and brief therapy is not suitable to all client situations. Although brief approaches view problems in a different manner than some other methods, they do not excuse the social worker from ethical and competent practice, including the assessment of mental status, medical concerns, and risk for suicide, homicide, child abuse, intimate partner violence, or other factors.

LOOKING AHEAD

It is common in social work for terms, interventions, and techniques to evolve and change over time. When managed care quickly moved

behavioral health services to a time-limited model, the interest in brief techniques escalated. Now the use of this approach is more in the mainstream of methods from which a social worker may choose, depending on the situation. Social workers are likely to continue to operate in environments that are tight on financial and human resources. Therefore, it will be important for them to continue to master the basic skills of brief practice in future years. Used appropriately by qualified and trained social workers, brief therapy models offer an approach that has been found to be helpful to a wide range of clients across many problem areas. Brief social work practice fits well with the profession's values of being with the client, self-determination, empowerment, and respect and dignity for the value and worth of each individual.

29 Common Factors in Psychotherapy

James W. Drisko

“Common factors” refers to a way of thinking about the “active ingredients” that generate change in psychotherapy and social work services. Simply put, the common factors perspective views the client–worker relationship, client factors, social environmental factors, and similarities in worldview between client and social worker as more important to creating change than any specific intervention technique. That is, rather than highlighting specific techniques, like Ellis’s ABC technique for tracking irrational beliefs, the common factors approach views the larger interpersonal context, such as being able to establish a therapeutic alliance, as most important to generating change. This perspective challenges researchers and scholars to take a broader view of what makes services effective. This broader view fits well with client interests, the practice wisdom of social workers, and key social work values.

The common factors perspective also fits well with clients’ own ideas about change. On a February afternoon, snow had been falling for several hours. I was unsure if I should leave my office—one client had not shown up, and another cancelled, but I had one more scheduled. Later, when Mr. B came into the office, he had a big grin

on his face. He said, “I was driving over here and conditions were awful. I was sure you’d have left to go home yourself. Then I got near and even from the street I could see the lights were on. I was really sure you wouldn’t be here, but you were! Now I know you care about me.” As we talked about his experience, it became clear that my reliability and trustworthiness meant more to him than anything I did as a specific treatment plan. He said he had learned to doubt words spoken by people in authority, and always judged more by actions than words. A few weeks later Mr. B. said his girlfriend, who had been negative on his therapy, had also changed her view because of this story. She had begun to be supportive, which made it easier for him to invest in our work together. Our work flourished.

A SCIENTIFIC UNDERSTANDING REQUIRES KNOWLEDGE OF BOTH OUTCOMES AND THEIR CAUSES

Both social work practitioners and researchers are concerned with knowing “what works” to help a given client and what aspects of

intervention lead to improvement. There are two questions here. First, what is the desired outcome of intervention, and second, what caused the change? It is important to keep in mind that determining outcomes and identifying the active ingredients that lead to it are both necessary components of a full scientific understanding. Documenting outcomes alone, without knowing what caused them, is not an adequate scientific understanding of a problem (Drisko, 2000). Stated more fully, the question for clinicians and practice researchers is “*what treatment, by whom, is most effective for this individual with that specific problem, under which set of circumstances?*” (Paul, 1967, p. 111, italics in the original). Client needs, characteristics, social circumstances, and treatments are each complex and multidimensional.

Based on compilations of high-quality studies of adults with depression and anxiety problems, there is strong evidence that psychotherapy leads to improvement compared with untreated comparison groups (Lambert, 2013). How much improvement is found? Wampold (2001), synthesizing several studies using meta-analysis, provides a summary statistic called effect size from 0.75 to 0.85 for the impact of these treatments. Effect size statistics range from 0.00 to about 3.0 in value. A 0.75 to 0.85 effect size is characterized as a large impact. According to Rosenthal (1984), it means that clients who complete therapy are better off than 79% of people without treatment. Such effect sizes show that “psychotherapy is more effective than many evidence-based medical practices” across several specialities (Lambert, 2013, p. 172). This research shows that many treatments work to yield improvement on these disorders.

A great deal of recent outcome research focuses on comparing one treatment model or technique to another model on the same disorder. This is useful to determine what treatments are most effective. However, the way in which such research is done tends to emphasize only specific techniques and ignores the impact of the client–clinician relationship and other nontechnique factors that may also influence outcomes. This is because many researchers assume all providers offer sufficient warmth, empathy, and genuineness to clients (e.g., Truax & Carkhuff, 1967). If this is a core condition of psychotherapy, some say, it does not need to be specified in psychotherapy research because it is always present. On the other hand, to ignore such factors may lead to

misleading or incomplete conclusions about what causes change.

As long ago as 1936, Rosenzweig stated that many different psychotherapies could lead to positive outcomes. His view was based on the idea that common factors—not specific therapeutic techniques—were indeed the most important ingredients of psychotherapeutic success. In the mid-1970s, a research method called meta-analysis was developed. Meta-analysis is a method for combining the results of many studies on the same topic to determine an overall rating of effectiveness, usually an effect size. Since then, several meta-analyses of the outcome of psychotherapy with adults who suffer from depression and anxiety have been completed. Since 1977, few enduring differences across types of psychotherapy have been demonstrated. Even as the technology of meta-analysis has been refined, a common conclusion is that there are no or minimal differences across therapies on these key adult problems (Ahn & Wampold, 2001; Grawe, Caspar, & Ambuhl, 1990; Smith & Glass, 1977; Smith, Glass, & Miller, 1980; Wampold, 2001; Wampold et al., 1997). Furthermore, researchers did not find differences in effect sizes by using a method intended to control for researcher allegiance to particular therapeutic models. Different therapies seem to produce very similar outcomes for these adult disorders.

To be thorough, some meta-analyses of psychotherapy outcomes have reported differences among treatments (see Drisko, 2004; Wampold, 2001). Systematic reviews of research, synthesizing the results of several experimental studies, may document that some psychotherapies do lead to significant outcomes while others do not. Still the question remains: If psychotherapy works, what factors within it lead to change? Given the frequent finding of no or minimal difference between therapies, perhaps technique is not the main or sole active ingredient leading to change. If so, factors other than therapeutic technique need to be more fully studied in outcome research, as well as given greater emphasis in social work education.

COMMON FACTORS IN HEALING

Psychiatrist Jerome Frank studied the characteristics of “healers” in several cultures worldwide. He identified numerous similarities in their practices despite clear diversity in their belief

systems. He concluded that a number of factors might lead to change in psychotherapy, much as it did in the healing practices of other cultures (Frank, 1971). Based on Frank's work, Lambert (1992) estimated the percentage of variance attributable to each of the four common factors in psychotherapy.

In an early estimate, Lambert (1992) identified four key common factors from a synthesis of about 100 outcomes studies. These are (1) extratherapeutic factors, (2) the therapeutic relationship, (3) technical factors (specific therapeutic techniques), and (4) expectancy or placebo effects. He estimated that 40% of the variance in outcome is due to extratherapeutic factors, 30% is due to the therapeutic relationship, 15% is due to technical factors, and 15% is due to expectancy. This common factors model might explain why meta-analytic research finds no or minimal difference between therapies: extratherapeutic factors and the therapeutic relationship may outweigh the impact of technique and are rarely included in outcome research.

In an update of Lambert's original work, Norcross and Lambert (2011) revised these common factor estimates by including a large percentage of "unexplained variance." Because psychotherapy and other human endeavors are extremely complex, most statistical analyses in the social sciences "explain" only a fraction of the variance found in outcomes. This is because factors that were not specifically examined in a study may also affect its outcome. Errors in measurement and in research methods also lead to fairly large amounts of unexplained variance in outcomes.

Norcross and Lambert's (2011) current common factors model attributes 40% of the variance in psychotherapy outcomes to unexplained variance. Of the remaining 60% of explained variance in outcome, Norcross and Lambert assign 30% to the "client contribution" and another 12% to the therapeutic relationship. Another 8% of outcome variance is assigned to specific therapeutic techniques. In addition, 7% of variance is assigned to individual therapist characteristics and 3% to other factors (pp. 11–14). Norcross and Lambert also state that common factors are "spread across the therapeutic factors" (p. 14). That is, each common factor component can interact with the others to influence outcomes in combination. Common factors pertain in part to the client, some to the therapeutic relationship, some to the specific model of therapy, some to

the specific practitioner, and some to interactions of these components.

It is important to note that in both these variance estimates, the client's contribution—personal capacities, the impact of social supports, motivation, and readiness—remains the largest source of variance in client outcomes. Next is the nature and quality of the therapeutic relationship. Techniques of therapy or models of therapy are the third largest influence on outcomes, but are closely followed by therapist factors. These results support the view that factors other than specific therapeutic techniques are the largest sources of variance in client outcomes.

EXPLORING THE COMMON FACTORS

The Client Contribution or "Extratherapeutic Factors"

In any client's life there are factors that will support change and others that may limit or impede change. They shape the effectiveness of psychotherapy but may not always be amenable to change using psychotherapeutic techniques. Specific to the client, Lambert and Asay (1984) list:

- Level of motivation
- Capacity to trust
- Ability to tolerate affect
- Intelligence
- Psychological mindedness
- Resilience.

These factors combine with the number and severity of challenges the client faces and the client's ability to identify and stay with a focal problem in the treatment. Outcomes will likely be better where these influences are present and positive; outcomes will probably be worse where they are absent or pose challenges. These findings suggest that pretherapeutic interventions may be helpful or even crucial for some clients to engage and make use of specific therapies.

Prochaska (1999) and others state that readiness to change is another client factor that influences capacity to change. Prochaska suggests that treatment readiness may not be a stable trait but rather a variable or cyclic phenomenon, so efforts to maximize it may enhance overall treatment effectiveness (or may undermine efforts when treatment readiness is not present). Further, recent work by Castonguay and Beutler (2006) identifying the

principles of change behind empirically supported treatments suggests that very intensive, highly structured intervention from the outset is associated with positive outcomes for people with personality disorders who may prove inconsistent in motivation. To enhance motivation, pretherapeutic interventions may be useful along with attention or involvement with social supports. Motivational interviewing with the client, as well as the client's family and other supports, and working through differences early on, are all helpful approaches.

Bohart and Wade (2013) suggest two approaches to individualizing psychotherapy based on current research on the client's impact on outcomes. First, they recommend matching clients by aptitude to specific psychotherapy approaches. This recommendation links specific client factors to choice of treatment. Bohart and Wade also recommend efforts to enhance the knowledge and skill of clinicians to be responsive to different client abilities and contexts. Such knowledge and skills allows a specific clinician to work more effectively and differentially with clients who have varied needs, aptitudes, and abilities. Both client and clinician are active agents in psychotherapy and social service interventions.

Expanding The Client

Contribution: The Client's Context

Social workers know that the client's context can play an important role in sustaining involvement in psychotherapy or in undermining this effort (Lambert, 1992). On the other hand, the lack of family and social support—or their absence, or active hostility—can hinder therapeutic change (Drisko, 2004). Similarly, peer and workplace supports can serve as aids, hindrances, or neutral influences to therapy. For many people, spiritual supports and support groups sharing common concerns (such as the therapeutic problem or other issues) can also influence therapy participation and outcome. All this suggests that pretherapeutic or early therapeutic work to engage the support of key people in the client's life will be likely to reduce dropout risk, enhance motivation for change, and limit undermining influences. On a larger scale, neighborhood resources or challenges may ease involvement in therapy or increase the effort required to enter and remain in therapy. It is also clear that the meaning of engaging in psychotherapy, and its very appropriateness as a source of improvement,

differs across cultures (e.g., Sue, Zane, & Young, 1994; Zayas, Drake, & Jonson-Reid, 2010). Thus, the wisdom of seeking therapy and support for the undertaking over time may not be simple or steady for many potential clients. In this case, the following are helpful:

- Similarity of race/ethnicity between client and clinician
- Similarity of religious background
- Acceptance or openness to the client's religious/spiritual views (Castonguay & Beutler, 2006).

Extratherapeutic Factors: The Policy and Agency Context

Though he is not a social worker, Lambert (1992) concentrated on the inner world of the client and did not address the impact of policy and agency factors on the client. I argue that for a client to enter and remain in therapy, several agency factors must be present (Drisko, 2004).

- Clients need to know that services are available.
- Clients need to have trust that the services are likely to help.
- Cost of services must be reasonable in terms of the client's ability to pay.
- Services must also be accessible—within reasonable geographic proximity, accessible to transportation.
- Services should have no significant barriers for people with disabilities.
- Services also must be culturally sensitive to the potential client.
- Services should be user-friendly, even inviting, to people under stress and doubtful of being treated with respect and care.

Contacts prior to meeting the clinician (e.g., the receptionist, agency financial staff) also may aid or hinder engagement in the therapeutic work. Costs should be reasonable, and there should be no undue obstacles in referral procedures and management paperwork. In addition, reimbursement to service agencies must offset the cost of doing business and be sufficient to create supportive working conditions (pay, diversity, supervision, and site) for all staff. Sadly, reimbursement rates for many clinical services are low and may fail to fully meet the actual cost of delivering the

service. In turn, insensitive events in the agency may undermine a fragile client's ability to engage with clinical services (Drisko, 2004).

Castonguay and Beutler (2006) also note that clients with a high level of impairment are less likely to benefit from therapy than those with a better level of functioning at pretreatment. In addition, clients diagnosed with a personality disorder are less likely to benefit from treatment than those without a personality disorder. Together, these extratherapeutic factors influence client engagement in services, dropout rates, and overall outcomes. They may account for more of the variance in treatment participation, completion, and outcomes than do any of the four common factors described by Lambert (1992).

The Therapeutic Relationship

The therapeutic relationship is usually what clinicians label as the *common factor* in psychotherapy (Rosenzweig, 1936). Some believe it is the single most important curative factor (Orlinsky, Grawe, & Parks, 1994). Yet the impact of the therapeutic relationship is difficult to study, because it appears to be differentially important for varied clients, with different diagnoses or problem types, and also interacts with treatment techniques (Crits-Christoph, Gibbons, & Mukherjee, 2013). Still, the psychotherapy literature since the 1950s emphasizes that the caring, warmth, empathy, and acceptance demonstrated by the clinician is vital to therapeutic result. Castonguay and Hill (2012) assert that relationship factors—as perceived by a given client—are central to a positive and productive therapeutic relationship. In addition, Lambert (1992) and Lambert and Hill (1994) note that mutual affirmation (which may include accurate and sufficient affective attunement) as well as active encouragement to support affective, cognitive, and behavioral changes, including the taking of risks by the client and clear acknowledgment of change and new mastery, are all elements of the therapeutic relationship. The importance of recovering from missteps or failures of attunement is also associated with positive outcomes in the practice literature (Tracey et al., 2003). For all clients, empathy is another vital aspect of the therapeutic relationship (Beutler et al., 2012). Bachelor (1995) found that various types of empathy (nurturant, insight-oriented, and collaborative) were more apparent and useful during different phases of treatment. Key aspects of the therapeutic relationship include:

- Affective attunement
- Mutual affirmation, including support for risks and appreciation of positive changes made
- Making efforts to discuss and resolve missteps or failures of attunement
- Goal congruence
- Use of varying types of empathy over the course of therapy.

Crits-Christoph, Gibbons, and Mukherjee (2013) argue that research seeking to identify the specific mechanisms through which the processes and outcomes of psychotherapy are linked warrants greater priority and funding. A large body of research documents that the alliance is a vital part of positive outcomes across a range of psychotherapies. Research on the therapeutic relationship has controlled for prior symptomatic improvement, the dependability of measures, and the views of both clients and clinicians. They assert that few other areas of psychotherapy research have been so fully conceptualized and so carefully examined.

Specific Techniques

Although this chapter addresses common factors rather than specific therapeutic techniques, this does not mean that knowledge of a range of intervention models and the clinical skills to implement them are unimportant. Rather than viewing common factors as a simple contrast to technique, it is optimal to think of a “both/and” relationship. Social workers do need to be knowledgeable, skilled, and well-supervised on therapeutic techniques and consistently attentive to the common factors active in intervention.

In defining principles of therapeutic change based on empirically effective treatments, Castonguay and Beutler (2006) report some technique-based findings.

- Therapy is likely enhanced if a strong working alliance is established and maintained.
- Clinicians should attempt to facilitate a high level of collaboration with client during therapy.
- The most effective treatments are those that do not induce client resistance.
- Clinicians are likely to resolve alliance ruptures when addressing such ruptures in an empathetic and flexible way.

- Clinicians should not use relational interpretations excessively.
- When relational interpretations are used, they are likely to facilitate improvement if accurate.
- Treatment benefit may be enhanced when interventions are responsive to and consistent with the client's style and level of problem assimilation.

Social workers should bear in mind that training to maximize professional use of self during interventions can be viewed as a set of techniques. Mastering such a broad set of techniques requires specific training and close supervision. Knowledge and skills in these areas can enhance the effectiveness of technical interventions.

Individual Clinician Characteristics

The characteristics of the clinician also impact on service outcomes (Blow, Sprenkle, & Davis, 2007). Castonguay and Beutler (2006) report that:

- Clinician effectiveness is increased by demonstration of open-mindedness, flexibility and creativity.
- A secure attachment pattern in the clinician appears to facilitate treatment processes.
- Positive impact is likely increased if the clinician is comfortable with emotionally intense relationships and able to tolerate his or her negative feelings toward the client.
- If clinicians are open, informed, and tolerant of various religious views, treatment effects are likely to be enhanced.
- If clients have a preference for religiously oriented therapy, benefit is enhanced if clinicians accommodate this preference.

Further, clinicians must complete thorough assessments of clients, with agency support, to fully understand and formulate client's needs and strengths (Grady & Drisko, 2014). Consistent with social work's values and ethics, the clinician's openness to differences of many kinds, including religious views and the ability to accommodate and work with religious differences, enhances therapeutic effectiveness.

Outcome research shows that clinicians vary widely in overall effectiveness. Baldwin and Imel (2013) argue for more research on individual clinician's effectiveness to identify what distinguishes

more and less effective clinicians. This would allow both remedial training and improvements to the general education of clinicians across disciplines. It would also allow for the improvement of outcome research by removing an important confounding variable. That is, by removing poor outcomes due to ineffective clinicians from research studies, and focusing on demonstrated effective clinicians, research studies would yield results of greater value. Currently the effects of psychotherapy may be underdocumented in research due to the negative contributions of clinicians of limited effectiveness who yield less than optimal outcomes. Baldwin and Imel also argue for more within-clinician research. Such research would seek to identify the attributes of clients and settings that lead a specific clinician to facilitate the best outcomes. Such research could aid each clinician's professional development and point toward the types of work that produce the best outcomes they can foster.

Expectancy

Offering hope and an expectancy that change is possible can be a powerful aid to generating positive outcomes. Clients often feel stuck, bruised, or defeated by prior unsuccessful efforts to change. Clients of color or other socially marginalized groups may have suffered from insults and microaggressions from people with power over them. Thus, building a positive expectancy that change is possible may be a therapeutic gain in itself, as well as a catalyst for further progress.

Many studies show that placebos can generate useful change (Benedetti, 2008; Harrington, 1997). Placebos may involve sham medications as well as shared belief systems between client and professional and even the creation of an expectancy of change. Such studies indicate that expectancies can be very important influences on client outcomes even when known ineffective treatments are used.

Other Factors

Castonguay and Beutler (2006) found that clients with high level of impairments respond better when initially offered long-term intensive treatment than nonintensive and brief treatment, regardless of treatment model and type of treatment. This provocative finding suggests that people who do not expect to change, or who doubt that others will truly work to support their change, respond well to intensive and enduring interventions that build hope and demonstrate

investment and care from others. Nelson, Beutler, and Castonguay (2012) suggest the fit of common factors and treatment selection is vital to effectively serving persons who have personality disorders. This may also be so for persons who have histories of suffering from socially structured oppression.

Insight: How the Client’s Understanding of the Problem and the Therapy Influences Therapeutic Process and Outcomes

Wampold, Imel, Bhati, and Johnson-Jennings (2007) examine the idea that common factors are spread across the therapeutic processes. That is, each common factor component can interact with all the others to influence outcomes in combination. Wampold and colleagues examine how insight—which they define as a new understanding of the client’s core problem and its relationship to the process of intervention—is an interaction of several common factors.

To illustrate this interaction, Wampold et al. (2007) offer four vignettes showing how four clients, each with depression, can benefit from different models of understanding their depression. The first client develops an understanding of his depression as based on distorted, overgeneralized beliefs of failure. The clinician offers cognitive behavioral therapy. Through this therapy, the client’s depression improves. The second client has recurring dilemmas in interpersonal relationships with men. The clinician offers an insight-oriented therapy to explore how her early losses, including the death of her father, continue to shape her self-esteem and patterns of relationship. Through this therapy, her depression improves. The third client comes to view her depression solely as a brain disorder, rather than God’s punishment for an extramarital affair. Accepting antidepressant medication after a very brief therapy, her depression improves. The fourth client, a Native American man working in a frustrating high tech job, uses therapy to reconsider his relationship with his culture of origin, from which he has become estranged. Through reconnecting with his culture of origin, and undertaking healer recommended sweats, his depression improves. Wampold et al. (2007) note that each of these very different ways of understanding depression, and the treatment each particular way of understanding indicates, are each useful and ultimately effective. The differences emerge based upon a combination of client factors (the details of each client’s history, concerns, and context), therapist factors (how the clinician comes to formulate each case in context) and the therapeutic alliance

(that the client gains insight into the problem through therapeutic intervention that offers new ways of pursuing improvement).

Wampold et al. (2007) define insight as a shared way of viewing the problem developed through client–therapist interaction. Insight, defined this way, links back to the work of Rosenzweig (1936) and of Frank (1971) who believed that clinicians had to help clients develop new, acceptable, and therapeutically useful ways of understanding their problems. Wampold et al. note that such insight either can come from the client internally, or be offered by the clinician. How the insight is gained, and even its scientific truth value, are not crucial. What matters is that the new explanation makes sense to the client, fits within his or her worldview, and is fully accepted by the client. In turn, such an insight or way of viewing the problem is both adaptive and offers hope for problem resolution.

Wampold et al.’s (2007) insight model integrates the influence of several common factors. As such, it illustrates how common factors frequently act in combination. The common factors model helps clinicians and researchers conceptualize the complexity of clinical practice. It may also make some aspects of practice appear more independent or divisible than they appear at the level of intervention with a specific, unique, client. In practice, common factors are often interwoven.

COMMON FACTORS AND EVIDENCE-BASED PRACTICE

Evidence-based practice (EBP) refers to a four-part approach to practice decision making. EBP is comprised of efforts to include (a) the integration of research evidence with intervention planning that also *equally includes* (b) the client’s state and circumstances, (c) the client’s own values and preferences, and (d) the clinical expertise of the practitioner (Haynes, Devereaux, & Guyatt, 2002). The research evidence given the highest priority in EBP is research results based on large-scale, experimental research (Greenhalgh, 2010; Oxford University Centre for Evidence-based Medicine, 2011). Such experimental research examines the impact of one carefully defined intervention on one carefully specified disorder in order to limit the impact of unexplained factors and error terms. Most often the EBP experimental research model examines specific techniques or intervention models as though they were a single variable. This is very useful to ensure research integrity, but it

means other components that may influence therapeutic change, such as the client's contribution or the quality of the therapeutic alliance, are excluded from study (Drisko & Grady, 2012). Thus the common factors model offers a way to enhance the quality of outcome research and to help identify a wider range of factors that shape client outcomes (Barth et al., 2012). Such research results could be very useful in tailoring many aspects of therapeutic interventions to specific client situations and needs (Nelson, Beutler, & Castonguay, 2012).

Joining Common Factors and Evidence-based Practice

The common factors model asserts that techniques or models alone are neither complete nor accurate descriptions of what actually happens in psychotherapy. The characteristics of specific clients, the variation in their support systems and situations, the characteristics of each specific practitioner, and the synergistic way in which client, situation, practitioner, and therapy interact, all have an impact on client outcomes. Norcross and Lambert (2011) estimate that only about 8% of variance in outcome is attributable to specific therapeutic techniques. This percentage is much lower than the 30% attributable to the client's contribution and lower than the 12% assigned to the client-therapist relationship. From a social work perspective, both Drisko (2004) and Cameron and Keenan (2010, 2012) argue that the percentage of variance assigned to specific therapeutic techniques may well be considerably lower than that resulting from social and contextual factors. This implies that the EBP focus on techniques or types of therapy alone may be too limited an evidence base for fully and successfully guiding practice. Further, it implies that research on psychotherapy and service outcomes must take a much broader view of the range of factors that influence outcomes. EBP should employ a much broader perspective on causal influences shaping treatment outcomes including client factors, clinician factors, setting, and the client-therapist alliance (Drisko & Grady, 2012).

The EBP research evidence hierarchy and the common factors approach offer quite different ways of examining client outcomes. A useful response may be the combination of attention to both common factors and specific techniques. As Cameron and Keenan (2012) point out, it is the synergy of client and clinician that combine to create a successful experience. "What works"

for a specific client in specific circumstances may vary across specific providers of several different specific interventions (Barth et al., 2012).

FUTURE PRACTICE APPLICATIONS

The common factors model encourages practitioners and researchers to take a broader, much more encompassing view of what leads to change in psychotherapy and social work interventions. Techniques are indeed important but may not be the most active ingredients in generating change in human interactions. Both meta-analyses using sophisticated statistical models and principles drawn from analyses of interventions that have been demonstrated to be effective indicate that common factors are important sources of client change. In the future, social workers may want to examine more closely how to make use of these factors in their day-to-day practices because attention to common factors will enhance therapeutic outcomes (Saggese, 2005). Practitioners are wise to take a broad view of common factors that may help their clients make and sustain change. Attention to a combination of client, extratherapeutic, relationship, and technique factors may still achieve the best overall results in psychotherapy (Barth et al., 2012; Beutler et al., 2012; Cameron & Keenan, 2012).

30 Task-centered Practice

Anne E. Fortune, Blanca M. Ramos, & William J. Reid

Task-centered practice is a short-term, problem-solving approach to social work practice (Epstein & Brown, 2001; Jagt, 2008; Marsh & Doel, 2005; Reid, 1992, 2000; Reid & Epstein, 1972). It was developed by Laura Epstein (1914–1996) and William J. Reid (1928–2003) using an empirical Research and Development (R&D) approach that tested interventions, assessed results, refined the interventions, tested them

again, and so on, repeating the cycle with new clients and new problems (Reid, 1997; Fortune, 2012). It is among the few "home grown" empirical clinical practice (ECP) models in social work.

The task-centered model has been used worldwide in most types of social work settings, as a stand-alone, as part of a bundle of services, or integrated into multilevel, multisystem generalist practice (Fortune, McCallion, & Briar-Lawson,

2010; Hepworth, Rooney, Dewberry-Rooney, & Strom-Gottfried, 2013; Tolson, Reid, & Garvin, 1994). It has been used with voluntary and involuntary clients, with individuals, groups, and families, as a method of case management, as a system for agency management, as a model for clinical supervision, and as an approach to community work. Thus, it is a flexible approach to practice with many applications.

BASIC CHARACTERISTICS AND PRINCIPLES

A combination of key characteristics defines the task-centered model: a focus on client problems, problem-solving actions, integrative theoretical stance, planned brevity, a collaborative relationship, an empirical orientation, and structured interventions.

Focus on Client Problems

Task-centered practice is highly individualized in that the focus of service is on specific problems that clients explicitly acknowledge as being of concern to them. These problems-in-living usually involve personal and interpersonal difficulties, but contextual and environmental change may also be a focus.

Problem-solving Actions (Tasks)

Change in problems is brought about primarily through problem-solving actions (tasks) undertaken by clients outside of the session. The primary function of the treatment session is to lay the groundwork for such actions through systematic steps and structure. In addition, tasks by practitioner and others provide a means of effecting environmental change in the client's interest.

Integrative Theoretical Stance

The task-centered model draws selectively on theories and methods from compatible approaches—for example, problem solving, cognitive-behavioral, family structural, and interpersonal approaches. It also provides a framework and strategies that can be used with other approaches. For example, a core intervention—the task planning and implementation sequence—can be used with any intervention model. The sequence provides structured but

flexible guidelines to help clients plan and carry out between-session tasks.

Planned Brevity

Service is generally planned short-term by design (6 to 12 weekly sessions within a four-month period). The short time limits capitalize on the “goal gradient effect,” where individuals are motivated by deadlines and clear goals. Extensions beyond these limits are possible.

Collaborative Relationship

Relationships between clients and practitioners are both caring and collaborative. The practitioner shares assessment information and avoids hidden goals and agendas. Extensive client input while developing intervention strategies makes tasks more effective and develops the clients' problem-solving abilities.

Empirical Orientation

Within task-centered practice, methods and theories tested and supported by empirical research are preferred. Hypotheses and concepts about the client system are grounded in case data. Speculative theorizing about the client's problems and behavior is avoided. Assessment, process, and outcome data are systematically collected. Numerous studies, including eight controlled experiments, have been used to test and improve the model (Fortune, McCallion & Briar-Lawson, 2010; Reid, 1997).

Structured Intervention

Although the content of sessions (e.g., client problems, their context, task development) is individualized, task-centered sessions and intervention processes are structured. Each session in beginning, middle, and ending phases has a specific agenda that guides the client and practitioner work. In addition, some intervention processes are packaged and standardized; for example, the task implementation sequence includes steps appropriate for developing, implementing, and evaluating any client or practitioner task. Finally, because tasks are usually interim steps to a broader goal, task strategies are a series of tasks or a meta-approach to deal with specific common problems such as depression, bullying, or moving into a nursing home (Naleppa & Reid, 2003; Reid, 2000).

STRUCTURED ACTIVITIES AT THREE STAGES OF TASK-CENTERED PRACTICE WITH INDIVIDUALS AND FAMILIES

Sessions in task-centered practice are structured, although the content of sessions is individualized for clients and their problems.

- I. Initial phase (Sessions 1–2). To engage clients and develop consensus on future work, the initial session(s) include:
 1. Discussion of reasons for referral, especially with nonvoluntary client(s) (see Rooney, 2009; Trotter, 2006).
 2. Exploration and assessment of client-acknowledged problems-in-living.
 3. Negotiation and agreement on a service contract, including problems and goals to be addressed, explanation of treatment methods, and agreement on durational limits.
 4. Development and implementation of initial tasks (see II.3).
- II. Middle phase (each middle-phase session). Each session in the middle phase of task-centered practice includes the following activities, listed in logical order. Although task and problem review should occur early in order to focus the session, other activities are often interwoven with each other.
 1. *Problem and task review.* Problem status and accomplishment of tasks developed in previous sessions are reviewed in each session to determine progress. The task review provides a record for both the social worker and client as to how the task has gone and whether it affected the problem. This record is also useful in supervision and provides data generally about the kinds of tasks that are effective for particular clients and problems.
 2. *Identification and resolution of obstacles to task accomplishment.* If the client has experienced difficulty with the task, internal and external obstacles are reviewed and an effort is made to resolve them. If they cannot be resolved, an alternative task is developed to overcome or avoid the obstacle. For instance, a practitioner may help clients modify distorted perceptions or unrealistic expectations interfering with work on the task. Obstacles involving the external system, such as interactions between a child and school personnel or the malfunctioning of a welfare bureaucracy, may be addressed and a plan for resolving them developed.
3. *Task planning and implementation sequence.* The task planning and implementation sequence is central to completing tasks and resolving problems (Fortune, 2012). Again, the order of activities varies for each client and situation.
 - *Task selection.* Clients will “buy in” to task actions to the extent they are involved in planning the tasks. The practitioner may ask such questions as, “What do you think you might be able to do about this problem?” Or, “Of the things you have tried, what has worked best for you?” Task selection thus begins by eliciting the client’s ideas. The practitioner builds on these ideas and, if needed, suggests others. Such suggestions are intended to stimulate the client’s ideas and are not “assigned” unilaterally by the practitioner. Practitioners, caregivers, and other service providers may also take on between-session tasks.
 - *Task agreement.* Explicit agreement between practitioner and client on task(s) is important. Agreement may occur after alternative possibilities have been sorted out and the best possibilities selected. Generally, agreement at this point concerns the global nature of the client’s proposed action and not the detail, which is developed subsequently. If the client appears to accept the task, explicit agreement may be delayed until planning has been completed (see following item). In any case, by the end of the session, the client should agree to attempt the task.
 - *Planning specifics of implementation.* Once a task has been selected, the practitioner and client work on a plan to carry it out. Tasks suggested by practitioners should be customized and fleshed out in collaboration with clients. For example, if the practitioner suggests that a client with a drinking problem participate in a self-help program, an

implementation plan might involve determining how the program can be located, how the client can learn something about it, when he or she will attend the first meeting, what he or she might say at that meeting, and so on. Normally, the task is implemented prior to the next session.

The practitioner attempts to make sure that the task plan has a high probability of at least some success. It is better to err on the side of having the task be too easy rather than too difficult, because it is important that clients experience success in their work on their problems. Successful performance can create a sense of mastery, which can augment problem-solving efforts. For example, if it seems that the task of attending a self-help meeting has a low chance of being carried out, the task could be revised to partialize steps, for example, by first locating a group and then getting information about it.

For the task plan to work, the client must emerge with a clear notion of what he or she is to do. Generally, effort is made to spell out details of implementation that are appropriate for the task and fit the client's style and circumstances. For some tasks and some clients, a good deal of detail and structure may be required. For example, if the client is likely to procrastinate about doing the task, details like the time and place may be spelled out. For other tasks and clients, a minimum of structure and detail may make sense. For example, planning may be more general and completing the task may require a great deal of on-the-spot improvisation. In any case, the main actions of the task should be clarified, unless they are readily apparent. For example, if the task calls for a mother to show approval if her daughter cleans her room, ways of showing approval and what is meant by cleaning the room should be discussed.

- *Establishing incentives and rationale.* To help establish motivation, the practitioner and client develop a rationale for carrying out the task, if it is not already clear. "What might you gain from doing the task?" is an appropriate question. The practitioner reinforces the

client's perception of realistic benefits or points out positive consequences that the client may not have perceived.

- *Identifying and resolving anticipated obstacles.* An important practitioner function in task planning is to help the client identify potential obstacles to the task and to shape plans so as to avoid or minimize these obstacles. This function is implicitly addressed when the practitioner presses for specificity in the task plan. As details of how the tasks are to be done are brought out, possible obstacles can be identified through "what if?" questions. For example, suppose the task is "Discuss with your partner ways she can help you stay sober." Among the questions the client can be asked is: "What if your partner starts to lecture you?" More generally, the practitioner can ask clients to think of ways that a task might fail. Potential obstacles and ways of resolving them can be discussed. If the obstacles appear too formidable, the task can be modified, broken down into steps, or another approach developed. Often the proposed task relates to previous efforts by the client. Consideration of these efforts and how they may have fallen short can provide another means of identifying potential obstacles. For example, a task under consideration for Mrs. S. is to reward her son with praise and approval for completing his homework. Previous discussion of the mother-son relationship revealed her difficulties in expressing positive sentiments toward the boy. Her difficulty in doing so might be identified as an obstacle. The emphasis on identifying and avoiding obstacles—both before and after they are encountered—is an important step in task planning that is generally absent in other social work approaches (Rooney, 2010).
- *Guided practice, rehearsal.* To improve client skills or confidence, the social worker may model possible task behavior or ask clients to rehearse what they are going to say or do. For example, Mrs. S. might practice saying positive things about her son's behavior. Modeling and rehearsal may be carried

out through role-playing, if appropriate. For example, if the client's problem is social phobia, the selected task might be to "speak up in a class you are attending." The practitioner might take the role of the instructor, and the client could rehearse what he or she might say. The roles could then be reversed, with the worker modeling what the client might say.

Guided practice is the performance of the actual (as opposed to simulated) task behavior by the client during the interview; thus, a child may practice reading or a couple may practice communication skills. Guided practice can also be extended to real-life situations—a practitioner might accompany a client with a fear of going to doctors to a medical clinic.

- *Summarizing and recording the task plan.* As a final step in task-planning, to clarify between-session activities, the practitioner and client go over the plan in summary fashion. For complex tasks, it is useful to elicit from the client the essentials of the plan. The client is asked to present the plan as he or she sees it. The practitioner can then underscore the essential elements of it or add parts the client has left out. Summarizing the plan gives the practitioner the opportunity to convey to the client the expectation that it will be carried out and that his or her efforts will be reviewed. "So you will try to do [thus and so] I'll do [that and this]. We'll see how it worked out next time we meet." Writing tasks down with a copy for the client and another for the practitioner is also useful, especially when tasks are complex or when several people are to perform tasks.
4. *Implementation of tasks between sessions.* Clients and (depending on the case) practitioners and others carry out tasks in the environment.
- III. Terminal phase (final or last two sessions).
1. *Assessment of current status problems and overall problem situation.*
 2. *Identification of successful problem-solving strategies used by client(s).* Emphasis is on establishing

client's success in problem solving and using strategies in similar situations.

3. *Discussion of other ways to maintain client gains.* Maintenance may include "fail-safe planning" (what to do if a problem crops up), self-reinforcement, practicing new behaviors in additional situations (generalization), etc.
4. *Discussion of what can be done about remaining problems,* including possible task strategies.
5. *Acknowledge reactions to ending.* Because ending is expected, reactions to termination are more likely to be ambivalent—mixed satisfaction and regret—than negative. These reactions should be acknowledged as normal and healthy but not as reasons to prolong treatment. In many circumstances, a termination ritual helps bring closure, for example, a memento of the relationship, a review of clients' accomplishments, etc.
6. *Making decisions about extensions.* Decisions are jointly made by client and practitioner. Extensions are usually time-limited and focused on particular problems or goals. In most cases, a single brief extension will suffice, but in some cases additional ones may be needed. The critical consideration is what can be accomplished by extending service. Often, cases that show little progress by the twelfth visit will show no more progress by the twentieth.

TASK-CENTERED PRACTICE IN SMALL GROUPS

The task-centered model is readily used in group treatment of individual (or family) problems (Fortune, 1985). Small groups—usually from four to eight persons—are formed around problems that are similar, such as school failure or issues in caregiving. Members specify problems and undertake tasks related to them, as in individual work. Sessions follow the same structured agenda outlined above. However, in group treatment members assist one another in formulating problems and in work on tasks, including task planning and review. Group members may act as "buddies" between meetings.

Group norms are shaped to encourage task-centered work—for example, the expectation that clients will take action and reinforce

one another's successes. Group processes are used to enhance intervention. For example, when members have similar problems, group cohesion can occur more quickly and members have multiple role models and ideas for task strategies. Reviewing task progress in pairs makes individuals accountable for their own progress as well as aides to others' progress.

CONSIDERATIONS FOR WORK WITH ORGANIZATIONS AND OTHER CONTEXTS

The task-centered model has been adapted for use in clinical and educational supervision, case management, organizational management, and community organization. In these uses, the problems-in-living are replaced by other types of problems or goals, for example, by skills to be mastered by a supervisee, by an organization's lack of clarity about its mission, or by a community's need to develop stronger norms against violence. Once a problem/goal is negotiated among participants, the task-centered problem-solving steps are used to develop strategies and tasks to achieve the goals. Tasks are implemented, their accomplishment evaluated, and the situation reviewed systematically as in individual task-centered practice. Time limits are also used to increase motivation and participant action. The primary differences from individual practice lie in the dynamics of the unit. For example, in supervision, the employee is (we hope) motivated to improve competence, while the supervisor holds authority to enforce organizational rules to protect clients; the employee's choice of skill development may be constrained by rules about legally acceptable interventions. In interdisciplinary case management teams, disagreement about values and approaches from the different disciplines may inadvertently overshadow the client's perspective. In organizational management, problems may be readily identified, but getting the key organizational players to collaborate may require more effort than generating task strategies.

FUTURE

Task-centered practice is one of the few empirical clinical practice (ECP) models developed in social work. It has demonstrated its applicability to a wide range of problems, clients, modalities, and worldviews. It can be used as an all-purpose

tool, adapted to the immediate need, or embedded in other interventions. It now appears so well-embedded in social work that one critic suggested that it is "simply good social work practice. . . . [whose its major contribution is] a sturdy yet flexible practice technology that contains enough rigor to be consistently effective but also enough space to be adapted creatively to an incredible number of social work practice contexts" (Kelly, 2008, p. 199).

CASE ILLUSTRATION: ANA

Ana, 66 years old, was recently diagnosed with mild depression. A year ago she emigrated from Chile where she was heavily involved in her church and had an active social life. She lives with her daughter, Liz, and a teenage granddaughter, Sofia, with whom she rarely interacts. Ana resents Liz, blaming her for "forcing" her to leave behind her family and friends whom she fears she will never see again. This has strained the relationship to the point where Ana prefers not to ask Liz for help and support when needed. Ana describes her current life as "lonely," "meaningless," and "unhappy." She longs to be back in Chile and cries "all the time."

Initial Phase

Ana and the practitioner identified two target problems: her loneliness and limited support system. They tentatively agreed on three intervention strategies: expanding her social network, increasing contact with family in Chile, and improving her relationships with Sofia and Liz. They contracted to meet weekly for three months.

The practitioner mentioned a church near Ana's house that offered Spanish Mass and educational and social activities daily for Latino seniors. For an initial task, Ana suggested with little enthusiasm she would go to the church and give it a try. With prompting, she agreed to ask Liz to help her get there on her way to work and to pick her up on her way home. Ana would go to the church at least three times a week.

Middle Phase

At the beginning of the next session, Ana reviewed her task: as agreed, she had gone to the church three times. She shared with some

enthusiasm how she met other Latina immigrants to whom she could relate and found spiritual comfort attending Mass and talking to the priest. Ana was not sure she could continue working on this task because it was hard getting to the church. She struggled waking up so early and worried about making Liz late to work.

When prompted for ways to overcome this obstacle, Ana recalled befriending Tina who goes to the church daily and lives a block away. She agreed to ask Tina if she could stop by on her way over so they could go together. Ana would discuss this idea with Liz emphasizing her own concern about making her late for work.

The practitioner suggested another task: to ask Sofia to show her how to use e-mail to communicate with her loved ones in Chile. This task was also intended to facilitate closer interactions with Sofia.

During each session in the middle phase, Ana and the practitioner reviewed task progress, problem status, and obstacles to task accomplishment. Ana continues going to the church, sometimes more than three times a week, and participates actively. She walks over with Tina, and during bad weather Liz gives them both a ride. Ana was surprised when Sofia agreed to help her use e-mail. Electronic communication is challenging and frustrating, but Ana is highly motivated. Occasionally, Liz stops by the church to give Ana and Tina a ride home, and the three gossip about their days.

Terminal Phase

In the last few sessions, the practitioner reminded Ana how many sessions remained. At first, Ana wanted to continue, but she agreed that their work was almost completed and they would end when they had initially planned.

In the final session, Ana and the practitioner reviewed the status of the target problems. Ana did not feel as lonely: she talked enthusiastically about the positive changes in her life since she began attending the church. She has new friends, participates in meaningful activities, and benefits spiritually. Ana still misses her family and life in Chile and cries from time to time. She continues trying to learn how to use e-mail; it has been a long and slow process. As a result of this experience, she spends more time with Sofia, and they are successfully bonding.

Ana and Liz have grown closer. They often go grocery shopping after taking Tina home, and they prepare meals together. Ana enjoys teaching Liz the “old dishes,” while Liz likes hunting ingredients in the bodega. Ana now views Liz as a supportive, caring daughter who had good intentions inviting her to live with her in this country.

The practitioner pointed out Ana’s strengths including her tremendous problem solving abilities and resilience. They discussed how Ana could use these personal resources to continue working on her current and new problems. Ana plans to go to the church more often and even get there on her own when needed. She and the practitioner rehearsed what Ana would do if she found herself feeling lonely, crying when longing for her family and friends in Chile, or needing nurturing from Liz and Sofia.

Ana thanked the practitioner profusely, stating with sadness she would greatly miss their weekly sessions. The practitioner praised Ana for her accomplishments and acknowledged the sad nature of this ending and transition. Ana timidly, with teary eyes, gave the practitioner a small vase from Chile. This was graciously accepted and proudly placed on the practitioner’s desk. They both contemplated it and gave each other warm smiles before Ana left the room.

31 The Life Model of Social Work Practice

Alex Gitterman

AN OVERVIEW

In developing the Life Model, Professor Germain and I assumed that there were many common concepts and methods in working with people, no matter what the size of the system. We believed that services should be based on client needs and preferences rather than the worker's method specialization. We attempted to develop an integrated social work practice method in place of the traditional casework, group work, and community organization methods. In conceptualizing an integrated method, we recognized some distinctive knowledge and skills, such as what is required to form groups or to influence communities, organizations, and legislative processes.

Historically, the profession experienced ideological conflicts between those who emphasized bringing about social change on behalf of social justice, the "cause," as the primary characteristic of social work, and those who emphasized

"function" as the primary characteristic of social work practice, that is, the technologies used by practitioners to bring about individual change (Lee, 1929; Gitterman & Germain, 2008b). Based on our practice and teaching experiences, Professor Germain and I were committed to integrate these traditions. Hence, our second aim was to develop a model that began to build bridges between the treatment and social-reform traditions of the profession. Clearly, both cause and function must be hallmarks of practice and education for practice if social work is to be relevant in the new century. Melding cause and function is an essential part of life-modeled practice (Schwartz, 1969, 1971, 1976; Gitterman & Germain, 2008b).

In building on our original ideas, we adopted a *life course* of human development and functioning. In contrast to traditional stage models of development, this formulation takes into account diversity in race, ethnicity, sex, age,

socioeconomic status, sexual orientation, and physical/mental challenges, as well as environmental forces within historical, societal, and cultural contexts. We used “life course” to replace the traditional, linear “life cycle” models and their assumption that emotional and social development proceed in fixed, sequential, universal stages without reference to the diversity of life experience, culture, and environments (Gitterman & Germain, 2008a).

ECOLOGICAL PERSPECTIVE

Ecological theory is especially suited for social work because it emphasizes the interdependence of organism and environment. Given our historic commitment to the person-and-environment concept, the ecological metaphor helps the profession enact its social purpose of helping people and promoting responsive environments that support human growth, health, and satisfaction in social functioning. Ecology, a biological science that examines the relation between living organisms and all the elements of the social and physical environments, provides the theoretical perspective for an integrated practice and the theoretical foundation for the Life Model (Germain, 1981; Germain & Gitterman, 1986a, 1987, 1995, 1996; Gitterman, 1996; Gitterman & Germain, 1976, 2008a). Ecological concepts offer the theoretical lens for viewing the exchanges between people and their environments. The concepts include level of fit, transactions, adaptation, life course, and vulnerability and resilience. Principles from deep ecology further enhance our understanding that all phenomena are interconnected and interdependent as well as dependent on the cyclical processes of nature. These principles include the interdependence of networks, the self-correcting feedback loops, and the cyclical nature of ecological processes (Capra, 1996; Ungar, 2002).

Over the life course, people strive to deal with and improve the *level of fit* with their environments. When people feel positive and hopeful about their own capacities and about having their needs fulfilled, and when they view their environmental resources as responsive, they and their immediate environments are likely to achieve a reciprocally sustaining condition of *adaptedness*. Adaptive person:environment exchanges *reciprocally* support and release potential.

In contrast, when people feel negative and unhelpful about their own capacities and about

having their needs fulfilled, and when they view environmental resources as unresponsive, they and their environments are likely to achieve a poor level of adaptive fit. *Stress* is the outcome of a perceived imbalance between environmental demand(s) and capability to manage it with perceived available internal and external resources. To relieve the stressful situation, the level of person:environment fit must be improved. This is accomplished by an active change in either people’s perceptions and behaviors, or in environmental responses, or in the quality of their exchanges.

Poor clients live in oppressive social and physical environments. They are exposed on a daily basis to economic, social, and psychological discrimination. In *coping* with destructive environments, some people steel themselves and mobilize inner strengths and resiliencies—they become survivors rather than victims. Others internalize the oppression and turn it against themselves through such self-destructive behaviors as substance abuse and unprotected sex. Still others externalize the oppression, strike back, and vent their rage on others less powerful than they through such behaviors as violence, crime, and property destruction. Readily accessible targets often include family members, neighbors, and community residents. These *maladaptive* person:environment exchanges reciprocally frustrate and damage both human as well as environmental potentials (Gitterman, 2014).

In deep ecology, living systems are viewed as *networks* interacting with other systems of networks—“in intricate pattern of intertwined webs, networks nesting within larger networks” (Capra, 1996, p. 82). These intertwined, interdependent networks share certain common properties. Their intricate patterns are nonlinear—they go in all directions and develop feedback loops, which allow them to self-regulate by learning from and correcting mistakes. Through the process of self-regulating and self-organizing, new behaviors, patterns, and structures are spontaneously created and the networks’ equilibrium constantly evolves. The interdependence of networks and the self-correcting feedback loops allow the living system to adapt to changing conditions and to survive disturbances. Thus, interdependence of networks, the self-correcting feedback loops, and the cyclical nature of ecological processes are three basic principles of deep ecology.

SOCIAL WORK PURPOSE AND FUNCTION

The Life Model conceptualizes the purpose of social work as improving the level of fit between people and their environments, especially between people's needs and their environmental resources (Gitterman, 2010). This conception of professional purpose is further specified through two inter-related professional functions: (1) to help people mobilize and draw on personal and environmental resources to eliminate, or, at least, alleviate life stressors and the associated stress; and (2) to influence social and physical environmental forces to be responsive to people's needs (Germain & Gitterman, 1979, 1980, 1986, 1996; Gitterman & Germain, 1976; 2008; Gitterman, 2010).

(1) *Helping people with life stressors*: Over the life course, people encounter life stressors. These stressors emerge in one or more aspects of living and include: *difficult life transitions and traumatic life events, environmental pressures, and dysfunctional transactions in collective life* (family, group, and community). In life-modeled practice, practitioners and clients assess and intervene in single and multiple life stressors.

Life transitions include stressful developmental transitions, difficult social transitions, and traumatic life events (Gitterman & Germain, 2008a). Developmental transitions, such as adolescence, impose new demands and require new adaptations and coping. While puberty is biological, adolescence is a social construction. The norms related to developmental changes vary across subcultures and dominant society. Developmental transitions are accompanied with competing expectations, changes in family, peer, and social changes in status and roles. People must also deal with the challenges of new experiences and relationships as well as leaving familiar places and relationships. Beginning a new school or job, starting a new relationship, or having a child create new demands and expectations, and therefore, are often stressful social transitions. Leaving school or a job, ending a relationship, and dealing with death and other losses are even more stressful social transitions than new experiences. Traumatic life events, often unexpected and severe, include losses such as the death of a child, loss of a home, rape, and the diagnosis of AIDS and other illnesses. Such events are perceived as overwhelming disasters and lead to intense pain.

Biological and social transitions and traumatic events require changes in ways of looking at oneself and the world, and have profound impact on interpersonal transactions.

Environmental pressures can arise from the lack of resources and social provisions on the part of some or most social and physical environments (Gitterman & Germain, 2008a). Chronic poverty is the major force responsible for both prolonged and cumulative stress. Violence, insufficient affordable housing, poor schools, inadequate health care for children and adults, are consequences of our economic and social priorities and values. To manage environmental stressors, clients turn to institutions and organization (including social agencies) for assistance. Some provide the required resources. Others are inaccessible and inhospitable to people's needs; withhold needed resources through restrictive policies, regulations, and procedures; and exacerbate rather than ameliorate people's stress. Similarly, some social networks (kin, friends, neighbors, work mates, and acquaintances) provide essential instrumental (goods and services) and expressive (empathy, encouragement) resources. They serve as essential buffers against life stressors and the stress they generate. Others, however, are destructive, nonsupportive, or are missing altogether. Similarly, physical settings can be serious life stressors because of deteriorated dwellings, unsafe and insufficient space, and lack of required privacy.

Families, groups, and communities also experience the life transitional and environmental stressors noted above. They also experience additional stressors created by their own dysfunctional processes and exploitative and conflicted relationships (Gitterman, 2010, 2012; Gitterman & Germain, 2008a; Gitterman & Wayne, 2003; Wayne and Gitterman, 2004). Scapegoating and splintering factions are illustrative of dysfunctional processes, which simultaneously weaken individuals as well as the collective.

Life transitional, environmental, and interpersonal stressors are interrelated and, at the same time, distinct. When one is unsuccessfully managed, additional stressors often erupt in other areas of life (the "spread phenomenon"). Cumulatively, they can overwhelm individual and collective coping capacities, and the individual, group, family, or community/neighborhood may move toward disorganization.

(2) *Influencing social and physical environmental forces*: In helping people with

life stressors, social workers daily encounter the lack of environmental responsiveness. Thus, the Life Model also includes professional responsibility for influencing environmental forces and for bearing witness against social inequities and injustice. This is done by *mobilizing community resources* to improve community life, by *influencing unresponsive organizations* to develop responsive policies and services, and by *politically influencing local, state, and federal legislation and regulations* to support social justice (Gitterman & Germain, 2008b).

Intervention at the community level is essential to life-modeled practice. The social worker helps mobilize neighborhood and community residents to take action on their own behalf to secure desired formal and informal resources. Helping residents to pursue needed resources or services and to influence formal and informal structures to be receptive to their efforts are essential interventions to improving the level of fit between people and their environments. The social worker can also help neighborhood and community residents by improving the coordination of existing community resources and increasing their accessibility. When programs and services are unavailable, the social worker may engage his/her agency or a coalition of agencies to develop new programs and services.

Influencing the social worker's own organization to develop new services or improve existing ones is an essential component of the Life Model's conception of professional function (Gitterman & Miller, 1989). To be responsive to clients' needs, the social worker must have an active presence in his/her organization. An organizationally isolated worker is not in a position to influence policies, practices, and programs. Similarly, a social worker who does not question organizational structures and processes will limit his/her ability to improve agency services. The worker must move beyond prescribed organizational roles in a respectful and skillful manner. The professional task is to identify simultaneously with the organization's mission, the client's needs, and the profession's code of ethics. The Life Model proposes a professional methodology to fulfill this professional function.

The complexities of contemporary practice demand professional involvement in political activity to influence local, state, and federal legislative and regulatory processes. Political activity includes the simpler form of telephoning and writing

letters to policy-makers and policy-implementers and mobilizing others to do the same. In its more complex form, political activity includes lobbying, coalition building, testifying, rallying public support, and using the press and other media to influence legislative and regulatory processes (Gitterman & Germain, 2008b).

THE HELPING PROCESS

Like life itself, this model of practice is phasic. The helping process is organized into three phases—initial, ongoing, and ending. The phases ebb and flow in response to the interplay of personal and environmental forces. Although not always distinct in actual practice, they are separated to provide practice guidelines. The initial phase presents concepts and methods on the accomplishment of two professional tasks: (1) creating a supportive environment; and (2) developing commonality of purpose. All professional helping and environmental influencing requires clarity of purpose and shared definitions of needs, concerns, goals, and respective roles. The shared understanding and initiation of problem-solving activities usher in the ongoing phase. In this phase, people are helped with their life transitional, environmental, and interpersonal stressors and the major environmental influencing activities are launched. In the ending phase, the worker deals with the feelings aroused by the termination, evaluates what has been accomplished and what remains to be achieved, and develops plans for the future. In community, organizational, and legislative activities, the worker evaluates the outcomes and, if effective, attempts to institutionalize the innovation to ensure its permanence.

In the helping process, the professional relationship is characterized by mutuality and reciprocity and conceived of as a partnership. This conception of client and worker roles requires careful attention to variations, introduced by such things as level of functioning, age, cultural expectations, and lifestyles. If strains evolve between the partners, the social worker invites open and direct communication, reaches for disappointment and anger, and strives to develop greater understanding and mutuality in the relationship.

Social workers must consistently accept and respect each client's (a) race, ethnicity, religion, and spirituality; (b) gender; (c) sexual

orientation; (d) age; and (e) particular mental and physical challenges (Heller & Gitterman, 2010). Such sensitivity requires specialized knowledge about a particular population or person being served by the practitioner and a high level of self-awareness. The combination of specialized knowledge and self-awareness helps to assure a practice that is sensitive to diversity (objective) and difference (subjective) as well as sameness and is responsive to the needs and aspirations of vulnerable and oppressed populations and to the consequences of discrimination. Sensitivity to diversity also requires respect and understanding of people whose characteristics and values may differ from those of the group around them or of the worker. At times, working with people whose backgrounds are similar to ours creates its own special challenges (Lum, 2004; Swigonski, 1996).

CONCLUSION

Life model practice seeks to elevate the fit between people and their environments. In mediating the transactions between people and their environments, social workers fulfill a dual professional function: helping to eliminate, or, at least, alleviate life stressors; and influencing social and physical environmental forces to be responsive to people's needs. By integrating people's needs for individualized services (function) and for environmental reform and social action (cause), the life-modeled social worker is well positioned for the complexities of contemporary conditions and practice dilemmas. Increasingly, our profession will be called upon to bear witness against social inequalities and injustices by mobilizing community resources, influencing unresponsive organizations, and mobilizing political action, while, at the same time, providing services that build on individual and collective strengths.

32 Client-centered Theory and Therapy

William S. Rowe, Samantha A. Hafner, & Alicia J. Stinson

Those who seek the help of therapists have often been badly damaged by their experience of life.

(Mearns, Lambers, Thorne, & Warner, 2000, p. 90)

INTRODUCTION

Client-centered theory was originated by Carl Rogers more than five decades ago, at a time

when the humanistic approach to psychology was evolving and clearly differentiated from the more analytical styles of that period. Client-centered theory is hypothesized on the belief that all beings have innate means to grow and change beyond their perceived limitations of “self” (e.g., attitude, behavior, and self-concept) toward greater positive personal development when facilitated through consistent and reliable relationships in therapy (Cepeda & Davenport, 2006; Green, 2006; Rogers, 1957, 1961; Rowe,

2011; Snodgrass, 2007; Watchel, 2007). Although client-centered theory has recently lost focus in the United States, it has been explored by several international communities and continues to grow in popularity abroad. Along with influences on future practice, this section will discuss the foundation of client-centered theory, its relationship with social work, and its evolution within the psychotherapy community.

WHAT IS CLIENT-CENTERED THEORY AND THERAPY?

Client-centered therapy is a nondirective approach where the role of the therapist is not to offer direct advice for change or make any other type of suggestion that is usually found in the behavioral therapies but to use self-awareness in relationship to the client, focusing on the here and now of the presenting disparity, and provide a safe environment in which the client is capable of achieving self-actualization. The client-centered therapist shows respect in recognizing that the client is the expert, inherently capable of resolving his or her challenges in order to live a more complete and satisfying life (Cepeda & Davenport, 2006; Green, 2006).

Client-centered theory and therapy are not based on stages of development or steps of actions to take sequentially with the client; rather, they rely solely on the stance of the therapist to genuinely possess three key humanistic characteristics: empathy, congruency, and unconditional positive regard. Furthermore, these three attitudes are manifested by the therapist and accessed during counseling sessions with the client, who is often experiencing a sense of incongruence, vulnerability, and anxiety. In an analysis of each individual characteristic, researchers discovered several consistencies between each component. The analyses were designed to determine the effects on therapeutic outcomes when therapists incorporate a feature of client-centered therapy into their practice. It was concluded, however, that determining the effectiveness of one characteristic proved difficult, because all three often went hand-in-hand in a therapeutic environment. For example, empathy is considered to be indivisible from congruence and positive regard, and genuineness is necessary in order to portray empathy or regard adequately. Although limitations to this type of research are apparent, all three studies concluded an overall leaning toward

positive relationships between using the characteristics of client-centered therapy and therapeutic results (Elliott, Bohart, Watson, & Greenberg, 2011; Farber & Doolin, 2011; Kolden, Klein, Wang, & Austin, 2011). It is also essential to the theory of client-centered work that the client perceives and recognizes these therapeutic attitudes to some extent (Bozarth & Brodley, 1991). Table 32.1 offers a more detailed explanation of each of the three elements that are central to the therapist's behavior as client-centered.

In 1957, Carl Rogers hypothesized six conditions as "necessary and sufficient" to promote what he called "constructive personality change" in the individual (p. 241). It is also suggested that as long as the therapist is able to interrelate the three salient qualities discussed earlier (congruence, empathy, and unconditional positive regard), then at a minimum the client will experience positive growth (Snodgrass, 2007; Snyder, 2002). Table 32.2 represents the key principles of client-centered theory.

In addition to Rogers's explanation of the client-centered approach in the helping profession, there have been many others who built on his original hypothesis by expanding its application. One such contributor to this approach is Robert Carkhuff, who elaborated on the three core conditions by adding confrontation, immediacy, and concreteness, also noted as "facilitative conditions deemed essential for effective counseling" (Horan, 1977). In this realm, these qualities or conditions parallel Rogers's core conditions in the following way: concreteness in empathetic understanding is about "being specific"; immediacy with congruence refers to "what goes on between us right now"; and confrontation is seen as useful in "all three of Rogers' conditions" (Brazier, 1996) as "telling it like it is" (Carkhuff, 1971, as cited in Horan, 1977). Carkhuff's emergences in the client-centered approach are often seen as more active and direct than the original precepts and are recognized as qualities that further aid the helping process of the client.

The effectiveness of client-centered therapy is primarily dependent on the relationship between the client and therapist, whereby the therapist is completely aware of him- or herself in relationship to the client and the client is able to communicate unexpressed feelings and emotions that have caused confusion with his or her notion of self. When this ideal relationship is formed between client and therapist, even complex and deep-rooted issues can be addressed

TABLE 32.1 Characteristics of a Client-Centered Therapist

Core Attitude	Required Skill or Behavior of Therapist
Empathy	Sharing the clients' experience from their perspective and understanding it through their frame of reference. This is accomplished through verbal and nonverbal actions. This also includes seeking clarity to the client's experience, not through making an inference or assumption that is inaccurate but, rather, seeking to gain an understanding from the client when we are not certain. Requires truly being present to feeling what the client shares and also experiencing what we as therapists feel in response to the client. Empathetic understanding is not to be confused with simply mirroring or reflecting back to the client what was shared; it is more closely aligned with recognizing what the client is attempting to communicate or struggling with at a deeper level. Communicating this awareness and seeking clarity (e.g., "let me see if I have this correct") assists the client in exploring more deeply their internal process.
Unconditional positive regard (<i>respect</i>)	Communicating emotional warmth to clients' needs/issues/problems and notion of self or selves while not providing recommendations, opinions, advice, or solutions. This is referred to as "prizing" the client/individual for who they are as a unique individual. It is necessary to point out that this does not mean the therapist/counselor has to agree or condone the actions/attitudes of the client; likewise, it is not for the therapist to voice personal disagreement with such experiences of the client.
Congruence (<i>genuineness</i>)	Demonstrating through (congruent) verbal and nonverbal gestures (e.g., therapist's affect and mood are the same) a deep level of understanding and ability to be honest, genuine, and "whole." This is about being real with the client, not superficial. This does not require diagnosing the client or using terms that are unknown to the client. Truly meet the client where the client is.

and understood. A case study involving a client suffering from severe childhood abuse demonstrated that client-centered therapy can be successful in cases of extreme trauma. Psychologist David Murphy utilized a strategy of empathetic response and congruent acceptance of his client that resulted in the client's personal growth and understanding (Murphy, 2009). Ultimately, clients are able to experience on their own accord that they are loved and valued, which allows them to realize their fullest potential through self-actualization.

CLIENT-CENTERED PERSPECTIVE AND SOCIAL WORK

The conditions of client-centered theory match the fundamental values and skills of social work. The two have a historically organic relationship based on the shared belief and respect for

the individual's worth and dignity, autonomy, self-determination, and ability to improve whatever conditions exist through empowerment of the individual, group, or community. The core skills used by social workers in purposeful relationships include empathy, respect (unconditional positive regard), and authenticity (congruence), which are also noted as the key elements/attitudes to the client-centered approach (da Silva, 2005; Hepworth, Rooney, Dewberry Rooney, Strom-Gottfried, & Larsen, 2009; Rowe, 2011). The following case is presented to illustrate the use of the client-centered approach in social work.

Case Example

Liz, a single female, age 33, sought counseling because of conflicts between her personal needs and those of her family. Liz grew up in a lower to middle-class neighborhood outside of New York City as the older of two daughters to immigrant

TABLE 32.2 Key Principles to Client-centered Theory

Rogers's Conditions of Client-centered Theory	Underlying Assumption of Individual	Role of Therapist
Therapeutic <i>relationship</i> must exist between client and therapist/counselor	Willing to participate to some extent, capable and competent	Establishes a safe environment for cultivating the relationship; develops the conditions necessary and sufficient for constructive personality change
Client is in a state of <i>incongruence</i>	Anxious, vulnerable, distorted sense of real self vs. ideal self	Remains integrated in the relationship
Therapist/counselor is <i>congruent</i>	Will be able to recognize this through therapist's use of self and will develop trust	Genuine, sincere, authentic; demonstrates a fully integrated presence of self in relationship to client
Therapist experiences <i>unconditional positive regard</i> toward the client	Has the capacity to guide, regulate, direct, and control self providing certain conditions exist	Respect, acceptance, warmth, and a nonjudgmental attitude
Therapist is <i>empathetic</i>	Has rarely experienced this level of understanding, later begins to experience and verbalize unexpressed feelings/emotions	Feels what the client feels, active listening, verbally and nonverbally communicates back to the client in a validating (not evaluating) manner
<i>Communication</i> that the therapist's use of empathy and unconditional positive regard is understood	Experiences self-actualization and happiness; loved and valued by self and others	Maintains commitment to the advancement of love and peace as basic strivings; facilitates and recognizes the client's full growth and potential

parents from Europe. Her father, Edward, died suddenly from a heart attack at age 50 when Liz was 15 years old. Her remaining family includes her mother, Rose, age 65; and one younger sister, Angela, age 30. Both reside in New York. Liz lives and works in San Diego, California, where she is an executive marketing manager for a firm that she has been with for over ten years, since graduating from college. She provides financial support to her mother, who is unable to work due to poor health, and occasionally to her sister, who is unable to keep a job due to her substance use (among other problems).

Liz describes her relationship with her sister as strained. The last time they spoke it ended in a "shouting match as usual over Angela taking advantage of their mother, and her continued lack of responsibility with self-care." Liz states that she and her mother have a warm but contentious relationship. She claims that she talks with her mom every day and sends her money monthly

for medical and living expenses but is often criticized for being selfish for not doing more to help her sister. Liz says she understands her mother's concerns about Angela and sometimes feels guilty for being resentful of her mother's attitude; however, she doesn't see that it is her problem to take care of her sister any longer. She is also at a point in her life where she wants to meet someone, settle down, and hopefully start a family, but she dismisses the idea as being a "fantasy not reality." Liz describes herself as an over-achiever and the only "responsible one" in her family. She has a few close friends with whom she socializes occasionally, but she is adamantly private about her family dynamics and personal situation. Liz arrives at the social worker's office feeling depressed, withdrawn, and hopeless about her current and future situation. The following are excerpts from Liz and the social worker exploring her feelings about the people she identified as family members in her life.

Liz: [with certainty] I love my mother very much. I take care of her financially ... and I don't mind. I actually feel like it's my responsibility since she's all alone ... well, not really alone I suppose. My sister, I guess, lives with her, but that's a whole other story ... she's such a loser. [At this point the client has become restless and is looking away and pulling nervously on her sweater.]

Social Worker: I can see you really care about your mom and her well-being. I'm also sensing that maybe you wish your sister were more responsible and involved?

Liz: Yeah ... that's if she could stop using the drugs and alcohol. I get so angry when she is so neglectful of herself. It hurts my mother so much, but she just doesn't care.

Social Worker: Her lack of care upsets you the most?

Liz: Yes, care for herself and care for others. I almost don't know if I even care anymore about what she does to herself; it's just my mom that I care about. Well that's not totally true ... I feel guilty saying that [pauses and starts to become tearful].

Social Worker: [leans forward and offers the client tissues and gently responds] This seems like a really sensitive place for you to be right now.

Here the social worker's use of empathetic skills encourages the client to explore more deeply her feelings of discord around family relations.

Several sessions later, Liz explores her own needs, including the desire for an intimate relationship.

Liz: [hesitantly] I've met this great guy (John) at work and we seem to have a lot in common. I really think I'm beginning to like him and I think he likes me, too.

Social Worker: Tell me more.

Liz: [enthusiastically describes some of her initial conversations with John and her attraction for him, but as she continues to offer more around her feelings she becomes sullen] Well, the truth is it probably won't work anyway. I just keep telling myself that a relationship with him is only a fantasy; it will never be a reality for me.

Social Worker: Hmm. Let me see if I got this right. If you could, you would ideally have a relationship with John. It sounds like you

have a special connection with him, and you think he feels it, too, yet you believe that this isn't a real possibility?

Liz: [tearfully] Right. I would like that, but I'm so involved with my family's problems. Why would anyone want to sign up for that? It makes me so sad I'll probably just end up alone.

Social Worker: [softly] That makes me sad, too. I wonder if you realize how others see you ... how I see you. You have such a generous heart and really care deeply about relationships with people you love. These are wonderful qualities for a successful relationship. I wonder how it would feel for you to be that generous with yourself in meeting your own needs.

Again, we see the therapist is using empathetic skills, communicating her feelings of Liz's experience while remaining congruent. The social worker is able to acknowledge Liz's qualities of caring deeply for loved ones and helps her see how this does not have to mean she abandons herself or her own desires. This demonstration helps Liz accept that she is lovable, valuable, and capable of having a real relationship and not just the fantasy of one.

Liz returns for her final session after several weeks of continued therapy, where she has explored further her desire and need for a real and intimate relationship along with her feelings of responsibility to care for her mother.

Liz: [happily] John and I have been dating now for almost 8 months and it's going really well. I think he could be the one! [smiling] I feel so loved. He's a great guy. Also, I finally convinced my mom to move to California where she will be living with me until we find her a place of her own nearby. I'm so happy about this decision, especially since my sister just moved away and I was worried about [Mom] being alone. This move is really going to allow me to care for my mom in a more involved, sort of hands-on way.

Social Worker: It is such a pleasure to witness how you have grown through your process. It really gives me a great sense of hope. I can see how you have come to appreciate and accept yourself not only as a loving daughter who only wants the best for her mom, but also as a woman who is capable of having a successful relationship and meeting your own needs.

In reviewing this case, we can see that the stance of the therapist was to establish a trusting relationship with the client using the three key characteristics of a client-centered approach. Throughout this relationship the social worker shows *unconditional positive regard* for the client by being warm, accepting, and non-judgmental of the client’s presenting conflict; demonstrates *empathy* by being able to communicate an understanding through accurate reflection of the client’s feelings; and remains *congruent* even with expressing her own experience of Liz as lovable. Through verbalizing unexpressed emotions, Liz succeeded in reconciling her feelings of despair over the role of caregiver versus her need to be loved and was able to fully realize her potential for happiness and achieve a greater and more fully integrated sense of self.

The Larger Perspective

Social workers can use client-centered practice in a multitude of settings, including family and couples counseling, group therapy, and the larger context of community work (see Table 32.3). In each of these settings, the therapist uses the three key skills to address each individual or family member and his or her unique needs and concerns, ultimately facilitating an ideal scene from the present scene. Also in this framework, the social worker can empower participants by teaching them how to use the client-centered principles with one another to foster the optimum development within their particular system (Barrett-Lennard, 1998; Rowe, 2011; Snyder, 2002).

BRIEF HISTORICAL MILIEU OF ROGERS AND CLIENT-CENTERED THEORY

In 1951, Carl Rogers published the text *Client-Centered Therapy*, which he frankly surmises is a book “about life, as life vividly reveals itself in the therapeutic process—with its blind power and its tremendous capacity for destruction, but with its overbalancing thrust toward growth, if the opportunity for growth is provided” (Rogers, 1951, p. 5). This last remark reflects his well-known nondirective approach and attitude toward the counseling process.

To attempt to address the complete history of who and what influenced Rogers would not be suitable for this chapter; however, suffice it to say that in his 1961 book, titled *On Becoming a Person* (which is highly recommended reading), he provides the most intimate detail of what he coins “some of the psychological highlights of my autobiography, particularly as it seems to relate to my professional life” (p. 5). Rogers was clearly influenced and inspired by a number of social-cultural-contextual factors and beliefs and has been equally reciprocal and influential on the profession of psychotherapy, including social work, over the past 50 years. For example, Hill (2007) acknowledges this influence by citing a recently published report in the *Psychotherapy Networker* (March/April 2007), which “reported that in both 1982 and 2007 Carl Rogers was nominated by a landslide as the most influential psychotherapist in the United States” (p. 260). Apparently, this was the result of a voluntary survey of 2,598 mental health professionals who claim to be “eclectic” in their

TABLE 32.3 Client-centered Principles within the Micro, Mezzo, and Macro Systems

Family (or Couple)	Group	Community
<ul style="list-style-type: none"> • Facilitation of children’s needs to be fully functioning in the world and in the family • Recognition and encouragement of individuality • Facilitation of open and honest communication • Identification of family goals 	<ul style="list-style-type: none"> • Facilitation of group members to take responsibility for themselves in whatever way is realistically possible • Clarification and solution of problems • Recognition of clients perceived and real self 	<ul style="list-style-type: none"> • Facilitation of community self-perception • Recognition and encouragement of indigenous leadership • Facilitation of the communication among divergent groups • Identification of community goals

therapeutic orientations. Additionally, Goldfried (2007) reveals that Rogers's infamous 1957 article, "Necessary and Sufficient Conditions for Therapeutic Change" has been "cited in the literature over a thousand times in professional writings originating in 36 countries" (p. 249), positing that it is even "more popular now than it was 20 years ago" (p. 249).

International Advances in Client-centered Theory

Client-centered theory (more recently referred to as the person-centered approach) has continued to fluctuate in popularity in many countries throughout the world. In particular, Rogers's work and related literature have gained momentum in Australia, the United Kingdom, and Japan over the past several decades. According to Shimizu (2010), while the person-centered approach was developing in the UK, Japanese research on the topic had progressed substantially as well. One hindrance in Japan stemmed from translation barriers that prevented their literature from being published in English, and vice versa (p. 19). While professional and academic interest in Rogers's work within the United States began to trend downward, the impact on the international community picked up speed. The build-up surrounding client-centered theories in the UK also contributed to the reoccurring interest from Australia. Following Rogers's death, Australia experienced an influx of literature regarding person-centered theory. Many concepts based around client-centered theory and a humanistic approach have been utilized in a variety of training programs for counseling in Australia (Barrett-Lennard & Neville, 2010). It is also important to note that although client-centered theory is not formally used as much in the United States today, its founding principles have been incorporated into important aspects within many, if not most, counseling and interviewing practices.

CONCLUSION

If there were a code of conduct for client-centered therapy, it might read something like this. Client-centered therapy does not diagnose, judge, assess, solve, or otherwise profess to know what is "wrong" with the individual. Client-centered therapy focuses on the uniqueness of the

individual by respecting, nurturing, loving, and fostering the fragmented aspects of the client's notion of self while the therapist demonstrates and maintains an integrated sense of wholeness.

Client-centered therapy can be viewed as a significant precursor to other effective therapies that are intentionally directive, problem-solving, or behavior-changing in their focus. At a minimum, the client-centered approach is seen as significant in assisting the client to feel understood, loved, and fully integrated through establishing a safe, trusting, and reliable rapport with the therapist. Bohart and Byock (2005) recognize the uniqueness and value of the nondirective client-centered approach by asserting that "no matter how many new and effective interventions our field continues to generate, there may always be a place for providing people with a safe space where they can talk to another person who recognizes and tries to understand them primarily as persons and gives them room to think" (p. 209).

Although there are many positive attributes to traditional client-centered therapy, such as autonomy, respect, and dignity for the client, social workers need to remain culturally sensitive and aware of when this approach might not be appropriate or useful. For instance, some clients might come from a culture that highly respects the role of the authority figure and would be remarkably uncomfortable interacting in this nonauthoritative environment. Additionally, it is important to gain an understanding of the client's expectations of therapy and any desire on the part of the client for immediate and direct problem solving versus an approach that facilitates and encourages deeper exploration of the self. In these cases, the social worker/counselor is going to serve the individual better by using a different intervention or by referring to a different therapist. One other limitation to consider is that the client-centered approach assumes the client to have an intrinsic motivation to change, and there may be some instances where the individual "may lack motivation to change (e.g., substance abusers, batterers)" as cited in Goldfried (2007, p. 252), and this is obviously going to require the counselor to employ other means to assist the individual in developing this level of motivation.

The client-centered approach is often dismissed as being simple or ambivalent, when in fact it is quite the opposite—it requires the therapist to be highly skilled and evolved not

only as a practitioner but also as a fully integrated, self-aware, nonjudgmental, and mature individual capable of understanding and using the core concepts of this modality effectively. Rowe (2011) defends this point well and recognizes the complexity of this approach when he offers that “it is only when (*social*) workers have had significant experience that they are in a position to rediscover person-centered theory, with its many layers of depth and meaning” (p. 73).

33 Cognitive-behavioral Therapy

M. Elizabeth Vonk & Theresa J. Early

Cognitive-behavioral therapy (CBT) is actually a number of related therapies that focus on cognition as the mediator of psychological distress and dysfunction. As the name implies, CBT draws on and combines the theoretical and practical approaches of behavior therapy, dating to the 1950s, and cognitive therapy, dating to the 1960s work of Beck and Ellis (Ledley, Marx, & Heimberg, 2010). Behavior therapy, as developed in the United States from the work of Skinner, redefined various mental illnesses as behavioral problems, hypothesized to have arisen from faulty learning. The greatest progress achieved in behavior therapy came in reducing anxiety disorders and childhood disorders, such as aggressive and oppositional behavior, and in improving the quality of life for people with mental disabilities. Whereas behavior therapy is based on various theories of learning, cognitive therapy is based on the assumption that emotional and behavioral disturbances do not arise directly in response to an experience but from the activation of maladaptive beliefs in response to an experience. Treatment from a cognitive perspective, then, is directed at identifying and changing maladaptive cognitions, attributions, and beliefs that, in turn, affect emotional, physiological, and behavioral responses (Ledley, Marx, & Heimberg, 2010).

Before moving ahead to outline the basic concepts and applications of CBT, we present a case study that will be used throughout this

chapter to illustrate various aspects of CBT. John, a 38-year-old European American man, sought therapy at his wife's urging. He explained that he has worked for 15 years in the office supply business and recently received a significant promotion to a managerial position. Since receiving the promotion, he has become "extremely worried" that he will fail in his new role. His anxiety is interfering at work where he thinks that he "can't do anything right." He is particularly worried about his performance on various reports that he is responsible for completing. In spite of his efforts to get it right, minor corrections by his supervisor have been necessary on two occasions. He worries that he will lose his job and become unable to support his family if this continues.

At home, John's anxiety is interfering in his relationship with his wife, who has told him that she is irritated by his absence while he works long hours. She has also complained that when he is home, he is "off in his own world fretting." John wishes his wife would be less critical about his need to work longer hours and spend a lot of time thinking about work. He also worries, however, that he may be "a lousy husband and father"—just like he always feared. He describes a history of anxiety, particularly about work matters, with the current level of anxiety higher than at any previous time. Exploration of early history reveals that John was raised in an intact family in the rural Midwest. He describes his mother as

“loving, but always trying to please my father.” He describes his father as “mean-spirited and never satisfied with anything, no matter how much I tried.” John would like to be less worried and feel better about his relationship with his wife.

BASIC CONCEPTS OF COGNITIVE-BEHAVIORAL THERAPY

Three elements of cognition are important when assessing and treating various emotional and behavioral disorders, the first being the actual content of thoughts. We are most aware of the content of automatic thoughts; these are thoughts that come into our minds immediately as life unfolds. More hidden from our awareness are thoughts that are referred to as rules or assumptions; these are thoughts through which we interpret our experiences. For example, John may automatically think, “I can’t handle this situation” on receiving critical feedback at work. If he were able to identify a rule related to the situation, it might be “I must be perfect at everything I do.”

Specifically, clients’ perceptions of themselves, the world, and the future are key variables among emotional and behavioral disorders (Dienes et al., 2011). Like John, those with anxiety may view themselves as incapable, the world as threatening, and the future as holding great risk of danger. Also considered important for cognitive therapy are metacognitions, or thoughts about cognitive processes. For example, John believes that he has a “need to spend a lot of time thinking about work,” potentially indicating a belief that it is helpful to worry about the potential threat of losing his job.

The second area of cognitive focus involves core beliefs. Core beliefs are global, durable beliefs about the self and the world that are formed through early life experiences. They are maintained through a process of attending to information that supports the belief while disregarding information that is contrary to it (Beck, 2011). As a child, John experienced intense criticism from his father and seems to have formed a core belief such as, “I am totally inadequate.” As an adult, he seems to ignore his history of career successes and instead focuses on the few moments in his day in which he has made a mistake or was unsure of himself. At home, he focuses on his wife’s current irritation and discounts a 14-year

history of marriage that has been “mostly good for both of us.”

The third element of cognition involves maladaptive and ingrained styles of processing information, or cognitive distortions. There are many types of distortions (Beck, 2011; Wright, Basco, & Thase, 2006), a few of which follow, with examples that might be seen in John, who perceives himself as inadequate.

- Catastrophizing: “If my boss criticizes a piece of my work, I will lose my job, be unable to support my family, my wife will leave me, and I will end up homeless.”
- Emotional reasoning: “I feel horribly anxious about this report I just completed, so that proves I must have done a terrible job on it.”
- Minimization: “I got the employee-of-the-year award purely from luck; it has nothing to do with how well I performed.”

Many emotional and behavioral disorders have been characterized by specific cognitive content, schema, and information processing styles (Dienes et al., 2011). As already mentioned, those with anxiety disorders perceive themselves as inadequate and the world as dangerous and threatening. Regarding information processing, those with anxiety pay greater attention to anxiety-provoking stimuli than they do to neutral stimuli. In panic disorder, the attentional bias is toward bodily sensation, with sufferers more acutely aware of their heart rates than other people. People with social phobia, on the other hand, attend to and make negative evaluations of their own social behavior.

Depression also has been specified in terms of cognitive content and processing styles. Those who are depressed have a negative view of the self, the world, and the future (Beck, 2011). For example, someone who is depressed may think, “I never do anything right; people are never there for me; and moreover, things will never get better.” Core beliefs are most often related to perceptions of self-defect, and attention is directed to experiences that focus on loss and failure (Dienes et al., 2011).

Practitioners of CBT employ understanding of the elements of cognition and their relation to specific disorders, as described previously, in a therapeutic relationship with well-specified roles for both the practitioner and the client. The hallmark of the therapeutic relationship in

CBT is collaboration, and roles of both the client and the practitioner are active. The role of the practitioner most closely resembles that of a supportive teacher or guide who holds expertise in cognitive and behavioral therapeutic methods, as well as possesses interpersonal skills (Ledley, Marx, & Heimberg, 2010). The practitioner helps the client learn to identify, examine, and alter maladaptive thoughts and beliefs and increase coping skills. Although the practitioner lends methodological expertise, the client is the source of information and expertise about his or her own idiosyncratic beliefs and assumptions. The client and practitioner thus work together to define goals, set agendas for sessions, and uncover and explore attitudes and beliefs that are significant to the client's well-being. Successful replacement of maladaptive cognitions depends on collaboration between client and practitioner, for the client can provide the most lasting and effective cognitive replacements.

APPLICATIONS OF COGNITIVE-BEHAVIORAL THERAPY

The most prominent models of CBT are Beck's cognitive therapy (Beck, 2011), Meichenbaum's cognitive behavior therapy (Meichenbaum, 1994), and Ellis's rational emotive behavior therapy (Ellis, 1996). Although there are differences among them related to, for instance, the therapist's level of direction and confrontation, all of the models share basic elements. All rely on identifying the content of cognitions, including assumptions, beliefs, expectations, self-talk, or attributions. Through various techniques, the cognitions are then examined to determine their current effects on the client's emotions and behavior. Some models also include exploration of the development of the cognitions to promote self-understanding. This is followed with use of techniques that encourage the client to adopt alternative and more adaptive cognitions. The replacement cognitions, in turn, produce positive affective and behavioral changes. Other similarities of the models include the use of behavioral techniques, the time-limited nature of the interventions, and the educative component of treatment.

It is useful to consider the application of CBT in steps. At each step, a great number of specific techniques are available. Only a few are reviewed here due to space limitations.

Assessment

As in many clinical social work assessment processes, cognitive-behavioral assessments may result in a case formulation that includes psychiatric diagnosis; definition of the client's problem in terms of duration, frequency, intensity, and situational circumstances; description of client's strengths; and treatment plan. Cognitive analysis of a client's problem, however, is unique to cognitive-behavioral assessments. Assessment and case formulation includes many of the above-mentioned items, plus a prioritized problem list and working hypothesis that provide a cognitive analysis of the problems (Ledley, Marx, & Heimberg, 2010). Problems are described very briefly and are accompanied by the client's related thoughts, emotions, and behaviors. The working hypothesis, unique to each client, proposes specific thoughts and underlying beliefs that have been precipitated by the client's current experiences. Formulations may also include an examination of the origin of the maladaptive cognitions and information processing style in the client's early life. The working hypothesis is then directly related to treatment planning. As an example, we have created a cognitive conceptualization for John, shown in Figure 33.1.

Teaching the Client the ABC Model

Concurrent with assessment, one of the first tasks of the cognitive-behavioral therapist is to educate the client about the relationship of thoughts, emotions, and behaviors. Leahy (2003) suggests contrasting the client's usual way of describing the relationship of thoughts, emotions, and behaviors with the alternative ABC model. For most people, the usual way to think about it is that an activating event (A) causes an emotional or behavioral consequence (C). For example, John states that because he received criticism on his report (A), he is feeling anxious (C). The ABC model proposes that in actuality, a thought or image representing a belief or attitude (B) intervenes between A and C. Using the same example, following the criticism (A), John may think that he will lose his job (B), resulting in anxiety (C). Clients need to become very familiar with the model through presentation of and practice with personal illustrations.

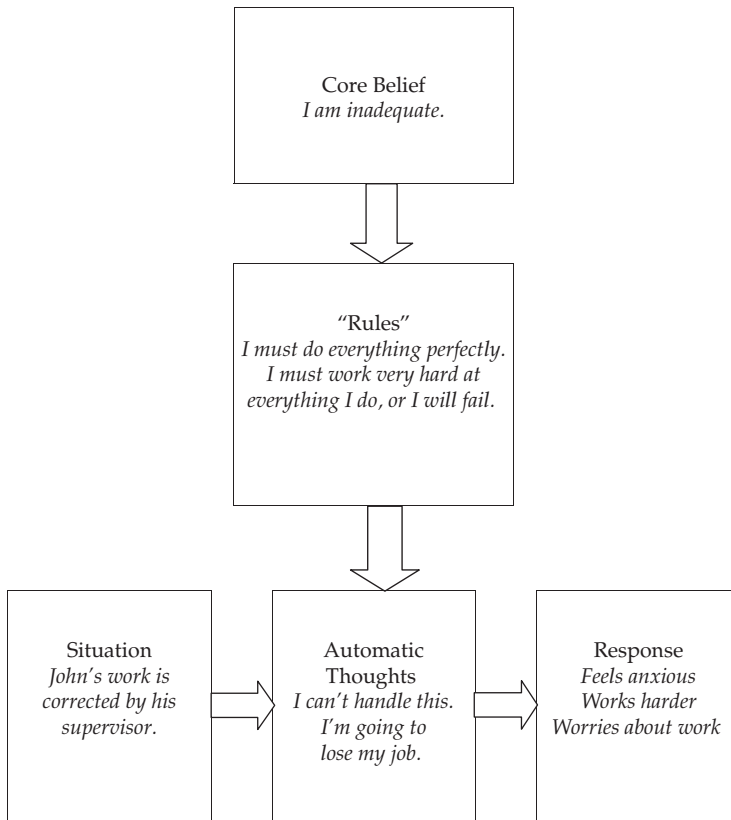

Figure 33.1 Cognitive formulation for John.

Teaching the Client to Identify Cognitions

Once the client understands the ABC model, the therapist helps him or her learn to identify thoughts and beliefs. Clients may find that many types of cognitions are relevant for analysis, including those related to expectations, self-efficacy, self-concept, attention, selective memory, attribution, evaluations, self-instruction, hidden directives, and explanatory style (McMullin, 2000). A great variety of useful techniques for the purpose of identifying cognitions are described by McMullin (2000); DeRubeis, Tang, Webb, and Beck (2010); and Leahy (2003). The daily thought record is a written method involving a form made up of columns within which clients record activating events (column A), corresponding emotional reactions (column C), and immediate thoughts related to the event (column B). In the case example, John would be taught to identify and record on the form an anxiety-provoking situation from the previous week, such as hearing from his boss that

a report needed correction. Next, he would be asked to identify his feelings when the situation occurred. Then he would be prompted to remember what went through his mind at the moment his boss spoke with him. In this instance, he would record his thought, "I can't handle this" in between the situation and the anxious feelings. Another method, the downward arrow technique, is a verbal way to discover the underlying meaning of conscious thoughts through the use of questions such as, "What would it mean to you if the [thought] were true?" Through the use of the downward arrow technique, the client may discover a core belief. John might provide an answer such as, "It would mean I'm incapable." People are generally unaware of their core beliefs that are, nonetheless, very fundamental to the way they feel and behave.

Teaching the Client to Examine and Replace the Maladaptive Cognitions

After identifying thoughts and beliefs, the client is ready to begin examining evidence for and

against the cognitions. In addition, the client is encouraged to replace maladaptive cognitions with more realistic or positive ones. Replacement requires frequent repetition and rehearsal of the new cognitions. Again, McMullin (2000), DeRubeis et al. (2010), and Leahy (2003) provide a wealth of information about specific techniques, a few of which are briefly described here.

Many of the techniques are verbal, relying on shifts in language to modify cognitions. In one technique, the client is taught to identify maladaptive thoughts as one of a list of cognitive distortions. Cognitive distortions represent maladaptive thinking styles that commonly occur during highly aroused affective states, making logical thinking difficult. Identification of the use of a distortion allows for the possibility of substituting more rational thinking. Thought stopping, a behavioral means to draw attention to the need for substitution, might involve snapping an elastic band. Another technique involves the use of a variety of questions that provide opportunities to evaluate the truth, logic, or function of beliefs (Beck, 2011; Leahy, 2003). Such questions include:

- What is the evidence for and against the belief?
- What are alternative interpretations of the event or situation?
- What are the pros and cons of keeping this belief?

Imagery and visualization are also used to promote cognitive change. For example, clients may be encouraged to visualize coping effectively in difficult situations or visualize an idealized future to provide insight into current goals. McMullin (2000) suggests that imagery techniques are particularly useful to encourage perceptual shifts, whereas verbal techniques help facilitate change in more specific thoughts and beliefs. A combination of the two types of techniques is often useful.

Other Techniques

Cognitive-behavioral therapists use a wide variety of behavioral techniques, according to the needs of the client. These include relaxation training, assertion training, problem solving, activity scheduling, and desensitization

(Beck, 2011; Wright, Basco, & Thase, 2006). More recently, mindfulness has been incorporated into cognitive-behavioral therapies, such as mindfulness-based stress reduction (Stahl, Goldstein, Kabat-Zinn, & Santorelli, 2010); dialectical behavior therapy (Koerner & Linehan, 2012); and acceptance and commitment therapy (Hayes, Strosahl, & Wilson, 2012). Most likely, both relaxation and mindfulness training would be useful for John.

- Relaxation training involves teaching the client to relax muscles systematically and to slow breathing. The client learns to discriminate between tension and relaxation. Through practice, the relaxation response can be easily activated.
- Assertion training provides clients with interpersonal skills that allow for appropriate self-expression. Often these skills are taught and practiced in small groups.
- Problem solving involves teaching the client to solve personal problems through a process of specifying the problem and then devising, selecting, implementing, and evaluating a solution.
- Activity scheduling allows clients to plan for activities that will provide pleasure, socialization, or another identified need during the time between contacts with the practitioner.
- Desensitization provides clients with graduated exposure to anxiety-provoking objects or situations while engaged in behaviors that compete with anxiety, such as relaxation. The exposure may be imaginary or real.
- Mindfulness training allows clients to purposefully attend to the experience of the present moment without judging or fighting against what is occurring. Such awareness is thought to reduce emotional reactivity and suffering.

In addition, cognitive-behavioral therapists often assign homework to their clients for the purpose of extending learning beyond the therapy session. Homework assignments vary according to the idiosyncratic needs of the client and generally are designed collaboratively. One common assignment is the use of a form such as the daily thought record.

STRENGTHS OF COGNITIVE-BEHAVIORAL THERAPY

Various features of CBT fit well with social work. The collaborative nature of the therapeutic relationship is consistent with the social work value of self-determination. Additionally, the client's active involvement in the change process is consistent with an empowerment approach. CBT's use within an integrative framework that allows for specification of techniques to match individuals' needs is consistent with the ideal of individualizing treatment. More recently, those who have proposed integrative therapy models have examined the role of the client's idiosyncratic meaning in CBT, noting a close kinship with constructive models of therapy (Dienes et al., 2011).

Many characteristics of CBT lend themselves to the demands of current practice settings. The structure of CBT and the extensive description of its methods in many sources make it an accessible therapy for both novice and experienced practitioners. Because the methods of therapy require initial and ongoing recording of thoughts and behaviors, mechanisms for evaluation are built in, lending support to the use of CBT by clinicians with interest in or need to document the outcomes of their work with clients. Additionally, CBT targets specific problems, thus lending itself to a short-term approach, which is consistent with both the desires of many clients and their third-party payers. Another feature of CBT that is attractive to managed care entities is the well-supported efficacy of the approach, particularly for the treatment of depression and anxiety (Wright, Basco, & Thase, 2006).

Mounting evidence attests to the versatility of CBT. Specific cognitive-behavioral treatments have been designed for a broad variety of disorders, including some that have been considered complex or difficult to treat, such as borderline personality disorder, depression, generalized anxiety disorder, posttraumatic stress disorder, substance misuse, eating disorders, grief and bereavement, and personality disorders are among those conditions for which CBT interventions have been developed (Wright, Basco, & Thase, 2006). (Please refer to Appendix A of Ledley, Marx, & Heimberg, 2010, pp. 259–273 for a detailed list of CBT resources related to specific psychological disorders, other problems that may be a focus of clinical attention, and populations.)

Future

As we look toward the future, CBT promises to remain vital to the treatment of emotional and behavioral disorders. In fact, it appears that the use of CBT will continue to expand as more is learned about specifying treatments and integrating additional techniques for particular problem areas and populations. At the same time, more treatment providers will apply wide-ranging techniques from CBT into integrative treatment models that include newer interventions such as mindfulness training. Moreover, the versatility of this treatment will enable its continued use in the changing environment of treatment settings. Finally, the fact that CBT has been used successfully across a variety of cultural groups from China to Sweden (Dienes et al., 2011) shows that it will be able to serve the rapidly changing needs of the increasingly diverse population of people who are served by social workers.

34 Psychosocial Therapy

Francis J. Turner

The term *psychosocial therapy* and its identification with a specific form of therapy has held and continues to hold a long-standing illustrious place in the history of social work.

It was initially used in a generic sense to stress that an identifying feature of social work therapy consisted of a focus on the interface of person and environment.

Later, as the theoretical bases of direct practice developed with the early controversy between the Functional and Diagnostic schools very much in the foreground, the term *psychosocial* became identified with the "diagnostic school." As other theories took their place in the profession's cadre of thought systems, and as we became more comfortable with the acceptability and even importance of a diversity of theories, the psychosocial school was identified as a particular theory in its own right.

Still later, as a more holistic view of treatment attained prominence in the profession, it was recognized that all therapeutic theories, whatever their origin, were based on a person-in-situation perspective when drawn on in social work practice. To reflect this, *psychosocial* (once again)

became a generic term describing the overall orientation of the clinical thrust of the profession.

More recently, this general use of the term has spread well beyond the borders of social work, and most human service professionals have moved to a broader based view of clients, their problems, their situations, and their therapeutic activities. In this way, *psychosocial* is widely used in a generic multidisciplinary, multi-theoretical manner.

Indeed, in recent years, as a part of the poly-disciplinary use of the term, there has been a growing usage, first in our profession and now in others, to add the prefix *bio-* to psychosocial. Thus, *bio-psychosocial* has become for many the basis on which all help is provided. Adding this further component serves to remind all social work practitioners that just as it is not possible to separate persons from their social systems, to understand the full gestalt of a client we also need to attend to our clients' physical condition and overall health.

However, even with this variation in usage and understanding, there is still extant in social work thinking a specific body of concepts, premises,

values, and patterns of intervention that together constitute a unique theory of practice properly titled Psychosocial Therapy.

Historically, this theory represents the most traditional of social work theories locating its basic origins in the work of Mary Richmond and the stream of therapeutic thought and practice that emerged from her early book, *Social Diagnosis*, and the later work, *What Is Social Casework?* These two works are mentioned specifically because this theory has suffered in the sociopolitical history of the profession owing to its strong identification with tradition and the two concepts of diagnosis and casework. That is, there is a sense that, because of its origins, it is, therefore, out of date and out of fashion as a distinct theory. However these early writers have provided a foundation for growth, development, and change.

The tradition that has served as the basis of psychosocial therapy's origins with its focus principally on treatment of individuals and families and later groups was the component of social work most closely identified with psychoanalytic thinking and other dynamic theories emerging from it, such as ego psychology. However, even with psychosocial therapy's interest in these psychodynamic theories, it was far from the total identification some would hold it to be. Rather, this approach drew its unique identity from a strong identification with the implications of the "person in situation" concept while adopting and adapting from psychodynamic thinking those concepts and therapeutic strategies that best suited and fitted social work. This approach developed in its own way while being open to thinking from other sources.

The primary conceptual identification of the psychosocial school was with a method rather than a theory. The method, of course, was casework, a term long a part of the social work lexicon. Casework as it developed as an identifying term for the profession's clinical stream has become a very broad-based methodological concept, far wider than its original therapeutic orientation.

The principal flag bearer of this tradition has been Florence Hollis, whose essential text is *Social Casework: A Psychosocial Therapy* (1963). This work built strongly on the work of earlier casework writers, especially Gordon Hamilton (1951).

This seminal work originally written by Hollis, then later coauthored by Mary Woods and solely by Woods after Hollis's death, has gone

through five editions, the latest one in 1999. All editions have carried the same title as the original. With the death of Mary Woods (2007) it will be interesting to see whether psychosocial therapy continues in the profession with a unique identification or whether it will be viewed more as an orientation or viewpoint for the whole profession rather than as a distinct theory.

Being identified with casework, this orientation to practice viewed itself, and was viewed by others, as focusing primarily on work with individuals and secondarily with families. However, as the lines between methods began to open and blur, authors in this tradition began to speak of work with couples, groups, and social systems. Additionally, authors such as Northen (1982) and Turner (1978, 1995, 2005), persons very much in the psychosocial tradition, began to urge a broader base to the system that included work with groups and larger systems.

It would be unfair to suggest that Hollis and Woods limited their perception of practice to individuals, couples, and families. These two leaders of the theory stressed the importance of all methods, but, having been shaped by the traditions of casework as being more individually client centered, the bulk of their writings and research focused on what Hollis called direct work. In addition, because of its close relation to the casework tradition, the psychosocial school of thought is sometimes viewed as being a bit out of fashion as a free-standing theory yet very much in fashion as an important identifying concept for the profession.

A further concept that has created difficulty for the reputation of psychosocial theory among other theories has been its earlier identification with, and continued commitment to, diagnosis as an highly important component of treatment. Although once an essential component of social work practice, for a variety of reasons diagnosis has become an unpopular term in the practice and sociology of the profession for many clinicians.

Diagnosis, for those opposing it, is viewed as placing an overemphasis on pathology; the word *assessment* is preferred. Nevertheless, in practice, the term *diagnosis* does get used but in a manner that highly identifies it with the various *DSM* formulations. It is frequently used in this specific way. This, rather than viewing it as an essential component of treatment comprising a much richer and health-oriented perspective on the series of judgments or conclusions that a social work practitioner needs to reach based on

the range of assessments made about the client and his or her situation, strengths and limitations, and resources.

Nevertheless, even with its collection of historical and sociocultural baggage acquired over the decades, psychosocial therapy is still an important theory in contemporary social work practice and the designated theoretical base for many North American practitioners.

A THEORETICAL OVERVIEW

Psychosocial therapy is built on the premise that ethical and effective treatment is an integrated process of assessment, diagnosis, treatment, and evaluation. These processes are not sequential in nature but are ongoing from the first instant with the client until the final closing. A component of these processes includes a formal commitment to a process of evaluation to expand our body of knowledge of evidence-based practice.

The interventive process is multifaceted and built on a paradigm that seeks to establish:

- Who is this client, historically and in the present?
- What are the current strengths and limitations?
- What does this client want?
- What does this client need?
- What can I or someone else do to assist this client in achieving the identified goals?
- What are the existing resources?

The interventive process also draws on the total range of theory and technique available from the profession or from others.

In working with clients or significant persons in their lives, there are six clusters of technique available to the therapist:

1. To utilize specific components of the relationships
2. To do specific things with the client
3. To have the client(s) do specific things within the interview
4. To have the client(s) do specific things outside of the interview
5. To do something with the client(s) outside of the interview
6. To do something for the client(s) outside of the interview

Case Summary for Psychosocial Theory

Mr. J. is a 19-year-old Latino man born in Mexico. He moved to the United States with his family when he was 10 years old. His father died in an industrial accident when he was 12. Mr. J. appears to be in good physical health and of at least normal intelligence with no evident mental health problems. He has completed high school and is currently working in the kitchen of a fast-food restaurant and living with his mother and two sisters. The family is minimally comfortable financially. He initially presents in a shy, mildly withdrawn manner and once comfortable in a relationship exhibits a quiet pleasant engaging mien.

He was referred to the family agency by his parish priest, to whom he had turned wanting help to better himself socially and economically, but he was uncertain as to how to go about this.

His male social worker used the first three interviews to help Mr. J. develop an open, trusting relationship based on his diagnosis of an early developing mildly strong positive transference, while keeping the content focused on his identified wish to “move ahead.” From this basis, the social worker made use of several rapid assessment instruments that focused on identifying areas of interest and skills. From these and material shared in the interviews, it was clear that his identified area of interest was in the management side of the restaurant business, but he was uncertain how to go about it except to talk about looking for a better job.

From here, the social worker engaged Mr. J. in some simulated job interviews, at which he did reasonably well with coaching. Next, a contract was established with him that he was to formally apply for two relevant advertised positions before the next interview.

These contacts, although not leading to a job offer, helped Mr. J. clarify that a more strategic route to achieve his goals would require further education, the nature and extent of which was unclear. To assist in this and with the client’s agreement, the worker arranged for an interview at the career counseling department of a local community college, and at the client’s request the social worker agreed to attend with him.

This interview was very useful; however, it appeared that the client did not have the requisite courses in his high school curriculum and that some make-up work would be required.

With the client's permission, the social worker pursued this matter further and established that the client, being fluently bilingual, could substitute for the missing academic material. Mr. J. was accepted into the next class of the college's hotel management program.

Over the next three months, the case was kept open on an on-demand basis with a focus on supporting Mr. J. in his early adjustment to the program. On a 6-month routine follow-up, it was noted that the client was doing very well in the program and becoming a much more confident and outgoing person.

BASIC CONCEPTS

General

From its earliest days, psychosocial therapy has been an open searching system strongly committed to the integration of new ideas. Although its roots are originally in a psychodynamic tradition, it has integrated concepts from most other theories currently driving social work practice. Principal among these are systems theory, existential theory, crisis theory, learning theory, ego psychology, and task and problem-solving theories. This interest in other theories stems partially from an understanding of the role of values in the human condition and the awareness that various theories are built on differing value orientations and will fit some clients better than others.

Psychosocial practitioners view practice theories as tools that are differentially used to respond to where and who the client is. Thus, just as this therapy moved from a position that viewed each social worker as having competence in a single modality such as casework or group work, it now deems it essential that practitioners not only be competent in multiple methods but also multi-theoretical in their orientations. Indeed, this openness to new ideas from whatever source has been one of the areas of criticism of this theory, as well as a factor that makes it difficult for some to put firm parameters around it.

Specific

Commitment to Knowledge Building. Psychosocial therapy is very much an open, changing, dynamic theory that appreciates the expanding base of knowledge reflecting the complexities of clients' lives and the myriad influences that affect them. Thus, there is the

responsibility to continually research and evaluate activities and incorporate new knowledge from whatever its source.

Positive Perception of the Human Potential. Within this system, there is a strong belief in the ability of a person to achieve high levels of satisfying functioning even with the most damaging of early histories. The therapeutic task is to build on a person's strengths and the resources of systems to foster positive growth in individuals and families.

Cognitive and Rational. Even though this system is rooted in a psychodynamic tradition, it has welcomed and adopted the insights from other therapies.

Some of the early research, as discussed by Woods, indicated that much of the verbal content of interviews consisted in reflection by the client of material that surfaced in the interviews. All of us use reflective abilities to deal with daily living. Sometimes we do this effectively, whereas at other times this leads to further problems. The opportunity to reflect with a helping understanding person, however, can lead to more effective functioning.

Power of the Helping Relationship. Much of the early writing in social work clinical practice focused on the importance and power of the helping relationship and its various characteristics. This type of relationship can and often does contain elements of significant relationships from the client's past that can affect in both positive and negative ways important relationships in the present. Thus, understanding of the reality of transference factors in relationships is still considered an important factor to be kept in mind in understanding the client, although it is much less stressed than in earlier days of this therapy.

Recognition of the Unconscious. In psychosocial therapy, the unconscious is still viewed as an important component of personality that influences but does not determine facets of present functioning. Although in day-to-day practice the major part of our work is oriented to the client's current reality, this powerful attribute of one's own personality cannot be ignored.

Importance of History. This theory recognizes that both social workers and clients bring to the present something of their respective histories. Thus, to fully understand a person we must assess to what extent their present functioning and future aspirations are influenced by their history. This does not mean that, as in earlier days, before we begin our work with a

client we take a long and detailed history. It does mean, however, that we remain on the alert for significant components of earlier history, and when such components appear to be important, we pursue them or build on them as it appears necessary. This endeavor depends on diagnostic acumen, as we seek to assess all components of a client's reality and the significance of each for the present reality with which we are dealing.

Understanding of Pathology. Even though this system is optimistic and strength-oriented, it understands that pathology in all its manifestations and intensities is a reality. Thus, it is critical that when it is present we understand its nature and influence on clients, their families, and significant others. The important aspect of our responsibility to assess pathology is to view it as a continuum. It is rarely a case of yes or no but rather a question of whether there is any degree of pathology existing that may be of significance to the presenting situation. This requires, of course, a knowledge and understanding of pathology and its many forms and the many factors that go into its development, maintenance, control, and treatment.

Importance of Social Work Diagnosis. Diagnosis is a broad concept with meaning, content, and focus varying from one profession to another. It differs from assessment, which is also a part of the therapeutic process. In social work, diagnosis is much more complex than seeking to assign a mental health label. Rather, it is a multifaceted dynamic process in which the practitioner sets out in a formal manner the judgments made about clients and their situations—judgments that serve as the basis for actions to be taken in the conduct of a case, actions for which the social worker takes responsibility.

Focus on Everyday Living. Stemming from a positive view of human nature and ability to find growth-enhancing ways to address the challenges of day-to-day living, psychosocial therapy understands that many clients can benefit greatly from having these challenges addressed in a therapeutic milieu. For some, dealing with these mundane realities in clients' lives is not seen as the real essence of therapy. However, learning to deal with such life factors often brings considerable relief to clients and leads them to find ways to address other life situations.

The Importance of "Indirect Treatment." The term *indirect treatment* seeks to describe the social worker's interactions with various persons and systems in a client's life. Such interactions are intended to bring about changes that

will help the client achieve his or her objective. Unfortunately, indirect treatment is often viewed as less important or less clinical than direct work with clients. Nonetheless, skill in this area can be of great assistance to clients and can help bring about important changes in their lives that would not be achieved in direct work.

Strategic Use of Time. Time is one of the important resources used in a psychosocial approach to therapy. Rather than seeing time from an administrative perspective only, time can be used therapeutically. Work with a client can be as short as a few minutes to as long as several years of weekly contact. Short-term treatment is not by definition better than long-term, nor is the reverse true. The time spent is what the client needs from our diagnostic perspective, not from some external imposition.

Practitioner Self-awareness. Not only are clients influenced by their unconscious, so, too, are therapists. Hence, it is important to ensure that responses to clients are as free as possible from distortion or misunderstanding stemming from our own histories. This, of course, is one of the important functions of our professional education.

Supervision and Consultation. Although we have moved far beyond the days when training was close to being a therapeutic experience for the student, there is still a place in our practice for a formal connection with a colleague to ensure objectivity in interactions with clients. Even though many practitioners would not see themselves as psychosocially oriented, today's pattern of student practicum and individual supervision stems from the psychosocial theorists' long-standing emphasis on the need for self-awareness as a critical component of ethical practice and for assistance in achieving it in particular situations.

Minimization of Technique. It is interesting to note that as committed as psychosocial theory is to evaluating our interventions, as with the rest of the profession to date, there has been little interest in discussing technique. That is, any ongoing effort to assess not only what is observed in treatment but how and why observed change has taken place. That is, more attention to what we have actually accomplished in our time with the client or significant others in their lives. This phenomenal also exists regarding other applications to treatment. Yet, in a profession committed to evaluating the correlations between what we do with, to, and for clients and the outcome emanating from these activities, this lacuna in

evaluative activities will need to assume greater importance in the days ahead.

CONCLUSION

Psychosocial therapy is an approach to social work practice with a long tradition in the profession. It builds on a broad understanding of individuals, dyads, families, groups, systems, and other societal factors and the resources of each. Its overall goal is to assist people in achieving the highest level of psychosocial functioning through an understanding of their past, present, and future potential.

The theory reflects social work's century-old commitment. Throughout its history, social work has been committed to tested knowledge and innovations. Psychosocial therapy will continue to stay relevant and stand as the conceptual and operational basis of much of contemporary social work practice.

35 Solution-focused Therapy

Peter De Jong

The late Steve de Shazer, one of the inventors of Solution-focused Therapy (SFT), informally referred to it as a way to carry on a useful conversation with clients. The purpose of the conversation is to co-construct solutions. Practitioners ask the questions that so clearly define the approach; clients respond out of their frames of reference. The questions are not-knowing because they put clients into the position of being experts about

their own lives. Therapeutic conversations focus on what clients want to be different and how to make those things happen.

HISTORY AND DEVELOPMENT

Although rooted, in some respects, in the "uncommon" therapy of Milton Erickson and the

strategic family therapy of John Weakland and his associates at the Mental Research Institute (Miller, 1997), SFT was largely developed inductively through careful observation of therapy sessions using the one-way mirror at the Brief Family Therapy Center (BFTC) in Milwaukee, Wisconsin.

In this natural inquiry, de Shazer and his colleagues attempted to set aside past assumptions about client change and pay attention to which clients seemed to be making progress and what the practitioner might be doing that was useful (de Shazer et al., 1986). During this process they made several discoveries about therapy and invented related techniques, which they continued to refine through ongoing use and observation. It soon became clear that clients who made progress had clearer visions of what they wanted to be different (goals) and could identify times in their lives when problems were not occurring or were less serious (exceptions). Consequently, more time in therapy sessions, more questioning techniques, and new assumptions about therapy and client change developed around the importance of goal formulation and exception finding.

ASSUMPTIONS

- Clients are competent to co-construct goals and strategies.
- Clients are the experts about their own lives and the meanings of their experiences. Practitioners should ask about client perceptions and accept them.
- There is not necessarily a connection between problem and solution.
- Clients must *do* something differently for change to occur.
- “Only a small change is needed.” Once a small step is taken, change often snowballs beyond client and practitioner expectations.
- “If it ain’t broke, don’t fix it.” Practitioner agendas for clients invite client resistance.
- “If it works, don’t fix it.” When clients can describe how exceptions occur and their contributions to them, suggest they do more of the same.
- “If it doesn’t work, do something differently.” Do not suggest clients do what they say is not useful. (Quoted assumptions from de Shazer, 1985; 1988).

USEFUL QUESTIONS

Goal-formulation Questions. After the client briefly describes a problem, practitioners begin the co-construction of goals by asking the following:

- When your problem becomes less of one, what will be different?
- What would have to be different by the end of our session for you to say that our time together was useful and not a waste of time?

The miracle question is the best known of SFT’s goal-formulation questions. It reads:

Suppose while you are sleeping tonight a miracle happens. The miracle is that the problem that has brought you here today is solved—just like that! Only you don’t know it because you’re sleeping. So when you wake up tomorrow morning, what is the first thing you’ll notice that will tell you: Wow! Things are really different, a miracle must have happened!

The miracle question is an opener for a series of follow-up questions formulated around the client’s beginning answer to what will be different when the miracle happens. These follow-ups use who, what, when, and where questions to get details. (“Why” questions are not asked because they have not proven useful in promoting client change.) For example, to the depressed client who starts out by saying the first difference he will notice is “feeling better,” the practitioner continues by asking: So, when you are feeling better, who will be the first to notice? When might (that person) notice? What will she notice? What else? What will she do when she notices you doing that? What will you do then? What will you notice that’s different? And so forth.

Exception-finding Questions. Exceptions amount to client successes. Identifying them is the best route to discovering and amplifying client strengths and resources. Exceptions that are related to what clients want are the most useful for building solutions. Examples of exception-finding questions include:

- Are there times when you are even a little bit “less discouraged” (client’s words)?
- Are parts of the miracle you described to me happening already?

- If your friend were here and I were to ask him about whether there are times when you are “less discouraged,” what would your friend say?

Once the client identifies an exception, the interviewer follows up with several who, what, when, and where questions for details.

Scaling Questions. Scaling is a useful way to help clients express complex, intuitive observations about their past experiences and future possibilities in concrete terms. Clients are asked to scale an observation or possibility from 0 through 10 with the ends of the scale defined by the practitioner:

- On a scale from 0 through 10, where zero means there is no chance of this miracle happening and 10 means every chance, what are the chances of your miracle actually happening?
- If 0 equals where things were regarding your problems when you made the appointment to see me, and 10 equals the problem is solved, where are things today?
- Where 0 equals “no confidence at all” and 10 means “every confidence in the world,” how confident are you that you will find a solution to this problem?

Once the client gives a number, the practitioner asks for details about the meaning of that number as well as what will be different when things move up one and more numbers on the scale.

Coping Questions. These are a form of exception question and used when clients seem overwhelmed and discouraged beyond the point of trying. Examples include:

- What are you doing to cope—even a little bit—with this situation?
- I’m amazed! With all that has happened to you, I don’t know how you make it. How do you do it? How do you get from one minute to the next?
- Ah, so you do it by reminding yourself that “my children need me.” You must love your children very much! So, how is reminding yourself that your children need you helpful to you?
- Could things be worse? How come they are not?

- Who has been most helpful to you in these struggles? What is it they do that you find helpful?

“What’s Better?” Questions. Many other approaches begin second and subsequent sessions of therapy with a review of assigned suggestions or the client’s estimate of progress. In SFT, practitioners simply ask another form of an exception-finding question, namely, “What’s better?” This procedure is tied to the recognition that solutions are built from exceptions, and to observations at BFTC that asking this question most readily elicits mention of successes that occurred since the last session. When given time to think and answer, most clients can identify something better, which the practitioner then invites the client to amplify through additional questions.

SOLUTION-FOCUSED CO-CONSTRUCTION

The questions used in solution-focused interviews are intended to set-up a therapeutic process wherein practitioners listen for and select out the words and phrases from the client’s language that are indications (initially, often only small hints) of some aspect of a solution, such as articulating what is important to the client, what he or she might want, related successes (e.g., exceptions), or client skills and resources. Once having made the selection, the therapist then composes a next question or other response (e.g., a paraphrase or summary) that connects to the language used by the client and invites the client to build toward a clearer and more detailed version of some aspect of a solution. As the client responds from his or her own frame of reference, the therapist continues to listen, select, and compose the next solution-focused (SF) question or response, one that is built on what the client has said so far in the conversation. It is through this continuing process of listening, selecting, and building on the client’s language that therapists and clients together co-construct new meanings and new possibilities for solutions.

Recent and ongoing research into face-to-face therapeutic dialogues called microanalysis is adding observable detail to the understanding of how SF co-construction occurs (De Jong, Bavelas, & Korman, 2013; Froerer & Jordan, 2013; Korman, Bavelas, & De Jong, 2013; McGee, Del Vento, and

Bavelas, 2005; Jordan, Froerer, & Bavelas, 2013). (These studies indicate that therapist questions and responses (paraphrases and summaries) are not neutral or objective but contain embedded assumptions about clients and their situations. Clients, in answering the questions and accepting therapist paraphrases and summaries, are collaborating with therapists in constructing new common ground (i.e., shared understandings) about themselves and their situations. SFT, whose questions and therapist responses embed assumptions of client competence and expertise, thereby set in motion a dialogue in which clients participate in discovering and constructing themselves as persons of ability with positive qualities who are in the process of creating more satisfying lives. Here is an example of this conversational process with a client who has just answered the miracle question and is asked about exceptions related to the miracle (from De Jong & Berg, 2013, pp. 15–16):

Therapist: Rosie, I'm impressed. You have a pretty clear picture of how things will be different around your house when things are better. Are there times already, say in the last two weeks, which are like the miracle you have been describing, even a little bit?

Rosie: Well, I'm not sure. Well, about four days ago it was better.

Therapist: Tell me about four days ago. What was different?

Rosie: Well, I went to bed about ten the night before and had a good night of sleep. I had food in the house, because I had gone to the store and to the food pantry on Saturday. I had even set the alarm for 6:30 and got up when it rang. I made breakfast and called the kids. The boys ate and got ready for school and left on time. [remembering] One even got some homework out of his backpack and did it—real quick—before he went to school.

Therapist: [impressed] Rosie, that sounds like a big part of the miracle right there. I'm amazed. How did all that happen?

Rosie: I'm not sure. I guess one thing was I had the food in the house, and I got to bed on time.

Therapist: So, how did you make that happen?

Rosie: Ah, I decided not to see any clients that night, and I read books to my kids for an hour.

Therapist: How did you manage that, reading to four kids? That seems like it would be really tough.

Rosie: No, that doesn't work—reading to four kids at the same time. I have my oldest boy read to one baby, because that's the only way I can get him to practice his reading, and I read to my other boy and baby.

Therapist: Rosie, that seems like a great idea—having him read to the baby. It helps you, and it helps him with his reading. How do you get him to do that?

Rosie: Oh, I let him stay up a half hour later than the others because he helps me. He really likes that.

Later in the conversation, the therapist asks the client to scale how far along to a solution she is:

Therapist: I'd like you to put some things on a scale for me, on a scale from 0 to 10. First, on a scale from 0 through 10, where 0 equals the worst your problems have been and 10 means the problems we have been talking about are solved, where are you *today* on that scale?

Rosie: If you had asked me that question before we started today, I would have said about a 2. But now I think it's more like a 5.

Therapist: Great! Now let me ask you about how *confident* you are that you can have another day in the next week like the one four days ago—the one that was a lot like your miracle picture. On a scale of 0 to 10, where 0 equals no confidence and 10 means you have every confidence, how confident are you that you can make it happen again?

Rosie: Oh, about a 5.

Therapist: Suppose you were at a 6; what would be different?

Rosie: I'd have to be sure that I always had food in the house for breakfast for the kids.

BREAK AND MESSAGE

After 30 to 40 minutes of asking questions and making SF responses, the SF practitioner takes a break for 5 to 10 minutes to reflect, either individually or with a team, about how far the client has come in his or her solution building. The practitioner then formulates a message composed of compliments focusing on the client's achievements and strengths, a bridging statement reflecting the client's goals, and, in most cases, a suggestion to observe for and/or do certain things. All three components

are based on the common ground the client and practitioner have co-constructed in the interview. Here is a message based on the case illustration:

Compliments: Rosie I'm impressed with how much you care about wanting to be a good mom and make a good home for you and your children. I'm also impressed with how clear your miracle picture is about what your home and life will look like after the miracle, and especially that you already are at a five on the way to that miracle.

Bridge: I agree that being a good mom and making a good home is very important right now.

Suggestions: So I suggest that between now and when we meet next, you continue to do the things that got you and your family to a 5 and pay attention for what else you might be doing to get things to a 5 that you are doing but have not noticed yet. Also, since you have an idea of what will be different when things move up to a 6, be thinking about what it will take to make that happen.

PROTOCOLS

The first session in SFT proceeds from a brief problem description to extended co-construction of goals to identification of related exceptions and scaling. Second and later sessions begin with exception finding followed by scaling to measure progress and identify next steps (ongoing goal formulation). Protocols with question prompts are given below (De Jong & Berg, 2013):

First Session

- Problem (How can I be useful? What tells you that is a problem? What have you tried so far? Was it helpful?)
- Goal Formulation (What do you want to be different as a result of coming here? Ask the miracle question.)
- Exceptions (Are there times when the problem does not happen or is less serious? When? How does that happen? Are there times a bit like your miracle picture?)
- Scaling
 - How close things are to the miracle
 - Pre-session change
 - Motivation to work on a solution
 - Confidence in finding a solution

- Break
- Message for Client(s)
 - Compliments
 - Bridge
 - Suggestion

Later Sessions

- What's better?
 - Elicit (What's happening that's better?)
 - Amplify (How does that happen? What do you do to make that happen? Is that new for you? Now that you are doing that, what do you notice that is different between you and [significant other]? What else is different at your house?)
- Reinforce/Compliment (Not everyone could have said or done.... So you're the kind of person who is/does/believes....?)
- Start Again (What else is better?)
- Doing More (What will it take to do again? To do it more often?)
- If Nothing is Better (How are you coping? How do you make it? How come things aren't even worse?)
- Scaling Progress
 - Current level
 - Next level(s) (When you move from [number for current level] to [one number up the scale], what will be different? Who will be first to notice? When s/he notices, what will s/he do differently? What would it take to pretend a [one number up the scale] has happened?)
 - Termination: (How will you know when it's time to stop seeing me? What will be different?)
- Break
- Message for Client(s)
 - Compliments
 - Bridge
 - Suggestion

Evidence Base

The main elements of SFT as we know it today began to appear during the mid-to-late 1980s (de Shazer, 1985; 1988). Consequently, outcome studies only have been added to the professional literature in the past 20 to 25 years. Despite its youth, the case for SFT's evidence-based status is persuasive (Franklin, Trepper, Gingerich, & McCollum, 2012; Gingerich & Peterson, 2013; Macdonald, 2011, 2013). Macdonald's (2013)

summary of the research lists 120 studies of SFT. Twenty-three of these are randomized controlled studies, all showing benefit from SFT with twelve indicating benefit over existing treatments. Forty-five are comparison studies with thirty-six favoring SFT. Effectiveness data are available from more than 5,000 cases with a success rate exceeding 60% over an average of three to five sessions. Two meta-analyses (Kim, 2008; Stams, Dekovic, Buist, & de Vries, 2006) indicate small-to-moderate effect sizes with equivalent outcomes to other psychotherapies over a lower average number of sessions.

Gingerich and Peterson (2013) and Trepper and Franklin (2012) both document that SFT is effective across a wide variety of client groups, settings, and problems. These sources cite studies documenting SFT's effectiveness in adult mental health, child academic and behavior problems, crime and delinquency, domestic violence and abuse, health and aging, marriage and family, medication adherence, occupational rehabilitation, organizational management and coaching, and substance abuse.

SFT is now included in the U.S. federal government's Registry of Evidence-based Programs and Practices (www.nrepp.samhsa.gov), and has been approved by the State of Washington and the State of Oregon (www.oregon.gov/DHS). It is also listed in the U.S. Department of Justice's Model Programs Guide with other evidence-based programs (<http://www.ojjdp.gov/mpg/mpgProgramDetails.aspx?ID=712>). For those interested in conducting research on SFT, the European Brief Therapy Association (www.ebta.nu) and the Solution Focused Brief Therapy Association (www.sfbta.org) offer research manuals on SFT.

APPLICATIONS

SFT is not problem specific; instead, it is an approach to having conversations with clients about change built around their definitions of what they want different in their lives and drawing on their past successes and other relevant resources. The approach is fast being adopted in a variety of practice settings, is used the same way with voluntary and involuntary clients alike, and is practiced with individuals, couples, families, groups, organizations, and in supervisory relationships (Berg, 1994; Berg & Kelly, 2000; Berg & Miller, 1992; Berg & Shilts, 2005; Berg & Steiner, 2003; Burns, 2005; Connie, 2013; De

Jong & Berg, 2013; de Shazer & Isebaert, 2003; Fiske, 2008; Jackson & McKergow, 2007; Kelly, Kim, & Franklin, 2008; Lee, Sebold, & Uken, 2003; Nelson & Thomas, 2006; Pichot & Dolan, 2003; Sharry, 2001; Simon, 2010; Thomas, 2013; Walker & Greening, 2011; Young, 2009). The approach is now well established and continues to gather momentum.

FIT WITH SOCIAL WORK VALUES

Although SFT parts company with the profession's historic use of a problem-solving paradigm, it comports as well or better than problem-solving with core professional values such as respecting human dignity, individualizing service, fostering client vision, building on strengths, and maximizing self-determination (De Jong & Berg, 2013). It does so largely by consistently working within the client's frame of reference and asking questions in ways that always return choice to clients (De Jong & Berg, 2001; de Shazer et al., 2007).

THEORETICAL IMPLICATIONS

Although clinical observation and theory can never fully be separated, the former has played a greater role in the development of SFT than the latter. Once the techniques were refined, more writing began to appear about the approach's theoretical implications (Berg & De Jong, 1996; De Jong, Bavelas, & Korman, 2013; de Shazer, 1991, 1994; de Shazer et al., 2007; Miller, 1997). Social constructionism offers the most satisfying account of how clients change through exposure to SFT. Herein, therapeutic solutions are thought to be new or altered meanings. As explained and illustrated earlier, they are co-constructed between client and practitioner through language interaction. The key role for practitioners in this interactive process is always to struggle to formulate the next useful, solution-focused response and question from the language and meanings contained in the client's last and earlier answers.

36 Theoretical Pluralism and Integrative Perspectives in Social Work Practice

William Borden

INTRODUCTION

Although most social workers come to characterize their clinical approach as eclectic, there is surprisingly little consideration of the ways in which practitioners engage differing theoretical perspectives, empirical findings, and technical procedures over the course of psychosocial intervention. This chapter reviews comparative approaches to clinical theory and shows how mastery of the foundational schools of thought strengthens efforts to carry out integrative forms of psychosocial intervention. The first part summarizes four lines of inquiry that have shaped integrative approaches to practice, broadly characterized as technical eclecticism, common factors perspectives, theoretical integration, and assimilative integration. The second section describes pluralist approaches to clinical theory and outlines core domains of concern in comparative analysis of explanatory systems. The third part presents a case report and shows how a pluralist

point of view informs use of differing perspectives over the course of intervention, broadening the range of theoretical concepts, empirical research, and technical procedures applied in the clinical situation.

INTEGRATIVE PERSPECTIVES IN CONTEMPORARY PRACTICE

As a starting point, it is important to acknowledge the growing emphasis on integrative approaches in contemporary psychotherapy and psychosocial intervention. Clinical scholars have increasingly realized the strengths and limits of differing theoretical perspectives, over the years, and practitioners have drawn on psychodynamic, cognitive, behavioral, humanistic, and ecological perspectives in fashioning integrative models of practice, seeking to engage a wider range of clients, broaden the scope of intervention, and improve outcomes. Borden (2010, 2013) and

Stricker (2010) review orienting perspectives and recent developments in integrative conceptions of psychosocial intervention.

Four lines of inquiry have shaped efforts to link theory, empirical data, and technical procedures in integrative conceptions of psychosocial intervention over the last quarter century, broadly characterized as technical eclecticism, common factors approaches, conceptual synthesis or theoretical integration, and assimilative integration (Goldfried & Norcross, 1995; Stricker, 2010). The perspectives emphasize differing elements and strategies in their attempts to enlarge the frame of psychosocial intervention and improve therapeutic outcomes.

TECHNICAL ECLECTICISM

According to conceptions of technical eclecticism, practitioners apply procedures pragmatically on the basis of clinical efficacy (Safran & Messer, 1997). The goal is to match specific techniques with circumscribed problems in functioning in light of empirical evidence and clinical expertise. For example, empirical findings and clinical experience support the use of cognitive and behavioral techniques for treatment of a range of problems in functioning associated with post-traumatic stress disorders and borderline personality organization. Procedures are frequently outlined in manuals that guide application in the clinical situation.

The foundation is empirical rather than theoretical, and practitioners assume that therapeutic methods can be applied independently of the theories from which they originate. Technical procedures are drawn from a variety of sources without necessarily endorsing—or even understanding—the supporting conceptual frameworks (Arkowitz, 1992; Goldfried & Norcross, 1995). In this sense, it is the most technically oriented approach to integration. The practitioner could, for example, combine procedures from cognitive, behavioral, experiential, and family systems perspectives in the course of an individual treatment. Representative examples include Arnold Lazarus' multimodal perspective (2002) and Larry Beutler's prescriptive model of intervention, specifying strategies and techniques for treatment of circumscribed problems in functioning (Beutler, 2004).

COMMON FACTORS APPROACHES

In his classic work, *Persuasion and Healing*, published in 1961, Jerome Frank explored the ways in which all forms of psychological healing share common elements, emphasizing the functions of the therapeutic relationship, the healing setting, conceptual schemes that provide plausible explanations of what is the matter and what carries the potential to help, and the core activities of psychosocial intervention that foster change and growth (Frank & Frank, 1991). More than half a century of psychotherapy research has documented the comparable effectiveness of a range of approaches, and there is growing agreement that all of the major systems of psychotherapy—psychodynamic, cognitive, behavioral, humanistic, and ecological—share common elements that account for their relative effectiveness (Wampold, 2010; Stricker, 2010).

The common factors approach is based on the assumption that all therapeutic systems exert their effects largely through the same underlying principles and processes. Clinicians reason that common factors are more important than the specific procedures that distinguish the particular schools of thought, and argue that shared elements can serve as the basis for development of more effective approaches to practice.

Accordingly, practitioners focus on the core conditions and basic elements shared by the major schools of thought encompassed in the broader field of psychotherapy. In doing so, they consider client factors, such as motivation and expectations of change; practitioner characteristics, such as warmth, empathic attunement, and authenticity; the provision of a rationale for problems in functioning and a coherent conceptual framework for interventions; and strategic processes, such as experiential learning through interpersonal interaction; interpretive procedures that enlarge understandings of self, relationships, and life experience; and the role of reinforcement, exposure, modeling, and identification in change and growth (Arkowitz, 1992; Borden, 2010; Stricker, 2010).

Practitioners attempt to identify which elements would appear to be most useful in the treatment of a particular individual on the basis of assessment data and experiential learning in the clinical situation. Some clients, for example, find it useful to explore earlier life events or process their experience of the helping

relationship; others, however, make more effective use of task-centered, action-oriented, educational modes of intervention. Sol Garfield's integrative model of intervention, emphasizing experiential learning, insight, hope, and the sustaining functions of the helping relationship, exemplifies the common factors perspective (Garfield, 2000).

THEORETICAL INTEGRATION

A third approach emerged out of efforts to develop unifying frameworks that bridge theories of personality, problems in living, and methods of intervention; the aim is conceptual synthesis, beyond a blend of common factors and technical procedures (Goldfried & Norcross, 1995). Although the intervention strategies of the integrative system may encompass the procedures used in technical eclecticism, there are crucial differences in the assumptions and conceptualizations that inform decision-making and use of particular strategies (Stricker, 2010). Such frameworks broaden the range of psychological and social phenomena that potentially serve as the focus of treatment and offer varying points of entry. The enlarged conceptual perspective allows clinicians to expand the range of technical procedures used over the course of intervention (Borden, 2010).

By way of example, Paul Wachtel has developed a psychodynamic approach that encompasses behavioral, cognitive, humanistic, systemic, and ecological perspectives, extending his earlier integration of psychoanalytic theory and behavioral concepts (Wachtel, 2011). In the field of social work, Sharon Berlin has developed an integrative cognitive perspective that links neuroscience and cognitive psychology, the major schools of psychotherapy, and framing perspectives in the social work tradition (Berlin, 2010).

ASSIMILATIVE INTEGRATION

A fourth approach, conceptualized as assimilative integration, encompasses elements of technical eclecticism and theoretical integration (Messer, 2001). In working from this point of view, the clinician establishes a "home base" in a primary theoretical system and draws on ideas and techniques from other schools of thought in light of

the particular needs and circumstances of the clinical situation. The concepts and techniques are blended within the conceptual framework of the central theoretical perspective. The approach potentially encompasses ideas and methods that would be viewed incompatible in purer conceptions of the helping process.

The Role of Theory in Practice

The foregoing lines of inquiry deepen our understanding of common factors that operate across the schools of thought and the range of technical strategies employed in eclectic modes of treatment, offering pragmatic frameworks for psychosocial intervention. *If clinicians are to carry out integrative forms of practice effectively, however, they must develop an understanding of the foundational theories of the field.* In the absence of theoretical knowledge, practitioners do not have conceptual frames of reference to understand the dynamics of change processes or the technical elements they are trying to integrate in eclectic, individualized approaches to intervention. Procedures are deprived of context, and clinicians run the risk of carrying out reductive, mechanized approaches to practice, lacking theoretical rationales for strategies and methods of intervention (Borden, 2010; Messer & Gurman, 2011).

Pluralism as Comparative Perspective

Clinical scholars have drawn on philosophical conceptions of pluralism in their efforts to develop frameworks for critical thinking and decision-making in comparative approaches to clinical theory (Borden, 2010, 2013). Although a review of this work is beyond the scope of the chapter, it is important to identify the defining features of pluralism and its implications for pragmatic use of theoretical concepts, empirical findings, and technical procedures in the clinical situation.

Pluralist points of view emphasize the limits of human understanding and assume that no single framework captures the variousness and complexity of actual experience in the real world. Thinkers and practitioners approach concerns from multiple, independent perspectives, realizing that there are mutually exclusive descriptions of the world and equally valid points of view that inevitably contradict one another.

In this respect pluralist perspectives challenge notions of grand theory, which presume to assert universal truths, and take the more realistic position that theoretical formulations and empirical findings *at best* provide partial, incomplete understandings of experience. William James emphasizes the importance of immediate experience, practical consequences, and implications for action in his conceptions of pluralism and pragmatism (Borden, 2013).

From a pluralist point of view, then, theories serve a range of functions, providing tools for critical thinking and decision-making as practitioners carry out their work. Every theoretical system is distinguished by its particular concerns, purposes, methods, strengths, and limits, and no single approach—however encompassing it may seem—can possibly meet all needs over the course of intervention.

In spite of the diversity of theoretical perspectives that inform psychosocial intervention, clinical scholars have identified core domains of concern that facilitate efforts to carry out comparative study, encompassing the following areas:

- Historical origins of the theoretical perspective; intellectual traditions, world views, and social, cultural, political, and economic conditions that have influenced the development of guiding assumptions and basic concepts; the types of clients, problems in living, and settings that have shaped clinical approaches;
- Conceptions of personality, self, person in context, and development across life course; empirical support for basic propositions; congruence of concepts with core social work values;
- Conceptions of resilience, health, well-being, and the common good;
- Conceptions of vulnerability, problems in living, and psychopathology; extent to which theorists encompass social, cultural, political, or economic contexts of understanding in formulations of vulnerability, need, and problems in functioning; and
- Conceptions of psychosocial intervention: core assumptions, change processes, and curative factors; structure and process of intervention; range of application; empirical support for efficacy and effectiveness of approach; implications for emerging models of evidence-based practice (see Messer & Gurman, 2011, and Wampold,

2010, for comparative review of classical and contemporary therapeutic systems).

In comparative approaches to theory, practitioners master the foundational schools of thought and engage a range of ideas as they carry out their practice, without committing themselves to any single school or tradition. Pluralist perspectives attempt to foster dialogue across the divergent perspectives that shape contemporary practice, enlarging ways of seeing, understanding, and acting as clinicians work to understand what is the matter and what carries the potential to help. The practitioner enters into different points of view and critically evaluates possible approaches, concepts, and methods in light of the particular circumstances of the clinical situation, assessing choices and potential courses of action as intervention proceeds. The validity of any theoretical concept or method is determined by its *practical outcome* in the context of the particular case (Borden, 2010, 2013).

CLINICAL APPLICATION

The following case report illustrates the ways in which a pluralist frame of reference guides use of concepts and methods from divergent perspectives over the course of intervention.

Case Report

The client, age 63, developed diffuse anxiety, signs of depression, and dissociative states eight months after he was injured in an automobile accident. He had completed a course of rehabilitation in an extended care facility, following recovery from life-threatening injuries, and had recently returned to his home. He described fluctuating periods of numbing detachment and intrusive recollections of the events surrounding the accident, and reported a growing sense of dread—the feeling that “something bad is about to happen.”

The client related a range of symptoms that met diagnostic criteria for posttraumatic stress disorder. Further sources of vulnerability emerged in his developmental history. His mother had died shortly after his birth, and he described ongoing disruptions in caretaking arrangements through childhood and adolescence. He reported ongoing difficulties in establishing relationships in adulthood, and described

limited contact with extended family or friends; his experience of dependency and isolation following the accident had intensified longings for closeness and connection with others.

Although the focus of intervention centered on problems in functioning precipitated by the traumatic event, the practitioner realized that the client's history of early loss, disruptions in caretaking, and subsequent modes of attachment potentially limited his capacity to establish a collaborative relationship and negotiate the interactive experience of the therapeutic process.

In light of the crucial role of the therapeutic relationship in efforts to sponsor change and growth, the practitioner attended carefully to the development of the working alliance, seeking to create conditions that would sponsor the client's engagement in the therapeutic process. The clinician's warmth, attunement, and responsiveness facilitated the client's experience of acceptance, understanding, and support. The practitioner's use of self and relational provisions were informed by person-centered conceptions of the helping relationship, psychodynamic formulations of the therapeutic alliance and the holding environment, and developmental research on the ways in which early loss and disruption in caretaking influence modes of attachment and interpersonal functioning. The clinician reviewed conceptions of posttraumatic stress syndromes with the client to help him understand the nature of his problems in functioning and the core activities of the therapeutic process.

In the first phase of treatment the client related the course of events following the accident in a detached, impersonal fashion, sometimes speaking in the third person. He showed an absence of emotional responsiveness, consistent with the denial phase of posttraumatic stress reactions, and appeared indifferent as he described events: "I don't know what good it does to talk about any of this ... we can't change what has happened ... I should be able to get beyond this and live my life." Relational concepts from self psychology and person-centered perspectives guided the clinician's reflection and validation of the client's underlying feelings of fear, helplessness, and hopelessness. The worker's attunement and empathic processing of his reactions appeared to strengthen the relationship and the holding environment, creating conditions for more active, focused exploration of traumatic events.

The client's experience of numbing detachment fluctuated with periods of diffuse anxiety as he continued to process traumatic states in the middle phase of intervention. The clinician drew on cognitive and behavioral approaches in efforts to help the client manage intrusive recollection of events and disrupt vicious circles of thought, feeling, and behavior that perpetuated problems in functioning. He had come to see the world as a "dangerous place," restricting patterns of activity, and viewed people as unsupportive and unreliable, avoiding opportunities to resume contact with extended family and friends in spite of longings for connection.

The clinician used a range of cognitive procedures in efforts to help the client challenge and revise maladaptive schemata ("The world is a dangerous place."), working assumptions ("Nobody really wants to see me."), and automatic thoughts ("I am broken"; "My life is over.") that perpetuated his experience of fear, demoralization, and disengagement from activities. The practitioner drew on behavioral methods of exposure in efforts to help the client engage feared aspects of inner experience (memories, images, and thoughts related to the accident) and feared activities in the outer world (interaction with others, activities of everyday life). The client and clinician worked collaboratively to identify tasks that provided occasions to expand patterns of activity and carry out social interaction. Such active modes of intervention provided opportunities for mastery and development of coping strategies and social skills, strengthening the client's morale, self-esteem, and sense of possibility.

He made considerable progress in efforts to recognize and accept the experience of trauma, manage fluctuations in internal states, and engage relational life. In the final phase of intervention, the clinician drew on humanistic and existential perspectives as the client explored the meaning of the accident and the implications of the event, working to clarify core values and essential concerns that would shape his life plan.

The practitioner's mastery of psychodynamic, cognitive, behavioral, humanistic, and existential perspectives provided the theoretical underpinnings for use of differing concepts, empirical findings, and technical procedures over the course of intervention. Movement from one orientation to another was guided by the nature of specific problems in functioning, the focal concerns of intervention, and

the client's capacities to make use of differing strategies. The clinician emphasized the following approaches and procedures in efforts to facilitate change and growth: (1) processing of interactive experience in the therapeutic situation to deepen understanding of modes of attachment and interpersonal behavior; (2) cognitive restructuring; (3) exposure to inner and outer domains of feared experience; (4) development of behavioral skills through modeling and experiential learning, and (5) interpretive procedures to enlarge assumptive world and deepen understanding of self, others, and life experience.

Summary

In the pluralist approach to theory described here, the foundational schools of thought provide contexts of understanding for use of differing concepts, empirical findings, and technical operations over the course of intervention. The clinician

- Learns multiple theories, therapeutic languages, and modes of intervention
- Draws on concepts from a variety of perspectives in light of the specifics of the clinical situation
- Judges the validity of theoretical concepts on the basis of practical outcomes in the context of the particular case.

Comparative perspectives make the multiplicity of competing approaches a defining feature of psychosocial intervention. The practitioner aims to establish an ongoing dialogue among representatives of the major schools of thought that sponsors clarification of differing points of view and theoretically informed integration of concepts, empirical findings, and techniques in eclectic, individualized approaches to psychosocial intervention.

37 Animal-assisted Interventions in Social Work Practice

Yvonne Eaton-Stull

In the era of technology, few social workers have to carry various treatment resources around in their briefcase; there is, however, a new invaluable tool they may be seen transporting today. Many have elected to integrate their best friends into their practice, and they are now armed with a leash and doggie bags. According to a recent national study, almost 25% of social work practitioners are using animals in their workplace (Risley-Curtiss, 2010). Risley-Curtiss (2010) also contends that many of these providers, however, lack essential education on this specialized topic. This chapter is written in an effort to increase knowledge and provide valuable resources to practitioners interested in utilizing animal-assisted intervention (AAI).

A “therapy dog” is a commonly used term to describe dogs that have been evaluated and registered by a professional, volunteer organization. The therapy dogs work with a handler, who is usually their owner. There are just about as many of these therapy dog organizations today as there are breeds of dogs; thus, one must carefully investigate how the handler and dog team have been evaluated. A few key questions include: Did the handler receive any special advanced training? How was the dog trained and evaluated? Is the dog re-evaluated on a regular basis to determine whether its temperament and obedience skills are still acceptable? What type of insurance accompanies this team? And are the veterinary records current and adequate? Practitioners who are using their own dogs in their employment setting should assure that their professional liability insurance covers this treatment modality because it is not covered by these volunteer organizations. Practitioners, who see the value of this intervention but do not own their own therapy

dog, can request a volunteer team to assist them from one of these organizations. Obviously, this route would also require additional permissions, consents, and agreements to bring another person into the sessions. With this latter option, it is also suggested that the practitioner meet both the handler and the dog before committing to using them so that the practitioner is comfortable with the team and believes they are well-suited to working with the intended individual or group.

Pet Partners (2012), formerly known as Delta Society, one national volunteer organization, provides a host of valuable information including research, resources, training, access to evaluators, and a registry of teams (www.petpartners.org). Pet Partners also rates a team in terms of what type of environment they are suited to work in. Dogs who are rated at a predictable environment do well with quiet environments and minimal activity; whereas dogs with complex ratings are able to handle active settings with high activity levels (Delta Society, 2000). It is essential that the dog is matched to the level of interaction and environment expected in the practitioner’s setting.

These specially trained animals can fill numerous roles. Animal-assisted intervention (AAI) is an umbrella term to describe the many strategies of utilizing these animals in social work, which can include animal-assisted activities (AAA), animal-assisted therapy (AAT), and/or a highly specialized service known as animal-assisted crisis response (AACR). AAA includes activities that provide opportunity for motivational, educational, recreational, and therapeutic benefits; interactions are spontaneous and there are no required treatment goals or notes (Pet Partners, 2012). For the social work professional, AAA can

be thought of as the non-client specific intervention. This can include providing professional presentations, talking with groups about services, or teaching student interns. AAT, on the other hand, is goal-directed intervention delivered by a professional within their scope of practice, which includes documentation and measurement of treatment progress (Pet Partners, 2012). Therapy dogs can be integrated into treatment plans to address a variety of issues. Finally, AACR is a very specialized service that includes the use of certified crisis dogs in providing comfort and support following crises and disasters (HOPE AACR, 2008). These dogs have extensive training and ongoing education, and they are comfortable in very chaotic, loud, crowded environments. There are many wonderful therapy dogs out there who could not handle crisis situations, thus it is important that the dogs have the proper credentials for the job. Two national AACR organizations meet the published national standards for AACR work: HOPE AACR (www.hopeaacr.org) and National AACR (www.naacr.org). Social workers can contact these organizations for voluntary assistance following crises or disasters.

It is likely that more dogs will enter social services, working alongside practitioners in a variety of settings. To prepare social workers for this inevitability, several colleges and universities throughout the United States offer specialized curriculum or certification in AAT (Chandler, 2005). In fact, the University of Denver Graduate School of Social Work houses an Institute for Human-Animal connection and offers courses in animal-assisted social work practice and integration of animals into therapeutic settings (Tedeschi, Fitchett, & Molitor, 2005). For those on the east coast, the Virginia Commonwealth University (VCU) has a Center for Human-Animal Interaction, which engages in cutting edge research, clinical work, and educational activities (VCU Medical Center, 2011). Both practitioners and educators need to consider the many benefits these dogs offer, which can help enhance and improve the lives of those we serve.

COGNITIVE BENEFITS

Case Example: A special preschool for children with autism requested a one-time visit with a therapy dog. The teacher felt it would be especially useful for a young boy who was not using language effectively and becoming increasingly

frustrated and injuring himself. She knew he loved dogs and thought a visit might provide the encouragement to talk. During the first visit, Maggie the therapy dog lied down, and this young boy came over and began to pet her. He pointed to a body part, her ear, and looked at me (the handler). I responded, "That's her ear." He quietly said "ear." We continued to play this game where he pointed to something on Maggie. I told him the word, and he repeated it. The teacher was in awe, and she consequently requested a second visit. Amazingly on this second visit, this boy ran up to greet Maggie and offered more than a single word. He asked, "Read to Maggie?" I enthusiastically responded, "Of course you can read to Maggie." He grabbed a picture book and brought it to Maggie, pointing to picture after picture telling her what she was seeing. The teacher cried as she witnessed the student's dramatic increase in verbal communication.

Some of the cognitive benefits associated with AAI include learning and language. Bassette and Taber-Doughty (2013) conducted a small pilot study with three elementary school students who participated in an AAT intervention reading to dogs; all participants increased on-task behavior and sustained improvement over time. In a similar study targeting identified students with fluency and reading deficiencies, Newlin (2003) paired 15 students with therapy dogs. Following this AAI, most of the participants improved their reading skills by at least two grade levels (Newlin, 2003). Van Fleet (2008) concurs that these special canines can help develop language skills and facilitate communication in children. She offers examples and strategies for integrating therapy dogs into treatment plans addressing shyness, stuttering, and other communication difficulties (Van Fleet, 2008).

Various educational institutions have found that a therapy dog's presence enhances concentration, attention, and motivation (Beetz, Uvnas-Moberg, Julius, & Kotrschal, 2012). School social workers or those who are consulted to assist in developing cognitive interventions would be wise to consider this intervention.

PHYSICAL BENEFITS

Scientific evidence also supports various physical benefits of AAI. Short- and long-term health benefits, such as prevention of health issues and improved recovery are well documented (Wells, 2009), as is decreased pain (Sobo, Eng, &

Kassity-Kritch, 2006) In a literature review of health benefits, Morrison (2007) found AAI produced significant improvements in blood pressure and heart rate. A more recent review concurs and adds to these results resulting from AAI improvements in cardiovascular health and reduced cortisol (Beetz, Uvnas-Moberg, Julius, & Kotrschal, 2012). According to Sable (2013), these health-related benefits have important social work implications. For example, practitioners who are providing early intervention to those exposed to traumatic events can utilize AAI, a non-medication based solution, to prevent more serious disorders, such as posttraumatic stress disorder (PTSD). Many specific factors contribute to the development of PTSD, but one known predictor is elevated heart rate (Bryant, Creamer, O'Donnell, Silove, & McFarlane, 2008; DeYoung, Kenardy, & Spence, 2007; Kassam-Adams, Garcia-Espana, Fein, & Winston, 2005; Kuhn, Blanchard, Fuse, Hickling, & Broderick, 2006). AAI has been shown to decrease one's heart rate (Barker, Knisely, McCain, Schubert, & Pandurangi, 2010; Kaminski, Pellino, & Wish, 2002; Morrison, 2007). Perhaps physicians will see the value and write prescriptions for AAI instead of for beta blockers.

EMOTIONAL/MENTAL HEALTH BENEFITS

Testimonial: Mandy Fauble, PhD, LCSW, has utilized AAI in both individual and group therapy. She states "utilizing pet therapy helps to facilitate the alliance and rapport between clinician and client, as the dog enhances the feelings of safety, comfort, and mutuality. With children, particularly, dogs help to provide opportunities for projective identification and empathy that are unconditional and safe, allowing for practice of skills in ways that seem more like fun than therapy." (M. Fauble, personal communication, August 9, 2013).

AAI has demonstrated value in the treatment of many mental health conditions. Five randomized controlled studies, the gold standard in evidence-based practice, have contributed a wealth of valuable evidence regarding the benefit of AAT in improving symptoms of schizophrenia (Barak, Savorai, Mavashev, Beni, 2001; Berget, Ekeberg, & Braastad, 2008; Chu, Liu, Sun, & Lin, 2009; Marr et al., 2000; Nathans-Barel, Feldman, Berger, Modai, & Silver, 2005). Additional research with individuals suffering from depression has demonstrated significant benefits from

AAI (Berget et al., 2008; Marr et al., 2000; Moretti et al., 2011). Finally, in Barker and Dawson's (1998) large-scale study of 230 participants, a single AAT session resulted in significant decreases in anxiety. Similarly, decreases in anxiety have been supported in other studies as well (Hoffman et al., 2009; Lang, Jansen, Wertenaue, Gallinat, and Rapp, 2010).

SOCIAL/BEHAVIORAL BENEFITS

Testimonial: A staff member from a state correctional institution recently shared an interesting story. The prison, after experiencing significant assaults by inmates, conducted an extensive sweep of the facility to search for hidden weapons. Interestingly, home-made weapons were discovered on every unit except for the one where inmates have and train future service dogs. (Anonymous, personal communication, August 10, 2013).

The social and behavioral benefits of AAI are critical to consider if they can assist in preventing serious injury or death. Several studies in correctional settings have demonstrated increases in prosocial behavior (Counoyer & Uttley, 2007; Fournier, Geller, & Fortney, 2007; Jaspersen, 2010). In addition, Fournier et al. (2007) found decreased behavioral infractions and improved treatment progress in their prison study. Besides forensic social work, many practitioners seek to influence behavior and improve social skills. School-based AAI's have found similar results. Two studies found decreases in aggressive behavior and increased empathy (Anderson & Olson, 2006; Sprinkle, 2008). Use of an AAT anger management group was found to result in a calming effect and increase empathy (Lange, Cox, Bernert, & Jenkins, 2006). Finally, research of adults in psychiatric settings has documented significant increases in social interactions (Barak, Savorai, Mavashev, & Beni, 2001; Hall & Malpus, 2000; Marr et al., 2000).

SELF-CARE/STAFF BENEFITS

Any practitioner who owns a pet can most likely attest to the joy and benefits they bring to one's life. As we all know, having strategies for stress management is critical in this profession fraught with burnout and compassion fatigue. In an exploratory study of behavioral health staff's perceptions, treatment staff expressed a desire for more AAT groups, a positive effect on

the therapeutic environment and staff morale, and enhanced communications between clients and staff (Rossetti, DeFabiis, & Belpedio, 2008). Integrating such a valuable modality in practice settings can be of great benefit to staff. Pichot and Couter (2007) indicate that the presence of a therapy dog has an incredible impact on the staff, the ability to transform the agency, and the power to facilitate positive community relations. Some case examples and practical strategies will help to illustrate the utility of this intervention in individual, group, and crisis intervention.

INDIVIDUAL INTERVENTION

Case example: A young man was mandated for counseling following an incident of fighting. He reluctantly agreed to see the counselor who had the dog. One treatment goal focused on identifying what was fueling his acting out behavior. During one session, he lowered his head and began to share a history of abuse and foster care placements. At this very moment, Maggie the therapy dog looked up from her bed, jumped onto the futon next to him, and began to kiss his face. He embraced her, and she sat beside him laying her chin on his thigh. "Why did she do that?" he asked. I replied, "Maybe she thought you needed a little comfort when discussing this hard stuff. What do you think?" He smiled and nodded his head. For the remainder of the session, Maggie remained by his side providing a consistent, comforting presence as he stroked her and talked about his past. Ultimately, we were able to identify underlying cognitive distortions that were contributing to his increased anger and acting out behavior. Was it the symbolism, a corrective emotional experience, or just a magical Maggie moment? One thing is for sure, it was a turning point. In subsequent sessions we identified times when he had received comfort and support, demonstrating that not everyone is untrustworthy. Integrating a Cognitive Behavioral Therapy (CBT) and Solution-focused Therapy (SFT) approach, we began to challenge his cognitive distortions and strengthen his supportive resources. About a year later with no further conduct violations, he graduated.

The above case example illustrates several essential elements of social work intervention: engagement, assessment, and intervention. During the first therapy session, this young man shared his love of dogs and his plan to have his own dog in the future. Wilkes (2008) indicates

that animals increase trust and act as a catalyst for sharing and healing. With Maggie's help, rapport was quickly built and an initially resistant client became engaged in treatment. Developing this therapeutic alliance was a critical first step.

The second step involved assessing the problems and underlying issues. According to Wilkes (2008), dogs enhance the environment by creating a warm, friendly, nurturing, and safe place. Maggie provided comfort and support, which made it easier for this young man to share his traumatic past.

The final step is intervention, as professionals use the dog to complement their work, as in the cognitive behavioral approach outlined above. No matter what theoretical foundation a practitioner endorses, AAT can be easily integrated. The versatility of this approach can be applied to person-centered, cognitive-behavioral, behavioral, psychoanalytic, gestalt, existential, reality, and solution-focused counseling (Chandler, Portrie-Bethke, Minton, Fernando, & O'Callaghan, 2010; Fine, O'Callaghan, Chandler, Schaffer, Pichot, & Gimeno, 2010). Grover (2010) provides many creative activities integrating the therapy dog into the treatment plan. As a result of the flexibility of this approach, an immense number of consumers stand to benefit from the implementation of AAT.

GROUP INTERVENTION

Case example: An anger management group with 10 young boys sounds like quite a challenge; however, with Maggie's assistance, it was one of the most successful groups. One particular group session focused on how to identify anger and its effects. We used Maggie to start the discussion. The boys eagerly talked about how Maggie might show her teeth, growl, bark or bite, and how those behaviors could make others scared or cause them to avoid Maggie. It provided an easy transition to what behaviors they have engaged in and how these affected others. During a subsequent session, a boy started to become upset, sighing heavily and pounding the floor. Before staff intervention was needed, another boy empathically said, "Hey, don't do that, you might scare Maggie." This boy immediately stopped his behaviors, apologizing to Maggie. Results from a pre- and post-test empathy scale demonstrated significant changes in all participants.

Integrating the dog into the group can be done in a variety of ways. One common practice that can

be utilized at the beginning of group meetings is the check-in where members take turns offering an update from the past week. During this process, the therapy dog can move from member to member as they share. Another useful strategy is to include the dog in various group activities. For example, in a group on stress management, Maggie eagerly offers her belly for clients to use a handheld massager to relax her. This fun activity often lends itself to sharing of personal stress management strategies. A third strategy includes using animal-themed books, games, or music. An extensive bibliotherapy list by clinical topics is provided in Fine et al. (2010). Fourth, Maggie has an array of pre-made collages to share with clients for discussion or as an example prior to them creating their own. These include a feelings collage (with her photos and labeled feelings), a coping collage (the many ways she copes with stress), and an eco-map (with her identified supports). Finally, transitional objects can be especially useful to maintain the progress made in treatment. Maggie frequently provides trading cards or book marks with her photo that say, "Maggie says you're MAGNIFICENT." Even adults love these reminders. One adult client, who was initially very afraid of dogs, wanted a photo of Maggie to put on her refrigerator so that she could prove to her family that she overcame her fear.

CRISIS INTERVENTION

Case example: We were called to the Virginia Tech tragedy to provide support to students and faculty as they returned to campus and resumed classes after the shootings. On the drill field one day, a young girl ran up to Maggie and threw her arms around her declaring, "That's my dog." As it turned out, she had a dog at home who looked remarkably similar to Maggie. This young girl shared how she witnessed events and was thus required to remain on campus to be interviewed by law enforcement; unlike other students, she wasn't able to go home and be with her family and dog. In this example, Maggie was able to assist in reducing her stress, offer an opportunity to share her feelings, connect her with a source of support, and facilitate coping. As Watson, Brymer, and Bonanno (2011) indicate, these are the goals of providing psychological first aid following such traumatic events.

AACR offers the addition of a certified crisis response dog to practitioners as a way to help people affected by crises and disasters. Dogs help to establish rapport, build therapeutic bridges,

normalize reactions, and act as a calming agent (Greenbaum, 2006). HOPE animal-assisted crisis response (AACR), a national organization whose mission is "to provide comfort and encouragement through animal-assisted support" has about 120 certified teams across the country able to assist practitioners when needed (HOPE AACR, 2008). According to Graham (2009), these dogs offer a compassionate presence. Chandler (2008), who observed AACR during Hurricane Katrina, found these dogs were much more effective than other interventions in providing nurturance and alleviating anxiety.

CONCLUSION

It appears that dogs are quickly becoming a social worker's best friend, assisting in the provision of care to a host of individuals and groups in need. The use of properly trained, registered, and certified (in the case of crisis work) dogs offers valuable tools that can enhance the work of the practitioner. The cognitive, physical, emotional/mental health, social/behavioral, and self-care/staff benefits are well documented in the literature. Additionally, AAI is easily adaptable to a variety of settings, populations, and practitioner theoretical orientations. I hope this chapter has helped to validate AAI and convince practitioners that they should seriously consider utilizing this intervention when indicated.

38 Narrative Therapy

Patricia Kelley & Mark Smith

This chapter is dedicated to Michael White (1948–2008)

As the 20th century drew to a close, narrative therapy (NT) became an important trend in clinical social work and family therapy and was part of the

postmodern movement that crosses many disciplines, from arts and literature to the social sciences. The postmodern movement is a reaction to modernism, which holds that there are universal laws and truths that can be uncovered through scientific discovery and that all phenomena can be explained

if these truths are discovered. Postmodernism challenges the idea of absolute truth and grand theories that explain human behavior.

The narrative approach was developed in the 1980s by Michael White, a social worker/family therapist from South Australia, and David Epston, a social worker/family therapist from New Zealand who also studied community organization. It has received worldwide attention since the publication of their book in North America in 1990 (White & Epston, 1990). Although NT began in the family therapy movement, it has also been applied to work at the individual, group, and community levels.

NT developed within the context of the social constructionist and second-order cybernetic movements, which have influenced the field of family therapy since the 1980s. In addition to positioning themselves within the epistemological perspective of social constructionism, White and Epston (1990) drew from the ideas of constructivism, the work of Foucault, and the field of literary criticism. Constructivism focuses on individuals' perceptions and cognitions as shaping their views of reality, whereas social constructionism focuses more on the social and cultural narratives individuals internalize, taking them for granted as constituting "reality." Both views deny objective reality, believing that one's view of reality is constructed out of language use and social interaction. White and Epston incorporate both social constructionism and constructivism in their use of a narrative metaphor in therapeutic work, believing that people create stories of their lives to make sense of all their lived experience. The stories people develop incorporate the dominant social and cultural stories of gender, ethnicity, and power, as well as personal stories co-constructed in interaction with others (family, friends, and professional helpers), and constitute the knowledge that people hold about themselves and their worlds. As in post-modern literary criticism, the narrative therapist helps clients "deconstruct" the story lines around which they have organized their lives, assessing the plot, characters, and timeline for meaning, and then look for other "truths" that also exist.

The goal of narrative therapy in social work practice is to help clients first understand the relational nature of the stories around which they have organized their lives and then challenge and broaden these, thus creating new realities that are

consonant with preferred lives. These discoveries can help clients see more alternatives and ways out of an impasse. They can also help clients see more aspects of themselves, including strengths and coping skills they already have, which can be mobilized to fight the effects of the problems they are facing. Conversation is important because language creates our reality; through discourse, reality (including history) is socially constructed (created). NT is more than storytelling, it is story *changing*. The narrative therapist does not deny the harsh realities facing clients, such as poverty, racism, or illness, but rather challenges the power given to these adverse aspects of their lives and the control the problems have over their lives.

USING A NARRATIVE APPROACH

Narrative therapy takes a collaborative approach in working with clients; where clients are experts on their lives, and as the story lines unfold, the client and social worker together discover other realities and join in fighting the effects of the problem. Key concepts of NT are as follows.

- *Problem-saturated stories.* These are the one-dimensional stories clients have about themselves that they have co-constructed in interaction with others and are influenced by social-cultural forces that have restricted them. These stories are examined in session as clients are challenged to expand their views of self.
- *Double-listening.* Also referred to as attending to the *absent but implicit*, therapists listen to both the explicit expressions of client complaints/distress as well as what is absent from the expression but implicit in its meaning. This practice can help elicit a range of intentional or historical understandings for clients and set the stage for them to become more active agents in countering disabling narratives.
- *Externalizing the problem.* In conversation with clients the problem is externalized, or separated from the person, whereby the problem not the person is the target of change.
- *Mapping the problem's domain.* The effects of the problem over time (past, present, and possible future) and over many domains are examined; in so doing, the client can assess what might be done. In addition to

mapping practices, clients are often enlisted to undertake an “archeology of the present,” which acknowledges influences and personal historical precursors of the client’s present resolve to seek help in restoring a preferred sense of self. This reinforces client readiness and motivation to enact change behaviors.

- *Unique outcomes.* These are the times clients have not been overcome by their problems. For clients, these times may represent new truths and discoveries about themselves that are often strengths or aspects of the client’s story that are not consistent with the problem-saturated dominant story. These episodes are highlighted and moved into prominence in descriptions of the client’s situation.
- *Outsider witness practices.* Problems are seen as being situated relationally; therefore, clients are encouraged to call upon those who may have unique understandings that contrast, challenge, provide insight, or add perspective to the problem-saturated story. These outsider witnesses may be present in one’s life, may be imaginary characters, or may even be dead, but they do provide confirmation and support for intentions and preferred actions.
- *Re-membering/Praxis.* Once clients start experiencing some positive change, they are encouraged to let others know about their successes in fighting the effects of the problems or in not giving in to the problems. This may involve celebrations, certificates, awards, letter writing, or even talking to groups of others facing similar problems. Rather than positioning the client as victim or even survivor of difficulties, client insider expertise regarding experience with this kind of problem is acknowledged, and therapists often encourage clients to join with others in forming new memberships of community engagement and advocacy.

Using this approach, the social worker does not design an intervention to do something “to” a client. Neither does the clinician assume that a problem or symptom serves a function for the individual (as in psychodynamic approaches) or the family system (as in the family systems approaches), although the problem may have influenced a family’s behavior. There are no pre-sumptions about the client.

Clients are carefully listened to so the therapist can understand their perceptions of the problem and the meanings they ascribe to it. Then, through respectful listening and deconstructive questioning, problems are externalized and the problem-saturated stories are examined through mapping and questioning. In the reconstruction stage, some truths are gently challenged through questioning, and unique outcomes are isolated. Therapy is terminated by mutual agreement with plans for spreading the news, often with celebrations or awards, and engagement in community education or advocacy. NT contains many “wondering” questions to help clients think about and reflect on their interpretations and beliefs about their lived experiences. Through such reflections, they consider other interpretations and other meanings, expanding their view of self. The concept of self is considered fluid and changing.

Even though the focus is more on meanings than specific behaviors, NT is usually short-term, with a few sessions spread over a longer period of time. The concepts and interventions of NT bear some similarity to solution-focused therapy (SFT) (de Shazer & Berg, 1993; Lee, 2011) and the strength perspective (Saleebey, 2002) in that they all are empowerment-based approaches aimed at mobilizing clients’ strengths and resources. However, these approaches also have some distinct differences.

- The “Unique Outcomes” of NT are different from the SFT’s “exceptions” in that they are not asked for but rather discovered through careful listening.
- In NT, the discussion of possible futures does not just focus on the hoped for (positive) future but also assesses the potential future if the problem continues to dominate clients’ lives.
- Because clients come into the relationship with a problem to solve, ameliorate, or cope with, narrative therapists do not avoid discussing problems but attend to them as part of the whole story, which is then expanded.

CASE EXAMPLE

Family therapy sessions were held for a blended family comprising a mother who had married before, her 14-year-old daughter, Mary Ann, and her second husband, who had never married before. A mutual daughter, aged 7 years,

was not brought to the sessions. The family was concerned that Mary Ann had become rebellious and dropped her previous friends to run with an older boyfriend and his crowd who engaged in dangerous and illegal activities and did not attend school. These activities represented a dramatic shift from her previous good behavior. Her mood had changed to surly and her grades had dropped dramatically.

In sessions, they all discussed perceptions and stories of the situation. Mary Ann discussed how she felt that she was living in a house designed for little girls, with little accommodation for her to grow up and achieve some independence. She also felt that her stepfather did not love her, was mean to her, and favored the younger daughter. The mother discussed how she lived in terror, fearing what might happen to Mary Ann if the illegal and dangerous activities continued; she mourned the loss of her close relationship with Mary Ann; and she felt torn between loyalty to husband and daughter. The stepfather discusses feeling left out of the family by the close relationship between the mother and daughter. He admitted being overly strict sometimes as he tried to join the family. After each member had heard the stories of fears and frustrations of the others, the meanings they made of events shifted. Double listening helped the family recognize that expressions such as “stepfather did not love her” and “mourning the loss of close relationships” implied that close relationships and feeling love from the stepfather were values the family shared. Control and strictness were seen as love and caring, and rebelliousness was perceived as attempts to change and grow.

After thorough discussion, adolescence was externalized as a new force entering their lives. They discussed ways to welcome the “new member,” making it a positive force instead of a negative one. As the family developed more empathy and understanding for each other and began laughing as they found ways to welcome the new member, compromises were reached, where new independence could be earned by following certain rules. Better judgments equaled new freedoms. Family meetings to agree on the rules were set up and involved the father more. The biological father, 1,000 miles away, agreed to support the new rules, demonstrating that all three parents cared enough about Mary Ann to cooperate. Many old truths were deconstructed and new ways to deal with problems emerged.

NARRATIVE THERAPY AND SOCIAL WORK

Narrative therapy is compatible with the traditional social work methods and values of individualizing each client as unique, respecting each client’s story, respecting cultural differences, and separating one’s own beliefs and values from those of clients through self-understanding and conscious use of self. Social work values are demonstrated through the following methods.

Respectful listening. By taking a “nonexpert, not knowing” position about the clients’ lives, we show respect for their knowledge, and we listen carefully to their ideas. This stance is not the same as neutrality, for some stories are clearly less useful or even harmful (e.g., violence) than others, but here the therapist assesses the outcomes and consequences with the client and may challenge the story through deconstruction and by assessing its origins.

Avoidance of labels. The use of labels and categories for totalizing clients as to who they are is questioned, and through externalization the clients are seen as afflicted with a problem but not constituted of it. For example, persons may be afflicted with a particular medical condition, such as cancer or a serious mental illness, but that affliction is just one part of who they are, not their total being. Thus, a person would not be viewed as a schizophrenic but perhaps as a person contending with the influences of schizophrenia and the effects of the diagnosis.

Fostering empowerment. The political nature of NT, wherein clients are “liberated” from dominant familial and cultural stories that have restricted them, and instead are urged to take a stand on their own behalf, makes it especially compatible with social work practice.

Emphasis on social justice. NT also takes a stand on social justice issues, as exemplified in the work of New Zealanders Waldegrave, Tamasese, Tuhaka, and Campbell (2003), who developed their own version of NT, called “just therapy” because it focuses on social justice. White worked on social justice issues and has worked with oppressed communities to challenge the dominant narratives oppressing them. Beginning in 1999, White and others at the Dulwich

Family Therapy Training Centre in Adelaide, South Australia, organized international narrative therapy conferences that focus on work with families, communities, and social justice issues.

Extensions beyond the office. The bridge between micro and macro practice is useful for social workers and fits in with newer community practice approaches. Narrative therapists work beyond office walls to foster communities of support and empower clients.

POTENTIAL CONCERNS

Although narrative therapy seems consistent with good social work practice, some problems regarding it have been raised. There is little empirical research supporting NT, partly because postmodernism denies the objectivity that is at the core of empiricism. Other research approaches, such as qualitative methods and case studies, may address this concern. In addition, family therapists might be concerned that narrative therapists have turned their backs on the defining characteristics of family therapy, not taking family dynamics into account and often not seeing the family as a unit. Kelley (1998) noted that two major trends in clinical practice, postmodernism and managed care, seem at odds with each other. Managed care demands *DSM-IV* or *DSM-5* diagnoses with preapproved treatment plans designed by the clinician and based on empirically proven methods, whereas in NT the emphasis is on the therapist and client co-constructing new realities through dialogue rather than conducting problem-solving activities designed by the therapist. Some aspects of narrative therapy, for example, its short-term nature and cognitive focus, could bridge this gap.

FUTURE PRACTICE APPLICATIONS

The questions regarding narrative therapy have not diminished its impact. As Minuchin noted (Minuchin, Nichols, and Lee, 2007), "narrative therapy ... is a perfect expression of the post-modern revolution" (p.2). The approach that was once considered revolutionary has become more mainstream as evidenced by inclusion in social work (ex. Turner, 2011) and family therapy texts

(Nichols, 2012), and several books and articles on the subject. A book by Freedman and Combs (1996) has long been considered a classic in the field. White and Epston continued to develop ideas and publish (Epston, 2011; White, 2007). Furthermore, changes have developed over time as NT broadened its scope to more community and group work (Kelley & Murty, 2003; Vodde & Gallant, 2003; Carey & Russell, 2011), decreasing the distinction between micro and macro practice. The movement demanding more consumer participation in decision making has called for newer methods for social work practice. NT is a product of its time.

39 The Neurobiology of Toxic Stress Implications for Social Work Practice

Julie M. Rosenzweig & Stephanie A. Sundborg

The past two decades have witnessed an explosion of psychological trauma-focused research, scholarship, and practice applications. Consequently, social workers are scrambling to keep up with a burgeoning amount of information and translate the knowledge into service design and delivery. Integrating this emerging stream of knowledge across a wide range of settings has included both trauma-informed approaches (see e.g., Esaki et al., 2013; Fallot & Harris, 2001; Saakvitne, Gamble, Pearlman, & Lev, 2000) and trauma-specific interventions (see e.g., Briere & Scott, 2006; Herman, 1997; Ogden, Minton, & Pain, 2006; Wilson & Tang, 2007).

Trauma-informed organizations or systems acknowledge the pervasiveness of traumatic events and adversity in the lives of service users and act accordingly by developing policies, practices, and processes that integrate knowledge about traumatic stress (Hopper, Bassuk, & Olivet, 2009). In comparison, trauma-specific interventions include therapeutic models purposefully designed to address trauma-based impairments (Cook et al., 2005) and promote healing and recovery. Trauma-specific interventions are often

evidence-based models that are particular to the type of trauma exposure, the developmental stage of the individual (child, youth, or adult), co-occurring disorders, or a specific population (e.g., veterans, refugees, or survivors of interpersonal violence). They may also integrate culturally specific approaches.

Central to the development, training, and implementation of both trauma-informed approaches and trauma-specific interventions have been advancements in knowledge about the neurobiological underpinnings of psychological trauma. Following the United States Congressional designation of 1990s as The Decade of the Brain, multiple research initiatives were launched from which findings emerged that have profoundly changed how the brain is understood. Innovations in neuroimaging technology, such as functional magnetic resonance imaging (fMRI) have provided neuroscientists opportunities to learn about brain growth and development to a level of complexity unparalleled in history. New information about the brain, particularly brain plasticity, has stimulated the development of improved medical and mental health treatments.

Neurobiological research has also shed new light on the dynamics of nature–nurture, resulting in increased attention on the importance of infant and early childhood caregiver attachments, particularly to resultant lifelong physical and mental health challenges (Shonkoff, Richter, van der Gaag, & Bhutta, 2012).

Neuroscience research in general, and specific to psychological trauma, is reshaping how social workers understand typical development, the bio-psychosocial effects of traumatic events on the brain, and the resilient capacity of individuals to transform peril into wisdom. As Shonkoff (2010) asserts,

The challenge before us is to capitalize on the capacity of this scientific revolution to stimulate creative ways of thinking about how to address a much broader range of societal concerns, including education reform, workforce development, health promotion, prevention of disease and disability, protection of children from the consequences of maltreatment and exploitation, reduction in violent crime, and the alleviation of poverty (p. 357).

The purpose of this chapter is to provide social workers with neurobiological information about toxic stress that can be integrated into policy, practice, and advocacy. Information about the neurobiology of toxic stress, coupled with an understanding of affect regulation, provide an effective framework for social workers to develop and provide services to those suffering a range of sequelae from adversity. The discussion begins by defining toxic stress as an expansion of traumatic stress. An overview of key brain areas that are activated by exposure to adversity is presented, followed by a description of the mind-body stress response systems. The chapter concludes with a discussion and guiding questions to assist social workers in developing a neuro-trauma lens for their work.

WHEN STRESS BECOMES TOXIC

Potentially traumatizing events have been categorized in multiple ways: intimate partner violence, child abuse and neglect, combat, natural disasters, terrorism, and geographic displacement are only a few examples. Knowing the array of events that produce psychological trauma exposure can assist policymakers, administrators, and providers in advocating for trauma prevention, trauma-informed, and

trauma-specific services in communities. Identifying and assessing the psychological effects of trauma exposure on individuals, families, and communities is more complex. The type of trauma, age at trauma exposure, duration of events, relational factors, prior trauma exposure, social ecological conditions, and cultural beliefs are only some of the variables that make differential contributions to one's individual bio-psychological experience of trauma. Importantly, in addition to understanding how trauma impairs development and functioning, researchers are learning more about resilience as it relates to trauma. Especially promising is the emerging examination of resilience as an ecological construct as well as an individual characteristic (Ungar, 2013).

Psychological trauma has been most commonly associated with the concept of traumatic stress and the diagnosis of posttraumatic stress disorder (PTSD). Once the domain of the *Diagnostic Statistical Manual (DSM)* and psychotherapy, reference to PTSD is now commonplace in the media and social conversations. However, from its inception as a diagnosis in 1980, the conceptualization of PTSD has been criticized as too restrictive in its criteria. Particularly vocal have been practitioners serving children, who have advocated for the inclusion of a developmental trauma disorder in the *DSM-5* (D'Andrea, Ford, Stolbach, Spinazzola, & van der Kolk, 2012; Ford et al., 2013).

This advocacy effort has, in part, been fueled by neuroscience research that was not available when the diagnosis of PTSD was first conceptualized. Criticism notwithstanding, increased public awareness of PTSD, largely due to media coverage of veterans returning from combat in Iraq and Afghanistan, has benefited many individuals and families. Still, defining traumatic stressors, traumatic stress responses, and recommended interventions solely by criteria within a diagnostic category used primarily by clinicians is limiting.

Toxic Stress

Bringing together neuroscience, epidemiology, developmental psychology, and ecology, The Center on the Developing Child at Harvard University proposed a bio-developmental framework that underscores the significance of the mind-body's stress response system and the concept of *toxic stress*.

Toxic stress refers to strong, frequent, and/or prolonged activation of the body's stress-response systems in the absence of buffering protection of stable adult support. Major risk factors include extreme poverty, recurrent physical and/or emotional abuse, chronic neglect, severe maternal depression, parental substance abuse, and family violence. The defining characteristic of toxic stress is that it disrupts brain architecture, adversely affects other organs, and leads to stress management systems that establish a lower threshold for responsiveness that is persistent throughout life, thereby increasing the risk of stress-related disease or disorder as well as cognitive impairment well into the adult years (Shonkoff, 2010, p. 360).

In contrast to traumatic stress, toxic stress is a more inclusive concept that comprehensively acknowledges the intricate intersection between biology (genetics) and environmental conditions, as well as the lifelong consequences of a child's stress response system being relentlessly activated (Lanius, Vermetten, & Pain, 2010). *Epigenetic adaptation*, the process by which an individual's environment shapes gene architecture and expression even influencing succeeding generations, is beginning to be better understood and will contribute significantly to understanding the complexities of toxic stress, including intergenerational transmission (Peckman, 2013). Simply stated, adversity becomes biologically embedded and creates developmental vulnerabilities that can last generations. This expanded perspective on the chronic stress of adversity is crucial for the development of trauma-informed service delivery systems, especially prevention and early intervention programs.

BRAIN STRUCTURES AND FUNCTIONS

A thorough description of all key brain structures that participate in responding to toxic stress is beyond the scope of this chapter; interested readers are encouraged to pursue the references mentioned for additional information. To facilitate understanding, a picture of the brain with key areas identified is included (See Figure 39.1). After briefly describing the fundamental features of brain regions that are most prominently involved in responding to traumatic events, the remaining portion of this section elaborates on the stress response systems. Learning more about the specialization of each area provides the practitioner with a deeper understanding of emotional

regulation strategies and meaning-making processes, both fundamental to working with individuals affected by toxic stress.

Hemispheric Specialization

The cerebral cortex has two halves, a right hemisphere (RH) and a left hemisphere (LH). Although these two halves appear identical in size and structures, there are important differences in function and processing style. The right hemisphere (RH) is dominant at birth and continues to be the primary hemisphere for the first three years of life with its functions focused on survival, attachment patterns, emotional regulation, and sensory experiences (Chiron et al., 1997; Schore, 2000). The RH is the relational hemisphere, mapping the emotional terrain of our earliest attachment experiences through cycles of dysregulation and regulation as infant and caregiver engage in reciprocity of attunement and resonance. These imprints, or internal working models of self and the world, serve as signposts for safety and promote or inhibit exploration (Beebe, Lachmann, Markese, & Bahrck, 2012).

The LH develops more slowly than the RH, not becoming fully wired-up (myelinated) until 18 to 24 months. Compared with the RH, the LH tends to be more logical, analytical, and sequential, and focuses on details in order to construct complex theories and narratives (Phelps & Gazzaniga, 1992). The *interpreter*, a name dubbed by Michael Gazzaniga (Gazzaniga et al., 1996; Gazzaniga, Holtzman, Deck, & Lee, 1985) to reflect the LH's preference for stories and understanding, "seeks explanations for internal and external events in order to produce appropriate response behaviors" (Gazzaniga, Ivry, & Mangun, 2009, p. 465).

The two hemispheres each contribute uniquely to communication. The LH is understood to be primary in producing and comprehending language, in the traditional sense; however, the RH plays an important role in understanding emotion-based nonverbal cues such as body language and facial expressions (Blonder, Bowers, & Heilman, 1991; Semrud-Clikeman, & Hynd, 1990). Both are important not only for communicating with others, but as a way of maintaining a sense of order. Meaning making is the way individuals interpret their worlds and give explanation to events that happen. Whereas the RH is dominant for emotions and relationships, the LH specializes in providing context and perspective. In other words, the LH provides

Figure 39.1 Brain structures involved in responding to traumatic events (illustration by Halorie Walker-Sands).

the narrative to emotional experiences; expanding on what is known in the present and making inferences based on past experience. This is how individuals develop a worldview, against which events are scanned to provide explanation (Roser, Fugelsang, Dunbar, Corballis, & Gazzaniga, 2005). Individuals with traumatic histories, especially early childhood experiences, are more likely to have a worldview of self-as-bad and others-dangerous and filter relationships and experiences through this lens.

The Amygdala

Responding to traumatic events and toxic stress involves many brain regions and of primary importance are the amygdalae (one in each hemisphere). Acting as a first responder, this small, almond-shaped area processes input from our sensory systems, including tactile, visual, olfactory, auditory, and gustatory stimuli, determining whether the incoming information is life-sustaining or life-threatening. The amygdala automatically coordinates with brain areas involved in long-term memory (hippocampus) and inhibitory control (prefrontal cortex) through elaborate neural networks, and if warranted, participates in initiating a survival-based response.

All sensory input associated with a dangerous or threatening situation is encoded by the amygdala as a threat to survival and is formed into

memory. Before the development of language, the encoding of memories is automatic and outside of conscious awareness. These implicit-type memories do not contain autobiographical or chronological references, thus are devoid of a sense of self, time, or place and cannot be recalled voluntarily. Implicit memory encoding continues throughout the lifespan and is fundamental to encoding traumatic experiences (Amir, McNally, & Wiegartz, 1996; Elzinga & Bremner, 2002). The amygdala and the implicit memory making processes build a database of all information associated with the threat. This database is used to anticipate and respond to danger, both actual and perceived.

The Hippocampus

The hippocampi (one in each hemisphere) are also key brain areas involved in processing traumatic experiences; and are highly susceptible to the damaging effects of toxic stress. Named appropriately for its sea horse-like shape, the hippocampus is critical for learning and long-term memory processing. The explicit-type of memory, processed by the hippocampus, differs in several ways from the implicit memory formed and stored by the amygdala. First, explicit memories can be voluntarily recalled and explained using language, which is why it is often referred to as declarative memory. Second, the information encoded is factually based and represents details

of people, places, and events, giving these memories a sense of self, time, and place (Kandel, 2007). Together the amygdala and hippocampus both contribute to the rich, detailed autobiographical story of our lives. “Exchange of information between the hippocampus and amygdala link the emotional and contextual aspect of events,” (Joëls, Pu, Wiegert, Oitzl, & Krugers, 2006, p. 155).

The Hypothalamus and Pituitary

Located in an area between the cerebrum and the brain stem, essentially above the roof of the mouth, is the hypothalamus. This area “coordinates behavioral response to insure bodily homeostasis, the constancy of the internal environment” (Kandel, Schwartz, & Jessell, 2000, p. 960). In particular, the hypothalamus works to maintain life-essential functions, such as the regulation of blood pressure, body temperature, thirst, hunger, and reproductive behaviors (Saper, 2009). Although much of this activity engages the “rest and digest” system, under threatening conditions, the hypothalamus coordinates with the brain stem and the pituitary gland to initiate the body’s stress response system, preparing for fight, flight, or freeze. The pituitary, considered to be the master gland, lies beneath the hypothalamus and acts as the “mouth piece through which the hypothalamus speaks to the body” (Bear, Connors, & Paradiso, 2007, p. 485). When activated under stress, the pituitary releases a cascade of stress hormones.

The Medial Prefrontal Cortex and Anterior Cingulate Cortex

The brain areas discussed thus far act reflexively and subconsciously, for the most part, and are involved in what can be termed *bottom-up* processing. Areas of the brain involved in *top-down* processing are located in the frontal lobe. The frontal lobe offers comparatively slower processing by filtering reactions, inhibiting responses, regulating emotions, engaging in problem solving, directing attention, making plans, and integrating information. In the case of a threatening situation, areas of the frontal lobe, specifically the medial prefrontal cortex (mPFC) and anterior cingulate cortex (ACC) help interpret threat, evaluate emotional conflict, and distract from fearful stimuli (Etkin, Egner, & Kalisch, 2011; Milad et al., 2007). Segments of these brain frontal lobe areas focus on immediate threat, while

others plan responses to anticipated threat (Etkin et al., 2011). The mPFC and ACC also monitor bodily changes, for instance, increased heart rate and breathing; insight referred to as interoceptive awareness (Critchley, Wiens, Rotshtein, Öhman, & Dolan, 2004). After interpreting the situation, these frontal lobe areas may promote a stress response, or they may quiet reactive areas such as the amygdala and hypothalamus (Schore, 2002). As discussed in the next section, when threat is consistently present or perception of danger sensitized, bottom-up processing becomes normative and the involvement of the frontal lobe in threat assessment is by-passed and thus, emotional regulation impaired.

THREAT, SURVIVAL, AND ADAPTATION

Working together through a system of complex neural networks, the brain areas described continually process physiological and affective arousal in order to maintain a state of regulation in the body and mind. When the brain interprets stimuli or experience as life-threatening, there is an automatic, subconscious activation of survival strategies, most commonly flight, fight, or freeze responses. Accompanying the physiological activation of survival responses is the affective experience of fear. The innate initiation of survival strategies to ensure safety is based both on genetically encoded ancestral memories of what was dangerous in past environments and what the individual’s neurobiology has learned about threat in current environments. This on-going cataloging of threat stimuli is an example of the nature–nurture interaction, an essential part of adaptation, also known as fear conditioning (LeDoux, 2003; Perry, Pollard, Blakley, Baker, & Vigilante, 1995).

Typically, when threat has been averted, or the perception of threat by the amygdala determined to be nonthreatening by the hippocampus, the stress system response is shut off and a state of regulation is restored. However, when the threat is frequent or prolonged, the ability of the brain to bring about regulation becomes impaired. Deficits or alterations in the stress regulatory processes are the basis of many mental health impairments, including posttraumatic stress and complex trauma disorders. Recent research, most prominently the Adverse Childhood Experiences Study (Felitti et al., 1998), has established a clear

link between early childhood adversity and adulthood health problems including cardiovascular and immune diseases. Practitioners working with individuals who have a history of trauma exposure, affected by adversity, are indeed working with altered stress regulatory systems. The following is a more detailed description of the stress response system and the effects of toxic stress on specific brain areas.

Stress Response Systems

When danger is detected, the hypothalamus engages two distinct stress response systems, the Sympathetic Adrenomedullary (SAM) system, and the Hypothalamic-Pituitary-Adrenal (HPA) system. Both systems respond to real or perceived threat, initiating fight, flight, or freeze behaviors. During activation, the brain prioritizes resources for activities that are essential for survival, such as heart rate, blood pressure, and muscle tension, while activities, such as digestion and higher cognitive functions are decreased (Kandel et al., 2000). The SAM system is quick acting, releasing the neurotransmitter adrenaline (Gunnar & Quevedo, 2007).

Comparatively, the HPA system is slower, exerting more prolonged effects, including toxic stress. After receiving a message of threat by the amygdala, the hypothalamus releases corticotropin-releasing hormone (CRH). This signals the pituitary gland to release adrenocorticotropic hormone (ACTH), which prompts the adrenal gland to release cortisol (Ehlert, 2013). All types and levels of stress, whether physical, psychological, or emotional, can initiate a release of cortisol (Kandel et al., 2000). Although a dysregulated cortisol level can be problematic, an adequate amount of this hormone is necessary for motivating activity as well as turning off the stress response (Gillespie & Nemeroff, 2007). When the stress system is continually activated by threat in a person's environment, the brain adapts to this environment by resetting the norm to a consistently fired-up state. This heightened, persistent level of stress-response becomes toxic to the mind and body.

Cues associated with the threat, such as visual prompts, smells, ambient sounds, time of day, etc. which ordinarily do not cause a stress response, are automatically associated with the threat itself, and the information is stored in the amygdala's implicit memory file as a warning of potential harm. As a result, negative affective states (fear,

shame, rage, numbing, dissociation, etc.) and physical sensations (muscle tension, increased heart rate, rapid breathing, etc.) are easily activated to cues even in seemingly nonthreatening environments (Levine, 2010; Ogden et al., 2006; Yehuda & LeDoux, 2007).

The amygdala stores only implicit type memories and relies on the hippocampus for contextual information about its perception of threat and emotional memories (Shin, Rauch, & Pitman, 2006) to determine the "realness" of the danger. For example, an individual may initially experience a racing heart and the emotion of fear at the sound of scratching on a window in the night, because the stress response system has been activated by the amygdala's perception of threat. However, the hippocampus, based on contextual memory, sends a message that it is a tree brushing up against the house and the stress response shuts off, restoring emotional and physiological regulation. In order to not be frightened by every shadow or unknown object, this coordination between the reflexive (amygdala) and rational (frontal cortex and hippocampus) brain areas is essential (Schore, 2002). In addition to the hippocampus, the mPFC and ACC offer interpretation and regulation (Aupperle, Melrose, Stein, & Paulus, 2012; Shin & Liberzon, 2010).

Altered for Adaptation

Toxic stress profoundly impairs the HPA system and alters the structure and functioning of brain areas. A number of studies have demonstrated that the HPA system becomes highly sensitive and over-reactive when exposed to unmitigated chronic stress (Gunnar & Quevedo, 2007; Heim et al., 2000; McEwen, 2008), particularly in developing brains (Gillespie & Nemeroff, 2007; Gunnar & Loman, 2010). Closely aligned with the HPA processes, the hippocampus appears exceptionally vulnerable to the effects of stress. When there is chronic over-activation of the stress response system resulting in the brain being flooded with excess cortisol, hippocampal-dependent learning and memory processes become impaired (Joëls et al., 2006). Excessive cortisol causes a reduction in hippocampal dendrite density reducing the overall volume of the hippocampus and impacting function (Conrad, 2008). When altered by toxic stress, the hippocampus has a significantly reduced capacity to provide important contextual information to the amygdala about which

conditions represent danger and which represent safety. When the hippocampus is compromised, it is not effective in sending messages to the hypothalamus to stop producing CRH and turn off the stress response (McEwen & Gianaros, 2010). Many individuals who suffer from PTSD show low baseline levels of cortisol, suggesting an exhausted HPA system, which account for the intrusive memories they experience (O'Donnell, Hegadoren, & Coupland, 2004).

The amygdala working in concert with the hippocampus and the HPA system is also changed structurally and functionally by toxic stress. The amygdala is central to relational processes and development of attachment strategies, making it extremely sensitive to excessive activation in early life. Infants, children, and youth are particularly sensitive to toxic stress and impairment in regulatory functioning in the PFC and the ACC. Again, excessive activation in the areas that respond to emotions and an underactivation in areas involved in cognitive processes of assessment and evaluation lead to developmental disruptions.

SOCIAL WORK THROUGH THE NEURO-TRAUMA LENS

Learning from research findings about the neurobiological consequences of toxic stress provides social workers with a depth of understanding about the profound effects that trauma exposure can have on individuals, families, and communities. There is still much to learn about how toxic stress affects the structures and functions of the brain, mind, and body, as well as the resultant consequences on regulating emotions, cognitions, behaviors, and sensory and somatic experiences; moreover, how the social ecology promotes, inhibits, or exacerbates these effects. Knowledge about how to infuse human service organizations with trauma-informed culture and embed trauma-specific practices across systems is only in the beginning stages. Such an expansive service transformation takes time and an investment of resources. Knowing that trauma induces alterations in the physiology of the stress response systems and brain structures will not alone shift policy and practice decisions toward those that recognize the pervasiveness of adversity among service users. This final section of the chapter presents implications for trauma-informed and trauma-specific social

work, including a series of questions that practitioners can ask themselves to enhance their work through a neuro-trauma lens.

The principle and practice of universal precaution within the context of trauma-informed approaches and trauma-specific practices are based on the high prevalence of trauma-exposure, poly-traumatization, posttraumatic stress, and complex trauma among services users (Hodas, 2006). The vast majority of individuals and families who are served by social workers have significant trauma exposure; indeed, compromised neurobiological functioning due to early trauma and ongoing adversity has contributed to their need for services or involvement with mandated services.

Simply stated, implementing universal precaution means designing and delivering all aspects of services to all consumers/clients with an understanding of how trauma shapes neurobiology. The practice of universal precaution is not a model or technique; it is a frame of reference. With the understanding that service users have compromised stress regulatory systems comes the challenge to create service environments and agency-consumer interactions with the first and foremost goal of maximizing the service user's experience of physical and emotional safety. In other words, service design and delivery from the perspective of universal precaution is developed in such a manner as to minimize activating clients' trauma-based neurobiological response patterns. Service users can only establish and utilize regulatory strategies within nonthreatening environments and relationships. Brain areas necessary for cognitive processing, new learning, and meaning-making can only be accessed if emotional regulation is first established.

Both social-ecological and neuro-regulatory intervention strategies are necessary for resilience and recovery to be possible. Organizational cultures and practices that are trauma-informed create environments that are essential to initiating and maintaining neurobiological healing.

Clients' trauma-anchored neurobiologies have exquisitely perceptive threat response systems. The slightest trauma reminder—a voice tone, a question, a closed room—can set off a powerful cascade of somatic, emotional, physical responses, which are not within the service user's conscious awareness or immediate control. Agency staff and providers may misunderstand these automatic hyperarousal or hypoarousal survival oriented reactions as manipulative,

oppositional, hostile, uncooperative, withdrawn, disinterested, etc. As suggested by Bloom (1999), instead of taking the position of “What’s wrong with you?” to a client’s behavior that is challenging or not understood, thinking or asking about “What’s happened to you?” begins to shape a trauma-informed response (p. 15).

The following sample of questions is designed to assist social workers to think and act through the neuro-trauma lens.

- What changes can be made in the physical space of the service setting to increase the service user’s experience of safety?
- When I apply the principle of universal precaution, how does my work change?
- When I acknowledge the service user’s behavior or affect is serving a learned protective function, what changes in my response?
- How do I use knowledge about the functions of the two hemispheres to better understand the service user’s state of mind and shape my response accordingly? For example, how do my verbal and nonverbal responses match with the service user’s right hemisphere functioning?
- What do I know about the amygdala and hippocampus that helps me observe service users’ trauma re-experiencing and intervene accordingly?
- What are some examples of service users’ behaviors, emotions, and relational capacities that might represent survival responses? (Fight? Flight? Freeze?)
- What is my plan to learn more about the neurobiology of toxic stress and advocate for more trauma-informed services?

The intent of this chapter has been to focus on the neurobiology of toxic stress that is a result of psychological trauma exposure. The focus has been primarily on the individual’s neurobiology and regulatory capacity because the majority of service users with whom social workers interact have pervasive trauma exposure and live in adverse circumstances. However, trauma-informed approaches must also be focused on the social ecology in which consumers live. Reduction of traumatic exposure is of equal importance. Knowledge about the enduring effects of adversity on mind and body is also the basis of addressing social policies and prevention programs.

40 Fundamental Principles of Behavioral Social Work

Denise E. Bronson

Applied behavioral methods, derived from the experimental analysis of behavior and learning in psychology, were introduced to social work in the mid-1960s when the first social work book on behavioral methods was published (Thomas, 1967). Several key texts followed (Fischer & Gochros, 1975; Schwartz & Goldiamond, 1975; Sundel & Sundel, 2005; Wodarski & Bagarozzi, 1979) and behavior therapy courses began to appear among the course offerings in many social

work programs. At that time, the emphasis was clearly on the use of *behavior therapy* (also commonly referred to as *behavior modification*). But behavioral methods have continued to evolve and today include cognitive-behavioral interventions (Gonzalez-Prendes, 2012), dialectical behavioral treatment (Dimeff & Koerner, 2007), and other strategies that are based on behavioral principles. These behaviorally based methods are some of the most widely used interventions (Thyer,

2012) and share several characteristics that distinguish behavioral social work from other treatment approaches:

- Behavioral social work is based on extensive empirical work in basic and applied settings, and ongoing empirical evaluation of service is an integral part of behavioral practice.
- Behavioral interventions are highly individualized and address the unique learning history of each client. An individualized behavioral assessment (functional behavioral assessment) is, therefore, extremely important and focuses on identifying the environment in which the problem behavior occurs (antecedents), the behavior itself (response), and what happens afterwards (consequences).
- Principles of learning are applied to understand how behaviors are acquired and maintained. This occurs at all levels—individual, family, group, societal, and cultural.
- Behavioral interventions focus on the presenting problem and strive for outcomes that are clinically and socially meaningful to the client and significant others.
- Maintenance and generalization of changes are not assumed to occur automatically once the desired goals are obtained. Instead the conditions for ensuring maintenance and generalization are carefully assessed and become an important consideration in developing a successful intervention.

Contemporary behavior therapy has been used to address a variety of issues in a variety of social work settings. Systematic reviews and other outcome studies have demonstrated the effectiveness of behavioral strategies to address individual issues (e.g., anxiety disorders and phobias, anger management, depression, academic performance, employment skills, and substance abuse), family concerns (e.g., family violence, parent training, communication, and decision-making), and community/social needs (e.g., ecological behavior, seat-belt usage, littering, and recycling).

With all the developments in behaviorally based interventions it is easy to lose sight of the fundamental principles that are the foundation of all behavioral methods. This chapter will use two case examples to review these principles and

illustrate the use of behavior therapy in social work. The references and additional readings at the end of the chapter provide resources for exploring these principles in much greater detail. Another chapter in this volume discusses the use of cognitive-behavioral-treatment (CBT) specifically (Vonk & Early, 2014).

CASE EXAMPLES

Case Example 1: Sally Adams developed a fear of driving over or under bridges following the collapse of an interstate highway bridge in Minneapolis. She lives in a city with many bridges and this phobia has escalated to the point that she is unable to drive without planning long, time-consuming routes to her destination. This has interfered with her ability to get to work on time and she is in danger of losing her job.

Case Example 2: John and Mary Brown's four-year-old daughter Megan has become unmanageable. Bedtime is especially problematic and it can take up to three hours to get Megan into bed. Megan pleads with her parents to stay up later then throws temper tantrums when she is told that she must go to bed. This has started to cause problems between her parents who argue over how to handle their daughter.

KEY CONCEPTS IN BEHAVIORAL SOCIAL WORK

A number of key concepts and technical terms are important in behavioral assessment and intervention (Antony & Roemer, 2011; Bailey & Burch, 2006; Cooper, Heron, & Heward, 2007; Martin & Pear, 2007; Spiegler & Guevremont, 2010). Behaviorists generally classify behavior into two broad categories—respondent behaviors and operant behaviors. *Respondent behaviors* are elicited by stimuli in the environment and involve the autonomic nervous system (i.e., blood pressure, heart rate, rapid breathing, or changes in the glandular system). For example, Sally Adams's fear of bridges in Case 1 triggers a number of physiological reactions (rapid heart rate, heightened alertness, sweating, etc.) whenever she approaches a bridge. *Operant behaviors*, on the other hand, are those which "operate" on the environment and are controlled by the

environmental consequences that follow. Most overt, observable behaviors fall into this category, including language. For example in Case 2, if Megan is praised by a parent for going to bed on time, she is more likely to go to bed on time in the future and conversely, if her parents attend to her temper tantrums it is likely that the tantrums will increase in frequency or intensity. Furthermore, parents are more likely to use praise in the future if it increases the probability that their child will comply with parental requests. Historically, it was believed that respondent behaviors were controlled by antecedent stimuli and that operant behaviors were controlled by consequential stimuli. Although this distinction is still useful, recent research has demonstrated considerable overlap in the processes described by these concepts. In addition, it is clear that genetic and biological factors will set limits on the range and type of respondent and operant behaviors that are possible.

Respondent and operant behaviors are learned in two ways—respondent conditioning and operant conditioning. In *respondent conditioning*, a neutral stimulus (*conditioned stimulus*—CS) is repeatedly paired with an eliciting stimulus (*unconditioned stimulus*—UCS). Eventually the neutral stimulus will also elicit a similar response, which is now referred to as the *conditioned response* (CR). For example, the sudden bright light of a flashbulb (UCS) elicits an eye blink (UCR). Unfortunately, the camera (CS), through its repeated pairing with the flash (UCS), can also begin to elicit an eye blink (CR), often resulting in family pictures in which the subject's eyes are closed in "anticipation" of the flash. Or in Sally Adams's case, repeatedly viewing the images of the interstate bridge collapse in Minneapolis elicited emotional reactions that were associated with a previously neutral stimulus, namely, bridges. In this way, phobias are acquired through respondent conditioning when neutral stimuli begin to elicit physiological or fear responses.

Operant conditioning refers to the process of learning in which the future likelihood of the behavior will either increase or decrease depending on the *contingencies* associated with that behavior. Contingencies refer to both the *consequences* that follow the behavior as well as the *antecedents* that precede the behavior indicating the type of consequence that is likely. For example, telling a joke at a party will probably be followed by a friend's laughter. If the

same joke is told to the same friend during a lecture, however, the friend might respond with "sshhhh" rather than laughter. In this case, the antecedent conditions associated with a party signal that a positive response (a positive reinforcer) will follow telling a joke while the same behavior in class will receive a negative reaction (a punisher). Our jokester soon learns to *discriminate* the conditions under which jokes will be reinforced. Similarly, in Case 2, it is important to conduct a *functional analysis* to determine the antecedents (e.g., parental request to go to bed), the *behavior* (e.g., Megan's temper tantrums) and the *consequences* that follow Megan's outbursts, which might be increasing the future probability of those tantrums (e.g., parents acquiesce and let her stay up or parental attention).

Behaviorists refer to four types of consequences—*positive reinforcers*, *negative reinforcers*, *positive punishers*, and *negative punishers*. Any consequence that increases the future probability of the behavior it follows is a *reinforcer*. Positive reinforcers are stimuli that are presented contingent on the occurrence of the behavior (e.g., receiving an allowance for household chores). The termination or removal of an aversive stimulus (negative reinforcement) will also increase the behavior it follows (e.g., putting on a sweater when you feel cold). Conversely, any consequence that decreases the future probability of the behavior it follows is a *punisher*. *Positive punishment* is the presentation of an aversive stimulus contingent on a behavior (e.g., saying "no" to a child who asks for cookies before dinner) while negative punishment is the removal of a reinforcer contingent on a behavior (e.g., turning off the TV when children fight about which program to watch). What serves as reinforcers and punishers is highly individualized and varies according to one's learning history, biological and genetic characteristics, and the setting. The only way to really determine which stimuli are reinforcers and punishers is to observe the affect of those stimuli on future behavior.

The *schedule of reinforcement* is another important concept that refers to the frequency with which a behavior is reinforced. Often when new behaviors are being acquired they are reinforced after every occurrence; this is called a continuous reinforcement schedule. Usually in the natural environment, however, behaviors are reinforced only intermittently depending on

the number of times the behavior is performed (ratio schedules of reinforcement), the amount of time that passes (interval schedules of reinforcement), or the rate of responding (differential reinforcement of high or low rates). Intermittent schedules of reinforcement are most resistant to periods of *extinction* when reinforcement that was previously available is withdrawn.

Finally, operant behaviors are often preceded by antecedent stimuli (*discriminative stimuli*) that cue which behavior will be reinforced in a particular setting. Through a process of discrimination training in which a behavior is consistently reinforced only in the presence of specific stimuli, individuals learn which behaviors are likely to be reinforced in each setting. To illustrate, consider Megan in Case 2. When Megan's request to stay up later is made to her mother permission is usually given; when the request is made to the father it is usually refused. Megan learns quickly to discriminate those situations (i.e., presence of mother) in which requests to stay up late (behavior) are likely to be reinforced (permission granted)

from those situations in which the behavior will not be reinforced.

ENGAGING IN BEHAVIORAL SOCIAL WORK

Behavioral Assessment. Assessment in behavioral social work is an extremely important process that is closely linked to decisions about which intervention strategy to use. During assessment (also referred to as a *functional analysis*) the social worker collects information to determine the antecedents and consequences of the problem behavior, specifies the desired outcomes (the *target behavior*), and selects the most appropriate therapeutic technique. Clients and significant others are an important part of this process. A summary of the steps used by behavioral social workers during assessment is presented in Table 40.1.

Intervention Strategies. Following the assessment and collection of baseline data, behavioral social workers (1) specify the desired target behavior, antecedents, and consequences; (2) identify data

TABLE 40.1 Steps in Behavioral Assessment

Steps	Activities
1. Identify the problem areas and priorities	<ul style="list-style-type: none"> • Obtain a list of problem areas from the client(s) using interviews, observation, and standardized assessment questionnaires • Determine priorities for service • Select the problem(s) to be addressed and the desired outcome (target behavior)
2. Specify the target behaviors	<ul style="list-style-type: none"> • Describe the problem and target behaviors in observable and measurable terms • Determine whether the problem is one of behavioral excesses or behavioral deficits • Determine whether the problem is primarily operant or respondent in nature • Begin collecting pretreatment (baseline) data, if possible, using direct observation, client self-reports on internal states or emotions (using rating scales or standardized questionnaires), and physiological measures
3. Assess the controlling conditions (antecedents & consequences)	<ul style="list-style-type: none"> • Collect information about the environmental antecedents that precede the problem behavior • Collect information about the consequences that immediately follow the problem and target behavior • Determine whether the problem is primarily one of: <ul style="list-style-type: none"> • Poor stimulus control (i.e., lack of cues for the appropriate behavior, poor discrimination training, or the presence of stimuli that elicit inappropriate respondent and emotional behaviors) • Behavioral deficits (i.e., client lacks skills to perform the desired behavior) • Inadequate or inappropriate consequences (i.e., client has the necessary skills but reinforcers for the desired behavior are missing, the reinforcers are conflicting or delayed, or the reinforcers consist of inappropriate personal reinforcers that cause harm to others or are culturally disapproved)

collection strategy for monitoring changes in the target behavior; and (3) develop an intervention plan. Maintenance and generalization of changes, once they are obtained, are not assumed to occur naturally and strategies for ensuring lasting change are included in the intervention planning.

Generally, behavioral interventions can be categorized according to whether the primary activity focuses on modifying the stimulus conditions preceding the behavior, developing the behavior itself, or altering the consequences of the behavior. In many cases, one or more strategies from these three categories are employed simultaneously to address the target problem.

Table 40.2 presents examples of commonly used intervention techniques for modifying

TABLE 40.2 Interventions for Modifying Stimulus Conditions

<i>Discrimination Training</i>	Procedure in which the desired behavior is reinforced in the presence of appropriate stimuli and not reinforced in the presence of inappropriate stimuli to teach when/where to perform target behavior. Fading can be used to gradually change dimensions of the stimulus to teach difficult discrimination.
<i>Prompting</i>	Cues to remind or guide client to engage in the desired behavior; can be combined with <i>fading</i> to eventually remove prompt
<i>Respondent Extinction</i>	Process of breaking the connection between the conditioned stimulus (CS) and the unconditioned stimulus (UCS) by repeatedly presenting the CS without the UCS until it no longer elicits the conditioned response (CR)
<i>Systematic Desensitization</i>	Method used to treat phobias by gradually exposing client to increasingly anxiety producing stimuli while engaging in responses incompatible with the anxiety (usually relaxation)

stimulus conditions (antecedents). These strategies are used when the assessment shows that the client is able to perform desired behavior but unable to discriminate the appropriate time/place for the behavior or that environmental stimuli elicit problematic emotional states (e.g., phobias).

In some cases the assessment indicates that the client has not learned the desired behavior and is, therefore, unable to perform it. The behavioral social worker will select an intervention designed to teach or train a new behavior. Table 40.3 presents examples of some of the commonly used strategies.

The assessment may indicate that the desired behavior does not occur because the consequences of the behavior are faulty. For example, the environment might not reinforce the desired behavior or could be reinforcing an incompatible, inappropriate behavior. Interventions to modify the consequential contingencies can be grouped into two types of strategies—those that focus on increasing the desired behavior and those that focus on decreasing an undesirable behavior. Frequently, behavioral social workers will use techniques from both groups simultaneously. Table 40.4 presents examples of both types of strategies designed to alter

TABLE 40.3 Interventions for Developing New Behaviors

<i>Shaping</i>	Teaching a new behavior through gradually reinforcing increasingly complex or precise approximations to the final desired behaviour.
<i>Chaining</i>	Procedure used when the final behavior consists of several steps needed to complete the action (e.g., dressing). Chaining can either begin at the beginning or end of the sequence to train each of the stimulus-response sequences needed for the desired behavior.
<i>Modeling</i>	Presenting a live or filmed demonstration of the desired behavior in which the client learns which behaviors are desired and the contingencies under which they occur.

TABLE 40.4 Interventions for Modifying Response Consequences

Increasing Desired Behavior	<i>Positive & Negative Reinforcement</i>	Presenting a reinforcing stimulus or removing an aversive stimulus, respectively, immediately following the performance of the desired behavior
	<i>Escape & Avoidance Conditioning</i>	Similar to negative reinforcement in that an aversive stimulus is removed (escape) or prevented (avoidance) after the occurrence of a response
Decreasing Undesired Behavior	<i>Operant Extinction</i>	Process in which a reinforcer is withheld following an operant response that had previously produced that reinforcer
	<i>Positive & Negative Punishment</i>	Presenting an aversive stimulus or removing a reinforcer immediately following the performance of the undesirable behavior
	<i>Differential Reinforcement</i>	Manipulating the schedule of reinforcement to decrease behavior by reinforcing low rates of responding, zero responding, or incompatible responding

the consequences following a behavior. The effectiveness of interventions to modify the consequences of a behavior will depend on a number of factors including the immediacy of the consequence, the salience of the reinforcer or punisher, and the schedule of reinforcement. The behavioral social worker will assess each of these factors and address them in deciding how to intervene.

AREAS OF APPLICATION WITH EMPIRICAL SUPPORT

Behavioral assessment and intervention techniques have been used to treat a range of problems, from individual to societal concerns, effectively. Due primarily to behaviorists' commitment to a scientific approach, a large body of empirical research exists to support the effectiveness of behavioral methods to deal with diverse problems and issues such as obsessive-compulsive disorders, parenting difficulties, treatment compliance problems, sexual dysfunction, drug and alcohol abuse, urinary incontinence, disruptive classroom behavior, attention deficit hyperactivity disorder, and juvenile offenders. Systematic reviews on the use of behavioral methods can be found on the Campbell Collaboration (<http://www.campbellcollaboration.org/lib>) and Cochrane

Collaboration (<http://www.thecochranelibrary.com/view/0/index.html>) libraries. Research articles on the clinical applications of behavioral methods are reported in journals such as *Behavior Therapy*, *the Behavior Analyst*, *Journal of Applied Behavior Analysis*, *Journal of Positive Behavior Interventions*, *Journal of Behavioral Education*, *Behavior and Social Issues*, *Behavior Modification*, *Behaviour Research and Therapy*, *Behavioral Interventions*, and *Journal of Behavior Therapy and Experimental Psychiatry*.

FUTURE DIRECTIONS

Although behavioral social work has evolved considerably since the introduction of the first textbook on behavioral social work in 1967, the paucity of articles in social work journals is problematic. Considerable misrepresentation and misunderstanding of the behavioral approach continues and those engaged in behavioral social work generally find it easier to publish their work in non-social work publications. Consequently, social workers are often not aware of recent research and developments in behavioral treatment and, unfortunately, this means that social work clients are not benefiting from intervention strategies with proven effectiveness. Greater access to systematic reviews of the

research literature in electronic, online databases may make current research more accessible to practitioners in the future.

Over the years, practitioners have been reluctant to use the term *behavioral* to describe their interventions (Gambrill, 1995; Bronson & Thyer, 2001) and this situation does not seem to be changing. However, with the advent of evidence-based practice in social work the future of behavioral social work is very promising. The behavioral approach offers empirically tested, change-focused, client-centered, and environmentally based social work interventions that are highly consistent with the values and objectives of social work practice (Thyer, 2012). Increased efforts to ensure that social workers are knowledgeable and skilled in using behavioral methods will certainly enhance the effectiveness of services and the credibility of the profession.

41 The Miracle Question and Scaling Questions for Solution-building and Empowerment

Mo Yee Lee

The miracle question and the scaling question are an integral part of solution-focused brief therapy (SFBT), which was originally developed at the Brief Family Therapy Center at Milwaukee (Wisconsin) by Steve de Shazer, Insoo Kim Berg, and their associates. Solution-focused brief therapy begins as atheoretical, focusing instead on finding “what works in therapy” (Berg, 1994). Building on a strengths perspective and using a time-limited approach, solution-focused brief therapy postulates that positive and long-lasting change can occur in a relatively brief period of time by focusing on “solution-talk” instead of “problem talk” (de Shazer, 1985; Lee, 2013; Nelson & Thomas, 2007). One definitional characteristic of SFBT is that it equates therapeutic process with the therapeutic dialogue, with a focus on what is observable in communication and social interactions, instead of intentions, between client and therapist (Trepper et al., 2013; McKergow & Korman, 2009). Change happens through the therapeutic dialogue in which the therapist and client co-construct what is beneficial and helpful to accomplish the client’s self-determined goals (Lee et al., 2003). Solution-focused brief therapy uses the language and symbols of “solution and strengths” as opposed to the language of “deficits and blame” (Lee, Sebold, & Uken, 2003). Treatment focuses on identifying exceptions and solution behaviors, which are then amplified, supported, and reinforced through a systematic solution-building process (De Jong & Berg, 2013).

Miracle question and scaling question, in many ways, synthesize the treatment orientation and

practice characteristics of solution-focused brief therapy. Its conversational- and solution-based characteristics are intimately related to three definitive assumptions and practice principles of solution-focused brief therapy:

1. The power of language in creating and sustaining reality. Solution-focused therapy views language as the medium through which personal meaning and understanding are expressed and socially constructed in conversation (de Shazer, 1994). Because “what is noticed becomes reality and what is not noticed does not exist” (Lee et al., 2003, p. 32), there is a conscious effort by the therapist to help the client stay focused on envisioning a desirable future and finding small steps to actualize the solution-oriented future. Pathology or problem-talk sustains a problem reality through self-fulfilling prophecies and distracts attention from developing solutions (Miller, 1997).
2. A focus on solutions, strengths, and health. Solution-focused brief therapy assumes that clients have the resources and *have the answer*. The focus is on what clients can do versus what clients cannot do. One basic assumption of a systems perspective is that change is constant. No matter how severe the problem, there must be some “exceptions” to the problem patterns. These exceptions serve as clues to a solution and represent clients’ “unnoticed” strengths and resources (de Shazer, 1985). Consequently, the task for the therapist is to assist clients

in noticing, amplifying, sustaining, and reinforcing these exceptions regardless of how small and/or infrequent they may be. Once clients are engaged in nonproblem behavior, they are on the way to a solution-building process (De Jong & Berg, 2013).

3. Solutions as clients' constructions. Solutions are not objective "realities" but are private, local, meaning-making activities by an individual (Miller, 1997). The importance of and the meaning attached to a goal or solution is individually constructed in a collaborative process. Solution-focused therapy honors clients as the "knowers" of their experiences and "creators" of solutions; they define the goals for their treatment and remain the main instigators of change (Berg, 1994).

THE USE OF QUESTIONS IN THE THERAPEUTIC PROCESS

Influenced by these assumptions and practice principles, the primary purpose of solution-focused interventions is to engage the client in a therapeutic dialogue that is conducive to a solution-building process. In this dialogue, the clinician invites the client to be the "expert" by listening and exploring the meaning of the client's perception of his or her situation. The use of solution-focused questions is instrumental in this solution-building dialogue. People need useful feedback in the process of change (Lee, 2013). The therapist can directly provide feedback via listening responses, affirming responses, restating responses, and expanding responses (Lee et al., 2003). Instead of directly providing feedback to clients, evaluative questions serve to initiate a self-feedback process within the client. Evaluative questions represent questions that ask clients to self-evaluate their situations in terms of their doing, thinking, and feeling. The therapist abstains from making any interpretation of a client's situation or suggesting any ideas; s/he just asks good questions that help clients evaluate different aspects of their unique life situation (Lee et al., 2003). Questions are perceived as better ways to create open space for clients to think about and self-evaluate their situation and solutions. Evaluative questions operate from the stance of curiosity and convey the message that we believe that clients have the answers and we do not have the answers.

The therapist utilizes solution-oriented questions, including miracle questions and scaling questions, to assist clients in constructing a

reality that does not contain the problem. These questioning techniques were developed by de Shazer, Berg, and their colleagues to fully utilize the resources and potential of clients (De Jong & Berg, 2013; de Shazer, 1985).

LISTEN, SELECT, AND BUILD

The SFBT Treatment Manual endorsed by the Solution-Focused Brief Therapy Association (Bavelas et al., 2013) provides a detailed description of this co-constructive therapeutic process through the steps *listen, select, and build* (De Jong and Berg, 2013; de Shazer, 1991, 1994; de Shazer et al., 2007). In this dialogue, the therapist first listens for and selects out the words and phrases from the client's language that are indications of some aspect of a solution, including things that are important and salient to the client, past successes, exceptions to the problem pattern, resources, etc. Building on the client's descriptions and paying attention to the client's language and frame of reference, the therapist composes a next question or other responses that invites the client to further elaborate the solution picture. It is through this continuing process of listening, selecting, and building that therapists and clients together co-construct new meanings and new possibilities for solutions (Trepper et al., 2013).

MIRACLE QUESTION

The development of the miracle question was inspired by the work of Milton Erickson (the "crystal ball" technique) (de Shazer, 1985). According to Berg (1994), the miracle question invites clients to create a vision of their future without the presenting problem. A major challenge encountered by most clients in social work treatment is that they know when they have a problem but they do not know when the problem has been successfully addressed. When this happens, clients may be in treatment for a long time because there are no clear indicators of health and wellness. Helping clients to develop a clear vision of their future without the presenting problem becomes crucial in successful treatment because it establishes indicators of change and helps gauge clients' progress toward a self-defined desirable future (De Jong & Berg, 2013; Lee, 2013). When defining a future without the problem becomes a major focus of treatment,

accountability for changing one's behavior can be effectively achieved. Defining a desirable future also shifts the focus of attention from what cannot be done to what can be accomplished; it moves clients away from blaming others or themselves and holds them accountable for developing a better, different future (Lee et al., 2003).

The miracle question is intended to accomplish the following therapeutic impact:

1. Allow clients to distance themselves from problem-saturated stories so that they can be more playful in creating a beneficial vision of their future.
2. Facilitate clients to develop a clear vision about a desirable future as "what is noticed becomes reality and what is not noticed does not exist" (Lee et al., 2003, p. 32).
3. Because the focus of the miracle question is for clients to identify small, observable, and concrete changes that are indicative of a desirable future without the problem, it establishes indicators of change and progress that help clients to gauge success and progress.
4. Increase clients' awareness of their choices and offer them an opportunity to play an active role in their treatment (De Jong & Berg, 2013).
5. Allow clients to be hopeful about their lives, which can be different from their current problem situation.
6. Empower clients to self-determine what constitutes a desirable future for them. "It creates a personal possible self, which is not modeled after someone else's ideas of what his life should be like" (Berg, 1994, p. 97).

A frequently used version of the miracle question is the following:

Suppose that after our meeting today, you go home, do your things, and go to bed. While you are sleeping, a miracle happens and the problem that brought you here is suddenly solved, like magic. The problem is gone. Because you were sleeping, you don't know that a miracle happened, but when you wake up tomorrow morning, you will be different. How will you know a miracle has happened? What will be the first small sign that tells you that the problem is resolved? (Berg & Miller, 1992, p. 359).

Using the process *listen, select, and build*; the therapist carefully *listens* to the client's response to the miracle question and *selects* descriptions

that are indicative of the client's goal, desirable future, successes, and resources. The miracle question only initiates the process for clients to envision a desirable future. Paying particular attention and using the client's language and frame of reference, the therapist responds by developing other solution-focused questions or responses that help the client to continuously *build* and *expand* the solution picture. Note that the focus is on small signs of change. It is also important to invite the client to describe in great detail their solution picture and how that is different from their current behaviors, feelings, and thinking. The more detailed and refined the description, the clearer the indicators of change, which will increase the likelihood that the client will actualize their solution picture, because "what is noticed becomes reality" (Lee et al., 2003, p. 32).

- "Who will be the first person to notice the change? What will they be noticing about you that will tell them that you are different?"
- How will your spouse, your child (or any significant others) know that something is different? (Relationship question)
- "What are the times in your life when you have already been doing this?" (Exception question)

The essence of the miracle question is to allow clients to envision a future without problems. Given this, social work professionals can be creative in coming up with other versions of future-oriented questions. This can be helpful especially with clients from other cultures or religions, who might have their own culture-based interpretation of miracles. Some variations can be:

- If I run into you a year later and by that time you have already solved the problem that brought you in today, how will I know that you are different? How will you be like then?
- If I were to videotape you on a good day, how would you be doing/feeling/thinking differently?
- Five years down the road, what do you want yourself to be like?

Another version is the dream question that reinforces clients' sense of personal agency and, therefore, is consistent with the goal of empowering clients (Greene, Lee, Mentzer, Pinnell, & Niles, 1998).

Suppose that tonight while you are sleeping you have a dream and in this dream you discover the answers and resources you need to solve the problem that you are concerned about right now. When you wake up tomorrow you may or may not remember your dream, but you do notice you are different. As you go about starting your day, what will tell you that you discovered or developed the skills and resources necessary to solve your problem? What will be the first small sign to tell you that you solved your problem?

SCALING QUESTIONS

Scaling questions ask clients to rank their situation and/or goal on a 1-to-10 scale (Berg, 1994). Usually, 1 represents the worst scenario that could possibly be and 10 is the most desirable outcome. People need feedback on the process of change. Therefore, for change to happen, clients will need to be able to self-evaluate their progress and make adjustments accordingly. Scaling questions provide a simple tool for clients to quantify and evaluate their situation and progress so that they establish a clear indicator of progress for themselves (De Jong & Berg, 2013). More importantly, this is a self-anchored scale with no objective criteria. The constructivist characteristic of the scaling question honors clients as the “knowers” and the center of the change process. Scaling can be used to help clients rate their perception of their progress, their motivation for change, confidence to engage in solution-focused behaviors, etc. Scaling questions are also helpful in assisting clients to establish small steps and indicators of change in their solution-building process. Some common examples of scaling questions are:

1. Problem severity or progress: On a 1-to-10 scale, with 1 being the worst the problem could possibly be and 10 the most desirable outcome, where would you put yourself on the scale? What would be some small steps that you can take to move from a 4 to a 5?
2. Motivation: On a 1-to-10 scale with 1 being you have no motivation to work on the problem and 10 being you would do whatever to change the situation, where would you (or your spouse, your boss, your child, etc.) place yourself on the scale? How, on a 1-to-10 scale, would your wife (or another significant other) rank your motivation to change?

3. Confidence: “On a 1-to-10 scale, with 1 being you have no confidence that you can work on the goal and 10 being you have complete confidence that you will continue to work on the goal, where would you place yourself?” “On a scale of 1 to 10, how confident are you that you could actually do that?” “On a scale of 1 to 10, how confident are you that this will be helpful?”

Similar to using a miracle question in co-constructing change in the treatment process, the therapist carefully *listens* to a client’s responses, *selects* and *focuses* on descriptions that are connected with indications and hints of solutions, and then helps the client to *build* and *expand* further on desirable change and solutions.

THE CASE OF LINDA

Linda was a 47-year-old woman who suffered chronic back pain after a car accident. The pain also affected her mobility. She was living on her own. The therapist uses the miracle question to help her envision a more hopeful future.

SWR: Suppose that after our meeting today, you go home, do your things and go to bed. While you are sleeping, a miracle happens and the problem that brought you here is suddenly solved, like magic. The problem is gone. Because you were sleeping, you don’t know that a miracle happened, but when you wake up tomorrow morning, you will be different. How will you know a miracle has happened? What will be the first small sign that tells you that the problem is resolved? (*Use miracle question to engage the client in a solution-building process*)

Linda: I won’t be so cranky, like an immovable mountain.

SWR: Instead of being cranky, how do you see yourself being? (*Help client move from a negatively stated description to positively stated description*)

Linda: Be a little more upbeat, cheerful, and perky. Get my mind off of it and focus on areas not on the mountain of pain.

SWR: So you want to be more upbeat, cheerful, and perky, and distract yourself from the mountain of pain and do something different? (*Select positive description and use client’s language*)

Linda: So when I am around people they are not affected by it and they aren't dragged down by it.

SWR: Let's say you woke up tomorrow after this miracle happened; what would be the first small thing you would do that you are not doing now? (*Build and expand solution-picture*)

Linda: I don't know. (Pause) Maybe instead of lying in bed staring at the wall, I would get up and open the curtain and turn on my computer, open a book, talk to the cat, anything beside lying in bed and staring at the wall.

SWR: That is what you do now, lie in bed and stare at the wall?

Linda: Yeah.

SWR: When this miracle happens, you would get out of bed, open the curtain, talk to the cat. What else would you do? (*Select and further build solution-picture*)

Linda: Turn on the computer and get out of bed and do something.

SWR: Do something? (Invite a more detailed description)

Linda: Maybe sweep, dust, or mop.

SWR: Anything else? (*Use presuppositional language that embeds an expectation of change*)

Linda: Go outside and sit in the sunshine.

SWR: Who in your home would notice the change? Is there somebody else living in your home? (*Relationship question*)

Linda: No, just my cat.

SWR: So what would your cat notice that is different about you that you are not doing now? (*Use relationship and difference question to further build the solution-picture*)

Linda: I would be up and maybe play with her.

SWR: be up and play with her? How would that make a difference in your day if you were having more fun with your cat? (*Use relationship and difference question to further build the solution-picture*)

SWR: So who else would notice the change besides your cat? (Further build and expand the solution using Relationship question)

Linda: My neighbors, friends.

SWR: What would they notice? (Invite a more detailed description)

Linda: A more positive outlook.

SWR: How would they notice? (Invite an observable description)

Linda: I would respond to them, not giving them dirty looks when it is not their fault. I would run over. I sort of give them a dirty look. It is a major hurdle for me.

SWR: Who would be most affected by this change? (Invite a description of the expected effect of change)

Linda: I suppose that it would help other people as well as me.

SWR: How so? (Invite further elaboration of the effect of change)

Linda: You know it would help me because I don't want to be a big drag and that way I won't be dragging people down and it won't be dragging me down because everyone around me is all bummed out. "Oh you poor thing," and all this and I don't want that. I want to get over it. I want to get over it; I want to get over the top of the mountain and go on from here not just hang around the base all the time.

SWR: Tomorrow, meaning the following morning or next morning, you can do this. On a 1-to-10 scale, 10 being certain that you can do this, and 1 being no chance at all, where would you think you are? (*Scaling question regarding feasibility of the change effort. Good timing to use scaling question as the client has just clearly articulated her desire and motivation for change*)

Linda: I am at a 6 right now.

SWR: So you are saying getting out of bed in the morning, opening the curtains, turning on the computer, and talking to the cat is quite doable because you are at a 6?

Linda: It is doable. I can do that.

SWR: Using the same scale, 10 being you are motivated to do this because it would improve your life, and 1 being you are wishy-washy about it, where would you put yourself on the scale? (*Scaling question regarding motivation for change*)

Linda: I would say an 8, because I don't want to be cranky anymore.

THE CASE OF ELISE

Elise was a 45-year-old Caucasian single mother with three children from 10 to 16 years of age.

Her husband passed away a year ago and she felt extremely overwhelmed trying to take care of her three children. She became depressed and attempted to commit suicide by overdosing on sleeping pills. She requested that her children be placed in foster homes while she tried to work things out for herself. She received treatment as part of her case plan to reunite with her children. While thinking what might be a helpful goal for her to work on, Elise pondered and struggled. At first, she mentioned developing a better relationship with her children as something she would like to see happen. However, she also felt overwhelmed as a single mother without the support of her husband. The therapist encouraged her to think about what will be personally meaningful and helpful to her at this time. Elise said that she would like to be more productive, although she did not have a clear idea of what a productive life would look like.

Elise: I don't know. I guess I would feel a little different. Maybe just be more productive.

SWR: In what way? (Invite a more detailed description)

Elise: I am not sure. ... I am raising three kids and my husband passed away a year ago, and I am doing nothing myself.

SWR: So life is not cool.

Elise: Yes, not whole lot to do, so. . .

SWR: So what would you do differently to be more productive? (Use client's language, listen and select what is important for the client)

Elise: I don't know, but I could be more productive than I am right now. I am reading and doing the seven steps right now. That is about it.

SWR: Do you feel being more productive by reading the seven steps and maybe, as you've just said, taking walks? (Important for the client to evaluate whether she has been more productive)

Elise: I am thinking about when my kids come home, my relationship with them is going to be more productive. I have to feel like I've changed a little bit. (Client is still somewhat unclear about what she can do to get herself to be more productive.)

SWR: Let me ask you this, You wake up tomorrow morning, you do this and whatever else it is to make you more productive. At the end of the

day you look at yourself and say, "Man, I am doing well. I am ready to do it now for myself." What do you think that might be? (This is a different version of the miracle question that helps Elise to be more playful about envisioning a future when she is more productive.)

Elise: Going through the seven steps program changes my ideas and personality more toward being a single woman.

SWR: How will people notice that you are standing as a single woman? They know that you are different. How will they know that? (Select what is important to the client and use relationship question to invite elaboration)

Elise: By the way I am acting.

SWR: What will tell them you have changed your attitude and you are different from before?

Elise: Oh, gosh, my weight.

SWR: So your weight will be different. I am curious, pretend for a moment that between now and next week, your weight has changed. What will be different for you in your daily life? What will you be doing that you are not doing right now? (Invite elaboration of the expected effect of change)

Elise: If my weight changed, I would not watch the same TV shows, I wouldn't want to read the same books, and I wouldn't eat the same junk food.

SWR: You are making big changes in your daily life.... (Invite client to self-evaluate the feasibility of the proposed change)

Elise: You're right, but this is something that I do want to change.

SWR: What would be the first things that you could possibly do to make this happen? (Invite client to make a doable plan)

Elise: I'm already walking every day. Maybe I could walk longer and not watch the eight o'clock show.

SWR: Anything else? (Presuppositional language that embeds an expectation of change)

Elise: Don't go to the "snack" aisle when doing my grocery shopping. That'll probably do it.

SWR: So what will you get from the store instead? (Help client to move from a negatively stated description to a positively stated description)

Elise: Maybe more fresh food, like veggies and fish.

SWR: What do you want to see happen when you take walks and eat more fresh food? (Build and elaborate expected effect of change efforts)

Elise: I'll feel like I'm having more control and being more productive in my life, not just lying around like a couch potato and doing nothing.

SWR: So, how confident are you on a 1-to-10 scale that you will be able to take a longer walk and eat more fresh food between now and next time we get together? (*Scaling question regarding confidence about change*)

Elise: Well, I do want to change, but you know the temptation. (*pause*) Maybe a 3.

SWR: So, what are some small things you can do to move from a 3 to a 4? (Use scaling question to establish small steps for Elise to feel more confident)

Elise: That's not easy. Maybe talking to my sister so she can remind me once in a while.

SWR: So, maybe take it to the next step. Next week, just pretend this change is going through. Watch and see what you do differently as a result of that. I will be very interested to hear what you say next time about how just going through that next step made you do things differently and be more productive? Is that possible?

Elise: Oh, yes.

SWR: Just pay attention to, "If I would like my life to be better, what small things can I do to make it happen?"

GUIDELINES FOR USING MIRACLE QUESTION AND SCALING QUESTION IN SOCIAL WORK PRACTICE

Knowing *when* to use miracle questions and scaling questions is as important as knowing the questions. Perhaps the most important skill is to pay attention to our client's and our own moment-to-moment communication and responses in the co-constructive therapeutic process. The following are some guidelines for using

these questions, including when to use them in a beneficial way:

- Use miracle questions to assist clients develop a clear vision of a future without problems.
- Miracle question is frequently used during the first session after the client has shared a description of the problem context and the therapist has an adequate understanding of the problem context.
- A shift to solution-building by using miracle question is indicated when client's description of the problem context is getting repetitive and no new information is offered
- Scaling questions can be effectively used for the following purposes:
 - Evaluate confidence, ability, and motivation with respect to clients' change efforts
 - Establish small steps for further change
 - Help clients gauge their perceptions of problems and goals
- To fully utilize the constructive effect of scaling questions, use scaling questions when the client has adequately articulated his or her desire for change.
 - Avoid inviting clients to scale confidence, ability, or motivation early on in the session when there are clear indications that they are not confident or motivated to change; or, are hopeless about the problem situation.
- Be patient: Clients do not have the solution in mind when they seek treatment, and it is the responsibility of the therapist to create a safe space for them to slowly "paint" their solution picture.
- Go for details: Assist clients to move beyond vague descriptions of a desirable future, and instead describe it in terms of small, observable, specific, or behavioral steps.
- Reinforce clients' motivation: Assist clients in carefully evaluating what may be personally meaningful and useful for them.
- Respect clients' personal choice and ownership
- Compliment and acknowledge client's desire for change
- Assist clients in evaluating the feasibility of the solution picture

- Focus on small steps that can make clients' lives better
- Assist clients in developing clear indicators of change so that they can recognize successes

CONCLUSION

The purpose of the miracle and scaling questions is to assist clients in establishing indicators of wellness and gauging their progress toward a desirable future. These self-evaluative questions represent a specific type of conversation, in which the therapist talks "with" the client (instead of talking "at" the client) to co-develop new meanings and new realities through a dialogue of "solutions" (Bavelas et al., 2013; de Shazer, 1994; Lee et al., 2003). The challenge for social work practitioners is to collaboratively work with clients so that clients can find a future in which they feel comfortable as well as feel good about their choices. The therapist cautiously refrains from providing/suggesting any predetermined solutions or desirable future. Through *listen, select, and build* (Bavelas et al., 2013), the therapist creates a therapeutic dialogical context in which both clients and therapists co-construct a solution-building process, which is initiated from within and grounded in the client's personal construction of reality and cultural strengths (Lee, 2013). The therapeutic process is a collaborative and egalitarian one, in which the client's self-determination is fully respected (De Jong & Berg, 2013). The ultimate goal of miracle and scaling questions, therefore, is consistent with the goal of empowerment that focuses on increasing clients' personal and interpersonal power so that they can take relevant and culturally appropriate action to improve their situation (DuBois & Miley, 2013; Gutierrez, DeLois, & GlenMaye, 1995).

42 Gestalt Therapy

William P. Panning

INTRODUCTION

Gestalt is a German word that encompasses several concepts, including wholeness, configuration, and pattern. To those in the field of mental health, it implies a unique form of psychotherapy that holds a holistic view of human nature, focuses on the present moment-to-moment experience to develop awareness, and is more curious about *how* people have come to where they are in life than *why*. Instead of making interpretations, Gestalt therapists work to increase the client's awareness. Gestalt therapy is an existential/phenomenological, experiential approach with a holistic commitment to the intellectual, emotional, physical, and spiritual nature of the client. Therapy focuses on improving contact and awareness in the here and now. Unlike other therapeutic approaches, treatment does not specifically highlight mental illness or dysfunction, but considers the growth, enthusiasm, and liveliness of the patient. The therapist encourages patients to focus on the subtleties of how they stop themselves from being fully present and contactful. Teaching patients how to focus on being in the here and now, trust their own internal process, and welcome deep vulnerable feelings will lead to what one patient described as a "heavy, deep, and real" experience.

The main emphasis in Gestalt therapy is to not get caught up in talking about what happens in the day-to-day life of the client but to experience as fully as possible what is unfolding in the therapeutic encounter. From this here-and-now vantage point, the therapist can deal directly with what is observable in the client's style. The goals are to:

- Work through blocks to contact
- Teach awareness
- Expand contact boundaries through the help of well-crafted experiments

The therapist encourages clients to attend to themselves in the emerging process to become who they are authentically rather than trying to be something they are not. With this in mind, there is little interest in "fixing" the person. Furthermore, the therapist believes that he or she does *not* know what is best for the client *nor* how the client should think, feel, or behave. Instead, the therapist honors the client's lively process and helps clients:

- Connect their awareness with their experiences
- Develop good contact skills
- Grow through experiential learning
- Take responsibility for their thoughts, feelings, and actions

THE HISTORY OF GESTALT THERAPY

Frederick "Fritz" Perls and his wife, Laura, founded Gestalt therapy in the 1940s. Perls was trained as a psychoanalyst. In 1926, he worked under Professor Kurt Goldstein, who introduced him to the principles of Gestalt psychology and provided him with many of the organizing principles for Gestalt therapy (see Table 42.1). Perls was later influenced by the theory and practices of Wilhelm Reich, who focused on the body in therapy and introduced the concept of *character armor*. He incorporated Reich's method of present-centered examination into Gestalt by heightening awareness of the client's nonverbal communications and focusing on the client's actions and behaviors. This was practiced by paying careful attention to the stylistic ways the client communicated through gestures, body movement, breathing, musculature, speech, and posture. Thus, Gestalt therapy draws on

TABLE 42.1 Basic Principles of Gestalt Therapy

1. Careful attention to the contact experienced during the therapeutic encounter
2. The development of the experiential “present moment”—the “here and now” of experience, considered to be more reliable than interpretation
3. Field theory, which states that all phenomena are linked to a part of a larger network of interactions and can be understood only in relation to one another
4. Figure/ground formation, which states that what is most important in the moment becomes figural and invites attention, and the unimportant drifts to the background
5. Identification and exploration of resistances through awareness, exploration, and working through
6. Identification and working through of introjects, the messages internalized in childhood
7. The use of the experiment to heighten awareness and promote growth and change

knowledge and expertise from psychoanalysis, flavors of Zen Buddhism, Gestalt psychology, existentialism, phenomenology, field theory, psychodrama, theater, modern dance, and awareness achieved through the five senses.

THE PRACTICE OF GESTALT THERAPY

Although Gestalt therapy may be briefly introduced in graduate social work programs (Congress, 1996), most instruction is received postgraduate through an intensive three-year training program taught by seasoned therapists. Mentoring and ongoing supervision from a Gestalt practitioner round out the ideal education process. It is not uncommon for dedicated students also to engage in their own therapy to develop self-awareness and enhance their contact skills. Thus, there are as many different ways of practicing Gestalt as there are therapists. Differences arise from the fact that each therapist brings his or her own unique awareness, ability to make healthy contact, and creativity to the process of designing and implementing growth-producing experiments. In addition, “the competent practice of Gestalt Therapy requires a background in more than just Gestalt

theory. Knowledge of diagnosis, personality theory, and psychodynamic theory is also needed” (Yontef, 1993).

Rather than a strict, concrete, step-by-step series of actions, Gestalt therapy is a process that unfolds over time out of the encounter between the client and therapist. This process varies with each client depending on such factors as:

- Level of awareness of self and other
- Ability to make contact
- Personal history
- Unique resistances and introjects
- Diagnostic indicators that determine if the client is neurotic, character disordered, or psychotic

Much of the actual practice of Gestalt therapy consists of carefully examining the contact that is made in the therapeutic encounter and the resistances that emerge at the contact boundary to protect the person—in the moment—from his or her anxiety. Gestalt therapy is an exploration—a “peeling of the onion”—rather a direct modification of behavior. The intention is not to solve patients’ problems directly, but rather to help them discover that through the heightening of their awareness comes choice.

The Paradoxical Theory of Change

The Paradoxical Theory of Change, which states that the more one tries to be who one is not, the more one stays the same (Beisser, 1970), is a hallmark of Gestalt therapy. Many times patients are driven by who they think they should be, instead of uncovering who they are. The more they push to be what they are not, the more resistance is set up, and little or no change occurs. Thus, the paradox: the more people attempt to be who they are not, the more they stay the same. On the other hand, when patients identify more fully with their present moment experience, growth and change are supported. Beisser (1970) says that change comes about as a result of “full acceptance of what is, rather than striving to be different.” Gestalt, therefore, supports the individual in being who he or she really is as fully as possible. Thus, Gestalt Therapy is extremely useful for patients who are psychologically inclined and open to working on their own awareness. This raising of awareness will help patients understand better how they are functioning in their world—with family, friends, at work, school, and at play.

An old adage states that the gods gave people two eyes—one to view the outside world and the other to keep an eye on their internal world. From this perspective, it is not uncommon to begin a session by asking patients to slow down their thoughts, turn their attention inward, and attend to what they are aware of in the present moment. This can help them experience not only their senses, but more subtle inner awareness and bodily sensations. “Getting close to sensation is intended to enable us to just experience without the interference of thinking, accepted as it comes without judgment” (Sheldon, 2012–2013). This sets the tone for the session and emphasizes the understanding that the work will focus on the individual’s process, and not exclusively on their story. Content can be seductive, but it is ultimately the villain of the creative process. The foundational questions in the following list invite patients to go deeper into their own processes.

- “What are you aware of now?”
- “What are you feeling?”
- “Can you put that thought into words?”

Dialogue between the therapist and the patient helps the individual reveal his or her “true self” with genuineness and authenticity, and communicate this experience to the therapist. Honest, direct dialogue sheds light on how the patient avoids contact with others, and highlights other important aspects of the here-and-now, such as emotions, bodily sensations, and emerging resistances. Throughout the work, the therapist evaluates the patient’s contact boundaries to assess what this individual can tolerate from moment to moment. Repeated respectful contact builds trust.

CONTACT

Perls, Hefferline, and Goodman (1980) define *contact* as the experience of the individual at the boundary between *me* and *not me*. “Contact is thus interactive and emerges from the moment-to-moment experience between individuals.” At any given moment, contact represents a person’s best creative adjustment, the best he or she can do in the present moment. In Gestalt therapy, the contact between the therapist and the client (rather than interpretations of thoughts, feelings, or actions) forms the basis for the therapeutic encounter. Contact is the

psychological process of engaging with our environment and ourselves. Good contact means to be consciously aware of the present, fully engaged in the experience, and nurtured by it. The hallmark of good contact is excitement. When you are in contact with someone, it is an energetically charged experience that you will feel as concern, interest, or curiosity. Poor contact, on the other hand, is indicated by lack of interest, boredom, or fear of being engaged by the experience. Therapeutic contact can be thought of as fully seeing and hearing the client and responding to what the individual says and does. Strengthening contact will ultimately help clients express more clearly what is on their minds, express what they feel, and take ownership of the quality of contact they are making. Ingredients of good contact include:

- Clear awareness of what am I doing in this moment
- Word choices that are clear, concise, and appropriately charged with feeling
- Responses to the here-and-now experience with an acknowledgement of each person’s presence
- Integration between the body and the spoken word.

In *Gestalt Therapy Integrated*, Edwin and Sonia Nevis outlined seven contact functions/modes to be assessed: looking/seeing; listening/hearing; tasting; smelling; touching; talking; and moving. When these contact functions are weak it becomes important to teach patients how to make good contact so they will come to understand both intellectually and emotionally that good contact is vitally important to the therapeutic process, as well as for effective interpersonal relationships, closeness, and intimacy. To accomplish this, the therapist must teach clients to be present and engaged in an authentic way by focusing on the contact and resisting the temptation to get caught up in the content of the story. Although what is being said is always important, it is rarely as important as what clients do—how they are engaging as they share their story.

In the beginning stage of therapy, therapists need to ask themselves “can this patient make emotional contact?” If the answer is no, contact functions need to be addressed before the work can go any deeper. When people come into therapy they are experiencing a disturbance of some sort at the contact boundary. It is the task of the

therapist to discern the type of disturbance and help the patient understand how to correct the mostly unconscious mechanisms used to diminish contact. These unconscious mechanisms are called resistances. Without first addressing disturbances in contact, the patient will not engage deeply in the therapy process; sessions risk becoming merely an exercise in questions and answers. Yet, once the disturbed contact skills are identified, the therapist can begin to point out when the contact disturbance is noticed, and provide a here-and-now experience to develop the contact skill. Examples of diminished contact include:

- An inability to listen or respond directly to what is being said
- Not acknowledging the other has spoken
- Being oblivious to another's feelings
- Not communicating in a clear direct manner that is understandable to others (i.e., being vague).

To monitor your degree of contact, ask yourself whether you are sharing your thoughts and feelings clearly and in terms the client can understand. Are you staying present with the client's process or is your mind wandering? Monitor your listening to stay focused on what the client is saying. In addition, ask yourself whether you are responding to the client directly and relevantly. In this way, you will stay aware of both the client and your own responses to the client. Awareness is for the therapist as well as the client.

Awareness

The idea of developing awareness of "what is" is originally found in Eastern philosophies, such as Taoism and Zen Buddhism. "Awareness includes knowing the environment, responsibility for choices, self-knowledge, self-acceptance, and the ability to connect" (Yontef, 1993). Perls believed awareness, or focusing attention on what is actually happening, was so important that he originally called Gestalt therapy "concentration therapy." From a Gestalt perspective, awareness is a never-ending process of self-discovery. This requires an ongoing process of "observing and attending to one's thoughts, feelings, and actions, which include somatic sensations and perceptions, language and movement" (Schilling, 1984, p. 151). This may sound like a simple task, but

to be aware moment-to-moment, and to use this awareness to be an effective therapist, is a life-long challenge.

Developing awareness in your clients involves teaching them to notice, name, and report on their internal processes. The intention of this focus is to develop insight. Fritz Perls used to encourage his patients to "lose your mind, and come to your senses." The role of the therapist is to bring into awareness that which the patients do not see. Perls used to say "a neurotic is someone who is not aware of the obvious." With increased awareness, clients discover that their sensations are saying something to them about their present experience. The therapist's task is to help clients learn to listen to what their own sensations are saying. This often begins with teaching clients to notice simple body sensations, which, if attended to, will lead to a feeling. As this process unfolds, clients learn to trust themselves and to develop valuable self-support.

Specifically, developing awareness in a session involves asking patients to take notice of any racing thoughts and slow them down; turn their attention inward; and get quiet and notice what emerges. In effect, the therapist is teaching patients to notice, label, and report their internal processes. This may include sharing thoughts, body sensations, gestures, postures, movements, facial expressions, vocal tone, breathing quality, and moment-to-moment resistances as they emerge. The therapist accomplishes this by learning to trust his or her observational skills, paying special attention to the most obvious, and giving feedback to the patient about:

- Verbal messages—noting what is said as well as how it is being said
- Content reported to you by the patient—"I feel angry," "My stomach hurts."
- Muscular constrictions—noticeable tensions and how clients are holding themselves
- Posture, gestures, and body movements
- Breathing patterns—Are clients holding their breath? Is breathing shallow or labored?
- Quality of contact and any notable resistances to contact emerging at the contact boundary
- Direct attention to internal sensations, which if followed will lead to feeling
- How you are impacted by this person—what you see, hear, and feel—Does the patient make you feel anxious, tired, bored, angry?

Although these observations may seem like obvious strategies, they will help patients to see themselves more clearly in the moment. By developing awareness, clients can expect to:

- Understand their internal process by realizing that what emerges inside them has significance
- Improve their ability to be intimate with others by valuing and reporting their moment-to-moment internal and external experiences
- Develop an increased understanding of identity by noticing, reporting, and responding to any emotional or physical sensations that lead to feelings or actions
- Develop their ability to live in the moment and to expand their contact boundaries.

THE THERAPEUTIC RELATIONSHIP

The *therapeutic relationship*, defined as the process of making contact over time, is the emotional heart and soul of Gestalt therapy. To be impactful, therapists, as well as patients, must let themselves be affected. Only then can the therapeutic relationship become the most powerful means of working through a client's problems and the medium of growth and change. Once the relationship is established, clients become more willing to explore the vulnerable areas of their lives. "The client comes into therapy expecting that their needs will meet the same traumatic fate in the hands of the therapist that they were met with in childhood" (Cole, 1994, p. 84). To alter this belief, the therapist must attend to how the client relates in the present and develop a meaningful, trusting relationship that provides nonmanipulative feedback. Therapists must practice good contact, self-awareness, and sensitivity to the emerging contact boundaries of the client. To do this effectively, the therapist must be present-centered and guided by theory that is known so well that it becomes second nature. The focus then becomes the client's humanity.

A Gestalt therapist is generally fairly active within the session, and, therefore, must possess characteristics that include sensitivity, a good sense of timing, creativity, empathy, and respect for the patient. These characteristics, along with an unshakable ethical practice, reflect the training, experience, and judgment of the therapist. The intensity of a particular therapist may not

suit every patient, so discretion must be observed and exercised. A respectful fit between the therapist's style and the needs of the specific patient is essential. To this end the therapist must keep in mind the personal boundaries of patients and support them in working at their contact boundary. The challenge is to balance being appropriately detached with being appropriately engaged—to not be too distant or removed/disengaged, and to not violate the patient's boundary, which may threaten or overwhelm the patient and cause him or her to resist or shut down.

RESISTANCES

In Gestalt therapy, resistance is accepted as *what is* for clients in their experience of the present moment. When clients are resisting, they are just being themselves. Thus, resistances are to be celebrated and encouraged. Resistances represent how clients avoid contact, block energy, and limit themselves in the present from doing things that would require them to stretch their boundaries.

Inasmuch as resistances are essential to being in the world, they are not something to be broken or beaten down. Instead, therapists work to bring them into awareness, to explore how the resistance is being expressed in the body. Supporting the resistance will help patients to feel affirmed in their character, especially before they are aware themselves of their favored or dominant means of resistance. Only with the therapist's support of the resistance will the client be able, over time, to give it up. Helping patients work through resistances will psychologically free them to deal effectively with their feelings.

Resistances are identified by observing the client's posture, body movements, expressions, breathing, speech quality, voice tones, and verbal communication. Observable indicators of resistance include:

- Body posture and movements, including legs, arms, and chest: Is there flexibility/rigidity/range of motion of body movements (e.g., clenching a fist, tightening the jaw)?
- Facial expressions: inappropriate smiling, frozen, poker-face, tightness, eye movements, quality of eye contact
- Breathing: Is it rapid and shallow or labored? Is the client holding in breath?
- Voice and speaking style: Are there noticeable changes in the voice such as the

voice cracking, jarring, harsh, or strident; changing in loudness, softness, or pitch; is the voice monotone; is there excessive wordiness or a rambling quality without silence or pause; is there frequent starting and stopping to indicate self-restraint or self-interruption?

- Verbal content: impersonal language, lack of direction or focus, frequent changes in the subject indicating deflections; use of absolutes, shoulds or ought-tos, indicating introjections, rationalizations, or intellectualizations; avoidance of specific content such as sexuality; excessive use of jargon

Once resistances are identified and named, clients are taught to report any internal cues that help them track how they experience blocking contact in the present. Growing beyond a boundary is subsequently accomplished through experimentation. The five primary resistances are briefly discussed here.

Retroreflection

Retroreflection is a mechanism by which people hold in what they are afraid to express to others or turn back on the self that which they would like to do to others. In both instances, they are turning back on the self what needs to be turned toward the world. The disadvantage of retroreflecting is that energy is blocked and not successfully discharged. This can lead to a build-up of anxiety, constant muscle tension and pain, and physical ailments, such as ulcers, psychosomatic illnesses, and depression. Common examples of retroreflection that can be witnessed in the therapeutic encounter include:

- Holding the breath
- Shallow or labored breathing
- Excessive swallowing
- Body tension
- Clenching of the jaw and/or grinding of the teeth
- Biting fingernails
- Shaky and/or monotone voice
- Stopping midsentence while speaking
- Directing anger inward toward the self instead of outward toward others.

The key to resolving unhealthy retroreflection is to help clients get back into their feelings and let go of them appropriately.

Deflection

Deflection is the avoidance of contact and/or awareness by turning aside or pushing something away. The client is taking action but misses the mark by either making no contact or reducing contact. This process of distraction provides a way of avoiding contact and awareness through being vague and indirect. Deflection detracts from genuine contact and makes it difficult to maintain a sustained sense of self. Common examples of deflection include not looking at the person with whom you are attempting to make contact, using verbose/excessive language, vagueness, being abstract or indirect, over-use of humor or laughing off important things, and not receiving or taking in what someone is saying.

Projection

Projection is the confusion of self and other that results in attributing to the outside world something that truly belongs to the self. By doing so, aspects of the self are disowned and assigned to others. A part of the self or feeling about the self is experienced, but not understood or owned as self, and is attributed to another person outside the body. Projection can take the form of blaming and lack of responsibility for oneself or one's actions. Psychological growth suffers when "unacceptable" parts of the self are disowned. Proverbially, it is said that when someone points the finger at others, three fingers are pointing back at the self. Projection can take healthy forms, for example, through empathy, by which you are able to acknowledge someone else's pain by understanding and feeling your own.

Introjection

Introjection is passively and uncritically internalizing the values and norms imposed by family, religion, and society without discrimination, assimilation, or review of these beliefs and standards. As a result, foreign, undigested information is swallowed without adequate processing or ownership, and people are left not knowing what they want or need. When a client constantly takes in everything without discrimination and doesn't reject what doesn't fit, it creates an "amorphous" personality, someone who is vague, nondescript, and lacking in personality definition.

Confluence

Without well-defined boundaries, it is hard to get to know a person. *Confluence* is the fusion or merging of boundaries, the fuzzy lack of contact in which there is no clear distinction between where “I” leaves off, and “You” begins. This pseudoagreement to avoid differentiation or separation blurs and melts interpersonal boundaries and causes a loss of separate identity. When two people parallel each other without making contact, they are unable to experience each other’s true feeling or opinions. No contact can develop when there is no clear distinction between where you end and another person begins.

Prolonged confluence deadens the potential for conflict to emerge. Without conflict, interactions become flat and dull. This may lead to pathological compliance, codependency, and a suppression of one’s personal preferences. There is no struggle to develop one’s own interests and convictions. Not surprisingly, confluent people have an extremely high need to be accepted and liked. To avoid conflict, they continuously agree with everything the other says without question or debate.

STAGES OF RESISTANCE WORK

The therapist’s task is to help the client develop an understanding of the resistance process by first explaining what a resistance is, discussing how it operates, and then identifying how it surfaces in the present moment to block meaningful contact. As taught by Norman Shub, BCD, LISW, LPCC, at the Gestalt Institute of Central Ohio (Columbus, Ohio), resistance work involves the following steps:

1. Identifying and witnessing the resistance and noticing how it emerges in the client. This is accomplished through observing nonverbal behavior, attending to how it feels to sit with the client, and listening to the words in which the story is presented.
2. Sensing internal cues to assist clients in developing awareness of and connection to their internal process by noticing the unique sensations they experience.
3. Encouraging clients to begin to report their own process to the therapist (after they learn to feel/sense their resistances). This marks a shift away from the therapist doing all the

work and toward clients taking responsibility for tracking their own processes.

4. Encouraging clients to move beyond their resistances by experimenting with alternatives that may stretch the contact boundary.

Playing all our hunches is an important aspect in this experiential approach. If the perception does not ring true the therapist can let it go and move on to the next emerging awareness. Yet, if the therapist observes or suspects conscious or unconscious resistance at play, it is important to circle around and attempt the intervention again, in a slightly different fashion.

THE GESTALT EXPERIMENT

“A unique quality of Gestalt therapy is its emphasis on modifying a person’s behavior in the therapy situation itself. This systematic behavior modification, when it grows out of the experience of the client, is called an experiment” (Zinker, 1977a, p. 123). Gestalt experiments can take on many forms, and are the cornerstone of Gestalt therapy’s experiential learning. Experiential learning transforms talking about a problem into dramatically heightening awareness through creative experimentation. With the support of the therapist, who acts as consultant and coach, clients are given the opportunity to explore their underdeveloped side, try new behaviors, and focus on verbalizations, dramatization, dialogue between self and other, fantasies, or physical functioning in the here and now to promote growth and change. Knowing when to introduce an experiment, and when to leave the patient alone is a critical step in the process. Properly preparing the client for an experiment will soften their resistance and improve the odds of a successful outcome. Once the patient engages in the creative experiment it is not uncommon to suggest that they “stay with it ... lean into that ... feel the feeling ... put that into words” to help nurture and deepen the process.

Zinker, in *In Search of Good Form* (1977b, p. 194), states that an experiment comes out of the therapeutic encounter and generally involves the following developmental sequence:

1. Laying the groundwork
2. Negotiating consent between the therapist and client. Gaining consent is accomplished

by asking the client, “Would you like to try something?”

3. Grading the work up or down by making the experiment equal the client’s readiness, need, and ability. This makes an experiment safe enough to warrant implementation, yet challenging enough to be realistic.
4. Surfacing the client’s energy and motivation
5. Developing a theme
6. Generating self-support
7. Choosing an experiment, carrying it out, and debriefing the client.

SPEED, NOISE, GRAVITY

Psychotherapy is considered to be both an art and a science. Understanding Gestalt theory represents the science portion of the challenge in having a successful therapeutic encounter. The art of psychotherapy requires the therapist, as well as the patient, to be fully present in the process, with a willingness to engage emotionally and be impacted by the experience. Thus, the therapist must slow down, take notice of the present moment, tap into what is going on inside the patient, and assess what it feels like to be with them. Developing this intuitive sixth sense requires therapists to access their own internal process. “If we were to choose one key idea to stand as a symbol for the Gestalt approach, it might well be the concept of authenticity, the quest for authenticity. If we regard therapy and the therapist in the pitiless light of authenticity, it becomes apparent that the therapist cannot teach what he does not know. A therapist with some experience really knows within himself that he is communicating to his patient his own fears as well as his courage, his defensiveness as well as his openness, his confusion as well as his clarity. The therapist’s awareness, acceptance, and sharing of these truths can be a highly persuasive demonstration of his own authenticity. Obviously such a position is not throughout one’s career but throughout one’s entire life” (Levitsky and Simkin (1972, pp. 251–252).

Dr. Joseph Zinker often said the unique challenges of the therapist can be boiled down into three basic concepts that must be assessed at all times—*speed*, *noise*, and *gravity*. *Speed* refers to the therapist’s own level of nervous energy. When distracted by their own racing thoughts, agitation, or jumpiness therapists are unable to slow down and focus on the individual. *Noise*

refers to the internal chatter that is going on inside the therapist’s own head. Without a quieting or reduction of the internal background noise, it is nearly impossible to meet the challenge of focusing on the other person. *Gravity* refers to the ability to sit and listen while feeling supported by the present moment. This “sitting power” allows a solid touchstone from which the therapeutic experience can unfold.

Throughout the encounter the therapist is constantly monitoring and attending to various aspects of the patient to assess the patient’s ability to be in good contact. Questions therapists may ask themselves are:

- How well can this patient hold a contactful gaze? What is the quality of eye contact?
- What is the patient feeling? Can clients make contact with themselves on an emotional level, or do they constantly disrupt their experience—does sadness lead to an expression of tears or are the tears retroflected?
- How is the patient responding to the therapist? Is the patient comfortable? Irritated? Agitated? What, if anything, is happening in the moment to generate these thoughts and feelings? Is something being projected onto the therapist?
- Can this patient identify and report his or her internal experience?

The Termination Process

Termination of an ongoing therapeutic encounter is generally a decision that is mutually decided and agreed upon between the therapist and patient. Changes that one can expect as a result of a successful course of treatment in Gestalt Therapy are:

- An increased awareness of a client’s interior and exterior worlds
- Improved contact skills that utilize all of the five senses for awareness and decision making
- Improved identification, understanding, and management of resistances
- Heightened ability to take care of themselves, identify their needs, and search for healthy ways to get needs met
- Increased energy as a result of dealing with unfinished business of the past that had previously stolen energy and joy

- Assumption of more personal responsibility and ownership for thoughts, feelings, and actions without projecting onto others
- Improved ability to give to and receive from others in a meaningful way.

As a practicing Gestalt therapist for 30 plus years, I have witnessed the growth of managed care, a strategy by which health insurance companies provide mental health benefits in exchange for monitoring and “managing” the individual’s mental health treatment. Thus, the insurance company has the power to limit or deny coverage for treatment that the patient and the therapist feel is warranted. The difficult question is whether to continue ongoing treatment if insurance benefits are discontinued. In such cases the patient is often forced to make a critical decision based on finances rather than treatment considerations. The therapeutic process may be damaged when treatment deemed necessary by the health care professional is judged unnecessary by a case manager of a managed health care organization.

What does it mean (as a patient and as a therapist) for an insurance company to become part of therapy? What happens when a direct conflict exists between the goal of helping patients with their complex mental health needs and the managed care goals of cutting costs and enhancing profits? Can business decisions impact the mental health needs of the individual?

A second dilemma centers on confidentiality. Managed care is based on a “medical model of necessity.” The patient must give the therapist permission to disclose to the insurance company the intimate details of the individual’s life—as a condition of receiving benefits. Disclosure includes providing an appropriately coded clinical diagnosis for the “problem” being treated, services rendered, and the duration of treatment. The insurance company may request additional information such as a detailed treatment plan with specific goals, means of achieving these benchmarks, and an acceptable “end date.” Each of these is contrary to the stated process of Gestalt, which is open-ended and unfolding.

As a result of these concerns some practitioners decide not to work with managed care organizations, providing services for a stated fee; others believe that patients are entitled to use their insurance provided they understand the limitations and consequences. One advantage of a fee-for-service practice is that no private

information is shared with an outside third party. The patient and the therapist together determine the length of treatment and payment plan. This tailors treatment to the patient’s (rather than the insurance company’s) needs.

Managed care has undoubtedly changed the practice of psychotherapy. Every social worker will face dilemmas and opportunities related to the intervention of insurance companies into their practice. Efforts are being made at many levels of government to have mental health services treated equally to any other medical illness, with the same systems of monitoring and rates of reimbursement. It will be up to future social workers to establish the validity of the Gestalt process and its relationship to a general improvement in the health, productivity, and well-being of treated clients.

Future Applications

Whether working with an individual, couple, family, or group, the practitioner provides good contact that transcends people, diversity, and cultural differences. Gestalt therapy develops a common ground for living, relating, and learning. It is more practice-driven than research-driven. As stated earlier in the chapter, there are as many different ways of practicing Gestalt therapy as there are therapists. Thus, the future of Gestalt therapy will be a holistic sum total of the practices of its therapists, guided by the basic, client-centered principles of the field.

CONCLUSION

In the early years of my practice I worked with a patient who upon termination left me a gift. She had cross-stitched the following poem that I have hanging on my office wall to this day. How often I have recognized this simple but powerful statement to be true. The poem goes like this:

I’m OK, You’re OK,
That’s only sometimes true,
The tricky part is when we are not,
To make that OK too.

Gestalt therapy is about humanity and human relationships. It is thus much more than a mode of treatment. It is a philosophical approach to life that recognizes the importance of awareness and genuine contact to mental health and happiness.

“To some, Gestalt is a way of life that embodies a spiritual practice, to help become more centered, more aware, more alive, more creative and present with others in a deep and meaningful way” (Sheldon, p. xi). Learning the skills of Gestalt therapy helps individuals and therapists develop the confidence to move from a self focus out into the world to get their needs met. This is accomplished by respecting the whole person as being more than the sum of independent parts and acknowledging that a trusting therapeutic relationship is indispensable in fostering growth and change. The rewards of engaging in this process will be great for you and for your clients.

William Borden

INTRODUCTION

Object relations psychology has emerged as a major paradigm in contemporary psychodynamic thought. Although the perspective encompasses a variety of theoretical systems, thinkers have increasingly come to share fundamental assumptions, core concepts, and essential concerns. This overview traces the development of object relations psychology, introduces basic theoretical formulations and clinical perspectives, outlines empirical lines of inquiry, and shows how overlapping points of view deepen conceptions of personality development, psychopathology, and therapeutic action in psychosocial intervention. In doing so, it explores the ways in which relational perspectives enlarge understandings of vulnerability and interpersonal processes in emerging models of evidence-based practice.

Object relations perspectives have informed efforts to develop realistic and flexible approaches to psychosocial intervention for a range of problems in living, and relational concepts continue to shape development of empirically based methods of psychodynamic psychotherapy (see Shedler, 2010, for review of empirical evidence for the efficacy of psychodynamic treatment). Clinicians have established guidelines for treatment of maladaptive patterns of interpersonal behavior as well as problems in functioning associated with acute stress reactions, posttraumatic stress syndromes, the personality disorders, and other forms of developmental psychopathology (Roth & Fonagy, 2005). In the broader domain of social work practice, object relations perspectives deepen understanding of interactive processes and intervention approaches with couples,

families, groups, and organizations (Borden, 2009; Borden & Clark, 2012). Emerging lines of research in neuroscience and developmental psychology promise to strengthen the empirical base of object relations psychology and broaden conceptions of interpersonal behavior, experiential learning, and clinical expertise in reformulations of evidence-based practice and integrative approaches to intervention.

DEVELOPMENT OF OBJECT RELATIONS PSYCHOLOGY

Sigmund Freud first introduced the term “object” in the development of his drive psychology, but he linked the construct to notions of instinctual process rather than to concepts of relationship and social interaction; he saw the person as an “object” through which one achieves instinctual gratification. Although drive psychology served as the central paradigm in psychoanalytic understanding through the early decades of the 20th century, growing numbers of thinkers challenged Freud’s vision of human nature and elaborated alternative perspectives that increasingly emphasized relational concepts and social domains of experience.

The earliest attempts to establish relational points of view encompassed the psychodynamic perspectives of Alfred Adler, C. G. Jung, Otto Rank, and Sandor Ferenczi, originally members of Freud’s inner circle. They placed growing emphasis on the role of relationship and social experience in their formulations of personality development, psychopathology, and therapeutic intervention. Adler, for example, envisioned persons as “social beings” and emphasized concepts

of relationship in his therapeutic approach. Jung saw persons as inherently relational and innately social. Rank based his humanistic model of personality on concepts of autonomy, dependency, and relationship, viewing psychology as the science of interpersonal relations. Ferenczi recognized the importance of the early caretaking environment in his conceptions of psychopathology, and he increasingly stressed the curative functions of the therapeutic relationship and interactive process in his reformulations of therapeutic methods. Careful readings of these revisionist thinkers, long neglected in the mainstream literature, show the extent to which they prefigure fundamental object relations concerns.

The widespread experience of separation, loss, and mourning after World War I informed further development of relational perspectives in London during the 1920s. Ian Suttie rejected Freud's drive psychology and proposed that innate needs for love and relationship are the fundamental motivational forces in personality development. He stressed the importance of the social environment in his formulations of health and psychopathology, and increasingly emphasized the curative functions of relational process in therapeutic intervention.

A second generation of British thinkers, including Melanie Klein, W. R. D. Fairbairn, Donald W. Winnicott, and John Bowlby, began to extend psychoanalytic theory in the 1930s. Working within the Freudian tradition, Klein preserved classical notions of drive and emphasized the internal realm of fantasy in her theoretical system. Over the course of her work, however, she introduced concepts of internal representation ("internal objects") and defensive process ("splitting," "projective identification") that provided crucial points of departure for Fairbairn and Winnicott in their efforts to elaborate relational and social perspectives. In this sense, Klein emerges as a key figure in the transition from drive to relational perspectives.

Fairbairn departed from the classical drive paradigm and introduced models of personality development and psychopathology that led to major reorientations of psychodynamic thought. He theorized that the core tendency in human development is to establish contact and preserve connections with others, and focused on progressive experiences of dependency in the mother-child relationship. In his model, personality is constituted and structured through ongoing internalization and representation of relational experience. Winnicott emphasized the crucial functions of caretaking figures in personality development, and

he saw relational provisions in the "holding environment" of infancy and early childhood as crucial determinants of health and psychopathology. He increasingly focused on domains of self-experience, emphasizing notions of inner coherence, agency, vitality, creativity, play, and personal meaning.

Bowlby argued that the fundamental need to establish contact and connection has adaptive roots in biological survival, and his attachment theory emerged as a major paradigm in empirical study of the mother-child relationship. He proposed that working models of self and others, established in interaction with caretaking figures, guide information processing about relational experience and shape patterns of behavior and adaptation through the life course. More than any other theorist, Bowlby attempted to bridge internal and external domains of experience and describe the processes that lead to establishment of psychic structure and modes of interpersonal functioning.

Three lines of theorizing in America have influenced the development of object relations thought, including the interpersonal tradition of Harry Stack Sullivan and Karen Horney; the self psychology of Heinz Kohut; and the overlapping contributions of Heinz Hartmann, Edith Jacobson, Margaret Mahler, and Otto Kernberg. The last group preserved Freudian concepts of drive, however, and did not embrace the interactive "two-person" psychology that has become a defining feature of contemporary object relations thought. Greenberg & Mitchell (1983) carried out the first comparative study of object relations theories; for review of subsequent accounts of relational perspectives see Borden (2009, 2012).

Theoretical Formulations and Core Concepts

Although the object relations paradigm encompasses divergent lines of inquiry, contemporary theorists increasingly share basic assumptions about the nature of personality development; notions of health, well being, and the common good; conceptions of vulnerability and psychopathology; and therapeutic elements in psychosocial intervention. The following section examines core concepts, guiding themes, and fundamental concerns in each of these areas, and considers the implications of object relations perspectives for continued development of evidence-based practice perspectives in clinical social work.

PERSONALITY DEVELOPMENT

Concepts of motivation emphasize the fundamental need for attachment and relationship through the life course. Relational experience shapes the development of mind, personality, or self. The interactive field is the central organizer of psychic structure and function; the core of the person is constituted through ongoing interaction with others in the social environment. Developmental lines of study consider the nature of early caretaking experience, social environments, and emerging capacities for relatedness. According to object relations perspectives, basic prototypes of connection, established in infancy and childhood, are preserved in the form of internalized representations of self and others. Working models of self and others influence subjective states, perceptions of persons, and modes of interpersonal behavior.

Theorists differ in their conceptions of motivational, affective, and cognitive processes believed to mediate the development of personality, but they assume that internalization of interpersonal experience shapes inner representations of self, other, and modes of relating (self in relation to others). Although core representations are derived from interaction in the social environment, they are not memories of events; rather, they are schematic structures formed from the cumulative experience of interpersonal life. Elaboration of schemas is influenced by constitution and temperament, early developmental experience, unconscious fantasy process, and life events. Presumably, ongoing experience generates multiple representation of self, others, and modes of interaction. Investigators theorize that the particular representations that guide perception and behavior at any given moment are determined largely by immediate needs, life circumstances, and social contexts.

HEALTH, WELL-BEING, AND THE COMMON GOOD

Conceptions of health center on the establishment of basic structures of mind, personality, or self and corresponding capacities for relatedness that influence overall levels of functioning. From this perspective, optimal development leads to a cohesive sense of self; affirming but realistic views and expectations of self and others (inferred self and object representations);

and stable and enduring relationships. Theorists stress the role of others in the development of the person and the sustaining functions of relationship, social interaction, and community through the life course. Most thinkers encompass concepts of mastery, coping, adaptation, and self-actualization in formulations of health and fulfillment.

VULNERABILITY AND PSYCHOPATHOLOGY

Theorists focus on the organization of the self and corresponding modes of interpersonal functioning in their conceptions of vulnerability and psychopathology. Winnicott, Fairbairn, and Kohut emphasize “arrests,” “splits,” and “deficits” in the organization of self structure. Bowlby describes rigid, anachronistic models of relational experience that shape problematic patterns of attachment and social interaction. Other thinkers, influenced by Klein and Kernberg, center on pathological manifestations of defensive processes, notably splitting and projective identification, associated with the personality disorders. Another group of theorists, drawing on the interpersonal theory of Sullivan and Horney, emphasize constricted patterns of interaction or “vicious circles” of behavior that perpetuate problems in functioning (Wachtel, 2008).

Thinkers distinguish predisposing, precipitating, and perpetuating factors in formulations of dysfunction. Because the relational field is the primary organizer of psychic structure and function, however, they tend to see early caretaking systems, patterns of interaction, unresponsive social environments, and traumatic events as critical determinants of vulnerability and psychopathology. Although the first generation of theorists centered largely on the nature of the maternal-child relationship and critical periods of care in infancy and early childhood, subsequent investigators have broadened perspectives to consider ways in which contemporary relational experience, life events, and social environments influence problems in living.

Object relations theorists recognize the impact of deprivation and trauma in relational and social domains of experience, just as they realize the organizing and sustaining functions of maladaptive behavior. Following contemporary relational views, most theorists assume that psychopathology is self-perpetuating because

it is embedded in more general ways of being and relating that persons have established over the course of development. As Mitchell (1988) explains, there is “a pervasive tendency to preserve the continuity, connections, and familiarity of one’s personal, interactional world” (1988, p. 3). Accordingly, however problematic certain behaviors may be, established modes of functioning serve to maintain cohesion and continuity in sense of self; to preserve connections with internalized representations of others; and to promote safety and security in interpersonal interaction. Clinicians assume that improved interpersonal functioning strengthens self organization and reduces problems in living associated with all forms of psychopathology.

EMPIRICAL RESEARCH

Empirical lines of study in the fields of neuroscience, cognitive psychology, developmental psychology, experimental psychology, and social psychology corroborate the basic propositions and core concepts of object relations psychology. In the domain of attachment research, findings show that infants are pre-adapted to form relationships and engage in complex forms of behavior with caretaking figures. Research on attachment and neurological development documents the crucial functions of caretaking and relational experience in personality organization, affect regulation, and patterns of interpersonal behavior over the life course (Schore, 2012). Cognitive studies of perception, learning, and memory support object relations conceptions of mental representations of self, others, and patterns of interpersonal behavior and unconscious mental processing of interpersonal functioning across the course of life (for reviews see Borden & Clark, 2012; Shedler, 2010).

In the domain of clinical practice, researchers have examined the ways in which inner models of relational experience and patterns of social cognition perpetuate problems in functioning associated with acute stress reactions, posttraumatic stress disorders, depression, personality disorders, and other types of developmental psychopathology (Luborsky & Barrett, 2006; Roth & Fonagy, 2005; Shedler, 2010; Westen & Bradley, 2005). Clinical researchers have drawn on object relations perspectives in conceptualizing patterns of interactive experience over the course of the helping process. In doing so, investigators have explored the relationship between social

information processing and transference phenomena, centering on motivational, cognitive, and affective domains of experience and activation of interpersonal schemas or scripts that correspond to particular patterns of interpersonal behavior. Empirical findings in cognitive neuroscience support relational conceptions of transference, documenting the ways in which interpersonal experience activates representations of self and others; motivational, cognitive, and affective processes; and corresponding patterns of behavior in the social field (Borden, 2009; Borden & Clark, 2012; Schore, 2012; Shedler, 2010).

PSYCHOSOCIAL ASSESSMENT AND INTERVENTION

Practitioners describe guiding perspectives, core concepts, and basic principles that inform approaches to assessment and treatment. Concepts of therapeutic action emphasize the primary role of the therapeutic relationship in the process of change and the functions of *interpersonal interaction* and *experiential learning* in efforts to deepen self understanding, strengthen coping capacities, and negotiate problems in living. From this perspective, the clinician provides reparative experiences that modify maladaptive representations of self and others, reorganize patterns of defense, and facilitate more adaptive and fulfilling ways of living. The emphasis on the dynamics of the therapeutic relationship and current patterns of interaction distinguishes object relations perspectives from classical psychoanalytic approaches that focus on childhood conflict and development of insight through interpretive procedures.

Assessment. Object relations perspectives emphasize the following domains of concern in assessment of functioning:

- Subjective states, emotions, and moods
- Inner representations of self, others, and modes of relating as inferred from accounts of persons, events, and views of self
- Capacities for relatedness to others, defensive strategies, and patterns of interpersonal behavior

The following guidelines serve to focus the assessment process:

- Using a narrative perspective, the clinician encourages clients to relate problems in

their own words; the practitioner explores the interpersonal contexts of symptoms or difficulties and presses for concrete detail in accounts of experience.

- The clinician explores the nature of past and current relationships as well as representative themes and concerns that emerge in discussion of self, interpersonal experience, and life events.
- The clinician observes patterns of interaction during the clinical interview, explores clients' experience of the therapeutic relationship, identifies patterns of defense, monitors evolving transference and countertransference reactions, and notes potential enactments of dysfunctional behaviors in therapeutic interaction.
- In establishing the focus, the clinician links the presenting problem to representative patterns of interaction that would appear to perpetuate difficulties.

The aims of assessment are to (1) determine general levels of personality organization and interpersonal functioning on the basis of the foregoing criteria, and (2) identify core relational themes, modes of defense, and representative patterns of interaction that precipitate problems in functioning.

Intervention. Object relations theorists recognize the potential influence of common elements believed to facilitate change across the major schools of thought (Frank & Frank, 1991), but they emphasize the role of relational provisions and experiential learning in concepts of therapeutic action. Ongoing interaction between client and clinician facilitates efforts to identify "vicious circles" of behavior and to develop more effective ways of processing information and negotiating interpersonal experience. The therapeutic relationship itself serves as a medium for change, and transference and countertransference states provide crucial sources of experiencing and understanding in efforts to revise internalized representations of self and others, reorganize patterns of defense, develop interpersonal skills, and improve social functioning. Enactments of maladaptive behavior in the therapeutic situation facilitate efforts to clarify problematic modes of interaction and to establish more effective ways of negotiating interpersonal situations and life tasks. Theorists view the clinician as a *participant-observer* and stress the reciprocal nature of therapeutic interaction.

In doing so, they deepen appreciation of subjective elements and mutuality in the helping process. Over the course of intervention the client internalizes positive aspects of the therapeutic relationship, modifying inner representations of self and others, and establishes more adaptive ways of managing vulnerability and negotiating problems in living. From the perspective of cognitive neuroscience, the core activities of the therapeutic process alter associational networks established over the course of development and facilitate formation of new, adaptive linkages and patterns of behavior (Schore, 2012).

Practitioners working from object relational perspectives emphasize the following principles of intervention:

- The clinician clarifies enactments of maladaptive behavior, exploring their defensive functions, and processes transference-countertransference reactions as they occur in order to help clients recognize and understand problems in living.
- When possible, the clinician links patterns of interpersonal functioning in the therapeutic situation to behavior in past and current relationships.
- The clinician uses descriptive, clarifying, and interpretive statements in efforts to help clients deepen awareness of their own and others' behavior, process subjective experience, better understand reactions to interpersonal events, and alter dysfunctional beliefs and maladaptive forms of behavior.
- The clinician uses problem-solving strategies, task-centered approaches, modeling, and reinforcement in efforts to help clients strengthen coping capacities and interpersonal skills.

CASE REPORT

Assessment. The client, age 28, initiated psychotherapy in a community mental health center after he was suspended from his job. He explained that his manager had placed him on leave because he was "unable to get along with people," and reported growing feelings of frustration and anger in his interaction with coworkers, characterizing them as "incompetent." Over the course of the interview the client described ongoing strain and rupture in his dealings with peers and managers, rendering relational life in

absolute terms: "People are either with you or against you," he explained. He challenged the social worker's attempts to explore concerns beyond the workplace, becoming impatient and argumentative, coming to see the session as "useless." He pressured the worker to "come up with a solution" for his difficulties, showing little capacity to process his experience in the give and take of the interactive process. On the basis of his accounts of relational experience and patterns of interaction during the interview, the practitioner hypothesized that the client used splitting defenses and aggressive behavior as means of managing his experience of vulnerability. The worker realized that the client's constricted patterns of functioning would potentially limit his capacity to form a collaborative relationship and engage in the therapeutic process.

Intervention. In spite of the foregoing concerns, the client responded to the clinician's *attunement* and *empathic processing* of concerns and established a working alliance. The conditions of acceptance, understanding, and support facilitated the development of the *holding environment*. The worker attempted to validate his experience, realizing the protective functions of attitudes and behaviors. The client was increasingly able to explore the antecedents and contexts of current problems in functioning. Since childhood, he had been the object of his father's teasing, bullying, and anger. The worker hypothesized that he had internalized the experience of his father's assaults over the course of development, coming to identify with a representation of his father as hateful, relating to others as his father had interacted with him. Presumably, the representations of self and others encompassed in his working models of interactive experience shaped ways of processing information in interpersonal life and perpetuated aggressive modes of behavior, precipitating strain, rupture, and loss.

Transference and *countertransference* states provided points of entry into the dynamics of earlier family life. The client was cold, sarcastic, and bullying in his interactions with the worker. The ongoing cycle of rupture and repair in the therapeutic relationship served as a crucial source of *experiential learning*, offering opportunities to process earlier trauma, explore defensive processes, and develop skills in managing his experience of vulnerability, fear, anger, and disappointment. The clinician used *interpretive procedures* to link past experience with current patterns of behavior in the

therapeutic relationship and in the workplace, deepening his understanding of life experience, protective strategies, and ways of relating. The worker *modeled* ways of processing subjective experience and problem-solving, and used *explanation* as an educational strategy in efforts to help the client understand the nature of his reactions, defenses, and patterns of interaction, helping him to *disidentify* with aggressive aspects of his father. Over time, the client strengthened capacities to regulate emotion, disrupt "vicious circles" of interaction, limit self-defeating behavior, and negotiate the vicissitudes of interpersonal life in more adaptive and constructive ways.

RELATIONAL PERSPECTIVES AND EVIDENCE-BASED PRACTICE

Relational perspectives promise to strengthen approaches to assessment, case formulation, and treatment planning in emerging conceptions of evidence-based practice. The helping relationship serves as the facilitating medium of intervention, and object relations formulations emphasize the role of *interpersonal expertise* in efforts to establish the therapeutic alliance; address vulnerabilities and patterns of behavior that potentially compromise engagement, precipitate strain, and limit change; and make flexible use of interactive experience in light of differing capacities, problems in functioning, and the individual, social, and cultural contexts of the client. Converging lines of study document the ways in which each participant in the relationship influences the process and outcome of intervention, and relational perspectives provide nuanced ways of conceptualizing interactive experience that deepen current formulations of interpersonal behavior in models of evidence-based practice (APA Presidential Task Force on Evidence-Based Practice, 2006; Borden, 2009; Shedler, 2010; Westen & Bradley, 2005).

CONCLUSION

Overlapping domains of understanding in object relations psychology, focused on concepts of self and relationship, continue to reflect fundamental concerns in contemporary culture, social life, and psychosocial intervention. The theoretical systems encompassed in this paradigm shape

ways of understanding personality development; health, well being, and common good; vulnerability and psychopathology; and modes of therapeutic action. As such they will enlarge understandings of vulnerability, problems in living, and helping processes in continued development of social work theory, research, and practice guidelines.

Human Trafficking and Trauma-informed Care

Kristin Heffernan, Betty J. Blythe, & Andrea Cole

A young man around the age of 30 comes to the emergency room with an injured wrist. He is accompanied by another man around the same age who states that he is the patient's cousin. The social worker asks the patient what happened. The cousin says that they are both farm workers and that his cousin fell while picking apples; the patient remains quiet. The social worker makes small talk about

picking apples and asks the patient the name of the farm where he works, but the cousin quickly answers the question. The patient appears nervous and uncomfortable as the cousin continues to answer most questions for him.

Are there any signs or “red flags” indicating this person could be trafficked?

Karen is a 14-year-old girl who lives in Manhattan. Her mother's boyfriend sexually abused her. When Karen told her mother what had happened, her mother threw her out of the home. Having nowhere to go, Karen went to the Port Authority where she was approached by a man in his thirties. He told Karen she was gorgeous and that he would take care of her as her boyfriend. After they had been living together for a while, he told Karen that they needed money and that prostitution was the only answer. Before she was prostituted the first time, the man gave Karen cocaine to "take the edge off." From then on, Karen was required to give all of the money she earned to this man. If she refused to be prostituted on a particular night, he would beat her and threaten to tell her family that she was a prostitute.

Although these two cases appear very different, they both are instances of human trafficking. One is no worse or better than the other, and both victims' human rights are being desecrated. Social workers and other health and mental health practitioners are in a unique position to help identify victims of human trafficking as well as assist these clients in re-establishing their rights and beginning the healing process. The following chapter will provide a brief summary of the state of human trafficking in the United States, and identify strategies that social workers and other practitioners can use to help identify victims of human trafficking, and to implement a trauma-informed lens when providing services to individuals who have been trafficked. Throughout this chapter, we will use the term "victim" to refer to persons that continue to be trafficked or have escaped or been rescued from their trafficker and "survivor" for those who are actively seeking help to escape their trafficker and/or are receiving services.

HUMAN TRAFFICKING IN THE UNITED STATES

The United States did not offer legal protection for victims of human trafficking until 2001 when the federal anti-trafficking law, the Victims of Trafficking and Violence Protection Act of 2000 (TVPA) was passed. The TVPA is one of the United States' most important tools in the fight against human trafficking. Its purpose is threefold: prevention, protection, and prosecution.

The Act established the President's Interagency Task Force to Monitor and Combat Trafficking in

Persons to coordinate anti-trafficking efforts in the United States. In the TVPA, Congress defined human trafficking as:

1. "Sex trafficking in which a commercial sex act is induced by force, fraud or coercion, or in which the person induced to perform such an act has not attained 18 years of age." (Hence, all children engaged in sex exploitation are seen as victims under federal law.); or
2. "The recruitment, harboring, transportation, provision or obtaining of a person for labor or services, through the use of force, fraud, or coercion for the purpose of subjection to involuntary servitude, peonage, debt bondage, or slavery" (U.S. Department of State, 2006, p. 25).

Although most Americans think of human trafficking as an issue occurring in other countries, the United States is both a source of transit and a destination for U.S. and foreign national adults and children who are trafficked. Persons who are trafficked can be subjected to forced labor, debt bondage, involuntary servitude, and prostitution, which can occur in many licit and illicit industries or markets. These include but are not limited to brothels, massage parlors, street prostitution, hotel services, hospitality, agriculture, manufacturing, janitorial services, construction, health and elder care, and domestic service.

In recent years, many states have passed laws to address human trafficking. These statutes provide supports for victims, such as vacating prostitution convictions for individuals who were trafficked for sex, and make trafficking a criminal act. At least 32 states have passed significant legislation in this regard (http://www.polarisproject.org/storage/documents/POC/2013-State-Ratings_pamphlet-3pgr.pdf).

Human trafficking is a horrific crime against humanity, bringing both physical and emotional trauma to its victims. The very nature of human trafficking is a violation of basic human rights. In many human trafficking cases, the perpetrators induce psychological coercion by destroying the victim's sense of self in relation to others. Perpetrators frequently terrorize their victims through threats of death and/or serious harm against both the trafficked individuals as well as their families (Shigekane, 2007). They may tell victims trafficked from other countries that they will be deported if

they seek help from law enforcement (Hopper, 2004), leaving their victims feeling helpless and hopeless. Hence, even if victims come into contact with law enforcement or social services, they often are hesitant to ask for help, partly as a result of psychological coercion, but also because they fear retribution from the trafficker (United States Department of Justice [US DOJ], 2006). Thus, before services can be provided to victims of human trafficking, they have to be identified and given the opportunity to leave the trafficking situation. This can be accomplished through outreach and educating others about how to identify people who have been trafficked.

Social workers need to adopt a human rights approach to dealing with this issue, especially when developing services for survivors of human trafficking. Using this perspective, social workers put the survivor's priorities and voice at the center of anti-trafficking work. Central to this approach is a model that relies on providing services in a nonjudgmental way, emphasizing client self-determination when setting both short- and long-term goals.

IDENTIFYING TRAFFICKED INDIVIDUALS

Unlike drugs and arms, human trafficking is very profitable because the victims can be sold over and over (Batstone, 2007). Trafficked victims, as well as traffickers, come in many forms. More often than not, persons are sold or recruited by someone they know; often tricked into trafficking by false promises of a better life (Sigmon, 2008). Due to the clandestine nature of trafficking, it often goes unnoticed by practitioners. Therefore, one of the key duties of the social worker is to look beneath the surface of the client's story. There are several "red flags" that social workers, doctors, nurses, practitioners, and other care workers may observe in health and social service settings. Obviously, the presence of a single red flag does not mean that a person has been trafficked, but it does mean that further exploration is indicated.

Potentially trafficked clients:

- Are accompanied by someone they refer to as their relative, friend, and/or interpreter
 - They look to this person to speak for them.
- Are not sure how long they have worked or are vague about where they work
- Do not have a sense of time (the day, month, or year)
- Are not in control of their personal schedule, money, passport, or other identity card or travel documents
- Live and work at the same address
- Have conflicting stories about why they need agency services
- Appear anxious, nervous/paranoid, submissive, or frequently shift in their seats
- Are confused and unable to answer questions
- Avoid eye contact
- Have many inconsistencies in their story or answers to questions

Specific to emergency room or visits to health care providers, another red flag is extremely poor health. If a patient is in poor health or has other physical conditions unrelated to the illness, this may indicate abuse or neglect beyond the human trafficking. An individual who has been trafficked may present with bruises, fractures, sexually transmitted diseases, or other medical conditions that have not been treated and may not be able to give a clear explanation as to why or how the injuries occurred. Malnutrition or poor personal hygiene also are commonly observed in trafficked individuals. Traffickers avoid bringing their workers in for care, and may do so only when the health condition is preventing the trafficked individual from working.

Not all victims of human trafficking recognize that they are being controlled. Some may actually identify with their trafficker and be hesitant to leave or speak against the trafficker. Social workers need to be prepared for a range of responses when assessing for trafficking in light of the trauma that has been experienced by clients. Following are some responses that individuals who have been trafficked may give to social workers and other service providers who are offering assistance. Given their circumstances, clients should not be judged or blamed if they respond in these ways:

- They state they do not want to leave the situation, and or may even say that the trafficker has treated them well.
- They do not show emotion when telling their story.

- They become angry or irritable with service providers (especially if they feel that the provider is trying to control them).
- They complain of physical symptoms, but have a clean physical examination.
- They refuse services.
- They defend their trafficker.
- They tell conflicting stories.
- They do not want to sign consent forms.
- They want to return to their trafficker.

THE PRACTITIONER'S RESPONSE

Social workers who notice any of the aforementioned red flags should ask themselves, "What has happened to this person?" as opposed to "What is wrong with this person?" If the practitioner suspects a client has been trafficked and he or she is accompanied by someone, the practitioner should attempt to separate the potential trafficking victim from the other person before asking the client any further questions. It is best to try to do this without raising the suspicions of the accompanying person. For example, the social worker might say that it is agency policy to see the client alone to ensure confidentiality. If the client has limited English skills and the worker does not speak the client's language, then a trusted interpreter who also understands the victim's cultural needs should be procured. Once these elements are in place, the worker can further question the possible victim about working conditions, asking questions such as:

- Is everything okay at your job?
- Are you able to leave your job?
- Are there any issues with your pay?
- Do you owe money to anyone?
- Have you ever experienced violence at your work?
- Does your employer control your housing, food, and/or transportation?
- Is there a lock on your door or window so you cannot get out?
- Has anyone threatened your family?
- Were you recruited for this job through false promises?

If any of the client's responses suggest a trafficking situation, the worker should make sure they feel confident to proceed and, if not, the worker should consult with a supervisor while

continuing to keep the suspected trafficker separated from the suspected victim.

A priority during this interaction is to help the client feel as safe and comfortable as possible. The worker can also begin to provide information on human trafficking; indicating that the trafficked situation is not acceptable, and that the worker can help the client escape. The victim also needs to understand his or her rights, what legal options are available, and how to access an attorney. It is vital to remember, however, that a service provider cannot force intervention. In fact, the practitioner needs to build rapport with clients who have been trafficked to meet them where they are and allow them to decide if they want help. The practitioner's role at this stage is to offer information about available services that will help clients escape from their traffickers.

TRAUMA-INFORMED CARE (TIC) WITH HUMAN TRAFFICKING SURVIVORS

Trauma-informed practice suggests the service providers at an agency are aware of potential triggers and reactions to triggers for the survivors under their care and, as such, have developed methods of engaging, assessing, planning, and intervening to minimize such triggers in their practice when they are providing direct services. Such triggers may include, but are not limited to: not feeling in control of the helping interaction, being forced to stay in the confinement of a shelter, a lack of culturally sensitive foods and/or décor at the agency, asking the client to reveal more about his or her situation in order to obtain services, or having a male present in a female-designated area. When working with human trafficking survivors through a trauma-informed lens, it is presupposed that the experience of trafficking in and of itself is traumatic. So while there is no single definition of what constitutes a traumatic event, it is widely accepted that a traumatic event is overwhelming and can occur either as a single catastrophic event or as a series of ordeals (Terr, 1990). Traumatic events can lead to a profound disruption or loss of one's sense of safety, predictability, and/or sense of control over one's own life, regardless of whether the threat is actual or perceived. Not surprisingly, the experience of trauma is often pervasive, encompassing all bio-psychosocial aspects of one's life.

Ideally, when engaging human trafficking victims in services, an entire agency would restructure their services to adopt a trauma-informed approach (Hummer, Dollard, Robst, & Armstrong, 2010). However, TIC also can begin with the work of a single practitioner. These principles should underpin work with any individual who experiences trauma, but more specifically here, TIC principles will be used to describe best practice when working with survivors of human trafficking. Principles of TIC include:

1. Recognize the impact of the trauma
2. Identify recovery as a primary goal
3. Employ an empowerment model
4. Maximize choice, control, and collaboration
5. Provide an atmosphere that is respectful and safe
6. Be culturally competent
7. Involve the consumer in service feedback and evaluation (Hopper, Bassuk, and Olivet, 2010)

There are a number of ways that these principles can be integrated into an individual worker's practice to help individuals who have been trafficked feel safe and comfortable.

Telling the Story

As stated earlier, the practitioner needs to move away from asking, "What is wrong with this person?" and begin asking, "What has happened to this person?" Traditional social work often requires or assumes that clients should tell the complete story of what happened to them under the pretext that this is necessary to offer the appropriate services. Some social workers also consider the sharing of information as essential to building a trusting relationship. TIC, however, recognizes that human trafficking is a traumatic event and that it may be re-traumatizing for clients to tell what has happened to them. Rather, they should be empowered to make the choice of what they want to reveal and what they want to keep to themselves.

Needless to say, the stories of trafficked persons often are devastating. Asking or demanding that clients "tell their story" as a condition of receiving services is tantamount to asking them to relive their experiences before they may be ready to do so, hence re-traumatizing them. Furthermore, due to the nature of human trafficking, many clients are referred to services via the police and already have had to tell and retell their

story before even getting to see a service provider. If their experience with law enforcement officials was negative, this can cause them to view social services with suspicion or even dread.

Another concern with regard to asking clients to tell their stories relates to legal issues. If law enforcement is involved, whether it is a criminal case or civil litigation, documentation of the history can be damaging to the client's case. Agency files on clients who have been trafficked often are subpoenaed for such trials. The traffickers' attorneys are looking for inconsistencies within the trafficked persons' stories in order to discredit the trafficked individuals. The more detail within a case file, the higher the chance of discrepancies in the story.

There are other concerns with regard to obtaining a case history. Due to the extreme psychological distress that they may have experienced, clients may not be able to provide accurate or detailed information under pressure. Moreover, clients understandably may not trust a worker whom they have just met. In fact, the trafficked person may purposely give the worker incorrect information because the trafficker has told them to do so. Social workers should remember that many trafficked persons have been forced to tell lies about who they are and what they do in order to survive. So again, it is generally advised to minimize the amount of history recorded in case notes when working with human trafficking victims.

Empowerment and Offering Control

Many human trafficking victims will need immediate concrete services such as housing, food, health care, an interpreter, and legal assistance. Longer term services may include mental health, income assistance, vocational training, and further legal aid. As much as possible, the social worker needs to let the client prioritize these needs and set goals. Recovery, however, is the primary goal. Having undergone human trafficking, victims may be experiencing fear, anxiety, and lack of trust. An empowerment model will normalize their reactions to the trauma and maximize their sense of choice and control.

There are many ways a practitioner can help the client gain control. To begin, clients should be provided with the information that is necessary to help them decide whether they want to accept services. Toward this end, and following a TIC framework, the social worker should:

- Clearly state his or her role and the role of the agency
- Speak in the client's native language or provide an interpreter
- Introduce the client to other people at the agency, possibly giving the client an agency tour
- Let the client know approximately how long meetings will last
- Allow the client to control the pace of the meeting
- Make sure the client knows that they do not have to provide any information or answer any questions that they do not wish to and that they understand this will not influence the services they will receive.
- Provide a choice of beverages or refreshments (e.g., different types of tea)
- Offer choices whenever possible
- Obtain informed consent
- Actively involve clients in all steps of the process
- Make sure the client understands what they can expect from the worker and/or the agency and what is expected of them as a client.
- Allow time for questions.

TIC principles are used to help the person who has been trafficked to regain trust, a sense of safety, and self-sufficiency. The process cannot be rushed and must occur at the client's pace. The survivor is the one who chooses to accept or decline services and remains the expert with regard to his or her needs and experience. Although this mantra is often heard at every level of social work training, in practice it is still challenging for social workers to truly understand that they are not the experts on someone else's life. It can be difficult for social workers to accept clients' choices when they conflict with what the social worker thinks best for the clients.

For those who have experienced human trafficking, empowerment is a life-long process that can start with TIC. It is the practitioner's responsibility, whether offering case management, counseling, or therapy to promote client choice, self-determination, and collaboration. For example, when clients change their appointment or cancel and reschedule, especially if they have done this more than once, the worker may get irritated or may even start to believe that the clients are not serious about recovery. Some workers view such behaviors on the part of the

client as a personal affront. A related problem may occur if clients assert their own will and the practitioner describes them as "difficult." When working through a trauma-informed lens, this view of the client as "difficult" does not exist. The TIC principle of maximizing choice, control, and collaboration means that clients' ability to make decisions for themselves is celebrated insofar as they are taking back control over their lives and recovery. Does this mean that such behavior is not inconvenient to service providers? No, in fact it can be very inconvenient when clients change their minds about when they can meet with us or what services they want to receive. But, practitioners need to remember that victims of human trafficking have not had control over their lives while being trafficked. Simple decisions about when to eat, sleep, and even go to the bathroom may have been taken away from them by their traffickers.

Establishing Safety

Safety is key to the process of recovery. The practitioner needs to help the client feel grounded both physically and emotionally. There are many different ways in which social workers can create a safe environment for clients when they come for services. Some of the following suggestions have already been included in the above list for helping clients gain a sense of control over their recovery. Working from a TIC perspective, these methods serve multiple purposes. Helping clients feel physically and mentally safe may look like:

- Orienting them to the agency by giving them a tour and introducing them to the other individuals they might see at the agency
- Making sure they understand everyone's roles (case manager, director, interpreter, etc.)
- Making sure they know the location of the building exits
- Never sitting between the client and the door
- Developing a safety plan and then reviewing this plan at every meeting in case it needs updating
- Ensuring the environment is culturally inclusive (décor, sign posting, food, etc.)
- Using the same interpreter for each meeting
- Making sure the location of the meeting is easily accessible
- Establishing regular agendas and consistent timelines for meetings.

Again, the underlying principle is that clients who have been trafficked need a safe and supportive environment that offers predictability. Making sure that there is consistency throughout interactions and within the agency environment is critical to helping the client recover. Helping the client understand the boundaries and expectations of the agency, and being clear about what the agency expects from clients and what clients can expect from service providers, helps create a safe and supportive environment.

Cultural Considerations

As referred to above, via a bio-psychosocial model, culture can influence the way a person experiences trauma. Practitioners must be vigilant about adapting interventions that are culturally appropriate. This starts with making sure that the social worker has a professional interpreter with whom the client feels comfortable if the practitioner does not speak the client's native language. Furthermore, human trafficking survivors need to be active in deciding whether they are comfortable with the agency's interpreter. If the agency is located in a small town or city, the client may know the interpreter from a previous encounter with this person outside the realm of the current situation. Continuing to allow this person to act as interpreter could actually hinder the client's recovery.

Interacting with Other Systems

Trafficked persons often are arrested and treated as criminals prior to an investigation of their case. They may be handcuffed and placed in jail for lacking legal immigrant status and/or for prostitution. Upon realization that the trafficked person is a victim, law enforcement officials commonly refer them to social service agencies for help. Not every state, let alone county or city, has services that specialize in helping victims of human trafficking. Therefore, they may be referred to services for refugees, immigrants, or domestic violence victims because these may appear appropriate at first glance. Such agencies may be able to help with some of the trafficked individual's needs. Without an understanding of human trafficking and the accompanying trauma, however, these services are woefully inadequate for survivors of human trafficking and may even re-traumatize them as described above.

As an example, many domestic violence shelters have rules and regulations about receiving or making phone calls while at the shelter. This rule

is intended to protect the domestic violence survivor so that his or her tormentor cannot track them during their shelter stay. Additionally, there are often specific check-in times and curfews at many of the safe homes for domestic violence survivors—again, to protect the survivors. Human trafficking victims have had little control over their own lives while being trafficked, including control over their movements. If they are allowed away from their trafficker, cell phones often are used to track and control them. They are held captive to the demands of their trafficker and, if they are placed in domestic violence shelters and made to follow the same rules and regulations as the other residents, they may inadvertently be subjected to the same barriers to freedom that they experienced at the hands of their traffickers. Such services can unintentionally re-traumatize trafficked individuals. Whenever possible, services need to be specific to the needs of survivors of human trafficking and service providers need to be aware of how services affect such clients.

Developing Trauma-informed Lenses at the Macro Level

Recognizing human trafficking as a traumatic event and having a clear understanding of what this could mean for clients is first and foremost among TIC principles. Although this recognition and understanding can begin with a single practitioner, ideally this knowledge will infiltrate the entire organization. It is beneficial to all clients and employees for all staff, including administrative, reception, and leadership staff, to become educated in the effects of traumatic experiences and the principles of TIC. This knowledge can decrease triggers that have negative effects for both clients and employees, while creating a safer and more efficient agency for clients and workers. Implementing TIC requires organizational readiness for change and evaluation of current practices (Rivard, Bloom, McCorkle, & Abramovitz, 2005). Such changes often require a freezing of what the social worker has already learned about service provision in his or her agency in order to relearn how to provide services via a TIC lens. In some cases, a social worker or other professional trained in TIC can slowly begin to educate others at the organization about the importance of understanding human trafficking as a traumatic event. Moving toward this model takes considerable time, conviction, and education and requires all staff to engage in vigilant self-care.

CONCLUSION

If practitioners can understand the ways in which their own practice, as well as their organization's policy and practices, can be re-traumatizing, we can work to change such policies and practices. Understanding and practicing a TIC model helps clients and individual social workers, as well as the agency as a whole. When social workers are affected by vicarious trauma, they cannot carry on with their work as usual.

Using Self Psychology in Clinical Social Work

Jerrold R. Brandell & Suzanne M. Brown

The psychology of the self, which has only recently attained begrudging acceptance among psychoanalysts, has enjoyed an early and enthusiastic reception among dynamically oriented social workers since its introduction as a

treatment framework in the late 1970s (e.g., Elson, 1986; Rowe & MacIsaac, 1991).

A relative newcomer among the psychoanalytic psychologies that constitute contemporary psychoanalysis (classical psychoanalysis, ego

psychology, object relations theories, and relational psychoanalysis, inter alia), the psychology of the self was introduced by American psychoanalyst Heinz Kohut in a series of essays and books published between 1959 and 1984. Although Kohut originally presented the theoretical and technical innovations of his new psychology within the extant classical drive theory (Greenberg & Mitchell, 1983; Kohut, 1966, 1971), he later expanded and revised his theory (Kohut, 1977, 1984), the end result being a distinctive and fundamentally new psychoanalytic psychology (Brandell, 2004).

The development of self psychology was, in large measure, guided by Kohut's clinical experiences with analytic clients who seemed unable to benefit from his efforts to use classical formulas in his interpretive work. Despite his assiduous efforts to refine and revise interpretations or alter his timing or the breadth of his interpretive remarks, Kohut found that certain clients failed to improve. He gradually concluded that the problem lay not with technical parameters of his interpretations but with basic theoretical premises of classical psychoanalytic theory. Although these assumptions had proved quite useful in treating the classical neuroses (hysterical, phobic, or obsessive-compulsive), the modal disorders of the late 19th and early 20th centuries, Kohut reasoned that such pathology had gradually been supplanted by other disorders that proved much less amenable to such a theoretical and clinical framework.

The essence of self psychology may well be captured in its vision of the human condition. The classical or Freudian view of humankind is usually expressed in terms of disturbing wishes and conflicts, an ongoing battle between primordial desire and societal requirements and prescriptions for civilized behavior, ontogenetically recapitulated with each successive generation in an endless cycle. Within such a framework and its oedipal foundation, the development of a capacity to experience guilt, painful as it may be, assumes supreme importance as a basis for the renunciation of instinct. Freud believed that without this ability to renounce instincts, civilized behavior was not possible.

Kohut's vision of the human condition contrasts sharply with that of Freud. He focused much less on primitive desires and the intrapsychic conflicts to which they gave rise, instead focusing on the loss of meaning associated with contemporary life. The dispirited Kohutian

man/woman, complaining of chronic ennui or boredom, often described the attainment of long-sought-after rewards or accomplishments as unfulfilling. Or he or she experienced life as a sort of emotional roller coaster, where "exuberant bursts of creative energy alternate with painful feelings of inadequacy," as recognition of individual failures extruded into consciousness. "Relationships, eagerly, even desperately pursued, [are] repeatedly abandoned with an increasing sense of pessimism" at the realization that the fulfillment of one's relational needs is so unlikely (Mitchell & Black, 1995, p. 149).

Kohut attempted to capture the fundamental disparity between the classical psychoanalytic view of human nature and that of self psychology in his explication of Guilty Man versus Tragic Man. "*Guilty Man* lives within the pleasure principle," attempting "to satisfy his pleasure-seeking drives to lessen the tensions that arise in his erogenous zones" (Kohut, 1977, p. 132). Kohut's archetypal Tragic Man, however—through his failures, uncompleted projects, and unrequited efforts at work and love—illuminates "the essence of fractured, enfeebled, discontinuous human existence" (p. 238). The pathological narcissist's efforts to assuage painful deficiencies, the fragmentation of the psychotic client, and the despair of parents whose children have failed to fulfill parental aspirations and ambitions may all be understood as clinical examples of this perspective, one that is considered unique to the psychology of the self.

BASIC CONCEPTS IN SELF PSYCHOLOGY

Like its psychoanalytic predecessors (classical theory, ego psychology, and object relations), self psychology encompasses not only a framework for clinical interventions but also a model for understanding certain aspects of normative human development and developmental deviations, as well as a theory of psychopathology. Though space does not allow a comprehensive examination of each of these, certain terms and concepts from self psychology are common to them all.

Selfobjects

Kohut coined the term *selfobject* to represent a specific kind of object relationship in which the

object is experienced as being a part or extension of the subject's self and in which no psychological differentiation occurs. He noted that the control one expects over such selfobjects approximates "the concept of control which a grown-up expects to have over his own body and mind" in contradistinction to the "control which he expects to have over others" (Kohut, 1971, pp. 26–27). Kohut believed that human beings require three distinctly different kinds of self-object experiences—(1) mirroring, (2) idealizing, and (3) partnering—each of which is, under optimal conditions, made available to the child in an attuned, empathetically resonant interpersonal climate. Mirroring selfobjects "respond to and confirm the child's innate sense of vigor, greatness, and perfection," whereas idealized selfobjects provide the child with the powerful and reassuring presence of caregivers "to whom the child can look up and with whom he can merge as an image of calmness, infallibility, and omnipotence" (Kohut & Wolf, 1978, p. 414). Finally, partnering selfobjects furnish the child with a range of opportunities through which a sense of belonging and of essential likeness within a community of others may be acquired.

The Tripolar Self

The tripolar self is the name given to that intrapsychic structure associated with the three kinds of selfobject relationships just described, in effect linking each selfobject relationship to a corresponding domain of self experience. Mirroring experiences are associated with an intrapsychic structure known as the *grandiose-exhibitionistic self* and reflect the need for approval, interest, and affirmation; idealizing, with the *idealized parent imago*, reflecting the developmental need for closeness and support from an (omnipotent) idealized other; partnering, with the *alter ego*, and associated with the need for contact with others who are felt to bear an essential likeness to the self. These three poles, in effect, are structures that crystallize in consequence of the various needs of the evolving self "and the responses of those important persons in the environment who function as selfobjects" (Leider, 1996, p. 141).

These three domains are also linked to particular transference configurations that "dramatize and reflect the persistence of archaic selfobject needs" (Leider, 1996, pp. 151–154), revealing

injuries to the client's self as well as particular mechanisms used to compensate, defend against, or otherwise conceal deficient self-structure. These three transference configurations (mirror, idealizing, and twinship or alter ego) may exist as pure types, though not infrequently a commingling of selfobject transferences may be observed in a particular client. Both the original, thwarted selfobject needs and the ensuing ruptures are frequently recapitulated in the transference relationship in psychotherapy.

Empathy and Transmuting Internalization

A large part of the appeal self psychology has held for social work clinicians may involve the considerable emphasis it places on the role of empathy, a concept possessing strong cachet in both the clinical social work literature and in the contemporary world of practice. Self psychology views empathetic processes as having their origin in early infancy and traversing the entire life span, imputing a special significance to traumatic breaches or disruptions in empathic attunement between self and selfobject. Defined as "vicarious introspection" or the feeling of oneself into the experience of another, the capacity of parents and others in the child's selfobject milieu for providing empathetically attuned responses is believed to be critical for healthy development of the self.

Somewhat paradoxically, Kohut also believed that comparatively minor, nontraumatic lapses in parental empathy are equally critical, constituting a *sine qua non* for healthy development. Such lapses, in a sense, may be thought of as optimally gratifying and optimally frustrating, serving as a catalyst for the child's development of transmuting internalizations. In other words, such breaches or lapses furnish the developing child with just the right amount of frustration to effect the development of a cohesive self-structure. Transmuting internalization is an intrapsychic process whereby a child gradually takes in or internalizes various functions associated with the selfobjects, ranging from self-calming and self-soothing to pride, humor, wisdom, and indefatigability in the pursuit of important goals. Stated somewhat differently, such functions are absorbed and metabolized in a virtually imperceptible process of incremental accretion, ultimately becoming enduring parts of

the child's own self-structure, altered by his or her individual *imprimatur*.

Key elements identified in the sequence of transmuting internalization are, in order: (1) optimal frustration, (2) increased tension, (3) selfobject response, (4) reduced tension, (5) memory trace, and (6) development of internal regulating (self) structures. Self-psychologists view this developmental sequence as analogous, though not identical, to the therapeutic process when one approaches treatment within a self psychological framework.

The Self Types

Self-psychologists believe that the self is best understood within intersecting matrices of developmental level and structural state, and have identified four principal self types:

1. The *virtual self*, an image of the neonate's self originally existing in the parent's mind that evolves in various ways as the parental "selfobjects empathically respond to certain potentialities of the child" (Kohut, 1977, p. 100).
2. The *nuclear self*, a core self emerging in the second year of life, that serves as the basis for the "child's sense of being an independent center of initiative and perception" (Kohut, 1977, p. 177).
3. The *cohesive self*, the essential self-structure of a well-adapted, healthily functioning individual, whose self-functioning evinces the harmonious "interplay of ambitions, ideals, and talents with the opportunities of everyday reality" (Leider, 1996, p. 143).
4. The *grandiose self*, a normal self-structure during infancy and early childhood developing that comes into existence as a response to the selfobject's attunement with the child's sense of him- or herself as the center of the universe.

Psychopathology in Self Psychology: Cohesion, Fragmentation, and Disintegration Anxiety

Self-psychologists use the term *cohesion* to refer to a self state characterized by vigorous, synchronous, and integrated psychological functioning. Self-cohesion not only makes the harmonious interplay of ambitions, ideals, and talents possible in the context of everyday life; it also confers a

modicum of protection from regressive fragmentation when an individual is faced with adversity or obstacles that prevent the gratification of object or selfobject needs (Leider, 1996). Those who are fragmentation-prone (who, under duress, might develop symptoms such as hypochondriasis, hypomanic excitement, or disturbances in bodily sensation or self-perception) have, by definition, failed to acquire stable, consolidated, and enduring self-structures. Such failures may arise from parental pathology, environmental uncertainties and deficiencies, or a combination of these, though invariably it is the chronic unavailability of parental selfobjects to provide needed functions that is at the root of such disturbances in self-functioning. The developmental basis for various disorders of the self (e.g., narcissistic pathology, borderline conditions, depression, and even psychosis), according to the self-psychologists, is strongly linked to chronically deficient and traumatogenic caregiving environments. Kohut believed that *disintegration anxiety*, defined as the fear of the self breaking up, was the most profound anxiety a human being is capable of experiencing; *disintegration products*, a closely related concept, refers to those symptoms generated by an enfeebled, disharmonious self. Symptoms within this system, as in other psychoanalytic theories of psychopathology, are viewed as manifestations or perhaps signifiers of important dynamic, genetic, and environmental themes. The self psychological focus on the significance of environmental deficits in shaping pathology, however, contributes to a perspective that may be somewhat unique, even when compared to other psychoanalytic perspectives on pathology.

CLINICAL CASE ILLUSTRATION

Terry is a 44-year-old unmarried white woman in a long-term heterosexual relationship with no children. She described her ethnicity as a mixture of English, Irish, and German and reports that she was raised in multiple faith traditions including Episcopalian, Quaker, and Unitarian Universalist traditions. Terry entered treatment at a local Community Mental Health Center complaining of depressed mood and episodes of angry outbursts directed at her partner and occasionally at colleagues. Terry and her partner George had been living together for 10 years. While actively involved and engaged with nieces and nephews, they eschewed parenting children of their own.

Terry was the youngest child of four, with three older brothers. Her father was an artist and a retired professor of art history who had taught at one of the city's many private universities. Her mother was deceased, having died of cancer 10 years prior to Terry seeking treatment. Terry described her father as very ambitious and self-involved throughout her life. While the children were small he had engaged in an extra-marital affair with a colleague and left Terry's mother to marry the woman with whom he had been involved. Terry experienced this as a significant abandonment. She described years of having little contact with her father who, while residing in the same suburb as Terry and her brothers and mother, was preoccupied with his new family, including two children he had with his second wife. Terry also described growing up in poverty. Although they were able to continue to live in the family home in a middle class suburb of a major Northeastern city, they were frequently unable to afford basic necessities such as food and clothing, and her father offered little in the way of financial assistance, needing his money to support his second family. Terry described moments of being asked by her mother to walk to the home of her father and his new family to beg him for some money for basic necessities for herself and her brothers. The feelings of emptiness, loneliness, and sense of abandonment were palpable as Terry described these moments. She frequently expressed the wish that her father had been physically or verbally abusive to them in that he would "at least be acknowledging her existence." She described a pervasive experience of being a "nonperson" in his eyes and to "not existing" as far as he was concerned. The fact that he resided in the same town as Terry and her brothers only intensified these feelings for her.

Terry's mother had few emotional resources with which to support or enliven her children. She was a woman who struggled with depression throughout Terry's childhood, exacerbated by the divorce and its ensuing loneliness and financial stress. As her depression intensified Terry's mother attempted suicide by overdosing on prescription medications when Terry was 13 years old. Terry found her mother unconscious and was responsible for calling the ambulance and enlisting treatment for her mother.

Terry was moderately depressed at the time she sought treatment and described frequent incidents when she would become enraged and verbally abusive toward her partner, George.

These incidents were often triggered by her perception that George was criticizing or judging her negatively and harshly. Although she described herself as having been somewhat depressed throughout her adult life, her current exacerbation of symptoms appeared to have been triggered by the presence of a new boss whose feedback she also experienced as harsh and critical. Over time, as Terry's trust in the therapeutic alliance increased, she disclosed that she used marijuana and alcohol daily, sometimes to the point of passing out, and that her arguments with George were often initiated by his complaints about her substance use. In spite of these arguments, Terry refused to limit her use of alcohol or marijuana.

Discussion

Terry suffers from what has been most aptly characterized in self psychology as a depletion depression and a tendency to fragment easily when experiencing conflict or criticism in important interpersonal relationships. Depletion states and depletion depression, in contrast to the classical syndrome of guilt depression, are born neither from intrapsychic conflict nor from the problems associated with the discharge of aggression implicit in the classical model. Instead, such depression is regarded as a disintegration product, one signaling a structural deficiency that is itself a developmental sequela of early problems in the subject's self/selfobject milieu. The angry outbursts and verbal abuse that Terry described may be conceptualized as disintegration products in the self psychological model, triggered by the absence of mirroring in her environment and her own structural deficits, rather than understood as a manifestation of an inborn drive for aggression, as it would be in classical psychoanalysis. In self psychological terms, Terry failed to attain self-cohesiveness, owing to the unremitting series of traumatic losses and neglect she had suffered in her relationships with her parents. Indeed, her history was replete with such selfobject failures. Terry's mother, who was chronically overburdened, evinced a marked insensitivity and lack of attunement with her daughter's emotional needs, further compounded by her own depression. Her father, despite his many successes in the academic and artistic worlds, offered little to his daughter in the way of mirroring, leading her to experience herself as inconsequential, unimportant, and unworthy of love or

attention. Lacking in self-confidence and inner vitality, Terry had come to feel an emptiness that could not be assuaged in her relationships or job. She felt devalued and ineffectual, was subject to mercurial fluctuations of mood, and responded to narcissistic slights with heightened anger. Terry's capacity for the regulation of her self-esteem was minimal, inasmuch as she was highly reliant on the daily use of marijuana and alcohol to bolster, enliven, and soothe an empty self.

UNIQUE FEATURES OF SELF PSYCHOLOGY AS A CLINICAL SYSTEM

Although it is no longer possible to speak of self psychology as a unified theoretical system, there are two hallmarks of any clinical self-psychological approach: (1) the central importance of the therapist's sustained, empathetic immersion in the client's subjective experience; and (2) the concept of selfobjects and selfobject transferences (Mitchell & Black, 1995).

Self-psychologists believe that the therapist's basic attitude of concern and compassionate acceptance and his or her promotion of an ambience of emotional vitality and responsiveness are necessary to bring about the therapeutic remobilization of various archaic selfobject needs, considered a *sine qua non* for meaningful psychotherapy. This therapeutic stance has often been presented in stark contrast to the "detached, cold, abstemious, surgeonlike demeanor" attributed to Freud and to his rendering of classical psychoanalytic technique (Leider, 1996).

The interpretive process in self psychology consists of two basic phases: a phase of understanding, superseded by a phase of explanation and interpretation. Both of these phases are deemed essential to the therapeutic process (Kohut, 1984). With the unfolding of the therapeutic process and the establishment of a selfobject transference, the client unconsciously perceives the therapist as fulfilling various selfobject needs. The client's dawning perception that the therapist has somehow failed to satisfy these selfobject needs (an unavoidable eventuality) leads to fragmentation, archaic affect states, and other sequelae of misattunement. Such therapeutic breaches, however, are not just unavoidable in the view of self psychology; they are necessary for further psychological growth and structural repair (Leider, 1996).

The phase of understanding commences with the therapist's recognition of the empathetic rupture or breach, which is then conveyed to the client. Such therapeutic communications, accompanied by the therapist's attempt to reconstruct and characterize the events leading to the disruption, serve to re-establish psychological homeostasis (Kohut, 1984). This makes possible explanation, in which the significance of the therapeutic breach is recast in dynamic/genetic terms, permitting the client and therapist to reconstruct "the circumstances of the [client's] childhood in which parental selfobjects" were chronically unavailable, "analogous disruptions occurred, and the self was permanently injured" (Leider, 1996, p. 157).

FUTURE

Self psychology offers the clinician a dynamic approach to practice applicable to a wide range of presenting problems, one that may be successfully adapted to the diverse clinical populations with which social workers work. The therapeutic requirements for producing enduring structural changes in the personality cannot always be met within a framework of managed mental health services, and this may be one limitation of a self psychological approach. However, many of the insights derived from psychoanalytic self psychology can be readily applied to such modalities as crisis intervention, brief and other time-sensitive treatments, and even supportive therapy. The clinician's capacity for empathetic immersion in the client's subjective experience, a *sine qua non* of any self-psychological approach to treatment, may not in itself lead to a permanent restructuring of the self, but its impact at a time of crisis should not be underestimated. Similarly, in parent guidance work, the worker may provide what has been termed "transference parenting" (Chethik, 2000) to a beleaguered parent whose own childhood consisted of an unremitting series of parental selfobject failures. This may have the effect of making the parent somewhat more attuned and responsive to his or her own child's requirements for affirmation, calming and soothing, or partnering.

In its view of normal development and developmental derailments, self psychology places considerable emphasis on the role of environment in particular, the chronic failures of the selfobject milieu within which individuals develop.

As such, it seems especially well suited as a framework for assisting social work clinicians in their continuing efforts both to understand dysfunction and pathology and to provide therapeutic responses to it.

RECENT DEVELOPMENTS IN SELF PSYCHOLOGY

Selfobject Transferences

Further elucidation of the selfobject and selfobject transferences has been the subject of more recent theorizing within the self-psychological tradition. Rowe (2005) has described the undifferentiated selfobject transference experience as a sense that there is something more, something better forthcoming in life. He identifies this as knowing or expecting that “unknown nonspecific happenings will occur throughout our lives and will be surprising, challenging, uplifting, and self-enhancing, no matter the ... nature of our current circumstances” (Rowe, 2008, p. 2). Wolf (1988) has conceptualized and described in clinical vignettes the adversarial selfobject transference. The adversarial transference is one in which the patient is frequently in opposition to the selfobject or in some way moving against the selfobject in order to grow and solidify internal structure. In this instance the client may concurrently attempt to enlist emotional support from the selfobject while also attempting to establish their autonomy; the client seeks both support and opposition from the selfobject in order to enhance self-cohesion. Not unlike those selfobject transferences discussed previously, both the undifferentiated and adversarial selfobject transferences have the potential to increase the self’s cohesion and vitality.

Integration of Self Psychology with other Perspectives

Along with development in identifying and understanding selfobject transferences, theorists have also attempted to integrate a self psychological perspective with other psychoanalytic or developmental perspectives.

Motivational Factors

Lichtenberg, Lachman, and Fosshage (2011) proposed a new understanding of selfobject transference as part of an attachment motivational

system with seven motivational system levels, each unfolding according to dynamic systems theory principles. These seven motivational levels include regulation of physiological demands, attachment and affiliation; exploratory-assertive, the need for antagonism or withdrawal, sensuality and sexuality, an affiliative system, and caregiving system. According to this theory, selfobject functions such as mirroring, idealization, and twinship are central to the development of attachment and to attachment motivation.

Infant Research

Infant researchers have also integrated self psychological principals with a systems perspective of dyadic relationships—specifically those between infant and primary caregiver. Daniel Stern has examined and written about the development of the infant’s self and the infant’s experience of that self. He delineated four senses of the infant’s self. These include the *Emergent self*, *Core self*, *Subjective self*, and *Verbal self*. Each of these develops through the empathic and sensitive responses of the caregiver to the infant, optimally enabling the infant to develop the internal structures needed for a cohesive and vital self. Lachmann and Beebe (1992) have also bridged empirical infant research and self psychology in their observations of self and mutual regulation within the infant caregiver dyad and its application to the client-clinician relationship.

Interpersonal Approaches

Finally, the influence of self psychology on interpersonal psychoanalytic approaches has also been observed (Fosshage, 2003). Both perspectives recognize the importance of the clinician and of the therapeutic relationship to enhancing the client’s experience of the self and self-cohesion, as well as the importance of the clinician maintaining empathic attunement and optimal empathic responsiveness.

46 Diagnostic Formulation Using the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*

Carlton E. Munson

Diagnostic formulation takes on new meaning in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)* because the multiaxial system introduced with the implementation of the *Diagnostic and Statistical Manual of Mental Disorders, Third Edition (DSM-III)* in 1980, was a major revision of the manual that introduced the modern method of diagnostic formulation. *DSM-5* remains consistent with the fundamental conceptualization of diagnosis introduced in *DSM-III*, but ties the diagnostic formulation to more recent focus on the role of clinical utility, clinical relevance, clinical significance, and clinical judgment. Although the recording and presentation of an official diagnosis has changed in *DSM-5*, some of the features of diagnostic recording introduced in *DSM-III* remain. For example, the recording of a core diagnosis, listing medical conditions, indicating level of severity, and noting principal and provisional diagnoses continue to be used with some changes. Conceptually, diagnosis is similar in *DSM-5* to earlier editions of the *DSM*, but there is no longer a sequential, numeric, formal format for recording diagnoses.

PURPOSE OF DIAGNOSIS

The American Psychological Association (APA) states the purpose of *DSM-5* is to assist mental health professionals in the diagnosis of client mental disorders as part of a “case formulation assessment that leads to a fully informed treatment plan” (APA, 2013, p. 19) for each client. The link between diagnosis and treatment has been

an evolutionary process as part of the history of the *DSM* diagnostic system. The first *Diagnostic and Statistical Manual—Mental Disorders* (APA, 1952) is referred to as *DSM-I* and its main goal was to establish a singular “nomenclature” for categorizing mental disorders due to the existing “polyglot of diagnostic labels and systems.” The APA viewed the situation as one in which the “official system of nomenclature rapidly became untenable” (APA, 1952, pp. vi–vii). The aim of *DSM-I* was to bring more clarity and consistency to classification of mental disorders and focused primarily on collecting statistical information about the incidence and occurrence of mental illness (APA, 1994, p. xvii). The word treatment was mentioned in *DSM-I*, but treatment did not receive emphasis because the focus was on establishing a solely descriptive statistical classification based on a two-category system. The first category included disorders directly linked to mental disturbance resulting from brain impairment, and the second category was associated with “general difficulty in adaptation,” and if brain impairment was present, it was secondary to the psychiatric disorder (APA, 1952, p. 9).

The *DSM-III* was released in 1980 and it gave rise to much controversy with some viewing it as ushering in the era of “science and objectivity” to guide the classification of mental illness (Sadler, 2005), while others saw it as a “political rather than a scientific document” (Taylor, 2013). The *DSM-III* did expand emphasis of the diagnosis and treatment connection. A subsection of the Introduction to *DSM-III* titled, “Evaluation for Treatment Planning” (APA, 1980, pp. 11–12),

gives detailed instructions on how to link diagnosis to treatment using different theoretical orientations. Although some of this information is no longer relevant, much of the information continues to be useful in doing intake interviews with a focus on linking diagnosis and treatment. The *DSM-III* clearly established the diagnosis–treatment linkage with the statement, “Making a *DSM-III* diagnosis represents an initial step in a comprehensive evaluation leading to the formulation of a treatment plan” (APA, 1980, p. 11).

In *DSM-IV* the diagnosis–treatment link was continued through a statement similar to the *DSM-III* statement, and a rephrasing of the expectation that “To formulate an adequate treatment plan, the clinician will invariably require considerable additional information about the person being evaluated beyond that required to make a *DSM-IV* diagnosis” (APA, 1994, p. xxv).

The linkage of diagnosis and treatment has been refined over the last three decades stemming in part from the case of *Osheroff v. Chestnut Lodge* (1980) that had significant impact on the diagnosis and treatment planning connection (Knoll, 2013). Dr. Osheroff was a physician who was admitted to Chestnut Lodge psychiatric hospital in Maryland in January 1979. Chestnut Lodge held an important place in the history of psychiatry. It was a major source of theory development and clinical practice of psychotherapy based on psychoanalytic theory (Klerman, 1990). Psychotherapy pioneers Harry Stack Sullivan and Frieda Fromm-Reichmann practiced at Chestnut Lodge.

Dr. Osheroff was admitted to Chestnut Lodge due to anxiety and depressive symptoms with suicidal thoughts. He was diagnosed with depressive disorders and a personality disorder. The only treatment provided was psychoanalytically oriented therapy. Dr. Osheroff deteriorated significantly during his stay at Chestnut Lodge. Symptoms of a severe agitated depression developed. His family intervened and had him transferred to Silver Hill Hospital in Connecticut in September 1979. He improved quickly after treatment with medications and was discharged in November 1979. After a series of legal maneuvers, Osheroff filed a medical malpractice, inter alia, lawsuit in 1985. The lawsuit was based in part on the failure to coordinate the linkage of the diagnosis and the treatment. The case was settled in 1987 before trial under a sealed settlement. In 2001, Chestnut Lodge closed and Dr. Osheroff died in March 2012 (Hirschkop & Mook, 2012).

Given the increased emphasis placed on the diagnosis–treatment connection, it is no coincidence that the release of the *DSM-III* and Dr. Osheroff’s lawsuit occurred in close proximity.

The Osheroff case has been described as “an important historical moment of transition in modern psychiatry” (Stone, 1990). The case surfaced a number of issues related to mental health intervention and highlighted the debate during the 1990s of the “decade of the brain” that symbolizes the evidence-based practice model and the role of clinical experience (Robertson, 2005). The impact of the Osheroff case has quietly shadowed and altered clinical practice standards over the last two decades with respect to the diagnosis and treatment connection. In *DSM-5* the historic diagnosis–treatment association has been reinforced and expanded in the section *Approach to Clinical Case Formulation*. The following quote from this section of *DSM-5* summarizes the expanded diagnostic formulation:

It requires clinical training to recognize when the combination of predisposing, precipitating, perpetuating, and protective factors has resulted in a psychopathological condition in which physical signs and symptoms exceed normal ranges. The ultimate goal of a clinical case formulation is to use the available contextual and diagnostic information and developing a comprehensive treatment plan that is informed by the individual’s cultural and social context. (APA, 2013, p. 19)

CASE FORMULATION

The concept of case formulation emerged in the 1970s and was being described in the clinical literature by the time the Osheroff case began to have impact. Despite the growing awareness about the diagnosis–treatment linkage, educational programs and clinical supervisors have not placed much emphasis on the conceptual association of diagnosis and treatment planning. Treatment planning has most recently been articulated as “case formulation.” Lazare (1976) in the early stages of modern case formulation defined the concept as “a conceptual scheme that organizes, explains, or makes sense of large amounts of data and influences treatment decisions” (p. 97). The diagnostic formulation model described in this chapter can be a standalone formulation or part of a comprehensive case formulation depending on the purpose of the diagnostic assessment. If the diagnostic formulation is part of a referral for psychotherapy

the diagnostic formulation should be combined with a case formulation and treatment plan. If the assessment is an evaluation in a forensic or other nontherapeutic case with no connection to intervention, the broader case formation would not be used and the diagnostic formulation would be one component of the evaluation.

A clinical case formulation used in conjunction with diagnostic formulations has not been well articulated in the past. Early studies show that training programs have placed little emphasis on the role of case formulations in mental health practice. One study (Ben-Aron & McCormick, 1980) found that 60% of psychiatry chairs and program directors believed that case formulation was important, but was inadequately stressed in training. A survey by Fleming and Patterson (1993) found that less than half of the psychiatric training programs provided guidelines for case formulation, and believed that standardized guidelines were needed. Both studies suggested that clinicians do not feel they are well trained in case formulation. Eells, Kendielic, and Lucas (1998) in a study of clinical case formulation made the finding that:

In light of the consensus that case formulation skills are important, it is striking that little research has addressed the formulation skills of clinicians. Research in this area would not only provide feedback to clinicians that could aid in training, but would also serve the goal of consumer protection by ensuring that a well-thought-out understanding of the patient has been attempted and an appropriate treatment plan developed. (p. 145)

Diagnostic formulation and case formulation as concepts are not generally used in clinical social work practice and rarely, if ever, appear in the clinical social work literature. This avoidance is not unique to the social work profession. Case formulation models have emerged and become more sophisticated over the last 30 years, but still are not widely used. This is the case because as Paris (2013) has pointed out:

All editions of the *DSM* have clearly stated that they are not intended to be guides to treatment. But that is not what happens in practice. Clinicians go directly from diagnosis to treatment. Moreover, they prefer diagnoses that lead to a specific treatment of some kind, even when they are wrong. (p. 13)

Clinical social workers and supervisors not familiar with clinical case formulation theory and

models should draw on the literature in this area to link their *DSM-5* diagnostic formulations with a comprehensive case formulation before initiating treatment/psychotherapy. Good books to utilize in designing case formulations are: *The Case Formulation Approach to Cognitive Behavioral Therapy* by Jacqueline Persons (2008); *Clinical Case Formulations* by Barbara Ingram (2011); *Collaborative Case Conceptualization* by Christine Padesky and Robert Dudley (2008); *The Biopsychosocial Formulation Manual* by William H. Campbell and R. M. Rohrbaugh (2006); *Psychoanalytic Case Formation* (1999); and *Psychiatric Case Formulations* by Len Sperry et al. (1992).

GENERAL DIAGNOSTIC CRITERIA

Formulating a diagnosis is based on general criteria that permeate all aspects of the diagnostic formulation process. The terms used here are defined differently from the terms used in mathematical statistical research based on probability theory. Terminology used in clinical settings currently is more descriptive ranking rather than precise, quantified measures. The criteria concepts are clinical utility, clinical relevance, clinical significance, and clinical judgment. The concepts are listed in the order that they should be applied to the clinical diagnostic process. The terms are defined and explained below.

Clinical utility is a term that applies to evaluation of the validity of classification systems such as the *DSM-5*. Clinical utility has been defined as “the extent to which *DSM* assists clinical decision makers in fulfilling the various clinical functions of a psychiatric classification system” (First, Pincus, Levine, Williams, Ustun, & Peele, 2004). Clinical utility deals with the question of how useable the system is for clinicians and how much people diagnosed using the system can rely on the accuracy of the diagnosis they have received. Clinical utility comes into play when the clinician compares the person’s symptoms to others who do not have the disorder. The symptoms/behaviors associated with a disorder have utility if they are observed in less than a given percentage of the nondisordered population (Angelini, 2002). Put in practical clinical terms, clinical utility is the degree of assistance a diagnostic system provides the clinician in distinguishing between illness and health in a given client (Greenberg, 2013).

The clinician should consider practical clinical utility in decision-making about the presence or absence of a disorder in a given client. The designers of the *DSM-5* have recognized that currently there is not sufficient scientific evidence to meet a high level of expectation for clinical utility and clinical significance of symptoms and behaviors because the “boundaries between disorders are more porous than originally perceived.” There is evidence many mental disorders are not separate entities and many disorders are “on a spectrum” with shared symptoms, behaviors, genetics, and environmental risk factors (APA, 2013, p. 6). To aid in dealing with practical clinical utility issues, “Other specified” and “unspecified” designations are included for most disorders in *DSM-5* (APA, p. 21). These categories are in part related to the Not Otherwise Specified (NOS) classification that was used in *DSM-IV*.

Research has shown that although most diagnostic concepts have limited validity, many are good working models that show clinical utility through information about outcome, treatment response, and etiology. The research findings indicate that clinical utility is a concept that clinicians need to understand and be conscious of when doing diagnosis. Practitioner use of clinical utility can be helpful in diagnostic interviewing, considering differential diagnosis, choosing interventions to improve outcomes, and communicating clinical information to colleagues, supervisors, clients, and their family members (Kendell & Jablensky, 2003). Assessing whether a disorder has sufficient clinical utility to use it is difficult with respect to a given client and may require an informed judgment decision by the clinician. Allen Frances (2013) chair of the *DSM-IV* revisions points out that “Every disorder has its story to tell,” (p. 2), and I would add every patient has a story to tell, and the clinician’s job in applying clinical utility in daily practice is to determine the fit of the two stories.

Clinical relevance is not applied here from a theoretical conceptual perspective. The terminology is used as a clinician-based concept that is part of establishing whether a unit of client behavior is relevant to the diagnosis under review. In other words, does a given symptom or set of symptoms identified by a client have relevance to criteria defined for a specific *DSM-5* disorder? For example, if an adolescent being evaluated for depression is having crying spells, the crying must be differentiated by determining if the crying is typical adolescent behavior or a part

of a depressive disorder. If the crying is clinically relevant (related to a disorder) the clinician moves to assessing clinical significance of the crying.

Clinical significance is identification of a set of behaviors and symptoms observed in an individual that are considered to be outside the range of normal functioning, and are the cause of distress and impaired functioning. Duration of the symptoms and behaviors can be a feature in determining significance. In *DSM-5* most disorders have a criterion of clinical significance. The expression of the criterion varies with specific disorders, but is generally indicated as impairment “in social occupational or other important areas of functioning” (APA, 2013, p. 21). Once clinical significance is determined, *DSM-5* uses specifiers to establish the level or degree of clinical significance. The most common specifier set in *DSM-5* is “mild, moderate, and severe.” There are various other clinical significance models outside the *DSM-5* system that can also be used to guide the mental process of deciding level of significance. For example, a very broad classification of behavior is the “four Ds,” in which a person’s behavior can be judged as: “different, difficult, dysfunctional or dangerous.” Another set of significance measures used in assessing potential difficulty in producing overall or specific change (treatment outcome) is: “simple, difficult, complicated, complex, and insoluble” (Munson, 2013, pp. 218–219).

Clinical judgment is the application of information based on actual observation of a patient combined with subjective and objective data that lead to a conclusion (Mosby, 2013). Clinical judgment is also referred to as critical thinking and clinical reasoning, but often these two terms are considered as working components of clinical judgment. When combining the three terms clinical judgment can be viewed as “the sum total of all the cognitive processes involved in clinical decision making” (Karthikeyan & Pais, 2010, p. 624). Dr. Allen Frances’s (2013) book, *Essential of Psychiatric Diagnosis*, can be helpful in the integration and exercising of clinical utility, relevance, significance, and judgment in daily practice with respect to the controversial disorders in the *DSM-5*.

DIAGNOSTIC FORMULATION

A diagnostic formulation is the result of a process in which the clinician interviews the client with a focus of compiling the chief complaints, identifying symptoms and behaviors articulated by the

client, as well as information provided by collateral sources (relatives, school officials, employers, etc.). Information is also gathered about the client's personal history and the possible prior history of diagnoses and mental health treatment and family history of mental illness. This information is assessed, integrated, and applied to the *DSM-5* criteria for various diagnostic categories. Ultimately the decision is made to assign a disorder or condition. The factual information, findings, rationale, and diagnosis are recorded through a formal written diagnostic formulation. Information in the *Introduction* and *Use of the Manual* sections of the *DSM-5* provides broad guidelines for the written diagnostic formulation. Based on the brevity of the guidelines the clinician has much flexibility in how the diagnosis is recorded. The key ethical consideration is that the written diagnostic formation must be sufficient to justify the content of the written treatment plan.

RECORDING A DIAGNOSTIC FORMULATION

The *DSM-5* expectations for recording a diagnostic formulation can be conceptualized in five categories: (1) history and background, (2) diagnoses, (3) medical conditions, (4) notations, and (5) disability severity. There is no standardized format prescribed in the *DSM-5* for recording these components of the diagnostic formulation. The diagnostic formulation becomes the guide for crafting the client's treatment plan. I recommend the diagnostic formulation be conceptualized and written before the treatment plan is established through collaboration with the client and/or family members. The *DSM-5* has a disclaimer indicating that recommendations for selection and use of treatment options for any disorder are not part of the *DSM-5* diagnostic system (APA, 2013, p. 19). The following information provides guidelines for recording a diagnostic formulation that is consistent with the *DSM-5* expectations in these five areas. A sample diagnostic formulation is illustrated for "Mr. Jones" in the descriptions of the five sections.

HISTORY AND BACKGROUND INFORMATION

The rationale for the history and background information is summarized in the *DSM-5* manual as the case formulation "must involve a careful clinical history and concise summary of the

social, psychological, and biological factors that may have contributed to developing a given mental disorder. ... it is not sufficient to simply check off for symptoms in the diagnostic criteria to make a mental disorder diagnosis" (APA, p. 19). A history and background section is important because the *DSM-5* no longer formally uses the "by prior history" or "by prior diagnosis" indicators used in *DSM-IV*. Also, the *DSM-5* "Diagnostic Features" sections for some disorders have risk and prognosis sections that describe possible genetic and physiological factors. Where heritable features of disorders are present they should be noted as part of the history and background information.

There is much flexibility in recording history and background, but the information included should be a concise summary of the key factors that are relevant to the diagnoses assigned in the diagnosis section of the diagnostic formulation. Basic demographic information should be included (age, cultural information, etc.) There should be a brief statement of the presence or absence of prior mental illness and mental health treatment episodes. Any factors that are outside the Other Conditions That May Be a Focus of Clinical Attention should be noted. An example of this first segment of the diagnostic formulation is illustrated below:

History and Background

Koma Jones, age 34, was seen today on self-referral because "I just can't shake the blues." He reports depression and anxiety symptoms for approximately two years. The depressive symptom and anxiety symptom onset occurred soon after meeting his current female companion. He and his companion have a 9-month-old son. He reports the companion has a "gambling problem" in several areas (off-track betting, casino gambling, sports gambling, and state lotteries) that preexisted their relationship. Mr. Jones reports his gambling is limited to casinos and lotteries, but he reports, "I gamble with money I can't afford to spend." Mr. Jones has been unemployed for seven months with "limited" prospects for finding employment. There is much verbal conflict between Mr. Jones and his companion. He is considering separation from the companion, but has not shared his plans with her. He reports receiving mental health diagnoses in the past during a marriage that ended in divorce six years ago. He received brief psychotherapy and medication for

Dysthymic Disorder and alcohol and substance abuse. He reports the alcohol/substance use was associated with chronic neck pain that was the result of an automobile accident. Based on Mr. Jones's self-report, screening measures, and clinical observation, he is not currently a threat to himself or others. There is a family history of bipolar disorder (paternal grandfather and maternal aunt). Based on the clinical interview, scales administered, and collateral information, the following diagnoses were made as part of this evaluation....

DIAGNOSES

Section II (Diagnostic Criteria and Codes) in *DSM-5* lists all the disorders that are cited as part of the diagnostic formulation. Section II is the core of the *DSM-5* system and combines the *DSM-IV* Axis I (Clinical Disorders), Axis II (Mental Retardation (Intellectual disability) and Personality Disorders, and Axis III (General Medical Conditions). In recording a diagnostic formulation, each disorder is listed preceded by the *International Classification Diseases* (ICD) diagnostic code. The Other Conditions That May Be a Focus of Clinical Attention listed at the end of the *DSM-5 Section II* are not diagnoses (APA, 2013, p. 715) and are recorded in a separate section of the diagnostic formulation as "Notations."

When multiple diagnoses are recorded, the previously used convention of listing the "principal diagnosis" first continues to be the recording procedure. "Principle diagnosis" is defined in *DSM-5* for inpatient settings as the condition primarily responsible for admitting the person, and in outpatient settings the "reason for the visit" is the disorder/condition that is primarily responsible for the services the person receives during the outpatient visit (APA, 2013, pp. 22–23). Other disorders diagnosed are listed in the order of how much they contribute to the treatment or service that is provided. Provisional diagnosis is also retained in *DSM-5* as a "specifier" (APA, 2013, p. 23). Provisional diagnosis is used when the information available about the client is not sufficient to determine whether the client meets the full criteria for a disorder. Provisional status of a diagnosis is indicated by entering "(Provisional)" to the right of the diagnostic entry. Generally accepted practice standards indicate that a firm diagnosis usually should be made by the third visit, but in some cases arriving at a diagnosis

may take longer. If the person ultimately meets the criteria for the disorder, the word provisional is removed or struck out in the written diagnostic entry. If the criteria for the disorder are not met, the disorder is removed or struck through on the written diagnostic entry. The following is a diagnostic formulation example of a multiple item diagnosis:

Diagnoses

- F34.1¹ Persistent depressive disorder, with anxious distress, moderate, Late onset, with pure dysthymic syndrome, moderate
- F63.0 Gambling disorder, episodic, moderate
- F10.10 Alcohol use disorder, in early remission, mild
- F12.10 Cannabis use disorder, in sustained remission, mild

MEDICAL CONDITIONS

DSM-5 indicates clinicians should continue to list the medical conditions as part of the diagnosis after listing the mental diagnoses. For nonphysicians, it is recommended that as part of nonphysician diagnostic formulation the medical conditions be listed as a separate section using the disclaimer "as reported by ..." (see Munson, 2001, p. 80). This disclaimer can prevent clinical social workers from being accused of practicing medicine by diagnosing medical conditions. Any medical conditions entered in a diagnostic formulation or other assessment/evaluation should use the "as reported by ..." disclaimer listing spouse, parent, employer, primary care physician, etc., as the source of the medical information. Below is an example of recording medical conditions for Mr. Jones's diagnostic formulation:

Medical Conditions as reported by Mr. Jones
(person evaluated)

- Gastritis, severe
- Erectile dysfunction, moderate
- Asthma, chronic
- Neck injury with significant pain associated with automobile accident

NOTATIONS

The *DSM-IV* Axis IV Psychosocial and Environmental Problems (PEPs) covered nine

key areas through brief narrative summaries that were part of the multiaxial diagnosis. In *DSM-5*, the PEPs were eliminated and moved into the end of Section II and titled *Other Conditions That May Be a Focus of Clinical Attention*. There are nine categories of conditions. The conditions are not considered mental disorders, but the conditions may impact the individual's diagnosis, the course of disturbance, the prognosis, or the treatment (APA, 2013, p. 715). In some cases the condition can simply be listed such as "homelessness" while others, such as "low income" may need a brief supplemental statement such as: "due to being unemployed and receiving unemployment of \$235 biweekly and having three children in his care with no other financial supports or resources." The details of the notations should be explained in the case formulation that should accompany the diagnostic formulation. The following illustrates the notations section for Mr. Jones:

Notations

Z63.8 High expressed emotion level within family

Z56.9 Other problems related to employment

V60.2 Insufficient social insurance or welfare support

DISABILITY SEVERITY

DSM-5 diagnostic instructions suggest that overall severity or "disability" should be recorded in the diagnostic formulation. Diagnosis is used to plan individual case and treatment plans, but it is also used to communicate diagnostic information to other clinicians who may work with the client. An overall severity indicator can be helpful in both clinical situations. No specific directions are provided in the *DSM-5* for recording this indicator as a severity specifier. There are a number of severity specifiers used within individual disorders in *DSM-5*. For example, persistent depressive disorder has five specifiers that are reviewed for the diagnosis. For clinical social workers it is recommended that clinical judgment be carefully used in determining the clinical significance of the overall clinical picture. The clinical judgment should be guided by the clinical significance criterion that is universally applied in the criteria for each disorder in the *DSM-5*. The *DSM-5* intentionally separates the concepts of mental disorder

and disability (severity of illness). Disability severity is defined as "impairment in social, academic, or other important areas of functioning" and the impairment should be assessed in the context of determining the individual's need for treatment (APA, 2013, p. 21). The overall disability severity can be presented through a brief summary statement. A sample of Mr. Jones's disability severity rating is summarized below:

Mr. Jones's overall functional severity is in the mild/moderate range. The moderate severity is present mostly in the area of personal concern about employment and his partner relationship issues. The alcohol/substance risk is in the moderate range given the early remission status, and the risk of relapse related to unemployment and personal stressors is in the moderate range. The gambling problem is at the mild level and may become nondisordered gambling if treated. The medical conditions present a moderate level of severity and if not addressed could result in alcohol/substance relapse. If Mr. Jones commits to a course of psychotherapy with a specific treatment plan the prognosis appears to be good, but the lack of insurance to cover treatment and low motivation for treatment may be barriers to a positive outcome. There is no apparent risk of harm to self and others.

ETHICS AND DIAGNOSIS

Social workers have been provided little guidance about the ethics of performing diagnosis even though the profession provides 40% to 80% of the mental health services in the United States. The National Association of Social Workers (NASW) Code of Ethics (1999) does not mention the words diagnosis, treatment, or psychotherapy. Some clinical social work organizations have adopted the NASW Code of Ethics as the guide for clinical social work practice (see for example, South Carolina Society for Clinical Social work website). The document *NASW Standards for Clinical Social Work in Social Work Practice* (NASW, 2005), which was issued in 1984 and revised in 1989 and 2005, makes one reference to the word diagnosis. Diagnosis is mentioned in the document based on Barker's (2003) definition of clinical social work as: "Clinical social work is the professional application of social work theory and methods to the diagnosis, treatment, and prevention of psychosocial dysfunction, disability, or impairment, including emotional, mental and behavioral disorders. . . ." (p. 9). The NASW practice

standards document indicates, “Clinical social workers shall adhere to the values and ethics of the social work profession, utilizing the NASW Code of Ethics as a guide to ethical decision making” (p. 4). As was mentioned earlier, the NASW Code of Ethics provides no ethical guidance related to diagnosis.

The Clinical Social Work Association (CSWA) (1997), formerly the Clinical Social Work Federation, does not mention the word diagnosis in the organization’s 3,546 word code of ethics issued in 1997 and last reviewed in 2006 when the code was “... found to still be an accurate statement of the ethical principles governing the clinical social work profession and the professional conduct of the members of that profession (Clinical Social Work Association, p. 4). The word “diagnostic” is used once in the statement: “Diagnostic and therapeutic services for clients. ... are rendered only in the context of a professional relationship” (p. 4).

The American Clinical Social Work Association (ACSWA, undated) formerly known as the American Board of Examiners in Clinical Social Work, mentions in its code of ethics the word “diagnostic” once and does not mention the word diagnosis. The ACSWA code statement on diagnosis is:

Clinical social workers observe the primacy of client need balanced with the right to self-determination. They take all reasonable steps to prevent the client from causing harm to self and others, and use their diagnostic and treatment skills to improve the mental health and social functioning of clients (American Clinical Social Work Association. (Undated)

Because professional organizations and regulatory boards provide clinical social workers little guidance about performing ethical diagnosis, providing adequate understanding of how to perform clinical diagnosis ethically is in part a responsibility of clinical supervisors through use of a mentoring and monitoring model (Munson, 2013). Supervisors need to mentor supervisees in how to develop diagnostic formulations accurately and monitor how they record diagnostic formulations, case formulations, and treatment plans. No research exists on how well clinical supervisors are prepared for this role.

Turner (2002) in his careful analysis of the history of social work diagnosis going back to the 1930s has pointed out that “unless our profession turns once again to a broad acceptance of

the concept and content of diagnosis as the heart of social work practice, we deprive our clients of a powerful helping resource and thus fail in our responsibility to them” (p. 1). Ethically, any clinical social worker who provides psychotherapeutic intervention or any other treatment aimed at producing change in the client’s functioning in relation to his or her mental functioning should only provide the intervention using a written treatment plan based on a case formulation that is derived from or connected to a thorough, written diagnostic formulation. The diagnostic formulation can be developed by the clinical social worker, or by an independent qualified psychiatrist, psychologist, or other qualified mental health professional within the last 30 days, and provides the treating clinical social worker with a written diagnostic formulation. In summary, Soren Kierkegaard, the famous 19th century Danish philosopher, in the broadest sense symbolically defined the bidirectional focus of diagnosis and treatment by pointing out “Life can only be understood backwards; but it must be lived forward.”

WEBSITES

International Classification of Disease, ICD-9
www.findacode.com/icp-diagnosis-codes.html
The Diagnostic and Statistical Manual, 5th edition, www.dsm5.org
 American Psychiatric Association, www.apa.org

Note

1. The *ICD-10-CM* codes are used in the sample formulation. The *ICD-9-CM* codes will be used in the United States until October 1, 2014 or other date established for the official implementation of the *ICD-10-CM* codes in the United States. In the interim, United States clinicians are to use the *ICD-9-CM* codes. Both *ICD-9-CM* and *ICD-10-CM* codes are listed in the *DSM-5* (see p. 23 of the *DSM-5* for details of this requirement and the APA website: <http://www.dsm5.org/Documents/FAQ>).

How Clinical Social Workers Can Easily Use Rapid Assessment Tools (RATs) for Mental Health Assessment and Treatment Evaluation

Kevin Corcoran

Clinical social work was once chiefly a three-party system. It was a matter between the patient and the provider, with reimbursement readily paid by insurance companies or governmental agencies. A person became a patient simply by deciding that he or she needed to see a social worker, and together they would decide what the problems and goals were, what the intervention would be, how long it should last, and the costs—although this was typically set solely by the provider. Then came managed care at both the private and public levels and everything changed; in particular, potential “clients” must be authorized for treatment based on “medical necessity.” This change continues with the Affordable Care Act (see Gorin and Moniz, 2014) and state-initiated cost-cutting programs. One such program is Oregon’s “Coordinated Care Organization,” which is akin to an interdisciplinary team of case managers where prevention and early intervention is supposed to save billions of dollars; in this case, the team decides who will be a patient, what services are needed, and by whom.

In essence, the need for services, then, must be demonstrated before treatment, in order to get authorization and payment. This need for services may, in fact, need to be demonstrated at various points in the treatment process for the continuation of services. In both circumstances the social worker must demonstrate that clinical services are medically necessary and that there is some evidence of progress; evidence of progress from a health and mental health care

administrative perspective is chiefly a reduction in symptomatology.

The critical question for the clinical social worker is how to demonstrate that the client’s condition warrants treatment. There are many ways to evidence that a client’s presenting problem is a mental health condition and is sufficiently distressing or disabling to require therapy. One method is a psychiatric evaluation that uses a variety of diagnostic tests. Examples of diagnostic tests include the Minnesota Multiphasic Personality Inventory and the Rorschach ink blots. These assessments have long been recognized as having a number of limitations for clinical social work (Arkava & Snow, 1978), including that they are costly, lengthy, time-consuming to administer, frequently require training to score and interpret, and some have questionable reliability and validity. Moreover, because of length, it is not practical to use them over the course of treatment and at follow-up. In contrast, there are a large number of relatively short, self-administered, and easily scored assessment tools available for use by practitioners for most clinical conditions (e.g., Corcoran & Fischer, 2013a, 2013b; Jordon & Franklin, 2011). These assessment tools are frequently called rapid assessment tools (RATs) and generally take only a few minutes to complete. RATs are useful to evidence medical necessity and when used throughout treatment to monitor symptom reduction and goal attainment.

RAPID ASSESSMENT TOOLS TO MEASURE TREATMENT NECESSITY

An additional use of RATs is to provide evidence of the need for treatment. This is based on scores obtained at the intake. Some instruments, such as Hudson's scales (Nugent, Sieppert, & Hudson, 2001), can provide this information because they have a cutting score. A cutting score is one that distinguishes those with a clinically significant problem from those without one. When using such a measure, if the score is greater or lower than the cutting score, it is persuasive evidence of a need for treatment.

Most psychological measurements do not have cutting scores. In these circumstances, an RAT score may be compared to a norm from either the general population or a clinical sample of patients in treatment. This is known as norm-referenced comparison, and it illustrates the client's problem relative to others with and without that problem. A client's score on an RAT should be different from the general population and similar to those with the same mental health condition. When these observations occur, it is reasonable to conclude that treatment is warranted.

When using RATs to illustrate the need for treatment, two assessments are recommended: a broadband measure of mental health along with a narrowband measure of the client's specific problem. Excellent broadband instruments are the various health and mental health surveys, which are all short forms (SF, Ware, Kosinski, & Keller, 1994; also see qualitymetric.com). These instruments are particularly useful because they have been evaluated in numerous countries, are inexpensive, and are accessible from the Internet (www.outcomes-trust.org; qualitymetric.com) as well as from published sources (e.g., Corcoran & Fischer, 2013b). The health and mental health survey has two composite scores, one measuring physical health and the other measuring mental health. The average score on the SF-36 and SF-12 is about 50 and 35 for the general population and a psychiatric sample, respectively; the standard deviation is 10 for both samples.

One precise way to show that a client's score is different from the general population and similar to a clinical sample is with a Z-score (Corcoran, 2008, 1997; Corcoran & Hozack, 2012; Corcoran & Vandiver, 1996; Thomlison & Corcoran, 2008). A Z-score is a standardized score that has a mean of zero, a standard deviation of 1, and generally ranges from -3 to +3.

A Z-score is easily determined by subtracting the sample mean from the client score and then dividing that difference by the standard deviation. With a Z-score, a social worker can compare a client's score with the norm by determining what percentage of the sample scored higher or lower than the client—in other words, what percentage have problems more and less severe. This is done by first finding the Z-value in Table 47.1 and then examining the percent above and below the client's score.

This information allows the social worker to interpret the client's score relative to the general population and a clinical sample. For example, if a client had a Z-score of 0.1 based on parameters from the general population, then he or she would be just about average and there would be little reason to aver treatment necessity. However, if the norm was from a clinical sample and the Z-score was 0.1 or so, it is reasonable to assert a need for treatment because the client is similar to the average person who is already in treatment. It is best to calculate a Z-score from the general population and a clinical sample, if the normative data are available. For example, a client with a Z-score of 1 from a general population would be different from 84% of the general population, and the social worker could conclude that there is likely a need for treatment. A score of -1 with a clinical sample is more severe than 16.5% of those patients in treatment, and it is still likely that treatment is necessary.

The use of Z-scores for determining treatment necessity is relatively easy after a few tries. The proportions above and below the level of the client's score enables the social worker to make rather precise statements of a client's performance compared to clinical and nonclinical samples. These data are persuasive for illustrating treatment necessity. In general, it is difficult to argue that treatment is not needed when the client is different from the general population or similar to a sample of patients already in treatment.

The above procedures allow the social worker to make comparison to a general and clinical sample for any instrument. The procedures, however, do involve some time, around 10 minutes. This time simply is not available for many clinical social workers in routine daily practice. This problem is easily solved with an Internet service (www.Do-I-need-therapy.com or www.Is-therapy-effective.com). These websites provide this

TABLE 47.1 Table of Z-Scores and Proportions

Z-Score	Proportion of Score		Z-Score	Proportion of Score	
	<i>Lower Than</i>	<i>Higher Than</i>		<i>Lower Than</i>	<i>Higher Than</i>
-3.0	0.13	99.87	0.1	53.98	46.02
-2.9	0.19	99.81	0.2	57.93	42.07
-2.8	0.26	99.74	0.3	61.79	38.21
-2.7	0.35	99.65	0.4	65.54	34.46
-2.6	0.47	99.53	0.5	69.15	30.85
-2.5	0.62	99.38	0.6	72.58	27.42
-2.4	0.82	99.18	0.7	75.80	24.20
-2.3	1.07	99.93	0.8	78.81	21.19
-2.2	1.39	98.61	0.9	81.59	18.41
-2.1	1.79	98.21	1.0	84.13	15.87
-2.0	2.29	97.73	1.1	86.43	13.57
-1.9	2.87	97.13	1.2	88.49	11.51
-1.8	3.59	96.41	1.3	90.32	9.68
-1.7	4.46	95.54	1.4	91.92	8.08
-1.6	5.48	94.52	1.5	93.32	6.68
-1.5	6.68	93.32	1.6	94.52	5.48
-1.4	8.08	91.92	1.7	95.54	4.46
-1.3	9.68	90.32	1.8	96.41	3.59
-1.2	11.51	88.49	1.9	97.13	2.87
-1.1	13.57	86.43	2.0	97.73	2.27
-1.0	15.87	84.13	2.1	98.21	1.79
-0.9	18.41	81.59	2.2	98.61	1.39
-0.8	21.19	78.81	2.3	98.93	1.07
-0.7	24.20	75.80	2.4	99.18	0.82
-0.6	27.42	72.58	2.5	99.38	0.62
-0.5	30.85	69.15	2.6	99.53	0.47
-0.4	34.46	65.54	2.7	99.65	0.35
-0.3	38.21	61.79	2.8	99.74	0.26
-0.2	42.07	57.93	2.9	99.81	0.19
-0.1	46.02	53.98	3.0	99.87	0.13

information for 10 major mental health symptoms: alcohol abuse, anger issues, anxiety, depression, drug abuse, eating problems, impulsivity, obsessions and compulsions, stress, and suicide. What would have once taken the social worker 10 or more minutes to complete is now done in .067 seconds with graphic, easy interpretation and clinically useful assessments. An illustration of the reports is displayed in Figure 47.1, which is from the following Case Study.

RAPID ASSESSMENT TOOLS AND DIFFERENTIAL DIAGNOSIS

A broadband measure, like the SF-36 or SF-12, and a narrowband measure do more than allow the social worker to determine the magnitude or severity of a presenting problem to evidence treatment necessity. RATs can also greatly facilitate the task of differential diagnosis. For example, whereas the SF-36 produces general scores

Your total score on this measure of depression is 32.0, and is shown below by the bold arrow. The area to the left of the arrow represents those with equal or less severe depression than you, and the area to the right represents those with more severe depression than you.

General

When compared to the general population of 2,293 adults, your depression score suggests that 99.99% of the typical adult has less severe depression than you and 0.01% have more severe depression.

Clinical

When compared to a sample of 1,340 adults who are already receiving therapy or counseling you are in the 44.31 percentile. This means that about 55.69% of patients in therapy or counseling have depression more severe than you, and you are as depressed as 44.31% of people in therapy.

Clinical Female

When compared to a sample of 373 *women* who are already in therapy or counseling you are in the 25.41 percentile. This means that about 74.59% of patients in therapy or counseling have depression more severe than you, and you are as depressed as 25.41% of women in therapy.

Compared to these groups, what is your opinion? Do you think you need therapy or counseling for depression? Does depression effect how well you function on a daily basis? If you answered “yes” to these questions, then you should obtain a referral to see a mental health professional.

If you do go for therapy or counseling, you might want to [print this report](#) and use it to discuss your depression with your therapist or counselor.

Figure 47.1 Easy RATs initial assessment.

on health and mental health, it also has more specific items and subscales of symptomatology, such as depression and social functioning; items and subscale scores, then, may very well point the clinician to a more specific differential diagnosis.

Differential diagnosis is essentially distinguishing one particular mental health condition from another. Although a provisional and final diagnosis are codified with the DSM-V (American Psychiatric Association, 2013), the use of rapid assessment instruments can help the social worker identify the particular pathology and concomitantly quantify this severity to observe change over the course of treatment and afterward. Moreover, a differential diagnosis is essential if the practitioner is to develop an effective treatment plan. If the client’s condition is not differentiated from similar ones, a viable and effective treatment plan is impossible. When benefits of treatment are gleaned nonetheless under circumstances of misdiagnosing a mental health condition, this is likely due to nonspecific factors in treatment, such as a caring relationship, or mostly a matter of chance—dumb luck, if you will.

One of the most critical examples of this is the distinction between the bipolar affective disorders, delusional disorders, schizoaffective disorder, and the schizophrenic disorders. These mental disorders are likely to include abnormality of affect, such as an elevated, expansive, or irritable mood. All might also include disturbed cognition, such as grandiose and persecutory delusions, catatonia, or flight of ideas. Most important, all may evidence psychotic features. The distinctions are subtle but critical: the psychotic symptoms of the mood disorder do not occur in the absence of a prominent mood symptom, whereas psychotic symptoms may be manifested in the others independent of mood symptoms. Similarly, the manic or depressive symptoms may be evident in the schizophrenic disorders but are often not sufficient in duration or magnitude to warrant a diagnosis of one of the mood disorders. In spite of these differences, social workers—like other professionals—are quick to assume that if there are presenting symptoms of psychosis, it is likely a schizophrenic disorder. In fact, however, bipolar disorders are more prevalent

than schizophrenia (APA, 2013), which should suggest the likelihood of a mood disorder, or possibly even a stroke, which has a defining feature of disorientation, or being out of touch with reality (i.e., a psychotic feature). As this illustration suggests, an inaccurate differential diagnosis may result in a treatment plan for schizophrenia when the focus of treatment should be for a mood disorder or the immediate admission to the emergency room in the event of a stroke.

RAPID ASSESSMENT TOOLS TO MONITOR CLIENT CHANGE AND GOAL ATTAINMENT

Another use of RATs is to monitor client change and evaluate practice (Corcoran & Fischer, 2013b). They have been used for quite some time by conscientious practitioners for these purposes. RATs are typically administered before, during, and after treatment to see whether the client's problem has changed and goal has been obtained. RATs may be used as a measurement of the treatment goal by establishing an ideal score on the instrument, one that reflects a successful outcome to be reached by the end of therapy. In the example of Olive given later, the goal of treatment was for her score to be around 6 plus or minus, which reflects depression at a nonclinical level and is about average for the general population. For a client to change from being similar to other clients to being similar to the general population would be a reasonable definition of "clinical significance."

Measurements before, during, and after treatment compose a simple AB design where scores during the treatment phase (i.e., B) are compared to the scores before treatment begins (i.e., A). This is known as self-referenced comparison. There are three essential elements in this approach to using instruments to monitor the treatment process: (1) a simple research design that reflects the treatment process, such as a treatment period (i.e., B phase) compared to a time of no treatment (i.e., A phase); (2) a systematic means to observe the client, such as an RAT or a broadband measure; and (3) the interpretation of scores by plotting them to see whether the client's behavior has changed. There are, of course, more sophisticated research designs and statistical interpretation of the data (see, e.g., Bloom, Fischer, & Orme, 2006). At minimum, however, the social worker needs to be able to see that change has occurred over the course of treatment.

For example, in the case study to follow, Olive enters therapy for depression and scored 32 on Lovibond and Lovibond's (1995) depression scale as found on Do-I-need-therapy.com and displayed in Figure 47.1. Olive completed the instrument twice to collect "retrospective baseline data" where she was instructed to answer the items she felt "at her worst," which was a score of 32 and "currently," which had a score of 32. Both are reflected under Sessions 1 and 2 in Figure 47.2. The instrument was administered weekly for seven weekly clinical sessions, which are reflected on Sessions 3 through 9. At the follow-up reported in Session 10 Olive's score was 7, which reflects the treatment goal. To compare her performance over the course of treatment, the scores are plotted on a graph for visual analysis of clinically significant change, as illustrated in the lower panel of Figure 47.2.

Visual analysis clearly requires clinical judgment, as does any statistical analysis. It must be stressed that scores on an assessment tool are simply supplemental information and not a substitute for clinical judgment. By using a simple design and RATs where scores are understood by visual interpretation, the social worker has additional information to evaluate treatment and evidence its effectiveness.

CASE ILLUSTRATION

Admittedly, the uses of RATs to evidence treatment necessity and throughout the treatment process are chores unfamiliar to many professional social workers. At first, it seems difficult to add this approach to the overburdened demands of practice. The following case illustrates how it is easy to determine treatment necessity (www.Do-I-need-therapy.com) and treatment effectiveness (www.Is-therapy-effective.com); both sites provide the same content. Olive is a college-educated woman in her late fifties who works in administration. For the past year or so, she has been feeling apathetic and is prone to crying spells. She reports she has not been able to sleep well, often waking up several times a night and early in the morning. When she is awake, she does not want to get out of bed. She avoids her family and friends. Olive was referred to a social worker after disclosing to her primary care physician that she had thoughts of suicide.

At intake, the social worker thought Olive likely had a mood disorder, and she was given the depression scale from Do-I-need-therapy.com

Your total score on this measure of depression is 7.0, and is shown below by the bold arrow. The area to the left of the arrow represents those with equal or less severe depression than you, and the area to the right represents those with more severe depression than you.

General

When compared to the general population of 2,293 adults, your depression score suggests that 65.8% of the typical adult has less severe depression than you and 34.2% have more severe depression.

Clinical

When compared to a sample of 1,340 adults who are already receiving therapy or counseling you are in the 1.34 percentile. This means that about 98.66% of patients in therapy or counseling have depression more severe than you, and you are as depressed as 1.34% of people in therapy.

Clinical Female

When compared to a sample of 373 *women* who are already in therapy or counseling you are in the 0.46 percentile. This means that about 99.54% of patients in therapy or counseling have depression more severe than you, and you are as depressed as 0.46% of women in therapy.

Scores Over Time

The dashed line represents the average clinical population score, 33.73. The solid line represents the average general population score, 3.95.

Figure 47.2 Easy RATs treatment evaluation.

and the mental health survey short form (Ware, Kosinski, & Keller, 1994). Remembering that the average score is 50 and 35 for the general population and clinical samples, Olive’s score at the beginning of treatment was 32, and reflects lower mental health status than about 99% of the general population while being similar to the typical psychiatric patient.

The social worker was able to reach a preliminary differential diagnosis of dysthymia because her symptoms were not due to a

medical condition and were not physiological effects of substances, and there had been no evidence of an elevated or expansive mood, which would suggest one of the bipolar disorders. The differential diagnosis must be considered preliminary because at this point in the assessment it is not known whether Olive’s condition has lasted at least two years, a criterion of this form of clinical depression. To help the social worker with this differential diagnosis, Olive was also asked to complete the RAT as representative of

when she felt “at her worst” and how she felt “currently.” Aside from showing that Olive’s depression is relatively stable, these numbers do not tell the social worker much until interpreted relative to the general population or a clinical sample.

Using the website *Is-therapy-effective.com*, Olive was compared to a sample from the general population that had a mean depression score of about 5 with a standard deviation of 6.0. A sample of psychiatric patients had a mean of 32 and a standard deviation of 9.3. As illustrated in Figure 47.1, Olive’s depression score was 32, which suggests she is more depressed than 99% of the general population and more severe than 44% of patients already receiving therapy; for women only, Olive is more depressed than 25% of the clinical sample. As for a treatment goal, Olive and her social worker decide that an appropriate goal would be to feel “as happy as the next person.” This was operationalized as a score similar to the general population. Olive’s progress is monitored by having her complete the scale throughout the treatment progress and at a one-month follow-up assessment. This is illustrated in the lower panel of Figure 47.2 and shows consistent decrease in depression. The case also evidences “clinical significance” in that Olive is no longer similar to patients at the end of treatment and quite similar to the typical person from the general population; this continued at the follow-up assessment.

SUMMARY

This case illustrates that RATs are useful to show the need for treatment, determine a differential diagnosis, monitor client progress over the course of clinical intervention, and set goals; that this is especially so when RATs are completed on the Internet. In summary, RATs serve three functions: (1) as evidence of treatment necessity and in determining an accurate diagnosis; (2) as a tool to monitor client progress; and (3) as an operationalization of a treatment goal. That is, they are useful almost from the beginning and throughout the course of clinical practice. When both broadband measures of mental health problems and narrowband measures of the client’s particular problem are used, the social worker has additional tools to evidence that treatment is necessary and, it is hoped, effective.

48 Bipolar and Related Disorders

Elizabeth C. Pomeroy

The *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5) has created a distinct category for Bipolar and Related Disorders (BP), separating it from Depressive Disorders (APA, 2013). The six mental disorders covered in this section are characterized as chronic, complex, disruptive, and multifactorial involving *mood lability* and extremes of behavior. The term *multifactorial disorder* refers to one caused by the interaction of genetic and environmental factors. *Mood lability* is defined as frequent or intense mood changes or shifts that are outside of normal experience. These characteristics present substantial challenges for diagnosis and treatment (APA, 2013).

Bipolar Disorders in the DSM-5 are organized around three different types of episodes that, in turn, serve as building blocks for determining specific diagnoses. An episode is a period of time during which a client evidences a particular set of symptoms and as a result, experiences a pronounced alteration in mood and/or a change in his or her social, vocational, and recreational functioning. Specifically, the three episodic states are major depressive, manic, and hypomanic. In addition, the Mixed Features Specifier replaces the Mixed Episode in the DSM IV-TR. Additionally, the DSM-5 includes developmentally appropriate symptom thresholds for children to facilitate better reliability of diagnoses and more targeted treatment for children. Furthermore, increased energy/activity has been added as a core symptom of Manic Episodes and Hypomanic Episodes (APA, 2013). The goal is to provide specific diagnostic criteria while still providing some dimensional criteria and a lifespan perspective when treating individuals with Bipolar Disorder.

Two of the diagnoses in this section are determined by the etiological factors relevant to the

illness. Specifically, Bipolar Disorder Associated with Another Medical Condition is used when a bipolar episode is directly related to a diagnosable organic problem. Similarly, Substance-Induced Bipolar Disorder is used when the problematic bipolar episode is directly related to the use of a recreational drug, prescribed medication, or a toxin (e.g., lead, carbon monoxide) (APA, 2013).

The most severe disorders in this cluster include Bipolar I and Bipolar II. Assessment of these disorders is based on the number and pattern of episodes the individual has experienced in his or her lifetime. Attention is given to the severity of symptoms and specific characteristics of the most recent episode in the coding scheme (APA, 2013). Cyclothymic Disorder represents a more chronic condition that is generally less disruptive to the individual's functioning. In Cyclothymic Disorder, an alternating pattern of mood states is present but not as severe as major depressive or hypomanic episodes. For a diagnosis of Cyclothymic Disorder, the symptoms must be present for at least two years.

Finally, a broad diagnostic category of Unspecified or Other Specified Disorders is included in this chapter of the DSM-5. These diagnoses replace the earlier Not Otherwise Specified diagnostic specifier, which was overused and found lacking in terms of clinical utility. These diagnoses are used when an individual's symptoms fail to fit any of the more specific diagnoses and are not attributable to the direct physiological effects of a substance or a general medical condition. The four new diagnostic terms for Other Specified Bipolar and Related Disorders found in the DSM-5 (APA, 2013) are as follows:

1. Short Duration (2–3 days) Hypomanic Episodes and Major Depressive Episodes

2. Major Depressive Episodes and Hypomanic Episodes characterized by insufficient symptoms
3. Hypomanic Episode without Prior Major Depressive Episode
4. Short Duration (less than 2 years)
Cyclothymia (APA, 2013; p. 148).

The Bipolar and Related Disorders section in the DSM-5 includes a comparatively large number of specifiers, including some that are reflected in the fourth and fifth digit of the numeric coding. A full description of the relevant specifiers is included in each disorder's diagnostic criteria. Practitioners are encouraged to take time and gather a full psychosocial history in order to ascertain the specifiers that might pertain to a particular diagnosis. It should be noted that specifiers are only used if the full criteria for a diagnosis are met (APA, 2013).

From a lifespan approach, the average age of onset for Bipolar I Disorder is 18 years; however, in rare instances it can begin in childhood. It tends to be chronic in nature, and unfortunately suicide is a common risk factor. In Bipolar II disorder, major depressive episodes alternate with hypomanic episodes. The average age of onset is in a person's mid-twenties or later. Persons with Bipolar II disorder who are experiencing hypomania are at greatest risk of suicide (MacQueen & Young, 2001). In both types of Bipolar disorders, practitioners should carefully assess clients for suicidal risk.

Advances in science and clinical research over the last quarter of a century have deepened our understanding of the diagnosis and treatment of debilitating mental conditions, including Bipolar Disorder. Individuals experiencing psychotic symptoms of either Depression or Mania, which often coexist with other conditions will likely not seek treatment independently. However, their behavior may well result in others arranging involuntary mental health treatment on their behalf. The clarification of diagnostic criteria in the DSM-5 for Bipolar Disorder is expected to help in clinical assessment and treatment.

When assessing someone suspected to have a mood disorder, particular attention should be focused on the person's emotional functioning. Although a thorough history of the presenting problem is required to make a diagnosis, it may be difficult for the client to present detailed and accurate information. People who are severely depressed can be virtually mute, and those

experiencing manic mood states may be unable to express themselves coherently. Clearly, the reliability of self-report is very uncertain if someone is experiencing psychotic symptoms. Someone with a history of psychiatric treatment may fear rehospitalization and deliberately minimize symptoms. Consequently, it is often helpful to gather data from collateral sources, such as close friends or relatives, employers, or other professionals to specify both the timing and severity of symptoms.

There are many challenges and complexities to diagnosing Bipolar Disorder. Individuals assessed on the basis of current clinical features alone are often misdiagnosed because of an overlap of symptoms, especially with depression. Assessment may be further complicated by comorbid conditions (medical, psychiatric, and substance problems). Understanding age-associated variations in the presentation of Bipolar Disorder across the lifespan is critical. Being able to differentiate age-appropriate behaviors from the symptoms of bipolarity is especially important when dealing with children. The DSM-5 Task Force made a concerted effort to reduce the number of children diagnosed with Bipolar Disorder by creating a new disorder, Disruptive Mood Dysregulation Disorder, under the Depressive Disorders category of the DSM-5. Knowledge of diagnostic specifiers and their pharmacological implications is key to successful assessment and will greatly improve the treatment of this lifelong disorder.

Quite a number of rating scales and tools can be useful when assessing depressive symptoms in Bipolar Disorder. The Patient Health Questionnaire (PHQ-9) is a simple, self-administered measure of depression severity that was developed and studied in primary care settings. It generally takes under 10 minutes to complete. The PHQ-9 scores each of the nine DSM-5 "Major Depressive Episode" diagnostic criteria (APA, 2013). Individuals rate their problems/feelings over the "past 2 weeks" on a 4-point scale (from 0 = not at all to 3 = nearly every day) with total scores ranging from 0 to 27. When total score is under 5, depression severity is seen as none to minimal. Totals ranging from 5, 10, 15, and 20 represent thresholds for mild, moderate, moderately severe, and severe depression, respectively (Kroenke & Spitzer, 2002). In order to assess manic symptoms in adults, two self-report instruments have been shown to have excellent reliability and validity. The

Internal State Scale (ISS) (Bauer, Crits-Cristoph, & Ball, 1991) is a 15-item instrument in which clients indicate the intensity of their mood by marking a line denoting the level of severity of symptoms. The scale has four subscales, including well-being, perceived conflict, depression, and activation. Mania is assessed by a well-being score equal to or higher than 125 and an activation score equal to or greater than 200. Each item is “biphasic.” For example, on the items indicating well-being, clients who mark the lower end of the line (scale) are assessed to have depressive symptoms, whereas clients who mark the upper end of the line are assessed to have manic symptoms.

The Mood Disorder Questionnaire is an easy to administer, 13-item questionnaire with “yes” and “no” responses. The instrument is designed to measure the presence of symptoms related to Bipolar Disorder. A total score of seven or more “yes” responses indicates that symptoms of Bipolar Disorder are present. The instrument has excellent reliability ($\alpha = .90$). Studies have indicated excellent discriminant and concurrent validity (Corcoran & Fischer, 2013).

For bipolar clients who are unable to complete a self-report instrument, the Young Mania Rating Scale (YMRS) (Young, Biggs, & Myers, 1978) can be completed by a skilled practitioner. The scale contains 11 items measuring internal mood states and behaviors experienced by the client and reported to the practitioner. Symptoms of mania are rated on grades of severity, some items graded on a 0 to 4 scale and others are graded from 0 to 8. Higher scores indicate greater symptom severity and more psychopathology. Scores may range between 0 and 56. (Youngstrom, Danielson, Findling, Gracious, & Calabrese, 2002). (Also see Chapter 47 for discussion of free Web-based assessments, including for depression.)

EMERGENCY CONSIDERATIONS

Assessing and managing suicide risk is one of the most important components of clinical practice, especially when treating individuals for Bipolar Disorder. In some situations, people experiencing severe emotional distress may constitute a danger to themselves or others. Suicidal thinking is part of the diagnostic criteria for a major depressive and hypomanic episode of Bipolar disorders. In these situations, practitioners must attend to

issues regarding the client’s safety and secure whatever level of supervision and treatment is necessary. A comprehensive suicide risk assessment will help identify the major risk factors for suicidal behavior. The risk of suicide attempts increases if clients exhibit an anxiety disorder and/or substance abuse disorder. Also, risk of death by suicide is higher in males and comorbid with anxiety disorders (Simon et al., 2007). Risk management strategies must be ongoing and should include a crisis plan that involves emergency resources such as emergency departments, telephone crisis centers, and local inpatient/outpatient mental health services. The Internet can be efficiently exploited.

Gender Differences

Gender differences in mental health utilization and symptom reporting as well as gender roles and stereotypes can affect accurate diagnosis and treatment of psychological disorders. Conformity to traditional gender roles for men, which emphasize emotional stoicism and self-reliance, may negatively impact the expression of symptoms, need for support and willingness to seek help. Women are socialized to be more emotionally expressive and are more likely to disclose symptoms and seek help. Men may be more likely to have problems with violence and/or substance abuse and women to have a history of suicide attempts (Baldassano, 2006). Female gender is a significant predictor of being diagnosed with depression; even when presentation symptoms and scores on standardized measures of depression are similar to males (World Health Organization [WHO], 2002). Gender sensitivity training and strategies aimed at decreasing biases and barriers to help seeking have important diagnostic and therapeutic implications. According to Kriegshauser, Sajatovic, & Jenkins et al. (2010) women rely on strong social supports as a coping mechanism for Bipolar Disorder, a positive factor in treatment adherence. For men, who may perceive fewer high-quality social supports, adjunctive social networks such as group therapies or advocacy initiatives (Web-based or in person) might be particularly helpful.

SOCIAL SUPPORT SYSTEMS

Bipolar disorders are serious, recurring, chronic illnesses that can overwhelm support resources

and cause impairment in social, occupational, or other important areas of personal functioning. The assessment of social functioning is a significant feature of the *Diagnostic and Statistical Manual* (APA, 2013). The goals for treatment must be more than just a reduction in clinical symptoms; they must also seek to improve social functioning. Recent studies have found that social impairments in individuals with Bipolar disorders were similar in type and severity to those seen in individuals with schizophrenia (Dickerson et al., 2001). Providing support for an individual with a chronic illness is inherently stressful. Conflicts between family, friends, and the person with the disorder can arise due to disruptive thoughts and behaviors and extreme mood swings on the part of the symptomatic individual. Caregiver burden is high and largely neglected in Bipolar disorders (Ogilvie, Morant, & Goodwin, 2005). Research attests to the low rates of treatment compliance for many bipolar patients. Providing clients and caregivers with realistic expectations and practical advice on illness management along with sources of support, such as peer and psycho-educational support groups, can help mitigate the impact of the illness. Caregivers should be encouraged to meet with others to share coping strategies. Joining a group can be hard for individuals experiencing symptoms of the disease. Treatment strategies for individuals with Bipolar Disorder must consider the stigma associated with the disease, the impact of symptoms on social functioning, and the risk of not maintaining positive social networks, which is high in this population.

Differential Diagnosis

Bipolar disorders are a set of complex illnesses with many challenges and conditions involved in differential diagnosis separation. A delay in diagnosis equates to a delay in correct treatment. The first step when diagnosing Bipolar disorders is to rule out substance use or abuse (e.g., alcohol, drugs, prescription drugs) or a general medical condition as the cause of symptoms. This disorder goes primarily underdiagnosed due to misdiagnosis as major depressive disorder (MDD). Other disorders involved in differential diagnosis include other psychotic disorders, such as schizophrenia or schizoaffective disorder; anxiety disorders; and, in children, conduct disorders and Attention-Deficit/Hyperactivity Disorder (ADHD). Its developmentally distinct

presentation in children makes diagnosis difficult with this population. Just as giving an antidepressant without a mood stabilizer (primary treatment for unipolar depression) may destabilize someone with Bipolar Disorder; giving a child a stimulant (primary treatment for ADHD) can lead to mood destabilization in children with Bipolar Disorder.

Furthermore, children are increasingly being diagnosed with Bipolar Disorder rather than ADHD or Conduct Disorder. In order to be diagnosed with a Bipolar I Disorder, the child must display symptoms of Mania. However, the practitioner should be careful not to make this diagnosis without a full understanding of the family situation. Some children can display manic symptoms when they are under stress. These symptoms may disappear once the stressful situation is remedied. The differential diagnosis involves the depressive episode in children with Bipolar Disorder. Children with ADHD or Conduct Disorder rarely display the depressive symptoms that are part of the criteria for Bipolar Disorder in children. In fact, Bipolar Disorder in Children should be considered a rare occurrence and a thorough psychosocial history is needed to rule out other possible disorders before a conclusive diagnosis of Bipolar Disorder is reached.

Cultural Considerations

Cultural variations impact symptom expression, and therefore, they can affect the diagnostic process. Addressing cross-cultural and gender differences is paramount when treating individuals who suffer from Bipolar Disorder. Cultural attitudes also influence whether individuals will seek help and which clinical pathways may be most effective. Multiple studies have found that individuals from Hispanic and Asian backgrounds are more likely to report physical ailments and less likely to report emotional symptoms when suffering from mental illness. In many cultures, the stigma surrounding mental illness is very strong, and the pressure “not to shame the family” often leads to underreporting symptoms. Another caution relates to the tendency for minority group members to receive more serious or more stigmatized psychiatric labels. For example, there is some evidence that Caucasians are more likely to be diagnosed with Bipolar I Disorder, while minority clients with the same symptom presentation are diagnosed with Schizophrenic Disorders (Neighbors, Trierweiler, Ford, & Muroff (2003).

These findings underscore the need to address racial and ethnocentric bias during the diagnostic process. According to the National Comorbidity Survey, Hispanic clients had surprisingly high prevalence rates of all affective disorders compared to the rates in non-Hispanic white persons and African Americans (Kessler, Chiu, Demler, & Walters, 2005). Although these higher rates may be due, in part, to the stress of acculturation and low socioeconomic status (SES), the higher reported incidence of affective disorders among Hispanic clients may be a result of communication barriers between client and practitioner. Cultural sensitivity education and training for English-speaking practitioners are important aspects of competent mental health practice.

The prevalence of mood disorders seems to be similar across subcultures, although it occurs more frequently in economically depressed areas. The practitioner should be aware of common variations in the diagnosis and presentation of mood disorders based on diversity. For example, women are roughly twice as likely as men to be diagnosed with a depressive disorder. In the United States, men have been raised to minimize emotional expression regardless of their internal state. On the other hand, women have been taught to use emotional expression as a tool for getting their needs met. Clearly, these gender differences concerning emotional expressiveness can influence the practitioner's perception and diagnosis of the client. Generally, practitioners should be careful to avoid overdiagnosing women with depression, as well as underdiagnosing men.

Social Support

Bipolar I and Bipolar II disorders are considered severe mental illnesses. Symptoms associated with these disorders cause serious impairment in the client's social and occupational functioning. Family members and close friends of a person with an affective disorder can feel confused, frustrated, fearful, or angry about the person's dramatic change in mood and inability to cope with daily life events. Families and friends may not understand the problem and why the client cannot just snap out of it.

A psycho-educational group for individuals with similar problems may be an additional source of support for the person suffering from a mood disorder. For example, there are support groups for persons suffering from Bipolar disorders as well as groups for those affected by depression.

These groups provide individuals with a sense of belonging, education concerning the illness, and mutual support. Mental health practitioners conduct some groups; others are organized and run by persons who have previous experience with the disorder (either clients themselves or their family members). With the recent increases in knowledge concerning depression and bipolar moods, there has been a corresponding increase in the numbers of organizations and agencies providing specialized support for individuals with these disorders.

For many people with affective disorders, joining a group may be problematic because of the person's symptoms or because of group availability. Similar constraints may also apply to members of the person's social support system. The Internet contains a wealth of information, including organizations specializing in the support and treatment of persons with mood disorders, online chat rooms and bulletin boards, and current reports and articles related to particular disorders. At the end of this chapter is a list of some useful Internet resources.

Following are two case examples demonstrating a strengths perspective approach.

Case Example 1

Client name: Mary Anne Philips
 Age: 30 years old
 Ethnicity: African American
 Marital status: Married
 Children: Danya, age 6

You are a caseworker in the emergency room of a large urban hospital. You work the day shift from 8 A.M. to 5 P.M. Several hours before you came to work, the police brought the client to the emergency room in restraints. The following information was gathered from the police at intake. The police state that Mary Anne Philips, a 30-year-old African American woman, was found dancing half-naked in the middle of a busy intersection in the center of the city at approximately 2 A.M. She appeared to be high on drugs when the police approached her. She told the police that she had not taken any drugs and that she was "just high on life." She said she was not doing anything wrong, just "having a party." Witnesses stated that Mary Anne had started the evening at a local restaurant and bar. She had been with a couple of gentlemen who seemed to know her. She began telling jokes and buying drinks for everyone at the bar.

At first, she seemed like a person just having fun, but she got louder and rowdier as the night progressed. The two men left, but she stayed at the restaurant, saying loudly, "I'm just getting warmed up here." She sang and danced and finally ended up shoving all the glasses onto the floor and standing on the bar, talking as fast as she could. Customers got irritated, and the bartender asked her to leave. She ignored his request and started singing at the top of her lungs. Finally, the bartender had to force her off the bar and push her out the door. At that point, she began dancing and singing in the street. The bartender told police that she had no more than two drinks throughout the evening. When the police attempted to get Mary Anne out of the road, she became belligerent and began swearing at the officers. They had to take her out of the middle of the intersection by force and handcuff her to get her into the police car. Lab tests indicated no evidence of excessive alcohol or other drugs. The physician on duty had prescribed a sedative, and Mary Anne went to sleep at approximately 5 A.M.

You go to see Mary Anne at 9:30 A.M. She is lying in bed, quietly staring at the ceiling. She seems very subdued in comparison to the description of the previous night. She glances at you as you enter the room but makes no attempt to sit up. You tell her who you are and your reasons for wanting to talk to her. Mary Anne makes no response to your introduction. You ask if she has any relatives you could call for her. She looks over at you and says, "I just want to die. If it weren't for my baby, I'd have been dead a long time ago."

"What's your baby's name?" you ask. "Danya," Mary Anne replies. "I'm such a lousy mother lying here like this. I should be home taking care of her." "Where is Danya now?" you ask.

"She's with my sister. She stayed with my sister last night," Mary Anne responds. "I knew I was racing, so I took her over to my sister's house." "You were racing?" you query.

"Yeah, you know, I start racing sometimes, feeling real good and full of energy like nothing can stop me," Mary Anne says. "But not now; I feel lousy now, like I just want to be left alone to die." "Can you tell me what happened last night?" you ask. "It's like living on a roller coaster," Mary Anne tells you. "One minute you're way up there, and the next minute you're in the blackest hole you can imagine." "And last night, you were way up there?" you query. "Yeah, I was just feeling good and having

a good time. It's like you're racing and you can't slow down. Like you're high or something, but I didn't take any drugs. I don't do drugs. This just comes over me sometimes, and I feel like I could take on the world." "Have you ever felt this way before?" you ask. "Oh yeah, up and down, that's how I am," Mary Anne says. "So, sometimes you feel really good and up, and then, sometimes you feel really down. Is that right?" you ask. "Yeah, I'm scared I'm beginning to crash now. It's bad when you come down. It feels real bad," she says. "It lasts for weeks and weeks ... just down all the time." "How often does this happen, going from one extreme to another?" you ask. "Once a day or once a week or once a month?" "See, for a few weeks I feel great. I can do anything—stay up all night having a good time. I don't sleep or eat or slow down. I just keep on going for a week, maybe two. Then, I begin to crash."

"Do you hear voices or see things when you're feeling high?" you ask. "No, except for my own voice. I can't stop talking either. Gets me into trouble, sometimes," Mary Anne admits.

"What else happens when you're feeling high?" you ask. "I want to party. I can party all night when I'm high. I'm the life of the party," Mary Anne says glumly. "Have you ever gotten in trouble before, like you did last night?" you ask. "Oh yeah," Mary Anne agrees. "I've gotten thrown out of places lots of times, but I usually just move on down the street." "Are you employed?" you ask. "I've tried to keep a job. Just can't seem to stick with it," Mary Anne replies. "How are you feeling right now?" you query. "Feel like hell," she tells you. "This is a rotten way to live, I'm telling you." "How long does the crashing last?" you ask. "Sometimes a few days, sometimes a few weeks," Mary Anne says bleakly. "Describe for me what these down times are like for you," you suggest. "It's like I'm a balloon and someone stuck a needle in me. I'm so sad that nothing looks good. It's hard to get out of bed and face the world. ... I sleep and sleep and sleep. When I do get up, I'm so tired that it feels like I'm carrying around invisible weights."

"What kinds of things go through your mind when you feel like this?" "I can't think of anything I want to do," Mary Anne tells you. "I can't seem to make myself think anything all the way through. Like making a decision about something no matter how trivial is just impossible. Sometimes, I just wish I were dead." "Are you wishing you would die now?" you ask. "Not yet ... but it usually does get to that point when I crash." "Have you ever

seen a doctor for these changes in your mood?" you ask. "One doctor told me it was just a 'female thing,'" Mary Anne states.

"Maybe it's more than a female thing," you suggest. "Maybe there's some medication that could help even out your moods. Would you be willing to talk to a doctor about how you've been feeling?" you ask. "Okay. I guess it wouldn't hurt," Mary Anne says.

The following are some questions you should consider:

- To what extent do you think Mary Anne may be a danger to herself?
- What other information would be useful in determining her risk?
- What would you like to know about Mary Anne's social support system?
- Are there any steps you would take (given the client's permission) to ensure that her support system stays intact?
- What internal and external strengths do you see in Mary Anne's case?
- What is your initial diagnosis? 296.42
Bipolar Disorder, most recent episode manic, moderate, rapid cycling.

The first three digits for bipolar I disorder are 296. The fourth digit indicates the nature of the current episode, with 4 indicating hypomania or mania (as in this case). The fifth digit would not have been used if the most recent episode were hypomania or unspecified. However, as this case indicates the most recent episode as manic, the fifth digit indicates the severity of the episode; 2 indicates a moderate severity, which is an extreme increase in activity and impairment in judgment. The specifier at the end of the diagnosis of rapid cycling is used because at least four episodes of a mood disturbance were seen in the previous 12 months.

Case Example 2

Client name: Sally Tannerg

Age: 36 years old

Ethnicity: Caucasian

Marital status: Married

Occupation: Homemaker

Children: Three children; currently pregnant with her fourth child

Little information was obtained from a phone call interview with Mrs. Tannerg by the intake

worker. She stated that her psychiatrist in Massachusetts had referred her to Dr. Browning in Southfork, Oklahoma, for prescription monitoring. Dr. Browning has referred her to the Southfork Counseling Center to see a therapist. She requested an appointment with a therapist and said only that she had been hospitalized recently in Massachusetts before moving with her family to Oklahoma. She stated that it was very important that she begin therapy immediately but did not want to discuss any details of the problems she has been experiencing lately. The intake worker scheduled her for the first available appointment with you later in the week.

Sally Tannerg is an attractive, 36-year-old woman whose warm and effervescent personality is apparent from the first meeting. You notice that she is several months pregnant. She appears eager to get to your office and asks you how long you have lived in Southfork. You explain to her that you moved to Southfork after completing your master's degree two years ago. "When did you move to Southfork?" you ask. Sally wriggles in her chair and enthusiastically begins talking about her husband being relocated to Oklahoma to accept a new position with his company, which develops software for computer companies. She states that she has never lived in the Midwest, having grown up in Boston. She moved to another town in Massachusetts when she got married 10 years ago. "We've been in Southfork for three months, and I feel like a fish out of water," Sally tells you. "I've got most of the responsibility for taking care of my three children and as you can see, I'm about to have another one. Bob, my husband, travels three or four days a week with his job, so I'm stuck at home with my children most of the time ... not that I'm complaining. Bob has a good job and he has to travel, but it's a lot of work for me, and I haven't made a lot of friends yet. When I lived in Revere, Massachusetts, I had a lot of neighbors who were young mothers like me with kids, and we'd get together and baby-sit for each other and take our children to different activities. It was nice until I got sick."

"What happened when you got sick?" you ask Sally. "Well, I've always been a pretty optimistic, upbeat type person with a lot of energy. Then, suddenly, I had no energy. I was drained. I was so tired I couldn't move and just got completely depressed. I was suicidal and felt hopeless about everything. I thought 'here I am with three little children and I can't get off the couch to take care of them.' I felt like a complete failure as a

mother, just completely worthless. I didn't want to do anything except sleep and block out the entire world. I wasn't interested in sex with my husband. I didn't care if I lived or died. It just got so bad that the psychiatrist I was seeing put me in the hospital." Sally slinks down in her chair and sighed deeply.

She takes a deep breath and then begins talking again. "Everything just looked so black. I couldn't imagine feeling any worse ... and my poor kids. All I could think about was that I would die and they would be motherless. And then I began to feel better. I mean like overnight I felt a whole lot better. I had plenty of energy, and thoughts and ideas just flew through my head and I was on top of the world again. I told the doctor I was just fine and he should let me go home." "How long had you been in the hospital when you began feeling so much better?" you inquire. "About four weeks," Sally says and sighs. "Then I was okay—or so I thought." "So initially, you were really depressed when you went into the hospital, and then you began to feel much better. Were you taking any medication?" you ask. "Well, that's the really scary part about this problem I have. You see, the feeling of being on top of the world didn't last very long. Pretty soon, I was in the depths of despair again, and the medicine wasn't working. So the doctor said I really needed to be on lithium. I didn't want to take anything because by then I knew I was pregnant again. But I was so depressed I didn't know what else to do. I'm so worried about the medicine affecting the baby. The doctor has put me on a low dosage until the baby is born. I'm just keeping my fingers crossed the baby will be okay. Do you think that makes me a bad mother?" "It sounds as if the psychiatrist thinks you really need to be taking lithium right now," you respond. "You're trying to take care of yourself."

"He told me it was absolutely necessary if I wanted to stay out of the hospital," Sally replies. "I never want to go through that experience again. And I'm not sure it's really helping. I have to go get my blood tested every two weeks, and I'm not sure I've got enough of the medication in me to do me any good. I have days when I feel like I can function pretty well, and then there are other days when I feel like I'm sliding into a black hole and can't get out of it. It's an awful feeling." "These feelings of depression just started about a year ago? Is that correct?" you inquire. "Yes, I never felt down in the dumps and completely hopeless like I have this year. You

know, I remember as a child, my father would have periods of deep depression. He was like Dr. Jekyll and Mr. Hyde. Some days he'd be great to be around and he'd play with us and laugh. Other times, he was really scary. He'd sit in a dark room and stare out the window for hours, and if any of us kids did anything that perturbed him, he'd get so angry that he'd take us behind the house and give us all a spanking. You could never tell what kind of mood he'd be in. I was scared of him my whole childhood. I sure hope I'm not turning into someone like him."

"Did you father ever see a doctor about his moods?" you ask. "No, he thinks only crazy people see psychiatrists. I told Bob not to tell my parents I was in the hospital. They would have disowned me. They are strict, conservative Lutherans, and believe me, they wouldn't ever understand. They'd tell me I'd be okay if I went to church."

It seems to you that Sally identifies with her father's mood swings to some degree, and you decide to get more information about her family of origin. "Tell me what it was like for you growing up in Boston," you say.

Sally sits back in her chair and looks out the window. "Well, it was your typical Lutheran family growing up in the sixties and seventies, I guess. I have five siblings—two older brothers, an older sister, and two younger sisters. My parents were strict and fairly religious. We went to church on Sundays every week without fail. My mother cared for us while my father worked. We were a middle-class family, I guess. We never had a lot of money, but we weren't starving to death either. My parents sent us all to a Lutheran school that cost more than public school but wasn't like a private school. I think I have a real problem with feeling guilty about everything. My father reinforced that feeling of guilt all the time. He was very distant and authoritarian. We got punished a lot as children, and although I don't think I really thought so at the time, it was pretty harsh punishment by today's standards. It seemed like I was always in the way when my father got mad, and I got punished more than my sisters and brothers."

"How do you feel about that time growing up?" you inquire. "I guess I consider it a pretty normal childhood," Sally suggests. "All the kids in the Lutheran school I attended grew up much the same way as I did. I think my mother saved us all from my father's wrath on many occasions. She had a way of diverting his attention away from us when we were in the line of fire." "And what

is your relationship like now, with your parents?" you ask. "Since I've been in the hospital, I've discovered I have all this anger toward my father," Sally states. "I've been scared of him my whole life, and I'm tired of feeling that way and I hate how he made me feel. I've never really had any self-esteem and have always felt like I'm cowering in the corner afraid of my own shadow because of what he did to me." "And your mother? How do you get along with her?" you ask. "We get along well. We always have. I think we have a lot in common and she's had to put up with a lot, too," Sally says with a smile.

"Do you feel that the way you were raised has something to do with the depression you've been experiencing, or do you think it's unrelated to your childhood experiences?" you ask. "I don't really know," Sally states. "It's something I want to figure out. The doctor told me some of this could be a neurochemical problem. Sometimes, I feel great and full of energy. In fact, it's hard to slow down. I become really talkative and friendly. It's like everything speeds up. Thoughts run through my head really fast, and I can't even sleep when I feel that good. It's like being high." "How often does that happen?" you ask. "It seems to happen about once a month after I've been really depressed," Sally states. "But it doesn't last as long as the depressed periods." "Do you ever feel that you place yourself in high-risk or dangerous situations when you have a 'high' feeling?" you query.

"No, I don't think so," Sally reflects. "I have some pretty fantastic thoughts, but I don't actually do anything. I've got to think about my children and the one on the way." "Okay, so you feel depressed a lot of the time, and sometimes, about once a month, you feel pretty good and full of energy. How long do you usually have that 'high' feeling?" you ask. "It can last from three or four days up to a week before I begin sliding downward again," says Sally. "I always hope it will last longer, but it never does." "So, it sounds like one of your goals is to learn how to cope with some of these ups and downs you've been experiencing," you note. Sally says enthusiastically, "Yes, exactly, I need some help with the best way of coping with these moods, especially during this pregnancy." "Would it be all right with you if I talked to the psychiatrist who is prescribing the medication for you?" you inquire. "I'll need you to sign a consent form." "Absolutely. I'll give you his phone number," Sally asserts. "Would you like to make an appointment on a weekly basis?" you ask.

Sally nods her head vigorously and says, "I'm so glad I've found someone I can talk to who

doesn't look at me as if I'm crazy. I definitely want to come once a week to talk to you." "Okay. We'll schedule an appointment for next week," you reply. Sally leaves your office with a little bounce in her step and talks about going to shop for the new baby as you walk her to the reception area.

From this preliminary interview, it would seem that Sally may not have much social support in Southfork.

- How would you go about exploring that issue?
- How important do you think securing local support would be?
- What is your initial diagnosis? 296.89
Bipolar II disorder, depressed, moderate, without full interepisode recovery.

A diagnosis of Bipolar II indicates recurrent major depressive episodes with hypomanic episodes. There are no additional digit specifiers because all five digits are used to indicate the diagnosis. However, you should indicate the current or most recent episode (depressed). If, and only if, the full criteria are currently met for major depressive episode, as in this case, you should specify its current clinical status or features. In this case, "moderate" is indicated. If the full criteria are not currently met for major depressive episode, you would indicate partial remission or full remission. An additional specifier of "with rapid cycling" was used to indicate that at least four episodes of a mood disturbance existed in the previous 12 months.

CONCLUSION

It is estimated that it takes an average of five years from onset of symptoms to reach the correct diagnosis of Bipolar Disorder (Evans, 2000). As such, Bipolar Disorder can be difficult to detect partly because Bipolar Disorder also shares many of the signs and symptoms associated with other psychiatric illnesses such as anxiety disorders and schizophrenia. It is important to keep in mind a common misperception that bipolar mood changes are usually quick and drastic. In reality, mood shifts are often quite gradual. An episode—whether depressive or manic—can last for weeks, months, or even years. People with Bipolar Disorder are not always depressed or manic; they can go for long stretches of time in a normal, balanced mood. The typical

person with Bipolar Disorder has an average of four episodes during the first 10 years of the illness (Keck et al., 2004).

A complete medical history and physical exam should be conducted to rule out other physical conditions. A complete psychiatric history should consider the possibility of other mental disorders. Furthermore, Bipolar Disorder is characterized by mood swings that tend to cycle. In reviewing a patient's history, previous mood swings (perhaps of less severity or duration) may come to light. A family history of medical and psychiatric concerns should be taken because current research indicates a strong genetic component. Finally, a thorough evaluation of current symptoms should be examined.

Guidelines for Selecting and Using Assessment Tools with Children

Craig Winston LeCroy, Stephanie Kennedy, & Andrea Kampfner

Assessment instruments play a vital role in both the clinical and programmatic aspects of social service delivery. Upon referral, these tools help guide effective treatment choices by providing insight into the client's presenting problem. Broadly speaking, these tools illuminate knowledge, attitudes, beliefs, behaviors, or conditions that are symptomatic and/or impede successful functioning. Instruments that track changes in these domains help establish the effectiveness of an intervention. These tools have become the central mechanism for program leadership to articulate and substantiate the positive impacts of their program to their stakeholders.

Until fairly recently the majority of high quality assessment tools were developed exclusively for adult populations. Unfortunately, the developmental differences between adults, youth, and children means that instruments designed for one group do not necessarily translate to other groups. To complicate matters further, the actual process of administering assessment instruments with children is far more nuanced than with adult populations. In addition to communication and comprehension issues, the uniquely vulnerable status of children as dependents adds new levels of complexity to assessing them. Very rarely, if ever, do children admit themselves for treatment. Consequentially, the adults in their lives—those who voiced “the complaint” or need for services—inevitably play a large role in the assessment process and often serve as a “proxy reporter” for the indicated client. The inclusion of caregivers, siblings, mentors, school

personnel, or case managers can create a rich, multifaceted understanding of the presenting problem; however, it can also raise difficult questions in terms of reliability and confidentiality. There is some evidence to suggest that children's perceptions of their conditions do not correlate with those of their caregivers, particularly in social or emotional domains (LaGreca, 1990; Rutter & Taylor, 2002; Sherifali & Pinelli, 2007). As the demand for short-term and effective treatment services for children and adolescents increases (LeCroy, 2008; LeCroy, 2011), so does the need for developmentally appropriate assessment instruments. There must also be an emphasis on guiding practitioners to administer the instruments in sensitive, engaging, and ethical ways. This chapter will review the fundamentals of the construction and utility of child assessment tools, and then move to a discussion of strategies to implement them successfully in social work practice.

BASIC TYPOLOGIES

Assessment tools crystallize information into a useful summary for analysis and comparison. The client's individual scores can be contrasted to normative data sets (i.e., other children at similar developmental stages) or compared to the results before the intervention was put into place (i.e., pre/post testing). Two of the most common forms of assessment tools are behavior rating scales and standardized interviews.

Behavior rating scales are widely used with children because they are brief, they can be filled out by multiple reporters, and they

generally do not require significant training to administer. Another benefit of rating scales is that they provide reporters with a more anonymous context than, for example, face-to-face interviews. This decreases the pressure on the child to report in socially desirable ways (King, 1997). Common examples of behavior rating scales include Child Behavior Checklist (CBCL), Conner's Rating Scales, and Children's Depression Inventory. Conversely, the simplicity of a rating scale can lend itself to bias, especially across ethnic groups. One example of ethnic bias is that Hispanic Americans have been found to choose the extremes ends of 5-point rating scales more than Caucasian Americans (Tyson, 2004). Optimally, a program should use measures that have been validated for their target population in terms of age, gender, ethnicity, and region.

A second typology is the standardized interview. This method refers to an in-person assessment of the child or family wherein the administrator is trained to use the same questions, procedures, and scoring of responses. In this format, clients respond to statements indicating a frequency of occurrence of a behavior, or they rate themselves on scaled items in terms of "a little" or "a lot" or "true" and "false" (see Table 49.1 for one example). The Diagnostic Interview Schedule for Children (DISC) uses software to adapt the interview as the responses are entered. The Child Assessment Schedule, while still standardized, is more qualitative. The benefit of the structured interview is increased engagement and the opportunity to include clinical observation in the process. These strategies, however, can be significantly more time intensive and complex to analyze. There is no single "best" assessment typology, but rather the aim is to find a good fit between a given instrument and the needs of the program.

ADDITIONAL USES FOR ASSESSMENT TOOLS

The main objective of assessment tools is to describe and classify a presenting problem. Additional uses for instruments include screening for early intervention, evaluation of treatment effectiveness, and diagnosis using *Diagnostic and Statistical Manual of Mental Disorders (DSM)* criteria.

TABLE 49.1 Hopelessness Scale for Children

True or false	I want to grow up because I think things will be better.
True or false	I might as well give up because I can't make things better for myself.
True or false	When things are going badly, I know they won't be as bad all the time.
True or false	I can imagine what my life will be like when I'm grown up.
True or false	I have enough time to finish the things I really want to do.
True or false	Some day I will be really good at doing the things I really care about.

Source: Kazdin, 1983.

1. Screening for Prevention/Early Intervention

Assessment tools are increasingly being used to screen children who are in the early stages of developing behavioral, social, or emotional problems (Merrell, 2007). Early screening minimizes the adverse outcomes associated with psychological disorders and "at-risk" environmental situations by initiating appropriate interventions at critical developmental stages. Screening instruments can be used to predict individuals who are at "high-risk" by offering a score that qualifies for preventive intervention. In general, there is a need for further evaluation when children score one or more standard deviations above a normative mean on an instrument.

2. Assessment of Treatment

Assessment instruments can also be useful for assessing changes over time and treatment effectiveness. Typically, these tools incorporate a Likert-scale format (e.g., "strongly disagree" to "strongly agree," "seldom" to "always") to evaluate the frequency or extent of behavioral, social, or emotional symptoms. To properly

function as a gauge of an intervention, the same instrument should be administered at least twice in order to create a standard of comparison. Pre/post assessments contrast the outcome at the end of treatment against a baseline assessment before treatment began. Assessments can also be more frequently administered at various points throughout treatment in order to build a progressive picture of change. Frequent assessment throughout treatment can improve the clinical relationship and has been shown to contribute to a significant decrease in drop-out rates (Miller et al., 2006). Assessment instruments track progress while providing clients with a forum for active participation and feedback. Examples of these types of tools include the Child and Adolescent Functional Assessment Scale and the Eyberg Child Behavior Inventory.

3. Diagnosis

Assessment tools can be used to determine the presence of major categorical psychiatric disorders in children (Rutter & Taylor, 2002; Verhulst & Van der Ende, 2002). Typically, these tools are in the form of structured or semistructured interviews, where certain responses from the child, adolescent, parent, or teacher will determine the interview questions leading to a specific diagnosis. Examples of these interview schedules include the Diagnostic Interview Schedule for Children (DISC) and the Anxiety Disorders Interview Schedule for *DSM-IV* (TR): Child Version ADIS for *DSM-IV* (see Verhulst & Van der Ende, 2002, for review). A frequent challenge to consider when diagnosing children according to the *DSM* is that the time frames for establishing chronicity have not always been structured to account for the rapid nature of growth and change that occurs in children (Lollar, Simeonsson, & Nanda, 2000). Regular application of assessment tools becomes especially important to help distinguish between transient and permanent conditions.

SELECTING ASSESSMENT TOOLS

Assessment instruments are widely used with children in educational, child welfare, and juvenile justice settings. Often these assessments inform life-changing placement decisions for the child. In many cases, children have not received

the appropriate care or placement as a result of clinicians using unreliable and invalid assessments (Tyson, 2004). There are numerous assessment tools available for purchase and many more that are accessible free of charge. However, not all instruments are of equivalent quality or utility, so considerable thought must be dedicated to selecting the correct measurement for a given setting. The main selection criteria are scientific acceptability, relevance, and ease of use.

The scientific acceptability of a measure is described in terms of “reliability” and established “validity.” Reliability refers to the stability and consistency of the results produced by an instrument. Validity, on the other hand, refers to how well the instrument measures what it claims to measure. If a measure is not reliable or valid, the benefits of a good intervention could be masked or the harmful impacts of a poor intervention could go undetected (LeCroy, 2010). Practitioners may need to refer to a standard research text to interpret both the reliability and validity data (See Krysik & Finn, 2006). As a general rule, however, a reliability of 0.80 is considered acceptable for most purposes.

Although documented scientific credibility is beneficial, in this developing field some helpful instruments many fall short of the ideal standard of evidence. In these cases, thoughtful analysis of the individual items on an instrument can help practitioners to make a determination of the “face-validity” of a tool. Do the questions appear to be measuring the concept in a clear and logical manner? Has the measure been tested with the target demographics of a program? Does the measure test similar items in a similar way to the better known instruments for this outcome? Finally, is the instrument sensitive enough to detect meaningful changes over time?

An instrument’s relevance—how well a given instrument correlates to a desired outcome—may seem like an obvious selection criteria. Yet relevance can be easily misunderstood by practitioners and administrators. The most common error is to select an instrument that is conceptually related to a desired change, but not in itself a direct indicator. For example, if a group program is designed to increase children’s social skills, it could seem reasonable to track self-esteem because of an assumption that the two are linked. A clearer and more direct approach is to use a measure that has been validated for demonstrating change in social skills, such as the Matson

Evaluation of Social Skills with Youngsters. Granted, there are outcomes that do not yet have a validated measurement instrument. In these cases, it is possible to use a “proxy outcome measure,” although the proxy measure should be supported by literature that draws a strong correlation between the proxy and the desired outcome. In assessing relevance, keep in mind this primary question: “Will this instrument determine whether a target is improving or deteriorating, so that any necessary modifications in the intervention plan can be undertaken?” (Bloom et al., 2005, p. 209).

Ease of use is an important criterion for real-world use of instruments. Instruments that are time intensive, costly, or require a high level of specified training to administer may not be practical in many settings. Instruments should be well designed graphically, have clear directions, and clear scoring procedures. Some instruments require software to score, which can delay results. Many rapid assessment scales—fewer than 20 questions and can be scored in minutes—are widely available. The trade off for using brief scales is that they have less specific and detailed information, which must also be weighed. High-quality assessment tools are relatively accessible in print and online resources. Some well-known resources include Corcoran and Fischer (2013); McCubbin, Thompson, and McCubbin (1996); Smith and Handler (2006); and Merrell (2007). Online resources include Measurement Instrument Database for the Social Sciences (www.midss.ie) and Ontario Centre of Excellence of Child and Youth Mental Health (<http://www.excellenceforchildandyouth.ca/support-tools/measures-database>).

ADMINISTERING CHILD MEASURES IN PRACTICE

One of the most important developments in the field of assessment has been the recognition that the child’s voice must be central in the process (Smith & Handler, 2006). As children are more regularly included in the assessment process, new types of instruments have been adapted. Table 49.2 lists the various assessment methods that practitioners use to conduct assessments with children and youth. The techniques range from more traditional checklists to more interactive tools such as role-play interviews.

TABLE 49.2 Examples of Different Types of Assessment Measures

Type of Assessment	Example
Clinical interview	Psychosocial history
Semi-structured interview	Child Assessment Schedule
Behavioral observation	Playground observation of behavior
Role-play test	Behavioral Assertiveness Test for Children
Parent reports	Child Behavior Checklist
Teacher reports	Walker Problem Behavior Identification
Peer assessment	Peer rating of status
Self reports	Children’s Depression Inventory
Client logs	Journal of critical incidents
Nonreactive measure	School records of days absent
Cognitive measure	Preschool Interpersonal Problem Solving Test
Performance measure	Matching Familiar Figures Test

In contrast to standard adult practice, with children it is critical to use multiple instruments that draw from multiple reporters (Achenbach, 2011). It is not advisable to rely solely on a parent’s report of a particular behavior without eliciting information from another adult (ideally from a distinct setting, such as school) and from the child. This method is more time intensive and does demand more sophisticated practitioner discernment; there are, however, two central reasons for taking the additional steps.

First, child behaviors are often environmentally contingent. Children are under the social control of others and, as a consequence, children’s

behavior can be situationally specific (Achenbach, 2011). For example, hyperactive behavior in the classroom may not predict overactivity in the home. Specifying exactly when, where, and to what degree the behavior exists helps create a multidimensional understanding of the problem which, in turn, illuminates the most strategic intervention plan. Using the above example, if hyperactivity is reported only in the classroom, then the focus can shift from exploring ADHD to possible environmental factors or learning problems.

A second consideration is that administering instruments to children requires particular clinical sensitivity. Many children may lack insight into their behaviors or they may fear consequences for telling the truth. The inherent pressure of assessment can be distressing. Under duress, children are susceptible to answering according to what they believe to be socially desirable. High-quality instruments have likely been specifically designed to mitigate this effect (Achenbach, 2011), yet the onus remains on the administrator to help the child feel more comfortable. The administrator must ensure that children understand exactly why they are being asked to complete instruments, what the information will be used for, and with whom the results will be shared. Failing to do so is not only unethical, but it undermines accuracy. Simple verbal reminders throughout the process, such as “there are no right or wrong answers,” can also help improve authenticity.

For certain topics—such as suicidal ideation, substance use, sexual experiences, or abuse—the administration of the measures is nearly as important as the content of the measure. In these areas, clients rarely spontaneously self-disclose (Lawrence et al., 2010). Tracking outcomes for sensitive content continues to be problematic; however, the use of touchscreen and computer-based technology has demonstrated promise as a more effective and accurate assessment format. Both adults and children are more likely to disclose sensitive information when using computer-based assessment instruments (Lawrence et al., 2010). Many children are comfortable with technology and may be more engaged in the process as a result. Opting for audio voice commands through headsets can help when literacy is a concern. Technology opens the possibility for ever more innovative and user-friendly measurement instruments. Katharina Manassis and colleagues (2009) found

that traditional measures for anxiety could not be validated with children under 8 years of age because of vocabulary barriers. This is problematic because the onset of anxiety can occur as early as preschool. Nonverbal assessments, such as visual “thermometer” scales, are helpful but are also heavily contingent on cognitive ability (Shields et al., 2003). The Mood Assessment via Animated Characters (MAAC) developed by Manassis et al. uses a computer-based program with animated cartoon characters to help young children identify symptoms in a way that is developmentally adapted. Emerging measurement instruments, such as the MAAC, highlight that in clinical practice with children it is vital to select the correct instruments but also critical to implement them in engaging and thoughtful ways.

50 Assessment Protocols and Rapid Assessment Tools with Troubled Adolescents

David W. Springer, Stephen J. Tripodi, & Stephanie Kennedy

Troubled adolescents present a set of unique challenges and opportunities to social work practitioners. Though there are clearly similarities between conducting an assessment with adolescents compared with children or adults, there are also distinct differences that warrant special consideration. Adolescents are negotiating specific developmental tasks, such as transitioning from the family to the peer group, developing a sexual identity, and managing encounters with drugs and alcohol. Anyone who has worked with adolescents will certainly agree that they bring a unique (and often refreshing) perspective to the helping relationship that a competent practitioner integrates into a thorough assessment protocol.

In addition to the importance placed on recognizing the developmental tasks of adolescence during the assessment process, this chapter rests on the assumptions about assessment presented by Jordan and Franklin (1995): "(1) assessment is empirically based, (2) assessment must be made from a systems perspective, (3) measurement is essential, (4) ethical practitioners evaluate their clinical work, and (5) well qualified practitioners are knowledgeable about numerous assessment methods in developing assessments" (p. 3). These assumptions serve as a guide for social workers when determining what type of assessment protocol to implement with adolescents (and their families).

The first of these assumptions, that assessment is empirically based, was addressed in 2005 when the *Journal of Clinical Child and*

Adolescent Psychology devoted a special section on developing guidelines for the evidence-based assessment of child and adolescent disorders, where evidence-based assessment (EBA) is "intended to develop, elaborate, and identify the measurement strategies and procedures that have empirical support in their behalf" (Kazdin, 2005, p. 548). In this special issue, Mash and Hunsley (2005) emphasize the great importance of assessment as part of intervention and acknowledge that the development of EBA has not kept up with the increased emphasis on evidenced-based treatment. In fact, there is a significant disconnect between EBA and evidence-based treatment. This is particularly true for youth with comorbid disorders.

COEXISTING DISORDERS

The terms comorbid disorders and coexisting disorders are frequently used interchangeably to describe adolescents who are struggling with several mental health issues, like depressive and anxiety disorders or posttraumatic stress and obsessive-compulsive disorder. The term dual diagnosis, on the other hand, refers to individuals who have both mental health diagnoses and a substance use problem. Although the newly released *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)* (American Psychiatric Association, 2013) has moved away from the multiaxial system and reframes mental disorder and substance misuse

categories as dimensions, the terminology above will be retained in this chapter to improve clarity. A substantial percentage of adolescents seen by social workers in the United States have coexisting disorders or a dual diagnosis. For example, findings from the National Comorbidity Study indicate that 41% to 65% of individuals with substance use disorders also meet criteria for a mental disorder, and approximately 43% to 51% of those with mental disorders are diagnosed with a substance use disorder (Kessler et al., 2005; Tripodi, Kim, & DiNitto, 2006). Roberts and Corcoran (2005) assert that dually diagnosed adolescents are, in fact, not a special subpopulation of adolescents but are instead the norm. The majority of adolescents seeking services today are thus likely to have substance use problems, mental health diagnoses, as well as myriad social, behavioral, and familial problems (Bender, Springer, & Kim, 2006).

Given the prevalence of coexisting disorders in clinical settings and the seriousness of making false-positive or false-negative diagnoses, it is critical that social work practitioners assess for the presence of coexisting disorders in a deliberate manner rather than making “on-the-spot” diagnoses. A social worker’s assessment often helps guide treatment planning. Misdiagnosing an adolescent as not having (or having) a certain set of problems (e.g., mistaking acting out behaviors related to poverty as conduct disorder, confusing symptoms of ADHD with bipolar disorder) can pose serious consequences for the course of treatment (e.g., the wrong medications may be prescribed, adolescents and their families may be turned off to treatment owing to repeated treatment “failures”). Using sound assessment methods can help eliminate such pitfalls.

ASSESSMENT METHODS

There are various methods of assessment available to social work practitioners that can be used with adolescents. These include but are not limited to interviews, individualized rating scales, rapid assessment instruments, and standardized assessment tools. Though the focus of this chapter is primarily on the use of standardized assessment tools and rapid assessment instruments with adolescents, the importance and clinical utility of other available assessment methods, such as conducting a thorough interview, are also underscored.

Interviews

The assessment process typically starts with a face-to-face interview (e.g., psychosocial history) alone with the adolescent so he or she does not feel restricted disclosing information in the presence of his or her family. The family, however, should also be interviewed, both separately and with the adolescent. This allows the practitioner to hear the perspectives of, and establish rapport with, all key players in the system and gain a deeper understanding of the adolescent’s life. Additionally, separate interviews enable the social worker to triangulate information, determining whether and how each version of the story differs. (It is important to note that the practitioner has to negotiate how to maintain the confidentiality of the adolescent client if also working with the family system.)

Consider the following case for illustration purposes. Robert, a 14-year-old Caucasian male, is brought to your agency by his parents because he is “failing most of his classes and is totally withdrawn.” The week before, Robert’s parents had discovered large quantities of marijuana and pills in his bedroom and note that he has made several recent comments about wanting to end his life. In addition to obtaining information from Robert’s parents typically covered in a psychosocial history (e.g., medical, developmental, social, and family history), some areas that the social worker may cover with family members during an initial interview are as follows:

- Presenting problem and specific precipitating factor (e.g., “Tell me in your own words what prompted you to bring Robert in for help at this point in time?”)
- Attempts to deal with the problem (e.g., “What has your family tried to deal with this problem(s)? What have you tried that has worked?”)
- Hopes and expectations (e.g., “What do you hope to get out of coming here for services? If you could change any one thing about how things are at home, what would it be?”)
- Exceptions to the problem (e.g., “When was the problem not evident in your recent past? What was different then?”).

In addition to these areas of inquiry (with variations of the corresponding sample questions), consider some questions that the social worker may ask Robert individually:

- Peer relationships (e.g., “Tell me about your friends. What do you like to do together?”)
- School (e.g., “What are your favorite [and least favorite] classes at school? What about those classes do you like [not like]?”)
- Suicide risk (e.g., “When you feel down, do you ever have any thoughts of hurting/killing yourself? Do you ever wish you were dead? How would you end your life?”)
- Substance use (e.g., “What do you drink/use? When was the last time you had a drink or used? How much did you have? Have you ever unsuccessfully tried to reduce your substance use?”)
- Targeted behavior/goal setting (e.g., “If there was anything that you could change about yourself/your life, what would it be? What do you like most about yourself?”).

Of course, the foregoing questions are meant only to illustrate the range of issues that one might address during an interview. A complete psychosocial history needs to be conducted. Information gathered from the face-to-face interview can subsequently be used to inform a more in-depth assessment in targeted areas, which, in turn, guides treatment planning. Individualized rating scales, rapid assessment instruments, and other standardized assessment protocols may prove useful for this purpose.

INDIVIDUALIZED RATING SCALES

Individualized rating scales are nonstandardized assessment tools that the client and the social work practitioner tailor to specifically meet the client’s needs and measure the client’s unique targeted outcomes (Bloom, Fischer, & Orme, 2009). These scales are used to measure change during the course of treatment, before, during, and after an intervention, or to track the strength or magnitude of a specific problem for one client across time.

Individualized rating scales can be an especially potent tool to show clients how they are progressing toward a goal. For example, imagine a client who comes to you for help managing severe panic attacks that occur at seemingly random intervals throughout the day. After conducting a thorough interview and obtaining a psychosocial history, you could ask the client to begin tracking the total number of panic attacks per day, the time the attacks occurred, and what

they were doing immediately preceding the attack. By the second session, you and the client would have a reference point, or baseline, of the problem (in this case, panic attacks) and a wealth of information about when and under what circumstances attacks are most likely to occur (Bloom, Fischer, & Orme, 2009). If treatment is successful, the client will be able to see the total number of panic attacks per day drop, reinforcing the good work they are doing. If, on the other hand, treatment is unsuccessful, it will be readily apparent in the client’s rating scales, allowing you and your client to discuss new strategies to tackle this problem. Individualized rating scales are often used in conjunction with standardized scales as an additional, and more personal, form of assessment.

RAPID ASSESSMENT TOOLS AND STANDARDIZED ASSESSMENT TOOLS

Rapid assessment tools (RATs; Levitt & Reid, 1981) are short-form, pencil-and-paper assessment tools that are used to assess and measure change for a broad spectrum of client problems (Bloom, Fischer, & Orme, 2009; Corcoran & Fischer, 2013; Hudson, 1982). RATs are used as a method of empirical assessment, are easy to administer and score, are typically completed by the client, and can help monitor client functioning over time. Given the proliferation of RATs and standardized tools in recent years that measure various areas of adolescent functioning, it can be an overwhelming task to select a tool for use with an individual client. Thus, some guidelines are provided here.

The social work practitioner needs to take several factors into consideration when choosing an RAT or standardized protocol for use with clients, such as the tool’s reliability, validity, clinical utility, directness, availability, and so on (Corcoran & Fischer, 2013). To the extent that an RAT has sound psychometric properties, it helps practitioners measure a client’s problem consistently (reliability) and accurately (validity). Using reliable and valid tools becomes increasingly critical as one considers the complexities surrounding assessment with adolescents who (potentially) have comorbid disorders. A brief overview of reliability and validity is provided next; however, the reader is referred to the other sources for a more detailed exposition on these topics (Abell, Springer, & Kamata, 2009; Corcoran & Fischer,

2013; Hudson, 1982; Springer, Abell, & Hudson, 2002; Springer, Abell, & Nugent, 2002).

Reliability. A measurement instrument is reliable to the extent that it consistently yields similar results over repeated and independent administrations. There are several types of reliability, including interrater, test-retest, and internal consistency. All three types of reliability are designed to assess, and it is hoped minimize, measurement error. Interrater reliability refers to the degree of agreement between or among observers. When raters are in agreement about how they would assess a client or behavior, then the researcher can be more confident that the outcomes observed are “real” and not purely a function of measurement error. Test-retest reliability is a measure of a tool’s consistency over time. Using a stable measure helps the researcher attribute changes in score to the intervention or treatment, rather than variations in measurement. Internal consistency is a measure of how strongly the items on a standardized scale correlate to one another. This information is represented through reliability coefficients, which range from 0.0 to 1.0. What constitutes a satisfactory level of reliability depends on how a measure is to be used. For use in research studies and scientific work, a reliability coefficient of 0.60 or greater is typically considered acceptable (Hudson, 1982). However, for use in guiding decision making with individual clients, a higher coefficient is needed. Springer, Abell, and Nugent (2002) provide the following guidelines for acceptability of reliability coefficients for use with individual clients:

- < 0.70 = Unacceptable
- 0.70–0.79 = Undesirable
- 0.80–0.84 = Minimally acceptable
- 0.85–0.89 = Respectable
- 0.90–0.95 = Very good
- > 0.95 = Excellent.

The greater the seriousness of the problem being measured (e.g., suicidal risk), and the graver the risk of making a wrong decision regarding a client’s level of functioning, the higher the standard that should be adopted.

Validity. Where reliability represents an instrument’s degree of consistency, validity represents how accurately an instrument measures what it is supposed to measure. There are various ways to determine an instrument’s validity: face validity, content validity, criterion-related validity, construct validity, and factorial validity.

Face validity refers to whether the concepts in an assessment tool are in agreement with common perceptions of those concepts. For example, if we designed a depression measure, respondents should be asked about sadness and thoughts of suicide, rather than given math problems to solve. Content validity takes face validity one step further, by evaluating whether a measure covers all aspects of a concept. In our depression measure example, we would want to be sure the assessment tool did not ignore key features of what depression looks like and feels like for many people.

Criterion-related validity and construct validity, on the other hand, assess how a measure relates to some external concept. That is, individuals who score high on our depression measure should also score high on other standardized depression measures. Likewise, if our measure suggests a person might be struggling with depression, then other facets of their life should not suggest otherwise. We would not expect a person with depression to state that they feel great, have plenty of energy, and are excited for the future.

Finally, factorial validity has to do with how many concepts an assessment tool measures. For instance, if our scale measures both the physical and the emotional experience of depression, we would expect a statistical factor analysis to show two distinct factors. The items about the emotional side of depression should group together and the items assessing the physical experience of depression should group together. If they group differently than we expected them to, or if a factor analysis suggested that only one construct (or ten constructs) were actually being measured on our scale, we would have to go back to our items and consider if our content really was measuring depression in the way we intended. Additionally, the social worker must make decisions about a measure’s validity in relationship to its intended use. In other words, he or she must determine if the measure is valid for that particular client in a particular setting at a given time. A measure may be valid for one client but not for another.

The number of standardized tools developed specifically for use with adolescents has grown considerably in recent years, and it is impossible to review them all here. However, selected standardized tools that may be useful in assessing for comorbid disorders in adolescents are briefly reviewed next. Each tool has sound psychometric properties and can be used to help guide

treatment planning and monitor client progress over the course of treatment.

Child and Adolescent Functional Assessment Scale (CAFAS). The CAFAS (Hodges, 2000; Hodges, Xue, & Watring, 2004) is a validated standardized instrument used to measure the degree of impairment in youth ages 7 to 17 years (Bates, Furlong, & Green, 2006; Boydell, Barwick, Ferguson, & Haines, 2005). It is a clinician-rated measure, covering eight areas of functioning: school/work, home, community, behavior toward others, moods/emotions, self-harmful behavior, substance use, and thinking. In each of these domains, the practitioner chooses behavioral indicators about the youth's functioning. Some sample items are as follows:

- Frequent display of anger toward others; angry outbursts
- Talks or repeatedly thinks about harming self, killing self, or wanting to die
- Frequently intoxicated or high (e.g., more than two times a week)
- Frequently fails to comply with reasonable rules and expectations within the home.

The youth's level of functioning in each domain is then scored as severe (score of 30), moderate (score of 20), mild (score of 10), or minimal (score of 0). These scores are graphically depicted on a one-page scoring sheet that provides a profile of the youth's functioning in each area. The CAFAS also contains optional strengths-based and goal-oriented items (e.g., good behavior in classroom, obeys curfew) that are helpful in guiding treatment planning. A computerized software program is available that scores the CAFAS, generates a treatment plan, and produces outcome reports to help practitioners track client progress (Hodges, 2000).

Behavioral and Emotional Rating Scale (BERS-2). The Behavioral and Emotional Rating Scale, Second Edition (BERS-2; Epstein & Sharma, 2004) is a strengths-based battery of three instruments that measure functioning in youth across five different areas: interpersonal strength, family involvement, intrapersonal strength, school functioning, and affective strength. A key feature that distinguishes the BERS-2 from other standardized tools (e.g., Achenbach's widely used Child Behavior Checklist [CBCL]) is that it is truly based on a strengths perspective (in contrast to a deficit model), and the wording of the

items reflects this outlook. The Teacher Rating Scale (TRS) has 52 items and is one of the three measures in the BERS-2 package. Some sample items from the TRS are:

- Maintains positive family relationships
- Accepts responsibility for own actions
- Pays attention in class
- Identifies own feelings.

The strengths perspective makes this tool particularly appealing to parents, adolescents, and social workers who strive for a helping relationship that centers on client strengths and empowerment. The BERS-2 has been validated with many different populations, including Hispanic and African American adolescents in the United States, and both Spanish and Arabic-language versions of the scale have been validated (Farmer et al., 2005; Gonzalez, Ryser, Esptein, & Shwery, 2006; Mooney, Epstein, Ryser, & Pierce, 2005; Mutairi & Khurinej, 2008; Sharkey, You, Morrison, & Griffiths, 2009).

Adolescent Drug Abuse Diagnosis (ADAD). The ADAD (Friedman & Utada, 1989) is a 150-item semistructured standardized assessment scale that addresses nine areas of functioning: medical, school, employment, social relations, family relations, psychological, legal, alcohol use, and drug use. Severity ratings (on a 10-point scale) are computed for each area to indicate the adolescent's need for treatment in each area. The ADAD has been validated in three recent studies—one of which compared it to another outcome scale for children and adolescents (Holzer et al., 2006) and two of which validated the scale in Swedish (Börjesson, Armelius, & Ostgård-Ybrandt, 2007; Ybrandt, 2013).

Additional Rapid Assessment Tools. In addition to the standardized tools reviewed here, there are numerous RATs that can be used with adolescents to measure functioning across various areas, such as risk of running away (e.g., Adolescent Concerns Evaluation), suicidal tendencies (e.g., Multi-Attitude Suicide Tendency Scale), posttraumatic symptoms (e.g., Child and Parent Report of Post-traumatic Symptoms), conduct-problem behaviors (e.g., Eyberg Child Behavior Checklist), family functioning (e.g., Family Assessment Device, Index of Family Relations), and peer relations (Index of Peer Relations), to name just a few (Corcoran & Fischer, 2013). There are also standardized

general behavior rating scales (e.g., Louisville Behavior Checklist, Child Behavior Checklist, Conners Rating Scales) and tools that are useful for measuring the degree of functional impairment (e.g., Children's Global Assessment Scale) (Shaffer, Lucas, & Richters, 1999).

CONCLUSION

The field continues to make progress in developing user-friendly standardized assessment tools with sound psychometric properties that can be used in assessment with adolescents. Although these tools should not take the place of a face-to-face psychosocial history, they should be used to complement the assessment process and track progress in client functioning over the course of treatment. It is important to emphasize that a standardized tool does not take the place of a solid therapeutic helping relationship. Social workers should take care to build rapport with adolescent clients prior to administering standardized assessments or RATs. Establishing a relationship and explaining why and how assessments will be used can help mitigate against making treatment decisions based solely on the score of an assessment tool. After all, the goal is to help adolescents make desired changes as they move forward into adulthood.

Social workers have an ethical obligation to use empirical assessment protocols and standardized tools whenever possible, rather than relying solely on gut feelings when conducting assessments with adolescents. The importance of empirical assessments with troubled adolescents was reiterated by a Blue Ribbon Taskforce in Texas, convened after several sexual abuse scandals surfaced at the Texas Youth Commission. Professor David Springer was appointed to serve as chair of the taskforce, and asked to create a proposal to better serve the needs of Texas youth, their families, and their communities. Together with a team of juvenile justice scholars from throughout the United States, Professor Springer's taskforce made recommendations to improve prevention policies, treatment strategies, and assessment among a juvenile justice population. Regarding assessments, the Taskforce suggested that: (1) Facilities should only incarcerate high-risk, serious, and chronic juvenile offenders (determined by extensive evidence-based assessments); (2) A continuum

of care should minimize the penetration of youth into the juvenile and adult justice systems (continuum of care is determined by extensive evidence-based assessments); and (3) Referral and treatment decisions should be formed by risk assessments that are multipronged and ongoing, with services that are flexible and tailored to meet the individual needs of the client system (Springer and Colleagues, 2007).

The potential consequences of misdiagnosing a client like Robert can be severe. Thus, social work practitioners are encouraged to make use of available empirically based assessment tools within a systems framework to guide treatment planning, monitor client functioning, and evaluate the effectiveness of their interventions.

51 Using Standardized Tests and Instruments in Family Assessments

Jacqueline Corcoran

DEFINITIONS AND DESCRIPTIONS

A measure helps determine the existence of certain behaviors, attitudes, feelings, or qualities—and their magnitude—in clients when they come to a social work practitioner for assistance. The first rule for using measures is to employ an already established measure, one that has been standardized, rather than devising and testing a new one. An inventory (the words *measure*, *inventory*, and *instrument* are used interchangeably) is standardized when it has been tested (normed) on a relevant group of people, a process that results in psychometric data—specifically, information about reliability and validity—that has to meet certain acceptable standards. *Reliability* refers to the consistency and the accuracy of the measure, and *validity* involves the extent to which the instrument measures what it purports to measure. For the different methods of determining reliability and validity, please see a social work research text (e.g., Rubin & Babbie, 2010).

Standardization of an instrument also means there are certain procedures for its administration: Items are completed in the order they appear, certain items cannot be taken out at the

administrator's discretion, nor can only certain items be chosen, because items are considered to be a set. A certain procedure for scoring the measure has also been developed (Corcoran & Fischer, 2013).

Standardized measures can be completed by the client (self-report); by an important collateral person who can make key observations about the client's behavior, attribute, or attitude (a parent, teacher, or spouse, for example); or by the practitioner using an observational measure. This discussion will concentrate on either client self-report measures or inventories completed by parents of children, because the emphasis here is on family assessment.

RATIONALE FOR USE OF MEASURES

Why should social workers use family assessment measures? After all, they take time away from service delivery, clients may resent filling them out and fail to see their relevance, and they require some effort for the practitioner to find and to figure out how to score. However, the use of instruments in family assessment offers several potential benefits (Corcoran & Fischer, 2013).

- They provide detailed information about feelings—attitudes and qualities, and their magnitude, information that may be difficult to observe overtly.
- They aid in the assessment process, helping the practitioner determine the specific issues to address and to select appropriate services.
- They track client progress to ascertain whether interventions proceed in the necessary direction.
- Positive changes may motivate the client to continue to participate in services and to make progress.
- If gathered in sufficient numbers, measures can provide information about the effectiveness of a particular approach or intervention with a group of individuals for an agency, funding source, or dissemination of knowledge to the field.
- They provide evidence to third-party payers for reimbursement or to establish the need for continued services.

SELECTING MEASURES

Selection of measures depends on the purpose for which measurement is targeted (screening, assessment, monitoring progress), the nature of the client's problem, practicality issues, and the psychometric capacities of the instrument (Corcoran & Fischer, 2013). In the purpose of measurement, for example, if the instrument is to assess progress, is it sensitive to clinical change (Johnson et al., 2008)? Issues of practicality include the length of the instrument and the ability of the client to complete it. Corcoran and Fischer (2013) suggest that a scale should take no longer than 10 to 15 minutes to complete. Some measures have both a longer and a shorter version. For instance, the Parenting Stress Index (Abidin, 1995) has a 120-item version and a 36-item version. Other issues of practicality specifically for supervisors and managers include the cost of purchasing measures, the resources involved in training social work staff, the length of time required to score and interpret measures (Johnson et al., 2008), and, if it is necessary to compile the results of multiple scores, the resources involved with finding a usable database system, the construction of a database, data entry, and data analysis.

Psychometric standards for selecting instruments include established validity and reliability.

Many agency personnel rely on instruments they have created to assess client functioning and to measure client change. This is ill-advised, despite the prevalence of this practice; without established reliability and validity, “various alternative explanations for the findings (e.g., examiner bias, chance, and effects of maturation) cannot be ruled out, which seriously restricts the usefulness of findings” (Johnson et al., 2008, p. 7).

Another question related to psychometrics is how similar the client population is to the characteristics of the sample on which the instrument was normed. Many psychological inventories have been normed on undergraduate samples, traditionally from white and middle-to upper-class populations, which may differ in significant ways from high school-educated, low socioeconomic status, and/or minority clients. Although a measure may not necessarily be rejected because it has been normed on a sample dissimilar from the characteristics of a particular client or client group, some care must then be taken on the interpretation of scores.

Several publications have compiled various family assessment instruments. Volume 1 of Corcoran and Fischer (2013) focuses on children, couples, and families. For child and adolescent problems, the interested reader is urged to consult Mash and Barkley (2009), which provides a comprehensive discussion of various self-report instruments, rating scales for teachers and parents, and behavioral observational measures. Corcoran (2000) compiled instruments organized by type of problems for which families may receive services. Corcoran and Walsh (2010) delineate measures that involve child and adolescent *DSM*-defined diagnoses, and Early and Newsome (2005) discuss measures that emphasize strengths for families. Finally, Johnson et al. (2008) specifically address family assessment in relation to child welfare.

The following section details information on family assessment measures, specifically family functioning, parenting practices, and marital functioning, with demonstrated validity and reliability that have been reviewed by Corcoran (2000).

FAMILY FUNCTIONING

Stemming from the field of family therapy and a family systems theoretical approach, three main self-report measures are widely used to assess

the family as the unit of attention (Johnson et al., 2008): the McMaster Family Assessment Device, the Family Environment Scale, and the Family Adaptability and Cohesion Evaluation Scale. These instruments are highly correlated with one another and may be used interchangeably (Olson, 2000; Beavers & Hampson as cited in Johnson et al., 2005).

The McMaster Family Assessment Device (FAD) (Epstein, Baldwin, & Bishop, 1983) is a 60-item, Likert-type self-report measure that assesses overall health/pathology in a general score, as well as six areas of family functioning: (1) problem solving; (2) communication; (3) roles; (4) affective responsiveness; (5) affective involvement; and (6) behavior control.

The Family Environment Scale (FES) (Moos & Moos, 1981) is a 90-item, true-false questionnaire assessing ten dimensions of family life in three general areas: (1) relationship dimensions, which involve cohesion, expressiveness, and conflict; (2) personal growth dimensions, which involve independence, achievement orientation, intellectual/cultural orientation, moral-religious emphasis, and active-recreational orientation; and (3) system maintenance dimensions, which involve organization and control. There are three different forms of the FES: the real form, which assesses members' perceptions of their families; the ideal form, measuring members' preferred family environments; and the expectations form, which assesses members' expectations about family environments.

The Family Adaptability and Cohesion Evaluation Scales, version IV (FACES IV) (Olson & Gorral, 2003). FACES-IV is a 62-item self-report measure in which members rate their families on two different dimensions: (1) adaptability (ability of a family system to alter structure, roles, and rules in response to situational and developmental stress); and (2) cohesion (emotional bonding). FACES IV also assesses family communication and satisfaction.

Parenting Assessment

Measures of parenting often stem from the field of developmental psychology with the caregiver-child dyad as the unit of analysis (Johnson et al., 2008). We focus on the Child Abuse Potential Inventory and the Parenting Stress Index as prime examples of these types of instruments.

The Child Abuse Potential Inventory (Milner, 1986), a 160-item, self-report survey, includes

a 77-item physical child abuse scale with six descriptive factor scales: (1) distress, (2) rigidity, (3) unhappiness, (4) problems with child and self, (5) problems with family, and (6) problems from others. The Child Abuse Potential Inventory can be completed by those with a third-grade reading level.

The Parenting Stress Index (Abidin, 1995) is a 120-item, self-report inventory for parents of children ages 1 month to 12 years. It yields not only a total score of parenting stress but also whether sources of stress may be related to child characteristics (child's adaptability, reinforcing qualities, demandingness, activity level, mood, and acceptability to the parent) or parental functioning (the parent's sense of competence, isolation, depression, attachment to the child, parent health, perceived restrictions of role, depression, and spousal and social system support). The short form (36 items) has the following subscales: (1) total stress, (2) parental distress, (3) parent-child dysfunctional interaction, and (4) difficult child (Abidin, 1995).

Partner Relational Functioning

Several instruments are designed to assess marital functioning. The Marital Adjustment Test (Locke & Wallace, 1959) is a 15-item self-report assessing the accommodation of partners to each other. The Dyadic Adjustment Scale (Spanier, 1999) is a 32-item self-report inventory measuring marital adjustment with four subscales: (1) dyadic consensus (agreement regarding marital issues), (2) dyadic cohesion (the extent to which partners are involved in joint activities), (3) dyadic satisfaction (overall evaluation of relationship and level of commitment), and (4) affectional expression (the extent of affection and sexual involvement). To measure the frequency of various forms of overt marital hostility (e.g., quarrels, sarcasms, and physical abuse) witnessed by children, use the 20-item O'Leary-Porter Scale (Porter & O'Leary, 1980).

Intimate partner violence can be measured by the Revised Conflict Tactics Scales (Straus, Hamby, Boney-McCoy, & Sugarman, 1996). This 78-item, self-report instrument assesses psychological and physical attacks on a partner, as well as the use of negotiation, in a marital, cohabiting, or dating relationship. The following subscales are included: (1) physical assault, (2) psychological aggression, (3) negotiation, (4) injury, and (5) sexual coercion. The items are asked in

the form of questions (what the participant did and what the partner did). They are written at a sixth-grade reading level.

GUIDELINES FOR USING MEASURES

The following are guidelines for the administration of measures:

When Will the Measure Be Completed?

Preferably, before services have begun (so the social worker can assess the impact of intervention), during intake, or at the first contact with the social worker.

Where Will the Measure Be Completed?

A quiet place, free of distractions, with a hard writing surface available—a desk or a clipboard—and appropriate writing utensils.

Why Should the Social Worker Be Present if All Family Members are Completing Measures?

Members might start discussing items among themselves, and the more powerful people in the family might influence others' responses. Children are particularly vulnerable because they often have difficulty reading and understanding items. If parents start reading the measure to the child, children may either respond in a way they think is desirable to the parent, or parents may more actively influence their responses ("You don't feel sad, do you?").

What Procedure Should the Worker Follow in the Administration of Measures?

- Explain the purpose of the measure (see rationale section).
- Read aloud the directions, which include how the client should respond to items.
- Check the instrument over.
- Score the instrument (in front of the client, if at all possible, so immediate feedback can be provided; Corcoran & Fischer, 2013).
- Repeat the measure at a later date (at a designated time frame, such as every month,

at the termination of services, and possibly as a follow-up to services) using similar procedures each time.

- Track scores over time and provide feedback to the client on progress.

What if Clients Seem Unable to Complete Measures?

If individuals are unsure of an answer, they should be encouraged to provide what they think is the best answer. The social worker should avoid interpreting the items or questions.

If a child seems to be struggling to complete an instrument or complains about not being able to understand the items, the practitioner can separate the child from other family members, and the measure can be read aloud to the child.

Adults will not usually volunteer that they cannot read, but if a person seems to be struggling, then the social worker may ask whether the client would prefer that items were read aloud with the worker recording responses.

For non-English-speaking clients, the best source of information on the availability of measures written in other languages is the author of the inventory or the publishing house.

If a client complains about difficulties completing a measure, perhaps he or she could agree to come earlier for subsequent sessions so that completion of an instrument can occur in the waiting area and does not interfere with session time. Other alternatives include selecting a measure with fewer items.

What Should the Practitioner Be Checking for When the Instrument Is Completed?

Items left blank, which can be pointed out to the client, so the measure is fully completed.

Bias in terms of social desirability (i.e., clients responding in a way that they think pleases the worker, or in a way to suggest that services are either not necessary or should not be terminated) or a response set bias, that is, clients answering items in a particular pattern (e.g., all 4s on a 6-point scale) (Corcoran & Fischer, 2013). Inquiring about a particular pattern may provide information about the client's level of comprehension of items or the level of cooperation.

CONCLUSION

The use of measurement instruments for assessment and evaluation will, in all likelihood, increase owing to the demands of managed care. The information provided will assist the social worker not only in choosing appropriate measures for use in family assessment but also aid in gaining familiarity with some of the practical matters involved so that the clinical utility of measurement instruments will be maximized.

Very Brief Screeners for Practice and Evaluation

Steven L. McMurtry, Susan J. Rose, & Lisa K. Berger

A child welfare worker provides in-home services to families in which allegations of abuse or neglect were substantiated, but risk levels were not great enough to warrant any child's removal for placement in out-of-home care. The worker's job is to assess the needs of the parents or adult caregivers in the home and provide services or make referrals. The problem is that in-home services last only about three months, so assessment must be done quickly to allow maximum time for service provision. Also, the worker's agency is under court supervision following a class-action lawsuit, so the worker must show that all assessments are carried out in the most valid way possible. Finally, the range of potential problems affecting caregivers is large, so the worker must be able to screen across areas that range from general mental health to substance use to domestic violence to food insecurity.

The program evaluator in a community mental health center seeks to determine the effectiveness of the center's outpatient services. These consist mostly of case management and short-term individual and group counseling for clients with concerns such as depression, alcohol and drug use, emotional and behavioral problems, and other concerns. Services are typically short-term, lasting from 10 to 90 days. The evaluator has been asked to compare clients' level of functioning on their primary presenting problem before and after intervention. However, as with the previous example, not all individuals have problems in all areas, and each assessment must be valid but brief in order to prevent the overall measurement package from becoming unmanageably lengthy.

A social worker in a Family Resource Center works to connect clients with job training or supported employment opportunities as a part of an integrated service approach in which clients receive assistance for behavioral health or other social service needs that affect their ability to find and maintain employment.

The social worker needs to determine what specific services might be helpful in the limited time available to meet with each client. Screening for potential problem substance use, domestic violence, or depression needs to be done with a measure that is valid, understandable to the client in light of their purpose for approaching the Center, and importantly, brief.

The above examples illustrate a dilemma facing many social workers in direct services and service-support roles: how to measure client problems and progress accurately but briefly. Similar to practitioners in disciplines such as psychology and psychiatry, social workers increasingly rely on *standardized scales*. These are measures composed of items and response options that are usually the same for all subjects and are scored in a specific way. The term "standardized" also implies that the measure meets certain psychometric standards and has been tested on enough subjects to provide a basis for evaluating each individual's score.

Standardized scales include broad-spectrum diagnostic tools such as the Minnesota Multiphasic Personality Inventory (MMPI). It and other early examples tended to be lengthy (100 items or more) and time-intensive (one-hour or longer to administer). Beginning about 1980, more attention was directed toward developing brief measures termed *rapid assessment instruments* (RAIs) (Fischer & Corcoran, 2007). RAIs usually have fewer than 100 items and can be administered in 15 minutes or less. These briefer measures were a better fit with the time available to social workers conducting client assessments, and RAIs such as those in Hudson's clinical measurement package (1982) became widely known. Still, the measurement

task facing many social workers is neither diagnosis nor assessment but screening, which involves rapidly scanning many potential problems and identifying those that require further services. For this, the type of measure needed is what we will refer to as a *very brief screener* or VBS.

CHARACTERISTICS OF VERY BRIEF SCREENERS

VBSs are defined here as measures of known psychometric accuracy that can indicate the potential presence of clinically meaningful problems in most subjects in two minutes or less. Measures containing 200 items or more have sometimes been called "screeners," but we consider brevity to be the signal aspect of a VBS. In practice, this means a maximum of about 12 items.

Other characteristics of VBSs are that they are "first warning" rather than full diagnostic instruments, and their use assumes that further testing will occur before a more definitive decision on the presence or absence of a problem can be made. VBSs may take several forms, including that of self-administered questionnaires, interviews by clinicians or others, and observer-rating checklists. To make them acceptable to non-help-seeking respondents, VBS items tend to be worded neutrally, and they have been used for purposes as diverse as service referral, needs assessment, epidemiological studies, and measurement of key variables in surveys. Constructs measured by VBSs include both psychological states (e.g., mood, anxiety) and behaviors (substance use, eating disorders). VBSs reviewed here *do not* include mechanical or other biometric measures such as blood pressure or body chemistry. Also, due to the volume of instruments available, we will restrict our discussion to measures of adult functioning.

CHOOSING A SCREENER

The most important attribute of any assessment tool is its reliability and validity, and the best measures are those for which published results from empirical tests of these qualities are available. Of particular importance are findings regarding known-groups techniques that demonstrate each instrument's screening accuracy. The two complementary aspects of this are sensitivity and specificity. *Sensitivity* refers to

the ability to assign a positive reading to all those who have the problem (i.e., minimizing false negatives). *Specificity* is a measure's ability to assign a positive reading only to those who have the problem (i.e., minimizing false positives). In a good screener both sensitivity and specificity are high, but one value can come at the expense of the other. The potential user of the measure must also consider the consequences of misidentification. The presence of false positives risks falsely stigmatizing some individuals, providing services to those who do not need them, and making the intervention appear less useful than it actually is, due to the absence of improvement among false positives. The presence of false negatives means that clients who need help will go unserved, and if the problem is a serious one, this can have dire ramifications for both the clients and others.

A technique called Receiver Operating Characteristics (ROC) curve analysis is often used to assess a measure's ability to find a balance between sensitivity and specificity (Metz, 1978). Results from the technique are usually reported as *area under the curve* (AUC). This ranges from 0 to 1 and reflects the ability of the measure to correctly classify respondents as having or not having the attribute in question (e.g., depression, alcohol dependence). Measures in which the area under the curve is large are those that accurately classify most cases, and AUC values of .80 or higher are typically seen as evidence of good measurement performance.

Another factor affecting screening accuracy is the prevalence of a problem in a population. When the target problem affects a relatively small proportion of individuals, even screeners with good specificity can produce unacceptably high ratios of false positives to true positives. For example, suppose 1,000 people are screened for a problem that affects only 2% of them, and the screener being used has a specificity of 95%. Twenty people (2%) can be expected to have the problem, and the measure will correctly identify 19 of those 20 (95%). On the other side, 980 people will not have the problem, but the screener, with its inaccuracy rate of 5%, will incorrectly identify 49 of these 980 people as having the problem. The performance of a screener in this regard is usually reported as its *positive predictive value* (PPV), which is obtained by dividing the number of true positives by the combined number of true and false positives. In the above

example, this would be $19/(19 + 49) = .279$. Multiplying this result by 100 yields a figure of 27.9%, which is the fraction of all cases identified as positives that truly are positives. A related statistic called the negative predictive value (NPV) helps evaluate performance relative to sensitivity. It is computed by substituting true and false negatives for true and false positives in the above equation.

SELECTED VERY BRIEF SCREENERS

In this section we will identify VBSs that assess client functioning in six major areas within which social workers may need to screen for client problems. These include mood, anxiety, eating behaviors, alcohol use, drug use, and general mental health. Our focus is on identifying brief screeners of potential value to both practitioners and those in roles as evaluators and researchers. Most of this information is presented in tables that show the name, number of items, and source reference for each measure. If multiple screeners are available in a given category, they are listed within each table based on the frequency of citations of the measure's source article. It is important to note that some brief measures that enjoy considerable popularity in the field are not shown in the table. This is likely because, though their administration times are relatively short, they did not meet the two-minute criterion for inclusion.

In the fourth column of each table, a summary of empirical findings regarding the screening accuracy of each measure is provided. This focuses particularly on sensitivity and specificity, plus AUC, PPV, and NPV, where available. For the sake of brevity, evidence related to reliability and other types of validity is not reported, except where this is the only type of evidence available and the measure is the only VBS in that category. Prospective users of any measure should always consult its source reference(s) and familiarize themselves with results on all aspects of its validity and reliability before deciding to use it.

The final column in each table provides information such as whether the measure is copyrighted (with those that are not being identified as "public domain"), whether its items were drawn from other instruments, and general notes about its intended or most appropriate use. It also notes whether versions are available in multiple languages.

Table 52.1 identifies VBSs for screening problems related to mood. Among the most common of such problems is depression. Two options for this are the two- and nine-item versions of the Patient Health Questionnaire (PHQ), which is the self-administered form of the PRIME-MD, an interview measure created for primary-care physicians. Both the PHQ-2 and PHQ-9 have good sensitivity and, in particular, good specificity, and the PHQ-2 is exceptionally brief. Also shown in Table 52.1 is the Edinburgh Postnatal Depression Scale (EPDS), which, as its name suggests, seeks to detect postnatal depression. It is sufficiently brief to qualify as a VBS, has good measurement accuracy, and has been widely used in both practice and research. It also has been translated and validated in at least 18 different languages in addition to English, with varying recommended cut-off scores. A measure of mania, one of the defining characteristics of Bipolar disorder, is also included. The Altman Self-Rating Mania Scale is becoming widely used in research and clinical practice and compares well to other, more lengthy measures, such as the Clinician Administered Rating Scale for Mania (CARS-M). Finally, a measure of suicidal behavior intent, the Suicide Behavior Questionnaire-Revised has been added to address this serious problem. This measure in its lengthier form has enjoyed wide clinical use, and the revised measure retains good measurement accuracy.

VBSs shown in Table 52.2 address anxiety-related problems such as General Anxiety disorders, panic, dissociation, posttraumatic stress (both civilian and military), and adult Attention Deficit Hyperactivity Disorder (ADHD). Although general anxiety is a very common mental health condition, the first brief measure developed to screen for this disorder has been the GAD-7. It has good reliability and construct validity and has been shown to differentiate anxiety from symptoms of depression. With respect to panic, the Autonomic Nervous System (ANS-2) questionnaire was developed to screen patients in primary care settings, where panic symptoms can complicate medical procedures. A less-common but equally serious anxiety-related problem is dissociation, seen in traumatized persons. One available screener is the DES-T, a short version of the Dissociative Experiences Scale. Given the rarity of dissociative disorders, its ability to produce a PPV of 87% in a large general population

TABLE 52.1 Depressive and Bipolar Problems

Category/Name	Items	Key Reference(s)	Measurement Accuracy	Comments
Depression				
Patient Health Questionnaire (PHQ-9 and PHQ-2)	9	Kroenke, K., Spitzer, R. L., & Williams, J. B. W. (2001). The PHQ-9: Validity of a brief depression severity measure. <i>Journal of General Internal Medicine, 16</i> , 606–613. Kroenke, K., Spitzer, R. L., & Williams, J. B. W. (2003). The Patient Health Questionnaire-2: Validity of a two-item depression screener. <i>Medical Care, 41</i> , 1284–1292.	Validated on 6,000 patients in primary care and obstetric-gynecology clinics. Using a cutoff score of 5, sensitivity for the PHQ-9, was 88% and specificity was 88% against the 20-item General Health Survey. Using a cutoff score of 3 for the PHQ-2, sensitivity was 83% and specificity was 92% against the GHS-20.	Public domain. The PHQ-9 is the depression module of the PRIME-MD, widely used to screen for common mental disorders. The PHQ-2 reduces the length of the measure even further by using only the two necessary DSM-5 criteria for depression—the frequency of depressed mood and anhedonia
Bipolar Disorder (Mania)				
Altman Self-Rating Mania Scale (ASRM)	5	Altman, E. G., Hedeker, D. R., Peterson, J. L., & Davis, J. M. (1997). The Altman Self-Rating Mania scale. <i>Biological Psychiatry, 42</i> , 948–955.	Validated with 105 outpatients. Significant correlations with the Mania Rating Scale ($r = .718$) and the Clinician-Administered Rating Scale for Mania subscale ($r = .766$). Principal components analysis suggested three factors—mania, psychotic symptoms, and irritability. Using a cutoff score of 5, sensitivity of 85.5% and specificity of 87.3% are reported for the mania subscale.	Designed to screen for the presence and/or severity of manic symptoms in inpatient or outpatient settings, and thus the presence of hypomania as well. One of the first very brief self-report scales of mania available. Permission available from the author.

Postnatal Depression

Edinburgh Postnatal Depression Scale (EPDS)

- 10 Cox, J. L., Holden, J. M., & Sagovsky, R. (1987). Detection of postnatal depression: Development of the 10-item Edinburgh Postnatal Depression Scale. *British Journal of Psychiatry*, 150, 782–786.
- Tested on 84 women who gave birth in the previous 3 months. Using a cutoff score of 12/13, sensitivity is reported as 86%, and specificity as 78%, with a PPV of 73% when tested against the Research Diagnostic Criteria of major and minor depression. Correlates well with the CPRS-Depression, the SADS, and the ICD-10 Versions with three, five, and seven items have been developed.
- Public Domain. Although the EPDS can be used to detect depression in postnatal women, some studies suggest it detects symptoms of anxiety or general distress as well. In other validation studies with prenatal women in non-English speaking countries, estimates of sensitivity are reported to vary from 65% to 100%, and specificity from 49% to 100%.

Suicide

Suicidal Questionnaire-Revised (SBQ-R)

- 4 Osman, A., Bagge, C. L., Gutierrez, P. M., Konick, L. C., Kopper, B. A., & Barrios, F. X. (2001). The Suicidal Behaviors Questionnaire-Revised: validation with clinical and nonclinical samples, *Assessment*, 5, 443–453.
- Tested on 120 adult inpatients, 135 young adults, 138 high school students, and 120 inpatient adolescents, a cutoff score of either 7 or 8, AUC was reported between .89 and .98, sensitivity .80 to .93, and specificity .91 to .96. PPVs ranged between .70 and .90, and NPVs reported between .86 and .99.
- Public Domain. Developed to identify adults and adolescents at risk of suicidal behavior by screening for lifetime, recent past, and likelihood of future suicidal ideation and/or behavior, as well as frequency of suicidal thinking and attempts.
-

TABLE 52.2 Anxiety and Trauma-related Problems

Category/Name	Items	Key Reference(s)	Measurement Accuracy	Comments
General Anxiety				
Generalized Anxiety Disorder—7 (GAD-7)	7	Spitzer, R. L., Kroenke, K., Williams, J. W., & Löwe, B. (2006). A brief measure for assessing generalized anxiety disorder: The GAD-7. <i>Archives of Internal Medicine</i> , 166(10), 1092–1097.	Results are from interviews with 965 adult patients in primary care sites. Using a cutoff score of 10, sensitivity is reported as .89 and specificity as .82. Correlates well with the Beck Anxiety Inventory and the anxiety scale of the SCL-90. AUC reported as .91	Public domain. One of very few measures concordant with DSM IV (and now DSM-5) diagnostic criteria. May be used to assess symptom severity as well as change over time.
Panic				
Autonomic Nervous System Questionnaire abbreviated (ANS-2)	2	Stein, M. B., Roy-Byrne, P. P., McQuaid, J. R., Laffaye, C., Russon, J., McCahill, M. E., Katon, W., ... Sherbourne, C. D. (1999). Development of a brief diagnostic screen for panic disorder in primary care. <i>Psychosomatic Medicine</i> , 61, 359–364.	Results are from 1,476 primary care outpatients in three primary care medical clinics. When tested against the Composite International Diagnostic Interview, sensitivity ranged from .94 to 1.00 and specificity ranged from .25 to .59 with a PPV of .18% to .4% and a NPV of .9% to 1.00.	Three- and five-item versions report only minimally improved specificity and reduced sensitivity. Responses from a subset of 511 patients were tested against the Beck Anxiety Inventory (using a cutoff of 20), resulting in sensitivity of .67.
Dissociation				
Dissociative Experiences Scale-Taxon (DES-T)	8	Waller, N. G., & Ross, C. A. (1997). The prevalence and biometric structure of pathological dissociation in the general population: taxometric and behavior genetic findings. <i>Journal of Abnormal Psychology</i> , 106, 499–510.	Results are from 1,055 adults in the general population. Using a cutoff score of 30, sensitivity of .74 and specificity of 1.00 is reported against the full DES, with a PPV of .87 and NPV of .99.	Reported to identify pathological dissociation with greater accuracy than the lengthier DES. A cutoff score of 20 is reported to identify 89% of those with dissociative identify disorder.

Posttraumatic Stress

Primary Care PTSD Screen (PC-PTSD)	4	Prins, A., Ouimette, P., & Kimerling, R. (2003). The primary care PTSD screen (PC-PTSD): Development and operating characteristics. <i>Primary Care Psychiatry, 9</i> , 9–14.	Tested on 188 male and female primary care patients recruited at VA clinics. Using a cutoff score of 2 yields sensitivity of .91 and specificity of .72 with a PPV of .51 and a NPV of .96. Results from 97 veterans seeking treatment for substance-related disorders used a cutting score of 3 and report sensitivity of .97 and specificity of .08.	Public Domain. This is the only PTSD measure that uses a “yes/no” response format. Currently in use by the Department of Veterans Affairs to screen for PTSD among returning service persons.
Combat Exposure Scale (CES)	7	Keane, T., Fairbank, J., Caddell, J., Zimering, R., Taylor, K., & Mora, C. (1989). Clinical evaluation of a measure to assess combat exposure. <i>Psychological Assessment, 1</i> , 53–55. Lund, M., Foy, D. W., Sippelle, R. C., & Strachan, A. (1984). The Combat Exposure Scale: A systematic assessment of trauma in the Vietnam war. <i>Journal of Clinical Psychology, 40</i> , 1323–1328.	Results are from 43 Vietnam era veterans seeking treatment at an outpatient VA facility. Sensitivity of .74 in identifying vets with PTSD.	Public Domain. Assesses severity of exposure to combat as a precursor to PTSD. Widely used as a clinical measure as well as in research studies.

Adult ADHD

Adult ADHD Self-Report Scale (ASRS) Screener	6	Kessler, R. C., Adler, L., Ames, M., Demler, O., Faraone, S., Hiripi, E., ... Walters, E. E. (2005). The World Health Organization adult ADHD self-report scale (ASRS): A short screening scale for use in the general population. <i>Psychological Medicine, 35</i> (2), 245–256.	Results are reported on 154 subjects from a large nationally representative sample of U.S. adults. PPV values are reported for different prevalence levels in the target population, Values ranged from 65.8 at 1% prevalence to 94.7 for 12% prevalence. AUC was .84.	Subset of items from full 18-item ASRS. Includes items measuring Inattention and Hyperactivity-Impulsivity. To improve classification, administration of the full version is recommended for subjects scoring positive on the screener.
--	---	--	--	---

sample is an indication of unusually strong measurement accuracy. Finally, measures of post-traumatic stress are being increasingly used to screen groups such as survivors of individual and large-scale trauma, as well as military personnel returning from combat areas. The Primary Care PTSD Screen has good measurement accuracy (PPV > 50%) and uses a simple “yes or no” format. It has most recently been tested with veterans who have served since September 11, 2001. The Combat Exposure Scale (CES) is now widely used among veterans to assess exposure to combat experiences, a common precursor to the development of Posttraumatic Stress Disorder (PTSD). With the increasing number of veterans of combat zones being seen by social workers in a variety of settings, these measures seem especially pertinent to include. A final anxiety-related phenomenon that social workers may need to assess is Attention-Deficit Hyperactivity Disorder, which can affect adults as well as children. The screening measure was taken from the World Health Organization (WHO) Adult ADHD Self-Report Scale (ASRS) as part of a study that revised and updated the larger WHO Composite International Diagnostic Interview.

Three VBSs designed to screen for the eating disorders and one that focuses on body dysmorphism are shown in Table 52.3. The most widely used in the first group is the SCOFF Questionnaire, named from words in its items such as whether respondents eat until they feel Sick. Though developed in Britain, and containing British terms unfamiliar to American respondents, a version using American terms has been produced and tested. Both versions appear to have good accuracy even with nonclinical populations. A second measure, the screening version of the third version of the Eating Disorder Inventory (EDI-3) showed particularly good ability to differentiate bulimia sufferers from subjects in a nonclinical population, but it is very new and has only been tested on a Danish population thus far. A third screener for eating disorders, the ESP, was developed for the purpose of screening primary-care patients. Its recommended cutoff score of 2 allows it to minimize false negatives, but the relatively low specificity this produces risks generating high ratios of false positives. Body image disorders can accompany eating disorder symptoms, and the seven-item Dysmorphic Concern Questionnaire (DCQ) has demonstrated good accuracy in discriminating between subjects in clinical and nonclinical samples. A positive

aspect of the three eating disorder screeners and the Body Concern Questionnaire BCQ are that all are in the public domain.

Table 52.4 displays six VBSs that screen for alcohol abuse, of which most are in the public domain. The CAGE is a longstanding and well-used screener for both abuse and dependence; its name is derived from four symptoms of problems with alcohol: tried Cutting down, Annoyed by criticism of drinking, feeling Guilty and needing a morning “Eye-opener”. Results are available from many studies, and these suggest it is highly accurate with some populations but not with others. Users should thus familiarize themselves with this literature before choosing the CAGE. Two alternatives are the AUDIT-C and FAST, which are both subsets of the Alcohol Use Disorders Identification Test (AUDIT). Results from tests of the FAST suggest that it may have better specificity than the AUDIT-C. However, the initial validation study of the FAST was conducted among patient groups, whereas the AUDIT-C has been tested among the U.S. general population. The National Institute of Alcohol Abuse and Alcoholism (NIAAA) Single Question Screen is a newer one-item screen tested among primary care patients. The final two measures listed, the TWEAK and T-ACE, are designed to detect alcohol use during pregnancy, and both show reasonable accuracy.

Table 52.5 lists three VBSs available to screen for the abuse of drugs other than alcohol. By far the most frequently cited in the research literature is the DAST-10, a short version of the Drug Abuse Screening Test. It was designed to detect substance use disorder in psychiatric patients, and both have good measurement accuracy when used for that purpose. The DrugAbuse/Dependence Screener is the only substance abuse VBS intended for use in general population samples. Results from its initial validation tests suggest it can perform well in that role. A newer one-item screener for drug use, the Single-Question Screening Test for Drug Use in Primary Care, shows promise for use in primary care settings. The final measure shown in Table 52.5 is the Substance Use Risk Profile–Pregnancy Scale for screening pregnant women for substance use, including alcohol. Sensitivity and specificity varied as expected depending on whether the population was low or high risk.

Table 52.6 offers two versatile and oft-cited screeners for general mental health—the K6 and the MHI-5. These instruments are short, accurate,

TABLE 52.3 Eating Disorders

Category/Name	Items	Key Reference(s)	Measurement Accuracy	Comments
General SCOFF Questionnaire	5	Morgan, J. F., Reid, F., & Lacey, J. H. (1999). The SCOFF questionnaire: Assessment of a new screening tool for eating disorders. <i>British Medical Journal</i> , 319, 1467–1468. Botella, J., Sepulveda, A. R., Huang, H. L., & Gambara, H. (2013). A meta-analysis of the diagnostic accuracy of the SCOFF. <i>Spanish Journal of Psychology</i> , 16, e92.	Original results were reported from studies of 214 British subjects (clinical and nonclinical) and 233 subjects (nonclinical). At cutoff of 2 or more, sensitivity ranged from 94.7% to 100%, while specificity ranged from 64% to 93%. A more recent analysis across several SCOFF studies found figures of .882 (sensitivity) and .925 (specificity).	Public domain. Results from tests of an American version in which some British vernacular was replaced completed on 305 graduate students (see Parker et al.). These show a PPV of 66.7% and NPV of 88.7%. Versions in a large variety of languages are available.
Eating Disorder Inventory (EDI-3) screening version	5	Friborg, O., Clausen, L., & Rosenvinge, J. H. (2013). A five-item screening version of the Eating Disorder Inventory (EDI-3). <i>Comprehensive Psychiatry</i> , 54, 1222–1228.	Identified items from the full 91-item EDI-3 that best discriminated between 112 patients diagnosed with anorexia or bulimia and 878 nonclinical controls. AUC, sensitivity, and specificity for the three anorexia items were .94, .91, and .86, respectively. For the two bulimia items they were .96, .94, and .94.	Public domain. The EDI is widely used in Europe and is available in multiple languages. At .70 for Cronbach's alpha, the measure's level of internal consistency compares well to other eating disorder screeners.
Eating Disorder Screen for Primary care (ESP)	5	Cotton, M. A., Ball, C., & Robinson, P. (2003). Four simple questions can help screen for eating disorders. <i>Journal of General Internal Medicine</i> , 18, 53–56.	Validated on 129 university students and 104 primary care patients in Britain. Comparing against results from the Questionnaire for Eating Disorder Diagnoses, sensitivity was 100% and specificity was 71%.	Public domain. A cutoff score of 2 questions answered "Yes" is recommended, and sensitivity and specificity values are based on this cutoff.
Body Image and Dismorphism Dismorphic Concern Questionnaire (DCQ)	7	Oosthuizen, P., Lambert, T., & Castle, D. J. (1998). Dismorphic concern: Prevalence and associations with clinical variables. <i>Australian and New Zealand Journal of Psychiatry</i> , 32(1), 129–132. Mancuso, S. G., Knoesen, N. P., & Castle, D. J. (2010). The Dismorphic Concern Questionnaire: A screening measure for body dysmorphic disorder. <i>Australian and New Zealand Journal of Psychiatry</i> , 44(6), 535–542.	Initial tests were conducted on small samples of psychiatric inpatients. More recent results compared the DCQ's ability to accurately differentiate clinical from nonclinical (college) samples. AUC was .98, and at the recommended clinical cutting score sensitivity was 96.4 and specificity was 90.6.	Public domain. A cutoff score of 9 is recommended. Items ask for level of concern with body appearance (e.g., whether malformed or misshapen in some way). Response options vary from "Not at all" to "Much more than most people." Most available results are from Australian samples.

TABLE 52.4 Alcohol Abuse

Category/Name	Items	Key Reference(s)	Measurement Accuracy	Comments
General Alcohol Abuse				
CAGE	4	Ewing, J. A. (1984). Detecting alcoholism: The CAGE questionnaire. <i>JAMA: Journal of the American Medical Association</i> , 252, 1905–1907. Dhalla, S., & Kopec, J. A. (2007). The CAGE questionnaire for alcohol misuse: A review of reliability and validity studies. <i>Clinical and Investigative Medicine</i> , 30, 33–41.	Tested on multiple samples. In a recent review, average sensitivity was 71%, and average specificity was 90% for alcohol abuse or dependence. The CAGE has generally not been found as effective among women, especially white women.	Public domain. Due to its brevity, the CAGE has become widely used in settings such as generalist medical care. cutoff score of 2 is recommended for alcohol abuse or dependence.
Alcohol Use Disorders Identification Test (AUDIT-C)	3	Bush, K., Kihlavan, D. R., McConell, M. B., Fihn, S. D., & Bradley, K. A. (1998). The AUDIT alcohol consumption questions (AUDIT-C): An effective brief screening test for problem drinking. <i>Archives of Internal Medicine</i> , 158, 1789–1795. de Meneses-Gaya, C., Zuardi, A. W., Loureiro, S. R., & Crippa, J. A. S. (2009). Alcohol Use Disorders Identification Test (AUDIT): An updated systematic review of psychometric properties. <i>Psychology & Neuroscience</i> , 2, 83–97.	Tested on multiple samples. In a U. S. general population survey using a risk drinking criterion, sensitivity was 91% and specificity 95% for men based on a cutoff score of 5, and sensitivity was 96% and specificity 70% for women based on a cutoff score of 3.	Public domain. Includes the first three questions of the full AUDIT, which is one of the most-used measures of hazardous/harmful drinking. The third item of the AUDIT-C, called AUDIT-3, shows some promise as a single-item screener (see FAST information below).
Fast Alcohol Screening Test (FAST)	4	Hodgson, R., Alwyn, T., John, B., Thom, B., & Smith, A. (2002). The FAST alcohol screening test. <i>Alcohol and Alcoholism</i> , 37, 61–66. Hodgson, R. J., John, B., Abbasi, T., Hodgson, R. C., Waller, S., Thom, B., & Newcombe, R. G. (2003). Fast screening for alcohol misuse. <i>Addictive Behaviors</i> , 28, 1453–1463.	Tested on patients in a variety of settings in the United Kingdom. Using the full Alcohol Use Disorders Identification Test (AUDIT) as a criterion, sensitivity ranged from 91% to 97% and specificity ranged from 86% to 95%.	Public domain. Comprises items 3, 5, 8, and 10 from the AUDIT. Item 3 can be used as a filter question. FAST scoring and item modifications, including a gender-specific asked item, can be viewed in the key reference.

NIAAA Single Question Screen (NSQS)	1	<p>National Institute on Alcohol Abuse and Alcoholism (NIAAA). (2005). <i>Helping patients who drink too much: A clinician's guide, 2005 Edition</i> (NIH Publication No. 07–3769). Bethesda, MD: Reprinted 2007.</p> <p>Smith, P. C., Schmidt, S. M., Allensworth-Davies, D., & Saitz, R. (2009). Primary care validation of a single-question alcohol screening test. <i>Journal of General Internal Medicine</i>, 24, 783–788. doi:10.1007/s11606-009-0928-6 Erratum (2010) in <i>Journal of General Internal Medicine</i>, 25, 375.</p>	<p>Tested on primary care patients. Sensitivity was 81.8% and specificity 79.3% for unhealthy alcohol use. Sensitivity was 87.9% and specificity 66.8% for active alcohol use disorder.</p>	<p>Public domain. Recommended by NIAAA. The NSQS item is “How many times in the past year have you had X or more drinks in a day” where X is 5 for men and 4 for women. A drink is considered 14 g of pure alcohol. A response of 1 or more is a positive screen. It is recommended that the question “Do you sometimes drink beer, wine, or other alcoholic beverages” be asked prior to the NSQS, as some individuals do not consider beer to be alcohol. If the answer is yes, the NSQS is administered.</p>
Risky Drinking in Pregnancy				
TWEAK	5	<p>Russell, M. (1994). New assessment tools for drinking in pregnancy: T-ACE, TWEAK, and others. <i>Alcohol Health and Research World</i>, 18, 55–61.</p> <p>Chan, A. W., Pristach, E. A., Welte, J. W., & Russell, M. (1993). Use of the TWEAK test in screening for alcoholism/heavy drinking in three populations. <i>Alcoholism: Clinical and Experimental Research</i>, 17, 1188–1192.</p> <p>Burns, E., Gray, R., & Smith, L. A. Brief screening questionnaires to identify problem drinking during pregnancy: A systematic review. <i>Addiction</i>, 105, 601–614.</p>	<p>Validation sample included 4,743 African American women visiting a prenatal clinic in Detroit. Against a criterion of periconceptual risk drinking and a cut point of 2 or more “yes” answers, AUC was 0.865, sensitivity 79%, specificity 83%, and PPV 22%.</p>	<p>Public domain. The TWEAK is derived from the CAGE. In a recent review, the sensitivity of the TWEAK was 71%–91% and specificity 73%–83% for risk drinking.</p>
T-ACE	4	<p>Sokol, R. J., Martier, S. S., Ager, J. W. (1989). The T-ACE questions: Practical and prenatal detection of risk drinking. <i>American Journal of Obstetrics and Gynecology</i>, 60, 863–870.</p> <p>Burns, E., Gray, R., & Smith, L. A. Brief screening questionnaires to identify problem drinking during pregnancy: A systematic review. <i>Addiction</i>, 105, 601–614.</p> <p>Allen, J. P., & Columbus, M. (Eds). (1995). <i>Assessing alcohol problems: A guide for clinicians and researchers</i>. Bethesda, MD: National Institute on Alcohol Abuse and Alcoholism.</p>	<p>Validated on a sample of 971 pregnant African American women at an inner-city clinic. Against a criterion of periconceptual risk drinking, sensitivity was 69%, specificity 89%, and PPV 23% when using a cutoff score of 2.</p>	<p>Copyrighted. Contact S. Martier, Ob/Gyn, 4704 Saint Antoine, Detroit, MI 48201. In a recent review, T-ACE sensitivity was 69%–88% and specificity was 71%–89% for risk drinking.</p>

TABLE 52.5 Substance Abuse

Category/Name	Items	Key Reference(s)	Measurement Accuracy	Comments
General Drug Abuse				
Drug Abuse Screening Test (DAST-10)	10	<p>Skinner, H. A. (1982). The Drug Abuse Screening Test. <i>Addictive Behaviors, 7</i>, 363–371.</p> <p>Bohn, M. J., Babor, T. F., & Kranzler, H. R. (1991). Validity of the Drug Abuse Screening Test (DAST-10) in inpatient substance abusers: Problems of drug dependence. Proceedings from the 53rd Annual Scientific Meeting: The Committee on Problems of Drug Dependence, Inc. Monograph 119, National Institute of Drug Abuse Research.</p> <p>Yudko, E., Lozhkina, O., & Fouts, A. (2007). A comprehensive review of the psychometric properties of the Drug Abuse Screening Test. <i>Journal of Substance Abuse Treatment, 32</i>, 189–198.</p>	Tests that report screening accuracy are from samples of psychiatric patients. In a recent review, sensitivity ranged from 41% to 85% and specificity ranged from 78% to 99% against a criterion of substance use disorder or the occurrence of substance use disorder symptoms.	A cutoff score of 3 is recommended, but one study found good sensitivity and specificity with a cutoff score of 2. The measure is copyrighted, but as long as the author, Dr. Harvey Skinner, is credited, it may be reproduced for noncommercial use. A DAST-10 manual is available.
Rost Drug Dependence Screener	3	<p>Rost, K., Burnam, M. A., & Smith, G. R. (1993). Development of screeners for depressive disorders and substance disorder history. <i>Medical Care, 31</i>, 189–200.</p> <p>Vernez, G., Buram, M. A., McGlynn, E. A., Trude, S., & Mittman, B. S. (1988). <i>Review of California's program for the homeless mentally disabled</i>. RAND Report #R-3631-California Department of Mental Health. Santa Monica, CA.</p>	Against results from a standardized diagnostic instrument using DSM-III criteria, the screener showed 57%–94% sensitivity, 95%–99% specificity, PPV from 67%–88%, and NPV from 98%–99% in population-based samples. It has also been tested among homeless populations.	The Drug Abuse/Dependence Screener is three items from the Diagnostic Interview Schedule and can be viewed in the source reference. The population-based test samples involved individuals who had utilized either outpatient health services for a physical issue or outpatient health or mental health services for a mental health issue within the past 6 months.

Single-Question
Screening Test
for Drug Use in
Primary Care

- 1 Smith, P. C., Schmidt, S. M., Allensworth-Davies, D., & Saitz, R. (2010). A single-question screening test for drug use in primary care. *Archives of Internal Medicine*, 170, 1155–1160.

Against several criterion measures, including current self-reported use and oral fluid testing, sensitivity ranged from 84.7% to 100% and specificity ranged from 73.5% to 96.2%. AUCs ranged from 0.89 to 0.93.

The Single-Question Screening Test for Drug Use in Primary Care is “How many times in the past year have you used an illegal drug or used a prescription medication for nonmedical reasons?” A response of 1 or more times is a positive screen test. Consult the key reference for more information.

Risky Substance Use in Pregnancy

Substance Use Risk
Profile-Pregnancy
Scale (SURPPS)

- 3 Yonkers, K. A., Gotman, N., Kershaw, T., Forray, A., Howell, H. B., & Rounsaville, B. J. (2010). Screening for prenatal substance use: Development of the Substance Use Risk Profile-Pregnancy Scale. *Obstetrics & Gynecology*, 116, 827–833.

The SURPPS items were derived from a training sample of 1,610 pregnant women from a larger cohort of 2,684. These items were tested in the validation sample of 1,074 against the criterion of self-reported substance use in the past 30 days. For low-risk populations, sensitivity was 91%, specificity 67%, and Akaike’s Information Criterion 579.75.

The SURPPS instrument and scoring information can be viewed in the source reference. For high-risk populations, sensitivity was lower at 57%, but specificity was higher at 88% (Akaike’s Information Criterion 616.93).

TABLE 52.6 General Mental Health and Personality Disorders

Category/Name	Items	Key Reference(s)	Measurement Accuracy	Comments
General Mental Health				
K6	6	<p>Kessler, R. C., Andrews, G., Colpe, L. J., Hiripi, E., Mroczek, D. K., Normand, S. L. T., Walters, E. E., & Zaslavsky, A. M. (2002). Short screening scales to monitor population prevalences and trends in non-specific psychological distress. <i>Psychological Medicine</i>, 32, 959–976.</p> <p>Kessler, R. C., Barker, P. R., Colpe, L. J., Epstein, J. F., Gfroerer, J. C., Hiripi, E., Howes, M. J., ... Zaslavsky, A. M. (2003). Screening for serious mental illness in the general population. <i>Archives of General Psychiatry</i>, 60, 184–189.</p>	<p>Validated on data from large mail (n > 1,000) and telephone (n > 10,000) surveys. Using Composite International Diagnostic Inventory (CIDI) results as a criterion, AUC was .875; specificity was .96; sensitivity was .36. Later studies have examined versions in other languages, typically confirming equal or better results (e. g., AUC or .92 for the Japanese version; specificity of .92 and sensitivity of .62 for French version).</p>	<p>Public domain. Two items address depressed mood; one item each addresses motor agitation, fatigue, worthless guilt, and anxiety. Results of follow-up studies suggest the K6 may be useful in screening for serious mental illness as well as general psychological distress. Versions in a variety of languages are available.</p>
Mental Health Inventory (MHI-5)	5	<p>Veit, C. T., & Ware, J. E. (1983). The structure of psychological distress and well-being in general populations. <i>Journal of Consulting and Clinical Psychology</i>, 51, 730–742.</p> <p>Kelly, M. J., Dunstan, F. D., Lloyd, K., & Fone, D. L. (2008). Evaluating cut points for the MHI-5 and MCS using the GHQ-12: A comparison of five different methods. <i>BMC Psychiatry</i>, 8, 1–9.</p>	<p>A study of 5,291 adults showed an AUC of 79.3% when compared against results from the Diagnostic Interview Schedule. Other results testing against scores from the PRIME-MD show specificity = .58 and sensitivity = .91 for major depression or panic disorder. Results from a British sample suggest an optimum cutting score of 76.</p>	<p>Public domain. Items are a subset of the SF-36. Focuses more than the K6 on screening for affective and anxiety-related aspects of mental health. Several studies have established accuracy levels and cutting scores by using the General Health Questionnaire (GHQ) as a criterion. Many translations available.</p>

Personality Disorders

McLean Screening
Instrument
for Borderline
Personality Disorder
(MSI-BPD)

- 10 Zanarini, M. C., Vujanovic, A. A., Parachini, E. A., Boulanger, J. L., Frankenburg, F. R., & Hennen, J. (2003): A screening measure for BPD: The McLean Screening Instrument for Borderline Personality Disorder (MSI-BPD). *Journal of Personality Disorders, 17*, 568–573.
- Chanen, A. M., Jovev, M., Djaja, D., McDougall, M., Hok, P. Y., Rawling, D., & Jackson, H. J. (2008). Screening for borderline personality disorder in outpatient youth. *Journal of Personality Disorders, 22*(4), 353–364.

For cutoff score of 7, sensitivity = .87 and specificity = .90 for age 30 and younger; .03 points higher for each in subjects 25 and younger. In a second study of adolescents, AUC was acceptable but lower than for the longer Borderline Personality Questionnaire, so screening for BPD with a very brief scale needs further empirical support.

Based on subset of items from the DSM-IV Borderline module. In the original study, subjects were 200 community volunteers selected for some BPD characteristics and some history of psychiatric treatment. Psychiatric diagnosis was used as the comparison standard. Versions have been developed in other languages, such as Dutch.

TABLE 52.7 Other Problems

Category/ Name	Items	Key Reference(s)	Measurement Accuracy	Comments
History of Abuse				
Two-Item Screeners for Detecting a History of Physical or Sexual Abuse in Childhood	2	Thombs, B. D., Bernstein, D. P., Ziegelstein, R. C., Bennett, W., & Walker, E. A. (2007). A brief two-item screener for detecting a history of physical or sexual abuse in childhood. <i>General Hospital Psychiatry</i> , 29, 8–13.	Data were gathered by surveying 1,225 women staff members of a health maintenance organization in the United States. Sensitivity was 84.8%, specificity was 88.1%, and the positive likelihood ratio was 7.1 for physical or sexual abuse in childhood, comparing against results from a semistructured interview of a subset of 216 respondents.	Public domain. The measure is intended for use by primary-care physicians and other professionals, and it is assumed that at only two items in length it is suitable for being embedded in larger interview protocols designed to gather basic information from patients.
Food Insecurity (FI) screener	2	Hager, E., Quigg, A., Black, M., Coleman, S., Heeren, T., Rose-Jacobs, R., et al. (2010). Development and validity of a two-item screen to identify families at risk for food insecurity. <i>Pediatrics</i> , 126 (1), e26–e32.	Data were drawn from 30,098 hospital and emergency room interviews of mothers of children under age 3 years in six U.S. cities. Interviews included the 18-item USDA Household Food Security Survey (HFSS), from which the items were drawn. Comparing against the full version, the screener’s sensitivity was 97%, and its specificity was 83%.	Public domain. Questions are: “Within the past 12 months we worried whether our food would run out before we got money to buy more” and “Within the past 12 months the food we bought just didn’t last and we didn’t have money to get more.” Responses correlated with child health and developmental risks and lifetime hospitalizations.

well validated, easily embedded in questionnaires, and available in the public domain. The K6 has also shown some capacity to screen for serious mental illness in general population samples, and both it and the MHI-5 are frequently used in the United States and Europe. One other measure shown in Table 52.6 that is brief enough to be considered a VBS, and that continues to receive relatively frequent use, is a screener designed to detect the presence of a borderline personality disorder. None of these measures should be construed as a diagnostic tool, and all should be treated as initial indicators of the need for more comprehensive evaluation.

Two other problems for which social workers may wish to screen clients and for which two-item VBSs are available are a childhood history of abuse and food insecurity. The screener for detecting a history of physical or sexual abuse in childhood was derived from a larger measure designed to be used for clinical data-gathering by primary care physicians, but they are easily adaptable to client assessment protocols used by social workers. Similarly, the FI (food insecurity) screener comprises two items from a larger measure developed by the U. S. Department of Agriculture. Food insecurity is often a proxy for serious poverty, and it is associated with a variety of threats to children's health and well-being.

The growing availability of VBSs has the potential to improve dramatically the quality of

social work assessments. We believe that accurate, versatile, easy-to-use, and no-cost measures such as the PHQ-2, CAGE, and K6 should become part of the basic measurement toolbox of all direct-service professionals in the field, and these instruments also have the potential to be similarly valuable in research and evaluation. A further rationale for their use is that they are becoming more commonplace in other disciplines, and knowing when and how to apply, score, and interpret them will allow social workers to work more closely with other professionals and to enhance the effectiveness of their own efforts.

PART VI

*Working with Couples
and Families*

Using Genograms to Map Family Patterns

Monica McGoldrick

Over the past several decades, genograms increasingly have been used by health care and human service professionals as a practical tool for mapping family patterns (McGoldrick, Gerson, & Petry, 2008). They are becoming a common language for tracking family history and relationships (see Figure 53.1). Genograms display family information graphically, providing a quick gestalt of complex family patterns; as such, they are a rich source of hypotheses about the evolution of both clinical problems and the family contexts within which problems develop and are generally resolved. The video, *Harnessing the Power of Genograms in Psychotherapy* (McGoldrick, 2013) demonstrates my first interview with a client. The video shows questioning around the presenting problem while gathering relevant genogram information, drawing it on the genogram, and helping the client to see its value. The video is available from www.psychotherapy.net.

Families are organized within biological, legal, cultural, and emotional structures, as well as according to generation, age, gender, and other factors. Where one fits in the family structure can influence functioning, relational patterns, and the type of family one forms in the next generation. Gender and birth order are key factors shaping sibling relationships and characteristics. When various family configurations are mapped on the genogram, the clinician can hypothesize about possible personality characteristics and relational compatibilities. Cultural issues including ethnicity, race, religion, migration, class, and other socioeconomic factors, as well as a family's time and location in history, also influence a family's structural patterns (McGoldrick, Carter, & Garcia-Preto, 2015; Congress, 1994; Hardy &

Laszloffy, 1995; McGoldrick, 2011; McGoldrick, Giordano, & Preto, 2005; Walsh, 2003). These factors, too, become part of the genogram map.

Genograms appeal to clinicians because they are tangible and graphic representations of complex family patterns. They allow the clinician to map the family structure clearly and note and update the family picture as it emerges. For a clinical record, the genogram provides an efficient summary, allowing a clinician unfamiliar with a case to quickly grasp a large amount of information about a family and have a view of potential problems. Whereas notes written in a chart or questionnaire tend to become lost in the record, genogram information is immediately recognizable and can be added to and corrected at each clinical visit as more is learned about a family.

Genograms make it easier for clinicians to keep in mind the complexity of a family's context, including family history, patterns, and events that may have ongoing significance for patient care. Just as our spoken language potentiates and organizes our thought processes, genograms, which map relationships and patterns of family functioning and cultural history, help clinicians think systematically about how events and relationships in their clients' lives are related to patterns of health, illness, and resilience.

Gathering genogram information should be an integral part of any comprehensive clinical assessment. There is no quantitative measurement scale by which the clinician can use a genogram in a cookbook fashion to make clinical predictions. Rather, it is a factual as well as interpretive tool, enabling social workers to generate tentative hypotheses for further evaluation in

Standard Symbols for Genograms

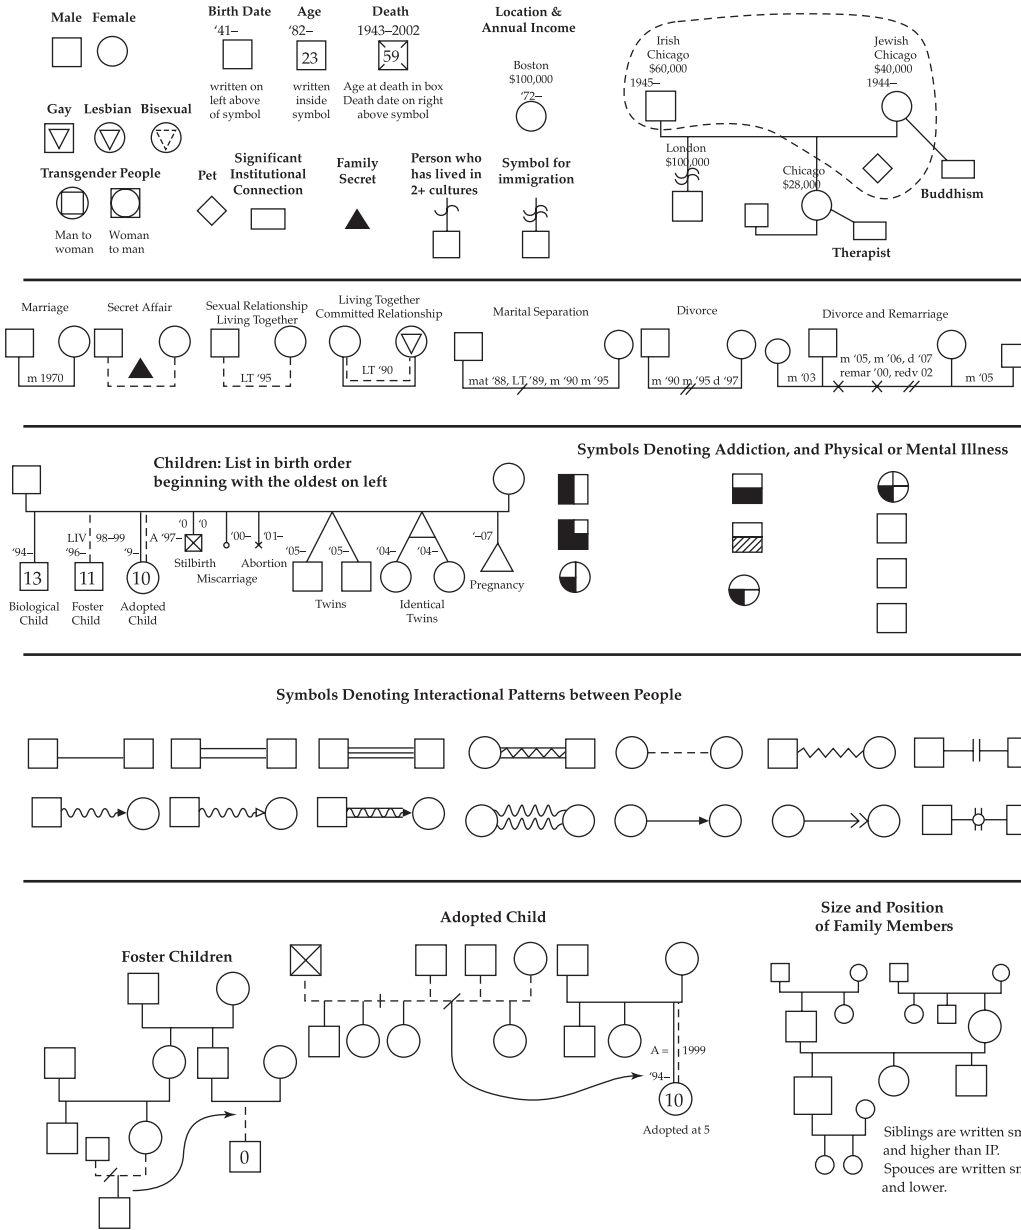

Figure 53.1 Genogram format.

a family assessment. Typically, the genogram is constructed from information gathered during the first session and revised as new information becomes available. Thus, the initial assessment forms the basis for treatment. Of course, we cannot compartmentalize assessment and treatment. Each interaction of the social worker with the family informs the assessment and thus influences the next intervention. *Harnessing*

the Power of Genograms in Psychotherapy (McGoldrick, 2013) demonstrates the back and forth necessary in learning about a client's history, while remaining relevant to his specific presenting problem.

Genograms help social workers get to know their clients; they thus become an important way of engaging with families. Creating a systemic perspective helps track family issues

through space and time, and genograms enable an interviewer to reframe, detoxify, and normalize emotion-laden issues. Because the genogram interview provides a ready vehicle for systemic questioning, it begins to orient clients to a systemic perspective as well. The genogram thus helps both the social worker and the client to see the larger picture—that is, to view problems in their current and historical context. Structural, relational, and functional information about a family can be viewed on a genogram both horizontally across the family context and vertically through the generations. Scanning the breadth of the current family context allows the social worker to assess the connectedness of the immediate players in the family drama to each other, as well as to the broader system, and evaluate the family's strengths, resilience, and vulnerabilities in relation to the overall situation.

We include on the genogram the nuclear and extended family members, as well as significant non-blood kin, friends, and pets who have lived with or played a major role in the family's life. We can also note significant events and problems. Current behavior and problems of family members can be traced from multiple perspectives. The index person (IP, or person with the problem or symptom) may be viewed in the context of various subsystems, such as siblings, triangles, reciprocal relationships, multigenerational patterns, life cycle stages and transitions, as well as in relation to the broader community, social institutions (schools, courts, etc.), and sociocultural context.

By scanning the family system culturally and historically and by assessing previous life cycle transitions, the clinician can place present issues in the context of the family's evolutionary patterns. Thus, we include on a genogram cultural and demographic information about at least three generations of family members, as well as nodal and critical events in the family's history, particularly as related to family changes (migration, loss, and the life cycle). When family members are questioned about the present situation in relation to the themes, myths, rules, and emotionally charged issues of previous generations, repetitive patterns often become clear. Genograms "let the calendar speak" by suggesting possible connections between family events over time. Previous patterns of illness and earlier shifts in family relationships brought about through changes in family structure and other critical life changes can easily be noted on the genogram, providing a

framework for hypothesizing what may be influencing a current crisis. In conjunction with genograms, we also create a family chronology, which depicts the family history in a timeline; the genogram itself maps first the structure and then the chronology of generations, but may not make the timing of different events as clear as a chronology, particularly around times of individual and family stress. We also often create a sociogram or eco-map (Hartman, 1978), which shows how clients are emotionally connected to family and other resources in their lives.

THE FAMILY INFORMATION NET

The process of gathering family information can be thought of as casting out an information net in progressively larger circles to capture relevant information about the family and its broader context. The net spreads out in a number of different directions:

- From the presenting problem to the larger context of the problem;
- From the immediate household to the extended family and broader social systems;
- From the present family situation to a chronology of historical family events;
- From easy, nonthreatening queries to difficult, anxiety-provoking questions; and
- From obvious facts to judgments about functioning and relationships to hypothesized family patterns.

THE PRESENTING PROBLEM AND THE IMMEDIATE HOUSEHOLD

In health care situations, genogram information is often recorded as it emerges during medical visits. In family therapy and social service situations, specific problems may be identified, which provide the clinician's starting point. At the outset, families are told that some basic background information is needed to understand their situation fully. Such information usually grows naturally out of exploring the presenting problem and its impact on the immediate household. It makes sense to start with the immediate family and the context in which the problem occurs.

- Who lives in the household?
- How is each person related?
- Where do other family members live?

The clinician asks the name, age, gender, and occupation of each person in the household to sketch the immediate family structure. Other revealing information is elicited through inquiring about the problem.

- Which family members know about the problem?
- How does each view it? How has each of them responded?
- Has anyone in the family ever had similar problems?
- What solutions were attempted by whom in those situations?
- When did the problem begin? Who noticed it first? Who is most concerned about the problem? Who the least?
- Were family relationships different before the problem began? What other problems existed?
- Does the family see the problem as having changed? If so, in what ways? Has it changed for better or for worse?

This is also a good time to inquire about previous efforts to get help for the problem, including previous treatment, therapists, hospitalizations, and the current referring person.

The Current Situation

Next, the clinician spreads the information net into the current family situation. This line of questioning usually follows naturally from questions about the problem and who is involved.

- What has been happening recently in your family?
- Have there been any recent changes in the family (e.g., people coming or leaving, illnesses, job problems)?

It is important to inquire about recent life cycle transitions as well as anticipated changes in the family situation (especially exits and entrances of family members—births, marriages, divorces, deaths, stresses related to health, the law, behavior changes, or the departure of family members).

The Wider Family Context

The clinician looks for an opportunity to explore the wider family context by asking about the extended family and cultural background of all

the adults involved. The interviewer might move into this area by saying, “I would now like to ask you something about your background to help make sense of your present problem.”

The clinician inquires about each side of the family separately, beginning, for example, with the mother’s side: “Let’s begin with your mother’s family. Your mother was which one of how many children? When and where was she born? Is she alive? If not, when did she die? What was the cause of her death? If alive, where is she now? What does she do? Is she retired? When did this happen? When and how did your mother meet your father? When did they marry? Had she been married before? If so, when? Did she have children by that relationship? Did they separate or divorce or did the spouse die? If so, when was that?” And so on. In a similar fashion, questions are asked about the father. Then the clinician might ask about each parent’s family of origin—that is, father, mother, and siblings. The goal is to get information about at least three or four generations, including grandparents, parents, aunts, uncles, siblings, spouses, and children of the IP.

Dealing with a Family’s Resistance to Doing a Genogram

When family members react negatively to questions about the extended family or complain that such matters are irrelevant, it often makes sense to redirect the focus to the immediate situation until the connections between the present situation and other family relationships or experiences can be established. An example of such a genogram assessment for a remarried family whose teenage daughter’s behavior was the presenting problem has been produced in the videotape *The Legacy of Unresolved Loss* (McGoldrick, 2001). This video also illustrates, as does *Harnessing the Power of Genograms in Psychotherapy* (McGoldrick, 2013), how to manage a client’s resistance to revealing genogram information. Gentle persistence over time will usually result in obtaining the information and demonstrating its relevance to the family.

Ethnic and Cultural History

It is essential to learn something about the family’s socioeconomic, political, and cultural background to place presenting problems and current relationships in context. When the questioning expands to the extended family, it is a good point to begin exploring cultural issues, because

exploring ethnicity and migration history helps establish the cultural context in which the family is operating and offers the therapist an opportunity to understand family attitudes and behaviors determined by such influences (McGoldrick et al., 2005). It is important to learn what the family's cultural traditions are for dealing with problems, health care, and healing, and where the current family members stand in relation to those traditional values. It is also important to consider the family's cultural expectations about relationships with health care professionals, given that this will set the tone for their clinical responses.

Differences in social class background among family members or between family members and the health care professional may create discomfort, which will need to be attended to in the meeting. Questions to ascertain class assumptions pertain not just to the family's current income but also to cultural background, education, and social status within their community. Once the clinician has a clear picture of the ethnic and cultural factors influencing a family (while preferably keeping his or her own biases in check), it is possible to raise delicate questions geared to helping families identify any behaviors that—even if culturally sanctioned in their original context—may be keeping them stuck (see McGoldrick, Giordano, & Garcia-Preto, 2005; McGoldrick & Hardy, 2008).

The Informal Kinship Network

The information net extends beyond the biological and legal structure of the family to encompass common-law and cohabiting relationships, miscarriages, abortions, stillbirths, foster and adopted children, and anyone else in the informal network of the family who is an important support. Inquiries are made about godparents, teachers, neighbors, friends, parents of friends, clergy, caretakers, doctors, and the like who are or have been important to the functioning of the family; this information is also included on the genogram. It is important to ask also about pets because they are often a primary source of support to family members. Pets should always be included on the genogram as a diamond (see Genogram Format) or with a small image of the pet. In exploring outside supports for the family, the clinician might ask:

- To whom could you turn for financial, emotional, physical, and spiritual help?
- What roles have outsiders played in your family?
- What is your relationship to your community?
- Who outside the family has been important in your life?
- Did you ever have a nanny, caretaker, or babysitter to whom you felt attached? What became of her or him?
- Has anyone else ever lived with your family? When? Where are they now?
- Do you have a pet, and if so, what role does s/he play in your lives?
- What has been your family's experience with doctors and other helping professionals or agencies?

For particular clients, certain additional questions are appropriate. For example, the following questions would be important in working with gay and lesbian clients (see Burke & Faber, 1997; Green, 2008).

- Who was the first person you told about your sexual orientation?
- To whom on your genogram are you out?
- To whom would you most like to come out?
- Who would be especially easy or difficult to come out to?
- Who is in your social network? (These people should always be added to the genogram.)

Tracking Family Process

Tracking shifts that occurred around births, deaths, and other transitions can lead the clinician to hypotheses about the family's adaptive style. Particularly critical are untimely or traumatic deaths and the deaths of pivotal family members (Walsh & McGoldrick, 2004). We look for specific patterns of adaptation or rigidification following such transitions. Assessment of past adaptive patterns, particularly after losses and other critical transitions, may be crucial in helping a family in the current crisis. A family's past, and the relationship family members have to it, provides important clues about family rules, expectations, patterns of organization, strengths, resources, and sources of resilience (Walsh, 2006).

The history of specific problems should also be investigated in detail. The focus should be on how family patterns have changed at different periods: before the problem began, at the time of the problem's onset, at the time of first seeking help, and presently. Specific genograms can be

done for each of these time periods. Asking how family members see the future of the problem is also informative. Questions may include the following.

- What will happen in the family if the problem continues? What will happen if it goes away?
- What does the future look like?
- What changes do family members imagine are possible in the future?

Seeing the family in its historical perspective involves linking past, present, and future and noting the family's flexibility in adapting to changes.

During the mapping on the genogram of the nuclear and extended family, and the gathering of facts about various family members, the clinician also begins to make inquiries and judgments about the functioning, relationships, and roles of each person in the family. This involves going beyond the bare facts to clinical judgment and acumen. Inquiries about these issues can touch sensitive nerves in the family and should be made with care.

Difficult Questions about Individual Functioning

Family members may function well in some areas but not in others, or they may cover up their dysfunction. Often, it takes careful questioning to reveal the true level of functioning. A family member with a severe illness may show remarkable adaptive strengths, and another may show fragility in response to little apparent stress. Questions about individual functioning may be difficult or painful for family members to answer and must be approached with sensitivity and tact, such as questions about alcohol abuse, chronic unemployment, severe symptomatology, or trauma. The family members should be warned that questions may be difficult, and they should let the clinician know if there is an issue they would rather not discuss. The clinician will need to judge the degree of pressure to apply if the family resists questions that may be essential to dealing with the presenting problem.

Clinicians need to exercise extreme caution about when to ask questions that could put a family member in danger. For example, if violence toward a wife is suspected, she should

never be asked about her husband's behavior in his presence, because the question assumes she is free to respond, which may not be the case. It is clinicians' responsibility to be sure their questions do not put a client in jeopardy. The following questions reflect issues of relevance, but not necessarily a format for ascertaining the information, which could require delicate and diplomatic interviewing.

Serious Problems

- Has anyone in the family had a serious medical or psychological problem? Been depressed? Had anxieties? Fears? Lost control?
- Has there been physical or sexual abuse?
- Are there any other problems that worry you? When did that problem begin? Did you seek help for it? If so, when? What happened? What is the status of that problem now?

Work

- Have there been any recent job changes?
- Has anyone been unemployed?
- Do you like your work? Do other family members like their work?

Finances

- How much income does each member generate? Does this create any imbalance in family relationships? How does the economic situation compare with that of your relatives or neighbors?
- Is there any expected inheritance? Are there family members who may need financial help or caretaking?
- Are there any extraordinary expenses? Outstanding debts? What is the level of credit card debt?
- Who controls the money? How are spending decisions made? Are these patterns different from the ways money was handled in the families of origin?

Drugs and Alcohol

- Do any family members routinely use medication? What kind and for what?
- Who prescribed it? What is the family's relationship with that physician?
- Do you think any members drink too much or have a drug problem? Has anyone else ever thought so? What drugs? When? What has the family attempted to do about it?

- How does the person's behavior change under the influence of the drug? How does the behavior of others change when a member is drug involved?

Trouble with the Law

- Have any family members ever been arrested? For what? When? What was the result? What is that person's legal status now?
- Has anyone ever lost his or her driver's license?

Physical or Sexual Abuse

- Have you ever felt intimidated in your family? Have you or others ever been hit? Has anyone in your family ever been threatened with being hit? Have you ever threatened anyone else in your family or hit them?
- Have you or any other family members ever been sexually molested or touched inappropriately by a member of your family or someone outside your family? By whom?

SETTING PRIORITIES FOR ORGANIZING GENOGRAM INFORMATION

One of the most difficult aspects of genogram assessment remains setting priorities for inclusion of family information on a genogram. Clinicians cannot follow every lead the interview suggests. Awareness of basic genogram patterns can help the clinician set such priorities. As a rule of thumb, the data are scanned for the following:

- Repetitive symptoms, relationships, or functioning patterns across the family and over the generations. Repeated cut-offs, triangles, coalitions, patterns of conflict, over- and underfunctioning.
- Coincidences of dates—for example, the death of one family member or anniversary of this death occurring at the same time as symptom onset in another, or the age at symptom onset coinciding with the age of problem development in another family member.
- The impact of change and untimely life cycle transitions, particularly changes in functioning or relationships that correspond

with critical family life events or untimely life cycle transitions—for example, births, marriages, or deaths that occur “off schedule.”

Awareness of possible patterns makes the clinician more sensitive to what is missing. Missing information about important family members, events, or discrepancies in the information offered frequently reflect charged emotional issues in the family. The clinician should take careful note of the connections family members make or fail to make to various events.

A FAMILY SYSTEMS PERSPECTIVE

A family systems perspective views families as inextricably interconnected. Neither people nor their problems or solutions exist in a vacuum. Both are interwoven into broader interactional systems, the most fundamental of which is the family. The family is the primary and, except in rare instances, most powerful system to which we humans belong. In this framework, “family” consists of the entire kinship network of at least three generations, both as it currently exists and as it has evolved through time (McGoldrick, Garcia-Preto, & Carter, 2015). Family is, by our definition, those who are tied together through their common biological, legal, cultural, and emotional history and their implied future together. The physical, social, and emotional functioning of family members is profoundly interdependent, with changes in one part of the system reverberating in other parts. In addition, family interactions and relationships tend to be highly reciprocal, patterned, and repetitive. These patterns allow us to make tentative predictions from the genogram.

Coincidences of historical events or concurrent events in different parts of a family are viewed not as random happenings but as occurrences that may be interconnected systemically, though the connections may be hidden from view (McGoldrick, 2011). In addition, key family relationship changes seem more likely to occur at certain times than at others. They are especially likely at points of life cycle transition. Symptoms tend to cluster around such transitions in the family life cycle, when family members face the task of reorganizing their relations with one another to go on to the next

phase (McGoldrick, Garcia-Preto & Carter, in press). The symptomatic family may become stuck in time, unable to resolve its impasse by reorganizing and moving on. The history and relationship patterns revealed in a genogram assessment provide important clues about the nature of this impasse—how a symptom may have arisen to preserve or prevent some relationship pattern or to protect some legacy of previous generations.

Families have many different types of relationship patterns. Of particular interest are patterns of relational distance. People may be very close or very distant or somewhere in between. At one extreme are family members who do not speak or are in constant conflict with each other. The family may actually be in danger of cutting off entirely. At the other extreme are families who seem almost stuck together in “emotional fusion.” Family members in fused or poorly differentiated relationships are vulnerable to dysfunction, which tends to occur when the level of stress or anxiety exceeds the system’s capacity to deal with it. The more closed the boundaries of a system become, the more immune it is to input from the environment, and consequently, the more rigid the family patterns become. In other words, family members in a closed, fused system react automatically to one another and may be impervious to events outside the system that require adaptation to changing conditions. Fusion may involve either positive or negative relationships—that is, family members may feel very good about each other or experience almost nothing but hostility and conflict. In either case, there is an overly dependent bond that ties the family together. With genograms, clinicians can map family boundaries and indicate which subsystems are fused and thus likely to be closed to new input about changing conditions.

As Bowen (1978) pointed out, two-person relationships seem to be unstable, under stress tending to draw in a third person. They tend to stabilize their relationship by forming a coalition of two in relation to the third. The basic unit of an emotional system thus tends to be the triangle. Genograms can help us identify key triangles in a family system, see how triangular patterns repeat from one generation to the next, and design strategies for changing them (Fogarty, 1973; Guerin, Fogarty, Fay, & Kautto, 1996).

The members of a family tend to fit together as a functional whole. That is, the behaviors of

different family members tend to be complementary or reciprocal. This does not mean that family members have equal power to influence relationships, as is obvious from the power differentials between men and women, between parents and children, between the elderly and younger family members, and between family members who belong to different cultures, classes, or races (McGoldrick & Hardy, 2008). What it does mean is that belonging to a system opens people to reciprocal influences and involves them in one another’s behavior in inextricable ways. This leads us to expect a certain interdependent fit or balance in families, involving give and take, action and reaction. Thus, a lack (e.g., irresponsibility) in one part of the family may be complemented by a surplus (over-responsibility) in another part. The genogram helps the clinician pinpoint the contrasts and idiosyncrasies in families that indicate this type of complementarity or reciprocal balance.

Clearly, a genogram is limited in how much information it can display at any time. Computer programs allow clinicians to examine the genogram with multiple levels of detail and explore different aspects one at a time: illness, cultural patterns, education and job history, couple relationships, and so on. Clinicians gather a great deal more important information on people’s lives than can ever appear on genograms. The genogram is just one part of an ongoing clinical investigation and must be integrated into the total family assessment.

MAPPING THE GENOGRAMS OF THOSE WHO GROW UP IN MULTIPLE SETTINGS: THE MEANING OF HOME

Many children grow up in multiple settings because their parents divorce, die, remarry, migrate, or have other special circumstances that require the child to live for a while or even permanently in a different place. Yet we often fail to keep track of important information about whom children have lived with as they grow up—biological, legal, foster, adoptive, or informal kin relationships. Genograms can greatly facilitate tracking children in multiple living arrangements or foster placements, where the many different family constellations a child lives in are otherwise extremely hard to keep in mind. Indeed, genograms are an exceptionally useful tool to track children’s experiences through

the life cycle, taking into account the multiple family and other institutional contexts to which they have belonged (McGoldrick, Garcia-Preto, & Carter, 2015). As we all know, an individual's sense of "home" or what some have referred to as "homeplace" (Burton, Winn, Stevenson, & Clark, 2004) can be a crucial aspect of developing a healthy identity. The more clearly the clinician tracks the actuality of a person's history, however complex, the better able he or she is to validate the child's actual experience and multiple forms of belonging and to understand the child's sense of home. Such a map can begin to make order out of the sometimes chaotic or sudden placement changes a child must go through because of illness, trauma, or other loss. It can also help validate for a child the realities of his or her birth and life connections that vary from traditional norms.

More children than we realize are raised in a number of different households or shift residences many times to foster homes or to various relatives or friends. It is useful for the genogram to show as much of the information as possible on transitions and relationships in children's lives. Although many situations are very complicated, creativity and a commitment to validate

all of a child's connections facilitate the clinician's efforts to track and map the family and kin connections. Sometimes the only feasible way to clarify where children were raised is to take chronological notes on each child in a family and then transform them into a series of genograms that show family context. Especially when children have experienced many losses and changes, a complete genogram both validates the losses and offers a rich picture of all the people to whom they have belonged. It can be an important clinical tool to help put children in context.

Adoption

Couple adoption and single-parent adoption can be indicated as in Figure 53.2.

This genogram shows the family of Mia Farrow, who had biological children (including twin sons, Matthew and Sasha) and interracial adopted daughters (Soon-Yi, Lark, and Daisy) with her second husband, André Previn. She then adopted another interracial child (Moses) and one who was American born (Dylan/Eliza) during her relationship with Woody Allen, after which they had a biological child together (Satchel, now called Ronan), and finally she adopted more children

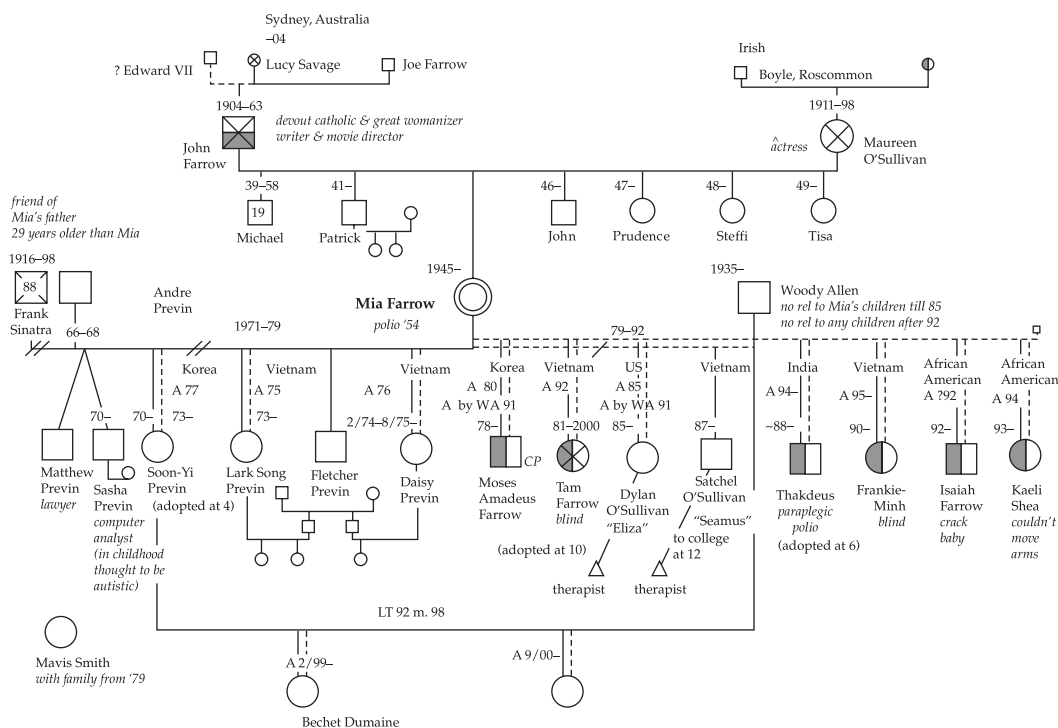

Figure 53.2 Genogram 2: Mia Farrow's Family.

on her own. If at all possible, we indicate the cultural background, because it is an important part of anyone's history. By looking at this map of the children of Mia Farrow, one may develop hypotheses about the position of different children. Soon-Yi, for example, came to the family as the oldest of three adopted Asian daughters two years after her younger Asian sister, Lark Song, and one year after her youngest Asian sister, Daisy. Not only were the two younger sisters "older" in their experience with the family, but they were both Vietnamese, whereas Soon-Yi was from Korea. So Soon-Yi's position as outsider among the three adopted Asian sisters may have been built in by the timing and her cultural difference from them. Of course, to more completely track the history of each child in this family, we would want to do genograms for each of the children, showing their biological parents and siblings and whom they lived with at every age growing up, as well as a more complete map of their caregivers and support systems. Friends and mentors, for example, may be important to show on a genogram, especially where children have experienced significant losses. Again, mapping out all these particulars is a way of assessing each family member's sense of home or homeplace and belonging, a crucial aspect of any clinical assessment.

Where living situations are complicated, a line can be drawn to encircle the households. This is especially important in multinuclear families, where children spend time in different households.

When the "functional" family is different from the biological or legal family, as when children are raised by a grandparent or in an informal adoptive family, it is useful to create a separate genogram to show the functional structure (Watts Jones, 1997). Where children have lived as part of several families—biological, foster, and adoptive—separate genograms may help depict the child's multiple families over time.

We can also indicate on a genogram (Figure 53.3) a lesbian couple with a child born to one of them and adopted by the other. The very small square indicated as the biological parent of Meg is a sperm donor. The grandparents and previous spouses of Fran and Martha are also indicated on the genogram. Burke and Faber (1997) have suggested using a "gendergrid" to help depict the liaisons, long-term bonds, communities, and social networks of lesbian couples.

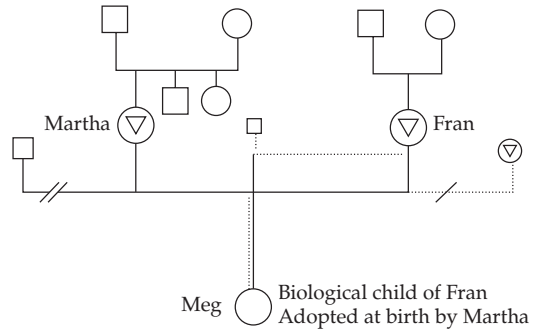

Figure 53.3 Genogram 3: Lesbian Family.

They suggest differentiating three levels of relationship: historical influences, key emotional and social relationships, and primary intimate relationships for the index individual or couple.

Foster Care

We need to acknowledge the relevance of specific foster family history for children who have lived in foster care. Psychologist Fernando Colon-Lopez grew up in several foster homes after the loss of his mother. As an adult, he has put much effort into exploring his own genogram (1973, 2006, 2008) and helping others think contextually about child placement and foster care as a valid and important aspect of a child's history, which should be attended to as any other experience (Colon, 1978). He has made it clear how important the genogram of the foster family is for the child through the life cycle. He kept ongoing connections with the biological grandchildren of his third foster mother. They shared holidays and frequent visits with their grandmother, his foster mother. They have much in common through this shared history, a history that is so often not acknowledged in our foster care system and in society at large, which underemphasizes family ties in its stress on individuality and self-determination.

Colon grew up mostly in foster homes from earliest infancy. The map of all his living situations, including three foster homes, an orphanage, his family of origin, and his family of procreation, is offered in Figure 53.4.

To understand better the sibling patterns with his brothers in the foster home where he spent most of his growing-up years, we might want to show the changing family constellations separately, as in Figure 53.5.

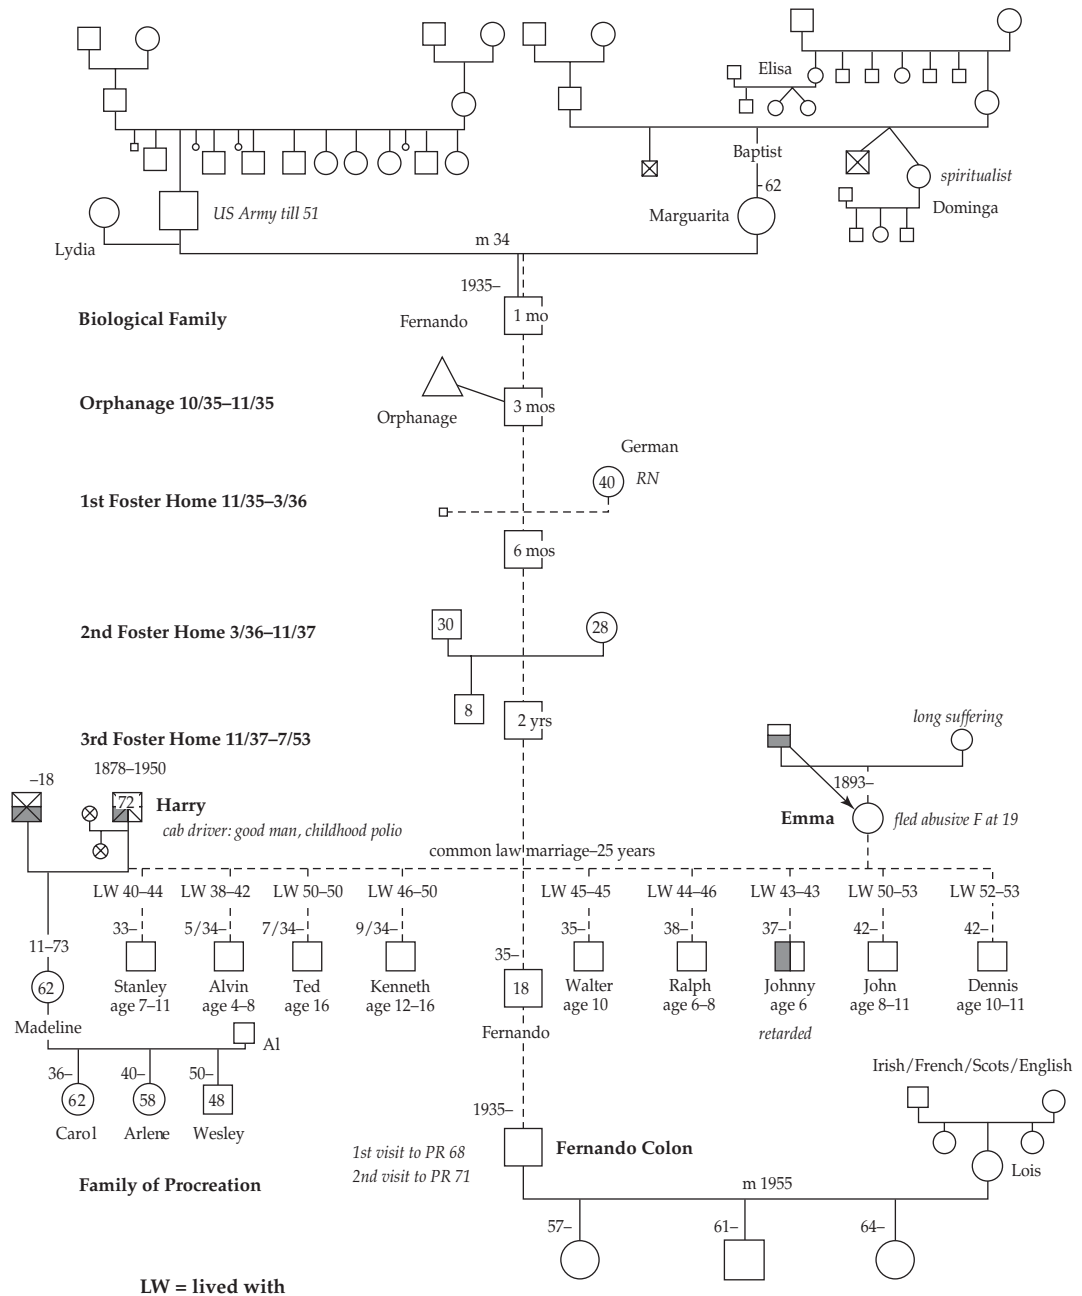

Figure 53.4 Genogram 4: Tracking Fernando Colon's living situations.

The genogram in Figure 53.5 makes evident the multiple losses that Colon and his foster family had throughout his childhood, but it also indicates their resilience and resourcefulness in being able to deal with these losses, as well as with new relationships almost each year. As is evident, Colon had experience in virtually every sibling constellation during his childhood years, a factor

that probably increased his flexibility in dealing with relationships. He was the youngest of three, the oldest of three, the middle of three, the older of two, and the younger of two, but rarely an only child, although, as the one child who remained with the family for his entire childhood, his position there was special. At the same time, the three brothers who stayed for long periods of time

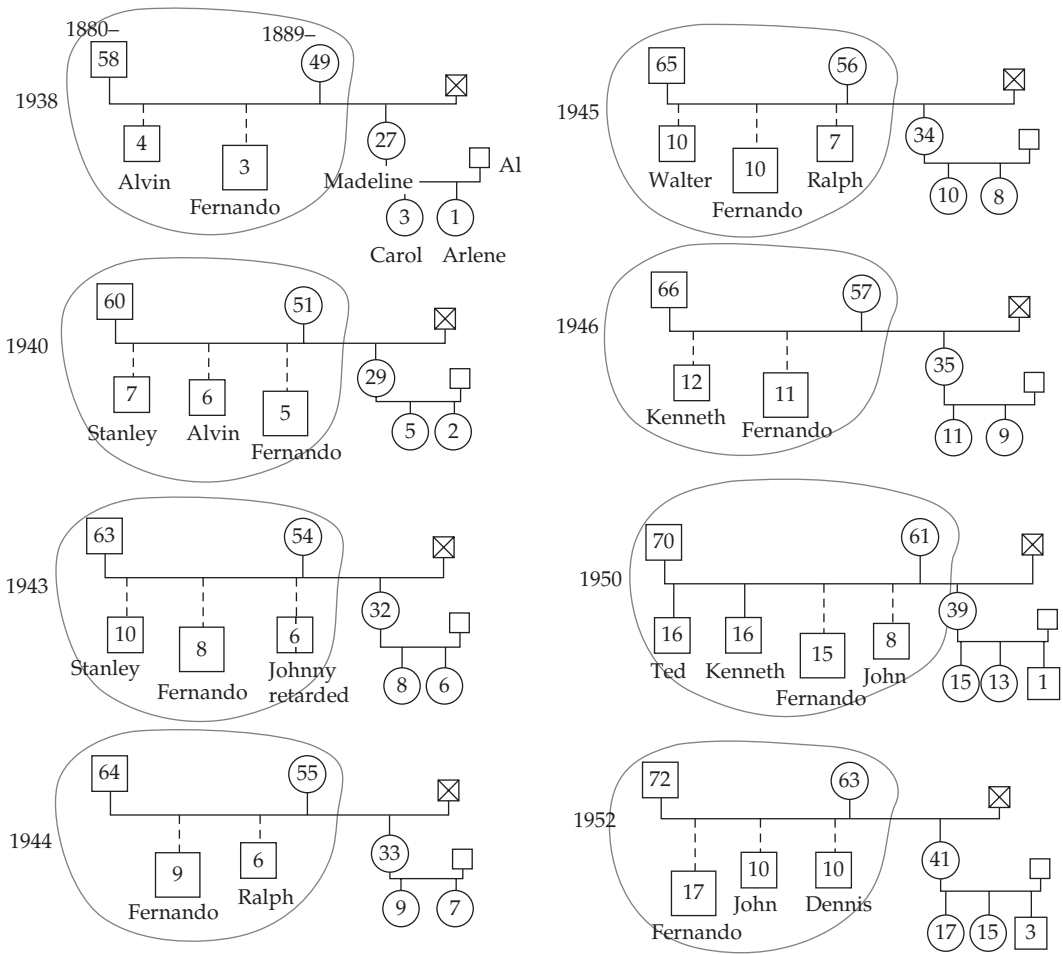

Figure 53.5 Genogram 5: Changing constellation of Colon’s foster home, 1937–1953.

(4 years each) not surprisingly had more significance for him, especially because they were all close to Colon in age. Less evident from the ages alone was the extremely special relationship that Colon and his foster mother had with his brother Johnny, who lived in the family for only 4 months but to whom they became very attached. In caring for this severely retarded brother, Colon remembers clearly how hard Johnny had tried to learn to say Fernando’s name and how he and his mother cried when they had to let Johnny go.

Although the foster care system at that time operated on the principle that children were never to have contact with the previous family once they moved to a new home, his foster mother did not believe in cutting off the past that way and made great efforts to reverse the process. In the early days of placement, one of Fernando Colon’s foster brothers, Kenneth, was especially depressed. Kenneth was one of five brothers, and

spite of the regulations, their foster mother asked Kenneth where the brothers were and took him to see them, after which he began to adjust to his new situation. The foster mother showed great courage to challenge the cutting-off process promoted by our social service system.

Colon remains connected to his foster mother’s grandchildren, in addition to his close, current connections with family members on both sides of his biological family. Whether the relationship is good or bad, beneficial or injurious, it is not to be dismissed. Organizing family data on genograms has enabled people to put the many fragments of their lives together into a meaningful whole.

Benefits of Open Adoption Policies

Genograms are equally important for children in adoptive care. Luckily, the policy of closed

adoption is increasingly shifting to a policy of open adoption. After the adoption, both the biological family and the adoptive family are involved in selecting each other for placement of the child and stay connected to each other through the growing years of the child and beyond. This paradigm, which is becoming more widespread in the United States, has eliminated the harmful effects of secrecy and is a process with integrity that enables all parties to be considered in a humane way. State laws still vary widely, however, in how open or closed the adoption process may be. By using the information from genograms, child care workers can help adoptive children create scrapbooks about their lives with information, photos, and stories about both the biological and adoptive families. In this way the child is truly shared and doubly enriched by having connections with two family systems, rather than one pitted against the “failed” other.

The accepted practice of severing family ties—be they biological, adopted, foster, or blended—is, in our view, extremely detrimental and disrespectful. It has often led to clinicians being drawn into replacing other relationships in a person’s natural system. Such cut-offs may leave practitioners depressed, bereft, and weakened, having a “hole” in our hearts. A cut-off of one person tends to potentiate cut-offs of other family members and the loss of other potentially enriching relationships. It weakens the entire fabric of the family. Social workers’ use of genograms can

help counter this tendency by making clear the enormity of the losses and validating the rich possibilities for connection and meaning.

Genograms can also be used for children who have been reared in orphanages, as the touching memoir of John Folwarski (2008) illustrates. Folwarski figures that he had approximately 3,000 siblings—that is, 3,000 other children in one generation shared the same home (St. Hedwig’s Orphanage in Chicago), the same food, the same holiday rituals, and the same foster parents and grandparents, the nuns and priests who ran the home.

Figure 53.6 shows Folwarski’s genogram for the family as he experienced it during the years he grew up (1937–1950). As adults, many of his “siblings” have come together to share memories, reconnecting after many years with teacher/mothers, and have strengthened their sense of family. Indeed, Folwarski describes the experience of creating and looking at his genogram, which had a powerful meaning in validating his history.

CONCLUSION

The physical genogram, which is a highly condensed map of a rich and complex family, can provide an awesome lesson for anyone unable to see beyond the cut-offs that may occur in a family (McGoldrick et al., 2008). We believe that no relationship is to be disregarded or discounted.

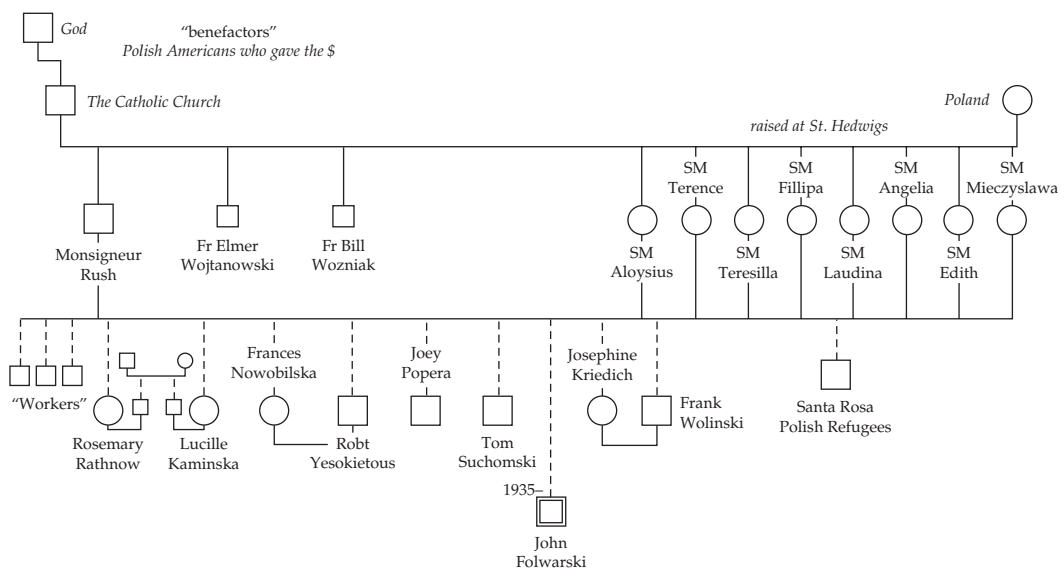

Figure 53.6 Genogram 6: St. Hedwig’s orphanage family.

All our relationships inform the wholeness of who we are and where we come from and, more important, can help us make constructive, conscious choices about who we will be in the future.

One of the most powerful aspects of genograms is the way they can steer people to the rich, ongoing possibilities of complex kin relationships, which are sources of connection and life support. It is not just a shared history that matters but the spiritual power of our survival and our current connections that strengthen us and can enrich our future.

54 A Family Resilience Framework

Froma Walsh

Over recent decades, the field of family therapy has refocused attention from family deficits to family strengths. The therapeutic relationship has become more collaborative and empowering of client potential, recognizing that successful interventions depend more on tapping into family resources than on therapist techniques. Assessment and intervention are directed to how problems can be solved, identifying and amplifying existing and potential competencies. Therapist and clients work together to find new possibilities in a problem-saturated situation and overcome roadblocks to change and growth. This positive, future-oriented direction shifts the emphasis from what went wrong to what can be done for optimal functioning and well-being of families and their members.

A family resilience approach builds on these developments to strengthen family abilities to overcome adversity. A basic premise guiding this approach is that serious life crises, disruptive transitions, and persistent adversity have an impact on the whole family, and in turn, key family processes influence the recovery and resilience of all members, their relationships, and the family unit. Fostering the family's ability to master its immediate crisis situation also increases its capacity to meet future challenges. Thus, the family is strengthened as problems are resolved, and each intervention is also a preventive measure.

THE CONCEPT OF FAMILY

RESILIENCE: CRISIS AND CHALLENGE

Resilience—the ability to withstand and rebound from adversity—has become an important

concept in mental health theory and research. Although some are shattered by traumatic experience, others rise above it, able to live and love well. Countering the deterministic assumption that early, severe, or persistent trauma inevitably damages lives, studies have found that the same adversity may result in different outcomes. For instance, most abused children did not become abusive parents (Kaufman & Ziegler, 1987). What makes the difference?

Early studies focused on individual traits for hardiness, reflecting the dominant cultural ethos of the “rugged individual.” Resilience was viewed as inborn or acquired on one's own, as “the invulnerable child” seen as impervious to stress owing to inner fortitude. An interactive perspective emerged, recognizing that the impact of initial risk conditions or traumatic events may be outweighed by mediating environmental influences that foster resilience. Major studies of resilient children and adults noted the crucial influence of significant relationships, with models and mentors—such as coaches or teachers—who supported them, believed in their potential, and encouraged them to make the best of their lives (Rutter, 1987; Werner & Smith, 2001). However, the skewed clinical focus on family pathology blinded many to the kinship resources that could be found and strengthened, even in troubled families.

A family resilience orientation fundamentally alters that traditional deficit-based lens, shifting the perspective from viewing families as *damaged* to seeing them as *challenged*. Rather than rescuing so-called survivors from dysfunctional families, this approach affirms the family's reparative potential, based on the conviction that both individual and relational healing and growth can be forged out of adversity.

The concept of family resilience has valuable potential as a framework for intervention, prevention, research, and social policy aimed at supporting and strengthening families facing adversity. Although some families are shattered by crisis or persistent stresses, others surmount their challenges and emerge stronger and more resourceful. For instance, the death of a child poses a heightened risk for parental divorce, yet couple and family bonds are strengthened when members pull together and support each other in dealing with their tragedy (Greeff & Human, 2004). The concept of resilience extends beyond coping and adaptation to recognize the enhanced strengths and growth that can be forged out of adversity. A crisis also becomes an opportunity for reappraisal of life priorities and greater investment in meaningful relationships and pursuits. Many find new purpose in efforts to prevent similar tragedies or help others who are suffering or struggling (Lietz, 2013; Walsh, 2006).

A family resilience practice approach aims to identify and build key relational processes to overcome stressful life situations, with the conviction that collaborative efforts best enable families and all members to thrive. The approach is grounded in family systems theory, combining ecological and developmental perspectives to view the family as an open system that functions in relation to its broader sociocultural context and evolves over the multigenerational life cycle.

ECOLOGICAL PERSPECTIVE

A bio-psychosocial systems orientation views problem situations and their solutions as involving multiple recursive influences of individuals, families, larger systems, and sociocultural variables. A family resilience approach recognizes that most problems involve an interaction of individual and family vulnerability with the impact of stressful life experiences and social contexts.

- Difficulties may be primarily biologically based, as in serious illness or disability, yet are largely influenced by interpersonal and sociocultural variables.
- Family distress may be fueled by external events, such as a major disaster (Walsh, 2007), or by ongoing stressors, such as persistent conditions associated with poverty,

racism, heterosexism, or other forms of discrimination (Anderson, 2012; Green, 2012; Orthner, Jones-Sanpei, & Williamson, 2004).

- Family distress may result from unsuccessful attempts to cope with an overwhelming situation or pile-up of stressors that overwhelm resources.

DEVELOPMENTAL PERSPECTIVE: FAMILY COPING, ADAPTATION, AND RESILIENCE

A family resilience approach attends to adaptational processes over time, from ongoing interactions to family life cycle passage and multigenerational influences. Life crises and persistent stresses have an impact on the functioning of a family system, with ripple effects to all members and their relationships (Patterson, 2002). Family processes in preparedness and response are crucial for coping and adaptation; one family may falter whereas with similar life challenges another rallies. How a family confronts and manages a disruptive or threatening experience, buffers stress, effectively reorganizes, and reinvests in life pursuits influences adaptation for all members.

As one example, the presumption that divorce inevitably damages children is not supported by the large body of empirical data finding that most children fare reasonably well over the long-term and nearly a third flourish. We need to take into account the multiple variables in risk and resilience over time that make a difference in children's adaptation, including the predivorce climate, postdivorce financial strains, reorganization of households, transitions with remarriage/repartnering and step-parenting, and persistent parental conflict or cutoff (Coleman, Ganong, & Russell, 2013; Greef & VanderMerwe, 2004; Greene, Anderson, Forgatch, deGarmo, & Hetherington, 2012). Research identifying family processes that distinguish those who are resilient can inform therapeutic and collaborative divorce efforts for optimal postdivorce child and family adaptation.

In resilience-oriented practice, family functioning is assessed in the context of the multigenerational system moving forward over time.

- A genogram and family time line (McGoldrick, Gerson, & Petry, 2008) are useful tools to schematize relationship

information and track system patterns to guide intervention planning, noting strengths and resources—past, current, and potential—as well as problems and limitations.

- It is crucial to note linkages between the timing of symptoms and recent or impending stressful events that have disrupted or threatened the family, such as a son's drop in school grades following his father's job loss and family financial strain.
- Symptoms frequently coincide with stressful developmental transitions. Each poses particular challenges, as new developmental priorities emerge, boundaries shift, and roles and relationships are redefined. Families must deal with both predictable, normative stresses, such as becoming parents, and unpredictable, disruptive events, such as the untimely death of a young parent or birth of a child with disabilities.
- Families are more resilient when they are able to balance intergenerational continuity and change and maintain links between their past, present, and future, especially with immigration (Falicov, 2012).
- Family history, stories, and patterns of relation and functioning transmitted across the generations influence response to adversity and future expectations, hopes, dreams, and catastrophic fears.
- The convergence of developmental and multigenerational strains affects family coping ability. Strains increase exponentially when current stressors reactivate past vulnerable issues or painful losses, particularly when similar challenges are confronted, such as life-threatening illness (McGoldrick, Garcia Preto, & Carter, 2014; Rolland, 2012).
- It is crucial to inquire about models and stories of resilience and extended family, cultural, and spiritual resources in overcoming past family adversity that might be drawn on or inspire coping strategies in the current situation.

ADVANTAGES OF A FAMILY RESILIENCE FRAMEWORK

Assessment of healthy family functioning is fraught with dilemmas. Postmodern perspectives have heightened awareness that views of family

normality, pathology, and health are socially constructed (Walsh, 2012b). Clinicians and researchers bring their own assumptive maps into every evaluation and intervention, embedded in cultural norms, professional orientations, and personal experience.

Moreover, the very concept of the family has been undergoing redefinition with the social and economic transformations of recent decades. Cultural diversity, varied family forms and gender roles, economic disparities, and a multiplicity of family arrangements require a broad, inclusive, and flexible view of family life (Cherlin, 2010; Walsh, 2012b). The life course is becoming more fluid, as children and their parents increasingly move in and out of varied and complex family constellations. Resilience is needed with disruptive transitions posing new adaptational challenges. Yet, a substantial body of research finds that children and families can thrive in a variety of kinship arrangements (Walsh, 2012b). What matters more than family form are the *processes* for effective family functioning and the quality of caring, committed bonds.

Systems-based research on family functioning over recent decades has offered empirical grounding to identify and facilitate key processes in intervention with distressed families (Lebow & Stroud, 2012). However, studies based on white, middle-class, intact families who are not under stress too often contribute to faulty assumptions that family distress and differences from the norm are pathological. Further, family typologies tend to be static and acontextual, not attending to a family's social or developmental influences and emerging challenges over time.

A family resilience framework offers several advantages.

- By definition, it focuses on strengths under stress.
- It is assumed that no single model fits all family situations. Functioning and resilience must be assessed in context: relative to each family's values, structure, resources, and life challenges.
- There are many, varied pathways in resilience. Processes for optimal functioning and the well-being of members will vary over time, as challenges unfold and families evolve across the life cycle.
- This approach to practice is grounded in a deep conviction in the potential for family repair, recovery, and growth out of adversity.

TABLE 54.1 Key Processes in Family Resilience

Belief Systems

Making meaning of adversity

- Relational view of resilience
- Normalize, contextualize distress; depathologize, decrease stigma, shame
- Sense of coherence: crisis as meaningful, comprehensible, manageable challenge
- Appraise adverse situation; options; future expectations

Positive outlook

- Hope, optimistic bias; confidence in overcoming barriers
- Encouragement; affirm and build strengths and potential
- Active initiative and perseverance (can-do spirit)
- Master the possible; accept what cannot be changed; tolerate uncertainty

Transcendence and spirituality

- Larger values, purpose
- Spirituality: faith, rituals and practices, congregational support
- Inspiration: new possibilities, dreams; creative expression; social action
- Transformation: learning, change, and growth from adversity

Organizational Patterns

Flexibility

- Rebound, reorganize to adapt to new challenges
- Regain stability: continuity, dependability, predictability to counter disruption
- Strong authoritative leadership: nurture, guide, protect
- Varied family forms: cooperative parenting/caregiving teams
- Couple/co-parent relationship: mutual respect; equal partners

Connectedness

- Mutual support, collaboration, and commitment
- Respect individual needs, differences, and boundaries
- Reconnection, reconciliation of wounded relationships

Social and economic resources

- Mobilize kin, social and community networks; models and mentors
- Financial security; work/family balance; institutional supports

Communication/Problem Solving

Clarity

- Clear, consistent messages (words, deeds)
- Clarify ambiguous information; truth seeking/truth speaking

Open emotional expression

- Share range of feelings with empathy; respect differences
- Pleasurable interactions, respite; humor

Collaborative problem solving

- Creative brainstorming; resourcefulness
 - Shared decision making; negotiation, fairness, reciprocity
 - Focus on goals, concrete steps: build on success; learn from failure
 - Proactive stance: prevent crises; prepare for future challenges
-

KEY PROCESSES IN FAMILY RESILIENCE

The Walsh Family Resilience Framework identifies nine key processes and subcomponents for resilience, as outlined in Table 54.1. It is informed by three decades of research in the social sciences and clinical field on resilience and well-functioning family systems. The framework synthesizes major findings within three domains of family functioning: family belief systems, organizational patterns, and communication processes (Walsh, 2003, 2006).

- Family belief systems support resilience when they help members (1) make meaning of adverse experiences; (2) sustain a hopeful, positive outlook; and (3) draw on transcendent or spiritual values and purpose (Walsh, 2009).
- In family organization, resilience is fostered by (1) flexible yet stable structure, with strong leadership; (2) connectedness for mutual support; and (3) extended kin, social, and community resources.
- Communication processes facilitate resilience through (1) information clarity, (2) sharing of both painful and positive emotions, and (3) collaborative problem solving, with a proactive approach to future challenges.

APPLICATIONS OF FAMILY RESILIENCE APPROACHES

Family resilience-oriented practice shares principles and techniques common among strengths-based approaches but attends more centrally to links between presenting problems and family stressors, focusing on family coping and adaptational strategies. Interventions are directed to strengthen relational bonds and tap resources to reduce vulnerability and master family challenges. The family resilience framework is designed to guide assessment, interventions, and prevention to identify and strengthen key processes that foster recovery and growth.

A family resilience framework and supportive research find useful application in a range of adverse situations (Lietz, 2013; Rolland, 2012; Walsh, 2006; 2007; 2013):

- Healing from crisis, trauma, and loss (e.g., family bereavement, relational trauma,

war-related and refugee trauma, disaster recovery)

- Navigating disruptive transitions (e.g., migration, separation/divorce, stepfamily formation, foster/kinship care)
- Mastering multi-stress challenges with chronic conditions (e.g., illness/disability, unemployment/financial strain; community violence/blight; discrimination)
- Supporting positive development of at-risk youth (family-school partnerships, gang prevention programs)

Efforts to foster family resilience benefit all family members, not only those currently presenting symptoms. A systemic assessment may lead to multilevel approaches to risk reduction, problem resolution, and individual/family well-being. Putting an ecological view into practice, interventions often involve community collaboration and change, peer groups and social networks; and workplace, school, health care, and other larger systems. Programs for youth mentoring, skill-building, parenting and caregiving and creative expression through the arts are important components of many resilience-oriented interventions (Saul, 2013).

Family resilience-oriented intervention approaches are increasingly being developed for situations of mass trauma, such as war-related trauma and major disasters (e.g., Landau, 2007; MacDermid, 2010; Saul, 2013; Walsh, 2007). In contrast to individual symptom-focused treatment programs, such multi-systemic approaches build healing networks that facilitate individual, family, and community resilience. Programs create a safe haven for family and community members to support each other in sharing both deep pain and positive strivings. They expand a shared vision of what is possible through collaboration, not only to survive trauma and loss, but also to regain their spirit to thrive.

Resilience-oriented family interventions can be adapted to a variety of formats.

- Family consultations, brief counseling, or more intensive family therapy may combine individual and conjoint sessions, including members affected by stressors and those who can contribute to resilience.
- Psycho-educational multifamily groups, workshops, and community forums provide

social support, with practical information, and concrete guidelines for stress reduction, crisis management, problem solving, and optimal functioning as families navigate through stressful periods and face future challenges.

- Brief, cost-effective periodic “modules” can be timed around critical transitions or emerging challenges in long-term adaptation, for example, a chronic illness, divorce processes, or disaster recovery.

CONCLUSION

Crisis and challenge are inherent in the human condition. In order to move beyond the rhetoric of promoting family strengths, research and practice priorities must shift focus from how families fail to how they can succeed. Conceptual and research efforts to date have laid important groundwork for understanding and facilitating family resilience in a wide range of adverse situations. Further mixed-method research is needed to advance our knowledge and practice (DeHaan, Hawley, & Deal, 2013). The field also needs to address emerging societal challenges, from workplace and health care restructuring to retirement, elder caregiving, and end-of-life dilemmas with the aging of families (Walsh, 2012a).

A research-informed family resilience framework can guide clinical and community-based practice by assessing family functioning on key system variables as they fit each family’s values, structure, resources, and life challenges and then targeting interventions to strengthen family resilience as presenting problems are addressed.

55 Treatment Planning with Families

An Evidence-based Approach

Catheleen Jordan, Cynthia Franklin, & Shannon K. Johnson

TREATMENT PLANNING WITH FAMILIES

For the past 20 years managed behavioral health care and other accountability and cost containment approaches have encouraged the move toward formalized family treatment planning and the trend toward efficacious, brief family therapy interventions. In order to develop a formalized treatment plan social workers must be able to identify measurable goals, objectives, and

outcomes as well as evidence-based treatments known to be effective with specific client problems and populations. A family treatment plan (see Figure 55.1 for an example) can be understood as a roadmap that can be used to guide a family’s pursuit of its shared goals. A family treatment plan should specify the overarching treatment goal, along with objectives and interventions. It is crucial that, during the treatment planning process the social worker devise a plan for measuring and monitoring ongoing progress

Problem: Adolescent behavior problems	
Definitions: Aggressive conduct that threatens physical harm to family members	
Goals: Eliminate adolescent aggressive behavior	
Objectives:	Interventions:
1. Family members learn anger management techniques	1. Teach the family the skills of recognizing one's escalating anger, taking a timeout to cool down, acknowledging one's contribution to the aggressive situation, negotiating a solution.
2. Parents and adolescent establish a behavioral contract	2. Teach the parents to negotiate a contract with the adolescent that specifies rules/expectations, consequences, and rewards
Diagnosis: 312.8 Conduct Disorder, Adolescent-Onset Type	

Figure 55.1 Treatment plan example.

on each objective over the course of treatment (Hepworth et al., 2012). This means that a treatment plan is not a one-time snapshot of the family's goals but a document that guides the progress of the family over time and may also be revised over the treatment process. Treatment plan content, for example, may be modified as the family's goals are achieved or change. If a treatment team is providing services to the family, the treatment plan should specify which provider is responsible for each specified intervention.

Special challenges in treatment planning with families include selecting problems, goals, and outcomes that are meaningful to all family members. For instance, the parents may desire their child to become more compliant; the child, on the other hand, may desire an end to constant parental nagging! Also, goals and interventions should be selected with consideration for issues of diversity (Gehart, 2013). For example, the social worker should select interventions that best match the client, their culture, preferences, and circumstances. Although individual treatment planning requires careful consideration of client characteristics (e.g., ethnicity, sexual orientation, religious beliefs, physical health) and life circumstances (e.g., income, transportation, employment, and parenting demands) (Antony & Barlow, 2011), family treatment planning requires consideration of these factors

for each member of the family unit. Another challenge in family treatment planning is that problem-focused treatment planning is sometimes at odds with the systems approaches that are used in family intervention and the social work strengths-based approach, which is also used to work with families. Hepworth and colleagues (2012) advocate stating goals in positive terms. For instance, rather than stipulating that an adolescent will *reduce* noncompliance, one can indicate that the adolescent will *increase* instances of compliance with household rules.

STEPS OF TREATMENT PLANNING WITH FAMILIES

Treatment planning requires the social worker to think through the therapeutic process from assessment to intervention and evaluation. Today's focus on brief, manualized interventions is perfect for this type of planned approach, because it requires the problem to be measured. Standardized measures are instruments completed by the client and/or social worker that provide a score indicating the extent or severity of a client problem. For example, a couple may complete the Hudson Index of Marital Satisfaction; each receives a score indicating the level of satisfaction with the marriage. A score

more than 25 indicates a clinically significant problem. Standardized scales should be administered repeatedly over the course of treatment so that scores can be graphed to assess, track, and evaluate client progress (Hepworth et al., 2012). Dattilio, Jongsma, and Davis (2010) identify six steps of treatment planning: (1) problem selection; (2) problem definition; (3) goal development; (4) objective construction; (5) intervention creation; (6) diagnosis determination.

Step 1: Problem Selection

Problem selection in family treatment requires the social worker to assess client problems and then prioritize them in a way meaningful to the family. Jordan and Franklin (2011) recommend a problem selection and specification process guided by a person-in-environment perspective. Problem assessment moves from a global, systems view to an operationalized view of specific problems. For example, a global assessment technique, such as an eco-map, is used to obtain a global view of the family in the context of their important environmental systems. From the map, the social worker is able to conclude that problems stem from a relationship pattern between an adolescent and parent, where the parenting and communication is not working well and the adolescent is having behavioral problems. Specific problem data specific to a particular problem or behavior (e.g., alcohol use by the adolescent) may be collected via standardized measures. In Figure 55.1, the treatment plan example, the problem is the adolescent's alcohol use. We further specify the meaning of the problem in Step 2, the problem definition.

Step 2: Problem Definition

After the problem(s) is selected, it must be defined. The *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)* is the most agreed upon way of categorizing or defining problems, but is not always the most meaningful to family social workers, especially considering the controversies around its' limitations and usefulness for social work practice. As mentioned before, standardized measures have gained popularity in social work and may be used to quantify client problems. Examples of problems that may be measured in this way include family relationships and satisfaction, marital satisfaction, sexual abuse and family violence, dual career

relationship, child and parent relationships, and so forth. Individual problems such as depression, self-esteem, or anxiety, which may be a part of a family's problem, can also be easily measured using standardized instruments.

Other ways of measuring problems include counting discrete behaviors (e.g., number of family arguments or number of child tantrums) or developing goal-attainment or self-anchored scales. Goal-attainment scales, developed by the social worker, are used to identify outcomes and to operationalize categories indicating successive approximations toward 100% goal completion. Numbers are assigned to each category with minus signs indicating lack of progress or deterioration. A typical scale range is from -2 to +2. Self-anchored scales are developed by the social worker in conjunction with the family. The targeted behavior, for example family satisfaction, is rated from 1 to 5. A rating of 1 may stand for "the most satisfied" and 5 "the least satisfied" that the family can imagine. Anchors, indicating specific family behaviors, are then matched with each numerical ranking. For instance, the family may describe a category 1 ranking, the "most satisfied," as a time when they were having dinner together as a family, engaged in pleasant conversation with no fighting, and so on.

In addition to a focus on problems, the value of a strengths-based approach encourages social workers to measure and intervene by building on client strengths (e.g., number of positive family communications or family outings). These positive behavioral objectives may be incorporated into the treatment plan. In the treatment plan example, Figure 55.1, the problem is defined as underage alcohol use, truancy, breaking curfew, and disregard for household rules. We then develop a goal statement in Step 3.

Step 3: Goal Development

Dattilio, Jongsma, and Davis (2010) recommend specifying one goal statement for each problem. The goal statement is a broadly stated description of what successful outcome is expected. Goals are not necessarily operationalized in measurable terms, as are objectives. Instead, they may be broad statements of the overall anticipated positive outcome. In the sample treatment plan (Figure 55.1), the goal is to achieve abstinence from drinking and increase compliance with household rules and expectations. We could

specify additional goals, such as improving parenting skills or increasing the amount of quality time the family spends together. Goals may be long-term expectations. We further operationalized the goal by specifying objectives in Step 4.

Step 4: Objective Construction

Objectives are the measurable steps that must occur for the goals to be met. Each goal should have at least two objectives that are operationalized in measurable terms and provide the short-term steps necessary to achieve the goal. In the sample plan (Figure 55.1), the social worker may measure the objective of, “adolescent to receive all services recommended by substance abuse and mental health assessors” by having the adolescent provide a copy of treatment recommendations, and then create and maintain a weekly log of participation in treatment activities. The objective is measurable. Target dates should be assigned to each objective to focus treatment sessions and to ensure brief treatment and problem resolution (Hepworth et al., 2012). As families progress through treatment, they may add additional objectives. The next step moves the treatment plan from defining and operationalizing problems to specifying the intervention.

Step 5: Intervention Creation

Interventions, the clinicians’ tools for treating the problem, should be matched with each objective. Although interventions are selected according to the social worker’s theoretical clinical orientation and clinical expertise, it is important to note that the trend in family social work is toward brief, evidence-based methods that have proven efficacy for specific families or family problems. When selecting interventions, social workers are advised to consider family characteristics, the target problems and diagnoses, and the evidence-base for potential interventions for those problems/diagnoses, respective to client family characteristics.

Another trend in treatment is toward manualized interventions and treatment planners that provide guidelines to the social worker as to how to proceed with specific problems. Manualized interventions involve greater operationalization of the treatment, which heightens the social worker’s ability to attribute positive changes to

the intervention. Meanwhile, treatment planners are designed to provide all the elements necessary to proficiently develop treatment plans that satisfy the demands of third-party payers and accrediting agencies. These elements include pre-written treatment goals, objectives, and interventions, organized around common presenting problems (Dattilio et al., 2010). In Figure 55.1, two cognitive-behavioral interventions have been specified, along with referral to individual services for the adolescent family member. Finally, the treatment concludes with a *DSM* diagnosis.

Step 6: Diagnosis Determination

Treatment planning assumes that an appropriate diagnosis will be determined, based on the overall client family picture. As mentioned before, the diagnostic approach has not been favored by many family social workers, due not only to its’ limitations (Jongsma, 2004), but also to the value social workers place on strengths-based treatment and a systems approach to assessment (Jordan & Franklin, 2011). Nevertheless, due to the demands of third-party payers, family therapy treatment planning is primarily based on a symptom-focused medical model (Gehart, 2013). Social workers face the reality of needing to know the characteristics of *DSM* criteria as part of a complete assessment picture. Fortunately, as *DSM* has gone into its’ fifth edition it has responded to some criticisms and required more of a complete assessment of a client’s bio-psychosocial presentation including cultural and life span issues across specific diagnosis. In Figure 55.1, the diagnosis is 312.8 Conduct Disorder, Adolescent-Onset Type. It is possible that the adolescent may be dealing with substance use in addition to Conduct Disorder because these two diagnoses often co-occur. The social worker has made a referral to specialized outside assessment to make this determination.

TREATMENT PLANNING RESOURCES FOR FAMILY SOCIAL WORKERS

Dattilio, Jongsma, and Davis (2010) emphasize the importance of developing an individualized treatment plan for each client family, based on its own uniqueness. Following are references helpful to the social worker proceeding through each step of the treatment plan.

Problem Selection and Definition

Jordan and Franklin (2011) provide a framework for assessment that teaches the social work practitioner to move from a global, person-in-environment family picture to a more specific, measurable focus on target problems and strengths. Specific standardized instruments for measuring child and family problems are presented by Corcoran and Fischer (2013). Bloom, Fischer, and Orme (2009) discuss a variety of ways available to measure problems, including goal-attainment scaling and behavioral measurement mentioned earlier. Finally, prewritten treatment goals, objectives, and interventions and a sample treatment plan that conforms to the requirements of most third-party payers and accrediting agencies are available from Dattilio, Jongasma, and Davis (2010).

Goal and Objective Development

Jongsma (2004) discusses goal and objective setting for general practice and for family practice. Social work research-practitioners, Bloom and colleagues (2009), discuss goal and objective setting from a single subject design perspective. Their text describes not only how to measure problems but how to set up a system for tracking therapeutic progress. Finally, Gehart (2013) provides a guide to writing useful client goals that includes a goal writing worksheet that walks the practitioner through a process of identifying the linkages between the presenting problem, family dynamics, and client symptoms before identifying the most appropriate intervention, based on evidence and theory.

Intervention Construction and Differential Diagnosis

Lambert (2013) reviews the efficacy of clinical interventions, including child, family, and marital therapy. Several texts written by social workers review methods available for treating families and children (Collins, Jordan, & Coleman, 2012; Franklin, Jordan, & Hopson, 2008; Janzen, 2006). Additionally, Reid's (2000) text provides a step-by-step guide for the practitioner in intervention task planning, including tasks for family social workers. Finally, Bloom and colleagues (2009) include software called Singwin, a computerized data analysis program for the ideographic data provided by single case analysis.

Future Applications for Treatment Plans

Treatment plans help ensure a positive future for client families. They help social workers to set measurable goals and objectives for clients and offer them in a brief and timely manner. Treatment planning requires that social workers specify what we will do in our way of helping. It provides a structure for an evidence-based approach to treatment, which is strongly encouraged and in some cases mandated. Finally, treatment planning requires that social workers document what is done to ensure accountability and to monitor progress through the treatment process. Family Treatment plans further ensure that social workers offer the best possible social work treatment based on considerations of culture, socioeconomic status, family preferences, and values.

56 Effective Couple and Family Treatment

Cynthia Franklin, Cathleen Jordan, & Laura M. Hopson

INTRODUCTION

The practice and research on couple and family treatment is supported by several disciplines, including social work, psychology, family science, and marriage and family therapy. As a result of this interdisciplinary participation, a number of effective therapeutic methods have developed. This chapter offers a review of couple and family therapies for social work practitioners. The goal of the review is to help practitioners be able to select practices that have research to support their effectiveness and to be knowledgeable about which couple and family interventions may be applied with different client populations. Other chapters within this section cover in more detail different approaches to couple and family practice.

COUPLE AND FAMILY PRACTICE METHODS

The 1950s and 1960s ushered in the development of specific family therapy models grounded in

systems theory that view individual problems in relationship to other family members and significant others in the social environment. One of the most influential places for early research and training on family therapy was the Mental Research Institute (MRI) in Palo Alto, California, which was founded in 1959 by psychiatrist, Don Jackson (Watzlawich, Beavin, & Jackson, 1967). The team included Gregory Bateson (1972), social worker, Virginia Satir, co-founder (Satir, 1964), John Weakland, and Paul Watzlawich (Watzlawich, Weakland, & Fisch, 1974). Many other influential family therapists were trained at the MRI such as social workers, Steve de Shazer and Insoo Kim Berg (de Shazer et al., 1986), who created the Solution-focused brief therapy and Jay Haley who founded the Strategic Family Therapy (Haley, 1976). Simultaneous to the work at the MRI, Murray Bowen developed a family systems approach in his work with families with a schizophrenic member at the Menninger Clinic, Salvador Minuchin developed structural family therapy (Minuchin, Montalvo, Guerney, Rosman, & Schumer, 1967), and Gerald

Patterson subsequently created behavioral family therapy (Patterson, 1975), an approach that is often integrated with systems approaches.

All family systems approaches have in common a focus on making changes in the family as a means of creating therapeutic change; and different approaches have increasingly been integrated in couple and family practice to develop empirically supported treatments. Family researchers, for example, are combining strategies across models to design empirically based treatments for high-risk groups, such as serious juvenile offenders and substance-abusing youths (Henggeler & Sheidow, 2012; Sells, 2000; Szapocznik, Hervis, & Schwartz, 2003). Systems approaches may also integrate diverse therapies, such as those from cognitive behavioral therapy in an attempt to create the most efficacious interventions for couple and family treatment.

Family systems models have spawned widely used couple and family practices within social work and allied disciplines as is indicated by surveys of practitioners. Results from a survey of clinicians ($n = 2,281$) in the *Psychotherapy Networker*, in 2007, for example, showed that couple and family systems approaches were the second most popular treatment modality (The Top 10: The Most Influential Therapists of the Past Quarter-Century. *Psychotherapy Networker*: 2007, March/April). It was also acknowledged by clinicians that client populations may be helped by the various treatment modalities differentially. Practicing therapists frequently use a combination of couple and family techniques from different models rather than adhering to one particular approach. This survey supports the trend toward integrationism, technical eclecticism, and the use of common factors as preferred ways that most practitioners work (Sprenkle, Davis, & Lebow, 2009). Multicomponent treatment programs, which emphasize the integration of more than one approach, are increasingly used with specific client populations and interventions are often purposefully designed that way as the field has moved toward evidence-based practice. Many evidence-based couple and family approaches also share common characteristics or core components. Parent management training is one of the primary components of effective treatment programs, for example (Kazdin & Whitley, 2003). Effective interventions typically include educational components and opportunities to practice new skills, such as communication and problem-solving skills. Practitioners model new behaviors and provide feedback to family members on their ability to implement the behaviors. Intervening on multiple ecological levels is also important, and many effective approaches intervene with family members, school

staff, and providers in the community (Schinke, Brounstein, & Gardner, 2002).

Couple and family approaches further may integrate feminist, postmodern, critical race, and multicultural theory into systems perspectives because these viewpoints are very significant to understanding how relationships in diverse family systems function (Boyd-Webb, 2013). Feminist theory, for example, helps practitioners be aware of the structural inequalities between men and women and the power dynamics within families that may maintain presenting problems. Multicultural perspectives help therapists to be responsive to many different kinds of families and to further be able to assess and intervene into structural inequities and issues of social justice that may be impacting on family relationships, such as issues of immigration and discrimination. A focus on couple and family treatment also calls for a broad understanding of how to define a couple or family unit. In implementing family interventions, practitioners define the couple and family system as those individuals that consider themselves a couple or family and those significant others who are involved with the presenting problem or who could be a resource in developing a solution. In addition to intervening with family members and significant people involved with the problem, therapists may intervene with an individual client, a live-in couple, a foster family, a social services agency representative, or a teacher. The phrase “problem-determined system” is sometimes used to describe this means of defining the system in which to work. Family system interventions commonly call for practitioners to intervene into whatever systems are necessary to resolve problems, whether it be, for example, an extended family, school, or peer system.

EFFECTIVENESS OF COUPLE AND FAMILY TREATMENT APPROACHES

Past meta-analyses have demonstrated that family therapy works as well as other therapies and that it can be especially efficacious for certain client groups (Shadish et al., 1993; Shadish & Baldwin, 2003). Stanton and Shadish (1997), in a meta-analysis of drug abuse outcome studies, found that family interventions are favorable to individual or peer group approaches and have higher retention rates. Among juvenile

delinquents, family interventions reduce the risk of rearrest (Woolfenden, Williams, & Peat, 2005). Studies also show that family therapy reduces client utilization of the health care system (Law & Crane, 2000). Several reviews of couple and family therapy approaches have also been written for practitioners and these reviews show effective applications of the different family interventions (e.g., Carr, 2009; Corcoran, 2003; Hoagwood, 2005; Sprenkle, 2012; Thompson, Pomeroy, & Gober, 2005). Sprenkle's (2012) review suggested that the most research support for family therapies was with conduct disorder, drug abuse, psycho-education with mental illness, alcoholism, relationship distress, including relationship education, and child and adolescent disorders. Recent guidelines for classifying evidence-based treatments in couple and family therapy, developed by Sexton, Coop Gordon, Gurman, Lebow, Holtzworth-Munroe, and Johnson (2011) may be useful in selecting interventions: Category 1—some evidence for the model as compared with reasonable alternatives (i.e., treatment as usual); Category 2—promising model, has some verification; and Category 3—effective model with strong scientific evidence of effectiveness, shows change with various problems and populations. The strongest studies have relevant comparison groups, random assignment, treatment fidelity measures, and use of multiple measures to measure outcome; as mentioned, a trend in family therapy is to integrate techniques from more than one family therapy model and to operationalize these using clinical manuals and protocols.

WHAT COUPLE AND FAMILY INTERVENTION TO USE WITH YOUR CLIENTS

Across family therapy models, characteristics of the therapeutic relationship are important factors moderating the effectiveness of family interventions. One meta-analysis indicates that therapeutic relationship variables are good predictors of family therapy outcomes (Karver, Hadelsman, Fields, & Bickman, 2006) and the use of self in couple and family interventions is particularly important because these therapies are directive and rely on the person of the therapist in the change processes. It is also important to keep in mind that even though all the models of couple and family practice show potential effectiveness, certain models have better outcome research,

and evidence has accumulated suggesting that these couple and family treatments show clinical efficacy or considerable promise when applied to certain client groups (Sprenkle, 2012). At the present time, Behavioral, Cognitive-behavioral, Functional, Psycho-educational, and Ecostructural and Strategic, including Multisystemic, Emotion-focused and Solution-focused models have accumulated considerable evidence for their effectiveness with client groups. Each one of these approaches also has well-developed clinical protocols, procedures, and treatment manuals to help social workers and other therapists learn how to do the interventions.

Behavioral family therapies have shown effectiveness with child and adolescent issues and couple's distress. A number of studies support Behavioral Parent Training Intervention where studies show statistically significant findings for treating hyperactivity, parenting, behavior problems, developmental and speech disorders (Sexton, Datchi, Evans, LaFollette, & Wright, 2013; Franklin, Harris, & Allen-Meares, 2012). Functional family therapy, which integrates systems theory and behavioral methods into its own unique relationship therapy, works with juvenile offenders and their families. There is also evidence to show that functional family therapy reduces arrests in younger siblings (Sexton, 2010). Skills training approaches based on behavioral therapies also work in prevention of substance use and antisocial behaviors. Functional family therapy has also shown empirical support for treating sexual or physical or verbal abuse (Sexton, Datchi, Evans, LaFollette, & Wright, 2013). Lebensohn-Chialvo (2014) further reports that treatment programs for child maltreatment have several behavioral methods including family preservation programs and the most successful child maltreatment prevention programs are family-focused, utilize home visits and a strengths based approach, and aim to increase social supports; these were found to decrease abuse and neglect as well as to improve child adjustment and overall family functioning. Two other family interventions that are integrated programs, and which use behavioral interventions and have shown success with youth behavior problems are Incredible Years and Triple P Positive Parenting (Sexton et al., 2013).

Behavioral couple therapies are also among the most well-researched and effective treatments for distressed couples and also for the treatment of alcohol problems (Johnson & Lebow, 2000;

Lebow, Chambers, Christensen, & Johnson, 2012; O'Farrell & Clements, 2012; Perissutti & Barraca, 2013; Shadish & Baldwin, 2005). Behavioral Couple Therapy has been shown in studies to improve family relationships, decrease relationship dissatisfaction, decrease substance abuse and depression, and improve the relationship in the case of infidelity (Sexton, Datchi, Evans, LaFollette, & Wright, 2013; Lebensohn-Chialvo, 2014; O'Farrell & Clements, 2012). Another type of behavioral family therapy called, Integrated Behavioral Family Therapy, further integrates family systems theory and cognitive-behavioral therapy and demonstrates positive outcomes with substance-abusing youth (Thompson, Pomeroy, & Gober et al., 2005; Barrett Waldron, Slesnick, Brody, Turner, & Peterson, 2001).

Family Psychoeducation is also associated with Behavioral interventions and has been used in mental health and hospital settings with chronic illnesses (Lefley, 2009). It has been found to be a useful approach when families have members with mental illness such as schizophrenia or chronic health conditions such as diabetes. Psychoeducation uses multifamily group interventions and provides education and social support; it is the family treatment of choice when working with chronic health conditions. Research also demonstrates that participation in Psychoeducation is associated with increased social supports and improved ability to manage social conflicts (Magliano, Fiorillo, Malangone, De-Rosa, & Maj, 2006).

Eco-structural and Strategic interventions are successful interventions for youth with conduct disorders, eating disorders, substance abuse, and attention deficit hyperactivity disorder (ADHD). The Maudsley method for treating Anorexia and Bulimia, for example, was influenced by Minchin's Structural family therapy and added elements from Strategic interventions and created its' own unique methods for empowering parents to get adolescents to resume normal eating. Maudsley has been investigated in clinical trials research and has become an important treatment for adolescents with eating disorders (Loeb & le Grange, 2009). Brief Strategic Family Therapy (BSFT) integrates concepts from systemic, structural, and strategic models in addressing issues of delinquency, substance abuse, and family relationship problems. The BSFT model has been evaluated repeatedly over the course of 30 years and has shown effectiveness in clinical trials research treating minority and nonminority

adolescents with behavior problems including drug use (Robbins et al., 2011). Other Integrated treatments that use Eco-structural and Strategic approaches, and which show promising results, include Multisystemic Therapy (Henggeler & Sheidow, 2012) and Multidimensional Family Therapy (Henderson, Dakof, Greenbaum, & Liddle, 2010). The Multidimensional approach also integrates a developmental approach to assessment and treatment. All of these family programs have repeatedly been shown to be effective with youth with delinquent behavior and substance use.

Multisystemic therapy (MST), which uses ecological approaches, intensive family preservation, and Structural family therapy, has also demonstrated positive outcomes with hard-to-reach juvenile delinquents and substance abusers (Henggeler & Sheidow, 2012). This approach also offers sophisticated protocols for engaging hard-to-reach clients and manuals for maintaining the treatment adherence of therapists. Past controversies regarding the effectiveness of MST, however, illustrate to social workers the challenges of identifying evidence-based interventions, because researchers may not always agree what therapies have the best evidence. MST, for example, is widely accepted as evidence-based intervention by federal funding organizations and practice settings (Franklin & Hopson, 2007). Yet one systematic review conducted by the Nordic Campbell Center of the Campbell Collaboration concludes that the intervention is not consistently more effective than alternative treatments (Littell, Popa, & Forsythe, 2005). Over time, new research may call into question the effectiveness of other approaches or provide more evidence for some of the promising programs that are not currently considered to show very much empirical support. For this reason, social work practitioners must continuously stay tuned to the ongoing developments in therapy, as well as evaluate their own practices. The Sexton et al. (2011) guidelines mentioned above may be especially helpful for practitioners to consider when evaluating the efficacy of various couple and family approaches for use in their own practices. Assessment and outcome measures are especially important to use in determining the relative effectiveness of the approaches with individual cases (Jordan & Franklin, 2011).

Another efficacious intervention is the Emotion-focused therapy for couples, which emphasizes the importance of attachment and

Box 56.1 Case Study for Brief Strategic Family Therapy: The Guerrero Family

CLINICAL PRESENTATION

The Guerrero family consists of a mother, a father, and 11- and 14-year-old sons. They were referred to the clinic by the 14-year-old's school counselor after he was caught smoking marijuana in the school bathroom. The counselor visited the home and found the youngest son and the mother eating dinner. The identified patient and the father were not there. The mother immediately began to list excuses why her oldest son was not home when he should have been. She had trouble accepting what the school counselor had done and insisted that the teacher who had reported him "has it out for my son." Toward the end of the counselor's first visit, the father came home. He ignored his wife and younger son and went directly to the kitchen. On finding no food ready for him, he shouted over his shoulder at his wife, asking her why she had not made him dinner. When the father was asked to join the session, he declined, saying that his wife was in charge of discipline and that she was not doing a good job at it. The 14-year-old did not come home during the counselor's visit.

Establishing the Therapeutic System

When the counselor first arrived at the Guerrero home, he began to join with the mother. He sat at the dinner table with the mother and the younger son and validated the mother as she complained about the father's disengagement and the oldest son's out-of-control behavior. The younger son chimed in periodically about his brother's sour attitude, and the counselor empathized with his grievances. Although the counselor's initial attempts to join with the father were unsuccessful, the counselor later adopted a more focused approach. When he spoke to the father, the counselor emphasized that his participation was needed to keep his son from getting into more serious trouble. The counselor also assured the father that participating in therapy could help reduce his wife's nagging about his disengagement from the family.

Joining with the drug-abusing son was somewhat more difficult. He resisted the counselor's first few attempts to join with him over the phone and was absent from the home

during the counselor's first few visits. Finally, the counselor approached the adolescent at the park after he and his father had had a major fight. The counselor assured the youth that being in BSFT could help ensure that that type of fight would not happen again.

DIAGNOSIS

When the counselor met with the whole family, the mother began to tell him about her son's problems. The counselor asked the mother to tell her son about her concerns. As the counselor encouraged the family members to speak with one another, he also observed the patterns of interaction along the following BSFT diagnostic dimensions.

Organization. A strong alliance exists between the mother and her 14-year-old (problem) son; the father is uninvolved. The children communicate with the father mostly through the mother. The mother and the father do not share much time as a couple. The mother is responsible for child-rearing nearly all the time. The mother and father ally occasionally, but only regarding unimportant issues, such as what to eat for dinner.

Resonance. The mother indicates what her 14-year-old son prefers to eat, and the mother and her 14-year-old son laugh together, both signs of enmeshment. The father is frequently "too busy" to participate in family activities, a sign of disengagement. Complaints of family members about other family members during the interview are highly specific, a sign of adaptive functioning along this dimension.

Developmental stage. The children are not allowed to play outdoors at night. The mother uses her 14-year-old son as her confidante, complaining to him that his father comes home late.

Life context. The father has a demanding job, while the mother finishes her work early and is home by 3 P.M. The family lives in a high-crime neighborhood; drug dealing gangs recruit in the area. The mother and father are not involved in arranging or supervising activities for their adolescent son and his peers. The 14-year-old son is associating with antisocial youth in the neighborhood.

Identified patient. The father comes home late and does not help with chores at home. His 14-year-old son is rebellious, refuses to do chores, and has conduct problems at home and in school. He also comes home late, often very excited and irritable. He stays up much of the night listening to music, then sleeps deep into the day. The 11-year-old son is a model child.

Conflict resolution. Conflicts are diffused through angry blaming and recriminations.

GENERAL DISCUSSION OF THE DIAGNOSIS

In the Guerrero family, the parents have assigned themselves separate role responsibilities. The mother is fully responsible for all child-rearing, and the father's responsibility in this area is very limited. Because there appears to be an unspoken agreement between the parents to be distant from each other, it can be assumed that they prefer their separate role responsibilities for their own reasons. This is maladaptive behavior in terms of child-rearing issues because the father and mother do not cooperate in parenting functions. Rather, it may appear that the mother and the troubled son are the ones allied, with the father off on the side. If one looks a little deeper, it would not be surprising to find that the same patterns of interaction occur around content areas other than child-rearing. In fact, these kinds of interactive patterns or structures are almost always found to reoccur in most aspects of family life. If they occur around one content, they are almost invariably occurring around most (if not all) contents. The lack of a strong parental alliance with regard to child-rearing issues undermines the family's ability to chart an effective and successful course of action. This is particularly troublesome when there are forces external to the family that influence the adolescent's development of behavior problems. These forces include the adolescent's peer group and the behavioral expectations that exist or to which the youth is exposed outside the home. These ecological forces provide training and opportunity for a full rebellion on the part of the adolescent.

A BSFT intervention will target changing the interactional patterns preventing the family from successfully charting the youth's path away from antisocial peer groups and

externalizing behaviors. This intervention involves restoring parental leadership capabilities by first creating a parental leadership alliance. In resonance, it becomes clear that because the father is outside of the mother-child alliance, he is less concerned about what goes on within that alliance. Because he stays out, he is emotionally distant (disengaged) from both his wife and his son. In contrast to this, the mother and her 14-year-old son are much closer emotionally and psychologically; thus, they are likely to be enmeshed. Whether one defines the mother as enmeshed with the son or the mother and son as disengaged from the father, it is obvious that there is a difference in the psychological and emotional distance that exists between father and mother and father and son on the one hand and mother and son on the other.

On the dimension of developmental stage, it appears that the 14-year-old boy may be burdened with emotional responsibilities that are more appropriately assigned to a spouse, such as being the mother's confidante. The other child is not allowed out after dark. This seems appropriate given the dangerousness of the neighborhood.

In this family, the identified patient is sometimes the troubled son and sometimes the isolated father. Although the negativity the mother and the 14-year-old show toward the father functions to keep him out of the family, both the mother and father blame their current problems on their oldest son. If he were not rebellious, their separate role arrangement would work quite well for each of them. Unfortunately, conflicts between the mother and the father are not being resolved because their attempts to address their differences of opinion degenerate into blaming wars.

PLANNING TREATMENT BASED ON DIAGNOSIS

Understanding the dimensions that describe family interactions goes a long way toward helping the BSFT counselor define what he or she must do as a counselor: diagnose the problem in terms of specific dimensions of family interactions and then implement strategies to correct problems along these dimensions. Often some dimensions are more problematic than others and need to be the greater focus of

the intervention. The counselor diagnosed the oldest son's drug abuse problem in terms of ineffective behavior control resulting from the following.

- Organization: absence of a parental subsystem that works together. Mother and father need to be assigned collaborative tasks that will bring them together.
- Organization: improper alliances. Boundaries must be strengthened between mother and 14-year-old son.
- Resonance: maladaptive boundaries in which one parent is too close (enmeshed) to the problem child, and a second parent is too far (disengaged) from the spouse and that same child.
- Boundaries need to be shifted so that the parents are closer to one another emotionally and interactionally, the children are more "in tune" with each other, and a healthy separation exists between the parents and the children.
- Developmental stage: developmental stage may be inappropriate in that the enmeshed child is burdened and confused by a spousal role (confidante to mom's unhappiness with dad). The counselor should encourage the mother and father to serve as each other's support system.
- Identified patient: enmeshed child is identified by the family as its major problem. The counselor needs to shift the family's attention to help family members understand that the whole system, rather than only the adolescent, is part of the problem. Also, family members need to eliminate negative attitudes and enabling behaviors they display toward the adolescent patient to "free" him to act in a socially appropriate manner.
- Life context: 14-year-old identified patient is involved with a deviant peer group. The mother, father, and patient should negotiate rules and consequences for the adolescent's misbehavior, and boundaries between the family and the outside world

need to be strengthened. Additionally, the parents may need to be more involved with the parents of their son's peers to make it easier to more effectively supervise their adolescent's activities.

- Conflict resolution: family may have certain conflicts repeatedly occur and never get resolved because each time differences emerge, they are either avoided or, more often, diffused through blaming wars. The counselor should refocus the interaction on the problem each time family members attempt to avoid the issue or change the subject so that the conflict may be negotiated and resolved.

PRODUCING CHANGE

Having diagnosed the problem in terms of these dimensions, the counselor was able to target interventions directly at the problematic interactions within these dimensions. One of the BSFT counselor's first moves was to help the disengaged father get closer to his estranged 14-year-old son. At the same time, the counselor initiated a dialogue between the parents about this youth to try to establish an alliance between the parents around the content of their mutual concern for their son. The next step was to help the parents negotiate rules for the youth that once implemented, would bring his out-of-control behavior under control. As these changes were being negotiated, the family displayed frequent conflict avoidance and diffusion. When the family attempted to diffuse or avoid the conflict, the counselor would intervene and return the topic of conversation to the original conflict. In the process, the family acquired new conflict-resolution skills. The parents were able to agree on rules and consequences for the identified patient's behavior; these were discussed and, where appropriate, negotiated between the parents and the son. Ultimately, the parents were able to set consistent limits, and the adolescent's behavior improved.

emotional processes (Basham & Miehl, 2004; Greenberg & Goldman, 2008; Johnson, 2004; Lebow, Chambers, Christensen, & Johnson, 2012). Research studies on emotion-focused therapy are rapidly progressing, and there is

evidence for its effectiveness with distressed couples, including those who experience trauma (Denton, Bureson, Clark, Rodriguez, & Hobbs, 2000; Lebow, Chambers, Christensen, & Johnson, 2012). A meta-analysis indicates that

emotion-focused therapy may be more effective than behavioral models for treatment of marital distress (Wood, Crane, Schaalje, & Law, 2005). The revised behavioral couples therapy that includes components of emotion-focused interventions has also been shown to be effective with distressed couples (Lebow, Chambers, Christensen, & Johnson, 2012). Integrative couples therapy uses Acceptance strategies that reframe hard emotions, such as anger, into soft emotions, such as sadness. Discussions about attachment patterns learned in one's family of origin help couples gain insight, empathy, and acceptance of each other's behavior (Christensen, Atkins, Yi, Baucom, & George, 2006; Jacobson & Christensen, 1996).

Solution-focused brief therapy (SFBT) is a strengths-based approach that developed within brief family therapy; it can be applied to individuals or families and the research has progressed significantly on this approach over the past 15 years. Several experimental and quasiexperimental studies have accumulated on SFBT showing that it is a promising model with a wide range of problems including adult depression, and problems with child and family issues. (Franklin, Trepper, Gingerich, & McCollum, 2012; Gingerich & Peterson, 2013; Kim, 2008; Kim & Franklin, 2008; Newsome, 2004). Kim & Franklin (2008), for example, conducted a systematic review of studies of SFBT in school settings and discovered that one experimental design study, six quasiexperimental design studies, and one single-case design study on SFBT had been published since 2000. The effect sizes calculated by the authors and reported in the individual studies also show SFBT to be a promising intervention for work with children and families within school settings, with most studies having medium and some large effect sizes.

EXAMPLE OF A FAMILY INTERVENTION

Brief Strategic Family Therapy

BSFT was developed by Jose Szapocznik and colleagues at the Center for Family Studies. The model has been used in the context of prevention, early intervention, and intervention for families with children between the ages of 8 and 17 years to address issues of delinquency and substance abuse. BSFT is provided in 8 to 24 sessions, depending on the severity of the

presenting problems. Sessions may be conducted in office, home, or community settings based on the needs of the family. The model aims to improve outcomes for youth by improving the family environment. Box 56.1 presents a case example from the series *Therapy Manuals for Drug Addiction*, published by the National Institute of Drug Abuse (Szapocznik, Hervis, & Schwartz et al., 2003).

SUMMARY

Family therapies based on systems theory emerged in the 1950s and 1960s and have become useful treatment approaches for many different client problems. There is consistent support for the effectiveness of couple and family therapies, although there is better research on the efficacy of specific approaches with various client populations. Behavioral, Eco-structural, and Strategic family approaches appear to have considerable experimental and clinical support for their effectiveness. They also have a long history of application within the field. Newer models, like Emotion-focused couples therapy, are also building a solid empirical base for their effectiveness. Other promising models, such as SFBT, are developing a growing experimental research base. Family therapy has come a long way in developing an understanding of the common factors shared by all effective approaches. A trend in family therapy is to integrate techniques from more than one family therapy model and to operationalize these using clinical manuals and protocols, making it possible for practitioners to apply these treatment manuals in their practices. Evidence-based approaches to family treatment share core components and are integrative by design. As we move into the future, it is important for social workers to continuously appraise the changing evidence for different approaches to couple and family treatment and to stay abreast of new developments in the field, as well as to evaluate the effectiveness of their own practices, using appropriate outcome measures.

57 Structural Family Therapy

Harry J. Aponte & Karni Kissil

INTRODUCTION

Structural family therapy (SFT) addresses client objectives in the context of the current organization of client relationships vis-à-vis the issues being addressed. It is a systems-based model with one of its primary organizing principles positing that “changes in a family structure contribute to changes in the behavior and the inner psychic processes of the members of that system” (Minuchin, 1974, p. 9).

SFT has the unique legacy of having been born to meet the needs of poor inner-city youth and their families (Minuchin, Montalvo, Guernsey, Rosman, & Schumer, 1967). Its approach speaks directly to how clients experience life more than to conceptual abstractions about their struggles. It aims to achieve quick, palpable results. Lessons learned from poor, underorganized families (Aponte, 1994b) who had been structurally undermined by psychological and social stressors are relevant to all families from the general population. SFT focuses on concrete issues, located in the present, mediated through the client’s experience in session, based on reorganizing the structure of relationships, built on client strengths, aimed at palpable outcomes, and characterized by active therapist involvement. What follows is a brief commentary on the seven basic principles of structural family therapy.

FOCUS ON CONCRETE ISSUES

SFT looks for the urgent issue that has the family’s attention and intensity of concern (Aponte, 1998b). The therapist attends to the concrete manifestation of the issue, that is, how it is being lived and experienced by the client. The underlying assumption is that the “pain” at the core of the problem-laden experience carries within it the individual, family, and social dynamics that are generating the issue. Moreover, inside the pain-filled experience of the issue lies the goad to prod the efforts needed for change. It follows that the living pain-filled experience confronts people with the challenge to make problem-solving choices. These choices carry within them the worldview, ideals, and moral imperatives that frame people’s drive to change. Structural therapists are looking for what motivates clients to action because they intend to build on momentum generated by the concrete manifestation of the client’s experience of the issue.

- *The therapist connects with the family around the specific issue and the urgency with which it is driving the family to seek help.*

Example: The parents come in with their adolescent son who is failing in school. Mother anxiously presents the problem. The son pouts, and

the father steams silently. The therapist asks the son and father each to react to mother's concern. He wants them all to address the boy's failing, with whatever distress they are feeling around it.

LOCATED IN THE PRESENT

Structural family therapy views the past as “manifest in the present and . . . available to change by interventions that change the present” (Minuchin, 1974, p. 14). The client issue contains the focal point of today's concern, the dynamics currently generating the distress, and traces of the family's history that explain the whys and hows of the problem's genesis. By working through the present, the therapist connects with not only today's urgency for relief but also the forces concurrently precipitating the problem. The turbulence of the present provides the therapist with the most immediate and reliable access to the forces from the past being played out in today's drama. The therapist's interventions relate to the present experience of the client with the full force of its impact on the client's life today. The therapy itself is treated as another immediate context in which the issues are now alive and commanding attention.

- *The therapist relates to how the issue is affecting the family today.*

(continuing with the example above) The therapist asks specifically for details regarding the school situation right now, and where each family member stands in relation to it. The present picture is being drawn, to include the school, the mother, the father, and the boy—the facts, the thoughts, and the feelings, as they exist at this moment.

MEDIATED THROUGH THE CLIENT'S EXPERIENCE IN SESSION

The principal field of intervention for SFT is the family's enactment of their issue in the session (Aponte, 1998b; Aponte & VanDeusen, 1981; Minuchin & Fishman, 1981). The structural therapist looks beyond the verbal account of what has happened at home to how family members interact with each other now as they attempt to articulate the issue and work for a solution within the session itself (Aponte, 1990; Aponte & Hoffman, 1973). That enactment is both the immediate

material for assessment and an opportunity for intervention to change attitudes and behaviors.

The very essence of the traditional understanding of *enactment* in SFT is, “an interpersonal scenario in the session in which dysfunctional transactions among family members are played out” (Minuchin & Fishman, 1981, p. 81). The structural therapist is reading and relating to the interactions of the family members around the issue that is the source of their distress. Reliving their struggle in the presence of the therapist brings to the therapist the fullness of their experience—the words, emotions, and actions that allow the therapist to see, feel, and touch the family and its individual members so as to connect, understand, and intervene with them in the throbbing intensity of the living moment of their pain and conflict. This enactment can take place in any combination of family members or even between family members and people in their network or community who are part of their problem and/or potentially part of their solution, such as school personnel (Aponte, 1976).

- *The therapist looks to work with the family and its members in the moment in session as they interact with each other and/or with members of their community network around their focal issue.*

The therapist asks each family member to react to what she/he hears from the other about what they are presenting. The mother is anxiously protective of the son. The father is impatient with her solicitude for him, and angry with the boy about what he perceives as the boy's “laziness.” The youngster appears tearful and scared. The therapist gets a glimpse of the family patterns of interaction around this issue.

BASED ON REORGANIZING THE STRUCTURE OF RELATIONSHIPS

The structural family therapist pays special attention to the structure of family relationships in relation to the focal issue. There are three basic structural dimensions to all relationships (Aponte & VanDeusen, 1981).

1. *Boundaries.* What defines who is in or out of a family's interaction vis-à-vis the focal issue, as well as what their roles are in this interaction.

2. *Alignment.* Who is with or against the other in the transactions generating the issue.
3. *Power.* What the relative influence is of the participants in the dynamics of the interaction.

A client's focal issue is connected to a characteristic pattern of family interaction that bears changing if the problem is to be solved at its source. This transactional structure is the underlying skeleton of the dynamics that generate the problem. In some circumstances, the pathological structure undergirds a conflict, whereas in others, a faulty structure is inadequate to resolve the client's issue. That is, some problems are the result of conflicting feelings and needs, and others are the consequence of weakly organized relationships, or of a combination of both conflicting and inadequate organization. Structural therapists relate to both the content and the underlying structure of issues the client presents.

Structural therapy was originally known for targeting the faulty structure of poor underorganized families (Aponte, 1994b; Aponte & DiCesare, 2000). These underorganized structures were seen as lacking the constancy, coherence, and flexibility to meet life's challenges. In working to help these families solve their problems, structural therapists deepened their appreciation of how all social functioning rests on strong and adaptable structures.

- *The therapist pays particular attention to the underlying structure of a family's relationships in terms of its boundaries, alignments, and use of power.*

The mother and son are aligned in defense against the frustrated father who is clearly on the periphery of that subsystem. However, when he intensely gives voice to the power of his anger both mother and son shrink back nervously. The therapist wants the father in the circle with his wife and son, and with the father supporting rather than attacking the boy.

BUILT ON CLIENT STRENGTHS

SFT works through a "search for strength" (Minuchin & Colapinto, 1980). The structural therapist actively engages with the family to impede old, pathological transactional patterns (Aponte & VanDeusen, 1981) while working

with the family's strengths to build new, positive patterns of interaction. The therapist aims for the family to experience these functional interactions in session as members work on the solutions to their problems. The therapist connects to aspects of the focal issue that are accessible for facilitating a positive change, however small. From an eco-systemic perspective, structural therapists build on the resources of the individual and of the family and its social context, including their psychology, personal relationships, spirituality, and community.

- *Even when the immediate objective may be to impede a dysfunctional interaction, ultimately every intervention of the therapist aims to support and mobilize the client's motivation and ability to make positive changes.*

The therapist sits next to the father, sympathizes with his worry about the boy's future, reframing the angry frustration as concern for his son. He then solicitously invites the father to ask his son whether he is afraid of him. The father is thrown off balance by the tone of the query, and tentatively asks the question. The boy so affirms, but then tearfully blurts out how he feels belittled by his father, which surprises and affects the father. The therapist will now build on how the father is moved by his son's obvious pain, a hurt inflicted by him.

AIMED AT PALPABLE OUTCOMES

In much the same way that the structural therapist looks to work through the concrete manifestation of the focal issue, the therapist looks for positive therapeutic outcomes to be represented in changes the client can experience. Because SFT builds experience upon experience, positive change builds upon positive change. The ultimate outcome of the therapy rests on positive experiences of change, session by session. These palpable goals are evident in the immediate objectives of in-session interventions with enactments and the assignment of home-based tasks. The palpable experience of change gives body to the intended goals of the intervention. The experiential emphasis is a way of looking for intensity that will mobilize motivation and energy to drive change and can reach deeply within the persons involved. The change that is actively experienced

in session is more likely to be lived outside the therapy. The goal is to have clients make these changes their own as they come to know their struggles as new, hopeful levels of experience, over which they have exercised their freedom and power to choose to change.

- *The therapist looks to create an experience of change in the present so that the family can feel what it is to live whatever it has come to understand from the therapeutic process.*

The therapist, now leaning close to the father, asks the father what it is like to witness what he just saw in his son's face. He treats the father like a loving parent who is looking upon his wounded son. The father says he understands, and spontaneously recalls how hurt he felt when his father would put him down. The father accepts the therapist's recasting the boy's hurt as an expression of how much the father's opinion of him matters to him, and how this speaks to the power he has at this critical moment to be of help to his son. The therapist looks to the mother at that moment to view her husband as her partner in the work now commencing. The family leaves the session having had a new experience that portends hope.

CHARACTERIZED BY ACTIVE THERAPIST INVOLVEMENT

Structural therapists actively engage in the present with family members as clients enact their struggle in session. From outside a family enactment, they will interpret, reframe, advise, and direct the action among family members. From within an enactment, they will personally engage in family interactions to stimulate changes in the patterns of their relationships (Aponte & VanDeusen, 1981).

- The initial effort of the therapist is to strategically join (Minuchin, 1974) the family interaction "in a carefully planned way" (p. 91). The initial joining action is to gain trust. Subsequently, connecting to the family's interaction becomes a strategic intervention to alter their dysfunctional patterns of interaction.
- *Where the structures of these dysfunctional relationships are more resistant to change, therapists may intensify a conflict within a*

family by drawing attention to their areas of disagreement. Surfacing the pathological dynamics in a live enactment bares them to better assessment and more effective interventions.

- *Therapists may seek to block a pathological interaction among family members, making it difficult for them to use the old, sick pattern to deal with the current issue. Structural therapists characteristically use any of a variety of techniques (Minuchin & Fishman, 1981) to affect the family's power balance, transactional alignments, and systemic boundaries.*
- *Whether or not the therapist needs to begin by disrupting old, dysfunctional interactions, in all cases the therapist will look to support new, more functional transactional patterns. The therapist may verbally affirm the new patterns or actively engage with clients in ways that promote new behaviors and attitudes in the family's in-session enactments.*
- *In this active engagement with clients, therapists intentionally use their person (Aponte, 1992; Aponte, 1998a) to strategically affect the dynamics and structure of family interactional patterns. To achieve the therapeutic mastery of self, they must have (1) a profound knowledge and awareness of their personal selves, (2) an ability to be connected to their inner personal experience in session, and (3) the discipline to use their person as strategically intended (Aponte, 1994a).*
- *Once family members have experienced something of their ability to do things differently, structural therapists often assign home tasks meant to embody the new change. The therapy is complete when the family is able to meet its challenges without the intervention of the therapist.*

In the example above, the therapist became an actor in the play, using himself and his joining the father to reframe what was happening in the session between the father and his son. The therapist made it safe for the son to speak from his pain, and for the father to allow himself to feel for his son from his own vulnerability. The therapist blocked the escalation of anger from father to son. He spoke from his own sense of fatherhood to appeal to the father's paternal tenderness toward his son. He helped to create a new experience for all three

members of the family by how he involved himself in their interactions. The therapist actively engaged the family in a way that created a new and positive experience for them to embark on the work of therapy with him.

THE FUTURE OF STRUCTURAL FAMILY THERAPY

SFT was created to meet the needs of families whose inner structure was seriously undermined by devastating social stress. This work has contributed a deeper insight into the basic nature of structure in family systems and reparative structural interventions that generate organizational changes in families. The underlying assumption is that change in patterns of relating affect the complexion and quality of emotional interchanges among family members, which, in turn, impact the psyche of the individuals in the family system. As the social ills of American society spread beyond the inner city to the general population, the need to attend to the foundational structure of families in all levels of society has become apparent. Other models of therapy could well consider using the insights SFT offers to understanding and working with family structure.

New developments in SFT are the added dimension of cultural values and spirituality. The original model spoke of structure in relation to function in human systems. Over time it became apparent, particularly in today's values-fragmented society that this original formulation needed to be amended to address structure in relation to function *within* the values framework of the system (Aponte, 1994b). Because SFT is one of today's more active therapies, therapists using the model inescapably communicate values about life philosophy, morals, and even religious practice. Now, as never before, there is a need for therapists to understand the values inherent in their therapeutic models and the values they personally bring to the work they do. Therapists' cultural, philosophical, and spiritual biases will influence what they consider healthy and pathological attitudes and behaviors. Their worldviews will affect the formulation of goals—that is, what is desirable for any particular therapeutic endeavor. Their perspectives on life will help determine the interventions they believe appropriate to people's circumstances. SFT needs to incorporate into its theory and

practice greater consideration of the cultural, philosophical, and spiritual aspects of the human experience at the interface of the therapist-client relationship.

In line with the above, SFT needs to give greater consideration to the use of self within its model because of the very active personal posture of the therapist vis-à-vis the client. Minuchin's perspective has been to "expand" the "therapist's [personal] style" thereby adding to the clinician's "repertoire" (Minuchin, Lee, & Simon, 2006, p. X). Aponte's model for the personal aspect of training calls for enhancing the therapist's ability to purposefully direct the use of self through self-knowledge and the ability to consciously access emotions, memories, and personal reactions at the moment of active engagement with clients (Aponte, 1992; Aponte & Kissil, 2012; Aponte & Winter, 2000). SFT will need to enlarge on its approaches to training in the use of self within the model if it is to include the spiritual with the emotional in a systematic person-training of therapists.

RESEARCH SUPPORTING STRUCTURAL FAMILY THERAPY

Outcome studies on SFT have been conducted since the late 1960s. The first area of SFT outcome research came out of the search for effective approaches to the work with disadvantaged youth and families, with the first study conducted by Minuchin and his colleagues at the Wiltwyck School suggesting that SFT was moderately superior to conventional treatment (Minuchin, Montalvo, Guerny, Rosman, & Schumer, 1967). Another focus of early SFT outcome studies was therapy with psychosomatic families. In several studies conducted during the 1970s SFT was found effective in treating families who were dealing with diabetes (Minuchin, Baker, Rosman, Liebman, Milman, & Todd, 1975), psychogenic pain (Berger, Honig, & Liebman, 1977; Liebman, Honig, & Berger, 1976), asthma (Liebman, Minuchin, & Baker, 1974) and Anorexia Nervosa (Minuchin, Rosman, & Baker, 1978).

In the last 30 years SFT has greatly influenced the development of new family therapy models and has been incorporated as a core component in many integrative family therapy models. Family therapy with troubled youth has been the main therapy area to build on SFT. Numerous evidence-based models for

treating adolescents with various problems have incorporated SFT into their models. For example, Multidimensional Family Therapy (MDFT; Liddle, 2010) is a family-based treatment model for adolescents' substance abuse. Effectiveness studies with MDFT in the United States and in various countries in Europe found MDFT effective in reducing substance abuse and related problems such as juvenile delinquency (Liddle, 2010; Liddle, Rowe, Dakof, Henderson, & Greenbaum, 2009; Rigter et al., 2012).

Two additional well-established models for treating adolescents with various problems are MST (Multisystemic Family Therapy; Henggeler & Borduin, 1990; Henggeler, Schoenwald, Borduin, Rowland, & Cunningham, 1998) and ABFT (Attachment Based Family Therapy; Diamond & Lebow, 2005; Diamond, Siqueland, & Diamond, 2003). Both models incorporate SFT and have been studied extensively and found effective in reducing adolescents' antisocial behaviors and juvenile recidivism (Henggeler, 2011), depression (Diamond, Reis, Diamond, Siqueland, & Isaacs, 2002), anxiety (Siqueland, Rynn, & Diamond, 2005) and suicidality (Diamond et al., 2010).

Szapocznik and his colleagues have studied the effectiveness of Brief Strategic Family Therapy (BSFT) with high-risk Hispanic and African American adolescents and their families since the late 1980s (Szapocznik & Williams, 2000). Their approach, founded on SFT, was found effective in reducing behavior problems, including drug abuse (Santisteban, Coatsworth, Perez-Vidal, Jean-Gilles, & Szapocznik, 1997; Santisteban, Szapocznik, Perez-Vidal, Kurtines, Murray, & LaPerriere, 1996; Szapocznik et al., 1988; Szapocznik et al., 1989; Szapocznik & Williams, 2000).

More recently, Santisteban and his colleagues (2011; 2013) studied the effectiveness of a new therapy model, CIFFTA (Culturally Informed and Flexible Family-Based Treatment for Adolescents), which evolved out of Brief Strategic Family Therapy and has SFT as its foundation. The results suggest that CIFFTA was better than traditional family therapy in reducing Hispanic adolescents' reported drug use and improving parenting practices as reported by the adolescents (Santisteban, Mena, & McCabe, 2011; 2013).

Family-Directed Structural Therapy (FDST; McLendon, McLendon, & Petr, 2005) is another family-based treatment approach,

designed to be utilized with a variety of family and relationship issues, and not necessarily with problem specific populations like the models mentioned above. It is also founded on SFT. A recent study comparing the use of this model in a therapeutic wilderness family camp to community mental health services found this model to be superior in increasing family cohesiveness and reducing child internalizing and externalizing problems. Treatment gains were maintained at 6 months follow-up (McLendon, McLendon, Petr, Kapp, & Mooradian, 2009).

Another area highly influenced by SFT is treatment for eating disorders. Some of the most well-studied models in the field for treating eating disorders have evolved from SFT, especially from Minuchin's seminal work with anorexic families (Minuchin, Rosman, & Baker, 1978). For example, the evidence-based and widely studied Maudsley approach for treating anorexia nervosa, which is based on SFT principles (Lock & Le Grange, 2012) was found to be superior to individual therapy in adolescents (Eisler, Dare, Russell, Szmukler, Le Grange, & Dodge, 1997), and to both individual supportive therapy and individual psychodynamic therapy in adults with Anorexia Nervosa (Russell, Dare, Eisler, & Le-Grange, 1992). The effectiveness of SFT based models in treating Anorexia Nervosa has been described in numerous articles (e.g., Raymond, Friedlander, Heatherington, Ellis, & Sargent, 1993; Stein, Mozdierz, & Mozdierz, 1998; Vetere, 2001) and has been supported enough to make family therapy the treatment of choice for Anorexia Nervosa (Fishman, 2006).

Although SFT and its derivatives were mainly utilized in treating adolescents, other models were developed that focused on non-adolescent populations. For example, Structural Ecosystems Therapy, a family-based ecological approach that was developed from Brief Structural Family Therapy (Mitrani, Szapocznik, & Robinson-Batista, 2000; Szapocznik et al., 2004), was found to be effective not only with drug-abusing Hispanic and African American adolescents (Robbins, Szapocznik, Dillon, Turner, Mitrani, & Feaster, 2008), but also in increasing adherence to medication and reducing psychological distress in HIV-seropositive African American women (Feaster, Brinks, Mitrani, Prado, Schwartz, & Szapocznik, 2010; Szapocznik et al., 2004).

In summary, SFT has been extensively researched for over 50 years. Even though it

appears that SFT has not been studied as a stand-alone approach in the last 30 years, and the integrative models incorporating SFT have not studied its specific contribution to their success, the fact that SFT is a main component in so many evidence-based models provides indirect but very strong evidence as to its effectiveness.

CONCLUSION

SFT is an active, focused approach to therapy that pays special attention to structure within family systems and does so within the client's experience in session. It pursues specific outcomes to present-day issues while addressing the underlying human relationships and their personal structure in the context of culture, ethnicity, and spirituality—all that gives meaning to their lives. Therapists actively engage with clients around the practical experience of their struggles and strategically join them in finding new ways of thinking about and acting on their issues. SFT looks for practical outcomes along with deep-seated changes in the underlying structures that generate and maintain the difficulties people face in life. Because of the active and involved nature of the work, the structural training of therapists draws particular attention to the fuller and more precise strategic use of self. The basic insights of the structural model about the nature of structure within systems and the use of self to influence those structures are concepts that are suitable to other models of today's active therapies. In a social and economic environment that greatly emphasizes outcome that is also enduring, SFT has much to offer.

58 Bowen Family Systems Therapy

Daniel V. Papero

The Bowen theory consists of eight formal concepts and a central variable (Bowen, 1978). One concept, the *scale of differentiation of self*, forms the core of the theory, and the remaining seven concepts describe different aspects of family functioning. The variable—*anxiety*—acts as a kind of pressure on the family system, waxing and waning in intensity. Bowen's observations

led him to conclude that the family is a system of interdependent people, that individual behavior cannot be understood adequately without including the relationship system in which individual lives and changing degrees of anxiety greatly affect the condition of that system. A highly anxious system behaves predictably differently from a less anxious one. Under the pressure of

increased anxiety, various sorts of relationship patterns or series of interactions can be observed, and these patterns tend to repeat whenever the family system is again under pressure.

The concept of the scale of differentiation of self describes individual variation, specifically in the arena of self-regulation and self-determination within the family system and the other important relationship systems of a person's life (Bowen, 1978; Kerr & Bowen, 1988; Papero, 1990). In practical terms, a person's degree or level of differentiation of self can be seen as a degree of resiliency or capacity to function well under the pressure of stress and tension. Bowen hypothesized that a well-differentiated person approached the situations of life with good integration between emotion and cognition and with clearly thought-out values and principles that guide decisions and behavior. Each (emotion and cognition) influences the other, neither dominates, and the person can use each in adapting to changing situations. In a less well-differentiated person, under pressure, emotion dominates cognition and behavior becomes more instinctive and automatic. The well-differentiated person can participate fully in relationships but does not depend completely on relationships to maintain emotional stability. In this sense, the individual is capable of self-regulation when important relationships are disturbed or unavailable.

Bowen observed that a change in one part of a family led to compensatory changes in other parts of the family. His observations led him to the realization that the family system could be influenced by the actions of an individual family member, particularly if that person occupied an important position in the system and when that individual could

- see and understand better his or her own emotional sensitivity and reactivity;
- become more thoughtful about his or her behavior and what he or she was trying to accomplish, using knowledge of how the family system operated;
- use thinking and knowledge to modify emotional reactivity and his or her own behavior in important relationships; and
- stay in meaningful contact with other members of the system; the entire system could change or shift its functioning.

When the system could change, the behavior and functioning of family members changed

as well. The clinical process involved in such an effort is so different from more conventional psychotherapy that Bowen referred to the process as *coaching*.

The coaching process draws heavily on the coach's understanding of family systems theory. It assumes the clinician (1) has direct and ongoing experience in the challenge of working on differentiation of self in his or her own family, and (2) understands and can reasonably operationalize the disciplines of self-regulation, emotional neutrality, maintenance of viable contact, self-definition, and the research attitude that families have found useful in their own efforts to manage their challenges and dilemmas.

The family members involved in the coaching effort:

- Regulate the endeavor
- Set the pace
- Identify and engage the challenges
- Monitor and evaluate the outcomes.

In his personal conversations, Bowen often referred to the process as "a do-it-yourself therapy—almost!" The coach functions as a supervisor of and consultant to the endeavor.

Bowen discovered that clinicians learned most about family systems in their efforts to improve functioning in their own families (Bowen, 1978), and effort with one's own family became a central element in the training of clinicians; it remains so today. In essence, clinicians learning to use the Bowen theory in their clinical efforts work on their own degree of differentiation of self, the central idea in the theory. In the clinician's own family, he or she learns about family systems and the pressures that come to bear on anyone attempting to shift his or her functioning. The clinician learns firsthand about emotional reactivity and its role in the relationship sequences or patterns that are the nature of family interaction.

In the course of his research project on schizophrenia at the National Institute of Mental Health (NIMH), Bowen observed that the families appeared to function more calmly, thoughtfully, and stably after time spent with a researcher than after time spent with a therapist. The researcher could remain more objective than the therapist and direct inquiry toward facts of family functioning. The researcher did not experience the pressure to help the family that the therapists did. The researcher could more easily remain emotionally neutral in the reactive

processes of the family. He or she could see all sides to the situation and could avoid taking sides in the dilemma fairly easily. This objectivity and neutrality appeared to bring out the best in the families.

These observations led Bowen to suggest that the clinician could be most helpful to the family when he or she could:

- Maintain an attitude and perspective of research and emotional neutrality
- Ask about family facts
- See the emotional give-and-take among family members without becoming distracted by the content of the family story or taking sides
- See and comment on both the serious and the humorous sides of the family dilemma
- Maintain a climate or atmosphere during the clinical session that allowed each participant to work toward becoming his or her most mature self emotionally in interaction with the others.

The clinical process begins with a history of family functioning across at least three generations. In general, the clinician gathers information on each person, living and dead, who has been part of the family. The information collected includes:

- Date of birth (and of death, where applicable)
- Health history
- Educational history
- Occupational history
- Social history for each person
- The nature of relationships in the family, currently and historically
- Dates of marriages, divorces, job changes, and changes in residence
- The frequency and nature of contact the informants maintain with the broader family.

As the information is gathered, it is entered on a family diagram, a visual representation of the family system (see Papero, 1990, 2000). The process of developing the family diagram helps the clinician (1) identify events that have contributed to the present configuration of the family; (2) note particularly important relationships, including those that display great tension and emotional reactivity; and (3) identify the particular kinds of relationship patterns that characterize the interactions of the family.

The diagram serves as a map or chart guiding the efforts of the clinician and the family. Additionally, informants often find the process interesting and useful, spurring their own efforts to learn more about their families.

The clinical process focuses on two goals: decreasing anxiety and increasing functional differentiation of self. Often, these goals go hand in hand. The effort to decrease anxiety requires that the individual learn to modulate intense emotion by using his or her cognitive or intellectual processes. Cognition comes into play as the individual learns to observe self and others, learning to recognize anxiety in its myriad forms, and in his or her efforts to engage in a discipline of self-regulation. Alongside the effort toward self-regulation, the individual works to observe the predictable patterns of the family relationship system that emerge and disappear in response to tension and anxiety in the system. The person also endeavors to define clearly his or her own sets of beliefs and values about the nature of living and about his or her own direction in it. These form the basis, along with knowledge of the system and self-regulation, for the person's effort to define his or her own positions to the important others in the relationship system and to maintain that position as the system responds with pressure to change back.

One of the common relationship processes that people observe, *triangling*, occurs as a two-person relationship becomes tense and anxious. As the discomfort in the pair rises, at some point the tolerance for discomfort is passed, and one makes a move to a significant third person, in effect telling a story about the other partner. Primarily a process of anxiety transfer, *triangling* alters the sensitivities, cognitive processing, and ultimately behavior of all involved. Triangles change configurations with tension. When the relationship network is fairly calm, the *triangling* process may be largely invisible. Under moderate tension, the triangle consists of a close twosome and an outsider, who tends to feel excluded and uncomfortable. That outsider responds in a series of well-known moves to gain closeness with one of the two and leave someone else in the outside position (Bowen, 1978; Kerr & Bowen, 1988). However, when tension develops in the close twosome, the outsider is in the more comfortable position, and either of the twosome engages in a series of maneuvers to gain the outside position for him

or herself and leave the other two in the tense positions.

One classic methodology derived from Bowen theory involves the effort with the two most responsible family members, often spouses. The clinician has four main tasks in using this methodology (Bowen, 1978):

- Defining and clarifying the relationship between the two family members
- Keeping self neutral in the family emotional system
- Teaching the functioning of emotional systems
- Demonstrating differentiation by taking well-thought-out positions for self during the course of the clinical effort.

A basic principle, based on Bowen's observations, underlies the approach: "the emotional problem between two people will resolve automatically if they remain in contact with a third person who can remain free of the emotional field between them, *while actively relating to each*" (Bowen, 1978, p. 251).

A second classic methodology involves the effort with one family member. Here the person works toward enhancing his or her own differentiation within a relationship system, usually the family. According to Bowen (1978), the person essentially strives to:

- Gain some control of his or her own emotional reactivity
- Visit the family as often as possible
- Develop the ability to be an objective observer of the family (Bowen, 1978)
- Develop person-to-person relationships in the broader family.

Generally, the family member learns to establish and maintain relationships in which two people can talk to one another about each other, without discussing others (triangling) or talking about impersonal things. The clinician, while fulfilling the four tasks just mentioned, serves as a consultant and supervisor to the effort.

Many people using Bowen theory in their efforts to improve their own functioning additionally work on structured processes of self-regulation. Many have found biofeedback (both classic and neurofeedback) beneficial. Sometimes with the aid of the technology, people

discover their own sensitivity to others and the impact that sensitivity has on their functioning and well-being. Some also engage in formal processes of relaxation training and meditation. The use of these adjunctive methodologies depends on the inclinations and motivation of those involved.

The family members involved in the clinical effort begin to use their families as laboratories for their own learning and development.

- They work on managing themselves in the very relationships that have helped shape their identity and in contact with the people to whom they are most sensitive and connected.
- The focus is on the actual relationships of a person's life, with corresponding decreased focus on the therapeutic relationship to the clinician.
- Change occurs in the effort to manage oneself differently in actual relationships, and the importance of the clinical hour decreases.
- The time with the clinician becomes time for reflection, review of efforts made, and planning for future endeavors.

As he or she gains knowledge about self and the family, the person begins in small, microscopic steps to define him- or herself to the family system. This process usually requires that the person (1) think through his or her own view about particular family issues, (2) represent that view in the family context, and (3) remain in viable contact with other family members during their reaction to this statement of position.

In the process, the individual becomes a leader of the family in the sense that his or her functioning begins to affect the entire system in positive ways. Bowen described the process as follows:

Operationally, ideal family treatment begins when one can find a family leader with the courage to define self, who is as invested in the welfare of the family as in self, who is neither angry nor dogmatic, whose energy goes to changing self rather than telling others what they should do, who can know and respect the multiple opinions of others, who can modify self in response to the strengths of the group, and who is not influenced by the irresponsible opinions of others. When one family member moves toward differentiation, the family symptoms disappear. A family leader is beyond the popular notion of power. A responsible family leader automatically generates mature leadership qualities in other family

members who are to follow. (Kerr & Bowen, 1988, pp. 342–343)

The following examples are composites of actual situations encountered. Many elements of the descriptions have been changed to protect the confidentiality of the families.

EXAMPLE 1

Emily, a bright, 7-year-old in first grade, suddenly developed discipline problems in school toward the end of the year. Her behavior had been outstanding, but now she spent several days a week in the principal's office. Previously a pleasant and gentle child, Emily had become surly and aggressive toward other children. Her mother sought clinical assistance.

Utilizing the Bowen theory to guide his efforts, the clinician made the decision to meet with Emily's mother and avoid a direct focus on the behavior of the child. The mother was willing to follow this plan. The clinician constructed Emily's family diagram. Her father and mother had been divorced for several years, and her father had moved to another state the summer before. Emily's paternal grandparents had maintained contact with her, but the arrival of a new grandchild and a serious health situation had resulted in them being less available. Her maternal grandmother had had surgery early in the winter and was recovering more slowly than anticipated. Her maternal great-grandmother had required nursing home care early in the winter, and Emily's grandfather was in charge of managing her care. Emily's maternal aunt and her husband had experienced a reversal in business and were involved in legal processes that caused family members to worry about their future. Finally, tension between Emily's mother and her partner had become very intense and difficult in the week preceding Emily's change of behavior.

The clinical hypothesis posited that Emily's behavioral problems emerged in a family environment of prolonged tension following the changes of the preceding few months. The family met each challenge well, but the cost was reflected in the gradual build-up of tension and anxiety. The immediate trigger for Emily's behavioral change lay in the surge of anxiety between her mother and her partner. The immediate treatment goal would involve reducing anxiety, and the longer range goal would involve the mother's

increased use of relationship resources in the family and an effort to address the problem with her partner more directly, working to contain the anxiety to that relationship.

Emily's mother quickly understood and accepted the clinical hypothesis that her child's behavior was linked to the changes in the family and to the surge in tension with her partner. With the clinician, she developed a plan that included increased contact with important family members, a direct nonconfrontational approach with the involved school personnel, and the development of a plan for her efforts toward her partner. She used family relationships to assist her with her thinking about the situation and began a focused effort to address the problem with her partner. Emily's grandparents and to some degree her father increased their contact with Emily, and the mother engaged the school personnel—the teacher and principal—thoughtfully and directly in a calm manner focused on solving problems. Emily's school problems rapidly abated, and her teacher reported that she seemed much happier. She finished the school year well and moved happily into her summer activities. Emily's mother continued the effort to address the difficulties with her partner directly, an ongoing and challenging process.

EXAMPLE 2

Jim Wilson, a 52-year-old physician's assistant, sought consultation around his reported intense anxiety about finances, recurring episodes of deep depression, a sense of being ill-equipped to function in the world, and deep anger toward his father. He reported at times feeling he would be better off dead but did not see himself as actively suicidal. Mr. Wilson was well regarded in his professional life, working in a clinical setting that assisted low-income people. He was interested in using the Bowen theory to look at his situation; previous therapy had been somewhat useful but had not alleviated the recurring problems.

In the initial meetings, the clinician collected a three-generation history of the family. Mr. Wilson was the older of two children; he reported that his younger sister had also struggled with life, perhaps even more than he had, and currently lived in another state in a troubled relationship with a man alleged to be alcoholic. He reported great reactivity to his sister, often being critical of her and avoiding contact with her. Their mother had died of a lingering degenerative illness when

both siblings were young adults. In the aftermath of his mother's death, his father had remarried. Mr. Wilson reported that he "lost his father" when he remarried. He meant that his father put his new wife ahead of his children in all matters. He also reported that his father had refused to help him financially, although he was a wealthy man and could easily have done so. Mr. Wilson was divorced from his wife; their two sons were now young adults. He reported that he remained angry and bitter with his ex-wife and avoided contact with her. She had married the man with whom she had had an affair. He resented the time their children spent with her.

The clinical hypothesis posited that Mr. Wilson's complaints reflected a condition of chronic anxiety in the family system marked by distant relationships and high degrees of emotional reactivity among family members. Mr. Wilson himself was relatively isolated emotionally from important other family members. The plan followed the points noted:

- Gain some control of his emotional reactivity
- Visit the family as often as possible
- Develop the ability to be an objective observer of the family (Bowen, 1978)
- Develop person-to-person relationships in the broader family.

Mr. Wilson thought the hypothesis made sense and agreed to begin an effort in his family to make progress on the four areas noted. He agreed to meet with the clinician once a month for consultation on his project. He began by addressing a health concern he had been avoiding, receiving medical assistance and a good outcome. He began to observe himself in the situations of his life and recognize his thought patterns and reactivity that seemed to underlie his anxiety and depression. He noted his own tendency to see himself as helpless and to be what he called "whiny" about his life. He also noted the degree to which he blamed others for his situation and began an effort to expand his perspective, decrease his complaining, and accept more responsibility for his own difficulties in life. He began an effort to be in more direct contact with his father and his wife, and to represent himself more clearly and carefully to them. His symptoms of depression were the first to disappear, and they did not return in any strength. After some time he was able to approach his father directly, requesting information about a trust fund established as part of

his father's estate. His father initially balked but then arranged for Mr. Wilson to speak directly to the managers of the trust. The information received helped allay Mr. Wilson's financial anxieties. He was subsequently able to arrange a loan from the trust that allowed him to move forward on a significant relocation project to be nearer to his children and achieve a long-term goal. He reported that the intensity of his anxiety decreased significantly. He could still experience episodes of acute anxiety, but the more chronic, constant anxiety seemed to have disappeared. He noted as well that his anger and bitterness toward his ex-wife abated greatly, and he was able to be in her presence at family gatherings with much decreased reactivity to her. He no longer tended to talk about her to their children and actually found he wished her well. Mr. Wilson continues his efforts, now with less frequent consultation.

In the case of Emily, the behavioral problem in the child was directly related to a recent series of events in the family and was resolved fairly quickly. In the case of Mr. Wilson, the problems reflected a long and slow build-up over many years and required a slower, persistent approach to attain resolution.

In recent years, the Bowen theory has received increasing attention from people working in corporations and organizations, as well as those who consult with them. The theory and its knowledge base offer insight and practical assistance to those who must work, manage, and lead in the increasingly stressful climate of the modern organization. Although organizations should never be mistaken for families, a number of the concepts transfer cleanly to the world of organizations. Topics such as the role of differentiation of self in leadership, triangling and its influence on the workplace, the predictable responses in relationships as tension increases, and the impact of anxiety on the individual and the relationship network can now be found on the agenda of training groups in management and leadership. People in leadership positions report that applications derived from Bowen theory, especially concerning differentiation of self, self-regulation, and self-management under pressure, are useful to them in their efforts to lead effectively.

59 Integrative Behavioral Couple Therapy

Katherine J. W. Baucom, Felicia De la Garza-Mercer,
& Andrew Christensen

CASE ILLUSTRATION

Janelle, a 32-year-old African American woman, and Adam, a 36-year-old Caucasian man, presented for treatment in a local clinic. The middle class, dual-earner couple had been in a relationship for eight years and married for four years. They had two young children, a 2.5-year-old son and a 1-year-old daughter. Janelle and Adam were in the dissatisfied range of relationship functioning, and reported arguments up to twice a day surrounding the amount of time Adam spent away from home. The couple reported that their arguments had steadily increased after the birth of their son; Janelle thought Adam did not give household tasks and their family enough time, and Adam was upset with Janelle's tendency to express her concern with criticism and anger. Janelle and Adam requested therapy after an argument resulted in Adam spending the night at a hotel. Both partners worried they could not overcome the difficulties they were currently facing. Their progress through therapy will be used below as an illustration of Integrative Behavioral Couple Therapy (IBCT).

INTEGRATIVE BEHAVIORAL COUPLE THERAPY

IBCT, developed by Andrew Christensen and the late Neil S. Jacobson (Christensen, Wheeler, Doss, & Jacobson, 2014; Jacobson & Christensen, 1998), seeks to target a wider range of couples than traditional behavioral couple therapy (TBCT; Jacobson & Margolin, 1979). IBCT combines interventions aimed at increasing emotional acceptance with change techniques from existing behavioral couple therapies.

ASSESSMENT AND FEEDBACK

In IBCT, couples typically participate in three assessment sessions as well as a feedback session. The goal of these sessions is to orient the couple to IBCT, determine whether they are appropriate for the treatment, develop a formulation of their relationship problems, and lay out a general plan for treatment.

The formulation of a couple's relationship problems includes a "DEEP understanding"

that conceptualizes the presenting problems for therapist and the couple. DEEP is an acronym that stands for **D**ifferences or incompatibilities between partners; **E**motional reactions, sensitivities, and vulnerabilities of each partner; **E**xternal circumstances or stressors; and the destructive **P**attern of interaction in which the couple often becomes engaged as they struggle with their problems. The purpose of the assessment sessions is to develop rapport with the couple, gather the information necessary to develop a DEEP formulation, and learn of the existing strengths the couple has.

The first assessment session of IBCT is a joint session with both partners of the couple. During this session the therapist orients the couple to IBCT, learns about the presenting concerns and history of the relationship, and begins to gather information for the formulation. In the discussion of current relationship problems, the therapist attends to the emotional and behavioral reactions of each partner and the typical interaction pattern that the couple enacts around issues in the relationship. To learn more about the couple's background, the therapist facilitates a discussion of the history of the relationship, including how the couple met, how their relationship developed, and how their presenting problems came about. The therapist seeks to learn about positive aspects of their relationship and the areas where the couple has particular strengths, in addition to the current problems facing them in their relationship. Finally, couples are introduced to *Reconcilable Differences* (Christensen, Doss, & Jacobson, 2014; Christensen & Jacobson, 2000), a text written for couples participating in IBCT, and are encouraged to read it during treatment.

In the first meeting with Janelle and Adam, the therapist discovered some important **D**ifferences between them. As is often the case, these differences were qualities that had initially attracted them to one another: Janelle was spontaneous and liked to make decisions on the fly, whereas Adam valued predictability and liked to have a plan for doing things. The couple was able to effectively navigate these differences early in their relationship and marriage, but they began to struggle when they became parents and were presented with many new demands. Despite the joys Janelle and Adam experienced as parents, this transition functioned as an **E**xternal stressor that increased the salience of their differences.

At the end of the first assessment session, the IBCT therapist typically gives partners objective

measures to provide information about important areas of the relationship. The most common areas assessed with these measures are relationship quality (e.g., the Couples Satisfaction Index; Funk & Rogge, 2007), intimate partner violence (e.g., Conflict Tactics Scale; Straus, Hamby, Boney-McCoy, & Sugarman, 1996), and target behaviors (e.g., the Frequency and Acceptability of Partner Behavior Inventory; Doss & Christensen, 2006). It is critical that therapists assess for intimate partner violence prior to beginning treatment; IBCT therapists do not treat couples whose problems include moderate to severe levels of violence (see Jacobson & Christensen, 1998). For those levels of violence, the therapist should recommend treatment that focuses on the violence rather than on the relational distress only.

The second and third assessment sessions are individual sessions with each partner. They typically begin with a confidentiality caveat that the therapist does not withhold information discussed in the individual sessions in joint sessions unless the partner explicitly asks the therapist. In the event that a partner reveals private information to the therapist that is relevant to the couple's relationship (e.g., an ongoing affair), the therapist stresses the importance of working together to share that information with the partner or to quickly resolve the issue (e.g., end the affair). IBCT therapists do not continue therapy if a partner discloses current infidelity to the therapist and is unwilling to stop the affair or reveal it to the partner. Therapists should follow these principles when practicing IBCT.

The goal of these individual sessions is to gain better knowledge of the current relationship problems and of each partner's personal history, with an eye toward the **E**motional vulnerabilities that each partner brings to the relationship, and the typical **P**attern of interaction that the couple enacts around problem areas. Often, the therapist begins by focusing on material that came up in the joint session as well as inquiring about particular items endorsed on the questionnaires. In the discussion of an individual's personal history, the therapist learns about the partner's relationships with close family members, the overall atmosphere in the partner's home during childhood, and previous romantic relationships. In the individual sessions the therapist learned that Janelle grew up in an upper middle class family. Her parents traveled for their jobs and spent much of the time they were at home working. Thus, Janelle was sensitive

to disconnection from Adam, often feeling abandoned and lonely as she completed an increasing number of childcare and household tasks. Adam grew up in a low-income family and watched his father spend a great deal of time outside the home to make ends meet while his mother took care of him and his siblings. Thus, having grown up in a family with traditional gender roles, and being intimately aware of the consequences of limited resources, Adam was committed to ensuring that his family had the opportunities he did not have as a child. This contextual information, most relevant to the Emotional vulnerabilities component of the formulation, helped the therapist make sense of *why* childcare and time at home were so difficult for Adam and Janelle in particular. In Adam and Janelle's case, knowledge about partners' families of origin also provided a framework for understanding Adam and Janelle's differences: the qualities of spontaneity and need for predictability were adaptive for Janelle and Adam in their respective families of origin.

Discussion of individual emotional vulnerabilities led to additional discussion in individual sessions with Janelle and Adam about the typical Pattern of interaction that the partners played out around problem areas: Janelle, feeling anxious and abandoned, often criticized Adam for not being at home more, while Adam, feeling ashamed as well as anxious, tended to throw himself further into work so as to better provide for the family. This pattern is referred to as the polarization process. As the term suggests, partners' attempts to change one another often serve to increase the conflict and distance between them, even when often the purpose of trying to change one another is to facilitate intimacy or closeness. The result of this polarization process is a mutual trap where both partners' efforts to solve the problem just make it worse. For example, the conflict that ensues from Janelle's frequent criticism of Adam for not being at home led him to feel more insecure about the future of their relationship. His insecurity about the relationship served to deepen his fear that he will be unable to provide his family with necessary financial support, and he increased the time he spent at work. The more time he spent at work, the less time Janelle had to criticize him, which reinforced his spending time away from home. Janelle criticized Adam to right the child care imbalance between them, but she found the imbalance increasing rather than decreasing. Thus, Janelle and Adam found themselves in a vicious cycle of interaction.

In addition to the development of the case formulation, another important function of the individual sessions is to evaluate the level of violence in the relationship as well as each partner's level of commitment. Therapists trained in IBCT explicitly ask about intimate partner violence, commitment, and extradyadic affairs, often by focusing on relevant questionnaire items the client may have endorsed. Neither Janelle nor Adam reported any violence or affairs; both reported a high level of commitment to their relationship despite their distress.

In the feedback session, the therapist makes explicit the level of distress of partners, their commitment to the relationship, and individual and couple strengths that may aid the course of therapy. However, the main focus of the feedback session is to present the DEEP formulation of the couple's problems, which is the foundation on which the course of IBCT treatment is built.

During the feedback session, the therapist also presents her treatment plan. The goals of treatment include both acceptance and change for various factors in the DEEP analysis, with acceptance being appropriate for the natural differences between partners and the enduring emotional sensitivities that each brings to the relationship, with change being appropriate for the patterns of interaction that frustrate them, and with acceptance and/or change being appropriate for their external stressors, depending on the nature of those stressors. The therapist describes how treatment will work by introducing the Weekly Questionnaire (Christensen, 2010), which will be the basis of treatment. In this short questionnaire designed to be completed shortly before the session, partners rate their satisfaction with each other during the week, describe any major changes that have occurred, identify the most positive and most difficult interactions they had with each other during the week, and identify what incident or issue they wish to focus on in the session. The therapist describes how a typical session will proceed. Assuming there were no major changes, the therapist would normally review the most positive events between the couple and then focus on the incident or issue that partners have identified as being of most importance to discuss, with the therapist being an active facilitator of these discussions. At the end of the feedback session, the couple should have a clear idea of how the therapist sees their concerns and how she will address them in therapy. The couple is

asked to consider whether they want to proceed with treatment and make a joint decision as to whether to do so. The treatment phase of IBCT does not begin unless all parties commit to move forward with the treatment plan.

TREATMENT

Beginning with the first treatment session (following the feedback session), and in most subsequent treatment sessions, the therapist focuses on emotionally salient incidents and issues related to the formulation that are identified in the Weekly Questionnaire. In addition to this focus on incidents and issues, she pays attention to the emotions of the partners within the session and often finds that examples of their problematic patterns of communication unfold in the session. These examples provide an ideal opportunity for the therapist to help the couple alter their pattern of interaction. For instance, when Janelle and Adam began to argue about Adam's work in a therapy session, the therapist began her intervention as follows:

Janelle: [crying, looking down] If you cared about our family, you would at least make it home in time for dinner.

Adam: I do care, Janelle. I just have a lot of responsibilities at work.

Therapist: I'd like you two to step back for one second and look at what is happening here. Janelle, it seems that you are feeling quite hurt right now, and Adam that you feel pretty put on the spot.

Emotional Acceptance Techniques

Therapists trained in IBCT often begin treatment with acceptance interventions to help partners understand and accept differences between them and their individual emotional vulnerabilities. IBCT therapists do this through three acceptance techniques: *empathic joining*, *unified detachment*, and *tolerance building*.

Empathic Joining. In facilitating empathic joining, the therapist works to reformulate relationship discord in terms of differences between rather than deficiencies within partners and in terms of the emotional sensitivities that such differences often trigger, thus allowing partners to empathize with one another's experience. The therapist also focuses on eliciting more vulnerable disclosures of "soft emotions" (e.g., sadness,

fear) rather than "hard emotions" (e.g., anger, blame) from partners by suggesting soft emotions as a potential basis of behavior. In the previous example, the therapist suggested that Janelle was feeling hurt when she expressed the harder emotion of anger.

Rather than attempting to increase the amount of time Adam spent at home, the therapist involved the couple in a discussion of what time at work means to Adam by eliciting his thoughts and feelings around work. Additionally, she invited Janelle to talk about her emotional reactions to the time Adam spends at work and what that meant to her. This discussion facilitated empathic joining in that it allowed Adam to better understand the impact of his actions on Janelle, and Janelle to better understand Adam's emotion-based reasons for spending so much time at work. In this case, Janelle was surprised to find that her husband worried their family would end up in a similar financial situation to that of his family when he was growing up.

Ideally, such conversations help modify the emotional reaction of one partner to the other's behavior. The conversations Adam and Janelle had in therapy helped Janelle see that Adam's long hours at work were fueled by his anxiety about money, which allowed her to offer support to her husband, rather than criticizing him for not spending adequate time at home. Adam began to seek support and connection from Janelle when he was anxious about their finances, and they worked to establish a savings account with a "prudent reserve" only to be used for emergencies. As sometimes is the case, this focus on acceptance actually created a paradoxical effect: Adam began to work less once he felt less pressure and more understanding from Janelle, and they worked together to reduce the anxiety underlying Adam's late nights.

Unified Detachment. Therapists using IBCT techniques help partners discuss problems with unified detachment; that is, help partners step back, take a nonjudgmental stance, and consider relationship problems in descriptive, behavioral terms rather than with blame and accusation. The goal is to create a kind of dyadic mindfulness in which partners change their view of the problem from a "you" or a "her" or "him" to an "it" that the partners can join around. A common strategy is to help partners describe the sequence of interaction between the two of them during emotionally provocative incidents, identifying the "triggers" or "buttons" that activate each of

them and elaborating the pattern of escalation between the two of them. Often, IBCT therapists help the couple give their interaction pattern or “dance” a name, which serves to further distance the partners from the difficult emotions of (and often bring humor to) the pattern. For example, Adam and Janelle labeled their interactional pattern their “cat and mouse game” in which Janelle, the cat, pursued Adam, the mouse. The emotional distance created through unified detachment allows partners to understand better the behaviors and reactions of one another.

Tolerance Building. IBCT therapists also use tolerance building to help partners cope with the other’s unwelcome but nondestructive behavior. If one partner is not willing or initially resistant to change, then working with the other partner to face and ultimately tolerate the behavior is likely the only way for them to maintain a happy, harmonious relationship. When one partner begins to demonstrate some acceptance of the specific behavior, the other partner’s appreciation of this tolerance may lead to increased closeness (and sometimes even change of the behavior).

An IBCT therapist uses a number of strategies to build tolerance: positive re-emphasis, highlighting the complementarity of partners’ differences, preparing couples for backsliding, helping them achieve alternative means of support, and faking bad behavior. Through positive re-emphasis, an IBCT therapist points out the positive functions of behaviors thought by one partner to be solely negative, while often still validating the negative qualities of such behavior. For example, Adam and Janelle’s therapist highlighted how Adam’s long hours at work are a result of his commitment to his job, and while it is distressing for Janelle to feel alone with home responsibilities, he demonstrates a similar commitment to his family: when he says he will finish something Janelle can count on him to do it.

Regardless of whether the change is one partner’s behavior or the other partner’s understanding of it, there will be times when the couple lapses into their typical pattern of interaction. Because they frequently engaged in this pattern when they entered therapy, these lapses are expected and common. Thus, IBCT therapists help partners plan responses to such lapses prior to their occurrence, helping them tolerate lapses when they do happen. Additionally, the therapist encourages each partner to consider alternative means of support (e.g., from friends) and ways of self-soothing (e.g., taking a warm bath,

listening to enjoyable music) when in difficult times. When individuals learn to care more for themselves, they may put less pressure on their partners to meet their emotional needs and be less susceptible to perceptions that their partners are at fault for needs not being met. Finally, the IBCT therapist may ask the couple to reenact or fake their problematic interaction patterns in the session to help them observe more carefully their dynamics when they are not emotionally invested in the interaction.

Change Techniques

Often, as in the case of Janelle and Adam, acceptance techniques bring about adequate, spontaneous change in behavior and perception, and traditional change techniques are not necessary. However, as needed, IBCT uses several direct behavior change techniques in treatment to alter the dysfunctional Pattern of interaction: redirection and replay, behavior exchange, communication training, and problem-solving training. Typically, these interventions and the rules underlying them are adapted maximally to the needs and idiosyncrasies of the couple.

Redirection and Replay. When the couple gets into a dysfunctional pattern of interaction in the session, which often occurs, the IBCT therapist will interrupt that pattern of interaction and redirect the couple, prompting them to interact differently. A common tactic is that the IBCT therapist may ask each partner to talk first to the therapist rather than to the partner and, with the therapist’s help, fashion the message they would like the partner to hear. The therapist would then direct them to say this message to their partner. Another common tactic is to have the couple replay difficult interactions that occurred during the week and see if they can improve them in the session, with the therapist’s assistance.

Behavior Exchange. In behavior exchange, the therapist seeks to increase positive behaviors in the relationship by first identifying those behaviors, then instigating those behaviors, and finally debriefing the occurrence of those behaviors. In a typical treatment scenario, the couple is first asked to identify positive behaviors that each could engage in that would increase the other partner’s satisfaction in the relationship. This may be a homework assignment that the couple is asked to bring to their next session. Then the therapist asks the couple to increase the daily frequency of one or more behaviors on their list,

with the only guideline being that partners not tell one another which behaviors they will enact. Finally, the therapist debriefs the couple on giving and receiving positive behaviors. In these discussions, partners may provide one another with feedback about specific behaviors so that the couple has a better idea of which behaviors truly do increase perceived satisfaction.

Communication Training. Couples are taught speaker and listener skills in communication training (CT), with the aim being to help partners become more effective communicators with one another. The partners first practice the skills in sessions with corrective feedback and direction from the therapist, and then are encouraged and sometimes given assignments to practice the skills at home. Speaker effectiveness skills include focusing on the self (i.e., using “I” statements), expressing emotional reactions, and highlighting specific behaviors of their partner that lead to emotional reactions (e.g., “I feel hurt when you stay late at work and forget to call to let me know”). Listener effectiveness skills include paraphrasing and reflecting what one’s partner says. This ensures that partners understand one another without the misinterpretation common to distressed couples.

Problem-solving Training. It is expected that there will be times when, regardless of how effectively partners communicate about an issue, they have a hard time reaching a solution. Thus, couples are also taught ways of problem solving that keep them from entering into the mutual trap of dysfunctional problem discussion. As with CT, the therapist first works with the couple during therapy sessions to use problem-solving skills and then recommends that they practice at home to find solutions to problems.

Couples are taught three sets of skills in problem-solving training: problem definition, problem solution, and structuring skills. They first learn how to define problems in terms of specific behavior and the environment in which it occurs. IBCT therapists often ask that partners disclose emotional reactions to also work toward emotional acceptance. Finally, each partner defines his or her role in the problem.

Next, partners learn problem solution skills. The first step in problem solution is brainstorming—the couple is asked to come up with all possible solutions, whether realistic or unrealistic. They then delete unrealistic solutions from the list until they are left with possible solutions to the problem. Partners then agree on a solution,

write down and sometimes sign the agreement, and discuss things that might get in the way of instituting the solution. The couple is instructed to post the agreement where both partners will be aware of it, and the therapist checks in with the couple about the agreement for several sessions. If necessary, the agreement may be renegotiated.

The final skills couples are taught are structuring skills. Couples are encouraged to structure their problem-solving interactions so that they set aside a specific time and place to discuss the problem, ideally outside of the immediate problem situation. During their discussion, they are instructed to use skills from CT as well as problem-solving skills and to avoid negative verbal and nonverbal behavior.

OTHER INTEGRATIVE BEHAVIORAL COUPLE THERAPY THERAPIST GUIDELINES

Therapists trained in IBCT seek to remain flexible throughout the intervention techniques. They tailor interventions to the specific areas of deficiency of the couple and sometimes use failed change techniques as indication that relying more on acceptance interventions may be beneficial for the couple. Therapists should attend to in-session interactions and help facilitate in-session repair between partners when necessary. IBCT therapists remain nonjudgmental and accepting of partners and the outcome of the relationship. The goal of IBCT is to help partners have a different type of interaction around difficult issues and allow them to make the most informed decisions for the two individuals within the relationship.

EFFICACY OF INTEGRATIVE BEHAVIORAL COUPLE THERAPY

One of IBCT’s strengths, alongside its clinical value, is its empirically demonstrated efficacy. In a random assignment of eight couples to a group format of IBCT and nine couples to a wait-list control group, Wimberly (1998) found significantly favorable results for the IBCT couples. In a preliminary clinical trial, 21 distressed couples were randomly assigned to either IBCT or TBCT (Jacobson, Christensen, Prince, Cordova, & Eldridge, 2000). Results indicated that 80% of IBCT couples evidenced clinically significant improvement in relationship satisfaction, compared to 64% of TBCT couples. Finally, In the

largest randomized clinical trial of couple therapy to date (Christensen et al., 2004), 134 seriously and chronically distressed married couples were randomly assigned to either IBCT or TBCT and provided with approximately 26 sessions with trained therapists. TBCT couples improved more rapidly at the onset of treatment than did IBCT couples but also plateaued more quickly than IBCT couples. In contrast, IBCT couples made steadier change throughout the course of therapy, suggesting that IBCT's tendency to immediately focus on central issues, rather than small, overt behavioral change, may foster an important environment of emotional acceptance and safety that permits continual, stable improvement. Doss, Thum, Sevier, Atkins, & Christensen (2005) found that although TBCT facilitated greater change in the frequency of targeted behaviors early in therapy, IBCT facilitated greater acceptance of target behaviors throughout the course of therapy and that acceptance of target behaviors had a stronger link with satisfaction later in therapy than did change in the frequency of these behaviors.

Other studies have examined these couples over five years of follow-up. While TBCT couples demonstrated significantly greater improvement in observed communication than IBCT couples at termination (Sevier, Eldridge, Jones, Doss, & Christensen, 2008), IBCT couples better maintained overall treatment gains in communication (i.e., reduction in negativity and withdrawal) relative to TBCT couples at the 2-year follow-up point when the last observational assessment was completed (Baucom, Sevier, Eldridge, Doss, & Christensen, 2011). Couples in IBCT had significantly higher relationship satisfaction at each 6-month assessment point for two years after treatment termination but over the remaining three years of follow-up, differences between the groups evaporated. At the 5-year follow-up, approximately half of each treatment group showed clinically significant improvement, with effect sizes of $d = 0.92$ for TBCT and $d = 1.03$ for IBCT (Christensen, Atkins, Baucom, & Yi, 2010).

In addition to these primary studies, other research has explored IBCT's applicability to specific couple-related issues. For example, IBCT may be an efficacious treatment for couples in which one or both partners experience chronic pain (e.g., Leonard, Cano, & Johansen, 2006), and for couples experiencing infidelity (Atkins, Eldridge, Baucom, & Christensen, 2005). Currently, Doss and Christensen are adapting IBCT for an online

treatment and the U.S. Veteran's Administration (VA) chose IBCT as an evidence-based treatment to be implemented in VA facilities nationwide. For additional information on IBCT research, please see ibct.psych.edu.

CONCLUSION

This chapter describes IBCT, a couple therapy that focuses on emotional acceptance as well as behavior change. A case illustration of an IBCT therapist's work with Janelle and Adam provides an example of an IBCT case that evidenced change through acceptance techniques. We also describe behavior change techniques used with couples in IBCT. The studies mentioned suggest that IBCT is an efficacious treatment for relational distress, as well as for specific couple issues (e.g., infidelity, chronic pain) and that its focus on emotional acceptance may function to allow couples to achieve more long-lasting gains than TBCT.

60 Family Therapy Approaches Using Psycho-education

Joseph Walsh

Social workers may conduct family interventions with traditional family therapies or through psycho-education. Family therapists, using systems perspectives that are germane to social work practice, practice from an assumption that all members of a family unit influence each other's functioning through reciprocal

influence. Psycho-education, on the other hand, emerged from a medical model of mental illness and assumes that interventions may be appropriate for focus on only one impaired family member. This chapter demonstrates how the two perspectives can be combined to resolve family challenges.

Psycho-education describes a range of individual, family, and group interventions, usually led by human service professionals, which are focused on educating participants about a significant challenge in living and helping them develop adequate social support and coping skills in managing the challenge (Griffiths, 2006). Psycho-education can be a standalone intervention, but it is often used as one method among several for helping clients and families with a particular problem in living. Other methods may include individual counseling, case management, and family therapy.

The distinctiveness of psycho-education is its didactic/educational approach, with a non-hierarchical relationship between the client and practitioner and an acknowledgment of the family's expertise in the topic area. The major purpose of psycho-education is to facilitate a sense of cognitive mastery in the client and family (Hayes & Gantt, 1992). To do so, psycho-education relies on learning theory (how people acquire, make sense of, and use new information), cognitive psychology (challenging maladaptive thinking processes and suggesting alternative ways of thinking), dynamic psychology (emotional aspects of motivation, purpose, fears, hopes, and perceptions of the self), and developmental psychology (maturation processes and stages of illness and adjustment for both clients and family members) (Constas & Sternberg, 2006).

Family therapy can be defined as interventions in which all members of a nuclear or extended family, as opposed to just one member, are considered together as a psychosocial system in need of change (Nichols, 2013). Family therapists propose that psychological problems are best explained in terms of circular events that focus on the mutually influential and interpersonal contexts in which problems develop. Some family therapies include only a portion of an identified family because of the members' differential availability or commitment to the process. In every case, the focus of family therapy is on interpersonal relationships rather than individual processes. Therapy is intended to alter the structure or nature of relationships among family members. Other chapters in this section describe and illustrate common approaches to family therapy, such as the Bowen, structural, and strategic approaches.

Recent literature reviews and meta-analyses support the effectiveness of family psycho-education

for a variety of problems in living, and many such interventions seem to be most effective when they are provided without the presence of the afflicted member. A 2012 review concluded that family psycho-education is effective with schizophrenia, bipolar disorder, and other diagnoses, including children with mood disorders (Lucksted, McFarlane, Downing, Dixon, & Adams, 2012). Common themes across programs include member access to information, skill building, problem solving, and social support provision. An older meta-analysis found that psycho-education is effective for reducing the symptoms of schizophrenia especially when family members are included (Lincoln, Wilhelm, & Nestoriuc, 2007). Another systematic review concluded that psycho-education for families with attention deficit hyperactivity disorder (ADHD) is effective for improving child behavior, parent behavior, parent satisfaction, member knowledge of ADHD, and child adherence to medication regimens (Montoya, Colom, & Ferrin, 2011).

CONTRASTING PSYCHO-EDUCATION AND FAMILY THERAPY

The philosophy of psycho-education does not necessarily value family therapy as practiced from different therapeutic models. Some approaches may combine methods, but for the most part, psycho-education focuses on the general "health" of a family as it works to understand and help one member with an illness or disorder. The illness is considered to be unrelated to major systems issues. Psycho-educational programs have become common for families that include a member with schizophrenia, bipolar disorder, and major depression, and they have proliferated among other types of client populations, as will be described later. Psycho-education developed at a time when many professionals, working from a family systems perspective, tended to label parents as pathogenic in facilitating the development or persistence of schizophrenia in one member. Research on family expressed emotion (EE), measured by ratings of family member hostility toward the ill relative, emotional overinvolvement with the relative, and frequency counts of critical and positive comments about the client (Hooley, Miklowitz, & Beach, 2006), has been criticized as further blaming families for a member's disorder (Mohr, Lafuze, & Mohr, 2000). As a research measure, however, EE provides a means

for determining the kinds of family environments that put the person with a mental illness at risk of or protected from symptom relapses.

Family therapists, though not blaming families for the creation or sustenance of a disorder in one member, assert that the presence of problem behavior in one member has effects on the entire system, and the system can be helped to make shared adjustments in the nature of their interactions so that the entire family can function with maximum effectiveness. Psycho-educational programs are clearly not conducive to family therapy when they are provided only for the member who is experiencing the problem. Other programs that tend not to focus on family systems issues include those based on a medical illness of one member. Psycho-education programs that seem appropriate to systems interventions include those dedicated to clients with severe mental disorders, ADHD, mood disorders, eating disorders, and chronic physical health problems (Griffiths, 2006).

PROGRAM EXAMPLES

Three examples of effective family psycho-education programs are provided in this section. The first, the *Caregiver Support Group*, is designed for any family members who provide care for frail elderly members (Toseland & Rivas, 2012). Led by a professional social worker, it illustrates a blend of a structured group format with unstructured follow-up meetings. The structured portion of the program involves eight weekly two-hour meetings focused on education (caregivers' emotional reactions to the illness, self-care, communication skills, resource awareness, and home management techniques), coping skills development (see below), and problem-solving skills development. Monthly follow-up meetings provide ongoing support and assistance as needed to members based on whatever practical problems transpire between meetings. The program has been adopted by a number of service providers and found to be effective in improving caregiver performance, morale, and self-care (Toseland, Haigler, & Monahan, 2011).

Although specific time is set aside during each meeting to cover the three components described above, leaders always provide support interventions as well. These include member opportunities to ventilate about stressful experiences, leader and peer validation of similar caregiving experiences, affirmation of members' abilities to

cope, praise for providing good care, a sense of hopefulness about the future, and mutual aid.

The structure of the coping skills element of the program is as follows:

Session 1. The leader assures members that their reactions to the ill relative's health problems are normal, and formally acquaints members with the concepts of stress, appraisal, and coping. She offers members an opportunity to discuss their reactions to the ill relative's behaviors, their beliefs about the sources of the relative's behavior, and the coping strategies they have been using.

Session 2. The leader helps members identify and label their emotional and bodily coping responses to the relative's physical and mental condition and to their own role as caregiver and reinforces their effective coping skills. She encourages members to work toward changing ineffective coping skills, teaches them how to better recognize signs of stress and their typical cognitive appraisal and coping reactions, and encourages the members to keep a diary to record their experienced stresses and their reactions.

Sessions 3–4. Two relaxation techniques for the participants are introduced and practiced (deep breathing and progressive muscle relaxation) to counteract the effects of strain associated with caregiving.

Sessions 5–8. The leader teaches and practices cognitive restructuring strategies including self-talk, taking the perspective of other persons, and self-instruction. She promotes the identification of early stress cues as signals to activate effective appraisals and coping strategies, emphasizes the use of "inner dialogue" to plan coping strategies, and introduces the concept of coping imagery as a means of identifying preferred coping strategies.

During Session #7, members are given the option of choosing to meet monthly as an ongoing support group, and they are encouraged to maintain regular telephone contact with each other if desired. This is not a mandatory element of the program, but many members welcome it, even though they may gradually "drop out" of the process over time (ideally because they have received sufficient help to manage their family situations).

William McFarlane (2002) and his associates have developed a *Multifamily Therapy Group* (MFT) intervention that includes family

members and their impaired relatives. This intervention includes family therapy components consistent with emotional systems theory, structural family theory, and strategic family theory because it attends to emotional, structural, and communications aspects of family life. The intervention targets each family's social networks, cognitive deficits, continuity of care, stress levels, stigma, quality of life, burden, and expressed emotion. The groups are long-term (one or more years in length), which requires a major commitment from participants. The four major activities of the practitioner include joining with the families, conducting an educational workshop, preventing relapse through problem-solving processes, and promoting social and vocational rehabilitation.

The intervention is further organized into four steps: self-triangulation, group interpretation, and interfamily management.

Self-triangulation. The leader is directive and becomes the central part of the triangle between family members. She initially focuses on individual families to link their specific problems with appropriate family management guidelines. The leader elicits family interaction patterns and takes the initiative in defining problems in behavioral terms. She is directive in helping the family identify problems and problem-solving sequences. The leader facilitates systems interactions by blocking interruptions of one member by another and controls any extreme displays of affect that can impair problem exploration and resolution.

Group interpretation. The leader works to engage the families with one another, pointing out their similarities and unique contributions to the whole group process. With these commonalities she sets and takes responsibility for processing family interaction themes. Unlike the position taken by some family therapists, she also encourages intragroup social conversation, as this is seen as an important means of developing ties and enabling later discussion of substantive issues.

Cross-family linkages. The leader uses her relationship with family members to promote relationships across family boundaries. When one family introduces a problem for discussion, the leader turns to other families to make this

problem relevant to their situations and then facilitates group discussion of solutions.

Interfamily management. The leader attempts to enhance and reinforce interfamily contacts and thereby promote the process of natural support group development. Families help each other develop appropriate roles, responsibilities, and consequences.

MFT outcome studies have shown that the programs are successful in expanding the client and family's social network (a variable that is associated with lower client relapse rates and fewer hospitalizations) (Jewell, Downing, & McFarlane, 2009). Clients and families become more open, cooperative, and appropriately involved across family boundaries. Harmful intrafamily interactions also diminish.

The *Unity Multifamily Therapy Group* (UMFTG) for treating eating disorders (Tantillo, 2006) is based on assumptions consistent with several family systems approaches. It is similar to structural family therapy because it assumes that negative relational patterns can exist in a family with a member who has an eating disorder. It is also consistent with strategic family therapy, because the eating disorder is presented as something that exists outside the family but creates a tension that obstructs normal development for all members. The group is run by a single therapist as a close-ended, eight-session group with up to six to eight families in an outpatient setting. Group members are often from the client's nuclear family, family of origin, or partnership, but they may also be others who make up the client's social network.

In UMFTG, families (including the client member) examine the impact of their relationships on the eating disorder and the impact of the eating disorder on their relationships. The goals of the program are to help the family by:

- Increasing the quality of family life by decreasing stress, stigma, burden, and disconnections incurred by the disorder
- Enhancing a sense of perceived mutuality with regard to the eating disorder symptoms
- Promoting relapse prevention.

Within UMFTG, eating disorders are conceptualized as "diseases of disconnection" because family interactions serve to disconnect clients from their genuine internal experience and from other members, and foster the displacement of

conflicts and unacceptable feelings onto their bodies. The disorder distorts cognition and convinces clients to stay connected to it as a means of avoiding feelings or addressing conflicts. The disorder also disconnects clients from family members through its ability to exhaust and disempower loved ones. Family members worry that whatever they do or say may worsen symptoms. The client usually feels guilt and shame about the burden incurred by the family and often protects them from his or her authentic feelings and needs. The UMFTG works to identify the sources of disconnection within the family and helps participants learn how to embrace difference and work through disconnection toward authentic connection with the self and others.

This program approach is based on the fact that eating disorders occur predominantly in women and on the subsequent role of disconnection in the etiology and maintenance of eating disorders. The gender-informed approach to treatment facilitates psychological change and growth through its family systems interventions. Similar to other multiple-family group approaches, UMFTG involves the development of a therapeutic social network in which there is a combined focus on strategies to improve communication, coping, problem solving, and management of the disorder. However, it moves beyond scientific problem solving toward an emphasis on promoting mutual relationships in recovery.

Outcome studies for the UMFTG have thus far been limited to the experiences of the author and her associates. They report that families are successful in honoring differences with a stronger commitment to one another, and that participants build new relationships in recovery that minimize the impact of the eating disorder. The author calls for randomized studies to further examine the effects of the program.

The importance of family systems theory in psycho-education has become more evident as the modality is used across countries and cultures (Sue, 2006). For example, in working with families from China, leaders need to be attuned to structural family characteristics in that culture, including power, roles, and authority. This has also been noted in working with Latino families, with special attention given to the cultural roles of family cohesion and spirituality. The nature of psycho-education (information giving, personal disclosure, mutual problem solving) must be consistent with traditions in the participants' culture. Fortunately, Lefley's (2012) literature

review indicates that with appropriate cultural adaptations, the basic model of psycho-education, featuring information about serious mental disorders, illness management techniques, behavioral skills training, problem solving strategies, and family support is effective across national boundaries.

CONCLUSION

Theoretical perspectives on family intervention have evolved over the past 50 years. Systems approaches were most commonly used by family practitioners from the 1950s through the late 1970s. Psycho-educational interventions took ascendancy in the 1980s because of the prevailing biological perspectives on mental illness and emotional disorders. In the past 20 years, a more holistic awareness has evolved that family systems can experience extreme dysfunction as a result of one member's problematic behavioral or health situation. Psycho-education has become integrated with family therapy toward the goals of developing and strengthening family structures and also changing patterns of emotional interaction.

Guidelines for Couple Therapy with Survivors of Childhood Trauma

Kathryn Karusaitis Basham

INTRODUCTION

Two decades ago, when the sociopolitical climate shifted in the United States, a strong influence of feminism reshaped the direction of psychotherapy modalities attuned to survivors of childhood trauma. Affirming the reality of physical, sexual, and emotional abuses of children provided strength to the voices of many adult trauma survivors who suffered the harsh effects of this ill treatment. During this past ten years of wartime in Iraq and Afghanistan, more than two million U.S. servicemembers have been repeatedly deployed to these combat zones. Current research data reveal elevated rates of intimate partner violence, divorce, family conflicts, and associated mental health problems affecting military children (Institute of Medicine [IOM], 2013). Because rates of premilitary childhood trauma are higher for both male and female servicemembers, we need to be mindful of how legacies of childhood trauma, including both strengths and vulnerabilities, intersect with the effects of combat trauma and/or interpersonal violence in adult life. Although most psychotherapy approaches with this population had previously focused on individual and group interventions, attention has subsequently been paid to developing couple and family approaches for adult survivors of childhood trauma. Psychodynamic theories, in particular object relations theory, provided a general conceptual frame for early couple therapy models (Scharff & Scharff, 1991). Efforts to help couples with improved communication and problem-solving skills were bolstered by a range of cognitive-behavioral couple therapy methods as well (Basham, 1999; Fredman, Mondon,

& Adair, 2011; Jacobson, Christensen, Prince, Cordova, & Eldridge, 2000). In particular, two cognitive-behavioral models that have demonstrated an emerging evidence base for efficacy are introduced. First, *Cognitive-Behavioral Conjoint Therapy* assists servicemembers to learn about posttraumatic stress disorder (PTSD) and find ways to reintegrate back into the community following a return from deployment. Although participants report improvement in knowledge and symptom relief, it is unclear if any relationship shifts have occurred (Fredman, Monson, & Adair, 2011). A limitation of the model is the lack of suitability for some servicemembers who suffer mild-to-moderate brain injury that affects cognitive abilities, concentration, and expressiveness. Second, a cognitive-behavioral model originally developed to help couples establish greater closeness has been adapted for military populations to address specific combat-trauma-related effects on intimacy and conflict resolution (Erbes et al., 2008). Although this method provides invaluable psycho-educational materials to traumatized couples, it does not address the relationship patterns directly.

In more recent years, leading-edge research in attachment theory and neurobiology has shaped the development of attachment-based models of couple therapy, specifically for trauma survivors (Basham, 2013, 2008; Johnson, 2002; Sneath & Rheem, 2010). Johnson (2002) has disseminated her empirically supported practice model, which focuses on affect regulation, mentalization, and restoring or developing a secure attachment between partners; while Sneath & Rheem (2010) have adapted this emotionally focused couple therapy to accommodate a military population.

In general, contemporary couple therapy models rest on a firm yet flexible foundation of a synthesis of social and psychological theory models (Basham, 1999, 2007; Basham & Miehls, 2004). Rather than relying exclusively and narrowly on only one theoretical stance, current models aim toward synthesizing multiple social and theoretical perspectives to respond to a wide range of presenting issues.

GUIDELINES FOR COUPLE THERAPY PRACTICE

The following guidelines highlight central principles that provide the basic scaffolding for couple therapy practice with trauma survivors. They include (1) the centrality of facilitative and empowering relationships; (2) complex theoretical scaffolding; (3) cultural responsiveness; and (4) research-informed and evidence-based approaches.

Centrality of Relationship

When traumatic events rupture an individual's experience of safety, secure attachment, and trust in other people, restoring positive connections and relationships is vital for healing. As a result, a clinician needs to gradually and thoughtfully engage a traumatized couple in a workable therapeutic alliance to re-establish more secure attachments.

Empowerment and locus of control help forge a workable therapeutic alliance with a single- or dual-trauma couple (i.e., one or both partners survived childhood abuse, respectively). Because traumatic events often overwhelm child, adolescent, and adult victims with a sense of powerlessness and helplessness, victims need to regain a sense of mastery and internal locus of control in their day-to-day lives. As a result, a clinician needs to facilitate constructive decision-making capacities and a renewed experience of agency with a traumatized couple without imposing disempowering management.

Resilience fortifies those individuals who have navigated the assaults of traumatic events during childhood, including physical, sexual, and/or emotional abuses. For example, constitutional "hardiness," social supports, proactive coping styles, and abundant socioeconomic resources serve as important protective factors in mitigating long-term negative mental health and health

outcomes (Lester, MacDermid, & Riggs, 2010). To reduce negativity and undue pathologizing of human responses to horrific events, we need to focus on the strengths and areas of resilience expressed by a traumatized couple. On the other hand, we must not ignore the deep pain and suffering endured by some adult trauma survivors who wrestle with an acute stress response, post-traumatic stress syndrome (PTSD), complex PTSD, panic disorder, and/or depression. Because these adult trauma survivors have been subjected to hurtful treatment by abusive offending adults during their childhoods, we need to extend compassion and empathy rather than blame them for subsequently developing serious mental health problems.

The "victim-victimizer-bystander" relationship pattern is a central dynamic that occurs both on an intrapersonal and interpersonal basis for trauma survivors. Having experienced victimization in childhood, an adult trauma survivor approaches new relationships with anticipation that other individuals may demonstrate helpless, victim-like stance, an aggressive victimizing manner, or detachment. Many survivors of childhood trauma have also internalized this relationship template and view themselves and others within this framework. When this conflictual trauma scenario is unconscious, aspects of the internalized pattern are projected through the process of projective identification.

For example, a dual-trauma couple who presented with relational conflicts around yelling, intense arguments, and inadequate problem solving also struggled with daunting individual trauma-related issues. Both Jesse, age 48, and Maria, age 45 suffered severe physical abuse as children, inflicted by their parents. During their 15-year marriage, Jesse also served two combat tours of duty in Iraq with an Army infantry unit. Although harnessing noteworthy resilience and effective coping, this couple has also been deeply affected by the complex aftereffects of childhood trauma and combat trauma. They regularly engaged in the destructive forces of a victim-victimizer-bystander relationship scenario. Jesse behaved in a controlling and victimizing manner, alternating with an overly zealous rescuing role where he orchestrated what Maria ate and what clothing she wore. In response, Maria experienced herself as a victim of Jesse's aggression without seeing her own hostility expressed in her verbal harangues.

Theoretical Scaffolding

A second core guideline involves formulating a complex theoretical scaffolding to support the couple therapy model. Synthesis, rather than integration, of social, neurobiological, and psychological theory models allows for pulling together discrete and at times contradictory theoretical constructs into a unified entity to inform our assessments and craft treatment plans. Integrative models often suffer from the untenable objective of trying to merge diverse theoretical constructs that are often incompatible. Metaphor is helpful in describing this synthesis. If you visualize staring through a crystal at a distant object, you may see differences in the texture and color of the object depending on what part of the glass you are looking through. Similarly, the fabric of a theoretical synthesis shifts color and shape over time during the course of different phases of couple therapy.

In a similar fashion, a case-specific practice model changes the synthesis of theoretical perspectives depending on the unique features and needs assessed for each couple. As a result, the assessment and therapy process sustains a dynamic and reflexive flow of theory models that advance to the foreground while other theoretical models recede to the background.

Although a range of psychological and social theories are available in the knowledge base of a clinician at any given moment, data forthcoming from the couple related to their presenting concerns determine which constellation of theoretical lenses advances to the foreground. Because a relationship base provides the foundation for a couple therapy practice model, we may turn to the lens of object relations or attachment theory to inform how early childhood experiences shaped ways of relating in adult life, including during the couple therapy sessions. Feminist and critical race theories help us understand the sociocultural and family context. Intergenerational family theory aims to explore patterns, worldviews, and rituals that may have perpetuated or thwarted the cross-generational transmission of trauma-related effects. In contrast, a narrative family perspective may illuminate the multiple and unique meanings of a trauma narrative. In recent years, the groundswell of cutting-edge research in trauma and attachment theories further informs our understanding of the neurobiological effects of traumatic exposure as well as

disruptions to attachment. Holding the tension of multiple, often contradictory theoretical perspectives, while also maintaining a broader view, require flexibility in perception, understanding, and action from the clinician.

Cultural Responsiveness

A third core guideline is cultural responsiveness—an ongoing, dynamic attunement to the complex intersections of sociocultural factors that influence and shape the social identities of each partner and the couple throughout couple therapy. Race, ethnicity, religion, sexual orientation, gender, age, ability, primary language, and socioeconomic status influence the ways a child experiences traumatic events and how he or she copes in the aftermath of trauma throughout his or her life. A culturally responsive stance moves beyond the accruing of specialized knowledge and skills inherent in a culturally competent practice. Instead, the clinician engages with the couple in a reflexive exchange of ideas that mutually influences their shared understanding of how these various themes shape their presenting issues, worldviews, and the clinical encounter.

Self-reflection presumes that a clinician explores, on an ongoing basis, the full range of emotional and cognitive responses in practice with traumatized couples. In a psychodynamic conceptual framework, countertransference phenomena involve a complex nexus of personal reactions, a more “objective” response based on projective identification processes, and culturally determined responses to clients.

Research-informed and Evidence-based

The fourth core guideline relates to a research-informed and evidence-based approach toward all domains of practice including assessment, treatment planning, interventions, and evaluation.

As research evidence emerges to support the efficacy of various couple therapy models for trauma survivors, we are responsible for educating ourselves in the models *and* recommending them during the decision-making period of work with a couple. Flexibility of the clinician supports client-centeredness in designing a couple therapy plan with a traumatized couple. Although certain manualized treatment

protocols are useful in helping couples work on developing communication and conflict resolution skills, these clients also benefit from establishing a reparative therapeutic relationship that facilitates rebuilding of attachment and connections. Many traumatized couples comment on how disempowering and objectifying a “cookie-cutter” approach feels to them as they yearn to talk about their unique experiences in navigating painful emotional terrain. Each treatment plan needs to be individualized while also recognizing the need to advance research-informed and empirically supported treatment models.

PHASE-ORIENTED COUPLE THERAPY MODEL
