A phase-oriented couple therapy model specifically attuned for survivors of childhood trauma relies on a thorough bio-psycho-social-spiritual assessment that reviews a full range of institutional/sociocultural, interactional, and individual/intrapersonal factors (Basham, 2013; Basham & Miehl, 2004). It includes three therapy phases: Phase I—Safety, stabilization, and establishment of a context for change; Phase II—Reflection on the trauma narrative; and Phase III—Consolidation of new perspectives, attitudes, and behaviors. Preliminary research findings from a pilot project reveal positive changes in affect regulation and knowledgeability as well as a reduction in trauma-related symptoms.

The clinician needs to consider cultural congruence, relational capacities, and the dimension of time while crafting a treatment plan with goals that guide choices of specific clinical interventions. While envisioning a metaphoric image of a therapeutic venture as a sailing journey, a thorough assessment serves both as a compass for directing the work and as a stabilizing anchor. In contrast to sequential, essentialist stage models, a phase-oriented couple therapy treatment model assumes that various issues may be revisited at different periods throughout the work. During the early sessions of couple therapy, the clinician needs to assess the strengths and vulnerabilities for the couple and each partner in these various institutional, interpersonal, and intrapersonal arenas. The following outline may be used as an assessment guide that highlights relevant content.

BIO-PSYCHOSOCIAL-SPIRITUAL ASSESSMENT

Institutional/Sociocultural (grounded in social constructionist, critical race and feminist theories)

1. Clinician attitudes and responses (countertransference and secondary trauma)
2. Social supports (e.g., family, community, faith-based organization, and military unit)
3. Service delivery context (social policies, finances, and political context)
4. Previous and current mental health treatment
5. Intersecting sociocultural factors (i.e., race, ethnicity, religion, socioeconomic status, primary language, ability, gender, sexual orientation; age; military and Veteran culture)

Interpersonal (grounded in intergenerational family and cognitive-behavioral theories)

1. Relational dynamics including “victim-victimizer-bystander” pattern (interactional and intergenerational)
2. Power and control struggles
3. Distancing and distrust
4. Boundary issues
5. Communication patterns

Individual (grounded in neurobiology, attachment, and object relations theories)

1. Individual cognitive, affective, and behavioral functioning
 - Indicators of resilience
 - Mental health diagnoses (e.g., Posttraumatic stress (PTS); Posttraumatic stress disorder (PTSD))
 - Co-occurring conditions (depression/suicidal behavior; substance use disorder; cognitive injuries; intimate partner violence)
2. Intrapersonal
 - Working models of attachment, affect regulation, and capacity for mentalization
 - Internalized victim-victimizer-bystander dynamic

- Capacity for whole? Part? Or merged object relations?

As clinicians, although we continually assess a couple's presenting issues and their progress throughout treatment, a focus with clear goals can typically be established after several sessions. Areas of strength and vulnerability in these various arenas of a couple's life set the stage for the crafting of such a plan. For example, Jesse and Maria benefited from an approach that addressed the multiplicity of their problems and helped coordinate their care. Not only was attention paid to interrupting the destructive force of their victim–victimizer–bystander relationship scenario, each partner set individual goals related to strengthening self-care and safety related to their trauma-related symptoms. For example, Jesse set a goal to re-establish his abstinence from alcohol, renew his connections with his sponsor, manage his unstable diabetes, and balance his erratic affect. Maria set goals to address her self-harming suicidal behavior and seek psychopharmacological relief from depression. In Phase I of couple therapy, we often see goals that improve relational patterns (i.e., minimizing the power conflicts and achieving greater mutuality, improving direct communication, and managing intense affect during conflict resolution). In addition, self-differentiating goals are also addressed to promote healing and growth both interpersonally and intrapersonally.

Phase I goals in couple therapy are relevant for all traumatized couples. These goals aim to: (1) develop a basic sense of physical and psychosocial safety; (2) stabilize trauma-related symptoms and manage crises; (3) strengthen self-care and self-differentiation; (4) develop stress-reduction and affect-regulation skills; (5) demonstrate communication and conflict resolution skills; (6) identify, strengthen and expand social supports; and (7) explore complex social identities.

During this phase of work the following themes are explored in depth with a variety of clinical interventions grounded in psychodynamic, cognitive-behavioral, and body/mind perspectives:

- Safety
- Self-care (physical health and mental health; sleep, nutrition, and exercise; substance use and abuse; bio-behavioral strategies for stress reduction and self-soothing)
- Support systems (e.g., religion/spirituality, family, community and military unit)
- Communication skills
- Assessment of partnership status (continuation, static, dissolution, growth)
- Exploration of complex social identities.

After a couple has accomplished all aspects of Phase I goals, they are typically ready to move along to Phase II tasks, which involve reflection on the trauma narrative. Given recent controversy in the mental health field related to the dubious benefit of prematurely uncovering traumatic memories, I assert that most couples benefit from a reflective sharing of their traumatic experiences, on a cognitive or titrated affective level, without full affective re-experiencing of early traumatic memories.

Work involves reflecting on the trauma-related effects in the present, recognizing and changing the victim–victimizer–bystander dynamic and healing relationships with extended family and family of origin in the here and now. Grieving the loss associated with childhood innocence along with losses of real relationships surface at this time. Traumatogenic family environments often rob everyone of ordinary transitional rituals that both celebrate wonderful accomplishments and grieve losses related to life transitions such as death, divorce, and reintegration post-deployment. For example, after Maria and John completed Phase I tasks, they shared their sorrow with exploring the roots of family violence. As they traced the histories of emigration, military service, and poverty for both families of origin, each partner was able to understand how unresolved emotion and distress were transmitted intergenerationally, affecting both of them as well as their children. After many shared tears, they talked about interrupting their pattern of emotional violence and shifted away from victimizing each other and themselves. In summary, therapy goals at this Phase II aim to:

- Explore the meaning of traumatic experiences and build shared empathy
- Explore the intergenerational legacy of the victim–victimizer–bystander dynamic
- Mourn losses (e.g., death, divorce, reintegration following deployment, disability, moves)
- Create healing and transition rituals.

Phase III goals focus primarily on consolidating the family of origin work started in Phase II, along with additional strengthening of family and community relationships. Couples often experience less shame and isolation as they move more actively into discussions of their intimate sexual partnerships. Parenting often improves as partners listen better and learn to set firm yet benign boundaries. Finally, couples no longer define themselves through the identity of victim or survivor. Instead, they view themselves with complex social identities, thriving in their new approaches to life. The following Phase III goals aim to:

- Remediate trauma-related symptomatology
- Demonstrate the capacity for empathy
- Develop equitable power relationships
- Enhance sexual relationship and intimacy
- Demonstrate capacities for self-differentiation and secure attachment
- Develop effective parenting skills
- Identify and express complex social identities
- Express a shift in social consciousness

PREPARING FOR FUTURE WORK WITH COUPLES

Given that engaging in couple therapy with survivors of childhood trauma challenges even the most experienced and resilient clinician, recognizing common therapeutic missteps can ease some of the difficulty. Clinicians might aim to: (1) address Phase I tasks of safety, self-care, and assessing co-occurring conditions without moving too quickly into a discussion of a primary trauma narrative; (2) educate themselves on the best practices available including couple therapy models that have established empirical support as well as those that have emerging evidence; and (3) engage in self-reflection regularly to heighten cultural responsiveness as well as minimize and address countertransference enactments. When clinicians recognize the benefit of a fluid, dynamic phase-oriented approach that titrates emotional intensity, they will be better able to manage their countertransference enactments and heal any relational therapeutic ruptures. Even so, this work is challenging. Yet, couple therapy has its rewarding moments as well. When couples experience a sense of growth and accomplishment, they often describe ways that their suffering and

distress transform into a renewed sense of hope for the partnership.

62 Working with Children and Families Impacted by Military Service

Eugenia L. Weiss, Jose E. Coll, & Tara DeBraber

GETTING STARTED

Due to the U.S. military involvement in the Global War on Terrorism (GWOT) for more than a decade, it is highly likely that civilian social workers will encounter military or veteran connected families seeking assistance from community mental health or family service agencies, especially given that military and government systems of care (e.g., Veterans Administration) may not be able to meet the demand for services. Social workers without exposure or having little knowledge of the military or veteran population may benefit from understanding military culture and lifestyle, as well as current issues facing military connected families, in order to provide comprehensive and informed services for this population (Savitsky, Illingworth, & DuLaney, 2009). Thus the objective of this chapter is to inform social workers on the unique strengths and challenges of military connected families and ways to serve them. Military connected families are often considered resilient in the face of experiencing unique stressors such as frequent geographic relocations, service member deployments and family separations, postdeployment adjustment, and family crises resulting from posttraumatic stress disorder or other injuries incurred by the service member. However, before we explore associated stressors as well as family strengths, military family-related demographics

will be provided first, followed by a bird's eye view of military culture and lifestyle, as a way of background and orientation for the reader. As of 2011, only 37% of military families lived on a military installation with the remaining 63% living among 4,000 communities nationwide (U.S. Department of Defense [DoD], 2011). Fifty-five percent of service members have children and almost 50% are married, 6.5% are single parents, and 2.1% are in dual-military families, where both spouses are members of the military and at times deploy simultaneously (DoD, 2011; Office of the Deputy Under Secretary of Defense, 2008). The majority of service members are young, with over half being below the age of 25 and 70% having one or more children (Kaplow et al., 2013). Of the active duty service members, 41% have children in the zero to five-year-old age range and 25% of members in the selected reserves have children in the same age range (Lieberman & Van Horn, 2013). According to the DoD (2009), there are 1.9 million children with a parent serving in the U.S. military of which more than 700,000 have experienced parental deployment especially in light of the GWOT, post 9/11, where service members and reserve components have been called to serve on multiple and lengthy deployments, most often to Iraq (Operation Iraqi Freedom, OIF; and Operation New Dawn, OND) and Afghanistan (Operation Enduring Freedom, OEF).

MILITARY CULTURE AND LIFESTYLE

Military culture is comprised of a distinct subset of American society governed by a separate set of laws, norms, traditions, and values (Exum, Coll, & Weiss, 2011). The authors note that key characteristics of military culture include an emphasis on “mission readiness,” as well as the importance of military unit cohesion within a hierarchical or rank-based system. The tenets or virtues of military service, regardless of the branch of service, include courage, honor, loyalty, commitment, integrity, and an expectation of adherence to these values, all of which may be imposed on the family; and at times are considered to be a reflection of the military member. A noted consequence for military families is the constant moving (including sometimes living abroad) that is part of the military lifestyle, and which can lead to the family becoming susceptible to isolation and alienation from extended family members and from civilians as well (Hall, 2011). Family members can become isolated because they often feel that their lives are transient; as a consequence, sometimes they do not readily invest in new relationships, communities, or schools. Additionally, military personnel who are deployed from the National Guard or Reserve units are civilians who are part-time military personnel activated into “active duty status.” Not since World War II, have reserve components been more deployed than they have been within what has been termed the mobilization of the “total force” (Exum, Coll, & Weiss, 2011). These families face additional stressors in relation to occupational and economic losses; the service member parent or spouse may take a leave from his or her civilian job to be deployed, and then often returns from deployment to find that the job is no longer viable (due to a poor economy). Or the service member may return to find that she has been passed up for a promotion in her civilian job. In addition, some service members may experience less earning potential while they are serving their country. Additionally, Guard and Reserve families often live at great distances from military bases and thus, they often lack resources that active duty personnel have in terms of greater access to built-in military support systems (see Harnett, 2013).

This chapter will outline the strengths and stressors associated with the military and veteran connected families with particular emphasis on deployment related stressors, and effects of parent (i.e., service member) injury upon the family,

as well as implications for civilian social workers working with this population. We will begin with providing an understanding of the impact of service member deployment on the family.

MILITARY DEPLOYMENT

Deployment is the assignment of military personnel to temporary, unaccompanied duty (i.e., without family members) and away from their permanent duty station (Stafford & Grady, 2003). Pincus et al. (2001) proposed a model for understanding the psychological phases and transitions (i.e., cycle of deployment) that military families undergo as a part of the deployment process. For example, the *predeployment* phase entails the psychological and physical preparation in the months preceding the actual deployment. It is typified by alternating feelings of anticipation and loss for both the service member and for the family (Pincus et al., 2001). During the *deployment* phase, when the service member has actually departed from the home, children’s responses will vary depending on their age and stage of development; some may feel angry, sad, numb, or lonely (Fitzsimons & Krause-Parello, 2009). Children may feel that the deployed parent has left the home because of their misbehavior or they may experience extreme emotions related to feelings of abandonment (Stafford & Grady, 2003). Older children or adolescents may resent the nondeployed parent if there are younger siblings who require increased attention from that parent (Paley, Lester, & Mogil, 2013). A study by Mansfield et al. (2011) demonstrated that Army children with a deployed parent (OEF/OIF) were experiencing a greater incidence of mental health-related problems, such as acute stress reactions and depressive and behavioral disorders, than their civilian counterparts. Furthermore, the longer the deployment, the higher the rate of adjustment problems. Another area of concern involves parental absence related to extended-combat deployments and military trainings away from home and the impact of these separations on children’s well-being. Combat-related deployments further exacerbate the stress of separation because children and youth worry that the deployed parent may be injured or killed in the line of duty (Burrell et al., 2006). In fact, for many, long-term parental separation can be detrimental to emotional and behavioral functioning across developmental stages (Windle, 1992). Research has

demonstrated the importance of developing healthy attachment relationships during the first years of life. Infant mental health, defined as a young child's ability to experience, regulate, and express emotions, as well as develop close relationships or secure attachments in order to learn and explore the environment, is affected by the stressors of the family, which can be exacerbated by the demands and stressors of the military lifestyle (Lieberman & Van Horn, 2013). These young children must cope with the caregiver parent's distraction with a deployment and the parent's role of managing a household alone. Military connected infants and young children can experience increased stress from their environments, which may affect the infant's ability to manage frustration and conflict while maintaining normal development trajectories (Lieberman & Van Horn, 2013). Mild-to-moderate stress is a developmental expectation that can provide the infant with an opportunity to practice dealing with displeasure or fear and manage frustration. During predeployment and deployment, childcare arrangements can frequently change leading to toddlers and preschoolers becoming easily frustrated, reverting to old behaviors, acting out, or being controlling and demanding (Lieberman & Van Horn, 2013). Parents or caregivers should assist young children in understanding what is happening or how things will change after a separation in developmentally appropriate ways and in a calm fashion. This is important for young children because they can assess their parent's emotional state through facial expressions and tone of voice. Caregivers (most often the nondeployed remaining parent, i.e., the mother) can experience additional stress during the time of separation if the young child exhibits emotional or behavioral difficulties in response to the deployment separation. During this phase, it is helpful for the caregiver parent to provide structure and routine for the child on a daily basis. The nondeployed parent or spouse typically manages the day-to-day activities of the household, including the majority of the parenting and parental decisions for children if there are children in the household. Military programs are increasingly addressing the needs of the family because the well-being of the spouse is related to the retention of service personnel (Green, Nurius, & Lester, 2013). Military families routinely experience a variety of stressors and changes with various levels of resources and support. Families can easily tip into a state

of crisis if an unexpected stressor, experience, or circumstance arises when a family is already experiencing high stress, or if an unanticipated event overpowers the family's coping abilities (McCubbin & Patterson, 1983). (For an overview on theory and practice with military couples and families, please see Weiss et al., 2013). Families can benefit from a social worker who can educate them on problem solving skills and goal setting, and who can make them aware of resources. Military families may not be aware of all of the resources, services, and programs that are available to assist in successfully navigating through the demands associated with military lifestyle. Overall family mental health and functioning can be negatively impacted if levels of chronic stress become the "new normal." Social workers can assist military families in relaxation and calming techniques to reduce stress levels (Green, Nurius, & Lester, 2013). According to the research, family stress levels and ability to cope with the demands of the military are also correlated with lower educational level of the remaining parent or spouse and early entry into adulthood and parenting as evidenced by the young ages of new military couples and parents (Green, Nurius, & Lester, 2013). Additionally, research has shown social media and the Internet can be positive factors in maintaining levels of connectedness during a deployment. These types of communication provide a level of immediacy that a mailed letter cannot. Families are increasingly using social media and the Web for real time events such as birthday parties, graduations, and births. Social media allows for continuation of family dynamics during times of separation through the sharing of pictures, videos, and real time conversations (Matthews-Juarez, Juarez, & Faulkner, 2013). The use of social media was found to be helpful for families who identified as having strong family unity and yet exacerbated the problems of families with preexisting issues (Matthews-Juarez, Juarez, & Faulkner, 2013). Therefore, a social worker should assess the family and couple history before encouraging use of the Internet or social media as primary modes of communication.

As military connected families experience heightened levels of stress, children may be at increased risk for being victims of child maltreatment. Child maltreatment can be a result of the parent's inability to manage his or her own stress, resulting in reactive behaviors toward children as opposed to appropriate parenting behaviors. If the

perpetrator is the nondeployed parent, maltreatment or abuse is likely related to the stress of the deployment or the reorganization of family roles and boundaries after deployment (Porter, 2013). Risk for child maltreatment may be impacted by lack of resources (or the perception of lack of resources), as well as substance abuse and mental health issues in the caregiver(s) (Thomsen et al., 2013). Poorly managed stress in the caregiver (i.e., the nondeployed parent) is a critical factor in cases of child maltreatment. A study by Gibbs et al. (2007) found that the rate of substantiated child maltreatment (i.e., neglect) among Army families was 42% greater during deployments. Adolescent children also can experience negative reactions to a deployment, such as depression, low self-esteem, or school problems that can result in child maltreatment, especially if the adolescent is rebellious or suffers from a mental illness or disability. Child maltreatment during a deployment with adolescent children can be attributed to the combination of the adolescent's emotional deregulation and the lack of parental control (Porter, 2013). If a service member is discharged from the military with "other than honorable" or as "dishonorable," he or she is then ineligible for veteran benefits, which can further increase the risk for child maltreatment because access to resources is then significantly diminished for the veteran and his or her family.

In order to assist military families under stress, Porter (2013) identified Child Parent Relationship Training (CPRT) as an effective intervention for these families. CPRT is a strength-based resilience training that teaches parenting skills and effective interactions through child-centered play (Porter, 2013). Filial therapy has also been found to be helpful in supporting military families facing the stressors of deployment (Chawla & Solinas-Saunders, 2011). Social workers can use these types of interventions to empower families and increase their resilience in order to decrease the risk of child maltreatment. When working with military families, social workers are further encouraged to build upon family strengths and develop a military family genogram as a tool to explore intergenerational family resiliency from a solution-focused perspective (Weiss et al., 2010).

The next phase in the cycle of deployment is the *sustainment* phase, which occurs from the first month of deployment through the month prior to the service member's return home. Sustainment is the time in which the family has

the opportunity to create new sources of support as well as new routines in the absence of the service member (Pincus et al., 2001). Children often assume additional roles and responsibilities in the home and are thus forced to become more independent; many will take pride in their newfound competencies (Weins & Boss, 2006). Military connected children and adolescents may also have more responsibilities at home or with younger siblings during the sustainment phase, resulting in the nondeployed parent ignoring the adolescent's need for supervision and support (Williams, 2013). As a result of many changes and stressors, adolescent children can feel resentment toward parents and the military lifestyle. Milburn and Lightfoot (2013) stated that adolescents with a deployed parent are more likely to engage in risky behaviors such as binge drinking, along with use of other substances and experience thoughts of suicide and depressed mood. Adolescents may also experience difficulty when the deployed parent returns, especially if the adolescent was a "parentified" figure in the family during the length of the deployment, and subsequently is reluctant to give up that role upon the return of the service member parent (Milburn & Lightfoot, 2013). Although adolescents can experience significant stressors associated with the military lifestyle, not all adolescents experience negative emotions related to deployments and changing family roles. Adolescents can develop or experience healthy coping skills and demonstrate resiliency to the multiple demands of the military lifestyle, especially when the parents are financially stable and know of or can access multiple resources and services (Astor et al., 2013). Military spouses have described the deployment process, not so much in terms of the linear stages of deployment, but more as a "roller coaster" of highs and lows and "contradictory emotions." Despite these feelings of powerlessness, a qualitative study on Army wives found that they engaged in positive thinking and coping, exhibited self-determination with new found self-confidence, and engaged in opportunities for self-discovery (Davis, Wards, & Storm, 2011, p. 55).

Below is a brief case scenario demonstrating what a social worker may see in working with a military family where the service member spouse/father is deployed and the family is experiencing some challenges. Recommendations for interventions are also presented. (The scenario is a composite of several cases and any similarity to real people or events is purely coincidental.)

DEPLOYMENT/SUSTAINMENT PHASE CASE SCENARIO

Bryce Jones is an 11-year-old Caucasian male who attends outpatient counseling twice a month with a private practitioner. The client is able to participate in counseling through his father's health insurance for military dependents (TRICARE). Bryce's father, Mike Jones, is in the Marine Corps and the family is stationed out of Camp Pendleton in California, where they live on the military installation. Bryce has a younger sister, age 3 years (Emma) who is "daddy's girl," and his father is currently on his fourth deployment to Afghanistan. This time he has been gone for six months and has five more months to go. Bryce's mother used to spend time with him and had signed Bryce up for various athletic activities, which he seemed to enjoy. Ever since his father deployed, however, Bryce has not played any sports and hardly spends any time with his mother. Instead, he stays in his room the majority of the time watching TV or playing video games. Bryce's sister, Emma, has been having temper tantrums and regressed to bed wetting despite being successfully potty trained eight months prior. Bryce's mother (Alice, age 29) has become increasingly depressed, has "no one to talk to" (family of origin is out of state), and is "at her wits end" trying to deal with her 3-year-old. She is not sure how much longer she can manage everything on her own, despite having fared well with the last three deployments (Emma was one year old at the time of the last deployment). Bryce is also having difficulty in school both academically and socially. Prior to the deployment, Bryce was an average student and interacted well with his classmates. The therapist has called a family session with Bryce, his sister Emma, and his mother Alice, to assess the needs of the family.

Bryce's therapist is concerned with the well-being of the family and after a thorough assessment, does not believe that there is child maltreatment or neglect at this time. However, to mitigate for the increased risk of child maltreatment along with other augmented risk factors the therapist recommends the following for the family. First, for the family to engage in Child Parent Relationship Training (CPRT) or filial therapy; the therapist provides a referral to a family therapist who is versed in these types of approaches and is covered in the TRICARE network. The goal is to bolster Alice's parenting skills and help her to engage effectively with both of her children through listening and being able to respond to their feelings. As part of the sessions, the family therapist will assist each family member in developing positive coping skills, as well as learning how to communicate effectively

with one another. In addition, the family will be able to identify desirable family activities that will promote family cohesion, as well as ways for the family members to feel connected with the deployed father. Additionally, the therapist will recommend several community programs to help the children and the deployed parent with maintaining attachment bonds. One such program is *United through Reading*, in which a deployed service member is recorded (while deployed overseas) reading a children's book. A DVD of the reading, along with a copy of the book, is mailed to the child for the child to follow along in the parent's absence (United through Reading, 2013). Another organization, *Daddy Dolls*, creates doll-size or life-size figures of the deployed service member for the child to maintain a feeling of closeness during the time of separation (Daddy Dolls, n.d.). For younger children, such as Emma, the organization, *Zero to Three* offers trainings, resources, and tips for parents to address feelings and behaviors in the youngest of military-connected children (Zero to Three, 2009). Furthermore, the popular, *Talk, Listen, Connect: Helping Families During Military Deployment*, is a Sesame Street media tool created a few years ago to assist preschool children in coping with separations and deployment (Sesame Street Workshop, 2006). More recently, this program has expanded in scope with support from the Defense Centers of Excellence, and includes Internet and digital technology types of tools in order to provide greater outreach.

Second, the therapist will refer Alice, the mother, for her own individual therapy to help promote her resilience and coping with stressors associated with being the nondeployed parent (i.e., acting as a single parent). The therapist will also refer her to on-base military resources for support groups specific to spouses/mothers during deployment. Third, the therapist will inquire whether there are school-related programs that can further support Bryce. After obtaining parental permission, the therapist may want to work closely with a social worker at Bryce's school. Schools are optimal environments for the provision of prevention and intervention services for school-aged children because these settings provide access to many children and are a familiar and safe context (Jaycox et al., 2006). This is especially the case when many military families will not seek military behavioral health services for reasons associated with stigma or for fear of negative work-related repercussions for

the service member parent. (For further information on schools and military connected children, please see Building Capacity, 2010; Leskin et al., 2013; Weiss & Coll, 2013). This case will be revisited later in the chapter after we discuss postdeployment/reintegration and service member injuries and impact on the family.

To continue where we left off before the presentation of the case scenario, the next stage in the cycle of deployment is the *redeployment* phase, which occurs within the month prior to the service member's return home. It involves the anticipation of homecoming, and the family and service member often experience mixed emotions consisting of excitement and apprehension (Pincus et al., 2001). The final phase in the cycle of deployment is the *postdeployment* or *reintegration* phase, when the service member is reunited with his or her loved ones. Initially the phase of homecoming can be a honeymoon period, but it is often followed by many families facing adjustment-related challenges. For instance, new roles and responsibilities need to be renegotiated at this stage. Children may have undergone significant developmental changes during the service member's absence, thus creating new parenting challenges for the service member parent, including a loss of parental authority and the need to attach or reattach emotionally to their spouse and children (Bowling & Sherman, 2008). During the reunion or postdeployment phase, it is important to give the returning service member time to adjust to the developmental changes the child experienced or achieved during the parent's absence. The reintegration phase becomes even more complicated if the returning service member parent is somehow changed by the war experience, either psychologically, behaviorally, or in terms of belief systems. The reader may refer to Weiss, Coll and Metal (2011) for further exploration of the alteration of veteran worldviews following combat experiences.

SERVICE MEMBER INJURY AND IMPACT ON FAMILY

Service member injury is another area that vastly affects military families and children in the reintegration of the service member spouse/parent. It is estimated that over 30,000 military children have been impacted by parental combat injuries during the current and continuous GWOT (Cozza & Guimond, 2010). Although

more service personnel are surviving combat due to better protective gear and technology than in previous wars, from 15% to over 30% of all returning veterans from OIF/OND/OEF will meet *Diagnostic and Statistical Manual of Mental Disorders* (APA, 2013) criteria for Posttraumatic Stress Disorder (PTSD), as well as a high number of mood disturbances, anxieties, and comorbid substance abuse. Some will have experienced mild traumatic brain injury (TBI) (e.g., concussion) associated with blast exposure from roadside bombs or intermittent explosive devices (Tanielian & Jaycox, 2008; U.S. Army Medical Department, 2008). Rosenheck and Fontana (1998) found that the more severe and complex the parental exposure to combat, the greater the extent of distress among children. The effects of a combat veteran's trauma on the family have been recognized in the literature as "secondary traumatization"; this refers to a phenomenon whereby the veteran's trauma is unwittingly transferred to his or her partner and children, who then experience similar symptoms as the traumatized veteran (Dekel & Goldblatt, 2008; Figley, 1995; Nelson & Wright, 1996). In fact, parental distress in either the returning combat veteran or in the caregiver parent (i.e., the nondeployed parent) has been demonstrated to contribute to poor emotional and behavioral adjustment in children (Chandra et al., 2011). Exposure to traumatic stress could overwhelm the child, leading to the collapse of age appropriate coping (Lieberman & Van Horn, 2013). These authors noted that trauma exposure or traumatic stress can destroy the child's ability to trust the caregiver(s) and create feelings of helplessness that can impact the child's feelings of self-worth.

An additional concern involves the high rates of interpersonal violence and child maltreatment among both active duty and veteran (i.e., separated or retired from military service) populations. These rates are estimated to be three times higher than rates among the U.S. civilian population (Houppert, 2005). Incidents of physical abuse also increased when the service member parent returned home (Gibbs et al., 2007). Even in service members who do not suffer from the symptoms of depression or PTSD, a study found that family violence is mostly related to family reintegration problems upon the service member's return home from deployment (Taft et al., 2007).

Combat injury can have a range of effects on the family members. It is important for the non-deployed parent to communicate with children

regarding an injury in developmentally appropriate language as early as possible and to create and encourage an atmosphere for discussion regarding the injury of the service member parent (Cozza, Holmes, & Van Ost, 2013). Family dynamics may shift or change as the noninjured parent attends to the injured parent's needs, limiting his or her availability for the other family members. The injured parent may also experience a multiplicity of changes, including a decreased ability to care for him or herself, changes in parenting ability, and emotional or physical withdrawal from the rest of the family (Cozza, Holmes, & Van Ost, 2013). Children of injured service members may blame themselves for changes in the injured parent's behavior. Social workers can work within the family system to provide education regarding symptoms of posttraumatic stress disorder/traumatic brain injury, as well as for cases of polytrauma (where the service member has had trauma to multiple body systems; e.g., limb loss, spinal cord injuries) and how family dynamics may have changed since the injury. Multifamily group modalities are helpful for providing psycho-education and support for families coping with veteran injuries (see Bowling, Doerman, & Sherman, 2011; Perlick et al., 2011). Social workers can teach the injured parent how to self-monitor emotional states and how to express feelings and needs to the other family members. If the injuries or disabilities take a chronic or long-term trajectory, a social worker can assist the caregiver (usually the spouse) in coping skills through a stress process model (see Matthieu & Swensen, 2013). Additionally, social workers are able to help injured veterans develop and set goals, have realistic expectations in their rehabilitation or recovery, and learn to use various strategies to cope with memory and concentration issues (in cases of PTSD and/or TBI) in a way that can benefit the needs of the family (Moore, 2013). Combat injury can also impact the relationship of the military couple through decreased intimacy and poor communication (Hanley et al., 2013). Balderrama-Durbin et al., (2013) stated that the symptoms of posttraumatic stress disorder contribute to poor relationship functioning. Emotionally Focused Couple Therapy (EFCT) can be particularly helpful with combat veterans in assisting with attachment bonds (Johnson, 2002). Furthermore, issues between a couple can be exacerbated if the service member experiences an injury that can also affect the ability of the couple to effectively parent or make unified family decisions. Developing family resilience

is important for families to be able to adapt successfully to changes in the family (Walsh, 2006). Family resilience can be positively affected through the use of family narrative because it allows the family to adapt to the circumstance, make meaning of the circumstance, and develop skills and beliefs to respond to the circumstance in a meaningful way (Saltzman, Pynoos, Lester, Layne, & Beardslee, 2013). Additionally, by incorporating a solution-focused approach (Weiss et al., 2010) social workers can assist families in recognizing their prior successes in having managed past deployments and stressful life events and find ways to empower them through any postdeployment challenges and beyond military life (i.e., military separation, discharge, or retirement).

Finally, the families of service members must also cope with the grief and loss associated with service member serious injury and death. Since the inception OEF/OIF there have been more than 5,600 U.S. casualties along with an alarming rate of service member suicides (Cohen & Mannarino, 2011). The authors commented that most bereaved military children will experience adaptive grief responses, but some may develop "traumatic grief." Traumatic grief, a form of complicated grief in this context, is understood as the child having repeated images of death scenarios, real or imagined (i.e., service member death as a result of combat or by suicide); engaging in revenge fantasies against the enemy; lashing out to others whom the child perceives as not understanding; and avoiding reminders of the deceased. All these may complicate the natural course of the grief experience (Cohen & Mannarino, 2011). Yet another type of loss faced by children is termed "ambiguous loss" (Boss, 2004), which occurs when there is uncertainty regarding the status of a family member. Boss stated that this lack of clarity around loss blocks the grief process, because it prevents the cognitions that are necessary for decision making, relational boundary making, and coping. Examples of ambiguous loss are paradoxical in nature, for instance, when a service member is physically present but psychologically absent, as in the case of a parent having PTSD, or in the case where a parent is psychologically present but physically absent, as in the case of service members who are missing in action or are prisoners of war (Dekel & Monson, 2010). Ambiguous loss can produce feelings of anxiety, worry, sadness, and guilt in children and spouses of military personnel.

Parental combat injury can disrupt the family given that the majority of young children will

live away from the injured parent during hospitalization. Young children may also be separated from their primary parent, who may be providing care for the injured parent, which can result in moderate-to-severe emotional difficulties for the young child (Lieberman & Van Horn, 2013). During the time of absence, children can regress in their development, be afraid they, too, will experience significant injury, or engage in magical thinking such as “my daddy will get better if I’m good” (Lieberman & Van Horn, 2013). Parental death can be a greater challenge with very young children because they do not understand the finality of death. Young children may speak of the deceased parent as though there will be a reunion. In these instances, it is important the surviving parent respond in a way that will allow the child to develop a concrete acceptance of death. Allowing the child to speak in a way that indicates hope for a reunion can result in the child’s distrust of adults (Lieberman & Van Horn, 2013). These authors noted that using dolls to role-play the process of death (i.e., body stops moving) and to have a funeral can reduce maladaptive reactions and symptoms in young children. Families can also incorporate any religious, spiritual, or cultural beliefs into the role-play of the parent’s death. Social workers can assist families with children in this process, as well as in the development of skills to cope with the loss. Kaplow et al. (2013) stated that the effects of a parent’s death can be cushioned by the surviving parent’s ability to communicate effectively, provide stable routines, and demonstrate high levels of functioning and warmth in day-to-day life. Additionally, social workers who are helping families cope with veteran suicide can refer to Heather Fiske (2008) on engaging clients in difficult conversations about suicide utilizing a solution-focused approach.

Next, we will revisit the Bryce case scenario that was presented earlier in the chapter. We fast forward in time to when Bryce’s father, Mike, returns home from deployment and the family is adjusting to the service member’s reintegration into family life.

POSTDEPLOYMENT/REINTEGRATION CASE SCENARIO

The family followed the treatment recommendations (including family and individual therapies and military/community resources) that had been provided by Bryce’s therapist and

were doing quite well. For instance, 3-year old Emma had stopped bed wetting and had reduced episodes of tantrums. Bryce was back in sports and his grades in schools were improving. Bryce was also participating in a school program for military-connected children and had made some new friends. Meanwhile, Alice, the mother, had been attending her own individual therapy and was involved in a bimonthly support program on the military installation for spouses/mothers. Mike had returned from deployment and things at home seemed to be going well for the first month, according to Alice. The children seemed to have reattached quickly to their father upon his return. However, about five weeks into his return home, Mike began to exhibit symptoms of PTSD. He was quick to react and seemed irritable. His sleep was also disturbed by nightmares. Mike seemed “on edge” and the children and Alice were apprehensive about his behaviors, Alice described this as she and the children “walking on eggs.” Mike began to assume authority in the household and this created friction between him and Alice because she had finally established routines with the children and had felt that their family and home life were “in order.” Mike was now interrupting that order. Bryce began isolating again and refusing to participate in sports; Emma became excessively clingy toward Alice. Bryce’s therapist once again saw this as an opportunity to assist the family, this time with adjustment to Mike’s homecoming. The first thing the therapist did was ask Mike whether he was willing to be assessed for PTSD at the Navy hospital on base. Mike reluctantly agreed to follow through and attended his own counseling to address symptoms of PTSD. She also recommended couples counseling, specifically EFCT, for Mike and Alice, so that they could realign themselves and present a united front to their children, as well as work on emotionally reconnecting as a couple after this long separation. The therapist continued to work with Bryce on an individual basis and assessed him for secondary stress and utilized Trauma-Focused Cognitive Behavioral Therapy (TF-CBT) as needed (Cohen, Mannarino, & Deblinger, 2006). The therapist also recommended that Mike be included in the family therapy (e.g., CPRT or filial therapy). The therapist did not see any signs that would indicate the occurrence of interpersonal violence or child maltreatment, but did continually assess for these throughout the duration of treatment.

CONCLUSION

It is imperative to recognize that military connected families are resilient given their experiences and unique stressors, such as those outlined in this chapter (e.g., frequent geographic relocations, service member deployments and family separations, and postdeployment adjustment and family crises resulting from posttraumatic stress disorder or other injuries incurred by the service member). Their resilience may be a product of military culture (i.e., perseverance, endurance) that is adopted by the family and/or a byproduct of the demands associated with military life. However, note should be taken that although many military families are highly resilient, there are nonetheless alarming rates of domestic violence, substance abuse, child maltreatment, and service member and veteran suicide. Therefore, social workers intervening with military families should seek to understand the unique aspects of military culture, lifestyle, and demands, while not losing sight of the family strengths and inherent assets that could be used to address maladaptive family functioning and coping. In addition, as a social worker, you will want to recognize the differences among the branches of the U.S. Armed Forces (these are not all the same) and understand the variety of resources that are available and allocated to those active duty families living on or off-base, as well as families associated with the National Guard and Reserve components, given that social workers likely will need to establish resources and provide linkages in those civilian communities (i.e., “building community capacity,” please see Huebner et al., 2009). Resources for veterans and their families (after military service) will also need to be found or created, because not all veterans and their dependents are eligible for VA services and not all veterans choose the VA (for a variety of reasons). Furthermore, veterans and their families are transitioning into civilian lives at a time in U.S. history when there are serious economic hardships and lack of employment opportunities. Many of these veterans and/or their dependents will be using the Post 9/11 G. I. Bill benefits to enter into higher education (Coll & Weiss, 2013). Thus, social workers are bound to encounter this segment of the population somewhere along their paths, whether at community agencies, schools, hospitals, the criminal justice system, social service agencies, homeless shelters, or in college counseling centers. Therefore,

it is imperative, now more than ever, to become informed on the needs associated with this population and the existing best practices, in order to provide the most effective services and advocacy efforts.

Key Points to Remember

The continued U.S. military involvement across the globe as a measure to combat terrorism has added unique stressors to military families. A plethora of literature addresses service member injuries such as posttraumatic stress disorder, traumatic brain injury, and other co-morbidities, while also recognizing the impact of deployments and war on military connected families. This chapter summarized the various challenges faced by military families since 9/11. It presented military culture as the contextual background presented evidence-informed clinical interventions to be utilized by social workers. This chapter for civilian social workers was written with the aim of providing culturally responsive services and thereby promoting resilience in military/veteran families as well as in communities.

As noted in the chapter, reactions of military connected children to separation from their deployed parent(s) vary according to age, developmental level, and how the remaining spouse (parent) copes. It is imperative for us to recognize that children from National Guard and Reserve families are especially vulnerable to stress because they are residing in civilian communities, as opposed to near military installations, and do not have easy access to military supports. Moreover, military connected children who have been exposed to 12 years of uncertainty tend to have varying reactions to service member parental injury or death, once again according to age, developmental level, and family dynamics. The long-term effects on children and families exposed to war time stressors (particularly the unique aspects of the Global War on Terrorism with multiple and prolonged combat deployments) remains unknown. However, social workers should keep in mind family resilience models when intervening with military and veteran families and always work within a strengths-based perspective. Finally, in terms of future direction, the authors propose that all social workers be informed and educated on aspects of military culture and the stressors inherent in military family life, because more than likely than not, civilian social workers will

be encountering military- and veteran-connected families in community settings (Coll et al., 2012).

FURTHER LEARNING AND RESOURCES

- **Military Child Education Coalition (MCEC)** is a one-stop shop for resources for teachers, parents, & professionals on assisting children and youth with military stressors and school transitions. Additionally, they offer workshops and training for professionals: <http://www.militarychild.org>
- **School Quest**, is a website geared for military families to provide information on school records and transferring school credits, provided by MCEC: <http://schoolquest.org/>
- **John Hopkins Military Child Initiative Training** offers a web course for school professionals on understanding military related issues as these impact children and ways to build student resilience: http://www.jhsph.edu/mci/training_course/
- **National Military Family Association**, provides information for military families, resources and toolkits: <http://www.nmfa.org>
- **Operation: Military Kids** is the U.S. Army's collaborative effort with America's communities to support children and youth impacted by deployment. It provides local resources for community support to enhance well-being: <http://www.operationmilitarykids.org>
- **The Yellow Ribbon Program** is for National Guard and Reserve Families and provides for benefit information, youth summer camps, community referrals, and activities for children during deployments.
- **Military Impacted Schools Association**, provides a variety of web-based resources: <http://www.militaryimpactedschoolsassociation.org>
- **Military Family Research Institute at Purdue University** offers publications, resources, news, grant information, and events: <http://www.mfri.purdue.edu/>
- **The National Child Traumatic Stress Network** provides childhood trauma information and treatment descriptions as well as web-based trainings. General information on the CBITs (school based intervention) can be found here: http://www.nctsn.net/sites/default/files/assets/pdfs/cbits_general.

- **Trauma Focused CBT**, free web-based training for professionals working with traumatized children from a Cognitive Behavioral therapy perspective and an evidence-informed practice. See: <http://tfcbt.musc.edu>

63 Preventing Antisocial and Aggressive Behavior in Childhood

Traci L. Wike, Jilan Li, & Mark W. Fraser

INTRODUCTION

Aggressive behavior in children has long concerned practitioners, researchers, and policy makers because of its strong relationship to antisocial and violent behaviors in adolescence and adulthood. Recent high-profile bullying incidents and school shootings have catalyzed efforts to develop interventions that address the factors leading to aggressive behavior in children. For example, in an effort to reduce bullying and aggression in school-aged children, many states have created policies mandating schools to provide violence prevention programming. Moreover, current policies emphasize the use of evidence-based interventions that have been shown to be effective toward reducing aggressive behavior and promoting the prevention of school and community violence.

Social and character development programs represent one approach to violence prevention designed to bolster children's social and emotional development. Implemented in school and community contexts, these programs are based on the rationale that violence and aggression can be prevented by strengthening protective factors (e.g., social-emotional skills) that reduce risk (e.g., peer rejection). Although theoretical frameworks vary widely among the various programs, the more promising of these programs use a social-cognitive approach to strengthen children's abilities to solve social problems (see Conner & Fraser, 2011; Domitrovich, Cortes, & Greenberg, 2007; Fraser et al., 2005; Frey, Nolen, Van Schoiack, Edstrom, & Hirschstein, 2005; Greenberg, Kusche, Cook, & Quamma, 1995; Thompson, Macy, & Fraser, 2011).

In particular, the *Making Choices* program (Fraser et al., 2005) is an evidence-based social and character development program that uses a social-cognitive approach to prevent aggressive behavior in school-aged children. This chapter presents a comprehensive review of the *Making Choices* intervention, including the program's theoretical framework, evidence of the program's effectiveness, and a discussion of the implications of the intervention for increasing positive outcomes among children. *Making Choices* is a prevention-based intervention aimed at building children's social competence by increasing their social problem-solving skills. Rooted in a social-cognitive perspective, *Making Choices* uses an activity-based curriculum to strengthen children's social information-processing skills, and thereby, increase positive social behavior and reduce aggressive behavior. The chapter first presents a brief review of the literature on aggressive and antisocial behavior and the effects of these behaviors on children's developmental outcomes. Next, using a risk and resiliency perspective (Fraser, 2004), we describe the design of prevention interventions. The risk and resiliency framework is a key concept in prevention science. We follow with a discussion of information on the growth of social-emotional programs and the social-cognitive approach in prevention interventions. We then review the design and theoretical framework of the *Making Choices* program, and provide a comprehensive review of findings from evaluation studies of the program. The chapter concludes with a discussion of the implications of *Making Choices* for social work practice.

DEVELOPMENTAL CASCADES FROM AGGRESSIVE BEHAVIOR TO NEGATIVE OUTCOMES

Aggression in childhood refers to a persistent pattern of behaviors that inflicts or threatens harm. Aggressive behaviors can manifest in a variety of forms, ranging from overt conflict (e.g., physical hitting, verbal taunting) to covert subterfuge, including social exclusion and manipulation of friendships. Regardless of the form, aggression can result in problematic consequences for perpetrators and victims (Coie, Lochman, Terry, & Hyman, 1992; Parker & Asher, 1987). From a developmental perspective, some aggressive behavior appears normative in childhood. However, children who consistently

use aggression to negotiate social situations are likely to learn to rely on aggressive strategies as their primary or only method of dealing with interpersonal conflict.

Aggressive behavior in childhood is associated with a variety of negative life course outcomes. In early adolescence, these include rejection by peers, victimization by bullies, and low academic achievement (Dodge & Pettit, 2003; Nansel et al., 2004; Werner & Crick, 2004). Children who exhibit aggression are likely to experience problems as adolescents and adults with substance use, relationship violence, and delinquency (Brame, Nagin, & Tremblay, 2001; Dodge & Pettit, 2003; Moffitt, 1993; Moffitt & Caspi, 2001; Prinstein & La Greca, 2004; Tremblay et al., 2004). In addition, aggressive behaviors that meet diagnostic criteria for mental health disorders such as conduct disorder or oppositional defiant disorder have been shown to predict long-term negative consequences, including court involvement (Williams, Ayers, & Arthur, 1997).

Although physical and social forms of aggression can be equally problematic, research has shown that children who exhibit physical, overt forms of aggression have higher levels of externalizing problems (i.e., conduct problems) and lower-quality peer relationships (Card, Stucky, Sawalani, & Little, 2008). In contrast, the same research found that social aggression was predictive of internalizing problems (e.g., depression, anxiety) (Card et al.). An earlier longitudinal study found that social aggression in third grade students uniquely contributed to social and psychological maladjustment in subsequent grades (Crick, Ostrov, & Werner, 2006).

Children who are victims of bullying report difficulty in social relationships, and they are more likely than nonbullied children to report internalizing problems, such as depression and anxiety (Nansel et al., 2004). Experiences of peer victimization also increase the likelihood of a child developing aggressive behaviors and becoming a perpetrator of bullying and aggression (Dodge et al., 2003; Miller-Johnson et al., 2002). Research has shown high correlations between physical and social forms of aggression (Card et al., 2008), indicating that children do not choose one aggressive strategy to the exclusion of others. Evidence suggests that as children mature from early childhood to middle and late childhood, their problem-solving strategies become more sophisticated, involving less use of physical aggression and greater use of social

manipulation, including indirect aggression (Cote, Vaillancourt, Barker, Nagin, & Tremblay, 2007; Murray-Close, Ostrov, & Crick, 2007; Xie, Farmer, & Cairns, 2003).

From the perspective of ecological theory, a child's aggressive behavior is understood as strongly influenced by interactions and relationships in the family, school, and neighborhood (Bronfenbrenner, 1986). The influence of each domain is further explained by the risk and resilience perspective (Fraser, 2004), which argues that the risk and protective factors that influence aggression can exist simultaneously in one or more of these domains. The evidence is clear that no single risk pathway exists for aggression. Rather, aggression appears to be the result of a combination of risk factors (over the course of development) with interactions (across multiple domains) that influence life course trajectories (Masten & Cicchetti, 2010).

These patterns of risk, also called *developmental cascades*, refer to a process in which functioning in one domain affects functioning in another domain, creating a cascade of effects that lead to aggressive behavior (Masten et al., 2005). For example, difficulty controlling emotions is an individual-level risk factor that can lead to disruptive classroom behavior and problems with peers (school- and peer-domain risk factors). In turn, these school- and peer-level experiences can influence further displays of aggressive behavior, leading to additional social and academic difficulties.

THE PROMISE OF EARLY INTERVENTION

To disrupt the developmental cascades leading to aggression, social interventions must target specific risk factors that are malleable to change. Research has identified peer rejection as a key-stone risk factor and intervention target, because peer rejection is a robust predictor of aggressive behavior. Therefore, researchers have focused on designing interventions to help children develop social-emotional skills and become more successful in peer relationships. Specifically, such interventions focus on both enhancing children's abilities to solve social problems and on strengthening basic skills in regulating emotions. By teaching children social-emotional skills, the interventions help children develop social competence and positive peer relationships, which

in turn, reduce risks for aggressive behavior. To reach this goal, two types of social-emotional skills interventions have been developed: universal approaches and selective approaches (Wilson & Lipsey, 2007).

As the term *universal* implies, universal interventions are delivered to all children in a given setting, regardless of an individual child's level of risk. Conversely, selective prevention approaches are implemented with only those children who have been identified as at-risk of the targeted outcome (e.g., aggressive behavior). Universal prevention approaches are often used in school and community-based interventions because of the potential benefits for all children. Delivering an intervention to all children eliminates the potential for negative effects such as labeling children (i.e., singling out from peers) selected for a program because of their risk status. Universal prevention minimizes the potential for *iatrogenic effects* that can reinforce behaviors, such as peer rejection or aggression, when children are placed together based on their high-risk behavior (Dishion, McCord, & Poulin, 1999).

Social-emotional training programs can be designed as interventions with a single element or multiple elements. A multiple-element program requires a comprehensive approach that focuses on correlated risk factors occurring across multiple environmental domains. For example, a multi-element program might include the delivery of a classroom curriculum, a complementary parent-training program, and a supporting school-wide campaign. In contrast, single-element programs typically target one risk factor and implement one primary intervention strategy; for example, a classroom-based violence prevention curriculum for students that focuses on managing peer conflict. Especially in the context of school-based programs, single-element designs are often economical choices because this type of intervention tends to be brief and to have a lower implementation burden.

A recent meta-analysis (Wilson & Lipsey, 2007) explored the effectiveness of school-based interventions in reducing aggressive and disruptive behaviors. The researchers found the more effective programs used cognitively oriented approaches and social skills training. Indeed, a variety of universal prevention interventions have demonstrated efficacy in increasing positive outcomes among children at risk for aggressive behavior by targeting the social-cognitive risk mechanisms contributing to aggressive behavior,

such as deficits in social information processing skills and regulating emotions (Dimitrovich et al., 2007; Farrell, Meyer, & White, 2001; Fraser et al., 2005; Frey et al., 2005; Greenberg et al., 1995; Holsen, Smith, & Frey, 2008). One of the programs with preliminary evidence of effectiveness is the *Making Choices* (Fraser, Nash, Galinsky, & Darwin, 2001) program.

THE MAKING CHOICES PROGRAM

Making Choices is a prevention intervention that strengthens the social problem-solving skills of elementary-school aged children. Using a social-cognitive approach, *Making Choices* promotes social competence and reduces aggressive behavior by building skills in processing social information and regulating emotions (Fraser et al., 2001; Fraser et al., 2005; Nash, Fraser, Galinsky, & Kupper, 2003). As a universal, prevention intervention, *Making Choices* is made up of lessons designed for children in kindergarten through fifth grade.

Though the intervention is focused on improving the skills of children at risk for aggression, it proposes to improve social skills and social problem-solving for all children. The classroom curriculum is additive, meaning that topics in the lessons are linked to the key developmental tasks of each grade level. For example, the first and second grade curricula include lessons on recognizing feelings and understanding emotions. The third grade curriculum builds on the first and second grade lessons by adding a full problem-solving sequence. Emotion regulation is integrated at the fourth grade level and the fifth grade curriculum focuses on instances of social aggression and bullying behaviors. The program

is designed for delivery in a group setting, and can be implemented in school-based settings or community-based contexts (Fraser et al., 2001; Fraser, Day, Galinsky, Hodges, & Smokowski, 2004; Smokowski, Fraser, Day, Galinsky, & Bacallao, 2004).

Making Choices is guided by the social information processing (SIP) framework (Crick & Dodge, 1994), but it is also informed by social learning theory. SIP theory holds that a child formulates a behavioral response to a social situation by processing information in five overlapping steps. These steps are largely cognitive in nature, but emotional development is also integrated in the process (for reviews, see Crick & Dodge, 1994, 1996; Dodge, 2006). The steps include:

- Step 1, encoding external and internal cues
- Step 2, interpreting and developing a cognitive representation of cues
- Step 3, clarifying and selecting a social goal
- Step 4, accessing and constructing alternative responses related to goals
- Step 5, making a response decision.

Making Choices is designed to strengthen SIP skills and alter skills patterns that lead to aggressive behavior. Figure 63.1 depicts the conceptual model of *Making Choices* that is based on the SIP framework. The *Making Choices* curriculum is divided into seven units, each with multiple lessons, which are sequenced to build competency in regulating emotions and processing social information. The first unit teaches children how to recognize their feelings and the feelings of others. It uses role-play and story-based activities focused on regulating emotions. See Figures 63.2 and 63.3 for a sample lesson plan and activity for Unit 1.

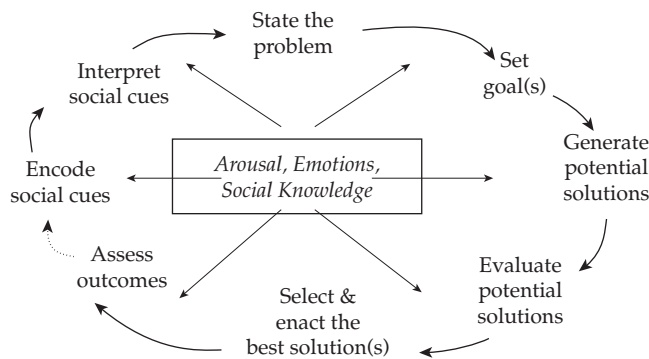

Figure 63.1 *Making Choices* Intervention Conceptual Model.

Figure 63.2 Sample lesson—lesson plan.

Figure 63.3 Sample lesson-activity.

Units 2 through 6 address each of the five cognitive steps of the SIP model. Unit 2 teaches children how to assess information in a social situation—that is, “search for the clues of what is happening” in a social situation. Unit 3 helps children understand intentions behind behaviors. Unit 4 centers on how to set positive goals for developing and maintaining friendships. Unit 5 focuses on constructing a choice of possible behavioral responses. Unit 6 teaches children how to select a behavior response by first assessing the consequences of their response. Unit 7 teaches children how to enact their chosen behavioral response (Fraser et al., 2005). Additional sample lessons are available at <http://sww.unc.edu/jif/makingchoices/>.

The *Making Choices* curriculum incorporates a rich array of age-appropriate exercises and activities that provide opportunities for children to develop SIP skills. The experiential activities focus on ways to think positively about social situations, how to formulate prosocial goals, and action steps to achieve prosocial goals. By strengthening skills in regulating emotions and by enhancing SIP skills, *Making Choices* is designed to build competency in working with others in a collaborative manner. It focuses on establishing and maintaining friendships with peers and authority figures. The program is adaptable for use with different ages, ranging from children in early elementary through early middle-school grades. It can be used in school, community, and agency settings. Sessions can be facilitated by teachers, school counselors, social workers, or psychologists. The *Making Choices* manual fully articulates the intervention content and contains copy-ready materials for each activity. Although designed for children in the United States, *Making Choices* can be adapted for children of different cultures. Recently, the manual was adapted and translated for children in China and Romania.

Findings from Evaluation Studies of *Making Choices*

Although *Making Choices* is appropriate for use in a variety of settings, most evaluation studies of the program have been conducted in school settings. In an early pilot test of *Making Choices*, Nash et al. (2003) examined the effects of three units—encoding social and environmental cues, interpreting cues and intentions, and setting relational goals—with a sample of 70 sixth-grade students. Positive program effects were found for skills in encoding cues and for skills in distinguishing prosocial goals. A large-scale test evaluating and comparing the program effects of *Making Choices* and an augmented program, *Making Choices Plus* (i.e., the core *Making Choices* intervention with added activities for teachers and parents) found significant effects for social competence, social contact, social aggression, overt aggression, encoding, and goal formulation. Broader effects were found for children in the *Making Choices Plus* classroom: cognitive concentration, social competence, social contact, social aggression, overt aggression, encoding, hostile attribution, goal formulation, and response decision (Fraser et al., 2005). The evaluation of program effects at 6-month follow-up found positive effects for the *Making*

Choices and the *Making Choices Plus* conditions on the children's overt aggression, physical aggression, and social aggression. Moreover, the findings indicated that *Making Choices Plus* did not yield significantly different gains than *Making Choices* (Fraser, Lee, Kupper, & Day, 2010).

A recent person-centered analysis grouped children into risk-based profiles and examined changes in group membership over time in relation to receiving the intervention. As compared with high-risk children in comparison cohorts, a greater proportion of children in intervention cohorts who were considered at high risk before the intervention had moved to lower-risk groups at the post-test data follow-up. At the same time, low-risk children in the intervention cohorts tended to remain at lower risk whereas a large proportion of low-risk children in the comparison cohorts moved to higher risk groups by post-test (Fraser, Thompson, Day, & Macy, in press). Additional evaluations of *Making Choices* have produced similar findings to the previous studies, with children receiving the intervention showing increased SIP skills (encoding, response selection, and regulation of emotions) (Fraser et al., 2009; Terzian, 2007), decreased overt aggression, relational aggression, and hostile attributions (Fraser et al., 2009), and increased prosocial behavior and social competence (Fraser et al., 2009). Although *Making Choices* was originally designed for elementary-school aged children, results from an evaluation of a preschool adaptation of *Making Choices* (Conner & Fraser, 2011) showed positive effects for children on academic competence, social competence, depression, and aggressive behavior.

Findings from the various evaluation studies of *Making Choices* are summarized in Table 63.1. These findings provide preliminary evidence supporting the effectiveness of *Making Choices*. When implemented with fidelity, the program appears to strengthen SIP skills and reduce aggressive behavior. Moreover, effects appear to endure into the postintervention period (Fraser et al., 2010) and are strengthened by supplemental or "booster shot" training (Fraser et al., 2009).

Implications of *Making Choices* Findings for Social Work Practice

Child development is influenced by a variety of biological, psychological, and environmental factors. A growing body of evidence has shown the initiation of aggressive behavior during childhood is a complex function of various risk factors

at the level of the individual child (e.g., poor social cognitive skills; Crick & Dodge, 1994), the family (e.g., harsh parenting; Eddy, Leve, & Fagot, 2001), the neighborhood (e.g., neighborhood disorganization; Brendgen et al., 2008), and the school (e.g., school violence; Dodge & Pettit, 2003). Among these risk factors, researchers have found that both a child's lack of skill in regulating emotions and a lack of skill in processing social information are important mediators of aggressive behavior (Bandura, 1989; Dodge, 1980, 2006; Huesmann, 1988; Lengua, 2003; Zins, Weissberg, Wang, & Walberg, 2004). Moreover, *recent findings have suggested the social-emotional skills developed in childhood are as powerful as academic achievement in predicting socioeconomic success in adulthood* (Borghans, Duckworth, Heckman, & Weel, 2008; Heckman, Stixrud, & Urzua, 2006; Heckman & Kautz, 2012). Interventions that target core behavior patterns in childhood appear to be effective in promoting future positive outcomes in adulthood (Heckman, 2008).

Guided primarily by SIP theory, *Making Choices* is aimed at altering social cognitive patterns that lead to conduct problems in childhood and early adolescence. Findings from evaluation studies of *Making Choices* suggest that SIP-based interventions hold the potential to promote social competence and reduce aggressive behavior. Other findings have suggested that boys may benefit more than girls from the *Making Choices* intervention (Terzian, 2007), indicating that program content might be strengthened by addressing gender-specific risk factors.

Although initial results are encouraging, two limitations of these evaluations must be mentioned. First, aside from its test in conjunction with the *Strong Families* program, evaluations of *Making Choices* have been conducted in school or preschool settings. Replications in different settings such as community and agency settings are warranted. One such replication is currently underway in the People's Republic of China, where SIP training is being provided through weekend activity programs for children at neighborhood centers. Second, although child reports and parent reports were available in many of the evaluation studies, most of the data analyses used child assessments of SIP skills and teacher reports of behavioral outcomes. Because children are likely to behave differently when interacting with their parents and others outside school, it is important to determine whether program effects generalize from school to other settings.

TABLE 63.1 Evaluation Studies of *Making Choices*

Evaluation Studies	Design	Sample	Program Component, Outcomes Assessed, and Overall Effects
Study 1 (Nash, Fraser, Galinsky, & Kupper, 2003)	Two group, controlled trial	Sixth-grade classrooms (N = 181; children 12 years of age)	Making Choices Unit 2, Unit 3, and Unit 4 No significant effects by treatment group Within the Intervention condition, a pre–post comparison of SIP skills: Encoding skills *** Interpreting cues + Intention attributions **
Study 2 (Fraser, Day, Galinsky, Hodges, & Smokowski, 2004)	Two-group, randomized controlled trial	Eleven after-school programs (N = 115; children 6 to 12 years of age)	Making Choices & Strong Families Teacher ratings of: Prosocial behavior ** Emotional regulation * Social contact * Cognitive concentration ** Relational aggression * Authority acceptance
Study 3 (Smokowski, Fraser, Day, Galinsky, & Bacallao, 2004)	Two-group, cluster-randomized controlled trial	Four third-grade classrooms (N = 101; children 8 years of age)	Making Choices Teacher ratings of: Social competence Social contact ** Cognitive concentration * Overt aggression * Peer acceptance **
Study 4 (Conner & Fraser, 2011)	Two-group, mixed randomized control trial—students in two preschools were randomized at school level; students in the other two schools were randomized at individual level	Four preschools (N = 67; children 3–4 years of age)	Making Choices & Strong Families Assessments of: Academic competence *** Social Competence *** Peer acceptance *** Depression/anxiety * Aggression/hostility *** Child behavior *** School performance *** Child relationship w/peers *** Child relationship w/caregiver*** Parent reports of: Parenting skills + Parent bonding *** Parent supervision *** Communication w/ child *** Parent developmental expectations ***

CONCLUSION

As a prevention strategy focused on strengthening children's social-emotional skills, *Making Choices* shows promise for interrupting developmental cascades that lead to aggressive behavior. Interventions such as *Making Choices* boost social development, which, research suggests, may be as important as academic achievement in promoting positive life course outcomes (Heckman & Kautz, 2012; Heckman, Stixrud, & Urzua, 2006). As a profession concerned with improving the mental, physical, and social health of children, social work can play a prominent role in providing social-emotional skills training. Social work training in child development and a person-in-environment perspective provides a strong conceptual foundation for implementing skills training programs. In addition, social workers are skilled in communication and groupwork. As a groupwork intervention, *Making Choices* is readily available to social workers for use in school or agency settings. The program offers social workers an evidence-based prevention strategy for building children's social problem-solving skills and promoting positive youth development.

Multifamily Groups with Obsessive-compulsive Disorder

Barbara Van Noppen

Clinicians who use this guide are presumed to have experience in Cognitive Behavioral Therapy (CBT) for Obsessive-compulsive Disorder (OCD) as well as a basic knowledge of CBT for OCD; recommended reading includes Steketee (1999), Steketee and White (1990) and Hyman and Pedrick (2010). For a review of expressed emotion implications for OCD family treatment, see Steketee, Van Noppen, Lam, and Shapiro (1998). For a full description of the clinical application of MultiFamily Behavior Treatment (MFBT), see Van Noppen (2002). It is also recommended that the practitioner be familiar with self-help books about OCD. Also, because this treatment guide is based on theoretical foundations used to develop psycho-educational groups for schizophrenia, it is recommended that the clinician be familiar with Anderson, Reiss, and Hogarty (1986) and McFarlane (1983).

Over the past decade, the concept of family accommodation (FA) has received much attention and recent studies point to FA as a predictor of poorer treatment outcome in both adults (Amir et al., 2000) and in children/adolescents (Storch et al., 2008). In 1995, Calvocoressi et al. published findings on a clinician administered FA questionnaire, which resulted in an association with poorer patient functioning, global family dysfunction, and stress. The original questionnaire as revised into a 12-item clinician administered Family Accommodation Scale (FAS), validated by Calvocoressi et al. (1999). The FAS-IR (Interviewer Rated) demonstrated excellent inter-rater reliability, good internal consistency, and convergent and divergent validity and has become the gold standard measure of family accommodation. More recently, Pinto, Van Noppen, and Calvocoressi have validated a 19-item self-report version, and the

FAS-SR (Self Report) is available online: <http://dx.doi.org/10.1016/j.jorcrd.2012.06.001>.

This MFBT guide is meant to instruct clinicians on the implementation of MFBT for OCD; it is not a substitute for clinical training and ongoing supervision. The MFBT differs considerably from traditional family therapy in that the clinician takes a very active role in providing information, facilitating problem solving, participating in direct and imaginal exposure, making suggestions directly to families, and assigning homework exercises (Van Noppen & Steketee, 2009). This may not be customary for dynamically trained clinicians. For MFBT to be effective, the clinician should be clear about and comfortable with the role described. This MFBT is written for adult patients (18 years and older); it can be adapted to be suitable for adolescents and children.

FEATURES AND PROCEDURES OF MULTIFAMILY BEHAVIOR TREATMENT

Features

MFBT treats five to seven families (no more than 16 total participants is recommended), including patient and identified significant others who are in considerable daily contact with the patient.

Co-leaders are optimal; at least one of the leaders should have an advanced degree in social work, psychology, or certified counseling, and experience in clinical work with individuals, families, and groups, as well as proficiency in cognitive behavioral therapy with experience in OCD populations.

The sessions are two hours long and typically meet in the late afternoon or early evening. The time-limited nature of this treatment program is used to motivate patients.

Procedure

Each patient and family has a pretreatment screening by phone with the therapist(s) to determine appropriateness for the group and readiness for treatment; following this, an intake session is scheduled.

At the intake session, pretreatment forms are completed, symptom severity and family response styles are determined, goals of the group and behavioral therapy principles are discussed, and pretreatment concerns and questions are addressed.

Agendas for Weekly Treatment Sessions

1. Introductions, ground rules, education about OCD, reading of self-help material
2. Definition of behavior therapy (exposure and response prevention), in vivo exposure and response prevention, plus homework and self-monitoring
3. Family responses to OCD and family guidelines; neurobiology of OCD, and medications
4. Behavioral contracting among family members and communication skills training, homework discussion with family group feedback, and problem solving.
- 5–11. Continued exposure and response prevention (ERP) and family behavioral contracting in vivo and homework assignments
12. Final weekly treatment session, termination issues, and planning for monthly booster sessions.

Maintenance of gains and relapse prevention are supported in six monthly sessions.

TREATMENT PROCEDURE

Following is a manual for an 18-session MFBT and one 90-minute intake gathering session conducted with each OCD patient and family members.

Information Gathering and Pre-group Screening (90 minutes)

1. Take a general bio-psychosocial history and collect information about OC symptoms for treatment planning (20 minutes). Use the Yale-Brown Obsessive-Compulsive Checklist and Severity Scale (YBOCS; Goodman et al., 1989 a & b) to indicate primary obsessions

and major compulsions and symptom severity.

2. Discuss onset of OCD and efforts to cope (10 minutes).
3. Begin exposure hierarchy, as in individual behavior therapy, by collecting information about triggers of obsession and compulsions, situations and objects avoided, intrusive thoughts, and ritualistic patterns of behavior (15 minutes).
4. Teach the patient and family how to rate anxiety according to the subjective units of distress scale (SUDS) and estimate at which treatment session the trigger will be introduced. Record all information on an exposure hierarchy form: the more detailed, the better. See hierarchies in Table 64.1 and use references for more examples. These are two sample hierarchies for a patient who has fears of contracting cancer from items associated with a sibling, contact with cigarettes, “chemicals,” and certain food.
5. Describe ERP (10 minutes). Offer treatment rationale including the following:
 - *Exposure* refers to gradual and direct confrontation of situations that provoke obsessive fears. It is designed to break the association between the sensations of anxiety and the objects, situations, or thoughts that produce it through the gradual reduction or habituation of fear. Use the patient’s own experiences as examples (e.g., “every time you touch anything associated with body fluids you feel anxious, distressed, or contaminated”).
 - *Response prevention* is designed to break the association between ritualistic behavior and the reduction of anxiety or distress. Because compulsions (specify them) lead to less distress temporarily, they are reinforced. Treatment breaks the automatic bond between the feelings of discomfort/ anxiety (specify the obsession) and rituals.
6. Description of MFBT program and review of overall goals (5 minutes).
7. Discuss the degree of family accommodation and response styles (20 minutes). Administer the FAS –SR in the group (Pinto, Van Noppen, Calvocoressi, 2012).
8. Homework assignment (5 minutes). Discuss the first homework assignment to read Hyman and Pedrick (2010), Chapters 1, 2, 5, and 6; suggested reading list.
9. Wrap up (5 minutes). Address concerns and questions.

TABLE 64.1 Exposure Hierarchies

Situation	Discomfort (1–100)	Treatment Session
<i>Hierarchy 1: Fears of contamination—“cancer” from brother and cigarettes</i>		
Holding unopened cigarette pack	45	1
Touching doorknobs at home	55	2
Holding opened cigarette pack	55	2
Touching “dirty” clothes (basement)	85	5
Touching cigarette filter	90	6
Stepping barefoot on a cigarette	95	7
<i>Hierarchy 2: Fear of contamination—cancer from “chemical” contact</i>		
Touching microwaved food	30	1
Holding batteries	40	2
Touching sand at beach	65	5
Eating food items “scanned” at checkout	75	6
Drinking diet soda	85	7
Eating chicken	100	8

Session 1: Building Cohesion**and Trust: “We’re Not Alone!”****Psycho-educational Phase: “What is Obsessive-compulsive Disorder?”****(2 hours)**

1. Welcome (5 minutes). The group leaders introduce themselves and ask each participant to do the same. The group leaders outline the agenda for all 12 sessions, giving dates and times for each.
2. Administrative issues (15 minutes): Review scheduling of sessions, cancellation policy, group guidelines about confidentiality, and therapist availability.
3. Goals (10 minutes). Each group member is asked to respond to the question, “What do you hope to get out of this group?” Encourage participants to be specific about behavioral change.
4. Definition of OCD (1 hour). Review Chapters 1 and 2 in Hyman and Pedrick (2010) biological and learned bases of OCD. Distribute YBOCS symptom checklist (self-rated version). Go over each example provided, with group members volunteering to read. Encourage disclosure by asking for examples from patients’ or family members’ experiences. Introduce concepts of ERP.
5. Homework (30 minutes). Go-round: each patient chooses a behavioral task challenge

to practice daily for homework. Distribute self-rating exposure homework form and explain how to use (*The OCD Workbook*, p. 93). If there is time in the session, ask for a patient to volunteer to demonstrate ERP and rate SUDS as a group. The homework for every patient for the first week is to practice the chosen ERP task and complete homework form.

Session 2: Psycho-educational**Phase: “How Do You Treat****Obsessive-compulsive Disorder?”**

1. Check-in (10 minutes). Review the previous group session.
2. Go-round (10 minutes). Each patient reports on homework completed during the week, including SUDS. If the homework is inadequately completed or reported, discuss problems identified by the patient and family. Encourage group feedback and troubleshoot to define obstacles.
3. Overview of behavior therapy (30 minutes). Define in vivo and imaginal exposure and give examples. A brief description of exposure in vivo might be: “This entails actual direct contact with an object or situation that evokes obsessions. For example, a person afraid of stabbing loved ones might stand in the kitchen before meal

times holding knives or scissors near others.” A brief description of imaginal exposure may be: “Sometimes people cannot actually put themselves into their feared situation, such as stabbing one’s child. A mental visualization of this situation in detail will evoke fears of harming one’s child that will offer exposure practice. Writing a scripted imagery to be read daily, or put onto a tape and listened to, is a way of going about this.” Provide a brief description of imaginal exposure for those patients for whom it is relevant (patients whose anxiety focuses on feared consequences that are not fully triggered by in vivo exposure or for whom in vivo exposure is difficult to execute. One possibility is a mental visualization of forgetting to check the stove and coming home to fire engines and a burning house. Another possibility is making a loop tape of a brief description or phrase (i.e., “I will kill my child”) or a few words (“kill,” “child-killer”) that are avoided, dreaded, or evoke aggressive obsessions.

Include a few statements about tolerating initial high anxiety that will decrease over time with repeated, systematic use of exposure and response prevention (habituation). Stress that response prevention must accompany exposure, whether imagined or in vivo. Following are instructions and examples of the sequences of in vivo and imaginal exposure for a patient with contamination fears, and the subsequent response prevention.

- *In vivo exposure.* The patient, Steve, felt contaminated by feces, urine, sweat, and contact with others. He feared contracting a debilitating disease. The following hierarchy was constructed for Steve: feces, 100 SUDs; urine, 90 SUDs; toilet seats in public bathrooms, 80 SUDs; sweat, 75 SUDs; newspapers, 60 SUDs; doorknobs, 50 SUDs. During in vivo exposure treatment, the following sequence was pursued.

Session 1—Steve walked with the therapist through the building touching doorknobs, especially those of the public restrooms, holding each for several minutes.

Session 2—Steve held newspapers left behind by people in the waiting room.

Session 3—Steve held newspapers and doorknobs. Contact with sweat was introduced by

asking him to place one hand under his arm and the other in his shoe.

Session 4—Exposure began with newspapers and sweat. Toilet seats were added by coaching the patient to stand next to the toilet and place his hands on the seat.

Session 5—Exposure began with contact with sweat and toilet seats. Urine was then introduced by encouraging Steve to hold a paper towel dampened in his own urine.

Session 6—Exposure included urine, toilet seats, and sweat repeatedly until SUDS decreased by at least 50%.

Sessions 7–12—Daily exposure to urine and sweat. Homework focused on the objects used during that day’s treatment session. Periodic contact with lesser contaminants was continued throughout.

- *Imaginal exposure.* First conduct in the present tense with the therapist describing images in second person (“you see” or “you are going”). When asked what he or she feels or sees or thinks in the image, the patient should respond in the first person (“I’m sitting on _____”). Imaginal scenes should be followed by in vivo exposure to objects or situations related to that scene and provoke similar levels of discomfort. The patient creates a script of a similar scene and records it to listen to for imaginal exposure homework.
- *Response prevention.* Remind participants of the specific instructions for response prevention on the first day of treatment, as well as periodically during treatment. Give a copy of the rules to each patient and his or her family, modeling the instructions after this example for washers.

Washers: During the response prevention period, patients are not permitted to use water on their body—that is, no hand washing, no rinsing, no wet towels, washcloths, wet wipes, or antibacterial gels except as negotiated with the therapist. Supervised showers are permitted every day for target time, including hair washing. Ritualistic washing of specific areas of the body (e.g., genitals, hair) is prohibited. If prevention of washing forces contamination to items very high on the hierarchy, patients may wash briefly and immediately re-contaminate with the items currently being exposed in treatment.

At home, relatives may be available to the patient should she or he have difficulty controlling a strong urge to wash. If the patient reports such concerns, family members can coach the patient to delay the urge until it decreases to a manageable level. Family members may attempt to stop such violations through firm verbal insistence, but no physical force should be used, and arguments should be avoided. Faucets can be turned off by relatives if the patient gives prior consent to such a plan. Showers can be timed by family, with no direct observation of showering behavior.

- *Review hierarchy* forms as a group and add any additional triggers for exposure. Arrange all designated items hierarchically according to anxiety evoked. The most disturbing item should be presented by Session 9 or three-fourths of the way through treatment. Final sessions should include repetitions of earlier ones with minor variations, focusing on those situations that provoke the most discomfort.
4. Homework go-round. ERP (60 minutes). Each patient chooses a behavioral homework task. Use feedback and support from group members to develop the optimal homework assignment. As each patient selects his or her homework, the group leader should try to translate the task into a form that can be rehearsed in the group—the therapists, patients, and family members who are willing participate in the ERP in vivo while others observe. For example,
 - For *harming obsessions* with reassurance seeking and checking, the group leader and patients dampen their hands and touch light switches; other group members follow by touching the same switch. No reassurance seeking or checking is allowed. Level of anxiety is discussed and rated. This is repeated several times to model the homework assignment and to begin the process of habituation. Another exposure challenge is to pass a pair of scissors around the group, point first.
 - For *contamination obsessions* with washing and/or passive avoidance, fear of being responsible for something bad happening and checking, hoarding,

ordering and arranging, and other obsessions and compulsions, devise in vivo ERP accordingly.

5. Family role (10 minutes). Instruct family members to offer support and encouragement for patient's completion of ERP homework. No changes in family responses should be made without prior negotiation.

Session 3: Psycho-education: Family Responses to Obsessive-compulsive Disorder and Family Guidelines: "What Should We Do?"

1. Check-in (10 minutes).
2. Go-round (10 minutes).
3. Psycho-educational lecture on neurobiology of OCD (15 minutes). (If a psychiatrist is not able to be present, a videotaped discussion on the neurobiology of OCD is viewed in the group).
4. ERP (60 minutes). In the group, each patient selects exposure items with SUD level of approximately 50 to 60; continue with in vivo ERP.
5. Family guidelines (15 minutes). Distribute *Learning to Live with OCD* (Van Noppen, Pato, & Rasmussen, 1997) and read as a group. Identify and label family response styles as they emerge in discussion (accommodating, antagonistic, split, oscillating). Encourage discussion.
6. Homework (10 minutes). Each patient reassesses behavioral homework task with family guidelines in mind and adds another challenge.

Session 4: Intensive Treatment Phase: Managing the Symptoms: "Out with Doubt!"

1. Check-in and go-round (20 minutes). Proceed as previously described.
2. Explain family behavioral contracting (20 minutes); see Steketee, Van Noppen, Lam, and Shapiro (1998); Van Noppen (2002).
 - One at a time, each family identifies problem areas. How does the family accommodate? Is there a lot of hostile criticism directed toward the patient by family? Review the FAS-SR as a group and facilitate discussion.

- Guide the family to focus on one problem area at a time and define it.
- Using feedback from the group, family members explore behavioral response options and the possible consequences of each.
- Patient selects an ERP and leaders elicit response options from the family and group. For example, if a patient is practicing exposure to leaving the house without checking appliances, the behavioral contract might be that the family gives a 10 minute “warning” when preparing to depart for an outing, then a 5 minute “warning” and if the patient is still checking, the agreement is that the family departs without the patient and without argument.

To address reassurance seeking, a behavioral contract includes that the family’s first responses are: “What do you think I will say?” “What have I told you before?” “What would the therapist say?” thereby placing the decision back upon the patient and interrupting the reassurance compulsion cycle.

- The leaders facilitate a negotiation process among family members.
 - When possible, the family rehearses the ERP and behavioral contract, during the treatment session in vivo, thereby beginning to implement a new solution.
- As described, the group leaders actively guide one family at a time through the process of negotiating a behavioral contract including all patients and family members in the exercise. Families are instructed to renegotiate the contract if they find it too stringent.
3. Homework (10 minutes). Each patient selects individual exposure homework and each family commits to behavioral contact homework.

Session 5: Behavioral Family Treatment Phase: “We Can Make a Difference!”

1. Check-in and go-round (30 minutes).
2. Continue behavioral contracting (80 minutes). Each family practices behavioral contracting in vivo. ERP with therapist and participant modeling should be

used extensively. Each family is allotted 10 to 15 minutes.

3. Homework (10 minutes). Patients and relatives commit to ERP homework and family contracts.

Sessions 6–11: “Practice! Practice! Practice!” and “We Can Take Charge!”

The group leaders follow the same format already described for the remaining weekly sessions. Progressively, patients are increasingly responsible for devising the in vivo ERP task challenges and family contracts, an expectation cultivated by the leaders.

Session 12: Exposure, Contracting, and Termination: “We Have Tools to Do This on Our Own!” (Last Weekly Multifamily Session)

1. Check-in (30 minutes).
2. Go-round (45 minutes). Each family modifies or adds to existing contracts. Group members devise in vivo ERP tasks. Each family presents the ERP plan for the next month.
3. Dealing with termination (25 minutes). Remind the group of the self-instructional nature of behavioral treatment. Review the steps that were taught: create hierarchy, assess distress levels, select exposure situation (either internal or external trigger), devise ERP challenge, record this on a form, and practice it repeatedly for long periods of time until anxiety decreases.
 - Initial anxiety will increase while using ERP.
 - Habituation takes time and practice.
 - Long-term gains are made through perseverance and commitment to treatment.
 - Encourage patients to refer to self-help workbooks.
 - Leaders are available to patients between monthly sessions.
4. Complete self-rated YBOCS and FAS-SR in the group (15 minutes).
5. Discuss monthly check-in sessions (5 minutes). Schedule dates and describe this as a trial period to develop confidence for independent individual ERP and family behavioral contracting.

Sessions 13–18: Monthly Check-in Sessions: “We Have the Tools to Beat Obsessive-compulsive Disorder” (2 Hours)

The main purpose of these six sessions is to assist patients and their families in the transition from the leader-directed behavioral treatment to the self-instruction form of therapy. Check-in sessions ensure maintenance of treatment gains in the vulnerable time period directly following the weekly 12 sessions. They also provide motivation.

Each session begins in typical fashion with the check-in and go-round, but no in vivo exposure takes place. Patients and family members report on homework tasks, contracts, successes, pitfalls, and general life events that may be influencing the OCD or interfering with behavioral therapy. Leaders are more passive, facilitating the group process and answering questions that require clinical clarification. Clinician-rated YBOCS are collected at each session for pre- and post-treatment comparisons.

At the last monthly session, issues related to treatment termination are acknowledged, and referrals are made for continued behavior therapy or medication if necessary. The FAS for each family in the group is completed. A post-treatment YBOCS under 16 is optimal.

CONCLUSION

MFBT offers several advantages over standard individual behavioral treatment. It is cost-effective by allowing for the simultaneous treatment of five to seven patients and their family members with one or two therapists in two hours a week, compared to the same six or seven families treated individually requiring 10 to 14 hours of therapist time per week. This is a savings of up to 12 hours of therapist time per week.

As typically practiced, individual behavioral treatment offers little structured psychoeducation, support, or guidance for the family members who have to cope with the symptoms and demands imposed by OCD. The MFBT can be modified to conduct family behavioral treatment with one patient and family members. In this age of managed care and short-term treatments, it makes sense to mobilize natural supports like family systems. Once families understand OCD symptoms and are taught behavioral strategies, they can participate effectively in ERP with the OCD patient. This treatment offers a marked

decrease in both cost for treatment and therapist time, as well as the possibility of improving long-term outcome.

65 Collaborating with Families of Persons with Severe Mental Illness

Tina Bogart Marshall & Phyllis Solomon

Practice guidelines for the treatment of severe mental illness recommend involving and engaging families in a collaborative treatment process (American Psychiatric Association [APA], 2006; Dixon et al., 2010). These recommendations are based on substantial evidence that partnering with families improves client outcomes (Dixon et al., 2001).

WHY COLLABORATE WITH FAMILIES?

It is often presumed that the hardship brought by mental illness leaves many individuals with little or no family contact. For this reason, families are frequently overlooked as potential members of a support network for individuals with severe mental illness. However, most individuals have a family member or significant other—friend,

roommate, partner—in their lives. Research indicates that more than 60% of individuals with mental illness live with their families (National Institute of Mental Health [NIMH], 1991), and 77% or more have some ongoing contact with family members (Lehman & Steinwachs, 1998). Moreover, families are often the first to recognize warning signs and symptoms of relapse (Herz, 1985). Family and significant others need information, education, and practical advice (Molinario et al., 2012) to effectively support their loved one with mental illness. Social workers can successfully collaborate with a client's family or significant others while keeping the treatment process client-centered (Jewell, Smith & Hoh, 2012).

Over the past 30 years, numerous studies have found that family psycho-education, family education, and family consultation interventions

have been associated with positive outcomes for both individuals with mental illness and their family member(s) or significant other(s). Family psycho-education has been found to reduce relapse and rehospitalization for persons with severe mental illness, lower levels of family burden and distress, and improve family well-being (Murray-Swank & Dixon, 2004; McFarlane et al., 2003). Family education has led to significant reductions in subjective burden, as well as increased knowledge of mental illness and the treatment system (Dixon et al., 2004). Family consultation has been associated with improved self-efficacy in family members (Solomon, Draine, et al., 1996), high family satisfaction, and a positive impact on caregiving (Schmidt & Monaghan, 2012). Although these interventions differ in their format, duration, and locus of service delivery, they all use a strengths-based approach, view services as client-driven, and provide families with:

- Information about mental illness
- Emotional support
- Communication skills
- Problem-solving or coping skills
- Crisis intervention, based on the notion of collaborating with family members in the treatment of their ill relative.

Furthermore, family interventions are based on the notion of collaborating with persons with mental illness and their family members in the treatment process (Mannion et al., 2012; Dixon et al., 2001; McFarlane et al., 2003), which is now understood to be a vital component to recovery-oriented, comprehensive care (Glynn, Cohen et al., 2006).

Partnering with families not only is associated with improved client and family outcomes but also holds benefits for social workers. Social workers gain a better understanding of the client's behavior, symptoms, and level of coping with their illness (Solomon et al., 2002). By working collaboratively with consumers and families, social workers can develop the most effective treatment plans. The following case study demonstrates how social workers can collaborate with clients and their family members to actively pursue clients' personal recovery goals.

CASE STUDY

Annie is a 39-year-old woman with schizophrenia. The symptoms of her illness respond fairly well to medication. Although she has been able to

live alone in an apartment for the past 12 years, Annie receives significant support from community providers. She lives an isolated life. Outside of her contact with the mental health center, she has few friends or hobbies.

The social worker at the mental health center talks with Annie about building a social support network. She lets Annie know that many people who receive services at the mental health center find it very helpful to involve a family member or close friend in their mental health treatment. She asks Annie if there is someone she would like to invite to their next session.

Annie tells her that she has a sister who visits regularly. Together, they call the sister and invite her to the next session. During the session, the social worker tells the sister that Annie is interested in building up a circle of supportive family and friends and would like her help. They ask the sister if she is willing to participate in Annie's sessions over the next few weeks, and they can discuss together the types of interests that Annie has had in the past and activities that she may want to get involved with again. Annie's sister agrees.

Over the next three weeks, the social worker meets with Annie and her sister. She learns that Annie's sister was very involved with the National Alliance on Mental Illness (NAMI) when Annie first became ill and has a good understanding of her illness. Annie wishes that her brother understood her better and that she could have more contact with him. Annie's sister offers to speak with him and encourage him to attend NAMI support groups with her. The social worker also discovers from the sister that Annie is very artistic. In her early twenties, she won an award for a sketch she had drawn. The sister agrees to help Annie find an art class in the community. Annie is hesitant about going by herself, and her sister agrees to take her there.

Six months later, Annie is taking a community art class. She has met several new friends and considers participating in an art exhibition. Her brother calls her regularly and occasionally takes her out to lunch. Annie remains in close contact with her sister, who occasionally joins her for a session.

COMPETENCIES NEEDED TO COLLABORATE WITH FAMILIES

Competencies for working with families of people with severe mental illness have been

developed by an expert panel of practitioners, families, clients, and researchers (Coursey, Curtis, & Marsh, 2000). Competencies include:

- Understanding the family experience
- Engaging the family in treatment and rehabilitation
- Addressing the needs of families
- Being knowledgeable about appropriate community resources for meeting family needs.

Trainings ranging from one and a quarter hours (Stanbridge, Burbach, 2007) to 30 hours (Farhall et al., 1998) have been offered to foster provider competencies. However, for social workers to be responsive to families does not necessarily mean that formal training in a specific intervention is needed. Social workers who are unable to implement a formalized intervention may still participate in some activities to address family needs. Specific attitudes, knowledge, and skills that are needed for social workers to collaborate with families of persons with severe mental illness were developed based on the evidence to date (Mannion, 2000; Mannion et al., 2012).

Attitudes

1. *Self-examination.* Attitudes in working with families are shaped by mental health providers' training and learning experiences. It is critical for social workers to examine their own feelings and attitudes and develop a conviction that families and significant others can positively affect recovery. Services should be client-centered and families should be engaged in the treatment process and understand the client's illness and recovery goals.
2. *Examination of organizational climate.* Social workers should assess the overall attitude expressed within their agency toward partnering with clients and their family or significant others. Negative attitudes may lead to interdisciplinary conflict in treatment teams. Social workers may also perceive a negative organizational climate through a lack of policies and procedures for working with families, a lack of training, or disincentives, such as inappropriate reimbursement mechanisms. Assess your organization's attitude and consider advocating for changes in your policies and procedures.

KNOWLEDGE

1. *Awareness of the family experience.* Social workers need to understand the normal emotional cycles that families experience as they cope and adapt to having a family member with mental illness.
2. *Knowledge of mental illness.* It is important for social workers to not only accumulate a breadth of knowledge about mental illness but also be able to convey basic knowledge to families in a way that they can comprehend and retain. Social workers should be aware that knowledge is a coping aid for families. Refer families and significant others to free educational resources that are available to families, such as those offered by NAMI, Mental Health America, and others, and make appropriate referrals to family support groups.
3. *Knowledge of confidentiality policies.* Social workers need to recognize that they can listen to families and offer general information about mental illness without obtaining client consent. Consent forms are often necessary before specific information about the client's illness or treatment may be shared with families. Explain the benefits of family collaboration to clients and ask if there is a family member or significant other with whom they would like to share specific information. Use the consent process to identify the types of information that the client is interested in sharing and the ways that they would like their family member or significant other involved.
4. *Knowledge of family interventions.* Social workers should be aware of the types of available family interventions and benefits for providers, clients, and families. Learn to assess family needs and be able to refer families appropriately.
5. *Knowledge of coping and illness management skills.* Social workers should be well versed in basic coping and illness management strategies for families, such as reducing stress, recognizing their limits, and avoiding blame. At a minimum, social workers can offer support, remind families of the basics, and connect them to other community resources.
6. *Knowledge of the mental health system.* It is critical for social workers to understand not only the services within their own agency

but also specific information about services and resources throughout the mental health system. Any printed information that may be shared is helpful to families. Contact your state mental health department or state or local affiliate of NAMI for access to this type of information.

7. *Cultural competency.* Social workers need knowledge of differences in the attribution of mental illness and other issues specific to different cultural/ethnic groups. It is important for social workers to be aware of the acceptability and effectiveness of treatment and services for families of various ethnic and cultural backgrounds (Solomon, 1998; Lopez et al., 2000). Social workers also should be aware of culturally/ethnically diverse community resources and support systems.

Skills

1. *Discussing family involvement with clients.* Social workers should acquire skills for communicating the benefits of collaboration, working with clients to identify supportive family or significant other, and discussing their choices in the type of involvement that the family member may have in the treatment process. Social workers should be skilled in developing client-centered treatment plans and effective recovery goals and convey how expanding the client's support network can support those goals.
2. *Strength-based approach.* It is important for social workers to acknowledge both client and family strengths. In coping with their relatives' mental illness, families may isolate themselves and question their emotional responses. Identifying the feelings that family members experience as common and natural is an essential component of developing a collaborative relationship with families. Social workers can listen to families' experiences, share their understanding of the normal cycle of coping and adaptation, reflect their strengths, validate their feelings, and demonstrate respect, empathy, and support.
3. *Mediation and advocacy.* Skills in mediation allow social workers to assist families with unresolved conflict that they may be experiencing at home or within the mental health system. Social workers may use advocacy skills to intervene

on behalf of families or improve the organizational climate within the agency. For example, social workers who encounter confidentiality policies as a barrier to sharing information with families may consider adapting model policies and consent procedures developed by the authors (Marshall & Solomon, 2003).

4. *Teaching and training.* Skills in transferring knowledge about mental illness, mental health treatment, coping, and illness management skills are critical to the work of social workers with families. It is crucial that the information offered is relevant and useful, while maintaining appropriate confidentiality. Convey information to family and significant others in a way that maximizes comprehension and retention of the essential points.
5. *Problem solving.* Social workers should acquire skills that assist clients and families in defining problems, generating possible solutions, and deciding on appropriate strategies. Social workers may use problem-solving skills to help address specific issues that arise. Social workers may also offer to train families to use problem-solving techniques on their own.
6. *Referral.* Referring families to appropriate community resources is a skill that can complement what social workers offer to families to assist them in meeting their needs. Successful referrals require a high degree of familiarity with the resource. Family members should be prepared as to what they should expect, how to best access the resource, and how the resource will address their specific need(s).

FUTURE

The best practice recommendations for partnering with families are based on research evidence that family psycho-education/education/consultation improves client outcomes. Although the research indicates that no one specific intervention is more effective than another, the core components of effective interventions are based on the provider–client–family collaboration. To achieve these outcomes, social workers must improve their skills for introducing the concept of collaboration to clients and increase their competencies for working with families.

The most recent research concludes that one intervention will not meet the needs of all family members and clients. It is important to offer a variety of interventions and tailor services to clients and families according to their individual needs (Drapalski et al., 2008; Jewell, Smith, & Hoh, 2012). Social workers can obtain the basic competencies to partner with families, assess their needs and identify the types of interventions that will be most effective for them.

66 Assessment, Prevention, and Intervention with Suicidal Youth

Jonathan B. Singer &
Kimberly H. McManama O'Brien

Suicide is a serious public health problem for youth in the United States. It is the second leading cause of death for 15-to-24-year-olds, and the fourth leading cause of death for 5-to-14-year-olds (Hoyert, 2012). In their lifetime, an estimated 12.1% of adolescents contemplate suicide, 4.0% make a plan, and 4.1% make an attempt (Nock et al., 2013). Given that social workers are employed in multiple settings where suicidal children and adolescents are encountered (e.g., schools, homeless shelters, emergency departments, outpatient mental health agencies, private practice), they have the potential to be at the forefront of suicide prevention efforts that include identifying and intervening with youth at risk, as well as advocating for suicide prevention programs and policies (Singer & Slovak, 2011). In an effort to educate social workers about the range of suicide prevention efforts, this chapter defines key terms, describes the components of a thorough suicide assessment, and reviews the current state of empirically supported evidence-based suicide prevention and intervention programs.

DEFINITIONS OF SUICIDAL THOUGHTS AND BEHAVIORS

The nomenclature of suicidal thoughts and behaviors (STB) has been the source of much debate over the past decade (De Leo, Burgis, Bertolote, Kerkhof, & Bille-Brahe, 2006). Table 66.1 identifies and defines recent consensus of the most important concepts in the identification and treatment of suicidal behavior (Bryan & Rudd, 2011; U.S. Department of Health and Human Services [DHHS], 2012; Whitlock et al., 2013).

RISK AND PROTECTIVE FACTORS

Although there is no single pathway to suicide, there are factors that increase the risk of STB. There are certain demographic characteristics related to risk for STB. The role of gender is important to consider, because females attempt suicide three times as often as males, but males die by suicide at three times the rate of females (Centers for Disease Control and Prevention

TABLE 66.1 Terms and Definitions

Term	Definition
Suicide ideation	Thoughts of ending one's own life
Suicide attempt	A nonfatal self-directed potentially injurious behavior with any intent to die as a result of the behavior. A suicide attempt may or may not result in injury
Suicide	Death caused by self-directed injurious behavior with any intent to die as a result of the behavior
Nonsuicidal morbid ideation	Thoughts about one's death without suicidal or self-enacted injurious content
Nonsuicidal self-injury	Deliberate direct destruction or alteration of body tissue without a conscious suicidal intent

[CDC], National Center for Injury Prevention and Control, 2013). With respect to ethnicity, suicide rates (per 100,000) are highest for American Indians/Alaskan Natives (9.72), followed by Whites (4.65), Blacks (2.76), and Asian/Pacific Islanders (2.68) (CDC, 2013). Youth who live in rural areas die by suicide at nearly twice the rate as youth who live in urban areas (Nance, Carr, Kallan, Branäs, & Wiebe, 2010).

There are important psychosocial factors that confer risk for STB. The strongest risk factor for STB is a prior suicide attempt (Bridge, Goldstein, & Brent, 2006; Zahl & Hawton, 2004). Additionally, psychiatric diagnosis and comorbidity greatly increase risk for STB (Groholt, Ekeberg, & Haldorsen, 2006). Specifically, youth experiencing depressive symptoms are at increased risk (Evans, Hawton, & Rodham, 2004). Mood-related psychological factors that contribute to risk include hopelessness (Negron, Piacentini, Graae, Davies, & Shaffer, 1997), elevations in suicidal ideation (Prinstein et al., 2008), higher levels of affect dysregulation, and greater numbers of self-injurious behaviors (Zlotnick, Donaldson, Spirito, & Pearlstein, 1997). Substance use, especially alcohol use,

is consistently associated with risk for STB in youth (Bagge & Sher, 2008). The disinhibition caused by alcohol intoxication can both facilitate suicidal ideation and increase the likelihood of acting on suicidal thoughts (Ganz & Sher, 2009). The presence of a substance use disorder has been implicated in suicide attempts of higher medical lethality in adolescents (O'Brien & Berzin, 2012).

Among youth with no clear psychopathology, the biggest risk factor for suicide is access to a loaded gun in the home (Brent et al., 1993). Other psychosocial factors that increase the risk for STB include chronic physical illness (Greydanus, Patel, & Pratt, 2010); low peer and/or parental support (Bridge et al., 2006; Joe, Clarke, Ivey, Kerr, & King, 2007; Wagner, Silverman, & Martin, 2003); family history of suicide (Bridge et al., 2006); identification as lesbian, gay, bisexual, transgender, or queer/questioning (LGBTQ) (Haas et al., 2010; Liu & Mustanski, 2012); having been a victim, perpetrator, or victim-perpetrator of bullying (Hepburn, Azrael, Molnar, & Miller, 2012) or sexual or physical abuse (Brodsky et al., 2008). Although nonsuicidal self-injury (NSSI) is by definition not suicidal behavior (and should be treated as distinct), some studies suggest NSSI may be a precursor and/or correlate with STB (Brausch & Gutierrez, 2010; Muehlenkamp & Gutierrez, 2007; Whitlock et al., 2013).

Essential to risk assessment and treatment planning is identifying what might protect youth from suicide risk. Skills and resources that act as a buffer to risk factors are considered protective factors. Protective factors for youth suicide include *internal* factors of skills in problem solving, conflict resolution, stress management, frustration tolerance, and nonviolent ways of handling disputes, and *external* factors of positive therapeutic relationships, social supports (peers and family), and cultural and religious beliefs that discourage suicide and support instincts for self-preservation (Borowsky, Ireland, & Resnick, 2001; Surgeon General, 1999).

ASSESSMENT

The suicide risk assessment must be conducted within a thorough bio-psychosocial evaluation. One can only assess for suicide in the context of other individual and family factors. Individual factors to consider when assessing the suicidal youth include mental status, risk and protective factors, supports currently in place, supports that

may be available, ability of the youth to employ coping strategies, future orientation of the youth, and willingness of the youth to engage in treatment. Family factors to consider include family structure and dynamics, willingness of family to engage in treatment, supports available to the family, culture, ethnicity, religion, immigration status, and language, family history of mental illness and treatment, family's ability to identify strengths within the system, current coping strategies, and flexibility in considering treatment options.

To conduct an effective suicide risk assessment with suicidal youth, the parents and the youth must be interviewed separately. Because of shame, stigma, or fear of punishment, youth are often hesitant to express the full extent of their suicidal ideation and intent in front of their parents. Even with their parents out of the room, eliciting suicidal ideation and intent can be challenging. Therefore, social workers should be well-versed in both the content of a suicide risk assessment and techniques designed to elicit suicidal ideation and intent, such as shame attenuation, behavioral incident, gentle assumption, symptom amplification, shame attenuation, and denial of the specific (Shea, 2002). These techniques will help social workers know how to respond when the client says "no," or "I don't know." It is critical to ask open-ended and detailed questions about suicide, including the "who, what, when, where, why, and how." If the youth endorses suicidal ideation, the social worker must then screen for plan, intent, and access. If the youth endorses having made a plan to attempt suicide, the social worker must ask about the timing and location of the act, the lethality and availability of means, and whether or not there are acts currently in preparation. To assess for intent, the social worker must inquire about the extent to which the youth expects to carry out the plan and how much the youth believes the plan to be lethal, as opposed to self-injurious.

Whether or not the youth has endorsed plan or intent, it is critical to ask about access to lethal means. Firearm access is a key risk factor for suicide because of the lethality of the method. In a seminal study, Brent et al. (1993) found that youth with no known suicide risk who lived in a home with a loaded gun were 32 times more likely to die by suicide than youth who lived in homes without a loaded gun. In 2010, firearms accounted for 38% of suicide deaths in youth ages 0–19 (CDC, 2013). Although the next most lethal method, poisoning, accounted for only 6%

of youth suicide deaths in 2010 (CDC, 2013), ingestion represents one of the most common suicide attempt methods. A recent study of 375 youth who presented to an urban general hospital for a suicide attempt found that 87% attempted suicide by ingestion (O'Brien & Berzin, 2012). Therefore, it is critical that social workers assess for the youth's access to over-the-counter medications, household cleaning supplies, and even the youth's own prescription medications. As with the risk assessment, the parent(s) and child should be interviewed separately about access to lethal means. In general with suicide inquiry, it is important to get a detailed, rich description of the current problem and precipitants to the STB. This involves understanding current symptoms and their severity, as well as recent suicidal thoughts, behaviors, attempts, plans, notes, etc. The social worker must also ask about precipitating events (e.g., bullying, fight with girl/boyfriend/parent, break-up) and stressors, and whether or not they are acute (e.g., recent humiliation) or chronic (e.g., school, illness, poverty, abuse/neglect). Prior suicide attempts and current substance use must also be assessed because of their strong association with suicide risk. See Appendix 1 for examples of questions to ask during a suicide risk assessment.

After the social worker has conducted the assessment, the next step is to determine level of risk and corresponding interventions (Rudd, Joiner, & Rajab, 2001). Levels of risk include:

- *None to Mild* = infrequent, low-intensity ideation, no intent or plan; supportive environment; youth can be managed in the community; focus of treatment is on underlying concerns and not suicide risk
- *Moderate* = suicidal ideation, some intent, no plan; youth may or may not be able to be maintained in the community based on the balance of risk versus protective factors; presence of supportive and healthy home, school, and neighborhood environment; focus of treatment is the current suicidal crisis and efforts to minimize risk factors and enhance protective factors
- *High* = frequent and disruptive ideation, strong intent, and specific plan; youth cannot be maintained in the community and is admitted to an inpatient facility; focus of treatment is ensuring safety, identifying and gathering environmental supports, and developing a discharge plan to ensure continuity of care.

Safety Planning. After conducting a thorough suicide risk assessment and determining that the youth is at mild or moderate risk and can return to the community, the social worker must develop a safety plan with the youth and family prior to discharge. Components of a thorough safety plan include engaging the youth in the planning as much as possible, identifying supports that the youth can access if STB worsens, limiting access to means, increasing positive coping strategies, increasing therapeutic support, keeping caregivers involved in the safety plan, and identifying supports at school, work, or other domains of functioning. The safety plan is not a “no-suicide” or “stay alive” contract. Such contracts do not reduce the client’s risk for suicide and do not reduce the clinician’s risk for a lawsuit following a client’s suicide. “No-suicide” contracts are ineffective because they ask clients to promise to say alive without providing a reasonable and agreed upon plan at a time when they are ambivalent about living, and such contracts provide clinicians with a false sense of security (Wortzel, Matarazzo, & Homaifar, 2013). Therefore, “no-suicide contracts” should be replaced with a clinically useful safety plan (Rudd, Mandrusiak, & Joiner Jr., 2006).

Documentation. Contemporaneous and thorough documentation of all interactions with suicidal youth is essential for continuity of care and risk management (Wortzel et al., 2013). In the event of a lawsuit, the only evidence that a social worker has provided ethical, professional, and competent services comes from the documentation. Social workers should document the presence or absence of risk factors and warning signs, suicide ideation, intent, plan, access to means, rationale for the treatment plan, and the disposition. Because it is never expected that a suicide assessment is conducted alone, the names of the professional(s) consulted and their recommendations should be stated in the note (Coleman, 2002).

PREVENTION

Suicide prevention takes a public health perspective in which targets for prevention efforts can be universal, selective, or indicated (Robinson et al., 2013). *Universal* prevention programs target an entire population in an effort to reduce risk factors or enhance protective factors. *Selective* prevention programs

target youth who demonstrate risk factors associated with STB, but who have not yet reported suicidal ideation or an attempt. *Indicated* prevention programs are designed to intervene with youth who have already displayed STB. Although it might seem counterintuitive that youth who already display STB would be targeted for a “prevention” program, the intention is to prevent future recurrence of either suicidal ideation or attempts. An “upstream” prevention perspective includes any efforts that “reduce risk factors or enhance protective processes that influence the likelihood that a young person will become suicidal” (American Association of Suicidology, AAS & Society for the Prevention of Teen Suicide, SPTS, 2012, p. 1). The most widely used suicide prevention programs for youth are in schools (Katz et al., 2013; Robinson et al., 2013).

School-based suicide prevention. Because youth spend most of their time in school, school-based suicide prevention programs have the potential to reach the greatest number of youth. The following are examples of school suicide prevention programs (Katz et al., 2013):

- **Suicide awareness and education:** These programs have the goal of raising awareness about suicide, identifying youth at risk for suicide, and improving social supports. Signs of Suicide (SOS) is an evidence-based awareness/education program that combines video-based education, classroom discussion, and a depression screen. Youth who participated in the SOS program had significantly lower rates of suicide attempts, and greater knowledge and adaptive attitudes towards depression and suicide (Aseltine, James, Schilling, & Glanovsky, 2007).
- **Screening:** Screening programs, such as Columbia University’s “TeenScreen,” have a main goal of identifying cases of suicide risk. Depending on how a “case” is defined, it can be considered a universal or selected prevention program. Screening programs are intended to prevent STB by casting a wide net, and then referring identified youth to the appropriate level of care. Some of the problems with screening programs are the burden to the school (e.g., interrupting class time, time consuming for teachers to administer the screen), the lack of appropriate resources, and the fact that parents have to “opt-in” to suicide screening programs.

- **Gatekeeper training:** The goal of gatekeeper training is to increase knowledge of both the problem and the resources. Question, Persuade, and Respond (QPR; Wyman et al., 2008) is designed to teach students and staff how to identify suicidal students and make appropriate referrals to mental health services. Although school staff participation in QPR training has been shown to significantly improve knowledge of and positive attitudes towards help-seeking, participation has not resulted in improved referrals (Tompkins, Witt, & Abraibesh, 2010).
- **Peer Leadership Training:** The principle behind peer leadership training is that youth are more likely to reach out to peers rather than adults during a suicidal crisis. Sources of Strength (Wyman et al., 2010) is a universal program that seeks to reduce risk factors and increase protective factors by enlisting and training peer leaders to establish a safe and nurturing school environment. Results of a randomized controlled trial found that students were four times as likely to refer a suicidal friend to an adult, and were significantly more likely to perceive adults and help-seeking as acceptable (Wyman et al., 2010).
- **Skills training:** Skills training programs can be universal or selected, and are intended to prevent the onset of suicidal ideation. Among the most successful skill training programs is the Good Behavior Game (GBG), which provides universal skills training to youth in elementary school. The goal is to create a safe, nurturing school environment that will foster positive social networks and reduce aggressive and disruptive behavior. In one longitudinal study, youth who were assigned to the GBG were half as likely to experience suicidal ideation compared with the control group, and significantly less likely to experience a suicide attempt (Kellam, Reid, & Balster, 2008).

INTERVENTIONS

Hospital-based

Inpatient Psychiatric Units. STB is the most common presenting problem for youth admitted to an inpatient psychiatric hospital (Wilson, Kelly, Morgan, Harley, & O'Sullivan, 2012). Inpatient psychiatric units represent the most restrictive level of care available to suicidal

youth. Inpatient hospitalization is necessary if the suicidal youth's behavior is so unstable and unpredictable that there is serious short-term risk (Shaffer & Pfeffer, 2001). The primary goals of short-term inpatient psychiatric care typically include safety and containment, mood stabilization, and follow-up care coordination.

Emergency Departments. Before admission to inpatient psychiatric hospitals, many youth are evaluated in a hospital Emergency Department (ED). Although the ED is typically used for evaluation only, it represents an ideal environment for a brief intervention with suicidal youth and their families. The *Family-Based Crisis Intervention* (FBCI; Wharff, Ginnis, & Ross, 2012) is a brief intervention designed for use with adolescents and their families when the adolescent presents to the ED in a suicidal crisis. The goal of FBCI is to decrease acute symptoms in the suicidal adolescent so that he/she may return home safely with the family, rather than experience an unnecessary psychiatric hospitalization. The social worker first meets separately with the youth and family to assess what led to the suicidal crisis. Next, the social worker meets with the family together to aid in constructing a unified perception of the problem. At the culmination of this family meeting the social worker helps the family to create a safety plan so that the youth can return home. In a pilot of the intervention, youth receiving FBCI ($n = 67$) were significantly less likely to be psychiatrically hospitalized than those in the control group (36% vs. 55%), and importantly, none of the youth receiving FBCI reported having attempted suicide in the 3-month follow-up period (Wharff et al., 2012).

The *Family Intervention for Suicide Prevention* (FISP; Asarnow, Berk, & Baraff, 2009; Hughes & Asarnow, 2013) is another brief (between 20 and 60 minutes) ED intervention for suicidal adolescents and their families. One of the major goals of FISP is to improve continuity of care between the ED and community mental health services. FISP is implemented after the adolescent has been evaluated and determined safe to return to the community. During FISP, the suicidal crisis is reframed as maladaptive coping skill within the context of a family crisis. FISP aims to promote the development of adaptive coping, make a strong case for the importance of attending follow-up treatment, and encourage healthy and supportive communication. The focus on linkage

and adherence to follow-up care is intended to decrease the risk of short-term repeated suicidal behavior. FISP has demonstrated success in connecting youth to follow-up care, but not reducing STB (Asarnow et al., 2011).

Community-based

Community-based practices for suicidal youth include crisis assessment and intervention, individual therapy, family therapy, integrated interventions, and psychopharmacotherapy. Group therapy was a promising modality in the early 2000s (Wood, Trainor, Rothwell, Moore, & Harrington, 2001), but subsequent studies have failed to demonstrate either clinical or economic value (Green et al., 2011; Hazell et al., 2009). An innovative social network intervention for suicidal youth, the Youth-Nominated Support Team-Version II, resulted in a rapid decrease in suicidal ideation within six weeks, but did not result in decreased suicidal ideation or attempts compared to the control condition (King et al., 2009).

Crisis Assessment and Intervention. The goal of a crisis assessment is to determine whether the youth can be maintained in the community for treatment, or if he/she needs to receive inpatient psychiatric services. Crisis intervention is often used to stabilize the current crisis, develop referrals for longer term individual or family treatment, and serve as an alternative to hospitalization (Singer, 2005). There is currently no empirical base for determining when a youth at high risk for suicide would be better served by remaining in the community than receiving inpatient psychiatric care (Lamb, 2009).

Individual Interventions. Because of the importance of parents, family, and the home environment as risk and protective factors, all interventions for suicidal youth must involve the parents/family. This chapter classifies interventions as “individual,” even when they have a distinct family component, because the suicide risk is conceptualized as an individual issue. Interventions are classified as “family” when they conceptualize suicide risk as a family issue.

Dialectical-Behavior Therapy for Adolescents (DBT-A; Fleischhaker et al., 2011; Rathus & Miller, 2002). DBT-A was adapted from DBT, which was initially developed to address self-harming behaviors in women with borderline personality disorder (Linehan, Armstrong, Suarez, Allmon, & Heard, 1991). The goal of

DBT is to improve a person’s ability to regulate his or her emotions by reducing distress associated with moving between opposing, or dialectical, thoughts, emotions, and behaviors. DBT-A was modified for adolescents to combine weekly individual therapy with a multifamily skills group and between-session therapist check-ins. The first evaluation of DBT-A compared it with treatment-as-usual (TAU) in a sample of suicidal youth with borderline personality disorder. Adolescents in the DBT-A condition had fewer psychiatric hospitalizations during treatment, and were more likely to complete treatment than those in the TAU condition (Rathus & Miller, 2002). Although subsequent studies have consistently found that youth who participate in DBT-A report significant improvements in borderline symptoms and suicidal behavior (Fleischhaker et al., 2011), no studies have found significant differences in STB between youth in the DBT-A condition and youth in a control condition (MacPherson, Cheavens, & Fristad, 2013).

Mentalization-Based Therapy for Adolescents (MBT-A; Rossouw & Fonagy, 2012). MBT-A is a year-long treatment protocol that includes weekly individual and monthly family therapy sessions. The goal of treatment is for adolescents to accurately represent their own and others’ emotions and behaviors during times of stress and conflict. MBT-A begins with an assessment and is followed by a written safety plan and case formulation (Rossouw & Fonagy, 2012). The remaining therapy is made up of unstructured sessions that focus on recent interpersonal experiences in order to process the mental states evoked by these experiences. The final phase of treatment addresses the end of the therapeutic relationship. Family sessions have the goal of improving the parents’ capacity to mentalize (i.e., make sense of their child’s emotional states and way of seeing the world), particularly in the context of family conflict. MBT-A was compared to TAU during a year-long randomized controlled trial (RCT). At 12 months, youth who received MBT-A reported significantly lower scores on a self-harm scale (which included suicidal ideation, attempt, and attempt with medical attention) than youth who received TAU (Rossouw & Fonagy, 2012).

Cognitive Behavior Therapy for Suicide Prevention (CBT-SP; Stanley et al., 2009). CBT-SP is a modification of the first CBT treatment ever evaluated with suicidal youth (Brent, 1997) and was used as one of the interventions in the Treatment of Adolescent Suicide

Attempters (TASA) study (Brent et al., 2009). The goal of CBT-SP is to address suicide risk and prevent future suicidal behavior by identifying and implementing suicide risk reduction strategies and developing or bolstering existing strengths. CBT-SP is divided into three acute phases (beginning, middle, and end), which typically take between 12 and 16 weeks, and a continuation phase, which can last up to an additional 12 weeks. In the beginning of CBT-SP (typically the first three sessions), the therapist meets with the adolescent and parents, establishes rapport, collaboratively develops a safety plan, conducts a detailed chain analysis (i.e., identifies the sequence of events that led up to the suicidal behavior), provides psycho-education, establishes reasons for living and hope, develops a case conceptualization of the adolescent's suicide risk, and develops a treatment plan for ongoing management of the youths' suicidal behavior (Brent, Poling, & Goldstein, 2011; Stanley et al., 2009). The middle phase (sessions 4–9) focuses on developing individual and family skills. The end phase (sessions 10–12) focuses on relapse prevention, during which the therapist tests the skills and coping capabilities of the client by going through an imagined re-creation of the suicide event. Following successful relapse prevention, the adolescent and parents are given the opportunity to apply their new skills to address other problems that were not the focus of the acute phase. CBT-SP was shown to be as effective as psychopharmacotherapy in treating suicide attempters in a 6-month open trial (Brent et al., 2009), and reported fewer reattempts than in comparable studies (Goldston et al., 1999).

Family Interventions. Family-based interventions also have also tested for their effectiveness in decreasing STB in youth. One of the original family-based treatment studies for suicidal youth compared individual CBT (the treatment that evolved into the CBT-SP described above) with Strategic Behavioral Family Therapy (SBFT) and a Non-directive Supportive Treatment (NST) (Brent, 1997). Although SBFT was not as effective as CBT in the short-term reduction of depression and suicide risk, at the 2-year follow-up, all three conditions were equally as effective (Renaud et al., 1998).

Subsequently, there have been studies of the effectiveness of two different family therapy treatments in reducing STB in youth; importantly, these family therapy treatments were not originally designed to reduce STB. The first

study evaluated the effectiveness of four sessions of home-based family problem-solving therapy on reducing STB in a sample of adolescents who deliberately poisoned themselves (Harrington et al., 1998). This study found no differences in STB between youth who received the treatment and youth who did not receive the treatment. The second study found that youth participating in Multisystemic Therapy (MST; Huey et al., 2004) were significantly less likely to make a suicide attempt, but not less likely to report suicidal ideation than youth in the control condition. The past decade has seen the development and empirical evaluation of family-based interventions and integrated interventions designed specifically to address STB in youth.

Attachment-Based Family Therapy. Currently, ABFT is one of the few empirically validated treatments for youth with STB (G. S. Diamond et al., 2010; Shpigel, Diamond, & Diamond, 2012). ABFT is designed to address depression and STB via a trust-based, emotion-focused psychotherapy model intended to repair interpersonal ruptures and rebuild an emotionally protective, foundationally secure, parent-child relationship. Through conjoint family sessions and individual sessions with the adolescent and the parents, ABFT strengthens the parent-child relationship, and re-establishes the family as a source of strength and support during suicidal and other crises. ABFT's approach to addressing suicidal youth is different than traditional cognitive behavioral treatment approaches in that it is grounded in attachment theory, relies heavily on emotion-focused techniques rather than cognitive or behavioral techniques, and aims to reduce youth suicidal behavior by repairing or strengthening the parent-child relationship, rather than focusing explicitly on either the youth or the suicidal behavior. Youth and parents in ABFT must complete five tasks over 12–16 weeks. In Task 1, "Relational Reframe," the youth's depression and STB are reframed as a family issue. In Task 2, "Adolescent Alliance," and Task 3, "Parent Alliance," the therapist meets individually with the adolescent and the parent in order to identify the attachment ruptures and prepare for Task 4. In Task 4, "Attachment," the adolescent explains to the parent why he or she does not go to the parent when feeling depressed or suicidal and has an experience of being heard and understood by the parent. In Task 5, "Competency," the adolescent and parent address day-to-day

issues (including suicide risk) within the framework of a more secure attachment (G. S. Diamond, Diamond, & Levy, 2013). ABFT has demonstrated reduction in suicidal ideation in two clinical trials with a range of youth, including those with a history of trauma, LGB youth, youth with depression and anxiety, and has been evaluated primarily with low-income, multi-problem urban families (G. M. Diamond et al., 2012; G. S. Diamond, Creed, Gillham, Gallop, & Hamilton, 2012).

Integrated Interventions. Integrated CBT (I-CBT; Esposito-Smythers, Spirito, Kahler, Hunt, & Monti, 2011) is a promising intervention for adolescents with comorbid STB and substance abuse that combines both individual and family treatment strategies. I-CBT targets the common maladaptive behaviors and beliefs that underlie the two problems of STB and substance abuse. Individually, the intervention addresses issues with cognitive distortions, coping, and communication by working with the adolescent on cognitive restructuring, problem solving, affect regulation, and communication skills (Esposito-Smythers et al., 2011). To bolster the effectiveness of I-CBT with adolescents, a parent training session and/or family session is added in which the mental health and substance abuse treatment goals of the adolescent are addressed with the parents, and skills of monitoring, emotion regulation, communication skills, and behavioral contracting are taught to the parents (Esposito-Smythers et al., 2011). In a randomized trial, Esposito-Smythers et al. (2011) found I-CBT, relative to enhanced treatment as usual (E-TAU), to be associated with significantly less global impairment as well as fewer suicide attempts, inpatient psychiatric hospitalizations, emergency department visits, heavy drinking days, and days of marijuana use.

PSYCHOPHARMACOTHERAPY

Psychopharmacological interventions are often used with youth with STB to treat the underlying psychiatric symptomatology. Social workers are not trained to prescribe psychiatric medications and thus should not give medical advice to suicidal youth and their families. However, social workers have an ethical obligation to understand and work with psychopharmacologists to best serve their clients, and therefore, should know about the properties and side

effects of psychiatric medications prescribed to youth with STB.

There has been much controversy about prescribing antidepressant medication to suicidal youth since the U.S. Food and Drug Administration issued a black box warning regarding antidepressants and STB in youth in 2004. However, a recent meta-analysis by Gibbons et al. (2012) found no increased suicide risk for youth receiving psychopharmacological treatment for depression. Social workers should take from these findings the importance of psychopharmacological interventions with suicidal youth and the corresponding need for monitoring of mood and behavior changes for youth who take these medications.

CONCLUSION AND FUTURE DIRECTIONS

In this chapter we have identified and described current assessment, prevention, and intervention strategies with suicidal youth. The existing empirical literature suggests that few prevention programs (GBG) and intervention programs (MBT-A, ABFT, and I-CBT) have been shown to reduce STB in youth, highlighting the need for continued research on effective interventions with this population. The following are some promising developments in suicide prevention and intervention. (1) Identification of risk factors and warning signs: The National Center for the Prevention of Youth Suicide (<http://www.suicidology.org/ncpys>) is coordinating an international expert panel to identify risk factors and warning signs for children and adolescents. (2) Screening for suicide risk. Currently screening occurs primarily in schools. The Affordable Care Act will provide financial and structural incentives to conduct screening for suicide risk in primary care settings (O'Connor, Gaynes, Burda, Williams, & Whitlock, 2013; Wintersteen, 2010), which could reduce the burden on schools, capture high-risk youth who are no longer attending school, and result in better identification and referral of suicidal youth. (3) Interventions. As described above, interventions for suicidal youth focus primarily on individuals or families. Two programs are currently being evaluated that would provide support and intervention to parents of suicidal youth. Hooven (2013) are developing and testing a suicide

prevention program for parents that combines psycho-education around suicide risk, emotion coaching, and communication skills training around parental assessment of youth suicide risk. Esposito-Smythers et al. (2011) are currently testing an extension of their I-CBT protocol for suicidal youth with substance use and/or NSSI, which uses two therapists, one for the youth and one for the parents, to help enhance treatment effectiveness and minimize suicide risk. A final development is suicide assessment, prevention, and intervention using computer and Internet technologies (CIT). Current CIT applications include text or chat-based crisis hotlines, suicide prevention video games, online therapy (using webcams, virtual reality environments, or text-based modes), and identification of suicidal statements on search engines or social networks using textual analysis (Luxton, June, & Kinn, 2011). These emerging advances in suicide prevention and intervention efforts will help guide our current treatment practices with suicidal youth.

APPENDIX 1

Specific Questioning for Suicide Inquiry

Ask about suicidal ideation, plans, behaviors, and intent openly and frankly.

- Have you been having thoughts about killing yourself either now or in the past?
- Do you ever feel that life isn't worth living?
- Have you ever wished you could just go to sleep and not wake up?
- Have you ever tried to hurt yourself, wishing you would die?
- Have you ever tried to kill yourself?
- What did you think would happen when you . . . (overdosed, etc.).
- How do you feel that you are still alive after having attempted suicide?

If the youth answers, "yes" to any of these, ask: who, what, when, where, why, and how.

- What are you thinking of doing?
- When do you think you might do it?
- Where might you hurt or kill yourself?
- How might you hurt or kill yourself?
- Why do you want to kill yourself?
- Who knows about this?

67 Intensive Family Preservation Services

Betty J. Blythe & Andrea Cole

Home visits and home-based services enjoy a long tradition in social work. An early proponent of home visiting by social workers was Mary Richmond, who wrote about the advantages of meeting clients in their homes where the social worker could observe how family members interacted with one another in their home environment (Richmond, 1917). Intensive family preservation services is a specific model of home-based services that provide supports to families in their homes and communities through a mix of case management and intensive therapeutic services. The model most often associated with intensive family preservation services is Homebuilders[®]. Developed in Tacoma,

Washington in 1974 (Kinney, Madsen, Fleming, & Haapala, 1977), Homebuilders originally focused on preventing unnecessary out-of-home placement of children who were at imminent risk of being placed in foster homes. Intensive family preservation services are not offered if there are concerns that the child(ren) cannot be safely maintained in the home and if the family refuses services.

Unlike traditional child welfare services, intensive family preservation services work with the entire family rather than focusing solely on one or more children. They are further distinguished from other home-based services by their intensity and duration. Although there is some

variation, most intensive family preservation programs share the following characteristics:

- Small caseloads, typically two to four families
- One worker provides the services, although support and backup is available from one or more colleagues.
- Services are provided 24 hours a day, 7 days a week, for regularly scheduled appointments and to handle crisis or emergency calls.
- Services include “hard” or “concrete,” services such as transportation, housing, or food, and therapeutic services as well as “soft” services.
- Most services are provided in the family’s home, including the extended family, and in community settings in the family’s environment such as the school or church.
- Services are intensive, with families being seen between 6 and 10 hours per week, and are time-limited, typically lasting one to four months (Haapala & Kinney, 1979; Kinney, Haapala, Booth, & Leavitt, 1990; Nelson, Walters, Schweitzer, Blythe, & Pecora, 2009; Walton, Sandau-Beckler, & Mannes, 2001).

Small caseloads are critical so that workers can work intensively with families and be available for crisis calls. The length and frequency of visits builds on Richmond’s (1917) advice about the advantages of seeing families in their home settings. One of the Homebuilders founders explained that early assessment visits, without time constraints, allowed the worker to get the “big picture,” and subsequent and frequent visits allowed the worker to understand what was happening before the family’s story had totally changed. Likewise, support and backup by colleagues make it possible for services to be available to families “24/7,” to ensure that family members are safe, and to provide consultation and other forms of support to workers who are dealing with difficult, stressful situations. Moreover, scheduling visits outside of a traditional work day increases the possibility that most or all family members will be available for the visit. Services tend to be broadly defined within the intensive family preservation services framework, and the treatment model is best described as highly flexible. Often, families who need such intensive intervention have become disconnected from their families of origin and communities and are not aware of possible sources of support. Hard services might include help with budgeting, or accessing resources to pay their utility bills. Or, the family

preservation services worker might familiarize family members with such community resources as food banks, health clinics, and recreational facilities. Similarly, so-called soft services are varied and emphasize teaching families skills to resolve real-life problems (Wells, Pecora, & Booth, 2014). These soft services include such things as

- Parent training
- Anger management training
- Cognitive-behavioral interventions
- Rational emotive therapy
- Communication skills training

Initial work with the family requires that the worker defuse the crisis that precipitated the referral and build a relationship with the family. Assessment of the family’s needs and developing goals occurs in partnership with the family. Time limitations of one to four months acknowledge that families referred for intensive family preservation services are in crisis and, therefore, are open to change. At the same time, once the “crisis” or the reason for referral has been resolved, families are less likely to be invested in services. Among other things, intensive family preservation services attempt to build a safety net around families so that they can continue to do well after the close of services. Given the stressors associated with poverty and other situational variables that they tend to experience in their daily lives, many of these multi-problem families will need booster sessions or additional services in the future.

CASE EXAMPLE

Although there is no such thing as a typical intensive family preservation case, a case illustration can help to illuminate the nature of such services. The following case example depicts the assessment, goal setting, and interventions for a case referred by the child welfare system to an intensive family preservation services professional in Washington State.

Meeting the Lopez Family

Homebuilders became involved with the Lopez family following a referral by child protective services. Lauren Blackwell, MSW, was assigned the case. The Lopez family consists of Maria Lopez (mother), Jason Lopez (father), Gorge Lopez (11-year-old child), Yessenia Lopez (10-year-old child), and Junior Lopez (1-year-old child). The

referral was due to founded cases of physical neglect, medical neglect, and supervisory neglect. Before the initial visit, Lauren reviewed the records of the case and was aware of the concerns of child protective services but planned to ask the Lopezes to describe their challenges in their own words.

Lauren conducted the first meeting, and many thereafter, in the family's home, where it would be most convenient for them. During the initial meeting with Mr. and Mrs. Lopez and their three children, she engaged the family and worked to develop rapport by explaining why Homebuilders became involved, asking the Lopezes to explain what needs they felt they had, and the goals they wanted to work toward. She also described the type of assistance she could provide.

During this initial visit, Lauren gathered information about the family, and it became clear that the Lopezes were facing many challenges. Lauren observed that the home was infested with multiple types of insects and was cluttered with dirty dishes, unlaundered clothes, and spoiling food. The family lived in a dilapidated apartment building that had unsafe public areas. The Lopezes divulged that there were times when the older children played in these areas, as there were so few other places for the children to play. Also, the Lopezes explained that due to a lack of health insurance, none of the children were up-to-date on their medical check-ups. The children's hygiene also was poor. In addition, both parents were abusing amphetamines on a regular basis, making it difficult for them to provide adequate supervision to keep the children safe and organization to maintain the children's physical needs and the household. At the same time, Mr. and Mrs. Lopez showed a number of strengths, including apparent concern for each other and their family, motivation to accept services, and a desire to work on the part of Mr. Lopez.

Creating Goals

Based on the information provided in the referral and the information that Lauren was able to gather from the Lopezes, including their own priorities, issues, and concerns, Lauren and Mr. and Mrs. Lopez agreed on a service plan with three overarching goals:

- (1) Enhance cleanliness of the home and improve hygiene of the family
- (2) Ensure the safety of the family
- (3) Connect the family with necessary community resources so that they can do well after Homebuilders services are terminated.

They agreed to work together on these goals over the course of the coming four to six weeks, meeting in the home multiple times a week, especially in the afternoons or evenings when the children would be home from school. The Lopezes seemed to feel heard and respected by Lauren and, given their motivation to keep their children in their home, agreed to this schedule.

INTERVENTIONS

Initially, Lauren prioritized safety and helping the Lopezes with concrete services. She met with Mr. and Mrs. Lopez to discuss strategies for keeping the home clean, such as creating a chore chart so that the older children could participate and a calendar with dates for certain chores. Lauren initially assisted the family in purchasing home cleaning supplies and also toothbrushes, toothpaste, shampoo, and bath soap to improve family hygiene. Lauren also provided psycho-education to the parents and older children around the importance of daily hygiene. The family's habits in both of these areas quickly improved.

Lauren also worked with Mrs. Lopez, Mr. Lopez, and the two older children, Gorge and Yessenia, to create a safety plan. It was decided that the children must always be home before 6:00 P.M. and were not to go into anyone else's home in the neighborhood. Lauren discussed with Gorge and Yessenia the importance of staying in a group with other children whom they know, and screaming loudly if anyone bothers them. Lauren discussed with the family options for other places for the children to play. Mr. and Mrs. Lopez were able to identify a local YMCA where the children could go after school for a few hours, instead of outside in the neighborhood.

Over the course of a few weeks, Lauren arranged for both Mr. and Mrs. Lopez to obtain a psychiatric evaluation, given their admission of amphetamine abuse. Mrs. Lopez was diagnosed with Attention Deficit/Hyperactivity Disorder, Obsessive-Compulsive Disorder, and Post-Traumatic Stress Disorder. Mr. Lopez was diagnosed with Post-Traumatic Stress Disorder and a traumatic brain injury. Mr. Lopez experienced the brain injury during the Gulf War. His symptoms included poor memory, irritability, and low frustration tolerance.

Given these diagnoses, Lauren worked with the family and local agencies to connect Mrs. and Mr. Lopez to the appropriate health and

mental health services. Mrs. Lopez was linked to a therapist and psychiatrist offering treatment for both her mental illness and substance abuse, including medications. In addition to a substance abuse outpatient program, Lauren connected Mr. Lopez with an institute at a local university that specializes in treating the specific type of brain injury he suffered. Lauren worked with Mrs. Lopez to obtain appointments for physicals for all of the children and accompanied the family to appointments with the pediatrician.

The family's housing situation was bleak. The apartment building had been condemned, and they were certain to be evicted in due time. Lauren researched the city rules and available services for homeless families and found out that once the Lopezes received an actual eviction notice, they would be moved to the top of the list to receive public housing. Lauren discussed this plan with Mr. and Mrs. Lopez, and they were in agreement.

With regard to finances, the Lopezes were receiving public assistance but it was not enough to meet the needs of a family of five. Lauren explored with Mr. and Mrs. Lopez their sources of income. Mr. Lopez frequently worked odd jobs under the table, but was not reporting this income to the government. Lauren researched the public assistance programs, and found out that if Mr. Lopez did report this income, the family's Temporary Assistance for Needy Families (TANF) benefit would increase. Lauren accompanied Mr. Lopez to the appropriate government office to begin reporting his income and to reapply for an adjustment in TANF benefits. Finally, Lauren showed Mr. Lopez how he could use the free Internet access at the library to locate additional odd jobs. All of these interventions, which occurred over the course of two weeks, significantly improved the family's financial situation, as did Mr. and Mrs. Lopez's abstinence from amphetamine abuse.

Lauren showed Mr. and Mrs. Lopez where the local food banks were located and explained the process of obtaining food at each venue. She assisted them with this until she was assured they could continue to obtain food on their own after services were terminated. Lauren talked with the other social workers at her agency and discovered that a local church provided free toothbrushes, clean clothing, and diapers. Lauren brought Mrs. Lopez to the church and was able to obtain various items of which the family was in need. Mrs.

Lopez was informed she could go to the church once a month for additional goods.

In the process of connecting the family to these multiple services, it became clear the family had limited knowledge of the public transit system. Lauren worked with Mr. and Mrs. Lopez to understand better which buses they would need to take and how to obtain discounted tickets. Lauren and the parents also created a family calendar that included the many appointments the family now had as well as the bus schedule.

To allow Mrs. Lopez a break from caring for the children during the day and also so that the youngest child could receive educational services, Lauren enrolled Junior in Early Head Start. Mrs. Lopez and Lauren reviewed the schedule for classes and the bus route to get to the agency several times so that Mrs. Lopez could be consistent in picking up and dropping Junior off there.

In total, Lauren spent about 40 hours providing services to the Lopezes over the course of five weeks. The majority of these hours were spent at the Lopez home or in the community. At the end of this period, the Lopez family had made significant gains in housing stability and safety, financial stability, cleanliness and hygiene, and health and mental health. They subsequently were allowed to keep their children in the home. Lauren worked with Mr. and Mrs. Lopez to assure that these changes were sustainable, but also offered to provide "booster sessions" (as Homebuilders does with all clients) after a few months to help to sustain change. The Lopezes agreed to maintain contact with Lauren.

Typical Day

Admittedly, there is no such thing as a typical day in the life of a Homebuilders therapist. They work roughly five to six hours per day, six to seven days per week. Families tend to be more readily available in the afternoons or evenings, and morning hours often are devoted to consultation, supervision, and making contacts on behalf of the families with whom they are working. The following depicts one example of a day's activities for a family preservation worker.

- 9:00–10:00 Check voice mail and make several phone calls to get electricity reinstated for Lopez family
- 10:00–11:00 Phone consultation with referral source and local mental health providers to

arrange for consultations for Mr. and Mrs. Lopez

11:00–12:00 Weekly supervisory meeting with Lauren's agency supervisor

12:00–1:00 Lunch and travel to Lopez family home

1:00–2:30 Lauren and Mr. Lopez visit the local offices of the Department of Social and Health Services to complete paperwork to adjust TANF payments

2:30–4:00 Work with the parents and children to create a safety plan

EXTENDING THE MODEL BEYOND

CHILD WELFARE

The intensive family preservation services model has been extended to several other populations but, in all cases, the underlying objective is strengthening and maintaining families. An early extension of the model was to use intensive family preservation services in family reunification cases where children are returning to their families from foster care or other out-of-home placements (Bell, 1995). The services also have helped to prevent family breakdown as part of postadoptive services (Berry, Propp, & Martens, 2007). Henggeler and his colleagues (Henggeler, Melton, & Smith, 1992) extended the model to work with juvenile delinquency cases, in a home-based program known as multisystemic therapy. In turn, multisystemic therapy has been applied to prevent suicide attempts in youth who are referred for emergency psychiatric hospitalization (Henggeler, Rowland, Halliday-Boykins, Cunningham, Pickrel, & Edwards, 2004). Intensive family preservation services also have been used in work with domestic violence cases (Findlater & Kelly, 1999). Finally, intensive family preservation services, based on the Homebuilders model, have been used in families where one or both parents are misusing substances (Forrester et al., 2012).

Evaluation

Intensive family preservation services have been subjected to considerable scrutiny by the general public and the research community. In general, the more rigorous studies indicate that intensive family preservation services, when delivered according to the prescribed model, are effective in reducing out-of-home placement (Nelson, Walters, Schweitzer, Blythe, & Pecora, 2009).

Kirk and Griffith (2008) further indicate that the program reduces racial disproportionality in the child welfare system.

Guidelines for Establishing Effective Treatment Goals and Plans for Mental Health Disorders

Sample Treatment Plans for DSM-5 Insomnia and Generalized Anxiety Disorders

Vikki L. Vandiver

We shouldn't deny the verdict (diagnosis/assessment) but defy the sentence (prognosis/outcome).

—Norman Cousins, *Head First: The Biology of Hope*

This chapter reviews the procedures of goal setting and treatment planning for mental health disorders commonly found in the *Diagnostic and Statistical Manual of Mental Disorders—Fifth Edition* (American Psychiatric Association, 2013a). Commonly referred to as the *DSM-5*, this manual is used by clinicians to assess and diagnose four major groups of conditions: mental disorders (e.g., generalized anxiety disorders), other mental disorders (e.g., unspecified mental disorders), medication-induced movement disorders (e.g., neuroleptic-induced parkinsonism) and other conditions that may be the focus of clinical attention (e.g., relational problems). See Table 68.1 for a full listing of these conditions. Regardless of the breadth or differences in disorders, the establishment of treatment goals and the development of a treatment plan are predicated on a thorough assessment, diagnosis, and understanding of the client's presenting problem. In fact, the process is sequential, starting with the bio-psychosocial-cultural assessment and accurate diagnosis, which in turn, facilitates establishing treatment goals and determining the treatment plans.

BIO-PSYCHOSOCIAL-CULTURAL ASSESSMENT

The bio-psychosocial-cultural model is based on two premises: (1) client problems are multi-causal and reflect an attempt to cope with stressors, given existing vulnerabilities, environment, and resources; and (2) treatment approaches need to be multimodal, flexible, and tailored to the client's needs and expectations rather than to a single treatment modality.

The first step in establishing treatment goals and an effective treatment plan is to conduct a clinical interview using the bio-psychosocial-cultural model of assessment. Generally speaking, a mental health interview revolves around three discrete areas: (1) the dynamic interplay of biology and psychology, (2) social and cultural factors of the client's present mental health status, and (3) past mental health history. The biological system deals with the anatomical, structural, and molecular substrates of disease and the effects on clients' biological functioning. The psychological explores the effects of psychodynamic factors, developmental impasses or distorted object relations, motivation,

15. Substance Related and Addictive Disorders			
16. Neurocognitive Disorders			
17. Personality Disorders			
18. Paraphilic Disorders			

and personality on the experience or reaction to illness. The sociocultural system examines cultural and environmental stressors, vulnerabilities, resources, and familial influences on the expression and experience of coping with illness. (Kaplan & Sadock, 2007; Sperry, Gudeman, Blackwell, & Faulkner, 1992; Vandiver, 2009). These three areas are discussed accordingly.

Beginning with the bio of the biopsychosocial-cultural section of the interview, the social worker gathers information on current health status (e.g., hypertension) and past health history (e.g., diabetes) or injuries (e.g., brain injury). Additional information includes current medication use (e.g., both allopathic and homeopathic), and health and lifestyle

behaviors (e.g., exercise, nutrition, sleep patterns, substance use). A familial health history would also be obtained. Screening tools would include sleep charts and health measures. Additionally, genograms are very useful tools to track family health history (e.g., cancer) and certain genetic disorders (e.g., schizophrenia, substance abuse, mood disorders) and to assess family patterns that may maintain the problem or facilitate the obtainment of treatment goals. Genograms facilitate understanding of the social networks as part of the actual treatment plan and illustrate how assessment and problem-identification tools are used in the entire treatment process.

Once the social worker has obtained health information, they should explore the psychological status of the client. This information would include a broad range of topics, including appearance and behavior, speech and language, thought process and content, mood and affect, and cognitive functioning (including orientation, concentration, memory, insight, and general intelligence). A critical area is the determination of suicidal or homicidal risk and possible need for an immediate referral. Common screening tools are self-reports (see Corcoran and Fischer, 2013) and mental status exam. In particular, the mental status represents an attempt to objectively describe the behaviors, thoughts, feelings, and perceptions of the client during the interview (Corcoran & Walsh, 2013).

A final section of the bio-psycho-social-cultural assessment interview includes information on the sociocultural experiences of the client. Broadly speaking, the social worker gathers information on cultural background (e.g., ethnicity, language, assimilation, acculturation, and spiritual beliefs), environmental connections (e.g., community ties, living conditions, neighborhood, economic status, and availability of food and shelter), and social relations (e.g., familial, friends, employers, strangers, and experiences with racism or discrimination). Useful assessment tools are eco-maps, which, like genograms, facilitate an understanding of how the social environment maintains the problems and may aid or impede the goal attainment.

ACCURATE DIAGNOSIS

The second step in establishing treatment goals and treatment plans is to accurately diagnose the mental health condition. One of the most useful aspects of the bio-psycho-social-cultural assessment is that the model pushes the social worker to consider various perspectives that aid in formulating a diagnostic picture. Toward this end, it is customary to use the *DSM-5* (APA, 2013a) for this purpose.

As Table 68.1 illustrates, clinicians have four *DSM-5* categories in which to identify mental health concerns: *all mental disorders, other mental disorders, medication-induced movement disorders and other adverse effects of medications and other conditions that may be the focus of clinical attention*. All *mental disorders*, commonly referred to as clinical conditions, generally refer to mental health conditions that result in distress or disability that is greater than expected from circumstances of living. This group of disorders includes 18 different diagnostic subcategories and criteria.

In addition to a diagnosis of a clinical disorder, the social worker can also consider *other mental disorders*, namely *other specified and unspecified*. These disorders are also used to help classify co-occurring medical conditions. This category is used when the presentation does not fit exactly into the diagnostic boundaries of commonly recognized mental/clinical disorders (e.g., schizophrenia). Both of these categories are recognized as “mental disorders” in that they are billable, have psychiatric treatment protocols, and require that clinicians refer to the diagnostic criteria listed for each diagnosis. However, *specified and unspecified* categories are meant to be short-term and should only remain in the chart until a more complete diagnosis is made.

A third category is *medication-induced movement disorders and other adverse effects of medication*. This section refers to 12 disorders that are related directly to the management by medication of mental disorders or other medical conditions (APA, 2013a). These conditions are not considered mental disorders but are, in fact, a side effect of managing mental disorders.

A final category that social workers can use in their assessment is the *other conditions that may be the focus of clinical attention*. There are 11 categories and over 100 different other

conditions or problems that may be the focus of attention. The social worker could use the “*other conditions*” category when:

1. The problem is the focus of treatment and the individual has no mental disorder (e.g., V61.20 [Z62.82]—Parent-Child Relational Problem—when the focus is to address the quality of the parent-child relationship)
2. The individual has a mental disorder, but it is unrelated to the problem (e.g., V61.8 [Z62.891]—Sibling Relational Problem—when the focus is on the sibling relationship)
3. The individual has a mental disorder that is related to the problem, but the problem is sufficiently severe to warrant independent clinical attention (e.g., V61.03 [Z63.5]—Disruption of Family by Separation or Divorce—when an individual with chronic schizophrenia in remission may present with marital distress).

Sometimes these categories are used when the medical condition is confounding the psychiatric diagnosis or no mental disorder is present and the client is coping with multiple stressors.

As in any bio-psychosocial-cultural assessment, the social worker is balancing information regarding the psychological, social, and medical status of the client. When assessing for these areas, the social worker will need to explore psychological factors that affect the medical condition (e.g., major depressive disorder delaying recovery from myocardial infarction), social/cultural circumstances that exacerbate the mental health condition (e.g., acculturation difficulty or target of discrimination). Similarly, medication-induced movement disorders and other medication-induced disorders are important assessment considerations because of their significance in the management of medication (e.g., anxiety disorder vs. neuroleptic malignant syndrome).

ESTABLISHING TREATMENT GOALS

Once the assessment is completed and a diagnosis determined, the social worker and client are ready to develop treatment goals. There are five guidelines to establishing treatment goals. Goals should (1) emerge from the assessment and diagnosis; (2) have maximum client participation; (3) be stated in positive terms; (4) be feasible, realistic, and within the resources of the client; and (5) be well defined, observable, and measurable.

Treatment goals should emerge from the assessment and diagnosis of the client’s problem. There should be a nexus between the assessment/diagnosis and goals. For example, if the assessment and diagnosis suggest that the client is experiencing sleep deprivation secondary to an anxiety disorder, the treatment goals (both short- and long-term) would focus on stabilizing sleep patterns while decreasing anxiety and its symptoms.

The establishment of a treatment goal must include the active participation of the client. A goal cannot be ascribed to the client. Clients who actively participate in establishing the treatment goal are more motivated to comply with the treatment plan. Active participation includes homework assigned and completed outside the clinical setting. Treatments that include homework assignments tend to enhance client compliance and facilitate generalizing the changing behavior to other environments.

Treatment goals should be stated in positive terms, if possible. For example, it is more motivating for a client to increase the frequency and intensity of pleasant events than to stop being depressed. Similarly, a substance abuser would not simply want to quit using drugs but to increase the duration between use and the number of days clean and sober. A positively stated goal has the inherent benefit of enhancing compliance with the treatment plan and encouraging clients to participate in what they want and value.

A treatment goal must be feasible for the client to accomplish. If the goal is vague or overly ambitious, the outcome will likely be failure. Instead of improved social functioning, the client could experience a lack of success, disappointment, and erosion in confidence. Though the goal must not be too ambitious, it must also be challenging and realistic. Specific and challenging goals are more likely attained than those that are vague and easy. Social workers must also examine what resources the client has to achieve the agreed upon goals. For example, does the client have the bus fare or day care help to attend the scheduled therapy group?

Finally, the treatment goal must be observable. The client, the social worker, or relevant others should be able to observe the change. One convenient way to observe goals is with assessment instruments that help formulate the assessment and diagnosis. In the most recent edition of the *DSM-5* (APA, 2013a), readers will find a variety of assessment measures, such as

the Adult Self-Rated Cross Cutting Symptom Measure, World Health Organization—Disability Assessment Schedule and others. These measures are in the public domain and accessible through www.psychiatry.org/dsm5.

Additionally, many of the mental disorders classified in *DSM-5* are rated for severity with the assessment recorded as the fifth digit of the DSM code. This is known as fifth-digit coding. Severity is defined as 1 (mild), 2 (moderate), 3 (severe but without psychotic features), and 4 (severe and with psychotic features). An ostensible goal of any intervention is to decrease the severity of the client's distress with the objective of changing some behavior. By assessing the severity before, during, and after treatment, the fifth-digit code provides a broadband assessment of treatment effectiveness.

Well-defined, observable, and measurable treatment goals provide a number of advantages, including reducing disagreements between the client and clinician, providing direction for the treatment plan (which prevents waste of time and resources), and serving as a measure of an effective outcome (Hepworth, Larsen, & Rooney, 1997). A well-defined operational definition of the treatment goal is a necessary condition of an effective treatment plan. Moreover, it is much easier to develop a treatment plan that is likely to be effective when the treatment goal itself is well defined, explicit, and observable.

ELEMENTS OF AN EFFECTIVE TREATMENT PLAN

Once the goals are determined, the final step is to develop a treatment plan. A treatment plan is often described to clients as a roadmap whose destination is determined through mutual collaboration. Effective treatment plans have the following characteristics: (1) they provide specificity, (2) they are guided by industry standards of treatment, and (3) they evidence mutuality.

An effective treatment plan will have specificity. Specificity refers to an intervention plan with well-defined components organized in meaningful sequence. In other words, the intervention outlines a set of procedures that delineates what will occur both inside and outside the treatment setting. Sperry and colleagues (1992) identify six factors that need to be specified in treatment planning: setting (e.g., crisis, outpatient, inpatient, and day hospital); format of intervention

(e.g., individual, group, medication group, marital/family, combined treatment); duration (short-term with termination date); frequency of contact (e.g., 1 week, 2 months, 1 month, other); treatment strategy (e.g., behavioral, cognitive, supportive/reality, interpersonal); and somatic treatment (e.g., antidepressant, neuroleptic, anxiolytic).

The social worker will want to include measures for monitoring the intervention effects. An integral component of an effective treatment plan is a systematic method to monitor client change and evaluate treatment effectiveness. Thus, the treatment plan should delineate what instruments will be used to monitor the client's condition and treatment process. These observations should be systematically integrated into the intervention as regular feedback and reinforcement for progress. This added degree of specificity helps ensure that the client and social worker accurately implement the agreed upon treatment plan.

As these factors suggest, there is more to the treatment plan than just the therapeutic procedures. Even so, this is often the area of greatest concern to the social worker. It is the part of the treatment plan that tells the worker and client what to do to implement an intervention. The task is facilitated by standards of treatment that include the use of treatment manuals and practice guidelines. Manuals are typically step-by-step/session-by-session delineations of a specific treatment protocol. A practice guideline, in contrast, is a condition of treatment that appears to have sufficient empirical support to suggest it should likely be included in practice by the reasonable and prudent provider. Currently there are many published guidelines for practice with a number of mental health disorders. Several of these are available through online resources such as Substance Abuse Mental Health Services Administration (SAMHSA; www.samhsa.gov) or through compendiums published through the American Psychiatric Association.

The final characteristic of an effective treatment plan is mutuality. By this, we mean a meeting of minds between the client and the social worker about the entire enterprise of treatment. The treatment plan should reflect this as an explicit contract between the client and the social worker. This contract should show the mutuality of the professional relationship and enumerate who will do what, to what extent, under what conditions, by when, and for what purpose or goal.

Overall, social workers need to remember that there is considerable variability between different disorders (e.g., schizophrenia compared with persistent depressive disorder/dysthymia), symptom expression (e.g., remission vs. active), and functioning (e.g., serious impairment vs. moderate difficulty). There is also considerable variability for what treatment is used for different persons with the same diagnosis. For example, a person with persistent depressive disorder/dysthymia may need a cognitive intervention with skill training, whereas another may need medication and a compliance program that includes family members. The right intervention correctly implemented for the wrong problem is likely to be ineffective, which underscores the importance of monitoring client change for assessment throughout the course of treatment.

One example of how to apply the right interventions toward a multi-problem situation is illustrated in Box 68.1. This treatment plan describes the sequential elements of the treatment process discussed in this chapter. These elements begin with the assessment model (e.g., bio-psychosocial-cultural), applying the screening tools (rapid assessment instruments), formulating a diagnosis, establishing treatment goals (e.g., short- and long-term), and concluding with formulating the treatment plan (e.g., setting, format, duration, frequency, strategy, and somatic treatment).

USING THE STRENGTHS PERSPECTIVE IN ESTABLISHING GOALS AND TREATMENT PLANNING

The strengths perspective focuses on the client's abilities in the assessment and emphasizes the discovery of resources within the client and his or her environment. In this view, the strengths-based perspective has considerable value when applied to the establishment of goals and treatment planning for individuals with mental health conditions. In general, a goal must be attainable by the client, and the easiest way to do so is by using and building on the client's strengths. The process involves mutual collaboration between the provider and the client to develop goals that frame the idea of developing new expectations, constructing new opportunities for the individual and his or her family, and discovering new resources within him- or herself and the environment (Saleebey, 1997). Regardless of the diagnosis, establishing treatment goals using the strengths perspective involves finding the resources within the client, their environment, and relationships and linking these strengths to the treatment plan.

A strengths-based perspective is integrated into the treatment plan by helping clients remember how they have been successful in the past (e.g., what steps they have used), affirming previous success and abilities (e.g., coping skills), and determining what skills, behaviors, motivations,

Box 68.1 Treatment Plan for Insomnia and Generalized Anxiety Disorder.

CLIENT: RALPH C., AGE: 45

Reason for Seeking Treatment: Mr. C is a single, white male who is employed as a bus driver. He states that his employer told him to "get help or don't come back." Mr. C reports insomnia ("only sleeps 2–3 hours a night") and feeling anxious about losing his job despite previous good work performance reviews. He recently has been complaining to coworkers about his sleep deprivation and fear of wrecking the bus due to nodding off at the wheel. He attributes the sleep disturbance to increased nightly altercations with a neighbor who plays "music all

night long." He states that his work has become his life now and he has abandoned friends, leisure reading, and church-associated activities. He feels that he is in vicious cycle of "all work and no play" and cannot seem to shake off feelings of doom and dread. He reports that he does not drink alcohol or use recreational or prescription drugs and has recently quit his health club so he could concentrate on his work responsibilities.

History of Past Treatment: Mr. C has not received any mental health treatment in the past. No remarkable health history. Receives annual physical and reports no complications.

Assessment Model	Assessment Tools	Diagnosis	Treatment Goals Short Term	Treatment Goals Long Term	Treatment Plan Setting, Format, Duration, Frequency Strategy and Somatic Treatment
Bio	1) Sleep chart	1) 780.52 (G47.00) Insomnia Disorder with non-sleep disorder mental comorbidity, recurrent; (generalized anxiety disorder)	1) Stabilize nightly sleep routine	1) Maintain routine sleep cycle	1) Outpatient setting, individual treatment sessions for 8 sessions using sleep diary; refer for sleep apnea assessment; refer for medication evaluation
Psych	2) Adult DSM-5 Self- Rated Level 1 Cross- Cutting Symptom Measure: Subscale IV- Anxiety (APA, 2013)	2) 300.02 (F41.1) Generalized Anxiety Disorder (Primary)	2) Decrease anxiety	2) Maintain employing stress reduction techniques	2) Outpatient, individual treatment for 8 sessions using cognitive behavior therapy techniques
Social & Cultural	3) World Health Organization Disability Assessment Schedule: Subscale Life Activities: Work; 2.0 (APA, 2013) 4) Eco-map 5) Genogram	3) V69.9 (Z72.9) Problem Related to Lifestyle: Poor sleep hygiene accompanying neighborhood conflict and loss of leisure and social activities 4) V62.29 (Z56.9) Other Problems Related to Employment: threat of job loss	3) Encourage incremental return to social activities (e.g., church & social activities) 4) Reduce work hours for one month	3) Maintain recreation/leisure schedule 4) Return to full work schedule	3) Home setting; refer to community events calendar and health club for 1x weekly participation in leisure activities; consider neighborhood mediation after one month if residential conflict continues 4) Employee worksite (e.g., bus and in office), use of Job Coach as part of company Employee Assistance Program to conduct observation and provide feedback of client activities for one month

and aspirations can be applied to bring the desired change. Together, client and provider search the environment for forces that enhance life chances while supporting client self-determination and personal responsibility (Saleebey, 1997). In summary, the strengths-based model is useful when applied to the particular goals and treatment approach to attain these goals. Goal-attainment plans that make use of a client's strengths capture a natural nexus that enhances the likelihood of treatment success.

CONCLUSIONS

The establishment of treatment goals and treatment plans is an integral part of a process that begins with assessment and diagnosis. Those goals and treatment plans enhance the likelihood that clients will change. This objective is facilitated by following five guidelines.

1. Treatment goals and treatment plans require a thorough biopsychosocial-cultural assessment and accurate diagnosis of the problem.
2. The treatment goals must be specified in observable terms at the beginning of treatment.
3. The intervention is determined by the goals and should have specific criteria for accomplishing the goals.
4. The intervention should be planned and include a well-explicated delineation of what will occur and when over the course of treatment.
5. The treatment goals and treatment plan should form the explicit contracts for helping clients change and should be implemented according to mutually agreed-upon parameters of the plan.

These guidelines form a rough sequence of the treatment process and help the social worker effectively and efficiently assist clients.

Treating Problem and Disordered Gambling

Often a Hidden Behavioral Addiction

Cathy King Pike & Andrea G. Tamburro

Gambling money or other valuable assets to such an extent that it interferes with normal, daily life has been labeled as “problem gambling” or “pathological gambling” in the past. Currently, the term “disordered gambling” is used to identify substantial problems with relationships, work, school, or other important life roles that are impacted by gambling (American Psychiatric Association, 2013). Because the earlier terms often have been used interchangeably and the current term changed recently in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)*, “problem gambling,” “pathological gambling,” and “disordered gambling” will be used interchangeably in this chapter.

Disordered gambling can have devastating consequences for the individuals who exhibit these problems, as well as for their families and communities. Consider the following case descriptions of actual individuals who developed disordered gambling that led to substantial and sometimes extreme consequences.

- Mr. Greg Hogan, Jr. was an outstanding student at Lehigh University (ABC News Internet Ventures, 2013). He was class president. His father was a minister. On the day that he robbed a bank, Mr. Hogan reported that he had lost \$8,000 through gambling, which was all of his savings, and had overdraft and bank fines of \$1,000 at his bank (ABC News Internet Ventures, 2013).
- In California, Mr. George Shirakawa, Jr. was convicted of 12 counts of criminal activity for misappropriating funds from the coffers of Santa Clara County (Seipel, 2013). Mr. Shirakawa said, “For years, I have suffered from depression and a gambling addiction . . . Unfortunately, my gambling addiction went untreated for too long, which led to bad decisions and actions that I deeply regret” (Seipel, 2013, paragraph 3).
- Sister Mary Anne Rapp, a Roman Catholic nun for more than 50 years, was convicted of grand larceny for stealing almost \$130,000 from parishioners’ donations (Crimesider Staff, 2013). Sister Rapp was charged after a routine audit was conducted (Kuruville, 2013). Sister Rapp reported that she had used the money to support her gambling habit (Kuruville, 2013).
- A 10-day-old baby, Joy Baker, died in South Carolina, because she was left by her mother in a locked car in more than 90-degree heat for approximately seven hours while her mother played video poker (Holland, 1997). Joy’s mother, Sgt. Gail Baker finally stopped playing after her husband came to the casino about 9:00 P.M. to ask her to return home (Associated Press, 1999). Worried that her husband was angry with her, Sgt. Baker drove around a bit before returning home (Associated Press, 1999). It was only after arriving home that Sgt. Baker realized that her baby had died (Associated Press, 1999).

These brief case presentations document the tragic and sometimes fatal results of disordered gambling. In some cases, family members or friends knew about individuals' disordered gambling. For instance, it is clear that Mr. Hogan's father was aware of his son's disordered gambling, because he had earlier required his son to receive counseling for his gambling problem and had telephoned his son's college to determine whether there were other options available to help with his son's gambling problem (ABC News Internet Venture, 2006, July 25). Sgt. Baker's husband knew where to find her on the night of their infant's death, and Sgt. Baker delayed going home because she was afraid to face her husband's anger about her having played video poker (Associated Press, 1999).

In other cases presented above, there is no evidence that family or friends were aware of individuals' gambling problems until the ultimate crisis or discovery. It is important to note that problem and disordered gambling occurs across varying developmental stages, socioeconomic statuses, professions, educational levels, gender, and ethnic and cultural backgrounds. This is how problem or disordered gambling has become labeled as a *hidden* addiction and why social workers should screen for problem or disordered gambling as a potential co-occurring condition when conducting client assessments. The purpose of this chapter is for social workers to learn

- How disordered gambling is defined
- The incidence and prevalence of disordered gambling
- How sociodemographic characteristics are related to gambling and to specific types of gambling
- How to use screening tools to identify and facilitate assessment of problem gambling
- To identify and apply effective treatment options for problem gambling.

DEFINITIONS, INCIDENCE, PREVALENCE, AND SOCIODEMOGRAPHIC CHARACTERISTICS

Definitions

The current *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (2013) (*DSM-5*) defines a gambling disorder (312.31) as a Non-Substance-Related Disorder that reoccurs and is a persistent gambling problem

leading to "clinically significant impairment or distress, as indicated by an individual exhibiting four (or more) of the . . . [nine criteria] in a 12 month period" (p. 585). Notice that the criteria have decreased from 10 in the *DSM-IV* to 9 with the *DSM-5* (Strong & Kahler, 2007). Levels of gambling problems refer to the number of criteria that are met for a given individual. Someone with a mild gambling disorder may meet only four or five of the criteria, most often including being preoccupied with gambling and trying to win back losses (*DSM-5*, 2013). A person having a moderately severe gambling disorder will exhibit six or seven of the criteria, including lying and stealing to continue gambling. Someone exhibiting the most severe gambling disorder will meet eight or all nine of the criteria, including seeking financial help from family and friends (*DSM-5*, 2013). Gambling problems also may be associated with distorted thinking including "denial, superstitious, a sense of power and control over the outcome of chance events, [and] over confidence" (*DSM-5*, 2013, p. 587). The *DSM-5* also identified some people with gambling disorders as "impulsive, competitive, energetic, restless, and easily bored . . . overly concerned with approval of others and generous . . . when winning" (2013, p. 587).

Not everyone who gambles can be considered to have a problem or be diagnosed as a disordered gambler. Some researchers have included the category of "subclinical" in their analyses; these are people who, at between one and four, meet less than the minimum number of gambling criteria identified in the *DSM 5*, and therefore, cannot be diagnosed with a gambling disorder using the *DSM-5* criteria (*DSM-5*, 2013). In earlier research, individuals who now might be labeled as "subclinical" were considered as transitioning in or out of problem levels of gambling (Nower & Blaszczynski, 2008). However, current research indicates that the progression of disordered gambling may take a variety of paths, including never transitioning to disordered gambling (Nower & Blaszczynski, 2008).

Incidence and Prevalence

According to the *DSM-5* (2013) based on past-year gambling, .2% to .3% of the U.S. population was diagnosed with a gambling disorder. The rate of lifetime prevalence of gambling disorder is .4%

to 1% (*DSM-5*, 2013). The lifetime prevalence rate for men in the United States was .6%, and for women the rate was .2% (*DSM-5*, 2013). African Americans had the highest percentage of gambling disorders with a prevalence of .9%, for whites the prevalence was .4%, and for Hispanic people about .3% (*DSM-5*, 2013). The gambling disorder percentages for Asian and Native American people were not included in the *DSM-5*. Five percent of the population met one to four of the *DSM-IV* criteria for problem gambling, falling into the subclinical category (Blanco, Hasin, Petry, Stinson, & Grant, 2006).

The gambling industry is a *multi-billion dollar* business in the United States. According to the American Gaming Association (2013), the casino industry gained \$37.34 billion in revenues during 2012, a steady rise from \$28.72 billion in 2003. According to the National Gambling Impact Study (1999) between 1975 and 1999, the revenues multiplied exponentially from \$3 billion to \$58 billion and included newer forms of legalized gambling. Over time, access to legalized gambling has changed dramatically. The National Gambling Impact Study (1999) reported that Nevada was the only state in the United States with legalized gambling from 1900 to 1960. People now have access to gambling through their cell phones, the Internet, casinos, lotteries, and machines at the local gas station or bar, as well as through off-track betting. Instead of limiting access, now 20 states have some form of legalized gambling (American Gaming Association, 2013). Two states currently offer Internet gambling to their residents (American Gaming Association, 2013).

Sociodemographic and Personal Characteristics Related to Gambling

A variety of sociodemographic and personal characteristics are related to disordered gambling. In comparison, the list of characteristics that predict less frequent gambling is very short, according to one study (Hodgins et al., 2012). A large study based in Canada found that individuals who were older than the typical sample age, those with relatively higher intelligence, and those who reported higher levels of religiosity gambled less frequently. However, Barnes, Welte, Hoffman, and Tidwell (2010) found that whether or not individuals were in college “did not predict gambling, frequent gambling, or problem gambling” (p. 443).

The Hodgins et al. study (2012) identified the following list of characteristics that predicted more frequent gambling: being male, being single, exposure to gambling within one’s family of origin, the tendency toward excitement-seeking, alcohol or other substance abuse, and a variety of mental health issues. Fully a quarter of the participants in the Grall-Bronnec et al. (2011) study had a history of attention deficit hyperactivity disorder (ADHD). According to the authors, individuals with a history of ADHD “were characterized as having more severe gambling problems and a higher level of gambling-related cognitions, a higher frequency of psychiatric comorbidities and an elevated risk of suicide” (p. 231). Dion, Collin-Vezina, De La Sablonniere, Philippe-Labbe, & Giffard (2009) found that having a history of child sexual abuse was related to gambling disorders but noted that the link is “complex and indirect” (para. 1). A systematic review of 11 studies (Lorains, Cowlishaw, & Thomas, 2011) found the following comorbidities: “nicotine dependence (60.1%) . . . substance use disorder (57.5%) . . . mood disorder (37.9%) . . . and any type of anxiety disorder (37.4%)” (p. 490). Hodgins et al. (2012) concluded that “having any mental disorder may make an individual more vulnerable to a gambling disorder” (p. 2438, 2440). Other sources (*DSM-5*; Larimer et al., 2011) cite increased risk of suicide, poor health, occupational problems, financial difficulties and problems among family and friends as related to problem gambling.

In the past, men engaged in many different forms of gambling, such as real estate, the stock market, sports, cards, casinos, and races. Volberg (2003) reported that white male problem gamblers gambled on lotteries, bingo, machines, pari-mutuel games of chance, and through private arrangements. Minority males who were problem gamblers used these forms of gambling more frequently than white males. Blanco, et al. (2006) reported that men who were diagnosed with pathological gambling preferred gambling on roulette, sports games, and stocks or commodities.

Women have begun gambling more frequently than historically has been the case (Gavriel-Fried & Ajzenstadt, 2011; Volberg, 2003). Safer, legal gambling has become more accessible (e.g., bingo halls, lotteries, and gambling machines in restaurants and stores). Some casinos now provide child care facilities (Conner, 1996), making gambling even more accessible

to women with child care responsibilities. In the United States, women diagnosed with pathological gambling were reported to prefer slot or video machines and bingo or keno significantly more than men (Blanco et al., 2006).

In general, youth are more at risk of problem gambling because they are less likely to have the impulse control of more mature individuals (*DSM-5*, 2013). Likewise, Shaffer and Hall (2001) found that adolescents and college youth are at significantly higher risk of gambling problems, perhaps due to risk-taking behaviors. Cell phone and Internet use have increased access to certain types of gambling, including access to pari-mutuel betting and lotteries (Petry, 2006). Further, teens who engage in Internet gambling are more likely to have a serious problem with gambling than other people who gamble (Petry, 2006). Teens who gamble on the Internet experience a greater frequency of physical health problems, circulatory problems, substance abuse, depression, and risky sexual behaviors than other teens (Petry, 2006). Youth are impacted by the availability of gaming on the Internet, including what is referred to as an “internet addiction,” which Young (2009) considers closely tied to problem gambling.

According to Blanco et al. (2006) men, especially younger men ages 18–29 years were significantly more likely to fall into the subclinical pathological gambling category than women, but women were more likely to fall within the subclinical category at age 65 or older. Men in the subclinical category were more likely to have never been married. Significantly more women in the subclinical category were within the lowest income bracket, but the men more often earned \$35,000 or more than the women (Blanco et al., 2006). In the subclinical category, men smoked and drank more often. Men were more likely to be diagnosed with lifetime drug and alcohol use disorders. According to Blanco et al. (2006), women in the subclinical category were more often diagnosed with either a mood or anxiety disorder. Several other studies have explored the gambling patterns of women, identifying multiple reasons for problem gambling including depression, personal pressures, a desire for reward, a need for personal space, and boredom with one’s personal lifestyle (Gavriel-Fried & Ajzenstadt, 2011; Hing & Breen, 2001; Schull, 2002). Hing and Breen (2001) found that some older women problem gamblers had experienced a loss of their roles as caregivers. Schull (2002)

characterized younger women problem gamblers as overwhelmed and stressed by responsibility.

SCREENING TOOLS

With the dramatic proliferation of the availability and types of gambling and the almost unlimited access to gambling, one may suppose that agencies routinely screen for gambling problems among their clientele. This does not seem to be the case. Only two studies were located in the literature review that examined screening practices related to problem gambling. One study found that “more than three-quarters of respondents had not sent staff for training in screening or treating gambling disorders, did not screen for problem gambling, did not treat problem gambling, and did not refer clients to other agencies for treatment of gambling-related problems” (Engel, Rosen, Weaver, & Soska, 2010, p. 611). The second study examined graduate-level curricula in social work in relation to assessing and treating problem gambling. In that study, nearly two-thirds (61.6%) of the programs responded that they did not have content in the curricula for the treatment of problem gambling (Engel, Bechtold, Kim, & Mulvaney, 2012). Among the reasons cited for the lack of gambling assessment and treatment content within the curricula were “a lack of faculty expertise, low-priority content, and the lack of interest in gambling-related issues” (Engel et al., 2012, p. 321).

Because problem gambling frequently is associated (comorbid) with many mental health diagnoses, it is important for social workers to screen routinely for gambling problems. There are many tools that can be used for screening purposes. Some of these are self-administered tools that can be accessed online and are available for download. Some are available through the literature on problem gambling. This section, however, will highlight several of the free, online screening resources that are available to anyone, and will provide information about the strengths and weaknesses of various resources identified within the literature.

The National Council on Problem Gambling (NCPG) (see Table 69.1, #1) includes a self-administered screening tool that is based on earlier research by the National Opinion Research Center (NORC). The tool used here initially was developed for use with the general population and was found to be reliable and valid

for this population (Gerstein et al., 1999). This screening tool, the NORC Diagnostic Screen for Gambling Problems—Self Administered (NODS—SA), includes 10 questions that relate to preoccupation with gambling, lack of control of gambling, relationship problems related to one's gambling, and using gambling as an escape mechanism (Table 69.1, #2). After completion of the screen, test-takers are provided information about the meaning of the various scores.

The Division on Addiction, Cambridge Health Alliance, a teaching affiliate of Harvard Medical School, provides access to a screening tool that was developed by Gebauer, LaBrie, and Shaffer (2010). This instrument, the Brief Biosocial Gambling Screen (BBGS) contains three items that measure restlessness or irritability when trying to cut back on gambling, lying about gambling to friends or family, and financial troubles related to gambling. In addition, respondents are asked to answer a question about their readiness to reduce gambling (Table 69.1, #3).

In addition to the above two websites, a screening tool can be found at the Gamblers Anonymous website (Table 69.1, #4, 5). This screening tool is self-administered and contains 20 questions related to problem gambling. It should be noted that no known research studies have been conducted to determine the reliability and validity of this tool.

A rather lengthy gambling screening tool is located on the "Check Your Gambling" website (Table 69.1, #6). This website is based in Canada and offers a five-page questionnaire that contains questions about types of gambling activities, the largest amount gambled at one sitting, gambling strategies, and a number of questions related to cognitive distortions about gambling (Table 69.1, #7). It is unclear whether or not this tool has been tested for reliability and validity.

In contrast to the longer screening tool above, the "Lie-Bet Tool" (Johnson et al., 1988) contains only two items. This screening tool was developed to address the need for simple, expedient, and effective screening for problem gambling (Johnson et al., 1988). These items ask respondents about the need to bet increasingly greater amounts of money and lying about their gambling (Table 69.1, #8).

Volberg, Munck, and Petry (2011) reviewed several gambling screening tools that have been used in the past and conducted research on those questions most likely to identify gambling problems. Among some of the weaknesses that they

noted in the screening tools discussed above were "the number of items, the domains assessed by the items, the lack of clinical validation of the underlying measure, and poor performance in clinical settings" (p. 220). In this high-quality study, the authors compared a 3-item subset of the earlier 10-item NODS Screen. They found that the 3-item subset correctly identified 99% of people who already had been classified in separate assessments as pathological gamblers and 94% of those assessed as problem gamblers. These items were labeled as the "NODS-CLiP" to indicate that the questions were related to "Loss of Control, Lying and Preoccupation" (p. 221). The authors found the NODS-CLiP performed well in this clinical sample in identifying problem and pathological gamblers, but it also captured some low-risk and subclinical gamblers. However, one set of four items had "better psychometric properties in (the) clinical sample . . . with somewhat higher sensitivity (99.7%) and positive predictive power (88.5%) and substantially higher negative predictive power (96.3%)" (Volberg, Munck, & Petry, 2011, p. 225). The authors labeled this subset of items the NODS-PERC, because it captured information about clients' "Preoccupation, Escape, Relationships, and Chasing" (p. 225), in problem gambling (Table 69.1, #9).

Characteristics of effective screening tools include the following: (1) consistency over time in identifying problem or disordered gambling; (2) accuracy in identifying problem or disordered gambling (i.e., sensitivity and positive predictive ability); and (3) ability to rule out individuals not having problem or disordered gambling (i.e., high negative predictive ability). One can think of the latter two of these characteristics as a screening tool having low false positives and low false negatives. In other words, a good screening tool consistently identifies problem or disordered gambling, has few instances where individuals are identified as having problem or disordered gambling when they, in fact, have no such problem, and has few instances of not identifying problem or disordered gambling when, in fact, problem or disordered gambling does exist. Taking these factors into account in evaluating the screening tools discussed above, the NODS-PERC performs better than the other methods discussed.

Social workers, however, should keep in mind that these are meant to be *brief* screening tools for use at assessment. Once problem or disordered gambling is identified, social workers will need to

explore further the specific nature of clients' problem or disordered gambling as an essential aspect of a comprehensive assessment. Problem gambling and disordered gambling arise from a variety of bio-psychosocial contributing factors. For instance, sheer accessibility to gambling may be a major factor in a sudden increase of disordered gambling in communities having had no or limited prior access to gambling. Nower and Blaszczynski (2008) discussed several contributing factors related to disordered gambling. Among these are the lack of comprehensive community approaches to reduce the incidence of disordered gambling, neurobiological responses to gambling, and the combination of a variety of preexisting states that are "either hypotensive (depressed) or hypertensive (anxious)" (p.1850) in combination with disordered cognitions and the need for escape.

TREATMENT OPTIONS

Treatment for disordered gambling should take into account the preexisting states and triggers that may have aided in establishing the disorder. These may include a variety of personal and emotional factors, mental health disorders, substance abuse, and individual and/or family problems. The Centre for Addiction and Mental Health (CAMH, 2008) published a treatment guide for problem gambling and recommended that the following approaches be used in treating disordered gambling: brief solution-focused approaches, harm reduction approaches for those who want to continue gambling but also want to limit its consequences, motivational interviewing, and cognitive and behavioral techniques. The CAMH (2008) also recommended that practitioners assist clients to (1) deal with their feelings, (2) address any unmet physical health problems, (3) work with clients to improve family relationships, (4) find a balance in their lives, and (5) develop strategies to prevent relapse (Table 69.1, #10).

Self-help Gambling Anonymous (GA) groups, similar in structure to Alcoholics Anonymous (AA) groups, are available in many locations to individuals with disordered gambling. In the literature, the findings on the efficacy of this approach when used alone, however, have been mixed. Petry, Litt, Kadden and Ledgerwood (2007) compared a comprehensive Cognitive Behavioral Therapy (CBT) intervention and GA referral alone and found

that participants who had the CBT intervention "reduced their gambling and gambling problems significantly (more) . . . than those assigned to a treatment condition consisting of GA referral alone" (p. 1287). Petry et al. (2007) found that "only about 10% of attendees become actively enrolled in the (GA) fellowship" (p. 5).

Boughton (2003) suggested that GA is more male-oriented and, in her study that used a feminist approach to the study of gambling treatment, found that many women did not feel welcome or supported in the GA environment. She discussed the variety of ways that women experience gambling that may be different from men's experiences with gambling. These included aspects related to women's experiences in society: in relationships, as caregivers, and less self-oriented approaches to dealing with personal stress and escaping stress. Important aspects reported by Boughton (2003) in treating women with gambling disorders were helping women to (1) develop support mechanisms that acknowledge women's unique experiences, (2) reconnect socially and replace gambling with meaningful activities, (3) deal with any comorbid disorders, (4) address any histories of abuse or trauma, and (5) deal with financial concerns.

Much of the literature suggested that a multidimensional approach is best-practice for treatment of gambling disorders. Larimer et al. (2011) found that both cognitive behavioral and a personalized brief motivational feedback were effective interventions with U.S. college-aged students. Nower and Blaszczynski (2008) suggested the following treatment interventions: "specific gambling-related cognitive-behavioral interventions supplemented by broader stress management, problem solving, and affect regulation . . . [to] boost the process of recovery . . . [and] . . . [improve] quality of life and personal development" (p. 1858).

CONCLUSION

In summary, problem and disordered gambling can have dramatic and tragic effects on the lives of individuals, families, and communities. These effects are not likely to diminish, given the dramatically increased types of gambling and the ready access to them. Social workers are uniquely situated to identify and intervene with clients having problem or disordered gambling. In doing so, it is important to remember the following points from this chapter:

- Gambling disorders are “equal opportunity” addictions and disorders, affecting individuals across socioeconomic and other statuses.
- A variety of personal factors may combine in complex ways to develop and perpetuate problem disordered gambling, including co-occurring disorders.
- Routine screening for problem or disordered gambling should occur during in-take or assessment and these tools can be very brief, as well as highly effective.
- Treatment for problem and disordered gambling should be individually based, taking into account clients’ gambling “triggers,” mental health diagnoses, and other personal characteristics.
- Multidimensional treatment is highly recommended, especially when it makes use of a variety of intervention strategies that match the needs of clients.

Developing Therapeutic Contracts with Clients

Juliet Cassuto Rothman

Contracts are agreements between parties that define and describe the nature of the relationship between the parties, including the responsibilities of each and the penalties that may accrue should one or more of the parties fail to keep the terms of the agreement. To be valid, contracts must be entered into freely by all parties. They may be formal or informal, verbal or written, or simply understood by all parties. They have been used since the beginning of recorded history, and can be adapted to many fields, such as government and politics, economics and business, and cultural and social settings.

In social work, therapeutic contracts are an essential element in working with clients. They provide a framework for focusing and goal setting, clarify roles and expectations, set time frames, and are helpful in evaluating progress and reviewing expectations. Like all contracts, contracting in social work is a voluntary joint effort, and provides a source of accountability in evaluating client change, as well as the efficacy of programs and services. Contracts have a specific form, which includes an overarching goal; a set of objectives that are both measurable and time-specific; specific interventions, which include tasks for both clients and workers; and a method of evaluation to determine the accomplishment of objectives. Contracts can be adapted to meet the needs of clients of all ages, cultural milieus, abilities, and concerns in all contexts of practice. A review of recent literature on the use of contracting in social work contexts finds that it includes individuals, families, teens, foster care families, mental hospitals, health clinics, substance abuse services, nursing homes, therapeutic groups, communities, and prisons.

Contracting in social work has a long and not uncontroversial history. However, modern social work practice, with its focus on accountability, has made contracting an integral part of the therapeutic process. Social workers have several contractual relationships as professionals that precede those with specific clients. Contracts with employers, with programs and funding sources, with insurance companies, with the social work profession, and with society as a whole direct, define, and often limit the therapeutic contract. As one of the essential components of the social work processes, therapeutic contracting is most commonly used in work with individuals, children, couples, families, and therapeutic groups.

Contracting with clients supports the profession's values and mission. Respect for the dignity and worth of the person, the importance of human relationships, and integrity are core values supported through the process of contracting. Core Competencies necessary to effective social work practice include "develop(ing) mutually agreed-upon intervention goals and objectives and select(ing) appropriate intervention strategies" (Council on Social Work Education [CSWE], Core Competencies).

The process of contracting is a powerful relationship-building tool; it empowers clients, focuses on client strengths and resources, and supports informed consent and self-determination. Alcabes and Jones (1985) state that prior to contracting, clients are not "clients" but "applicants," and the contracting process itself socializes "applicants" into their new role as "clients." Thus, the contract becomes the concrete symbol of the mutual commitment of client and worker to addressing and ameliorating the client's needs.

The process of contracting continues throughout the time that the client is receiving service, although the specific kind and content of the contract may vary (Hepworth, Rooney, & Larsen, 1997). Although, as noted above, contracting occurs in work with groups as well as with individuals, for clarity of concept development the discussion here will focus on individuals.

A TYPOLOGY OF CLIENT CONTRACTS

Three very different kinds of contracts are used with clients in social service settings, generally in the following order, from broadest to most specific.

The Service Contract or Service Agreement

Clients generally enter into *service contracts* at the point of contact. Service contracts commonly include (1) the agency's mission; (2) a description of the agency's programs and services; (3) time frames for the provision of services; (4) fees for service or arrangements for reimbursement; (5) policies on confidentiality, both within the agency, such as with supervisors or colleagues, and outside the agency, such as with other agencies serving the client, or with funding sources; (6) right of access to files, which may include the HIPPA regulations and how these will be applied; (7) releases for video- and tape-recording; and may also include (8) release of information forms (Rothman, 1998). Clients agree to respect agency policies, keep appointments, and use services appropriately. Service contracts are between a client and a service provider. They are *not* between a client and a specific worker. The client has come to the agency for service, not to the individual social worker, and the initial relationship is defined in this way. Workers in private practice may create service contracts for their practice by including many of the subjects just noted in a general policy statement for new clients. The worker is responsible for ascertaining that the client has understood the terms of the contract prior to initiating service.

Service agreements are often hastily read and signed by clients with minimal explanation or opportunity to ask questions. It is recommended that worker and client review the provisions carefully early in the relationship to clarify any parts that are unclear to the client. Where a client

does not have, or has only limited English proficiency, it is essential that arrangements be made to provide the service contract information in the client's language. Accommodations for clients with disabilities also need to ensure accessibility to service contract provisions. Clients who are minors may need to have contracts signed by parents or guardians to access certain kinds of services.

The Initial Contract

Initial contracts, developed with or immediately following the service contracts, simply state that worker and client agree that they will explore together whether worker and setting can assist the client to meet his or her goals. The work of this phase of service provision, which flows from the initial contract, includes gathering, sharing, and assessing information; defining the needs and concerns; developing potential desired outcomes; and exploring whether the agency can provide the needed resources. Initial contracts include time frames that are often defined by the setting, the funding source, or the program. This phase of the work can generally be completed in three interviews if the time frame for the entire process is about 12 to 15 weeks. Because involuntary and mandated clients often do not willingly seek services, motivational and relationship-building processes may require additional time, because it is essential that clients understand that they have a choice about entering into treatment and options about goals and objectives.

Unlike service contracts, initial contracts are often quite informal. However, it is recommended that the worker carefully document all of the terms and conditions of the initial contract, and, if possible, have the client sign or initial that he or she has agreed to the terms specified.

Content suggestions for initial contracts include (1) meeting times, number of meetings, and location; (2) a review of confidentiality guidelines; (3) an assurance that client is stable and safe, and an agreement about any immediate actions that must be taken; (4) a determination of who will be contacted for information gathering, by whom, and why; (5) a clarification in the client's own words of the reason the client is seeking help at this time; (6) and a discussion of any known policies, guidelines, or rules that may directly impact the client (Rothman, 1998).

During this initial period, "belief bonding"—the process through which client and worker

come together—has occurred; this is a necessary precondition to the development of a successful and viable therapeutic contract (Bisman, 1994). “Belief bonding” occurs when a social worker’s competence has been established, worker and client have agreed that change is possible, and the client has been seen as worthy of their joint efforts in effecting the change that both believe can occur (Bisman, 1994).

The Therapeutic Contract

The therapeutic contract builds directly on the service and initial contracts. These provide the general guidelines, information, and resources necessary for the development of a therapeutic plan. Therapeutic contracts are the blueprints for the change process that will occur. They are generally formal, written, and signed by both worker and client; variations should be considered, however, if they are appropriate to specific client needs.

In determining an appropriate theoretical framework and practice methodology for the therapeutic contract, workers may actively engage clients in the process of selection, use a personally preferred framework and practice method, or use the ones preferred by the agency. Clients should be made aware of the framework and methodology to be utilized. Choice of these will guide goal setting, as well as the development of objectives and interventions, and should be an integral part of the process of contracting. Although cognitive-behavioral and task-centered objectives and interventions may be easier to develop owing to the format of the contract, any theoretical framework and practice methodology appropriate to social work will adapt well to the contracting process.

It is also essential that therapeutic contracts be culturally sensitive and support the values and belief system of the client. Contracts developed without such sensitivity can cause additional stress to the client and be a major barrier to long-term success. This requires both sensitivity and self-awareness on the part of the social worker, and agency policies that support and respect the client’s cultural milieu and worldview. Ethnographic interviewing may be very helpful in this process, and can be a part of the initial relationship-building and assessment process, so that goals, objectives, and interventions more clearly reflect the client’s cultural experiences and concerns.

THE DEVELOPMENT OF THE THERAPEUTIC CONTRACT

Therapeutic contracts have four distinct parts: (1) an overarching goal; (2) several objectives; (3) interventions, treatments, or tasks that will fulfill the objectives; and (4) a mechanism for review and evaluation of the contract. In writing the contract, it is important to use language that is clear and comfortable for the client; professional jargon should be carefully avoided.

Contracts themselves should be separate from the main body of recording and progress notes. A clear and simple format is best. The form provided in Figure 70.1 can be adapted as needed to reflect both the client’s language and concerns and the agency’s context of services and programs. Suggestions are offered for forms of intervention; these can be used as appropriate to the objective.

To illustrate the development and functioning of therapeutic contracts, we will consider Peter, a client with a history of mental illness, who is about to be discharged from a recent hospitalization. Peter has difficulty in maintaining his medical regimen, has no known family support, is fearful and untrusting of social workers, and wants to return to the community. He has been referred to a community mental health agency. We shall follow Peter through the phases of contract development, assessment, and evaluation.

Step 1: Goal

The overarching goal is generally broad and inclusive. For Peter, this might be stated as “return to community” or, later, “remain in community setting.” There should be only one overarching goal; more would diffuse the focus of the work, and the goal selected should be broad enough to encompass many possible objectives and remain valid over time.

Step 2: Objectives

Each objective must include three related parts: (1) an action statement, (2) a time frame, and (3) a method for measuring success or failure. The form “*Action as evidenced by Measurement in Time Frame*” can be used. Other wording may be substituted as desired commensurate with client needs and preferences.

Name: _____

Overarching Goal: _____

Date	Objective	Interventions	Date	Evaluation
	(For each objective) #1 _____ (Action) in _____ (Time Frame) as evidenced by _____ (measurement)	(For each intervention) (Client, worker, client and worker, other entity) will do _____ (what). # 1. _____ # 2. _____ # 3. _____ # 4. _____ (Numbers will vary by what needs to be done)		Comment about objective and interventions #1 _____
		(Continue to list objectives and interventions)		

Client Signature: _____ Worker Signature _____ Date _____

Figure 70.1 Action in time frame.

The following guidelines will assist the client and worker with this task.

- Objectives should always be reflective of the client's values, worldview, and personal motivation, and should support the overarching goal.
- Objectives should be reasonably few in number: too many objectives can be overwhelming, or can diffuse the client's energy such that nothing is achieved. Too few objectives can severely limit options for action. Three or four is generally a good number to develop.
- Objectives should be reasonably simple, specific, and written using the client's own words.
- Objectives should be measurable and achievable in the specified time frame. Time frames can vary for each objective within the contract. However, they should be designed so that the contract is reviewed at least every three months to maintain continuity and evaluate progress.
- Objectives should be ordered in time. If one is necessary before another can be achieved, it should be placed first.
- Objectives should be ordered by priority. If a client is strongly motivated toward one objective, or one is more urgent than another, place the more vital one first.
- Objectives should be achievable with reasonable effort. Success with achievable objectives will inspire and motivate clients, while those that require major life changes and complex or difficult actions will be discouraging, will not be achieved, and will reinforce a client's sense of failure and low self-esteem (Rothman, 1998).
- Complex, global objectives should be broken down into several smaller, more specific objectives in order to facilitate achievement.

Possible objectives for assisting Peter to return to community setting might include:

1. *Assess housing resources in the community* (action) as evidenced by *the development of a list of possible housing* (measurement) in *1 week* (time frame)
2. *Arrange follow-up medical care in the community* (action) as evidenced by a

written agreement with a community health clinic (measurement) in *2 weeks* (time frame)

3. *Attend one community support group meeting* (action) as evidenced by *support group sign-in sheet* (measurement) in *2 weeks* (time frame)

Step 3: Interventions

Interventions are developed to support *each* objective. They are the *who* and the *what* of the contract. The *who* is generally the worker or the client, but it may be another person or group—a parent, siblings, friends, or another professional. When a person or persons in addition to the developers of the contract will be necessary for successful objective achievement, they should be consulted, and agree to both the actions that involve them and the time frames specified. The *what* describes what the person will do. Interventions often use the form *who* will do *what*.

Possible interventions for Peter's second objective might include the following:

- *Worker* (who) will *locate health clinics* (what) in the community that can serve Peter.
- *Worker and Peter* (who) will *review list and select a health clinic* (what).
- *Worker* (who) will *arrange appointment* (what) for Peter at health clinic.
- *Peter* (who) will *request his medical history* (what) from the hospital.
- *Peter* (who) will *take medical history to the clinic* (what) at the appointed time.

Because the therapeutic contract is a joint enterprise, it is vital that both worker and client have responsibility for interventions. If all of the defined tasks are for one person, the worker-client alliance will be minimized. It is not necessary, however, that there be an equal number of tasks for each person. This is a joint process for client and worker.

It is also important to consider the client's cultural context in the development of intervention strategies. These should support empowerment, maintenance of culture, and the unique personhood of the client. Cultural resources should be explored and considered when appropriate. It is

essential to recognize, however, that cultural attitudes and beliefs may not always support client objectives. In Peter's case, it is important to recognize that it may not be appropriate to involve cultural resources if Peter does not identify with the culture, chooses to separate from his cultural group, or if his culture's understanding and beliefs about mental illness would not support his overarching goal.

Goals, objectives, and interventions together form the therapeutic contract. The remaining piece, the evaluation or assessment, is completed when the contract is reviewed upon completion of the time frames, or upon the achievement of an objective, and is presented below.

THE THERAPEUTIC CONTRACT AS A DYNAMIC, EVOLVING SYSTEM

The therapeutic contract is an ongoing assessment tool in the therapeutic process. Each objective has several possible outcomes: (1) it is achieved, (2) it is not achieved, (3) it is partially achieved, or (4) it is unachievable for various reasons.

Achieved Objectives

When an objective is achieved, it should be noted on the contract in the "evaluation" column with the date of the review. It is best if the objective and interventions are not removed, because achievement can serve as a positive reinforcement for both client and worker. Crossing out, highlighting, or writing "achieved" across the objective allows it to remain as a testimony of success. A completed objective is an opportunity for the development of a new one. The new objective can build on the old or develop a new line of action in addressing the client's needs. If more than one objective is achieved, several new ones may be added during a review. New objectives should support the overarching goal that was defined when the original contract was developed.

Objectives Not Achieved

Objectives may not be achieved owing to difficulties in any of the three sections of the objective statement, development of the tasks and interventions, or external factors. Careful examination

and exploration by worker and client can locate and possibly amend the objective so that it may be achieved in another form. If, after review, it is found that the objective cannot be met, it should be discarded and replaced.

Problems with Objective Statement

- *Problems with the action.* Actions that are not possible due to physical, psychological, emotional, or social barriers will not support the success of an objective. For example, Peter's stated goal is to return to the community. An objective that states "Arrange placement with brother in Miami" when Peter lives in Phoenix does not address the client's stated wishes and desires and thus cannot be successful. An objective that states "Locate a bed in a group home for Peter" will not be met if there are no group homes in the area being considered.
- *Problems with the time frame.* Time frames must be reasonable and appropriate to the difficulty and complexity of the objective. Setting time frames that are too short will frustrate client and worker alike, and cause the objective to fail. Time frames that are too long can result in loss of motivation, interest, or impetus.

"Locate housing in the community for Peter within 3 days" may be setting too short a time frame, whereas "3 months" might be too long for this task. The worker must use knowledge of the community, the client, and resources to develop a time frame that permits achievement of the objective.

Worker and client may reassess and extend the time frame. Time frames should not be extended more than one time. If the problem persists, the objective should be reformulated or rephrased.
- *Problems with the measurement criteria.* There are times when the measurement criteria may measure something, but not necessarily the success of the objective. For example, Peter needs monitoring of his medication regimen. This activity has been addressed as the objective "Compliance with medication regimen as noted by worker for 1 month." The action and the time frame are appropriate, but how will the worker "measure" Peter's compliance without testing or medical monitoring?

“Locate housing in the community as evidenced by Peter’s placement in a community setting” has similar problems in measurement. Housing may be “located,” but Peter may refuse to go, or the hospital may decide he is not ready for release, or there may be a waiting list in the housing complex. “Locate” means something quite different than “placement.”

- *Problems with interventions, methods, or tasks.* Objectives may not be achieved if the interventions selected to achieve them are not adequate or are not related to the objective. For example, the objective “Worker and client will develop a plan for Peter to return to the community in 1 week” cannot be achieved through the task of “Exploring activities available in institution,” or even by “Contacting sister in Alaska,” much as that sister might be a support to the client.

The objective “Client will visit a halfway house with the social worker in 2 weeks” cannot be achieved with an intervention plan that sets up visits to day treatment centers rather than halfway houses. If these are to be included in planning, the objective must be rewritten to bring it in line with the intervention.

Partially Achieved Objectives

An objective that is partially achieved may have one of the previously noted problems. It may be possible to rewrite or rephrase the objective, extend the time frame, or alter the interventions, thus enabling another opportunity for meeting it.

Unachievable Objectives

Sometimes the objectives chosen may be unachievable owing to any number of factors: limitations in an agency’s program; restrictions grounded in policy; changes in need, the client’s life or support network, or the refusal of the client to work on the objective are examples of reasons an objective may be unachievable. These objectives should be changed as soon

as the worker or client becomes aware of the problem.

CONCLUSION

Therapeutic contracts serve several functions simultaneously. They can support self-determination, informed consent, and empowerment, and focus the worker and client on specific tasks, treatments, and objectives. Therapeutic contracts are excellent resources for assessment and for measurement of progress and also serve to provide an objective measure of performance for agencies, funding sources, clients, and social workers themselves. As limited time frames and the exigencies of managed care impact client–worker relationships, the therapeutic contract serves to ground, support, and enhance professional social work practice. Built on the foundation created in the work of the service contract and the initial contract, the therapeutic contract is an excellent tool to encourage workers and clients to explore avenues for effecting and enabling change within the client system.

71 Developing Goals

Charles D. Garvin

The development and clarification of client system goals are necessary steps in bringing about individual as well as environmental changes (Garvin & Seabury, 1997).¹ Goals indicate specifically what clients want to accomplish. Thus, goals are changes in clients' life situations that are derived from the wants and needs revealed when a client's concerns are explored and assessed. For example, one client's long-range goal was "to be employed as a social worker." That client's short-term goals were to enroll in a school of social work, pass the courses, and complete the other requirements of the school. A barrier to attaining these goals was the client's lack of money. This led to another goal of obtaining money from the client's parents to pay for tuition.

We recognize that different approaches to and models of practice define goals differently (Philips, 2009). An example of this is solution-based therapy, in which the client systems are asked to create a narrative of what their situation would look like if the helping process were successful (Connie & Metcalf, 2009).

The assessment process precedes goal setting. The assessment process is related to goals because the assessment provides the practitioner and the client with answers to the following questions: (1) What levels of goal attainment are possible given the resources and limitations present in clients and their situations? (2) What changes must be sought in clients and their situations to attain specified goals? These changes are specified in terms of short-term goals that must be attained before long-term goals are worked on. Blythe and Reithoffer (2000) recommend instruments that can be used to assess clients in ways that link closely to goal determination.

An example of this was work with John W., who had recently been discharged from a hospital following major heart surgery. A social worker helped him develop a discharge plan that will enable him to return to an active role in the community. This work began with an assessment that included John's previous level of functioning, the level of functioning he could be expected to attain, and the likely length of the recovery process. From this assessment, the social worker and John jointly developed several goals. One of these was to complete a physical therapy program. Barriers to this completion, such as a lack of transportation, were identified, and the social worker helped John develop various means of overcoming these barriers. The physical therapist helped John develop additional goals, one of which was to regain enough strength to enable him to resume his previous employment as a computer repair person.

RATIONALE FOR THE USE OF GOALS IN PRACTICE

According to Hepworth et al. (2013, p. 328), there are a number of reasons for seeking an agreement between client and practitioner with respect to goals. The agreement:

- Ensures that, where possible, you and the client are in agreement about outcomes to be achieved
- Provides direction, focus, and continuity to the helping process and prevents wandering off course
- Facilitates the development and selection of appropriate strategies and interventions

- Assists you and the client in monitoring progress
- Serves as the criteria for evaluating the effectiveness of a specific intervention and of the helping process.

It has also been demonstrated that when client systems and workers have not defined goals for their work together, client systems are likely to leave treatment prematurely (Meyer, 2001).

GOALS AND PRACTICE PHASE

Goals should be determined initially during the first phase of practice, when the practitioner is becoming engaged with the client system and assessing strengths and resources. As the client system develops relationships with the practitioner, it will be more likely to disclose problems and work toward solving them. As the system achieves an agreement with the practitioner on problems and goals, the people involved are more likely to have positive feelings toward the practitioner and the work they do together. Nevertheless, goals are not static and may be revised or replaced as time passes, situations change, and new information becomes available.

Movement beyond this first phase into a work phase cannot occur until an initial relationship has been established, problems identified, goals specified, and an initial work plan created. The amount of time this takes will vary depending on the nature of the problem, the strengths of the client system, the skills of the practitioner, the resources that are available, and the presence or absence of conflict between individuals in the client system and practitioners regarding the issues involved. When the agency imposes time limits, this also will be a factor in determining goals and the means selected to achieve them.

Goal issues may also arise during subsequent work phases. For example, client systems may wish to change their treatment goals (1) when they attain them and perhaps continue to work on additional goals, (2) when their situation changes, or (3) when goal attainment does not take place.

TYPES OF GOALS

The practitioner should recognize that there are different types of goals that require somewhat

different kinds of interventions in order for the client to attain them. These include the following.

Discrete versus Continuous Goals

Discrete goals are those in which a single outcome is sought, such as admission to a school. Continuous goals are those in which the individuals in the client system enact the behavior that constitutes the goal on a number of occasions, such as a parent who disciplines a child by offering rewards instead of punishments.

Goals Related to Different Types of Systems

Goals may relate to outcomes for an individual, a dyad, a small group (including the family), an organization, or even a larger system. The larger the system, the greater the number of people who may have to be involved, not only in setting the goals but also in working for their attainment. In a sense, the first goal in multi-person situations, such as families, is for individuals to attain agreement on the family's goals and the relationship of these to each individual's goals. Sometimes, this is the only or main goal for work with such systems, although other goals may stem from these as the "system" works to attain the goals that have eventually been agreed upon.

When the system is even larger, such as an organization or agency, arriving at goals may require various interest groups in the system to negotiate an agreement on organizational goals. An example of this was a hospital in which each professional group had to arrive at an agreement with other groups (e.g., nurses, doctors, social workers, administrators). This process may involve the differences in power between these entities—a subject that goes beyond the scope of this article.

Goals Related to Different Kinds of Behaviors

Goals may relate to affects, cognitions, or instrumental behaviors or combinations of these. An example of this is a client who experienced anxiety attacks when he spoke in class. One goal was that he no longer experience the anxiety (affect goal); another was that he speak in class (instrumental behavior goal); a third

was that he no longer label making a mistake in what he said in class as proving that he was stupid (cognitive goal).

Individual versus Reciprocal or Interpersonal Goals

A goal may relate to the behavior of an individual acting alone. An example of this is a person whose goal was to report on time to work every day. Another goal, however, may be reciprocal. An example of this was a family meeting with a family therapist. The parents agreed to take their entire family on an outing when the children had all completed their household chores every day for a week.

SELECTING GOALS

There are a number of criteria the practitioner should consider in helping client systems select their goals. The first of these, as should be obvious from the foregoing discussion, is that the goal, if attained, should reduce or eliminate the problem(s) for which the client system has sought help. The individuals concerned should also have an emotional investment in attaining the goals. In addition, if the client system or the practitioner is working toward a goal that is not known to the other, the process will be seriously flawed because communication is likely to be confusing to each party, and tensions between them will emerge as a result.

A special problem in negotiating goals is posed by involuntary individuals—those who are required by a court or other system with power, to keep appointments with the practitioner because the system otherwise will impose sanctions for nonparticipation in treatment. Hepworth et al. (2013, pp. 335–337) and De Jong and Berg (2001) suggest several approaches for goal setting with such clients. One of these is to look for a common ground between client and system.

GUIDELINES FOR ESTABLISHING GOALS

The goals agreed to by the practitioner and the client system should meet a set of criteria and become part of either a verbal or a written contract. These criteria are as follows:

- Goals should be explicit. This means that a specific behavior or circumstance should be indicated. The situation in which the behavior is to occur, as well as its frequency or intensity, should be described. When workers and client systems are vague in specifying goals, this can lead to a lack of focus in their work together (Ribner & Knei-Paz, 2002).
- The attainment of the goal should be measurable. The measures may be either qualitative or quantitative.
- The goal should always be stated in terms of client system (not practitioner) behavior. Some practitioners begin goal statements with such phrases as “help the client,” which is what we assume the worker will do.
- The goal should be chosen with due regard to feasibility of client system and practitioner. This depends on opportunities available in the environment, the attitudes and abilities of significant others, and social, political, and economic conditions. We recommend that the client system be given the benefit of the doubt on this issue.
- Legality should be a major issue in selecting a goal. Practitioners should not help clients work to attain illegal or immoral goals. This is not as easy to implement in some situations, such as a terminally ill client who wishes help to commit suicide when offering such help is illegal. Fortunately, the National Association of Social Workers and other professional associations have guidelines to help practitioners determine what to do in such situations. At times, the goal is counter to the practitioner’s ethics but not those of the profession or society.
- The goal should be one in which the skills and knowledge of the practitioner are adequate to help the client system attain the goal.
- The practitioner should consider the consequences for others of contracting with the client system to work toward the stated goals. We believe that professional ethics require that the worker not collude with the client system in such a way as to lead to harm to others. The situation becomes more complex when the client system seeks to overcome some form of oppression because this may, in fact, impose a “cost” on the target of the client system’s efforts (e.g., workers are helped to participate in a strike which, if successful, will impose a cost on the employers; or, clients of an agency may seek to obtain more or better service from the agency, which can prove costly).

- Goals should be stated in positive terms. An example of this is the parents' goal of acquiring ways of appropriately disciplining a child rather than refraining from inflicting inappropriate punishment on the child. We find that working toward positive goals is more likely to occur than the opposite, and this emphasis on client system growth enhances self-esteem and a sense of accomplishment.

The steps in establishing goals are the following (Hepworth et al., 2013, pp. 350–355).

Step 1: Identify and Prioritize Problems

The practitioner should ask client systems to indicate the problem(s) they hope to solve as a result of the help offered by the social worker. Many people will state the problem in terms of the behavior of another person, such as, "Our boss won't listen to us" or "My husband criticizes me too much." We have no objection to problems stated in this way. If the worker rejects such statements, many people will refuse to continue because they will conclude that the worker has no regard for their views. There will be time enough as goals are developed to help people to include their own actions in the definition of the situation.

Problem statements in family treatment may take on a different form than in one-to-one treatment. These statements are likely to involve relationships and interactions, such as a husband and wife who state that they cannot resolve arguments, agree on how resources are to be spent, or engage in satisfying sexual interactions. It will be useful later in treatment if the family or couple can state the problem in ways that are not solely focused on one family member (the so-called identified patient), but this is not absolutely necessary and may, in some situations, be an impossible demand.

In groups, the first members to define their problems will serve as models for others who find this task more difficult. If the group has been composed of individuals with similar problems, this stage of the process may not be difficult because members already may have decided, as part of an individual interview held before the group began, on the problems they will work on in the group.

Examples of Problems and Related Goals

Problem: Parent states problem is the destructive behavior of an adolescent child.

Goals: In ways that are satisfying to both parties, learn techniques for negotiating limits with child when child violates a rule set by parent; learn to state expectations of child's behavior in specific terms that indicate what is expected rather than what is unacceptable.

Problem: Client is failing college courses.

Goals: Organize a schedule for completion of assignments that is realistic in terms of work and recreation; negotiate with biology instructor a date to complete work that is realistic for student and acceptable to instructor.

Problem: Members of a community are not receiving necessary services from their city.

Goals: The city officials agree to provide these services and to receive reports from the citizens as to how effectively this has occurred.

Step 2: Determine Client's Readiness to Set Goals

Hepworth et al. (2013, p. 350–351) recommend that when the practitioner believes it is time to work on goals, she or he should determine whether the client system agrees that it is ready for this process. At times, individuals or groups will assert that additional information should be considered before goals are set; at other times, the client system will indicate a readiness to proceed.

Step 3: Provide a Rationale for Goals

The practitioner should examine the reasons for goals. He or she should convey the importance placed on client system self-determination and the relationship between setting goals and determining whether or not the service has been effective. The individuals in the client system should be helped to understand that goals represent changes they would like to see in relationship to the problem, should the treatment prove successful.

Step 4: Identify and Choose Goals

As indicated earlier, the individuals in the client system should be asked what they would

like to see changed if the social work service is successful in helping the client system ameliorate the problem. At times, especially when the individuals in the client system have limitations owing to age or disability, the social worker may suggest some goals and invite the individuals to choose from among them. These choices should be explained and illustrated so that as much input is obtained from the client system as possible.

Step 5: Explicate the Goals

There are several components of a well-formulated goal statement, that is, one stated so specifically that its attainment is measurable. The characteristics of such statements are:

- Performance (what the learner is to be able to do)
- Conditions (important conditions under which the performance is expected to occur)
- Criteria (the quality or level of performance that will be considered acceptable).

These characteristics can be used whether the goal is stated in terms of the client system's own behavior or the behavior of a person or system other than the client system. An example of a goal for an individual's own behavior is: "Joan, when faced with a derogatory statement from her employer (Sally) with which she does not agree, will calmly indicate her disagreement to the employer." The criterion for the quality of the performance is that the employer will acknowledge that she has heard and understood Joan's views.

Step 6: Determining Feasibility, Benefits, and Risks

The practitioner should avoid encouraging the client system to spend a great deal of time and effort trying to achieve a goal that is not feasible, especially when this could have been determined in advance. Hepworth et al. (2013, p. 334) suggest that the practitioner determine feasibility by asking the clients what obstacles they anticipate might block them from achieving their goals. Anticipating obstacles, of course, does not mean the clients should forgo striving to attain the goal, because all goal-attainment activities will come up against obstacles. Rather, are these obstacles so severe that no reasonable amount of effort will overcome them?

Step 7: Determining Goal Priorities

When the client's goals arise from several different problems, the priority attached to each problem will determine the priority of the goal.

SPECIAL POPULATIONS

The practitioner should take into consideration the cultural and social circumstances of specific populations when seeking to determine goals with members of these populations. The types of populations considered here are ethnic and cultural groups, age groups, and groups with limited capacities to select goals.

Nelson-Jones (2002) lists a series of topics that should be considered to help culturally diverse client systems determine goals:

- a. The past and current mistreatment of the individuals concerned
- b. The need for support when immigration/emigration occurs
- c. The likelihood that post-traumatic stress was incurred due to the experience of aversive circumstances
- d. The need for help with language, housing, health, education, and employment when in the process of settling into a new community
- e. The need for individuals to avoid further marginalization caused by clumsy efforts to adapt individuals to new cultural environments
- f. Discrimination individuals may face due to their status within their own cultures
- g. Individuals may need to manage cross-cultural relationships
- h. The likelihood that individuals may face intergenerational conflicts in their own cultures
- i. The likelihood of gender role and gender equality issues.

Because of the variation within groups related to degree of assimilation, specific life experience, and so forth, we do not believe in approaching this topic with such generalizations as "Native Americans will favor goal X." Nevertheless, we believe that the cultural experiences a person has had will help determine his or her values and aspirations, which, in turn, will help determine his or her goals. As a consequence, the practitioner should bear in mind questions such as the following, which may help him or her discuss goals in ways compatible with the client's beliefs.

1. How do individuals in the client system feel about creating long-term objectives as compared to having objectives that are very short range? That is, do these persons give much value to a future orientation as compared with one oriented to the present?
2. How does the individual feel about personal goals as compared with goals oriented to the welfare of one's family, community, or other reference group? Some individuals see it as much more important to work for the betterment of these systems and as almost inconceivable to put one's own welfare ahead of the group.
3. What aspects of living are regarded as the most and least important? Some cultures see family outcomes as the most important; for others, occupational outcomes are the most important; others see educational outcomes as the most important; and still others stress the kind of person the individual is or is becoming as of the highest value. These kinds of beliefs have a strong impact on the goals that the individual will be strongly motivated to attain.

An excellent example of the foregoing is the work of Walker (2008). This author describes a program called "youth circles" to help Hawaiian youth develop the skills of goal setting.

CONCLUSION

The chapter began with a definition of the term, "goals." Goals may refer to ultimate, intermediate, and instrumental outcomes, and these terms were also defined. Goals are chosen in relationship to an assessment of client systems and their circumstances. It is important to stress the connection between goals and assessment data.

Practice principles for the creation of goal statements were presented. These differ depending on such issues as whether the client is voluntary or involuntary. An important principle is that the goals should relate to the presenting problem, and consequently, the process of problem specification was also described. Finally, this chapter discussed goal issues that may arise with various populations, such as those related to gender and ethnicity.

In the future, goal setting is likely to be regarded as even more important than it is now. This will arise out of the emphases placed on attaining desired outcomes as a justification for providing managed care services, linking

interventions to goals, and empowering client systems to select the goals that are appropriate for their cultures and personal lifestyles.

Treatment Planning with Adolescents

72 *Attention Deficit Hyperactivity Disorder Case Applications*

Kimberly Bender, Samantha M. Brown, & David W. Springer

Treatment goals and treatment plans are a critical component of effective social work practice with adolescents; without explicit goals and plans, both social workers and clients run the risk of aimlessly “stumbling around in the dark” until they happen across a “problem” that needs to be addressed. As consumers of care, we expect our primary care physicians to deliver services with some sense of purpose, direction, and expertise. We should expect no less from social workers and the care they provide. To this end, treatment plans serve as very useful tools. Social workers and adolescents collaborate to establish treatment plans and treatment goals and select a focus of their work together. Goals specify what the adolescent wants to work on in treatment, and the treatment plan serves as a game plan for how these goals will be obtained. This chapter provides guidelines for establishing treatment goals and plans with adolescent clients.

TREATMENT GOALS

The first step in establishing treatment goals with any client is to conduct a thorough assessment. This entails allowing the client to tell his or her story, conducting a psychosocial history, seeking input from family, friends, and other professionals, and using standardized assessment tools and rapid assessment instruments as needed. Clients may also need to be referred for medical and/or psychological testing. Following a thorough assessment, the social worker and

client work together to establish goals for the client. In this sense, goals link the assessment and treatment process.

The following guidelines are helpful in establishing treatment goals. The goals should (1) be clearly defined and measurable, (2) be feasible and realistic, (3) be set collaboratively by the social worker and the client, (4) stem directly from the assessment process, and (5) be stated in positive terms, focusing on client growth. Treatment goals help direct the social worker and the client toward “cognitive, emotional, behavioral, and situational actions” (Cournoyer, 2005, p. 322).

Treatment goals need to be defined clearly and stated in such a way that progress toward the goals can be measured. If goals are stated too ambiguously, clients may become discouraged or feel as if the goals are out of reach. For example, compare the ambiguous goal of “improve school performance” with the more concrete goal of “complete at least 90% of homework assignments over the next 2 weeks.” The latter goal is more likely to be meaningful and obtainable to the client.

This leads to the second element of establishing treatment goals, which is that they must be feasible and realistic. “Improving school performance” is not only vague, it may not be feasible or realistic because it potentially covers so much ground. Additionally, little discussion between the social worker and the adolescent is needed to create vague goals. By contrast, concrete goals

require a serious dialogue to take place so that conceptual ideas about client functioning can be “wrestled to the ground” in clear, day-to-day terms.

To the extent that adolescent clients participate in this discussion, the more likely it is that they will feel a sense of ownership over the established goals, which, in turn, means that they are more likely to follow through with the treatment plan. Clients (especially adolescents) will experience less buy-in to the treatment process if goals are imposed on them by a social worker or parent. Thus, goal setting needs to be a truly collaborative process among the social worker, adolescent, and his or her parents (when appropriate).

Treatment goals need to stem directly from the assessment process. The assessment should be thorough, empirically based, and grounded in a systems perspective. This minimizes the likelihood that the worker is creating treatment goals based solely on gut feeling or an on-the-spot diagnosis.

Finally, treatment goals need to be stated in positive terms. In other words, the goal should state what the client *will* do rather than what the client *will not* do. For example, a client will be more motivated and goal directed by a goal that states “attend the entire school day every day for the next 2 weeks” in comparison to a goal that states “stop skipping school.”

TREATMENT PLANS

Treatment plans are the next logical step after goals have been formulated, and, in practice, these two steps often go hand in hand. Treatment plans reflect what specific and concrete steps or interventions are going to be implemented to help the adolescent client obtain his or her goals.

Similar to goal-setting, the process of establishing a treatment plan should be collaborative between the adolescent (and his or her family) and social worker. As a natural extension of the movement started under the Child and Adolescent Service System Program initiated in 1984 by the National Institute of Mental Health, many communities across the country received federal funding through the Substance Abuse and Mental Health Services Administration, Center for Mental Health Services to implement a community-based, wraparound approach to service delivery within a system of care (Rosenblatt, 1998). Today, the wraparound approach is

more prevalent, refined, and studied. An excellent resource on this approach is the National Wraparound Initiative (see <http://www.nwi.pdx.edu>). A major emphasis of this approach is providing individualized, client-centered services for youth with serious emotional disturbance and multiple mental health needs. One pragmatic way this is accomplished is to actively involve the youth and his or her family in the development of a treatment plan, recognizing the client as an expert on his or her own life (Schelenger, Etheridge, Hansen, Fairbank, & Onken, 1992).

Assuming the client is the expert on his or her own experiences, the social worker can (and should) lend expertise regarding what treatment approaches or interventions are most effective for a given problem. For example, if medication management or cognitive-behavioral therapy has been demonstrated to be effective for a given problem or disorder, the social worker has a responsibility to share this information with the adolescent and his or her family to provide guidance as they develop the treatment plan. Effective treatments should be described and the potential costs and benefits discussed with the adolescent and his/her family to reach consensus on the best plan of action as the client moves forward with treatment.

Case Illustration: Steven

Steven is a 13-year-old white male who has been referred to the school social worker by his teacher because “he won’t sit still and he doesn’t follow instructions.” The teacher also complains that Steven has a very short attention span, often gets into trouble in class for blurting out answers, and is easily distracted. Though not previously referred for services, Steven has been having trouble with impulsivity and inattention since starting elementary school. He has no history of past mental health treatment, no remarkable medical history, and denies any substance use.

A thorough assessment would need to be conducted. This would likely entail interviewing Steven, his family, and his teacher. During these assessment interviews, the social worker might inquire about Steven’s perspective on the problem, when and where he struggles most, as well as times when things are easier for him. The social worker might ask about what has been done to address the problem thus far and whether previous attempts have been successful. Importantly, the social worker would spend time

getting to know Steven, including his likes and dislikes, and would identify Steven's strengths and resources. In addition to conducting thorough bio-psychosocial interviews, the social worker might utilize standardized assessment instruments such as the Conners Parent Rating Scale Revised (Conners, 1997) to determine whether Steven's behaviors align with symptoms of attention deficit hyperactivity disorder (ADHD). Given time and access, the social worker would directly observe Steven in class to get a sense of when and how his behaviors manifest as well as teachers' and students' reactions to Steven. Finally, the social worker might refer Steven for a physical with his physician, as well as a medical consultation with a psychiatrist, to determine whether there are any medical explanations for his symptoms and whether medication would be recommended. Biofeedback/neurofeedback has garnered some support in the literature as an alternative to medication management, and this may also be considered (Arns, de Ridder, Strehl, Breteler, & Coenen, 2009).

Following this assessment process, the social worker would likely consult the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5). Just recently available in 2013, the fifth edition of the DSM might suggest Steven meets the following diagnostic criteria:

- 314.01 (F90.2) Attention-Deficit/Hyperactivity Disorder, Combined presentation
- V61.20 Parent-child relational problem
- V62.9 Unspecified problems related to social environment

In addition to a formal diagnosis, it would be just as important that the social worker clearly identify the problem behaviors in terms meaningful to Steven and his family. These areas of concern would be listed and treatment goals (both short- and long-term) would be established with corresponding interventions.

A sample treatment plan for Steven is provided in Table 72.1. Notice that the treatment plan includes both short- and long-term goals and specifies who is responsible for each task. Some treatment plans may also include target dates that reflect when a specific goal is to be reviewed to determine whether it has been accomplished or needs to be revised. The sample treatment plan for Steven is intended to serve as a template. It is important to note that different goals or interventions could have been included or emphasized

depending on how problem areas were identified and prioritized by Steven, his family, and/or the social worker. A treatment plan needs to be tailored to the individual and unique needs of the client.

Readers are cautioned against taking a cookie-cutter approach to establishing treatment plans. Suppose that Steven also presented with behavioral problems associated with oppositional defiant disorder, that he was at risk of running away from home, or that he and his parents wanted to enroll him in a different school. These areas of concern would also need to be addressed in the treatment plan, with corresponding goals and interventions. Obviously, the treatment plan provided here does not reflect the complexities of treating an adolescent with ADHD. Readers interested in a more detailed exposition on how to treat adolescents with ADHD are referred elsewhere (see Barkley, 2000; Ervin, DuPaul, Kern, & Friman, 1998; Evans et al., 2006; Pelham, Fabiano, & Massetti, 2005; Raggi & Chronis, 2006; Robin, 1998; U.S. Department of Education, 2006).

One additional note about the case illustration is warranted. The vignette focuses on an adolescent with a diagnosis of ADHD for a reason. ADHD is one of the most common diagnoses encountered by practitioners working with youth; however, other common disorders encountered by practitioners working with adolescents in clinical settings may include disruptive behavior disorders (oppositional defiant disorder and conduct disorder), major depressive disorder, and substance abuse (see American Psychiatric Association [APA], 2013; Christner, Stewart, & Freeman, 2007; Dishion & Kavanagh, 2003).

CONCLUSION

Adolescents are in a unique developmental phase of life where the struggle for autonomy and individuation are amplified. Add to this potentially tumultuous process a *DSM-5* (APA, 2013) diagnosis or a serious emotional disturbance, and these young people become even more vulnerable to life's ups and downs. Social workers have an ethical responsibility to work closely with the adolescent (and his or her family) to develop a treatment plan that is sensitive to the developmental, cultural, and individual needs of the client, while also recommending interventions that are empirically based and grounded in a

TABLE 72.1 Sample Treatment Plan for Steven

Areas of Concern	Short-term Goals	Long-term Goals	Treatment Plan
1. Difficulty paying attention	1. Steven will begin to take prescribed medication as directed by physician.	1. Steven will take prescribed medication on a regular basis.	1. Social worker will refer Steven to psychiatrist for medication management and will consult with psychiatrist regularly.
2. Has trouble listening	2. Steven will begin to increase his on-task behavior, as evidenced by completing 90% of homework assignments.	2. Steven will engage in on-task behavior on a regular basis, as evidenced by completing 100% of homework assignments.	2. Steven, social worker, his parents, and teachers will meet to set up a system to monitor his homework, set up a point system in the classroom (to reinforce positive behaviors), and enhance the classroom setting (to reduce distractions).
3. Has trouble organizing	3. Steven's parents and teachers will create and begin to use a system to monitor homework.	3. Steven's parents and teachers will consistently monitor homework.	3. Steven's parents will attend an 8-week parenting class to learn ways to set limits and boundaries, and use natural rewards and consequences.
4. Often avoids activities that require sustained mental effort	4. Steven will demonstrate improved impulse control, as evidenced by earning 3 points a day in every class (for staying in seat, waiting his turn to talk).	4. Steven will demonstrate improved impulse control, as evidenced by earning 5 points a day in every class (for staying in seat, waiting his turn to talk).	4. Steven will learn to use self-monitoring skills (e.g., internal self-talk) to control impulsive behavior at home and in school.
5. Loses things often	5. Steven's teachers will set up a reward (point) system to reinforce positive behavior and discourage negative behavior.	5. Steven's teachers will maintain a reward (point) system to further reinforce positive behavior and discourage negative behavior.	5. Steven and parents will attend weekly family therapy sessions with social worker to clarify rules, enhance communication, establish a behavioral contract, and learn about ADHD.
6. Easily distracted	6. Steven's parents will set firm and consistent limits, using natural rewards and consequences.	6. Steven's parents will set firm and consistent limits, using natural rewards and consequences.	
7. Often fidgets or squirms	7. Steven's teachers will work with him to create a classroom setting that reduces distractions.	7. Steven's teachers will help to maintain a classroom setting that reduces distractions.	
8. Often leaves seat during class	8. Steven and his parents will improve communication and establish a behavioral contract.	8. Steven and parents will maintain improved communication and will modify behavioral contract as needed to aid in parental limit setting and establishing clear rules.	
9. Has difficulty playing quietly			
10. Talks excessively			
11. Blurts out answers to questions			
12. Conflict with parents			

bio-psychosocial perspective. Most importantly, the adolescent must have input into the development of the treatment plan in a meaningful way to maximize the likelihood that he or she is invested in the treatment process and will sustain lasting change over time.

73 Eating Disorders and Treatment Planning

Nina Rovinelli Heller & Jack Lu

Eating disorders can be considered from medical, mental health, and public health perspectives. Social workers in a wide range of settings are in frontline positions to identify, treat, and prevent eating disorders, including bulimia, anorexia, and obesity-related issues, from several of these perspectives. From a medical perspective, eating disorders may involve neuroendocrine dysfunction and genetic vulnerability (Sadock & Sadock, 2007). In addition, the symptoms of eating disorders may create both acute and chronic medical complications and emergencies. For example, people with anorexia nervosa can suffer the biological effects of starvation, osteoporosis, and cardiac arrest; those with bulimia nervosa can develop severe digestive tract disorders and dental problems. Eating disorders are most commonly considered mental health problems with affective, behavioral, and cognitive causes and sequelae. Eating disorders and their rise in prevalence across groups can also be considered from a social constructivist position (Piran & Cormier, 2005) with an understanding of the myriad social messages and influences dictating preferred body image and shape.

Eating disorders are also understood descriptively in a categorization system that typically does not address issues of etiology. The *Diagnostic and Statistical Manual* is broadly used by mental health professionals. There were several changes to the eating disorder categories in the latest version of the *Diagnostic and Statistical Manual (DSM-5)* (APA, 2013). Binge eating, formerly lodged in an appendix, was included as a distinct category of eating disorder with criteria pertaining to recurring episodes of eating significant amounts of food during a brief period of time, sometimes rapidly; doing so while feeling “out of control,” having feelings of shame or disgust;

hiding the behavior; experiencing substantial distress, with a minimum of weekly episodes over at least a three-month period. The diagnosis of anorexia nervosa remains substantially the same, but with a focus on behaviors, rather than attitudes, related to the restriction of caloric intake. In part due to the increase in the diagnosis among males, the criterion for amenorrhea, the absence of menses was removed. Finally, for the diagnosis of bulimia nervosa, the requirement related to frequency of binge eating followed by purging was reduced to once per week.

Following much debate, obesity was not included in the *DSM-5* as a diagnosis. According to the *DSM-5*, obesity is considered the result of a combination of genetic, behavioral, environmental, and physiological factors, with high variability among individuals. That said, there are individuals who are obese who may meet, but not necessarily meet, criteria for bulimia nervosa and binge-eating disorders.

Diagnostic systems are imperfect ones; for example, in clinical practice, many social workers observe that anorexia nervosa and bulimia may be present at different times in the course of the life of a person who struggles with eating difficulties. In these situations, it may be helpful to consider a continuum model of disordered eating, rather than the notion of distinct conditions.

NOT JUST “THE WHITE WOMAN’S DISEASE”

There are shared and distinct presentations and risk factors for men and women and we highlight those here. Males with eating disorders are now estimated to account for somewhere between 10% and 25% of all cases, including anorexia

nervosa and bulimia (Collier, 2013; Peate, 2011; Stanford & Lemberg, 2012), with male athletes at elevated risk (Glazer, 2008). Additionally, Kjelsas, Bjornstrom, and Gotestam (2004) found that there is nearly 7% lifetime prevalence for all eating disorders among adolescent boys. Finally, older men with excess weight are also known to experience binge eating disorder due to cultural factors and influences (Greenberg & Schoen, 2008).

Disturbances in body image and self-perception remain consistent between men and women for both clinical and subclinical experiences with the diagnosis of an eating disorder (Glazer, 2008). Although men and women share many of the biological (e.g., signs of starvation, loss of libido, hormone dysfunction) and psychological problems (e.g., depression, suicidal ideations, mood swings, anger, shame, guilt, distorted body image) associated with eating disorders, the assessment, prognosis, and course of the illness for men may differ from that for women (Glazer, 2008; Peate, 2011). For example, differences within the relationship between eating disorders and low bone mineral density (BMD) for male athletes is not clearly linked when compared with the female athlete triad (eating disorder, BMD, and amenorrhea) (Glazer, 2008). Therefore, both assessment and intervention for males with eating disorders must continue to build from knowledge already known and specifically geared toward men and their developmental life cycle.

Multiple barriers exist in the assessment, diagnosis, and treatment for males with eating disorders (Peate, 2011). Barriers include the dominant focus of female-centric risk factors (e.g., irregular menstruation or amenorrhea), formats of therapeutic treatment (e.g., group-based, expression of emotional intelligence), stigma association with masculine and sexual identity, denial, shame, isolation, fear, and lack of education (Collier, 2013; Greenberg & Schoen, 2008; Peate, 2011; Robinson, Mountford, & Sperlinger, 2012). The widely assumed association between women and eating disorders serves as the greatest barrier toward expanding research, assessment, and treatment for men suffering from this illness.

Stanford and Lemberg (2012) developed the Eating Disorder Assessment for Men (EDAM) and identified four primary domains for diagnosis: binge eating, muscle dysmorphia, body dissatisfaction, and disordered eating (Stanford & Lemberg, 2012). Though preliminary results of this tool are high in both reliability and validity,

further research and implementation of the tool and others akin to it are required.

Risk factors for men with eating disorders include the following: families of origin that inflate the value of fitness or athleticism and have similar expectations for children; relationships with mentor figures (e.g., coaches) that promote behavioral extremes (e.g., food restriction, binge eating, excessive exercise); media and social influences (e.g., film, Internet); traumatic life events, including physical, sexual, or emotional abuse; adolescent experiences of teasing, taunting, and bullying due to body issues (e.g., overweight) or poor physical performance (e.g., athletics); difficulty with conventional and stereotypical masculine traits, (e.g., competitiveness, aggressiveness, strength, and independence); childhood obesity; and employment that emphasizes specific body shapes and sizes (e.g., sports, modeling, acting) (Collier, 2013; Glazer, 2008; Peate, 2011). These risk factors have important implications for both prevention and intervention.

Cognitive behavioral therapy has had good outcomes for both men and women. Cognitive behavioral strategies to address perfectionism, the social construction of body image, and achievement expectations for men may be particular areas of goal orientation (Greenberg & Schoen, 2008). Successful interventions may be measured by self-acceptance of eating disorder and redefined self-concept; engagement and alignment to treatment plan; prioritization of health over physical achievement (e.g., athletic excellence); absence of physiological laboratory abnormalities (e.g., cardiac, electrolyte); balanced energy; absence of malnutrition-based performance declines; and maintenance of a healthy weight (Glazer, 2008; Greenberg & Schoen, 2008; Robinson, Mountford, & Sperlinger, 2012). Greenberg and Schoen (2008) also found that gender-sensitive psychotherapy designed specifically for men promotes positive male socialization in individual and group formats.

In regard to sexual orientation, Carlat, Camargo, and Herzog (1997) reported on 135 male eating disorder patients and found that although they shared most characteristics with their female counterparts, self-identified homosexuals and bisexuals were more highly represented among those with eating disorders, particularly bulimia. In fact, of this group, 42% of the bulimics identified as homosexual or bisexual, and of the anorexic patients, 58% identified as asexual. Davids and Green (2011) found

that among women, bisexual, lesbian, and heterosexual women had similar rates of both eating disorders and levels of body dissatisfaction.

Eating disorders in the United States have been identified primarily in Caucasians; more recently, they have been reported among blacks, Latinos, and Asians (Rogers, Wood & Petrie, 2010; Alegria et al., 2007; Shuttlesworth & Zotter, 2009). This “debunks” the previously held belief that different cultural norms for ideal body shape and weight served a protective function for African American women. Treatment interventions need to take into account the differential cultural meanings of body image, shape, and weight, as well as the role that food and meals play in specific cultures.

Similarly, eating disorders have been considered a disease of the affluent, and indeed, early anecdotal studies of women have supported that generalization. However, researchers report that these assumptions are unfounded (Gard & Freeman, 1996; Gibbons, 2001) and that bulimia, in particular, is widespread among those in low socioeconomic groups.

ALTERNATIVE APPROACHES

Social work’s emphasis on a bio-psychosocial perspective ideally supports holistic assessment of and treatment for eating disorders. Holistic assessment and treatment may come in the form of mind-body-spirit (MBS) modalities or Complementary and Alternative medicine (CAM) practices. MBS modalities (e.g., mindfulness meditation) originate from systems of healing (e.g., Traditional Chinese Medicine, Ayurveda) developed by indigenous cultures, which practice with and respect the interconnectedness among the psychological, biological, and spiritual attributes of people. CAM practices (e.g., herbs, supplements, massage, and touch therapies, acupuncture when focused solely on biological intervention) are defined by biomedicine as evidence-based treatment interventions that do not exist in conventional western medicine practice. Each pathway promotes access to holistic health and wellness that may not be addressed through conventional, biomedical approaches (e.g., pharmacological treatment, CBT, behavioral weight loss treatment, and bariatric surgery) (Wilson, 2011).

As the knowledge and understanding of people diagnosed with eating disorders expands, so

will the efficacy and empirical measurement of MBS modalities and CAM practices to treat eating disorders. The comorbid factors that affect a person’s behavior and motivation are an essential consideration when treating eating disorders through holistic models. The range of comorbid factors to eating disorders includes the improvement in physical performance of athletes, limited external locus of control when dealing with relational stress (e.g., child’s reaction to parent divorce), and environmental stressors (e.g., social pressure with body image) that reinforce anxiety and depression (Breuner, 2010; Caldwell, Baime, & Wolever, 2012). Therefore, treatment of comorbid factors to the eating disorder diagnosis can benefit a client’s overall perception and experience in balanced health and wellness. MBS modalities are useful in treating the comorbid factors that undergird the complex psychological, physiological, and spiritual states that individuals with eating disorders may experience. A MBS modality that promotes a balanced approach to one’s self-control is Buddhist mindfulness meditation.

Buddhist mindfulness meditation promotes practices such as mindful eating, while also reducing stress by improving the relaxation response (Coffey & Hartman, 2008; Kissman & Maurer, 2002). This particular practice promotes nonjudgmental awareness to self-regulation and challenges negative self-conceptions that trigger reactivity (Hick & Chan, 2010). When reactivity is managed, self-regulation is promoted through healthier outlets (Caldwell, Baime, & Wolever, 2012). Finally, self-acceptance and compassion toward oneself promote the positive feedback loop of healthy self-regulation and self-care (McGarrigle & Walsh, 2011). Traditional mindfulness meditation is practiced from Buddhism; however, mindfulness meditation may also be utilized through programs such as Mindfulness-based Stress Reduction (MBSR), Enhancing Mindfulness for the Prevention of Weight Regain (EMPOWER), Acceptance and Commitment therapy (ACT), Mindfulness-based Cognitive Therapy (MBCT), and Dialectical Behavioral Therapy (DBT).

CAM practices have been useful with adolescents and adults for comorbid symptoms to eating disorders. These include Biofeedback to alter the body’s response to stress; massage and therapeutic touch to promote stress and anxiety reduction through lowering cortisol (stress hormone) level, while also increasing dopamine

and norepinephrine (neurotransmitters that are correlated with depression and anxiety); St. John's Wort for depression, anxiety, and sleep disorders; Chamomile's anti-inflammatory effects for promoting relaxation to treat gastrointestinal discomfort and mild anxiety; Valerian's anxiolytic and sedative qualities to promote health sleep; and Melatonin to promote and restore balanced sleep (Breuner, 2010). Additionally, CAM practices that originate from indigenous systems of healing may be accessed as targeted interventions: yoga (derived from Ayurvedic medicine) as a physical practice to promote balance and self-control (Sharma, 2011) and acupuncture (derived from Traditional Chinese Medicine) to promote healthy energy flow within the person's "spiritual, emotional, mental, and physical health" (Breuner, 2010, p. 77).

GUIDELINES FOR ASSESSING AND TREATING EATING DISORDERS

Social work intervention can and should occur in a variety of settings and with a three-pronged approach that includes prevention, identification (see table 73.1), and treatment. It is critical that any of these interventions reflect an understanding of the sociocultural influences that contribute to and maintain eating disorder symptoms.

Prevention

- Social workers should be familiar with the client groups at risk for developing eating disorders and design and implement psycho-educational efforts appropriate to the age and gender of those groups.
- Prevention programs should ideally take place in "natural" settings, such as school athletic departments, health classes, and recreation centers.
- Social action can take the form of targeting businesses and advertisements that perpetuate the image of an "ideal" body image for both girls and boys.
- Parent education efforts should be focused on both healthy eating strategies and the importance of physical activity.

Identification

- Social workers should assume that clients may not readily self-disclose their eating

disordered behaviors, which are often associated with secrecy and shame. Hence, disclosure may not occur until the disease has significantly impaired the client's medical status or social and psychological functioning. Social workers should adjust their history taking and style accordingly.

- Comorbidity is high in people with eating disorders. All mental health assessment should include questions about eating behaviors. The clinician is cautioned that in many cases the data will not emerge in a first session but should be raised nonetheless.
- People with histories of sexual abuse, alcohol abuse, and family histories of affective illness or eating disorder should be considered at risk.
- New clinicians should be reminded that normal body weight does not preclude the existence of an eating disorder; in fact, most clients with bulimia are within normal weight ranges.
- Any client who reports or is suspected of an eating disorder should also be referred to a physician, preferably one with expertise in the area, for a full physical examination and laboratory work. Particularly with critically ill anorexics, presenting clear, irrefutable evidence of the impact of starvation on one's physical body may be helpful in minimizing denial of the problem.
- Significant denial and minimization of the problem following disclosure often results in resistance to treatment. Because many people with eating disorders experience difficulties in the area of control and autonomy, establishing joint treatment goals is critical and often arduous.
- A complete psychological, social, and medical history is critical. In the case of young clients, the involvement of family as a collateral source of information is useful.
- Pay particular attention to eating disorders in non-White populations who have been significantly understudied, under-researched, and undertreated, in spite of the growing clinical awareness of incidence in people of color.

Treatment

- For those clients whose medical status is not seriously undermined and whose functioning is largely intact, an outpatient model of treatment, similar to that described for inpatients, is in order.

- In extreme cases, hospitalization may be necessary, and force-feeding for those in a state of severe starvation may follow. Inpatient treatment will include a behavioral protocol, cognitive restructuring, group therapy, nutrition counseling (although many people with eating disorders are nutritional experts themselves), individual treatment, and family interventions.
- Social workers who are working with clients with coexisting substance abuse problems must evaluate the severity of both sets of symptoms and prioritize initial treatment goals. A client who is actively using drugs and alcohol is unlikely to be able to participate fully in a treatment program designed to eliminate symptoms of an eating disorder. Here, too, it would be important to clarify the phenomenological and temporal relationships between the eating disorder behaviors and the substance using behaviors. For example, if a client reports that a feeling of aloneness typically precedes a binge eating episode, it is important to know if his or her feelings of aloneness are intensified by substance use.
- Though many treatment programs are designed as a protocol or as “manualized” interventions, it is critical to recognize that although many people with eating disorders share certain characteristics, there may well be idiosyncratic historical influences and factors that can either promote or impede the chances of treatment success. In other words, it is critical to understand the meaning and function of the particular behaviors to a particular client to find syntonetic, effective ways of intervening.
- An understanding of the meaning of the behaviors (restricting, purging, or overeating) and the phenomenology of the symptom development can yield important insights as to the relative importance of this behavior to the client.
- The social worker’s understanding of the relative rigidity or flexibility, ambivalence, or secondary gain related to the client’s symptoms can be enormously helpful in understanding how best to work with a particular client, regardless of the setting.
- Consider family evaluation and treatment to address both contributing and maintaining factors of symptoms and to identify family strengths.
- Because of the high comorbidity rates in both anorexia and bulimia, a good diagnostic evaluation is critical and may need to take place periodically throughout treatment. For example, it is not unlikely that once eating-related symptoms remit, the client will experience significant depressive symptoms. As with those who have coexisting depressive disorders, clients may also benefit from a trial of a selective serotonin reuptake inhibitor (SSRI).
- Social workers must make frequent use of emerging theoretical and empirical knowledge about incidence and treatment efficacy.

TABLE 73.1 Eating Disorder Measures

Name	Type of Measure	Focus
Eating Disorders Inventory (EDI). Garner, Olmsted, & Polivy (1983)	64-item, self-report instrument; children’s version available.	Behaviors and attitudes for onset and course of bulimia and anorexia nervosa.
Bulimia Test-Revised (BULIT-R). Smith & Thelen (1984 in Corcoran and Fischer, 2013)	36-item self-report measure	Binge-eating, eating attitudes when not in binge episode.
Eating Disorder Examination (EDE). Cooper & Fairburn (1987)	Semistructured interview for comprehensive assessment; children’s version available.	Anorexia and bulimia, including extreme behavioral methods of weight control.
Eating Disorder Assessment For Men. Stanford & Lehmberg (2012)	50-item self-report	Male-specific

PRACTICE EXAMPLE

Max is a 19-year-old White male who presented to the college counseling center with a vague description of not “feeling right.” A sophomore on the university wrestling team, he revealed that he was concerned about his weight gain over the summer and reluctantly reported that “my coach is giving me a bad time about it.” He reported that he had spent the last several weeks trying to “get rid of this horrible fat” but had been unsuccessful and “didn’t feel so great.” The social worker was struck by the discordance between his appraisal of his body and her observation of him; Max looked both extremely thin and haggard. On further investigation, Max revealed that he had been on a fast for the past several weeks and was feeling quite weak and dehydrated. He appeared somewhat listless as well. While the social worker tried to gain background information and further assess his mental status and social functioning, Max continued to perseverate on his weight status. He said that he felt “like a failure; my family never thought I could do this anyway; I’m letting my team down.” He did indicate that he was at his lowest adult weight and that he had become preoccupied since the summer about his body, specifically his muscle mass and his strength, the latter of which was waning. When asked whether he had made previous attempts at weight loss, he described a long pattern, since middle school, of extreme daily exercise, and idiosyncratic and ritualized eating behaviors.

Max was the middle of three children born to a middle-class family. His father was a salesman who often traveled and was a former collegiate football player, as was his older brother. Max had begun wrestling in his junior year of high school at his mother’s suggestion. He reported being close to his parents, who are “nice, well-meaning, but I think I disappoint them, particularly my father. . . my mother worries about me.” He reluctantly reported being bullied in middle school, but stated “it didn’t bother me much,” although the social worker found the reports of the bullying behavior quite alarming. Max reported having seen a counselor in high school and having a brief trial of an antidepressant. Although he thought it had helped, he said “I don’t like putting unnatural things in my body.” He did report having a group of close friends in high school, with whom he had remained close through social media once he went to college.

He reported feeling “like a member of the team” until a few weeks prior, but was unclear about the reasons for that other than, “I am letting them down.” He reported not having had any intimate relationships with men or with women, “I guess I’m just not a very physical person,” but “I like to have friends.” He denied being depressed and it was unclear the degree to which his current fasting regime was contributing to his weakness.

The social worker’s first concern was Max’s medical status. She referred him immediately to the nurse practitioner in the university health center for evaluation of blood work and vital signs. Because severe caloric restriction can cause mental status changes, she understood that clarifying his nutritional status and correcting it would be important in order to obtain a clear diagnostic picture. Fortunately, in the previous several years, the university health center, increasingly aware of the numbers of students, male and female, dealing with eating disorders, had developed a number of programs aimed at preventing and treating these problems. Once Max was medically cleared and began to work with the center’s nutritionist, he was referred to an eating disorder group for male students. He revealed in his individual session, however, that he was worried about his status on the wrestling team. One of the members of the health center’s interdisciplinary eating disorders team was a sports psychologist who had developed strong relationships with the university coaching staff. With Max’s permission, he arranged a meeting between himself, Max, and the wrestling coach. The coach had indeed had concerns about Max, but not for the reasons he had imagined. The coach had suspected an eating disorder, “but I didn’t want to confront him; he already seemed in pretty bad shape.” Together, they reviewed weight, height, and class requirements and the coach encouraged Max to follow the plan set up by his team, as a condition of returning to an active role on the team. This provided important leverage.

Within a month, Max was able to meet the minimum required weight and maintain it. However, his cognitions about weight, his behaviors in order to regulate it, and his affect and self-image were well established and his mental health team had concerns about his ability to maintain the gains he had made. He continued with his individual therapy, which utilized a cognitive-behavioral approach, and with the use of food and activity logs, which tracked behaviors and feeling states

as well. Through a mindfulness-based cognitive approach, Max was able to challenge his negative self-conception (e.g., amount of body fat) through stress-reduction techniques of breathing and guided meditation. Over time, Max developed healthier self-regulation and self-care through mindful eating, which ultimately improved his self-worth and self-efficacy in social activities and in his position on the wrestling team. He found his Male Eating Disorder Group, which allowed him to talk safely about issues related to body image and masculinity, very helpful. Max found great relief in talking about his wishes to “please” his father and how much he had focused on rigid notions of body type and strength as measures of masculinity. In his individual work he began to talk about what he called his “no-sexual identity” status and to explore what his avoidance of physical intimacy might mean to him.

Max did not meet the criteria for major depression, but he did have a history of a more chronic low-level form. He spoke with the center’s psychiatrist about medication, but did not want to do that. The psychiatrist, also trained in Alternative and Complementary Medicine, had other suggestions for him. He suggested the possibility of St. John’s Wort for depressive symptoms and valerian for sleep, both of which Max was willing to try. At the 60-day treatment planning meeting, Max was offered the opportunity to join a new class, Yoga for Healthy Eating, designed specifically for college athletes. He was also made aware of acupuncture services available off campus.

Max did some backsliding during his month-long semester break at home. He and his social worker had done some in vivo practice, however, as they anticipated some of the issues he would encounter with holidays and food, as well as with his family. Upon his return, he eagerly rejoined his Men’s Group and made plans to do outreach in the freshman residence halls for education about male eating disorders. He continued to work on issues related to interpersonal relationships.

CONCLUSION

Max was fortunate to be in a setting that promoted interdisciplinary, holistic interventions and had systems in place to address individual and community needs related to the prevention and amelioration of eating disorders. In addition to the individual therapy offered to Max, the

gender-specific eating disorder group provided the opportunity for mutual support and the exploration of issues confronting young men about weight, food, and body image. Additionally, the inclusion of a counseling staff member who had established relationships with university coaches ensured both micro- and macro-level interventions and cooperation. Finally, the availability of traditional therapeutic methods, including cognitive behavioral strategies and medical monitoring, in combination with alternative and complementary modalities, ensured a holistic approach that was both engaging and useful for Max.

As we learn more about both the distinct and overlapping risk factors, manifestations, and treatment approaches for groups of people not historically considered at risk for eating disorders, social workers must further develop our skills and knowledge in prevention, education, and intervention. Our bio-psychosocial perspective provides a very useful framework for incorporating a range of interventions that provide both relief from symptoms and a roadmap for healthier living.

74 Panic Disorders and Agoraphobia

Gordon MacNeil & Jason M. Newell

Panic disorders afflict about 4% of the population; about half of those so diagnosed also experience agoraphobia. Panic disorder is characterized by panic attacks and the pernicious fear of additional attacks. Two interventions have shown effectiveness in the acute phase of panic disorder with or without agoraphobia: cognitive-behavioral therapy alone and in combination with medications. In the long run, cognitive-behavioral therapy is the preferred intervention. Cognitive restructuring techniques are recommended to address panic attacks, and the behavioral technique of exposure is recommended for agoraphobia symptoms.

DESCRIPTION OF THE DISORDER

To meet the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)* criteria for panic disorder, one must experience recurrent unexpected panic attacks for at least a month, as well as (1) persistent concern about having more attacks, (2) worry about the consequences of the attacks or implications of the attacks, and/or (3) a significant change in behavior as a result of the attacks (American Psychiatric Association [APA], 2013). The attacks must not be due to a medical condition, nor are they better explained by some other disorder, such as social phobia, posttraumatic stress disorder, or a specific phobia (Schmidt, Norr, & Korte, 1997). For many, panic disorders are largely related to the person's fear of body sensations; in fact, panic disorder is sometimes referred to as a "fear of one's body" or a "fear of emotions." These individuals become alarmed at the presence of specific physical or psychosomatic sensations that they associate with the

onset of a panic attack. Because these attacks worsen over time, the anticipation of an attack can itself manifest panic. Avoidance responses frequently result in agoraphobia. *Panic attacks* are discrete periods of intense discomfort or fear that include at least four symptoms from the following list. The specific symptoms of panic disorder listed below tend to present themselves similarly across child, adolescent, and adult populations.

- Palpitations, rapid heartbeat, pounding heart
- Sweating
- Trembling or shaking
- Sensations of shortness of breath or smothering
- Sensation of choking
- Chest pain or discomfort
- Nausea or abdominal distress
- Feeling dizzy, light-headed, faint
- Derealization or depersonalization
- Fear of losing control or going crazy
- Fear of dying
- Numbness or tingling sensations
- Chills or hot flashes (APA, 2013)

In the case of panic disorder, these symptoms are not initially cued; they do not tend to occur in specific settings or situations. Indeed, the unpredictable nature of their appearance and the dread associated with anticipating them are hallmarks of panic disorder.

Agoraphobia is defined as an anxiety about being in situations in which escape is difficult or embarrassing or in which help would be unavailable should a panic attack occur (APA, 2013). These fears often relate to being in situations in which one is unable to "get back" to comfortable, secure surroundings and include the use of public

transportation, both vastly open and enclosed spaces, crowds, and in extreme cases leaving the safety of the home environment all together (APA, 2014). New to the *DSM-5*, Agoraphobia is considered a separate problem from Panic Disorders, and can be diagnosed independent of Panic Disorder (APA, 2013).

Panic disorder is a common condition, as is agoraphobia. Approximately 2%–3% of the population experiences panic disorder without agoraphobia, 1.5% experience panic disorder with agoraphobia, and 5% experience agoraphobia without panic disorder (APA, 2013; Eaton, Kessler, Wittchen, & Magee, 1994; Kessler, Chiu, Jin, Ruscio, & Walters, 2006). Women are twice as likely to be diagnosed with panic disorder. It is not unusual for persons to progress from panic disorder without agoraphobia to panic disorder with agoraphobia, as the latter may actually be the result of a dysfunctional coping response to panic disorder alone. The typical age of onset for these disorders is the early to mid-twenties. Although panic disorder and agoraphobia are most commonly comorbid with other anxiety disorders, unipolar depression and substance abuse are also noted in between 10% and 65% of panic disorder cases (APA, 2013). Perhaps more importantly, Panic Attacks are so frequent that they are a specifier for any other *DSM-5* disorder (APA, 2013).

Assessment

To establish the presence of panic disorder as well as agoraphobia, the social worker should first determine the specific nature of the client's symptoms as well as possible triggers for them and the client's responses to these symptoms, with specific attention to behaviors associated with avoidance. The use of an informal interview format to gather this information is common, but increasingly clinicians are employing established measures to assess the level of symptomatology exhibited by clients presenting with concerns about panic attacks. If the social worker prefers a more formal and structured method of assessment, the Structured Clinical Interview for the *DSM* Axis I Disorders (SCID) is an established and well-tested instrument for formal assessment purposes (First, Gibbon, Spitzer, & Williams, 1997) and can be used to confirm diagnostic impressions from the informal assessment and help to rule out other disorders. Identifying general symptoms

of anxiety may also prove helpful to the social worker in the initial assessment phase before the assessment of panic disorder or agoraphobia. The Hamilton Anxiety Scale-HAM-A (1959) is a clinician-administered scale that has been well tested as a measure of the symptoms of anxiety in children, adolescents, and adults (Bruss, Gruenberg, & Goldstein, & Barber 1994; Shear et al., 2001). The HAM-A is also useful in differentiating the symptoms of anxiety disorders with commonly diagnosed comorbid disorders such as major depression (Maier, Buller, Phillip, & Heuser, 1988). If generalized anxiety is ruled out, the Panic Disorder Severity Scale (PDSS) can be used in either clinician-administered (1992) or self-report form (1999) and is useful in identifying the frequency of panic attacks, the degree of distress resulting from them, and anticipatory anxiety related to them (Houck, Spiegel, Shear, Rucci, & Stat, 2002). The Anxiety Disorders Interview Schedule–Revised (ADIS-R) is particularly useful in assessment because it includes a checklist of specific symptoms as well as items about client thoughts concerning panic attacks, items about avoidance behaviors, and items focusing on functional impairment resulting from panic attacks (DiNardo & Barlow, 1988). The Mobility Inventory for Agoraphobia (Chambless, Caputo, Bright, & Gallagher, 1984) is well accepted as a measure of phobia avoidance.

Treatment

A number of reviews of literature and meta-analyses on the treatment of panic disorder and agoraphobia have been conducted recently (see Furukawa, Watanabe, & Churchill, 2007; Himle, Fischer, & Lokers, 2007; Roth & Fonagy, 2005). Although there are some differences in their conclusions, there is general consensus in recommending a treatment protocol that combines medications and psychotherapy; cognitive-behavioral therapy alone appears to be about as effective as the combined model in many instances. Cognitive-behavioral therapy is the most effective psychotherapy choice, with cognitive restructuring being most useful for addressing panic attacks and exposure techniques being preferred for addressing the avoidance behaviors of agoraphobia. Although prescribing psychotropic medication is beyond social work's scope of practice, it is prudent for social workers to have a basic knowledge and

understanding of the most commonly prescribed psychotropic treatments for anxiety and panic disorders. Selective serotonin reuptake inhibitors (SSRIs) and selective serotonin/norepinephrine (SSNRIs) are commonly considered “first line” treatments for mood disorders, but have also shown effectiveness in treating the general symptoms of anxiety independently of their effects on depression (Dziegielewski, 2010). SSRI treatments prescribed for anxiety and panic disorders include Prozac (fluoxetine); Paxil (paroxetine); Zoloft (sertraline); Celexa (citalopram); and Lexapro (escitalopram). Commonly prescribed SSNRI therapies include Effexor (venlafaxine); Serzone (nefazodone); and Cymbalta (duloxetine) (Bentley & Walsh, 2013). For actual panic attacks benzodiazepine therapies such as ativan (lorazepam), Klonopin (clonazepam), Valium (diazepam), and Xanax (alprazolam) are widely prescribed, but are short-acting and have addictive qualities that can potentially complicate treatment if not taken correctly (Bentley & Walsh, 2013; Dziegielewski, 2010). For panic disorder, psychotherapy seems to have more sustainable effect than the use of medications over longer periods of time (Roth & Fonagy, 2005).

TREATMENT PROGRAM

The remainder of this chapter presents a specific treatment program for addressing panic disorders and agoraphobia. This treatment program consists of two foci; intrapersonal and interpersonal aspects of the panic disorder. There is no specific protocol for the interpersonal foci associated with this treatment program, but it is an integral part of the program nonetheless. For instance, be careful to include social environment functioning in the assessment of the individual—both strengths and difficulties. Interpersonal problems in which the individual feels trapped or out of control can precipitate panic attacks and panic disorders. We have found that enlisting the help of supportive significant others can add to the prospects of success for this treatment program, especially with the in vivo component.

The intrapersonal aspect has three components: (1) education regarding the nature of anxiety disorders and panic disorders specifically; (2) cognitive therapy, including work on the identification of trigger stimuli and the

somatic physiological indications of panic, relaxation training; and (3) exposure of some form. In general, once the consumer is educated about the disorder(s), use interoceptive exposure techniques to address the panic disorder, followed by in vivo exposure techniques to address the agoraphobia. In instances where the consumer is not able to come to the office due to agoraphobia, we suggest phone, e-mail or even a Skype consultation as means of beginning the process. Clinicians who use this treatment program are presumed to have competence in delivering cognitive-behavioral therapy. This presentation is meant to instruct clinicians on the implementation of the program, but it is not a substitute for clinical training and ongoing supervision. We next present the procedures of this treatment program, and use the following case example to illustrate this process.

CASE ILLUSTRATION

Richard Summerall is a 30-year-old White male. He is trained as a mechanic and has operated his own garage for four years. For the past two years he has been a used car salesman. Mr. Summerall relates that his panic symptoms started nine years ago on his first night in the military. That evening, he woke up feeling very hot, short of breath, and panicky. Since then, he has experienced these symptoms rarely, but in the past three months they have become more frequent and intense. He also reports having diarrhea, nausea, shortness of breath, sweating, a fear that he is going crazy, trembling, and shaking. He describes a fear of elevators, car washes, business group meetings, and other places where he feels enclosed. He reports that the most extreme attack occurred two nights ago and that he spends considerable time worrying that these attacks will happen again.

PROCEDURES

Following are the procedures we use in the intrapersonal foci of this treatment program in sequential order, along with information describing the rationale for the interventions. Although most motivated clients will experience satisfying results within 10 sessions, there is tremendous variation in how long it takes people to address the psychological demons of panic and agoraphobia. Initial sessions take longer than

those at the end of the process, and sessions that require exposure techniques require that the client provoke, endure, and reduce their anxiety within the session. Therefore, this protocol is not presented session by session, because the introduction of new material to the client is flexible and contingent on his or her understanding and (where indicated) mastery of the content up to that point.

Assessment

We begin screening the client by conducting an initial assessment, which first includes a referral to a physician to rule out medical causes. Following this, we suggest completing a basic psychosocial assessment. One should be careful to explore cultural elements that may contribute to or influence the client's situation and experience. Clinicians should pay particular attention to the following aspects of the presenting problem: presentation, pattern, predisposition, perpetuants, and readiness for treatment. We usually use either PDSS-SR (Houck et al., 2002) or the ADIS-R (DiNardo & Barlow, 1988) to obtain this information. If the client does not appear to be ready to engage actively in change-making behaviors, focus on motivation and support until he or she is ready to begin this program.

With regard to our case illustration, Mr. Summerall described no fewer than six symptoms of panic attacks, and it is clear that he is concerned about the prospect of experiencing more of them. He meets the diagnostic criteria for panic disorder. He also appears to meet the criteria for agoraphobia, given that he is fearful of being in situations from which he cannot escape. Additional probing is needed to determine whether there are specific circumstances associated with his attacks; their frequency, duration, and intensity; and his response to them, both psychologically and physiologically, as well as what he has tried to do to counter the panic attacks. The social worker would also want to determine to what extent the attacks impair his functioning. Finally, although the attacks clearly are disturbing to Mr. Summerall, trying to determine his readiness to act to change his situation is important to the treatment process. Many people present with debilitating symptoms but are actually unwilling to "courageously leap off of the ledge" and act differently.

Psycho-education

As a first step, providing the client with information about panic disorders and agoraphobia is essential. Also, one should discuss the goals of the program and ask the client if he or she would like to have similar information provided to family members or friends. We emphasize that members of the client's social support network can assist the client by reinforcing and supplementing the gains made in-session.

Cognitive Restructuring

As a first step to this intervention, the client and the social worker determine initial levels of symptom severity. This is usually done by simply asking the client to talk about symptom severity; the information gained from the instruments used in the assessment is useful as well. In Mr. Summerall's case, the symptoms seem to be serious, but not extreme. That is, they are distressing to him but do not curtail his completion of tasks. His is not incapacitated, and friends and family have not noticed his symptoms to date.

Next, mutually identify the client's common responses to anxiety. This includes whatever he or she has tried as interventions for panic and anxiety and to what extent these measures have helped. Thus far, Mr. Summerall has been able to escape situations in which he experiences attacks around others. He has tried to control his breathing by taking deep breaths, he has used alcohol on occasion to distract himself from his hypervigilance to body sensations, and he has tried to increase his physical exercise to "wear myself out so that I don't have energy to freak out." We establish that his best efforts have not had any appreciable effect on his attacks; they continue to happen and without provocation.

The client and the social worker begin working on the first of two factors included in the cognitive restructuring intervention: misappraisals of body sensations as being threatening. This process has three parts. First, provide information about the rationale for the intervention, then identify misappraisals, and finally challenge these misappraisals. Panic disorders are largely related to the client's fear of body sensations. Because panic attacks can present at any time, learning to identify initial indications and how to reduce the physiological manifestations of panic is an important element in the treatment of panic disorder.

After a discussion with Mr. Summerall regarding his awareness of his breathing in general and when he becomes anxious, he confides that he is not aware of the former and is distressed by the latter. Mr. Summerall agrees that his becoming aware of his breathing as we speak seems to be distressing to him. (This is a common response among this clinical population.) This provides an opportunity to begin talking about misappraisals of body sensations and the common experience of tricking oneself into thinking that something is “wrong” simply by becoming aware of “normal” body functions and sensations. Even if one’s breathing is rapid, or one is sweating, there may be good reasons for these physiological responses; they do not necessarily denote an attack. The client and the social worker use this idea as we move forward in challenging his misappraisals.

The client and the social worker go through a process of challenging misappraisals of body sensations. First, they create a list of the specific thoughts that he or she has about his or her situation during panic attacks. After they have created a list of these thoughts, the social worker challenges the main items on it one by one, largely by questioning what other interpretations of the body’s “signals” might be possible and if these might, in fact, be likely. (Readers will find specific techniques for this in Barlow & Craske, 2006.) This must be done in a gentle manner that is not patronizing, humiliating, or condescending to the client. Remember, the goal of this part of the treatment program is to empower the client to challenge self-talk related to his or her body sensations (a truly challenging task), so frequent positive reinforcement is warranted. Also, the worker must remember that the intent here is to evoke the “misappraisals” and challenge them *as they are occurring*—in the present tense. We emphasize the use of “I am” statements rather than “I would be” statements in this task.

A good way to begin work with the client is to address anticipatory anxiety at the beginning of a session. Following general catching up and making sure that the client appears to be calm, make the following comment: “Right now you seem to be pretty calm and relaxed. Is this how you feel right now?” Once this is verified, comment that he or she seems “quite safe right here, right now.” Again, wait until this is verified, then ask the client to repeat this phrase a few times, becoming comfortable with it. This statement

becomes an anchor that clients use to assess the voracity of their sensations of panic.

Working in consort with the “right here, right now” anchor, start to educate the client about breath retraining as a response to anxious feelings. Detailed instructions for this are found elsewhere (see Barlow & Craske, 2006), so we only state here that it is important that the client complete the exercise of *experiencing* relaxed diaphragmatic breathing in the office; talking about it is insufficient. We cannot stress enough the importance of establishing the sensation of calmness and a relaxed state; it is this state the client must be able to access to succeed in later steps in the treatment process. It is well worth the time and effort necessary to solidly establish this anchor.

Interoceptive Exposure Treatment

Interoceptive exposure requires that the client be systematically exposed to bodily sensations in a therapeutic context so that he or she can learn at an emotional level not to fear these sensations. This differs from the misappraisals of body sensations in that rather than focusing on *cognitions*, a conscious effort is made to have the client evoke, endure, and reduce the *sensations* of panic in the office. Thus, sessions must be long enough to allow the client to fully provoke and reduce feelings of panic.

The client and the social worker develop a short list of hierarchically ordered body sensations associated with panic attacks. After which, the client recalls his or her most recent panic attack and describes the least significant body sensation and how he or she experienced it at that time. The client usually begins to demonstrate symptoms related to the body sensation at this point. Feel free to point this out to him or her, noting that he or she is indeed acting anxious. (Sometimes invoking the memory of a panic attack does not generate the symptoms of panic in the present. In these cases, have the client do exercises such as breathing through a straw or intentionally hyperventilating to produce the symptoms.)

Once the client reports being anxious (or demonstrates overt signs of anxiety), guide him or her in the breath retraining exercise. Be careful to reinforce positive responses during this exercise. Repeat this exercise (up to three times) for this initial body sensation in the office. The

client's ability to invoke the panic is often lessened by the end of the third iteration.

Use at least one follow-up session to reinforce gains made in the initial interoceptive session. After discussing what happened in the initial interoceptive session, have the client repeat the process him- or herself. Assuming that the client is successful in reducing anxiety, offer the comment that "right here, right now," he or she seems safe and calm. This anchor is reinforced as we begin the process of addressing additional body sensations associated with panic. Following the second interoceptive session, encourage the client to continue the exercise at home. If possible, a supportive family member should be enlisted as a helper in this exercise. (It is common for clients to report that after proceeding through three or four body sensations, they are no longer able to provoke them. In these instances it is possible to use the paradoxical injunction of "prescribing the symptom." When clients think they might be on the verge of an attack, we encourage them to "request" it . . . "bring in on, then!" Interestingly, it is sometimes a useful strategy for clients to face these sensations rather than avoid them.)

In Vivo Exposure

In vivo exposure treatment is used when the client experiences agoraphobia. It requires that clients engage in exposure practices by which they systematically venture into the situations they have been avoiding. Unlike panic disorders, agoraphobia is related to physical locations, and thus exposure to situations or places is warranted. A similar process to that previously described for interoceptive exposure is used (establishing a hierarchy of anxiety-provoking situations, exposing the client to these sequentially while assisting him or her in confronting and overcoming the anxious feelings). The sequence presented here often allows the client to conduct this component of treatment without the worker's direct assistance, sometimes with the aid of written or audio-taped journals. (This is one of the reasons we address the panic disorder prior to addressing the agoraphobia.) In vivo exposure administered by the client is comparable to that administered by the worker. Furthermore, including significant

others or spouses in treatment as coaches has beneficial effects for clients.

Although this program has been helpful to many people, it will not be successful with all clients. In such a situation, the reader is encouraged to use one of the additional healing methods, including meditation, exercise, herbal treatments, spiritual support, and self-help groups. With regard to the last item on the list, the resources offered by the Anxiety Disorders Association of America and the National Alliance on Mental Illness are particularly noteworthy, and their websites are provided in the reference section.

Eye Movement Desensitization and Reprocessing Therapy and Panic Disorders and Agoraphobia

Eye movement desensitization and reprocessing (EMDR) can be described as a form of structured exposure therapy combined with a specific "thought stopping" cognitive behavioral component (Feske & Goldstein, 1997). EMDR is used widely in the treatment of various clinical disorders including anxiety disorders, mood disorders, phobias, dissociative disorders, attention deficit hyperactivity disorder (ADHD), phantom limb pain and has proven to be particularly effective in the treatment of posttraumatic stress disorder (PTSD) and other trauma-related disorders (Davidson & Parker, 2001; Herbert et al., 2000; Maxwell, 2007). The literature is mixed, however, regarding the use of EMDR with clients diagnosed with panic disorder. There is insufficient evidence to suggest that EMDR is more effective than the other therapies discussed in this chapter in treating with panic disorder with or without agoraphobia (Davidson & Parker, 2001; Fernandez & Faretta, 2007; Feske & Goldstein, 1997; Sanchez-Meca, Rosa-Alcazar, Marin-Martinez, Gomez-Conesa, 2010). Clinicians considering the use of EMDR with clients diagnosed with panic disorder and agoraphobia should exercise caution in their professional judgment; these clients typically have highly sensitive fear networks that may become overwhelmed due to the intensity of the processing sessions (Fernandez & Faretta, 2007).

75 Treatment Plans for Clients with Social Anxiety Disorder

Bruce A. Thyer & Monica Pignotti

Contemporary social workers helping clients who experience significant problems with Social Anxiety Disorder (SAD) are in a very fortunate position indeed. The diagnostic conceptualizations of clinical anxiety have been considerably refined over the last five iterations of the *Diagnostic and Statistical Manual of Mental Disorders (DSM; American Psychiatric Association, 2013)*, and the newer nomenclature is closer to nature's truth about how clients experience pathological anxiety than the system described in previous editions. Clinicians are also fortunate in that considerable effectiveness and efficacy research involving very sophisticated randomized controlled clinical trials have demonstrated that selected psychosocial treatments are genuinely helpful in ameliorating SAD, a condition that, if left untreated, is typically chronic and unremitting, causing significant distress and impaired functioning. There are relatively few psychosocial problems facing social workers wherein the outcomes are so potentially favorable. Given this positive

state of affairs, it is incumbent upon social work practitioners who wish to practice both ethically and accountably to become familiar with research-supported methods of assessment and intervention found to be useful for socially anxious clients. This chapter will focus on diagnosis, assessment, research-based interventions, and treatment goals and planning for clients with social anxiety disorder.

CASE EXAMPLE

Fred W. (an actual client with social phobia treated by Thyer), was a self-referred 56-year-old male auto worker from Detroit whose presenting complaint was of extreme apprehension, fears of fainting, marked tremor, and agitation, which were reliably evoked whenever he was in situations involving face-to-face interactions with someone else. This was impairing his ability to work and had greatly restricted his social life. He could not stand in lines with people or participate in the

sacrament of communion at the Catholic church to which he belonged. The problem was absent in the presence of his wife and children, but otherwise always occurred when other people were near. When seated or able to lean against a wall or table, Fred could talk comfortably with anyone. If he had to stand unsupported while listening or talking, he would begin to tremble, perspire, and experience great anxiety. He dated the onset of this problem to an episode some 30 years earlier when he was in the military and was verbally abused by an officer in front of his fellow soldiers. He was unable to respond to the officer's angry tirade, which should have been directed against another soldier, not Fred. The problem has been continuous since that time without any remissions. The assessment and treatment plan that was carried out for Fred is described in Table 75.1.

DIAGNOSTIC CRITERIA AND PREVALENCE OF SOCIAL ANXIETY DISORDER

The term *social anxiety disorder (SAD)* is often used interchangeably with the term social phobia, with the former now the primary term used in the *DSM-5*. Many clinical researchers and consumer advocacy organizations are encouraging the use of *SAD* because it promotes recognition of the problem as a serious, treatable condition rather than something to be stoically endured (Liebowitz, Heimberg, Travers, & Stein, 2000).

The *DSM-5* lists about a dozen distinct disorders that may apply to children and adults seeking help and who present with the prominent features of anxiety, fear, avoidance, or increased arousal (American Psychiatric Association, 2013). The diagnostic criteria for Social Phobia (SP) first appeared in the third edition of the *DSM*, were revised somewhat in *DSM-III-R*, again in the *DSM-IV* and in the *DSM-IV-TR*, and now most recently in the *DSM-5* and renamed Social Anxiety Disorder (American Psychiatric Association, 2013). At present, SAD is defined by the following diagnostic criteria:

"A. Marked fear or anxiety about one or more social situations in which the individual is exposed to possible scrutiny by others. Examples include social interactions (e.g., having a conversation, meeting unfamiliar

people), being observed (e.g. eating or drinking), and performing in front of others (e.g., giving a speech).

- B. The individual fears that he or she will act in a way or show anxiety symptoms that will be negatively evaluated (e.g., will be humiliating or embarrassing; will lead to rejection or offend others).
- C. The social situations almost always provoke fear or anxiety.
- D. The social situations are avoided or endured with intense fear or anxiety.
- E. The fear or anxiety is out of proportion to the actual threat posed by the social situation and to the sociocultural context.
- F. The fear, anxiety or avoidance is persistent, typically lasting six months or more.
- G. The fear, anxiety, or avoidance causes clinically significant distress or impairment in social, occupational, or other important areas of functioning."

In addition, the features of SAD cannot be better explained by another mental disorder, a substance, or a medical condition (APA, 2013, pp. 202–203). There is only one specifier for SAD, *Performance Only*, that applies if the fear is centered around speaking or performing in public.

SAD is the fourth most common psychiatric disorder in the United States with a lifetime prevalence of approximately 12%, exceeded only by major depression, specific phobia, and alcohol dependence (Kessler et al., 2005). The 12-month prevalence rate for SAD in the United States is about 7% (APA, 2013, p. 204). The mean age of onset is during the teenage years (Thyer, Parrish, Curtis, Nesse, & Cameron, 1985), although some research has shown a bimodal distribution, with the onset for some individuals, who may have a more generalized form of social phobia, occurring earlier in childhood (Stein, Chavira, & Jang, 2001). Alcohol abuse can be a consequence of individuals with social phobia drinking to self-medicate symptoms (Thyer et al., 1986), and a careful assessment of possible alcohol and drug abuse is advisable in its own right. SAD has also been shown to be highly comorbid with major depressive disorder and appears to have a negative impact on its course and outcome (Zimmerman & Chelminski, 2003). The personal and societal ramifications of SAD can be profound. For example, Tolman et al. (2009) found that SAD can be

TABLE 75.1 Treatment Plan Worksheet for an Actual Client with Social Phobia

Assessment			
Assessment Domain	Assessment Method	Assessment Goals	Findings
Biological	Client interview	Eliminate possible role of biological factors in causing client's problems (n.b.—it is rare to find such factors)	Onset and course consistent with psychosocial etiology Extreme situational specificity of problem. Ruled out organic causes Client not taking any drugs
Diagnostic	<i>DSM</i> -based clinical interview <i>DSM</i> -based decision tree Rapid assessment instruments	Ascertain that client met <i>DSM</i> diagnostic criteria for SAD	Client met <i>DSM</i> criteria for SAD, and no other disorder
Familial	Interview with wife Interview with client (separately and together)	Investigate impact of client's problem on marital/family life	
Specification of situations where client experiences social anxiety	Client interview	Development of a rank-ordered list of social situations producing anxiety	Situations mentioned by client included standing in public waiting lines, church communion, and face-to-face interactions

Treatment Planning

Domain	Intervention Plan	Conduct and Results
Observable behavior (avoidance of unsupported face-to-face contact; observable tremor; seeking physical support)	Graduated real-life exposure; repeated exposure therapy sessions alone. Allow symptoms to develop while remaining standing in front of therapist without support. Find out if behaviors subside and discomfort lessens. Move to more intense and real-life situations outside private office.	Three 60–90-minute sessions in the office eliminated visible tremor and perspiration. Client became very comfortable standing in front of therapist. Subsequent sessions undertaken in large, empty auditorium. Moved to similar sessions involving long lines of people at movie theaters and fast-food restaurants. Therapist modeled and client subsequently imitated an obvious and deliberate tremor while standing in public waiting lines. Client self-conducted exposure exercises in between weekly sessions with therapist, at church and work. Treatment involved eight sessions with therapist, resulting in virtual elimination of problem. Three-year follow-up by phone found continuous absence of presenting problem and greatly enhanced functioning at work and social life.
Cognitive (thoughts of acting in an embarrassing manner; catastrophic thinking: “My boss will see me shaking and fire me!”)	Think-aloud during exposure sessions, recognize unrealistic nature of fears, voice more realistic coping responses.	Distressing and catastrophic thoughts gradually reduced after experiencing elimination of tremor, sweating, and support seeking.
Affective (severe anxiety when facing others unsupported; anticipatory anxiety about facing future situations)	Consciously control breathing during exposure sessions, rehearse coping responses in imagination and in real life.	Anxious feelings gradually eliminated during the course of treatment.

a significant impediment to returning to work among women welfare recipients.

FURTHER ASSESSMENT OF SOCIAL ANXIETY DISORDER

Arriving at a *DSM* diagnosis of SAD is only a part of a comprehensive social work assessment, which should involve an array of quantitative and qualitative methods of appraisal—the clinical interview; structured client self-reports (e.g., narrative diaries, logs of out-of-home social/public activities); rapid assessment instruments; structured clinical interviews centered around anxiety disorders; medical check-ups to rule out organic causes, including the possible role of medication effects and drug interactions; and, possibly, interviews with other family members.

There are highly specific rapid assessment instruments and rating scales developed for assessing aspects of SAD and related client functioning. A partial list of frequently recommended tools can be found in Table 75.2. Pretreatment assessment should involve using one or more of these reliable and valid outcome measures, ideally encompassing a rapid assessment instrument, as well as direct measures of behavior, perhaps systematically recorded by the client or a significant other. Some measures may be administered daily

or weekly. Other, more global, outcome indicators, such as a quality-of-life scale, a measure of family functioning, or a measure of overall health, simply could be administered pre- and post-treatment.

A functional analysis of the environmental and internal (e.g., troubling thoughts) antecedents to and the consequences that follow behaviors associated with SAD (overt actions, feelings, and thoughts) may be highly relevant. Mattaini (1990) and Filter and Alvarez (2012) provide a recommended review of the importance of such functional behavior analyses as a part of social work assessment.

Once it has been determined that clients meet the *DSM-5* criteria, it is essential to carefully isolate the parameters or boundaries of their anxiety-evoking stimuli, because various types of social phobia can be quite diverse. A well-established way of accomplishing this is for client and social worker to construct a rank-ordered list of specific social situations that lead to anxiety for the client (Heimberg, 2002). Such a list can then be incorporated into a treatment plan that will be described later in the chapter.

RESEARCH-BASED EVIDENCE AND PRACTICE KNOWLEDGE

Consistent with the recommendations to be found in the Surgeon General's report on mental illness (Satcher, 1999), social workers should become competent in providing contemporary research-based psychosocial treatments for anxiety disorders. A large body of research exists in support of effective psychosocial interventions for SAD, based on various combinations of behavioral and cognitive behavioral approaches (see Heimberg, 2002; Rodebaugh, Holaway, & Heimberg, 2004; Barlow, Allen, & Basden, 2007, for full reviews). Components of these interventions include exposure to feared stimuli, social skills training, relaxation training, and cognitive restructuring. These interventions have been successfully conducted in both group and individual therapy settings.

The most important component of the treatment is exposure, the element that all successful interventions for SAD have in common. The first step of the process is for the social worker and client to put together a rank-ordered list, from least to most frightening, of social situations that

produce anxiety (Heimberg, 2002). Exposure can be accomplished by imagining fearful scenes, usually narrated by the therapist (imaginal exposure); role playing with the therapist or others who resemble people the client fears; or by direct exposure to the feared situation (real life exposure). The client agrees to remain in the anxiety-evoking situation with the therapist's support until the anxiety considerably diminishes. Imaginal rehearsal and prolonged exposure in fantasy can be conducted in situations where real life exposure is not possible (e.g., an upcoming once-in-a-lifetime solo performance by a musician at Carnegie Hall), although real life exposure is usually preferable when possible. This is due to the fact that imaginal exposure is considerably removed from the real thing and considerably less effective at either inducing anxiety or helping the client develop genuinely effective coping and performance skills in real life. Exposure can be carried out in individual or group therapy settings, and clients are usually given exposure exercises as homework, to carry out on their own between sessions.

Social skills training (SST) is based on the premise that a lack of social skills, such as poor eye contact or poor conversation skills, can result in a negative reaction from others, thus causing unpleasant and anxiety-provoking social interactions with others. Even though there is still some debate as to whether all clients need SST (Rodebaugh et al., 2004), this approach has been shown to be effective as both a stand-alone intervention and in conjunction with exposure-based approaches. A controlled clinical trial (Herbert et al., 2005) compared cognitive-behavioral group therapy (CBGT) alone with CBGT and SST combined. The trial showed significantly greater gains for the CBGT and SST combination. Moreover, the effect sizes were reported to be the largest found to date for an SAD intervention, which means that the results were highly clinically significant and robust.

Relaxation training can be used in conjunction with exposure therapy, although relaxation training alone has not been shown to be helpful and has sometimes been used as a control condition in studies (Rodebaugh et al., 2004). The most commonly used form of relaxation training is progressive muscle relaxation, which is employed in a process called applied relaxation. It has been shown to be effective for SAD when clients are trained in it and then

use it while confronting feared situations (Öst, 1987). Systematic reviews and meta-analyses of the intervention research on SAD have shown medium-to-large effect sizes, indicating clinically significant results for exposure therapy with or without the relaxation component (Rodebaugh et al., 2004; Acarturk, Cuijpers, van Straten & de Graaf, 2008; Powers, Sigmarsson, & Emmelkamp, 2008). More recent work has demonstrated transferability of these research-supported behavioral therapies into everyday clinical settings, as well as into international settings, with similarly positive results (e.g., Kawaguchi, Watanabe, Nakano, Ogawa, Suzuki, Kondo, Furukawa, & Akechi, 2013).

Even though these highly effective psychosocial treatments for SAD exist, some clients are not helped by such treatments and others achieve only partial symptom reduction (see Herbert et al., 2005, for a review). Thus, the search for ways to improve existing interventions and conduct research on innovative treatments continues. When using any innovative treatment, it is crucial to provide full informed consent to the client on the state of the evidence and to try the interventions with the greatest empirical support first. One newer approach of interest to researchers is Acceptance and Commitment Therapy (ACT; Hayes, Strosahl, & Wilson, 1999). ACT is based on behavior therapy, with the addition of mindfulness and acceptance components. Pilot studies have shown promising results when the ACT model is incorporated into exposure therapy for SAD (Dalrymple & Herbert, 2007; Ossman, Wilson, Storaasli, & McNeill, 2006). ACT is based on the idea that the primary reason people suffer from psychological disorders is not negative emotions per se but rather the struggle to control and avoid experiencing such emotions. Unlike many conventional therapies, the explicit goal of ACT is not to eliminate negative emotions or reduce symptoms (although the pilot studies show that this can often occur), but instead to assist the client in giving up the struggle against emotions and thus promote a nondefensive acceptance (not mere tolerance) of emotions, including anxiety. The identification of client values and helping the client take committed value-directed action is also an important element of ACT. ACT has also been shown to increase a person's willingness to engage in exposure-based procedures (Hayes, Luoma, Bond, Masuda, & Lillis, 2006).

Considerable research has also gone into investigating the effectiveness of various

medications to help clients with SAD and the general consensus of reviews on this topic is that selected medications are indeed helpful in temporarily reducing symptomatology (Stein, Ipser, & van Balkom, 2004; Blanco, Bragdon, Schneier, & Liebowitz, 2013; Stein et al., 2010). However, unlike psychosocial treatments the effects are ameliorative, not curative, and relapse is high following the discontinuation of medication. Furthermore, medication treatment provides no behavioral benefits to clients whose SAD is related to a skills deficit (e.g., initiating and maintaining conversations, or underassertiveness), in terms of helping them develop such functional behaviors.

TREATMENT GOALS

- Ideally, the goal mutually arrived at with a client with SAD is the complete alleviation of pathological anxiety—in other words, a cure.
- More realistically, the goal would be more enhanced functioning and some relief of symptoms, not necessarily a complete remission of the difficulty. Incorporation of ACT principles may be helpful for such clients.
- Enhanced quality of life, improved relationship and family functioning, more effective vocational functioning, and increased ability to function in other areas of life valued by the client (e.g., hobbies, recreation, social activities, volunteer work).

These constructs are all amenable to reliable and valid qualitative and quantitative measurement (using some of the assessment protocols already described) before, during, and at the completion of treatment, and sometimes thereafter. Such data should be routinely gathered and shared with clients (and perhaps their family members) as appropriate. Graphing relevant data and including these in client records is also a recommended practice.

TREATMENT PLANNING

A representative assessment treatment plan taken from one of the authors' (Thyer) clinical work with socially phobic individuals was presented in Table 75.1.

Social phobia also lends itself very well to social group work treatment, which has been shown to be quite effective (Heimberg, 2002).

Former and current social phobics can themselves be very useful as lay therapists (Ross, 1980). Additionally, exposure therapy conducted in group work settings has been shown to be helpful, especially for clients with the generalized form of SAD, to assess for the need for social skills training, because, as previously noted, this was shown to enhance the effects of exposure therapy (Herbert et al., 2005). For public speaking anxiety, a very friendly and supportive organization called Toastmasters International, devoted to helping individuals improve public speaking and leadership skills, can be very helpful. The Toastmasters program is, in effect, a lay-developed program of graduated exposure therapy sessions.

Integration of Psychodynamic and Cognitive-behavioral Practices

Terry B. Northcut & Nina Rovinelli Heller

Many of the clients we work with have forms of acute or chronic depression that render daily life a struggle. Results from the 60-country World Health Organization (WHO) World Health Survey (<http://www.who.int/healthinfo/survey/whsresults/en/index.html>), which included depression as the only mental health condition surveyed, revealed, a 3.2% 12-month prevalence rate for major depression. Among participants with a chronic condition, however, the rate was much higher, at between 9.3% and 23.0%. In the United States, major depression is the most prevalent mental health condition, at a rate of 29.9% lifetime and 8.6% 12-month prevalence. Furthermore, WHO reports that major depression is the fourth leading cause of disability worldwide and identifies increasing prevalence in younger cohorts, although the reasons for this are unclear (Kessler et al., 2012). The human costs of depression are staggering; Kessler reports significant negative impacts in the areas of education performance and completion, marital timing and stability, teen childbearing, employment status, role performance, marital and parental functioning, financial success, and comorbid impairments (pp. 3–6). Theories regarding the etiology of depressive conditions include genetics and biology, as well as a combination of vulnerabilities and risk factors (diathesis-stress model; Paris, 1996). Furthermore, depressed people are at elevated risk for death by suicide (Kessler et al., 2012). Untreated depression affects individuals, their families, and communities, in nearly every domain of functioning. The restoration of adaptive functioning and full engagement in one's life—in work, in love, and in play—is the central focus of our attempts to help clients who suffer with this debilitating condition.

THEORETICAL APPROACHES TO THE TREATMENT OF DEPRESSION

Clinical social workers in a wide variety of practice settings work with clients who have both diagnosed and undiagnosed depressive disorders. The identification of people with depression has increased over the past decade, as has the range of available treatment options. With a strong legacy of employing a bio-psychosocial perspective, social workers are well positioned to accommodate the growing bodies of knowledge from biological/genetic, psychological, and sociological theories and evidence-based practices. Social workers in public and private settings are often on the front lines of work with individuals and families and are in positions in which they can pay attention to prevention, identification, and treatment of depressive disorders for all ages.

With the advent of second- and third-generation antidepressant medications, biological interventions have become common, whereas half a century ago, psychotherapy alone was the treatment of choice. At that time, psychodynamic or psychoanalytic theory and technique recognized depressive disorders as largely psychological in nature. This reflected the tremendous legacy of Freudian psychology, which interestingly enough, originated in Freud's interest in neurobiological processes, viewing depression as "anger toward inward"—in other words, in largely psychodynamic terms. Other psychodynamically oriented theorists have posited that depression is related to mourning, ambivalence regarding a lost object, narcissistic injury, abandonment fears, and disrupted attachments. Since the late 1970s, cognitive theory (Beck, 1979, 1987,

1995; Reinecke & Davison, 2002, among others) has been highly influential in the treatment and research of many psychiatric disorders, most notably depression. Cognitive theory posits that the negative affects experienced in depression are a result of cognitive distortions and faulty thinking processes. The prescribed intervention, then, is the identification and modification of those distortions through psychotherapy.

Various theoretical schools have historically tried to lay claim to superiority over other schools in terms of treatment success. This has been made possible, in part, by the increased availability of research funding, particularly from the National Institute of Mental Health, for psychotherapy evaluation studies. Simultaneously, there has been a shift in the social work field toward identifying evidence-based practices. Psychotherapy evaluation studies are labor-intensive and require sophisticated designs and data analysis (Abbass, 2002). Cognitive therapy, which lends itself well to research studies because of its clearly identified assessment and intervention strategies, has led the way in terms of psychotherapy research. Early studies suggest that cognitive therapy is at least as effective as antidepressant medication (Zeiss, 1997). Still others have found that the combination of cognitive therapy and medication therapy is superior (Reinecke & Davison, 2002). Treatment effectiveness studies of psychodynamic interventions have been slower to develop, but Fonagy, Roth, and Higgins (2005) have published an exhaustive review of evidence-based psychodynamic treatment. Although there exists a robust evidence base for the efficacy of cognitive behavioral interventions for depression, psychodynamic treatment may be worth another look. Luyten and Blatt (2012) note significant increases in psychodynamic outcome research and promising results; in regard to depression, both short- and long-term psychodynamic treatments are as effective as other psychological approaches and may have longer term positive effects. When compared with psychopharmacological approaches, they found that psychodynamic treatment is as effective in acute treatment of mild and moderate depression and may confer greater long term effects when used in combination or alone.

Social workers look to theory, "practice wisdom," and research to guide our practice. On the basis of all three components, we do have some general guidelines for the assessment of depression. Assuredly, any client who is demonstrating vegetative signs of depression

(significant changes in sleep, appetite, weight, libido, or psychomotor retardation or agitation) should be considered for referral to a medication evaluation. Likewise, clients who are suicidal or engaging in self-destructive behaviors, in addition to depressed mood, distorted thinking, and feelings of hopelessness or helplessness, could possibly benefit from medical intervention. Most of these clients will also benefit from psychotherapy (Areán & Cook, 2002; De Maat, Dekker, Schoevers, & DeJonghe, 2006; Finn, 2000; Reinecke & Davison, 2002; Sagar, Zindel, Grigoriadis, Arun, Ravindran, Kennedy, Lam, & Patten, 2009; Zac, Imel, Malterer, McKay, & Wampold, 2008). In addition, bio-psychosocial assessment can be enhanced with the use of depression measures.

INTEGRATING THEORETICAL PERSPECTIVES

We favor an integrative approach to psychotherapy with depressed clients, specifically one that uses a psychodynamic perspective and integrates specific cognitive techniques. The reasons for this bias toward an integrative approach lie in our understanding that modern psychodynamic theory inherently captures the complexity of the subjective experience of the individual, whereas cognitive theory offers very clear, sometimes prescriptive techniques aimed at increasing problem-solving skills and changing faulty thinking. The combination of the two approaches offers the opportunity to intervene successfully on both affective and cognitive levels, while doing so in a way that includes the idiosyncratic historical, social, and cultural experiences of the client. Strengths of psychodynamic theory as they pertain to the treatment of depression include (1) an understanding of the power of unconscious processes; (2) the awareness of the impact of interpersonal loss on feeling states; (3) the importance of early developmental influences; and (4) the power of the therapeutic relationship, specifically in regard to transference and countertransference phenomena.

Psychodynamic theory, then, pays particular attention to the feelings or affects of the client, considering these as a central focus for change. Hence, psychodynamic techniques include exploration of feeling states and their etiologies, particularly in the interpersonal realm. Exploration of the past, specifically in terms of its influence

in the present, is often central to the therapeutic work, particularly in crisis, or reactive, depression (Reinecke & Davison, 2002). Finally, the therapist actively uses the treatment relationship to explore issues such as loss, sadness, and anger. Interpretation of both conscious and unconscious material is central in the work.

Both psychodynamic theory and cognitive-behavioral theory have evolved to the point of focusing on the idiosyncratic meaning that clients make of the experiences in their lives, rather than recovering memories or applying standard treatments. Also commonly accepted is the understanding of the dynamic interaction between cognitions, affects, and behaviors and a focus on the treatment relationship. However, cognitive theory still retains its focus on cognitions clients report in the here-and-now as the focal point of interventions. In the case of depression, certain types of cognitive distortions are believed to be present, such as negative thinking, catastrophizing, overgeneralization, etc. The clinical social worker can utilize techniques including problem solving, cognitive restructuring, thought blocking, and Socratic questioning to identify and alter the depressive cognitions that color the client's view of him- or herself, others, and the world. Cognitive theorists have also been influenced by the constructivist philosophy, which views "truth" as contextual and personal. Likewise, the influence of neurobiology has demonstrated the ability of the brain to change over time through intimate relationships and the larger social world, which reinforces these patterns of meaning. Consequently, cognitive theorists may use the concepts of schemas and attributions to describe sets of beliefs and assumptions about meaning and causation (e.g., arbitrary influence, personalization) that may have early origins and have been confirmed by subsequent life experiences. Through identifying the schemas, cognitions, or faulty thought patterns, clients can practice in vivo and with homework assignments, confronting and correcting the cognitive distortions that are common to depression (Beck, 1961, 1979, 1987, 1995, 2011; Gega, Smith, Reynolds, 2013; Leahy, 2003; Neimeyer, 2010; Newman, 2010).

Traditionally, cognitive theory has been characterized by (1) a here-and-now orientation; (2) a belief that thoughts affect or determine feeling states; (3) a belief that people who are depressed demonstrate a certain set of cognitive distortions (such as negative thinking, dichotomous thinking, catastrophizing, overgeneralization, selective

abstraction, magnification, and minimization). More recently, cognitive theorists who lean more toward the constructivist position than to their behavioral origins see cognitive schemas and attributions that are particular to the depressed client because they have idiosyncratic meaning. These schemas and attributions are sets of beliefs and assumptions about meaning and causation (e.g., arbitrary influence, personalization) that may have early origins and have been confirmed by subsequent life experiences. In both the early and the more recent cognitive therapies, the therapist directs his or her attention to the identification and correction of faulty cognitions that reinforce the client's depressive stance. Techniques such as problem solving, cognitive restructuring, thought blocking, and Socratic questioning can be very helpful in changing the depressive cognitions that color the client's view of him- or herself, others, and the world. Through the use of these techniques, combined with in vivo and homework assignments, the client is able to identify, confront, and correct the cognitive distortions that are common to that feeling state (Coelho, Canter & Ernst, 2013; Gabalda, 2010; Gabalda & Neimeyer, 2010).

A client who is depressed is in subjective distress. Both psychodynamic therapists and those who hold a cognitive-constructivist perspective value the importance of the client's narrative of his or her own experience. One depressed client is not like another, although they may share certain characteristics, as noted. For example, one client's sense of lethargy or helplessness may have very different origins, meanings, and manifestations than another's. The psychodynamic therapist is interested in both the conscious and unconscious determinants of this as well as those factors that maintain such feeling states. As many of us have witnessed, however, insight alone is often not sufficient and sometimes not even necessary to effect therapeutic change. In these instances, the addition of cognitive techniques may be enormously helpful in terms of systematically addressing the cognitive beliefs and distortions that may interfere with the client's "feeling better."

CONSIDERATIONS IN ASSESSMENT AND TREATMENT PLANNING WITH DIVERSE POPULATIONS

Table 76.1 outlines the critical areas for attention, assessment, and intervention with *all* clients, and

TABLE 76.1 Guidelines for Assessment and Treatment Planning

-
- Evaluate carefully for safety risks, including passive and active suicidal behaviors and impulsivity. Consult recent research regarding suicide risk as associated with demographic variables, such as prior attempts, formulation of a plan, and age group.
 - In the event that the client is deemed to be at risk for harm to self or others, consider lethal means restriction through discussion with the client and family members where possible.
 - Create an empathetic connection with the client.
 - Refer for medical evaluation to rule out depression due to a general medical condition (*DSM-5*).
 - Evaluate for substance abuse and differential diagnosis.
 - Refer for evaluation for antidepressant medication, particularly in the presence of vegetative signs of depression.
 - Administer a standardized depression scale, such as the Beck Depression Inventory.
 - Evaluate and utilize family and social supports.
 - Assess socioeconomic issues and be familiar with relevant research literature.
 - Consider developmental and cohort factors and the related research.
 - Assess and refer to existing literature regarding incidence and manifestation of depression in certain demographic groups, such as gender, race/ethnicity, sexual orientation, and differential abilities.
 - Evaluate affective, cognitive, and behavioral manifestations of depression.
 - Encourage clients to verbalize their own understanding and hypotheses about their current depression.
 - Be aware of both conscious and unconscious elements of the depression.
 - Make judicious use of both insight-oriented exploration and cognitive-behavioral strategies, designed to restore optimum levels of functioning.
 - Identify and explore distorted cognitions.
 - Assess for and promote healthy self-care activities related to sleep, eating and exercise.
 - In cases of severe unremitting depression, consider referral for evaluation of emerging biological treatment interventions including repetitive transcranial magnetic stimulation (rTMS).
-

particular note should be made regarding the need for culturally sensitive and knowledgeable assessment with people from diverse backgrounds. For diverse populations, the following areas merit particular attention.

- Consider differences in the presentation of symptoms and the cultural meaning of those symptoms (e.g., somatic complaints).
- Consider possible assumptions and beliefs about mental health providers and mental health treatment within the client(s) cultural system (e.g., social workers are part of the majority culture; “probably won’t understand”).
- Consider different ways of describing depressive symptoms related to cultural differences and/or geographical differences (e.g., “nerves”).
- Consider the possible stigma associated with seeking mental health services from within or outside the client(s) system (e.g., shaming to family or “only for crazy people”)

(Boyd-Franklin & Lockwood, 1999; Falicov, 1999, among others).

CASE ILLUSTRATION

The Client’s Story

Jackie is a 53-year-old woman who describes herself as “chronically tired.” According to Jackie, the highlight of her day as a licensed practical nurse (LPN) at a local metropolitan hospital is the ride home on public transportation when she can sleep or “zone out” because she does not have to make any bus changes. Jackie remembers her mother coming home from “doing hair” at the beauty salon and soaking her feet after standing all day. “I may have more education but I’m just as tired Mama was.” Jackie’s husband Fred, 57, has early onset Parkinson’s disease and is not able to work any longer. He used to be “amazing with cars” but currently spends all of his time at home. Because he was self-employed, his health insurance has always come from Jackie’s

employment, so she feels she must stay at her job even if she had somewhere closer and less demanding to work. Jackie is able to pick up extra shifts when they are available. Their three children are 11 years, 15 years, and 19 years old. The 19-year-old son is in his second year at the community college, and although she is very proud of him, Jackie worries because he works or is at school all of the time. The youngest, a son also, still has his own quirky sense of humor but is “awfully quiet these days.” Jackie jokingly says her 15-year-old daughter scares her to death; “I don’t know whether to trust her or send her to a convent.”

Jackie reports being depressed, particularly this last year. Work has gotten more demanding and stressful but does not seem to have changed dramatically during this time. Fred’s health currently is at a plateau, which is a rarity in terms of the roller coaster of changes in his physical functioning. The children each have their own pressing needs, according to their mother, but “it’s easier to not ask too many questions about what is going on with them.” Jackie states that her general internist did not find anything wrong with her in a physical—her first in five years—that a month-long vacation would not help. Jackie did not find that much comfort or much help, but has not had the time to pursue any other opinions or specialists. She cannot remember when she had her eyes checked to update her glasses, when she has been to the dentist for the chronic pain she has in one tooth, or has been to see a gynecologist. Jackie says she just feels grateful that she has not had anything “go terribly wrong.” She does get yearly mammograms because the hospital where she works provides these as an employee benefit. Jackie says that she has gained weight in the last year but thinks that is just what happens when you get older. Jackie’s mother lives with them and has since Jackie’s father passed away five years ago from emphysema. Her health is good despite “slowing down” at the age of 79.

Case Formulation

Jackie is faced with challenges from a variety of perspectives: (1) life cycle—children in adolescence (early, middle, and late adolescence); (2) continuing adaptation to husband’s illness and declining health; (3) personal physical health changes and vulnerability; (4) increasing responsibilities associated with mother’s aging;

(5) economic demands and full-time employment. These challenges all exist in the historical context of her own mother’s difficult adaptation to Jackie’s father’s increasing frailty at mid-life and in the social context of women’s traditional roles as caretakers.

Certainly, Jackie’s presentation of extreme exhaustion, weight gain, and lack of self-care can paint a picture of depression as described by the *DSM-5*. In addition, as the social worker explores her symptoms further, Jackie reports feeling helpless and hopeless that things would change, also characteristics consistent with depression. Because Jackie has not been to a gynecologist recently and her understanding is incomplete about what kind of tests were completed with her internist, the social worker secures Jackie’s permission to consult with her doctor. The social worker will need to determine whether any other physical issues were found, such as problems with her heart, blood pressure, thyroid, and gastroenterology, all areas that are important to check at Jackie’s age. It also will be important for Jackie to see a gynecologist to check her hormone levels for evidence of perimenopause or menopause. Certainly, any of these physical issues could be contributing to, or causing her depression. When the social worker explores the issue of referrals, he or she takes cues from how Jackie describes her symptoms. For example, depending on culture, family, religious belief, ethnicity, and childhood environment, Jackie could describe her symptoms as being caused by a variety of factors, such as a punishment from God, the result of energy blockage or bad karma, or a bad genetic predisposition. Jackie’s ideas about what is causing these symptoms will be important to discuss in light of a possible referral for antidepressant medication.

From a psychodynamic point of view, it will be helpful to explore prior losses Jackie has experienced in addition to the current losses and stressors. For example, Jackie’s children are growing up and seeking more independence; her mother’s physical stamina is declining; her husband’s disease is not going to improve; and Jackie’s own health is changing. All these factors can stimulate other historical feelings of helplessness. In asking whether there were other times in her life when Jackie has experienced this kind of helplessness and hopelessness, the social worker can determine whether there is a history of trauma or other significant losses, and what Jackie’s prior methods of coping have been. Although the current losses

in Jackie's life are developmentally appropriate, they also compound what seems to be stress consistent with her gender role. The social worker is familiar with the research on the enormous pressures experienced by Jackie as a member of a "sandwich" household, which requires her to care for both her own children and her remaining parent while continuing full-time employment. Likewise, Jackie may have set schemas or cognitive distortions about what she should be able to manage as a woman in this situation. Cognitive strategies can be used to help Jackie confront her own faulty perceptions about what is "normal" and "appropriate" functioning in her situation.

As with any client, the social worker explores social supports for Jackie. What kind of friendships does she have or has she had in the past? Is there a church or religious or spiritual practice that is helpful for her? What kind of neighborhood does she live in? Does she know her neighbors? Is there a support group for caregiving spouses through her work? Does she have a history of substance use or abuse? Is substance use or abuse occurring currently? What positive or negative ways has she tried to handle stress now and in the past?

Conclusion

A social work perspective suggests that clinical conditions are multi-determined and best understood through a bio-psychosocial-spiritual lens. It follows then, that in the case of depression, interventions should be multi-pronged, making use of the best possible theoretical and intervention approaches, some of which, in combination, may provide the best chances for short-term and long-term recovery. A necessary step in reviewing evidence-based practice is "integrating our critical appraisal with our clinical expertise and with our client's unique values and circumstances" (Thyer & Pignotti, 2011, p. 331). In the case of Jackie, the social worker made use of her psychodynamic understanding of unconscious processes, as well as the role of early schemas and current cognitive distortions.

Historically, social work theory and practice have been integrative. Particularly in our current practice arena, which demands brief but effective and hence efficient treatment interventions, the integration of cognitive-behavioral and psychodynamic theory is useful. This synthesis draws on the best of both traditions in an attempt to capture the complexity of the human experience,

particularly as it manifests in the very common condition of depression. Furthermore, the increased attempts to understand the complicated processes of both depression and its treatment via research efforts in the areas of differential theoretical approaches and neurobiology hold great promise for the social worker. It becomes a professional responsibility to seek out the most recent research findings, in addition to the knowledge of theory and employment of social work practice skills. The conscious and deliberate use of perspectives and techniques from both theories allows swift and systematic interventions while preserving the value of the contextual and historical influences that impinge on the healthy functioning and experience of our clients.

M. Elizabeth Vonk

People who are exposed to a traumatic event, including those who help with recovery efforts, may perceive that their own or others' physical integrity is threatened and often react with horror, fear, or helplessness. Any number of a variety of symptoms may be expected following traumatic events (Woo & Keatinge, 2008):

- Emotional. Reactions are generally very intense and may include fear, anxiety, anger, guilt, depression, and numbing. Many may feel overwhelmed by the intensity of their emotions.
- Cognitive. Reactions include difficulty concentrating and intrusive thoughts. In addition, survivors must struggle to make sense of an experience that contradicts formerly held assumptions regarding sense of control, safety, trust in self and others, personal power, and self-esteem.
- Somatic. Reactions may include sleep disturbance, nightmares, eating difficulties, and a variety of bodily complaints.
- Interpersonal. Reactions include disruptions in intimate and familial relationships, vocational impairment, and generalized social withdrawal.

Although symptomatic responses to trauma are normal, 7%–8% of people in the United States will develop posttraumatic stress disorder (PTSD) during their lifetime (Woo & Keatinge, 2008). Many factors are related to the development of PTSD following a traumatic event, including demographics, the nature of the traumatic event, and pre- and post-trauma characteristics (Keane, Marshall, & Taft, 2006;

Woo & Keatinge, 2008). People of all ages develop PTSD, but it appears children and the elderly are particularly susceptible. In addition, women appear to develop PTSD at a significantly higher rate than men. Life-threatening or extremely intense traumatic events, a history of childhood abuse or psychiatric disorder, and elevated levels of life stress are additional risk factors for the development of PTSD. Conversely, the availability of social support following traumatic events appears to decrease psychopathology.

The current *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)* definition of PTSD includes eight criteria (American Psychiatric Association, 2013):

- Criterion A. The person must be confronted directly or indirectly by an experience of death or threatened death; actual or threatened serious injury; actual or threatened sexual violence; or repeated exposure to the aversive details of a traumatic event in the performance of professional duties.
- Criterion B. The person must have at least one symptom of persistently re-experiencing the traumatic event, including intrusive images or thoughts, dreams about the event, a sense that the event is recurring, intense distress when reminded of the event, or physiological reactivity to event-related cues.
- Criterion C. The person must have at least one symptom of avoidance, including avoidance of thoughts, feelings, or talk about the event; or avoidance of activities, places, or people that are reminders of the event.

- Criterion D. The person must have at least two negative alternations in cognitions and mood, including inability to remember parts of the experience; diminished interest in important pre-trauma activities; sense of detachment from others; inability to experience a full range of emotions; or negative thoughts about self or the world.
- Criterion E. The person must have a minimum of two symptoms of increased arousal, including sleep difficulties, irritability or aggression, trouble concentrating, heightened startle response, or hypervigilance.
- Criterion F. The person must have the required array of symptoms for more than one month.
- Criterion G. The person must be experiencing impaired functioning at school, at work, or in relationships.
- Criterion H. Symptoms must not be due to medication, illness, or substance abuse.

In addition, the *DSM-5* definition includes two specifiers: (1) with dissociative symptoms, if symptoms of depersonalization or derealization are present at high levels; and (2) with delayed expression, if full criteria for diagnosis do not occur until at least six months after the stressor.

CASE STUDY

Before moving ahead to describe assessment of and intervention for PTSD, I would like to present a case study that will be used throughout this chapter to illustrate various aspects of therapeutic work with people who have PTSD.

Ben, a 26-year-old European-American graduate student sought therapy at a university counseling center following a motor vehicle accident that occurred four months earlier. Ben was a passenger in the car and sustained minor injuries. The driver, a close friend, was fatally injured. Ben remembers very little about the accident, has not talked to his fiancé or parents about what happened, and has “buried himself” in school work hoping to keep his mind away from thoughts of it. He reports feeling numb about his friend’s death, stating, “I haven’t cried about it at all, even at his funeral.” He wonders why he lived through it and thinks that he “should have done something” to keep his friend

from dying. He is also worried about how he has changed since the accident, thinking that he should be “over it.” Formerly a confident driver, Ben now feels “jumpy.” While he used to think of himself as “mellow,” he now feels irritable and impatient with his friends’ “constant joking around” and his fiancé’s “trivial worries” about their wedding plans. What bothers him most and prompted his visit to the counseling center are increasingly disturbing nightmares that disrupt his sleep and “flashbacks” that interfere with his concentration during the day. Ben wants to return to his former high level of functioning so he can complete his dissertation and enjoy relationships with his fiancé and friends. Ben reported no previous trauma and no medical complications.

ASSESSMENT OF POSTTRAUMATIC STRESS DISORDER

The diagnosis of PTSD is generally made within the context of a complete bio-psychosocial assessment. The assessment and diagnosis are based on in-depth clinical interview and utilization of standardized instruments.

The clinical interview allows the interviewer to explore the traumatic event and its aftermath in the context of the client’s life. Such interviewing can be challenging, requiring the interviewer to maintain a focus on the trauma and associated memories, thoughts, and feelings; avoid victim-blaming; actively listen to frightening or horrifying stories; and tolerate expressions of strong emotion.

In general, the clinical interview should include the client’s story about the traumatic event and aftermath; current cognitive, emotional, somatic, and interpersonal difficulties related to the event; pre-trauma level of functioning; and ways in which the person has coped with the event. In addition, the client’s family history, previous traumatic or abusive experiences, current living situation, availability of support, and expectations of therapy should be explored. Consideration must also be given to the client’s cultural background in order to gain greater understanding of the context and meaning of the trauma from the client’s perspective (Woo & Keatinge, 2008). Finally, the interviewer must be alert to signs and symptoms of other difficulties that often co-occur with PTSD, such as suicidal or homicidal

ideation; problems in family functioning; and mood, substance use, and personality disorders (Woo & Keatinge, 2008).

The diagnostic interview may be enhanced with the additional use of one or more standardized assessment tools. Structured interviews provide opportunity for in-depth exploration including detection of potential co-occurring mental disorders. Self-report measures may be valuable for assessing change in symptomatology over the course of treatment. Detailed information about the following and other structured interviews and self-report measures may be found on the assessment page of the National Center for PTSD (NCPTSD). (<http://www.ptsd.va.gov/professional/pages/assessments/assessment.asp>). Please note that at the time of this writing, assessment tools are in the process of being revised in response to changes in the diagnosis of PTSD in the *DSM-5* (APA, 2013).

- Structured Interviews
 - The Clinician Administered PTSD Scale (CAPS): assesses PTSD symptoms and impact on functioning related to single or multiple traumas
 - The Structured Interview for PTSD (SI-PTSD): assesses PTSD symptoms and behavioral and survivor guilt
- Self-report Measures
 - Screen for Posttraumatic Stress Symptoms (SPTSS): assesses PTSD symptoms unrelated to specific trauma; used as a preliminary screen for presence of PTSD
 - Posttraumatic Stress Disorder Check List (PCL): available in three versions, namely, military, civilian, and in relation to a specific stressor; assesses symptoms of PTSD and is useful for monitoring change during and after intervention

Treatment Goals and Objectives

Treatment goals and objectives follow directly from thorough assessment and are always individualized to particular clients. The following types of goals, however, are frequently included in effective interventions for PTSD.

- Increasing knowledge about and “normalizing” responses to trauma and PTSD

- Strengthening coping skills and social support systems
- Reducing guilt and eliminating self-blame
- Reducing symptoms
- Increasing functioning in social roles, such as at work and in the family
- Integrating the trauma into the client’s life experience

Case Study: Assessment and Treatment Goals

Ben’s assessment included a thorough unstructured clinical interview, completion of the Structured Interview for PTSD, and completion of the self-report Posttraumatic Stress Disorder Checklist (PCL). Through this process, the social worker at the counseling center determined that Ben’s signs and symptoms met the DSM-5 criteria for PTSD. Ben experienced a traumatic car accident in which a close friend lost his life; he felt that his own life was threatened (Criterion A). Since the trauma occurred, Ben has had persistent re-experiencing symptoms including nightmares and intrusive thoughts and images (Criterion B). Ben has had symptoms of avoidance including avoiding thoughts of the accident (Criterion C). He has experienced alterations in cognition and mood, including feelings of numbness and inability to remember details of the accident (Criterion D). He also has had increased arousal symptoms of irritability and hypervigilance while driving (Criterion E). His symptoms have been present since the accident occurred four months ago (Criterion F) and they have been negatively affecting his dissertation writing and interpersonal relationships with his friends and fiancé (Criterion G). Finally, the symptoms are not due to medication, substance abuse, or medical condition (Criterion H).

In addition to making the diagnosis, the social worker noted that Ben functioned quite well prior to the accident, had experienced no previous abuse or trauma, and had a good support system that included family and friends. Although Ben did not appear to have a co-occurring mental disorder, his customary coping resources appeared to be overwhelmed. He had developed maladaptive cognitions related to survivor’s guilt and gender-related expectations of himself, and his attempts to avoid processing the experience were impeding his recovery.

Ben's treatment goals and objectives were defined collaboratively with the social worker. By working together, the following mutually defined goals and objectives were established:

- Increase Ben's knowledge about trauma and PTSD
 - Ben will understand "normal" emotional, cognitive, somatic, and interpersonal responses to trauma.
 - Ben will educate his fiancé about trauma and PTSD.
- Increase Ben's ability to actively manage his anxiety at work and in social settings
 - Ben will increase his ability to concentrate at work.
 - Ben will increase his enjoyment in social settings.
- Decrease the frequency of Ben's nightmares and intrusive thoughts of the accident
- Increase Ben's ability to tolerate exposure to thoughts and feelings that are reminders of the accident
 - Ben will be able to describe the accident to the social worker.
 - Ben will be able to describe his experience, its aftermath, and ongoing progress toward recovery with his fiancé and father.
- Modify Ben's beliefs about the accident that are associated with disturbing emotions
 - Ben will modify his belief that he is somehow to blame for his friend's death.
 - Ben will identify and modify other disturbing thoughts about himself, others, and the world in relation to the accident.

Ben and the social worker agreed to work toward these goals with weekly meetings for a period of three months, at which time they would reassess to see what additional work might be needed.

TREATMENT OF POSTTRAUMATIC STRESS DISORDER

A variety of interventions, both pharmacological and psychosocial, have been tested and found effective in the treatment of PTSD. The strongest evidence has been found for the use of exposure, cognitive, and anxiety

management therapies (Foa, Keane, Friedman, & Cohen, 2009; Veterans Administration [VA]/U.S. Department of Defense [DoD], 2010). Although each intervention is described separately, it is important to remember that most practitioners combine a variety of interventions when treating a client with PTSD. Because the range of symptomatology is so great, the particular combination of interventions must be based on the individual needs of each client. More detailed guidance on implementation and individualization of effective interventions for PTSD can be found in *Clinical Practice Guideline for Management of Posttraumatic Stress* (VA/DoD, 2010). In addition, several treatment packages have been developed that combine and focus efficacious interventions to treat PTSD in response to specific types of traumas. These include, for example, Trauma-focused Cognitive Behavioral Therapy (TF-CBT), developed to treat children between the ages of 3 and 18 years who have experienced traumatic abuse (Cohen, Mannarino, & Deblinger, 2006); and Cognitive Processing Therapy (CPT), developed to treat PTSD related to the trauma of rape (Resick & Schnicke, 1997).

Pharmacological Treatments

In general, psychotropic drugs are used to provide relief from specific symptoms, such as anxiety or depression, enabling the trauma survivor to make better use of concurrent psychosocial therapy. Based on an extensive review of empirical research, the NCPTSD's *Clinician's Guide to Medications for PTSD* (Jeffries, 2009) describes the classes of drugs that have been used to treat PTSD, evidence of effectiveness, and both benefits and risks of utilizing particular drugs. Among others, these drugs include antidepressants (tricyclics, monoamine oxidase inhibitors [MAOIs], and serotonergic reuptake inhibitors [SSRIs]), anxiolytics (benzodiazepines, buspirone), and sleep aids. Without question, the strongest evidence of effectiveness has been found to support the use of serotonergic reuptake inhibitors (SSRIs). Despite the positive effect of SSRIs on PTSD related symptomatology, treatment of PTSD through the use of pharmacology alone has not proven to be as effective as various psychosocial treatments (Keane, Marshall, & Taft, 2006).

Exposure Therapy

Exposure therapy is a behavioral intervention that involves activation of the traumatic memory through the use of associated imaginal or in vivo cues. It is used to decrease avoidance, intrusive thoughts, flashbacks, trauma-related fears, and panic attacks. The exposure must be of significant duration so as to allow the client's anxiety level to substantially subside in the presence of the feared, but harmless cue. Because the idea of confronting or reliving the traumatic event is frightening, survivors need to have a clear rationale and understanding of how exposure therapies work in order to be informed participants in the intervention. In addition, the development and maintenance of a trusting therapeutic relationship seems to be essential for successful completion of exposure therapies.

Cognitive Therapy

The goal of Cognitive Therapy (CT) is to learn to identify and eliminate specific thoughts that are causing negative emotional reactions and behaviors. This is achieved by challenging the thoughts through a process of logical examination of their veracity or functionality, followed by replacement of those that are dysfunctional with more reasonable ones. Dysfunctional beliefs following traumatic events vary, but several themes are common, including overgeneralizations about danger in the world and one's personal vulnerability, unrealistic self-blame and guilt about the event, loss of meaning for one's life, and broken trust in others and self (Woo & Keatinge, 2008).

Anxiety Management

A variety of behavioral and anxiety management interventions have been used to help people with PTSD cope with and manage emotions. One such anxiety management program, stress inoculation training (SIT) was developed by Meichenbaum (1997) to treat a variety of anxiety disorders, including PTSD. SIT aims to help clients manage and reduce anxiety through the development of skills such as relaxation and breathing techniques, cognitive restructuring, guided self-dialogue, thought-stopping, and role-playing. The treatment takes place in three phases. First, the client is educated about responses to trauma and PTSD. Next, the coping

skills are taught to and rehearsed by the client. Finally, the newly developed skills are applied through graduated exposure to stressful cues and memories associated with the traumatic event.

Eye Movement Desensitization and Reprocessing

Eye Movement Desensitization and Reprocessing (EMDR) combines aspects of cognitive and imaginal exposure techniques with saccadic eye movements in a specified protocol (Shapiro, 2001). Although many studies have supported the effectiveness of EMDR for the treatment of PTSD, some skepticism about the intervention remains. Specifically, the theoretical foundation and the necessity of eye-movements in the treatment have been questioned. Research examining effectiveness of the components that make up EMDR provide some support of the likelihood that clinically relevant components include exposure, cognitive restructuring, and emotional processing (VA/DoD, 2010).

Posttraumatic Growth

Calhoun and Tedeschi (2012) call attention to the potential for growth following traumatic experiences. Without minimizing the negative psychological consequences following trauma for many survivors, these authors examine the ability of some trauma survivors to experience significant personal growth following traumatic experiences. They review literature that identifies several areas of growth, including strengthened interpersonal relationships; changed self-perception that includes both increased vulnerability and strength; and changed philosophy of life that includes a shift in priorities and greater appreciation of life. In addition, the authors address facilitation of posttraumatic growth.

Case Study: Interventions and Evaluation

Having decided on treatment goals and preferred interventions, Ben indicated that he would like to start with exposure therapy to decrease his nightmares and "flashbacks." Secondarily, he hoped to be able to share some of his experience with his fiancé "to help her understand what I've been through." Knowing that the success

of exposure relies on a strong therapeutic relationship, the social worker spent time preparing Ben for the intervention. Imaginal exposure was used initially, but was soon followed by in vivo exposure in which Ben was asked to drive on the street where the accident took place.

During the course of the exposure intervention, the social worker began to identify Ben's distressing beliefs about the accident, his friend's death, safety, and self-blame. A maladaptive cognitive theme emerged in that Ben had come to believe he was to blame for the accident, in part because he asked his friend to wait for him before leaving the apartment, placing their car in harm's way. After teaching Ben the basics of cognitive therapy, the social worker and Ben began to work toward modifying his self-blaming and other dysfunctional beliefs related to the accident.

In addition to exposure and cognitive therapies, the social worker taught Ben a number of anxiety management skills including relaxation training and controlled breathing techniques. With encouragement from the social worker, Ben also was able to enlist his fiancé and one other close friend for increased support.

At the end of three months, Ben was pleased with his progress in several areas. His intrusive and avoidance symptoms had decreased, he was engaging in less self-blame, and he was once again enjoying his relationship with his fiancé. However, he was still experiencing more difficulty with concentration than he would like. The social worker reviewed options with Ben, including continuing with cognitive therapy, adding more focus on anxiety management skills, or augmenting treatment with medication. Ben preferred to continue with cognitive

therapy and learn more anxiety management techniques. As Ben continued to make progress with his goals, the social worker increased the time between sessions. During the last session, Ben reported that he felt ready to stop treatment. He went on to describe his current thoughts and beliefs about surviving a deadly car crash. Like many survivors of trauma, he was able to acknowledge personal growth along with the difficulties (Calhoun & Tedeschi, 2012). Although he still experienced sadness, moments of anxiety, and anger about the accident and loss of his friend, Ben believed that he had found strengths in himself that he was unaware of before the accident. He also had discovered the value of asking for and receiving support from his close friends.

Throughout treatment, the social worker monitored Ben's progress, relying both on Ben's report and on clinical judgment. In addition, however, she utilized two quantitative methods. First, she utilized goal attainment scaling (GAS) (Vonk, Tripodi, & Epstein, 2006). GAS is a useful tool for monitoring progress because the scales can be tailored to the individual's goals, are easy to administer, can be administered repeatedly, and can be weighted according to the relative importance of each of the goals. A 5-point goal attainment scale was developed for each of Ben's goals and at the start of each session Ben rated his progress on each of them. The use of the GAS method is illustrated in Figure 77.1, showing Ben's progress on the goal of decreasing the frequency of his nightmares. Finally, the PCL, administered at the outset of treatment was readministered at the close of treatment, at which time Ben no longer met the criteria for the diagnosis of PTSD.

Figure 77.1 GAS self-report for occurrence of nightmares each week.

Ben's assessment and treatment story provide an example of how empirically supported methods can be used for effective assessment and treatment of PTSD. Unfortunately, unlike Ben, not all clients have PTSD uncomplicated by previous traumas, co-occurring substance use or mental disorders, or support system deficits. In spite of complications, social workers will be best able to provide assistance to people with PTSD through the use of assessment and treatment methods for which effectiveness has been empirically supported.

DISSOCIATION AND THE DISSOCIATIVE DISORDERS

Dissociation as a construct is somewhat elusive; it refers to both an active process of defense as well as a state of mind (Howell, 2005). In the most basic terms, dissociation describes a rigid separation of parts of self or experience, including separation or splits between thoughts, consciousness, affect, memory, identity, behavior, or perception (Cozolino, 2002). People refer to this experience in everyday language as “spacing out,” “going into neutral gear,” or “being on auto-pilot.” Clinically, we refer to such processes as psychic numbing, dissociative amnesia, depersonalization, derealization, and identity fragmentation. In each of these manifestations of dissociation, there is a turning away from external reality and an intense, gripping focus on the internal world.

Dissociative experiences are thought to occur on a continuum from normative to problematic to pathological. Mild psychic experiences of dissociation are exceedingly common; for example, instances of so-called highway hypnosis in which you find yourself driving a car as if on auto-pilot, having little or no recall for how you got to your destination. On the other end of the continuum are dissociative experiences that serve a defensive function against overwhelming affect. When a person faces an external or internal experience that is too much to bear, the automatic response is to seek help, fight, or flee. If these attempts are unsuccessful, the person is left alone enduring overwhelming affect. He/she may then enter into a detached, trance-like state, effectively employing dissociation as a hypometabolic regulatory

process to produce numbness and a profound experience of detachment in order to regulate distress (Schore, 2001). The use of dissociation in this instance suggests a failed response to early help-seeking behavior.

Consider, for example, the young incest victim who cannot fight, cannot flee, and often feels she has no one to turn to for help. Dissociation steps in to provide, to paraphrase Putnam (1992), an escape when there is no escape. In the face of the horror of rape, the little girl imagines and experiences herself floating on the ceiling, looking down at the gruesome scene below. Although this helps the child to “forget” the abuse, surviving to go to school the next day, she must act as if the horrors of the preceding night did not occur. She begins to rely on dissociation not only as a defense to survive the moment of the trauma, but as a state of mind that allows her to hold these intolerable memories, affective experiences and bodily states “out of mind”—segregated from the conscious day-to-day experience of self.

Although dissociation as a defensive strategy can be normative under high levels of stress, when dissociation becomes a state of mind it signals that dissociation has become an adaptation to extreme or ongoing trauma. It is being relied upon relentlessly, and often outside of the person’s autonomous control. Dissociative disorders are diagnosed when pathological dissociative experiences such as those described above are pervasive and severe enough to interfere with the person’s ability to function.

The *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5) (American Psychiatric Association, 2013) catalogues five types of Dissociative Disorders:

- *Dissociative identity disorder*: a subjectively experienced and/or outwardly observed fragmenting of the person's identity into two or more distinct personality states
- *Dissociative amnesia*: in which the person suddenly loses the ability to remember important personal information in a manner that is experienced as traumatic or stressful and not part of ordinary forgetfulness
- *Depersonalization/derealization disorder*: characterized by experiences of depersonalization, that is, feelings of being disconnected from one's mental processes or body, and/or experiences of derealization, in other words, perceiving one's surroundings as if in a dreamlike or foggy state
- *Other specified dissociative disorder*: used when there are dissociative symptoms that cause significant distress and impairment but do not meet the full criteria for a dissociative disorder and the clinician chooses to further specify, for example by recording "other specified dissociative disorder: dissociative trance"
- *And unspecified dissociative disorder*: used in cases where the clinician decides not to specify why criteria for a particular dissociative disorder are not met.

A history of trauma is presumed in most cases of dissociative disorders. Although the *DSM* categorizes dissociative disorders separately from trauma- and stressor-related disorders, the two diagnostic entities were placed next to one another so as to acknowledge the "close relationship" that exists between them (American Psychiatric Association, 2013, p. 291). In fact, recent trauma theorists have begun to speculate that dissociation as both a defense and mental structure plays a role in many trauma-related and personality disorders, including posttraumatic stress disorder (PTSD), complex posttraumatic stress disorder, borderline personality disorder and antisocial personality disorder (Bromberg, 2011; Herman, 1992; Howell, 2005; Stein, 2010; Van der Hart, Nijenhuis, & Solomon, 2010).

Underlying the assumption that dissociative phenomena exist in many mental disorders is the belief that dissociation is a "normal hypnoid capacity of the mind" (Bromberg, 2011, p. 178) necessary to manage the overwhelming number of daily stressors that make contact with the brain. The distinction between this mundane and even adaptive human capacity and a dissociative

disorder is the degree of rigidity between these experiences of oneself. If a person can autonomously choose in which contexts to display which constellations of self and can move fluidly between experiences of self at will, then this is not a disorder. Despite various social roles, the person can maintain an awareness of one continuous identity with recall for experiences of him/herself in each of the other roles (Chu, 2011).

When the person loses control of the switches from one experience of self to the other, when he/she cannot move fluidly between states to adapt to the context, or when he/she cannot maintain conscious recall of his/her experience in alternate states, normative dissociation becomes pathological. The most extreme manifestation of this occurs in the condition known as dissociative identity disorder or DID.

DISSOCIATIVE IDENTITY DISORDER

At one time known as multiple personality disorder, dissociative identity disorder is a condition that develops post-traumatically, most often in persons with a history of severe childhood sexual and physical abuse. As the name implies, individuals with DID have difficulty maintaining a unified sense of self. They experience themselves as having more than one personality state or identity, each with its own thoughts, feelings, behavior patterns, likes, dislikes, history, and other characteristics. In some cultures, these personality states may be experienced and described as an experience of possession. Accompanying the distinct personality states or possession experience are dissociative experiences and defenses of the sort described earlier in this chapter—dramatic fluctuations and splits in affect, behavior, memory, consciousness, and cognition that may or may not be visible to people other than the afflicted individual.

Once thought to be a rare and exotic condition, DID has gained public attention and clinical recognition over the past 30 years, and reports of its incidence have grown. Widely varying explanations for this increase have been suggested, from identification of previously misdiagnosed cases, on the one hand, to suggestion, hysterical epidemic, and fad on the other. In any event, it is likely that various overlapping cultural trends helped to shape both current constructions of DID and the controversy surrounding it. Prominent among these are heightened public

and clinical awareness of child abuse, and a shift toward theories of psychopathology that emphasize trauma and dissociation over other explanatory processes. Popularized accounts of multiple personality, such as *The Three Faces of Eve* and *Sybil*, also undoubtedly exerted influence, serving as “prototypical illness narratives” that help to shape clinicians’ and clients’ constructions of the disorder (Hartocollis, 1998). Recent prevalence rates of the dissociative disorders have been reported in the range of 12%–38% in outpatient populations (Brand, Classen, Lanius et al., 2009), and 18% in the general population (Sar et al., 2007). In 2011, the International Society for the Study of Trauma and Dissociation Treatment Guidelines (ISST-D, 2011) put the prevalence rate of DID in the general population at 1.1%–3%.

DID has been described as a covert disorder because afflicted individuals often try to hide their distress and their multiplicity from others and sometimes even from themselves. This can make the condition difficult to recognize in a clinical setting. Further complicating the diagnosis and assessment process, persons with DID may experience symptoms that overlap with those of mood disorders, substance abuse disorders, eating disorders, obsessive-compulsive disorder, sexual disorders, or sleep disorders; and, in fact, all of these disorders are often comorbid with dissociative disorders (Howell, 2011). Historically, individuals with DID have been misdiagnosed as suffering from schizophrenia or borderline personality disorder, resulting in improper treatment choices and poor outcomes. This fraught assessment scenario makes it especially important that clinicians are armed with knowledge about dissociative disorders and DID.

The International Society for the Study of Dissociation (2005) lists the following clinical clues to the existence of DID: memory distortion and lapses, including fugue (e.g., reports of “lost time”); depersonalization; hearing voices experienced as coming from within the head or self; a history of unsuccessful psychiatric treatments; a history of severe and persistent emotional and/or physical childhood trauma; flashbacks of traumatic memories; identity confusion, and identity alteration.

During the assessment interview(s), clinicians should ask questions about and be alert to clients’ reports of strange experiences and happenings that could be markers for memory lapses, dissociative phenomena, depersonalization and derealization, and multiplicity. For example, a client

of one of the authors described finding clothes in her closet she couldn’t remember buying, waking up with a haircut she didn’t remember getting, and meeting strangers who claimed to know her though sometimes by a different name. To assess for the presence of derealization and depersonalization, Howell (2011) suggests asking the following questions: “Does it ever seem to you that things are not real?” and “Do you sometimes feel that you are not in your body?” (p. 152). However, as Howell (2011) cautions, questions aimed at uncovering a history of abuse should be approached with care, as they may trigger flashbacks and overwhelm the client’s capacity to regulate his or her emotions.

When assessing for the presence of DID, clinicians should also take note of changes in appearance and behavior, for example, a client who wears sexually provocative clothes and speaks and behaves in a flirtatious manner during one clinical session, and then comes to another session dressed in child-like clothing, speaking in a childish voice, and carrying a stuffed animal. The use of the word “we” when referring to oneself is also noteworthy. DID is generally diagnosed in adults and older adolescents. When assessing for DID in children, it is important to rule-out normative experiences of imaginary playmates or fantasy play. Females are much more likely to be diagnosed with DID than males.

A number of measurement instruments that detect the presence of dissociation and dissociative symptomatology can be used to aid screening and assessment of DID. The Trauma Symptom Inventory Dissociation Scale (TSI) rates 100 dissociative symptoms according to frequency on a 4-point scale (Briere and Scott, 2012). The Dissociative Experiences Scale (DES) is a self-report screening tool that taps disturbances in identity, memory, awareness, and other mental processes that are thought to be indicators of dissociation (Carlson & Putnam, 1993). As Howell (2011) cautions, although the DES screens for the possible presence of a dissociative disorder, a low score does not rule out the presence of a dissociative disorder nor does a high score confirm the presence. The Dissociative Disorders Interview Schedule (DDIS)—DSM-IV version is a structured interview based on the DSM-IV diagnosis for dissociative disorders. It may be administered in 30 to 45 minutes (Ross, 1997). Structured clinical instruments that map to DSM-5 dissociative disorders criteria sets have not been published as of the writing of this chapter.

CASE EXAMPLE: EVOLUTION OF A DIAGNOSIS

Making the diagnosis of DID comes with much questioning, doubt, and even angst. Research suggests that it takes between five and twelve years of (probably failing) treatment for a client with DID to receive the proper diagnosis (as cited in Howell, 2011). Clients may be unaware of their own alter identities or committed to keeping alter identities secret, either because of intense shame about the identity segregation or due to a desperate and perhaps life-sustaining need to keep parts of self separate.

Emily was the first client of one of the authors to be diagnosed with DID. It took seven months of nearly weekly treatment to accept this diagnosis. Emily entered treatment complaining of “poor memory.” She worried she was “blocking things out” and identified that she was especially prone to forget incidents of feeling in pain—sad, angry, or needy. Emily shared that she often felt “not like a real person.” She suffered a sense of inauthenticity and emptiness in her relationships. I suspected a dissociative process was at play. After many weeks of treatment, Emily shared that she thought her house was haunted. She identified a “friendly ghost” who inhabited her house and said his name was Rickie. She described Rickie as somewhat similar to an imaginary friend—itself a dissociative experience quite normative in childhood (Chu, 2011). In this case, the child learns to split off unwanted feelings and attribute them to his/her imaginary friend. It appeared Emily was utilizing this same mechanism. Rickie served as an antidote to her pressing loneliness as well as a repository of her rightful anger and self-protective functions, long since disavowed by her. Although I suspected Rickie’s presence was evidence of some splitting of her self-structure, I still held at bay the awareness that Rickie could be an alter personality. Instead, I wondered if Emily was hallucinating. I assessed for a psychotic disorder. I wondered if her house could truly be haunted. In retrospect, I am aware that I resisted the diagnosis of DID, which hovered over us as each session progressed. I worried that my fascination with the diagnosis of DID could unwittingly encourage the splits in her identity. Would further questioning about her ghost reify the split? Would my interest in this personality state encourage the further dissolution of her identity? Would I in effect create DID in my efforts to diagnose it?

The diagnosis of DID is indeed thorny territory. I tried to balance my interest in understanding each of the parts of Emily with my belief that she was one whole human being. Ultimately, Emily recounted an experience of feeling murderously angry, but identified it did not feel like “her” who was the angry one. It was Rickie. She felt herself watching this scene from the outside (depersonalization), while Rickie had taken over her body. She began to describe Rickie as an “internal ghost.” His presence was accompanied by trance episodes, recurrent amnesia for traveling (walking, being on the bus or train, and arriving at a destination and not knowing how she had gotten there), and a pervasive sense of feeling “not here.” She identified two types of handwriting in her class notes and noted amnesia for having written certain things. She had recurrent experiences of people recognizing her and calling her by a different name, with no recall for who these people were or how she knew them. Men would call her and indicate that she had given them her phone number at a bar, but she could not remember having done so. The evidence was leaning toward a diagnosis of DID.

I continued to hope that the splits in her identity were not so complete and that she kept an awareness of these personality states as being part of one continuous sense of “me.” And then I met Rosie. In the final minutes of a therapy session, Emily’s eyes glazed over. Her pupils dilated and the structure of her face changed entirely. Her cheeks looked wider and higher, with dimples under her eyes. I became aware of feeling distant, foggy, and mildly confused. And then Emily began to giggle. I shared with Emily my confusion and asked her what was happening. At that moment, Rosie introduced herself. I asked how old she was and she gingerly raised six fingers. She shared that she was very lonely and that she liked being with me in therapy sessions. I later learned that Rosie held all of the vulnerability and neediness for the personality system. Rosie was the part of Emily who gave out her number at bars, hoping indiscriminately and desperately for love and attention. Rosie was also the part who put Emily in danger, lacking the awareness of healthy boundaries, anger, or an ability to say “no” when needed.

Rosie’s emergence, approximately seven months into the treatment, solidified Emily’s diagnosis of DID. It took the succession of several clues to the existence of these parts of Emily’s identity (from hereon referred to as alter

personalities) in order for me to accept and to know what I had long suspected but not allowed myself to know. This process mirrored Emily's own experience of coming to know about the parts of herself kept sequestered in a parallel but segregated part of her consciousness. Emily and I engaged in this effort to resist the dissociative pull together. It was a relational experience that represented Emily's first attempt to trust—to allow me to see the parts of herself she held with profound shame and self-loathing and to trust I would not turn away.

DISSOCIATION AS A DISORDER OF RELATIONSHIP

How does this type of split in one's identity and experience of self emerge? When development is impeded by early trauma, neglect, attachment dilemmas, or gross misattunement, the linking of experiences of self becomes disrupted. Normal integration in developmental process cannot occur and the result is a fragmented experience of self, like that we witness in Emily.

The link between DID and early relational trauma has been well-established. For Emily, this came by way of severe medical problems in infancy and again in early adolescence, which left her separated from her primary caregiver. This was compounded by her caregiver's inability, due to her own difficulty regulating her emotional experiences, to stay attuned to Emily's needs. Layered on top of these early experiences of separation and misattunement were incidents of recurrent verbal abuse, profound emotional neglect, suspected physical abuse, and later instances of intimate partner violence and sexual assault. Her early developing ability to trust and depend on others for safety, self-regulation, and comfort was disrupted. Instead, others became a source of abandonment, violence, or exploitation. She learned she could maintain even the most cursory of relationships with others only when she was very, very "good." As a young child, she honed her ability to split off the "ugly" parts of self (namely her anger, sadness, and neediness) to have her basic needs met, breeding her fragmented experience of self.

Dissociation as a defense used by a young child first originates from a combination of hyperarousal and the lack of an attuned other to regulate this overarousal (Forrest, 2001). Dissociation persists as a state of mind when the child learns

that certain parts of self are deemed illicit and must be cordoned off in order to preserve some semblance of relationship or whatever safety or security is conditionally available. Thus, dissociation as a mental process steps in when there is a marked absence of an available and attuned other; it grows from a failure in relationship.

There are many ways to understand the manifestation of DID, however, at its core, *dissociative identity disorder is a relational disorder*. It derives from a breakdown in the basic human attachment system early in life. Later, the symptomatology manifests by way of relationships. Sufferers of DID struggle to maintain healthy relationships, often feeling either terrified of engaging intimately with another or alternately seeking the comfort and solace of human connection indiscriminately, entering into unsafe and exploitative relationships. There are also urgent pulls toward reenactment; the only templates that the DID sufferer has for relationships are ones in which there is a perpetrator and a victim, or a bystander who did not protect and a helpless self who felt neglected. A person with DID, then, enters into relationships with these expectations. Either the other has total power and control and the self is weak and helpless, or the self must take control of the other. Often, there are no templates for mutual and nonexploitative relationships. As a result, it is common for DID survivors to find themselves in endless cycles of abusive relationships. Emily, for instance, suffered rape from a boss, was in a long-term physically and emotionally abusive relationship with a boyfriend, and often found herself being stalked or followed by strange men in the city where she lived. She never developed a self-protective function and found it difficult to set healthy boundaries, assert herself, or say "no" in a way that was respected. She also became highly destabilized, more fragmented, and at times suicidal in the wake of any rupture in an important relationship. She had not yet had the opportunity to develop object constancy—the belief that a loved one will return after he/she leaves and an ability to tolerate such losses. Emily's most disturbing symptoms, like their origin, occurred in the context of a relationship.

The therapy relationship is not immune from these dilemmas. Emily, for instance, struggled with the "petit partings" at the end of each session, knowing she would not see me for another week and feeling wholly alone to deal with her intense emotions in the intervening time. She

often left sessions and found herself wandering around the city in a highly dissociative state. She also struggled to express any anger or disappointment in me or share her at times overwhelming needs, splitting off what she saw as the “ugly” parts of self as she had learned to do in her early life. She feared that if she allowed me to really see her, all of her, I could not possibly bear it and would either abandon or injure her, as she felt all others had done in the past. The development of trust in me and in the capacity of human connection has been the fundamental struggle in our work together and also the place where the healing has begun.

TREATMENT OF DISSOCIATIVE IDENTITY DISORDER

A relational disorder like DID requires a relational treatment. The social worker’s primary responsibility is to provide a new model of relationship—one marked by mutuality, collaboration, and respect for the integrity of the other. This aim is not without great difficulty. The social worker and client alike must withstand many cycles of connection and disconnection, rupture and repair in order for a sense of basic trust to develop (Chu, 2011). The social worker must resist all temptation to exert power over the client; she must withstand attacks from the client without retaliating and also without allowing herself to be abused; she must maintain presence and interest in the client even (and especially) when the client is dissociated or aloof; she must resist the temptation to be a caretaker of the dependent client and instead reinforce the client’s agency and strengths. The social worker must, above all else, believe the client. She must bear witness to the reality of the client’s traumatic experience and its often horrific aftermath. This new experience of being seen and responded to in a relationship can provide a corrective experience for the client and a context within which healing can occur.

STAGES OF TREATMENT

Research on the treatment of DID is in its earliest stages (International Society for the Study of Trauma and Dissociation [ISSTD], 2011). Most available research is based on case studies and naturalistic outcomes studies. Available studies

suggest that psychotherapy is effective in treating DID and that more “intensive” and “comprehensive” therapies have better outcomes (as cited in ISSTD, 2011). Despite this, there is no evidence-based practice (EBP) for the treatment of DID.

The consensus among experts in the treatment of complex trauma and dissociative disorders is that treatment should proceed in stages: (1) Establishment of safety and symptom reduction; (2) Confronting and working through traumatic memories; and (3) Continued integration and personal growth (Chu, 2011; Courtois, Ford, & Cloitre, 2009; Herman, 1992; ISSTD, 2011). Attention to where a client is in his/her own healing and developmental process dictates which stage of treatment is most appropriate. It also reflects the basic social work ethos of “starting where the client’s at.” Heeding this attention to the client’s unique and changing needs is a primary component of relational treatment—it represents attunement to the client’s needs and creation of a corrective relational experience in which the client feels safe and where her needs can be met.

The treatment of dissociative disorders is not a *laissez-faire* approach. This dictum is most evident in the need for so-called Stage One work—efforts to help the client to manage symptoms and establish safety and self-regulation. The biggest error made in the treatment of DID or any complex trauma disorder is the attempt to bypass Stage One work and “process the trauma” prematurely. The failure to help a client develop skills to keep him/herself safe and to regulate overwhelming emotions prior to engaging any trauma memories in detail holds the grave danger of retraumatizing the client—leaving him/her alone, again, with no way to regulate hyperarousal.

In Stage One, the social worker should first attend to the client’s ability to manage his/her body, including medical and basic health needs, the establishment of a safe living environment and financial stability, and the development of a healthy rhythm of eating, sleeping, and exercising. With the client’s explicit consent and cooperation, medications can be a useful tool, as can adjunctive and nontraditional therapies such as mindfulness meditation, yoga, acupuncture, or nutritional counseling (van der Kolk, 2009).

A critical element of helping the client to meet his/her basic needs is the establishment of safety. Persons with DID often have chaotic lives

and engage in behaviors that put themselves and others at risk, including promiscuity, unsafe sex, and involvement in abusive relationships either as victim or perpetrator. They also engage in self-destructive behaviors that reenact early traumatic patterns, including self-mutilation, substance abuse, and eating disorders, and are at high risk for suicide. One of the social worker's primary tasks in Stage One of treatment is to help the client to diminish and ultimately refrain from dangerous and destructive behaviors. It can be helpful to reduce the client's shame about these behaviors by reframing them as useful adaptations to extraordinary and traumatic early life environments. These behaviors began as a precocious attempt by the child to regulate affect or numb oneself from pain; however, these behaviors are jet-lagged. The child, now an adult, is no longer in danger and the mechanisms he/she developed to regulate distress are no longer needed.

Efforts to help the client reduce the reliance on unsafe behaviors should take paramount importance. In treatment, safety management should include (1) education about why safety is necessary for treatment; (2) assessment of the function of unsafe behaviors; (3) safety contracting (including negotiating a plan to keep oneself safe with all alter personalities, especially those that are violent or self-destructive); (3) strategies to help the client develop more effective strategies to manage distress (including grounding strategies, cognitive behavioral techniques, and dialectical behavioral therapy emotional regulation strategies); (4) development of self-soothing strategies; (5) development of a support network of safe others to rely on in crisis; (6) treatment plans or referral to specialized programs to treat eating disorders and/or substance abuse issues; and (7) inpatient hospitalization if the client is in imminent danger of doing serious harm to self or others (ISSTD 2011, pp. 136–137).

Once safety has been reasonably established, Stage One efforts should turn to management of symptoms. People with DID often have comorbid diagnoses of PTSD, chronic anxiety, depression, and disturbed sleep. Treatment should emphasize control of the client's most distressing symptoms prior to accessing any traumatic memories. Despite this aim, it is highly probable that traumatic memories will emerge in the form of flashbacks, nightmares, or intrusive recollections prior to the client developing effective skills to deal with the distress these recollections evoke.

In these cases, the social worker should not silence the client's recollection of the trauma. Instead, the worker should validate the reality of the client's experience and offer empathy for his/her feelings about the traumatic event, but refrain from asking for more details about the trauma. The worker instead should move to a present-day orientation, emphasizing the impact of these traumatic experiences in terms of the client's symptoms and functioning, offering containment, and encouraging the use of strategies to regulate affect (including the use of grounding techniques, emotional regulation skills, and relaxation and breathing exercises) (Chu, 2011). Jumping into premature processing of traumatic memories increases the likelihood that a client will do serious harm to him/herself when traumatic material is approached.

Emily, like many clients with DID, engaged in many dangerous behaviors, including the daily abuse of marijuana, indiscriminate sexual relationships with men she did not know well, and the manifestation of a child alter, Rosie, who was overly trusting and struggled to maintain boundaries to keep herself safe. The first stage of treatment with Emily, which persisted for many months, focused on the management of these behaviors, the reduction of her switching behaviors and comorbid symptoms of depression, and development of healthy strategies to identify her emotions and needs and express them safely to others. Despite both Emily's and my own very best efforts, many crises emerged throughout this process. This intrusion of crises into Stage One work was entirely expected, given that Emily was developing skills of self-regulation and a capacity for trust for the first time. My willingness and ability to stay in relationship with Emily through these crises, making myself available as a safe other to rely on while maintaining boundaries and an unwavering belief in Emily's ability to care for herself, was a crucial part of the work in Stage One.

Once the capacity for seeking and receiving support from safe others has been developed and the client can manage his/her most distressing symptoms, the second stage of treatment may begin. Stage Two emphasizes confronting and working through traumatic memories and beginning to integrate the personality. Again, the therapy relationship is a critical component of this work. The stability of this relationship enables the client to confront horrific memories from the past while maintaining safe anchorage in the

present. The client will be able to simultaneously re-experience feelings related to early traumas in their original intensity, but this time, holding onto a sense of safe connection that was unavailable in the traumatic moment (Herman, 1992). The goal of this stage is to help the client use the capacity of the adult mind to put language and form around the somatic and affective memories of earlier traumas. The social worker must remain attuned to the client's ability to manage the traumatic memories, helping the client titrate this exposure and contain the affect that emerges. The ability to do so offers a corrective experience for the client, both in her ability to rely on others and in her own capacity to have mastery and control where in the original trauma there was neither.

The final stage of DID treatment emphasizes continued integration and personal growth. In this stage of work, the client will evidence a shift in identity from "a dissociative" or "a traumatized person" into a more integrated and expanded understanding of self. Treatment in this stage will naturally move toward current life-stage issues, as well as career, vocational, or school stressors.

Although an ideal model of the treatment of DID is presented in discrete stages, treatment is never entirely linear and clients will move back and forth between stages. The integration of identity and resolution of trauma is never final. Clients might shift back to an earlier stage of treatment after a rupture in a relationship, a developmental milestone, or a trigger of an early traumatic memory. Additionally, alter personalities might be in different stages of treatment at the same time. The social worker should privilege attunement over technique, flexibly and responsively meeting the client's shifting needs, rather than dogmatically remaining in a particular stage of treatment.

WORKING WITH ALTERS

Throughout all stages of treatment, the primary aim in working with clients with DID is integration of identity—working toward greater harmony and cooperation among alter personalities. A common therapeutic pitfall in working with clients with DID occurs when the social worker becomes overly fascinated with the client's condition, especially the more florid symptoms of discrete personality states. This can lead the

therapist to unwittingly reinforce rather than alleviate the client's dissociative symptoms. An overemphasis on the client's various alter personalities may also lead the social worker to lose sight of important interpersonal dynamics within the therapy relationship. Rather than reifying the client's alter personalities, the client should be seen as a whole person, with each personality holding responsibility for overall functioning (ISSTD, 2011).

With this principle in mind, the social worker should help the client to develop co-consciousness—an increased communication and cooperation among alter personalities. As co-consciousness develops, each of the alter personalities will have access to the information held by the others. For instance, when Emily began treatment, she could observe what Rickie experienced and how he behaved, though she felt she had no executive control. She had no co-consciousness for the alter personality Rosie; Emily reported total amnesia for the periods of time when she functioned as this part of self. This lack of co-consciousness was maladaptive for Emily. When functioning as Rosie, she did not have access to an "adult" part of self to make good decisions to keep her safe. Throughout the course of treatment, Emily attained increasing amounts of access to each part of herself. Emily could be present simultaneously with both Rickie and Rosie, moving toward an integration of these alter personalities as all part of the same "me."

There are several strategies to promote co-consciousness. First, it is fundamental to acknowledge the value of each part to the functioning of the whole personality system. The social worker's role is to help the client find ways to take the needs of each alter personality into account in decision-making and to promote internal support among parts. It is contraindicated to align with one part or exclude parts from treatment. It is equally countertherapeutic to ignore alter personalities or refuse to communicate with them. According to the ISSTD (2011), "successful treatment of DID almost always requires interacting and communicating in some way with the alternate identities" (p. 140). This interaction should always be in an effort toward integration.

The social worker may at times need to speak with an alter personality, either to get information in order to assess the client's safety, or to ensure that all relevant parts of self are involved in negotiating a decision. For instance, Emily indicated that one alter, Jessica, had a profile on a website

offering sex and companionship in exchange for money. Emily had no co-consciousness for her functioning as Jessica, and therefore, had no way to understand what led this part of her to be involved in such risky and promiscuous behavior. She also felt she had no way to stop herself from engaging in such behavior. I used an indirect strategy to help Emily access this alter personality. I first used the strategy of *talking through*—talking both to and past the host (Emily) to the other parts of self. In this case, I explained that we had an important matter to discuss, which involved the well-being and safety of the whole personality system. I asked that all of the parts of Emily who needed to be involved in this conversation about her use of the sex website listen in, noting that each part had something important to contribute. I then used the strategy of *asking inside*. I asked Emily what she was getting out of involvement on this website, and suggested that she ask and listen inside for a response. Initially, she was not certain that Jessica would share any information, but Jessica did offer that she was on the website because she wanted to make money to purchase hair extensions; she was angry that Emily decided to cut her hair and make herself look less feminine. Emily continued to ask inside to get more information from this part of her, and she came to understand that Jessica offered sex in exchange for money both to have money in order to make decisions for herself and also as a way to be in a position of power and control in the context of a relationship. These men wanted something she had, and this offered her a feeling of security. Jessica was angry that Emily and Rosie allowed themselves to be taken advantage of, continually making themselves subject to the demands of others in relationships. I reiterated how important it was that the needs of each part of Emily be met. After some negotiation, Emily's personality system ultimately agreed that if Emily and Rosie worked harder to maintain boundaries to protect themselves and allow their voice and desires to be known, then Jessica would refrain from visiting the sex website. The participation of each part of Emily was essential in coming to this agreement and ensuring that all parts of her were committed to her safety.

It is always preferable to have the host internally communicate with other parts of self. This enables restoration of memory across the personality system, as well as development of empathy for the needs of each alter personality, and allows each part of self to feel less isolated. On

occasion, the social worker may need to access an alter personality directly without using the host to internally communicate. This might occur when an alter is putting the client into dangerous situations or when there is an impasse in the therapeutic relationship (Chu, 2011). When necessary, it can often be effective to simply ask to speak to a particular part of self, for instance, "I need to talk with the part of you who was at the bar last night." There are many other techniques to both directly and indirectly facilitate co-consciousness. Chu (2011) and Howell (2011) offer excellent introductory chapters elaborating on these strategies. Ultimately, the development of co-consciousness will reduce the need for switching, which is both exhausting and disruptive, and will enable the client to feel less fragmented.

CONCLUDING THOUGHTS

Despite the usefulness of these various techniques, good therapy with clients with dissociative disorders is less in the *doing* and more in the *being*. It is less important to master and apply highly discrete techniques, and instead far more important to embody certain relational principles: safety, trust, respect for the person of the client, curiosity without judgment, a willingness to bear witness to the client's trauma, and allowing for the entirety of the true self of the client to emerge and be welcomed into the therapy space. When these principles are upheld, the client is offered an antidote to his early wounds. She is given the opportunity to be in relationship and in a safe place in which integration of self can proceed.

PART VIII

Guidelines for Specific Techniques

79 Practice from a Technique Perspective

Francis J. Turner

What drives our choice of technique in a particular case? To answer this query, we first have to consider what we mean by technique. For those of us in social work, this is not an easy question to answer. Or at least to answer with any degree of consistency. Although we have frequently used the term “technique” in our clinical literature over the decades, we have not been precise in what we mean by the term. Thus, we have used it to describe various different things. There have been very few efforts to define technique in an agreed upon way. We seem to presume that we all understand what we mean by the term. One attempt to be precise about the term can be found in Dr. Howard Goldstein’s excellent book, *Social Work Practice: A Unitary Approach* (Goldstein, 1973).

Some time later, Dr. Joel Fischer (1978) brought into focus the importance of technique when he reminded us that everything we do with, to, and for clients, constitutes the application or utilization of a cluster of actions for which we need to take responsibility and upon which we need to build our theoretical base. This comes close to the idea of technique. Only when we can be precise and cognizant about what specifically we are doing in practice with, to, and for clients. And only when we are committed to understanding the different effects of these various activities on our clients, can we begin to understand the differential importance of our rich range of theories. In this way, we can search out richer and more effective ways of putting our theories to use. A greater attention to technique helps us to understand how various techniques can bring about different ways of helping our clients. And of at least equal importance, also help us to identify more precisely areas and situations where our theories can be harmful to some or all clients.

This reminds us that with the intensity of the impacts we have, or will have, on clients, an inappropriate use of some techniques can be harmful. Thus, we need to understand the element of risk that is introduced into our use of various techniques.

If we move to greater interest in technique, we should work to agree on a definition of technique that will assist us in moving toward a more precise use of the concept. Turner and Rowe (2013, p. 5) offer one definition that provides us with further precision in the use of the term. This definition states that, “a technique is the artistic use of some practical object or activity by a social worker as a component of treatment aimed at achieving an identified outcome. Such action or object is replicable by others, is ethical, has a level of professional approbation and is understandable from a relevant theoretical perspective.”

One of the difficulties for those of us in social work in dealing with the technique component of our practice in a conceptual way is that so many of our techniques are quite mundane in nature and lack the attractiveness of techniques in other disciplines. An example of this is something as mundane as a handshake. The question of whether we shake hands with a client is not a simple question. Among other concerns, it involves such things as gender, values, customs, religion, age, and occasion. When properly assessed and utilized, a hand shake can provide considerable positive impact for a client. But a handshake can also be totally inappropriate, even to the point of offending a client who might well misunderstand the action to such an extent that it will affect the relationship in a negative way. A handshake also could be seen as a very positive gesture on our part, one that the client perceives as very supportive.

Similar issues arise in regard to many of our techniques.

As we begin to appreciate that virtually everything we do in relationship with our clients can and frequently does have an impact on them, we can appreciate just how important it is that many of our apparently mundane actions be examined with care. It is so very important that we pay much more attention to all the things we do with, to, and for clients and seek to understand on an ongoing basis the significance of how we interact with them. We also need to learn to identify our differential actions to assess their impact both positive and possibly negative. That is, we need to ask ourselves on an ongoing basis whether what we are doing is the most effective and helpful way to achieve our therapeutic goals.

Of course, much of this assessment takes place outside of the interview, as we sit back and engage in a process of evaluation. We do not want to take away from the essential spontaneity of a therapeutic process, which is so essential to the effective engagement of our clients. But we do want to learn to view our interviewing partly as a wide assortment of discrete actions. This requires us to engage in an ever continuing process of examining what techniques we use and how we interact. We must ask ourselves, "What are the risks in making various uses of my technique repertoire?" "Can I better serve this client by a shift in my technique repertoire?" "Or by trying something from my own repertoire with this client?"

If we begin to analyze technique in our individual practices, then as a profession, we will expand our available data, which will help us understand and make fruitful use of the relationships among technique, theory, assessment, and diagnosis. Also, in the long-term, we will begin to develop patterns of theory and technique so that we can begin to differentiate among our clients based on who we are, who they are, and how we can best help them. We also will develop a better understanding of how some of the things we do are, in some cases, not helpful.

Of course, an obvious and appropriate response to this stream of thought would be to say, "But this is what I have always done and do in all my interviews with clients." We all are highly skilled interviewers and we can draw a client into a meaningful positive helping

situation quickly and effectively. We can even transform the most troubled and hostile of situations into relationships that are at last minimally helpful and at best enormously helpful. But what we do not do is identify how we do this, what techniques we use to accomplish this, and what we would have done differently, given a choice? "What could I have done to be more helpful?" we might ask. "What can I do to improve the effectiveness of many of my techniques?" Of course, we all do this to some extent already. What is different or novel about this train of thought is that we have not been sufficiently precise to ourselves, or to our profession, in defining the term "technique." Without that, and without a commitment to precision, we cannot make full use of our rich body of knowledge and bring this abundance to our clients, so that we can better serve them.

One way we can start down this trail is to work from a categorization of our techniques, as was done in the Turner and Rowe book, *101 Social Work Clinical Techniques* (2013). Obviously, many different ways of categorizing techniques could be used. Then, we would have to develop or work from an agreed-upon list. This latter effort is an interesting process, as was discovered in *101 Social Work Clinical Techniques*. From our work on this project, we are convinced that there are many more techniques used in social work practice that need to be identified and added to our repertoire. We need also to begin a process of considering whether some techniques better fit some theories more than others or whether all techniques fit all theories. At the same time, we need to continue the process of assessing the risk involved in making use of various techniques. On the other hand, we might ask ourselves whether the matters of effectiveness are related to inherent client strength rather than something inherent in the technique.

Developing Successful Relationships

The Therapeutic and Group Alliances

Lawrence Shulman

A middle-aged mother of three comes to a family counseling agency for help dealing with her young children. She has just started a difficult separation from her husband of 20 years. Her main concern is how to deal with her children, who are upset and have been acting out since their father moved out. She tells the agency intake worker that she wants help dealing with her own feelings of failure in her marriage, supporting her clearly upset children, and starting a new life. At the first interview with her 25-year-old, recently graduated MSW social worker, she notices the worker does not have a wedding ring and asks, "Do you have any children?" The worker responds, "We are here to talk about you, not me." For the balance of the interview, the client appears distracted and uncomfortable, providing minimal responses to the worker's effort to obtain a social history. The worker's notes at the end of the session describe the client as "depressed and resistant."

In this vignette, by putting ourselves in the shoes of the client, perhaps remembering a time in our lives when we sought help, we can see that she may really be asking, "Since you don't have children, can you understand my situation?" "Are you going to judge me?" and "Can you help me?" These are reasonable questions in the mind of this client in a first interview. Because of the taboo against directness in relation to authority, the concerns may be raised in an indirect manner. The young worker, feeling defensive, responded in a way that closed off this line of discussion. The client's resistance may actually be a reaction to the worker's defensiveness. An alternative response that responds directly to the underlying questions is shared later in this article.

In another example, we have a first session of an "Anger Management" group for inner-city

teenage African American girls. The members have been mandated to attend the group by the court or face incarceration based on minor criminal convictions. One of the group members confronts the two Caucasian, middle-class and suburban female group leaders and angrily says: "Why should I talk about my problems? What am I going to learn from two old women like you?" The two group leaders, both in their mid-twenties, report later that it was the "old women" comment that hurt the most. The rest of the session is marked by resistance and periods of silence. When conversation does take place it consists of an "illusion of work" with no real significance (Shulman, 2011).

The following week the leaders open the session by referring back to the comment from the confrontational member. The group leaders in the first session had interpreted the comment as an effort to obstruct the group. The leaders now realized she was an internal leader directly stating what other group members might have thought and felt as well. The leaders then comment: "We don't blame you for feeling this way. Not only are we older but we are also white and we live in the suburbs. No wonder you don't trust us or think we can ever understand what you go through. But how can we understand and help if you won't tell us?" The worker's directness and raising openly the under-the-surface taboo issues of race and class leads to the beginning of the development of the "working relationship," now more commonly referred to as the therapeutic alliance (Shulman, 2010, 2011). In the third group session, the same internal group leader angrily discloses that she has experienced sexual abuse in her family as a child. Other group members share similar traumatic experiences, which are one of the underlying sources of their anger.

In a first session of a group for parents of children with physical disabilities the group leaders, after explaining the purpose of the group and their roles, ask each parent to share the issues they faced in their parenting of a child who was different. The leaders acknowledged with empathy their understanding of some of the pain that the parents expressed over not having the “normal” child they had hoped for when they became pregnant. The leaders also asked other members of the group to respond to each parent’s presentation, emphasizing how healing the “all-in-the-same-boat” phenomenon can be when clients share similar thoughts, feelings, and concerns. One could see the beginnings of relaxation as the “group-alliance” grew and members began to have positive feelings for one another (Shulman, 2010, 2011).

THE THERAPEUTIC AND GROUP ALLIANCES

Although the concept of the “therapeutic alliance” between a therapist and patient has been found to have a positive impact on outcomes, alliance to the group-as-a-whole has not been as widely studied. Lindgren, Barber, and Sandahl (2008), citing their own research, suggest that, “In treatment formats in which the group process is predicted to be a curative factor, it is counterintuitive to emphasize only the relationship between an individual patient and therapists” (p. 164). In another study of group therapeutic alliance and cohesion, Joyce, Piper, and Ogrodniczuk (2007) examined the impact of each on outcomes in short-term group therapy. They found that group alliance variables were more consistently associated with improved outcomes (p. 273).

If the engagement phase is handled well by the social worker, it can increase the possibility of establishing an effective working relationship with the client. The working relationship, also referred to as the therapeutic alliance, is the medium through which the worker influences the client and the outcomes of practice. Elements of the working relationship have been defined in this author’s research as rapport (“I get along with my worker.”), trust (“I can tell my worker anything on my mind; I can risk my mistakes and failures as well as my successes.”), and caring (“My worker cares as much about me as she cares about my children.”) (Shulman, 1978, 2009, 2011).

Clients often bring a number of unstated questions to the first session. “Who is this social

worker and what kind of person will he or she turn out to be?” “Can I trust this worker?” “What will our work be about and what will we be doing together?” “Can this worker understand and help me or will he or she be judgmental?”

In those situations with more than one client present, such as couple, family, group, and community work, there are also often unstated concerns about the others in the session. Our experience is indicating more clearly that first the client must experience a positive therapeutic alliance with the social worker, and then they can address the group-alliance with others in the session.

When these relationship issues, also referred to as the “authority theme” and the “intimacy theme” (Shulman, 2011) are added to what might be ambivalence about seeking and accepting help or accepting that a problem exists, one can easily understand the complexities associated with beginnings. This phase of work requires that the client make a “first decision” to engage in the process. Whereas a skillful worker can influence that decision, she or he cannot make it for the client. The skills identified in the remainder of this chapter are those that increase the possibility that the client will take that first step. This chapter also identifies the skills that can encourage the client to make the second decision, which is associated with making the transition from the beginning or engagement phase to the middle or work phase. At this point the commitment to work on difficult and often painful tasks is completed. The dynamics and skills that are important in the ending and transition phase of work are beyond the scope of this chapter.

The focus of this article is on core skills or constant elements, which can apply to all forms of practice, and it is important to recognize that the helping relationship is also affected by variant elements. For example, the nature of the problem or the setting of practice can have an important influence. Working in a high school dealing with violence prevention might look somewhat different from working in a hospital with persons with AIDS.

Variations introduced by age (practice with children, teens, adults, and the elderly) may affect how the worker begins and the development of the relationship. Other factors, such as gender, race, ethnicity, sexual orientation, physical ability, and so on, can all impact how the client perceives the offer of help.

For example, Elze (2006) describes how a school social worker can be GLBT (gay, lesbian,

bisexual, and transgendered) sensitive in practice. This is a crucial stage of development for intervention, during which students attempt to come to grips with their sexual orientation and the larger heterosexual population begins to develop its attitudes toward difference. Elze suggests that the social worker needs to demonstrate that he or she is an “askable” person in response to all students, for example, using such strategies as employing gender-neutral language when exploring youth’s dating interests, sexual behaviors, and so on.

Strategies appropriate for one population may be quite ineffective with another. Working interculturally (for example, a Caucasian worker with a client of color) as well as working intraculturally (for example, a Hispanic worker with a Hispanic client) may modify the dynamics and the strategies employed. Practice with voluntary, involuntary (mandated), or semi-voluntary clients may also look quite different. For example, a first session of a voluntary parenting group requires a different strategy than one with a group of men who have been convicted of driving while intoxicated (DWI) and are court-mandated to attend or face a jail sentence.

In a first session of a DWI group, when the “deviant member,” once again an internal leader, crumples the paper listing the topic for discussion each week and then dramatically throws it into a waste basket, the young female leader does not fall into the trap of starting a “battle of wills” using the authority of the court to demand compliance. Instead, she recognizes that building a therapeutic alliance is best achieved by exploring the resistance. She says: “I can see you are not happy at being forced to attend this group. I don’t think you are the only one feeling this way. How about it? Are others also upset?” Members immediately respond with comments such as “I don’t want to be called an alcoholic or made to feel guilty. “Everyone drinks on weekends; I just got caught,” etc.

The leader, working from the productions of the group members, writes on a flip chart “Don’t Want” and lists under this the concerns raised by the members. She then points out that these issues are actually on the agenda she has handed out and will be the topics of discussion. The tone of the meeting changes as her skillful response to the denial and resistance begins the development of the therapeutic alliance through discussion of the work.

Finally, practice may be influenced by the worker’s theoretical orientation and underlying

assumptions. In spite of the many variations on the theme, the notion of understanding practice against the backdrop of time—the preliminary, beginning, middle, and ending/transition phases of work—and the skills identified in the balance of this article, are proposed as core elements in all of the variations described. Schwartz (1961) described the importance of these phases of work, adding a preliminary phase to beginning, middle, and ending/transition phases first identified in social work by Taft (1942, 1949).

THE PHASES OF WORK: THE PRELIMINARY AND BEGINNING PHASES

Schwartz suggested that because clients often raise many of their questions and concerns in an indirect manner, workers needed to prepare to hear the client’s indirect cues by developing a preliminary empathy. The skills of the preliminary phase include the following:

- **Tuning in:** An exercise in which the worker develops a tentative, preliminary empathy with the client’s feelings and concerns. The worker must also tune in to his or her own emotional state at the start of the relationship because it will impact the worker’s moment-by-moment responses to the client. The earlier example of the teenage girls’ “anger management” group was an example of tuning in between sessions.
- **Responding directly to indirect cues:** The skill of preparing to articulate a client’s thoughts and feelings in response to indirect communications in the first session or sessions.

A common illustration of the importance of these two skills was the vignette that began this chapter. The recently divorced mother of three children asks her 25-year-old, unmarried, recent graduate of a school of social work the question: “Do you have children?” Unless the worker has tuned in both to her own feelings of inadequacy because she does not have a child and the real feelings of the mother, it is not uncommon for the worker to respond defensively, for example, “We are here to talk about you, not me!” Or, “I don’t have children but I have taken courses on child development at the school of social work.” These responses miss what might be the underlying questions: “Can you understand my

situation?" "Will you be able to help me?" "Will you judge me harshly?" "Can I trust you?"

It is important to understand that, to be successful, a direct response will have three conditions: (a) It must be genuine, with the worker trying to experience the emotion; (b) the client must be ready to hear it; and (c) each worker must find a way to respond that reflects his or her own personality and artistry. With these conditions in mind, one more direct response to the indirect cue might be as follows: "I'm not married, and I don't have any children. Why do you ask? Are you concerned I may not understand what it is like for you? I'm worried about that as well. For me to help, I need to understand. For me to understand, you will have to tell me." In addition to illustrating the power of tuning in and responding directly, this example also illustrates a number of skills identified later in this chapter in the section dealing with the middle or work phase. These skills were found in this author's research to be associated with the development of a positive working relationship when used in the beginning phase of practice (Shulman, 2009, 2011). The importance of expressing genuine empathy in developing a positive relationship was supported by Truax (1966) and more recently in the work of Hakansson and Montgomery (2003).

It is important to note that there is a certain individual artistry to practice, and that the exact words used by workers may differ while the intent and impact of the skill will remain the same. Some have pointed to a problem with the implementation of some Evidence-based Practices, wherein the requirement to follow a strict protocol in one's responses to clients can lead to what this author believes is a false dichotomy between science and art. Science (research) should free the worker's artistry not restrict it.

It is also important to emphasize that the worker's empathic response must be genuine, rather than a phrase that has been memorized and is recited without feeling. Clients know when a worker is simply reflecting their words and not experiencing their feelings. Expressions such as, "I hear you saying . . ." with no real affect attached to them can be experienced by clients as artificial empathy.

Another crucial element of the beginning phase, which takes place during the first session(s), is the development of a contract or working agreement between the worker and the client or clients. This contract helps establish a structure that creates the freedom for the

work to proceed. A number of first-session skills are described next. It is important to note the following.

- A contract may not be fully developed in the first session, and this working agreement can change over time (re-contracting).
- The client must feel an investment in the work or the sessions will constitute an "illusion of work" in which conversations take place but nothing real happens.
- The worker must make clear the purpose and her or his role in nonjargonized terms to which the client can connect.

The specific contracting skills are as follows (Shulman, 2010, 2011).

1. **Clarifying purpose:** The skill of making a brief opening statement, without jargon, which helps clarify the purpose of the session. This skill should be used when initiating a service (for example, a first group meeting) or responding to a client's request for service (for example, "If you can let me know what brought you in today we can see how I might be able to help.>").
2. **Clarifying role:** The skill of describing in a brief, nonjargonized manner, the kind of help the social worker can provide. For example, "No, I can't give you the right answer for dealing with your husband. However, I can help you examine how you deal with him now, your feelings about the relationship, how you see yourself now and in the future. Perhaps if we work on this together I can help you find the answer that is right for you."
3. **Reaching for feedback:** The skill of encouraging clients to explain their perceptions of the problem and the areas in which they wish to receive help.
4. **Clarifying mutual expectations:** Developing an agreement on what the client may expect of the worker as well as defining the client's obligations (for example, regular attendance at group sessions; notification if a client must miss an interview).
5. **Discussing authority issues:** Dealing with any issues, raised directly or indirectly, that concern the authority of the worker (for example, the mandated nature of the service; the limits of confidentiality defined by the worker's responsibility as a mandated

reporter; the client's stereotypes of authority figures or past experiences with social workers).

Though contracting is always initiated in the first sessions, it is not unusual to have to recontract as the work develops. The client may not have fully understood the implications of the contract. It is not unusual for clients to begin with near problems, which are real to the client but not at the core of the work. As the work proceeds, the client begins to understand his or her issues more clearly and is better able to articulate them. The client may have been in what has been called the precontemplation stage (DiClemente, Prochaska, Fairhurst, & Velicer, 1991). For example, a client in substance abuse counseling, such as in the DWI vignette shared earlier, may not have accepted that she or he has a problem with alcohol. Thus, for a number of reasons, contracting remains fluid over time.

THE PHASES OF WORK: THE MIDDLE PHASE

As the work continues, the client moves to the crucial transition stage from the beginning to the middle or work phase. This change is dependent on having developed the therapeutic alliance and the group alliance in the beginning phase. When clients experience "rapport," "trust," and "caring" from their social worker, and in the group session from one another, they feel safer in moving into more difficult issues. This was referred to earlier as making the "second decision." Careful analysis of these transition sessions will reveal that clients may continue to use indirect forms of communication. The client may be embarrassed to raise a difficult issue. Some examples include taboo areas, such as sex, dependency, finances, health issues, or death. The client may not be consciously aware of the existence of the problem. The skills that follow are designed to assist clients in telling their stories and telling them with feeling. These skills also assist the client in examining his or her cognitions or thought patterns related to the client's self-perception, perception of the problem, or perception of others involved. An underlying assumption is that how one feels, affects how one thinks, which affects how one acts, which in turn, affects how one feels, and so on. This feeling, thinking, and doing connection is explored in the middle phase of practice.

The following skills can be helpful in this transition phase (Shulman, 2010, 2011).

1. **Sessional tuning in:** The skill of developing a tentative, preliminary empathy for issues that may emerge at the start of a specific session (for example, the impact of a traumatic event in a client's life; issues left over from the previous session; the client's potential reactions to information the worker must share; a traumatic community event such as the terrorist attacks on September 11, 2001; or a severe weather event such as the devastating hurricanes Katrina and Sandy).
2. **Sessional contracting:** A collection of skills designed to determine the issues or concerns facing clients at a particular session. These may include remaining tentative at the start of the session while listening for indirect cues, asking a client what is on her or his mind, raising previously agreed-upon issues directly with the client and checking to see if they are still relevant, checking in with group members at the start of a session.
3. **Elaborating skills:** The skills required for helping clients to tell their story (e.g., listening, containment, questioning, reaching inside of silences).
4. **Empathic skills:** The skills that address the emotional content of the client's experiences (e.g., reaching for feelings, acknowledging feelings, articulating the client's feelings).
5. **Sharing worker's feelings:** The skill of spontaneously sharing appropriate worker affects, which is in response to the productions of the clients. Boundaries need to be respected so that the sharing of worker affect is professional and responsive to the needs of the clients. Issues of countertransference, client stereotyping, inappropriate worker frustration, and so on need to be considered and closely monitored. However, a general prohibition on sharing affect represents a false dichotomy between the personal and professional mandating that the worker chose between the two. Over time, experienced workers learn to integrate their personal self and feelings into their professional role.
6. **Making a demand for work:** A facilitative confrontation in which the worker asks a client to engage in the work agreed upon in the contracting stage. Specific skills can include confronting denial, reaching inside

of a silence, directly raising a taboo issue, challenging the illusion of work, and so on.

7. **Providing data:** The skill of providing relevant, unavailable information the client needs to deal with the task at hand. Data can include facts, values, beliefs, and so on. Data should be provided in a manner leaving the information open to challenge.
8. **Sessional endings and transitions:** The skills involved in bringing a session to a close. These skills may include summarizing, evaluating progress, and discussion of transition issues (e.g., the client's next step, role-play of anticipated future conversations based on the work of the session).

It is not uncommon for a client to disclose a powerful issue at the very end of the session. In the literature, this has been termed “doorknob therapy,” with the image of the client dropping a bombshell with his or her hand on the office doorknob as he or she is about to leave the last session. Even after a good working relationship has been established, a client may be embarrassed to raise issues or concerns in taboo areas.

For example, a female college student may only hint at a difficult time at a party the previous weekend. She may talk at the beginning of a session about being concerned that she drank too much. This could be described as a first offering. The worker responding to the apparent issue of concern over drinking starts to explore the question of substance use in the student's life. As the interview proceeds, the student drops hints of how rowdy the party became and her increasing feelings of concern. This could be considered the second offering. Once again, the worker may begin to respond to issues of safety in a situation where alcohol is being consumed. Almost at the end of the session, the doorknob bombshell emerges, and the student describes having passed out, perhaps being drugged, and waking up in a bedroom in a state of undress and with evidence that she had been raped.

In a serious situation such as this one, the social worker may have to extend the session or arrange a later appointment that same day to deal with the powerful issue that has just emerged. The worker also has to consider the issue of mandatory reporting and whether he or she should be reporting the incident to the authorities or helping the client to do so. When the issue is addressed, it would be important for the worker also to explore why it was so difficult to raise the

incident directly in the beginning of the session. As the client discusses the feelings—which may include shame, self-blame, and so on—that made it difficult to discuss the sexual assault, she is actually beginning the discussion of the assault itself.

With this last example, we complete the discussion of the engagement phase of practice and the transition to the middle phase. For a more complete discussion of each phase of practice, see Shulman (2010, 2011). The dynamics and skills of the middle (work) phase of practice and the ending and transition phase are discussed in detail, as are the skills for developing a positive working relationship with other professionals and organizations. The use of concepts and interventions drawn from evidenced-based practice research is included, with an integrative approach suggesting less prescriptive strategies and more room for practitioner artistry. It is this personal quality expressed by the worker that contributes significantly to the development of the therapeutic alliance in individual practice and serves as the precursor of the group alliance.

81 The Use of Therapeutic Metaphor in Social Work

Stephen R. Lankton

There is a growing and continuing interest in the use of therapeutic metaphor among social workers, whether they are engaged in brief or long-term therapy, individual or family therapy, or the delivery of outpatient or inpatient treatment. Therapeutic metaphor belongs to that group of interventions referred to as “indirection.” The definition of metaphor as used in therapy refers to a complex story that holds the user’s attention and provides an alternate framework through which clients can entertain novel experience. Because this can be done without experiencing any threat, clients do not develop any resistance to entertaining new/novel experiences. While using metaphor, the therapist can accomplish the following.

- Make or illustrate an important therapeutic point to the client
- Suggest solutions (even potentially threatening ones) not previously considered by the client
- Seed ideas to which the therapist can later return and elaborate
- Decrease conscious resistance, a client might otherwise have, to experiential and cognitive changes
- Reframe or redefine a problem for the client so that the problem is placed in a different context of greater or lesser importance with a different meaning
- Retrieve and associate experiences, including emotions, thoughts, perceptions, and behaviors.

A CASE EXAMPLE OF SIMPLE METAPHOR

Client is a 28-year-old woman who recently broke up with her boyfriend of three years. As a couple they had purchased a home, and although he moved out, she was afraid to leave the house for fear that he would not pay the bills and she would be stuck with bad credit as a result. The young man is trying to obtain a loan so he can take over the entire house debt in his name alone. Each time a loan application is applied for or almost approved and then fails to result in him signing a new note she has mood swings.

Clearly she is excited about the possibility of completely ending all relations with him. But, she finds herself oscillating between excitement and depression whenever her hopes of being free of this financial connection do not materialize. This mood shift was interfering with her ability to perform at work. That is why she sought therapy. Of course, she is fully aware of this simple dynamic. However, her insight alone is not helping her reduce her mood swings.

The metaphoric intervention was designed to help her retrieve experiences of several periods of self-control that one learns to endure throughout childhood. What follows is an excerpt from the metaphor that was told to this patient.

"I want you to close your eyes and just be more comfortable for a minute. It is not necessary that you go into the hypnotic trance, but rather, I'd like you just to be relaxed so you can think about and remember a few things that might again occur to you while I speak."

"You know every child who's ever anticipated a birthday has something in common. When Sally was four years old she distinctly remembers that the ornaments on her Christmas tree were large and shiny. And she was fascinated as much by the tinsel and the decorations on the tree as she was by the ribbons, paper, and boxes below it. For the six days preceding Christmas morning she was unable to sleep normally. She would wander downstairs after everyone else had gone to bed and she would shake the boxes and wonder what kind of presents they contained."

"One night her mother happened awake to hear her shuffling the boxes. Knowing how hard it might be for a young girl to contain her excitement when something wonderful was about to happen, the mother made Sally some warm milk and gave her two cookies. As she ate, her mother explained to Sally, as parents often do, that Santa Claus would not be able

to come if he found her to be awake at night. She told her, 'You need to learn to calm down . . . and to sleep.'"

"Hearing the news about Santa Claus was, of course, not enough to make Sally fall asleep easily that night. She tried various ways of thinking in order to help nudge herself into sleep. She tried thinking about the smell of her sheets, taking a nap with her dog, and the comforting, warm feeling she got when her mother gave her the milk. Dwelling on any one of those memories would be enough to make anybody become sleepy and calm, I'm sure you sense that."

"Surprisingly this began working for Sally. She didn't do it very well at four years old—she did much better at five and six. But by the time she was seven years old she had learned to contain her excitement quite well. Even though she was very eager for Christmas to come she was able to sometimes put that excitement out of her mind sufficiently to appear to be a grown-up little girl."

"By the time she was nine she had become quite proficient at being happy and having pleasant anticipation—but not being so excited that it disrupted her. Somewhere along the way your mind learns a method of disconnecting itself from disruptive impulses. Children usually take pride in their ability to control their impulsive experiences. You go to bed knowing that you are excited about opening presents in the morning but you put that excitement into quiet pleasant thoughts. Little girls don't usually know that *you are* learning or how to say that they're putting their excitement into pleasant quiet thoughts."

"But, the unconscious can do that anyway. And if somebody says to Sally, '*remember that experience, remember that now,*' that feeling comes. The unconscious knows how to bring that feeling forward. And as that quiet feeling of excitement fills the mind, similar experiences are brought forward, developing a pleasant anticipation that's not disturbing and not distressing."

This short and simple intervention illustrates some of the value of using therapeutic stories in several ways.

- Metaphors retrieve *experiential resources* that are difficult to label and name.
- Metaphors provide an altered framework so clients use their own experiences to understand the story.
- Metaphors allow clients to retrieve experiences they may not believe they could retrieve.
- Metaphors eliminate the potential resistance, which could arise from clients feeling, in this case, that being calm was not possible.

- It helps a client understand a developmental sequence that suggests a change, in this case, in her impatience.

Immediately following the telling of that brief story, the client was asked to recall that and other feelings similar in her own life. That is to say, the therapist made a direct request for the client to remember similar feelings. The client's ability to carry out that direct request had been greatly enhanced by the telling of that story. She was able to remember times in her own life when she contained her mood and excitement. Those experiences were then used in therapy to help obtain the goal of keeping her mood stable in the context of waiting for her boyfriend to get the loan.

Let's look at a more complicated goal-directed metaphor used to retrieve the emotion of anger. The client is a 34-year-old male. He was doing his clinical residency in the state of Texas, but dropped out and moved to Arizona. His depression was complicated by, or even created, a further problem of reduced motivation. Being so poorly motivated he did not return to school, he did not complete his residency, he did not apply for jobs, and he became very self-critical.

Broadcasting this attitude in many ways to others, he found himself taken advantage of by others. He recently lost \$4,000 to a mere stranger, whom he thought he was helping as a friend. But instead of being outwardly angry at the thief, he is angry at himself. In this situation the use of direct communication about his feelings would be pointless. He would deny any anger and, were he to feel any anger, he would state that it is inappropriate for *him* to show it—he is not entitled to do so. In the second session, he is asked to go into trance after he relates the incident of being swindled. The following metaphor is a portion of that trance session.

"Pete worked as a dishwasher and was a classical guitar player. He had studied with Julian Bream and Andres Segovia and was a genuinely sensitive and accomplished musician. For a while, he drove a 1992 Mazda that had a bumper sticker reading "'Handel' with care, classical guitar player inside." After a while, he didn't think he needed that car anymore. When you change your car, you change a lot of things about yourself.

"When he came home from work one day, he found the door unlocked. He was temporarily surprised and angry at himself for not locking it. Fumbling for his keys, he fell into the door and hardly

gave a second thought as to why he had not locked it. But looking around, he saw the room was a mess. He was sort of struggling to understand his thoughts.

"When he saw the room in disarray, he thought how messy he was not to clean the room better. It says something about you when you keep your room in a mess. But then he saw shirts out on the couch and the situation changed. It occurred to Pete that he had not put his shirts on the couch, he would not have pulled them all out—he must have been robbed!

"Now for anyone who knew Pete, they would agree that there was one thing that came through loud and clear about him and that was his dependency on that guitar. He loved it. He would even fall asleep with it. He had slept with it once or twice and was teased by his friends. And he would spend hours a day dealing with it rather than dealing with another person. In fact, he got to where he would substitute playing his guitar forgoing on a date. Maybe it was like Linus and his blanket, and you know how fretful Linus gets if someone has taken his blanket. This does not begin to compare, however, with the feelings Pete was about to feel when he realized that he was being robbed. At first he thought he *had been* robbed and then he realized he *was being* robbed at that moment. He heard noise in the back room when the apartment should have been empty.

"And you know how your mind can change when you are in an auto accident, for example. You can remember every instance of that 10-second auto crash as though it had happened over a period of 20 minutes. You remember every change of posture, every movement of a pedestrian, every inch that the cars began to approach each other, everything you did to fasten a seatbelt or close a glove compartment or move something off of your lap. Pete must have had that sense of heightened memory, because he could explain every minute detail that occurred on that day from that moment on.

"It must have happened in a half of a few seconds, but it seemed like half an hour. The next thing he realized was a feeling in his legs and he felt his feet carry him across the threshold, hand on doorknob, shoulders relaxed on ribcage, which seemed odd to him. He could feel the blood flow through his arms and the adrenalin. But he felt somehow removed from it in a way that was surprising. He felt the momentum of his body open the door in a very aggressive fashion. But he did not have any thoughts about it except that he did not think it would have been so easy, and yet it seemed to be easier than he would have thought.

"In great detail he explained how he was running into the bedroom where his guitar was and what he was hollering. He heard words pouring out of his mouth that he didn't usually say. Then he saw the thief jump out the window holding *his* guitar. Then Pete dived out the window. He realized he was doing something one doesn't normally do. One's conscious

mind can observe one's body in action. Everyone has had the experience of hollering automatically when someone steps on your toes. You don't really realize what you are saying until you hear what you said.

"And before that moment had passed, Pete had both his tennis shoes on the grass outside his bedroom window and was racing across the parking lot. He felt weightless as his feet carried him across the grass. He was surprised consciously to realize he could have a feeling that seemed alien to him but have it comfortably when he might have thought he could not. He thought feelings had to be heavy, especially this one.

"And moving more rapidly than the man who was running, he passed the man, who dropped the guitar and let it hit the ground with a bong. The strings began resonating. They would do so for a good 20 seconds. Finally, Pete grabbed the thief by the shoulders and pushed him up against the back of that 1992 Mazda, and bent him over somewhat backwards against the back of the trunk.

"I do not know where you first feel your sense of muscular power when you do something like that. Maybe you feel your feet firmly on the ground. Maybe you feel a little taller than usual. Maybe you recognize that your breathing is easy and more rapid than usual and your skin is warm. And Pete stood there, pulled his fist back and held it chin level to himself and heard himself saying, 'I'm going to clobber you, you son of a bitch.' These were words he had never heard come out of his mouth before.

"He was about to hit the man, but then turned him around and putting his arms behind his back, wrestled him to the ground and held him there. There was a commotion. There was still a ringing in the background. Those guitar strings were still resonating from the topple and bong they had received.

"Other people now responded to the brawl. It had caught the attention of a passing patrol car and soon the police descended on the thief. As Pete walked away from the episode, he realized the guitar strings had still been faintly resonating while he held the man on the ground. He knew he could depend on the base notes resonating for about 17 seconds. The entire incident had taken just over 20 seconds from when he went out the back window to when he wrestled the man to the ground.

"Heart pounding, shoulders and sternum held high, jaw set firmly, feeling the blood pulsing through his neck, Pete would have expected that feeling that way would have been far more uncomfortable. He never thought of himself in any other way than "classical guitar player, handle with care." It's a lesson. One's unconscious knows of a good deal of experience and can put it together no matter what one's conscious mind thinks. Pete memorized that experience of anger, the impulse, the understanding that the unconscious intent is to have that impulse and use it for your needs—and memorized the recognition of not going

beyond the bounds of reason, even when he had the chance and it would have been justified."

Following the experiences he retrieved listening to this story, it was relatively easy to assist the client in thinking through how he could be angry at others, and be assertive while nurturing himself with angry and assertive feelings. Naturally, the therapy for each of the above individuals involved many more aspects of change. These excerpts are meant only to illustrate how therapeutic metaphor is used in nonhypnotic therapy as well as in hypnosis. As in the previous story, the metaphor allowed the therapist to elicit difficult emotional material—anger and assertiveness—without resistance by providing an alternate framework into which the client could project experiences he commonly avoided in his own life.

THE AMBIGUOUS ASPECT OF METAPHOR

Unlike directive and manipulative interventions that, through direct command, tell clients how to perceive, think, feel, or behave, techniques of indirection allow clients to project their own meaning into what they hear. This, in turn, allows the therapeutic material to be fit to their personal situation. Because clients *must* fit their life into the story being told, there is a high degree of relevance and deep meaning for clients. Contrariwise, if clients are instructed by therapists to conduct themselves in a certain manner, or say certain sentences in, say, directive couples therapy, the response from clients is compliance. That means that the learning, if any, has come from "outside" of themselves. However, when clients have determined for themselves a relevant meaning to an otherwise ambiguous story, they act on perceptions, behaviors, and feelings that truly belong to *them* and are a part of them.

Let's examine this ambiguous element more closely. The degree of ambiguity in a therapeutic story can be regulated by the teller so that the story is more or less vague to the listener. Regardless of the degree of vagueness, listeners create their own relevant meaning in order to understand the story. This accounts for the personalized nature of the understanding and the lack of mere compliance by listeners. However, as the degree of vagueness increases, there is an exponential increase in the number of possible

meanings that listeners can give to the story. It is assumed that listeners unconsciously sorting through several possibilities at what has been determined to be 30 items per second (Erickson & Rossi, 1979, p. 18) become increasingly absorbed in weighing the best fit for these possible meanings.

This ongoing process of weighing meaning has a number of therapeutic benefits. They include

- An increase in participation by listeners
- A heightened valuation in any meaning by listeners because the meaning has come from within their own experience
- A depotentiation of normal limitations or rigid ego controls as the listener seeks a "best fit"
- An increase in the duration of time given to examining possible meanings.

This last element, in fact, accounts for a therapeutic effect upon clients lasting long after the therapy sessions have ended. Indeed, for a highly meaningful and yet extremely vague metaphoric story, some clients have reported that they continued to turn it over in their minds for years and did this again for events that paralleled the original therapeutic learning incident years later. For this reason, the use of metaphor can be summarized as follows:

- It increases the relevance of therapy for clients and involves clients more highly in their own change process.
- It expands the usual limiting experience that has led to a stabilization of the presenting problem or dynamic that had brought the person to therapy.
- It offers an engaging element of ambiguity that may continue to alert listeners to their therapeutic learning for years after a therapy session.
- It offers a wide range of potentially correct responses within the therapeutic limits.

USES OF METAPHORIC STORIES

As listeners become increasingly engaged or absorbed in a story, there is a reduction in the defensive mechanisms that customarily constrain them to common sets experience (those which resulted in seeking therapy). That is,

listening to a story that symbolizes tenderness can lead a person who normally does not shed tears or weep to do so.

The definition mentions that clients can entertain *novel* experiences. The concept of a novel experience may need some elaboration. It pertains to experiences that have commonly been excluded from the experiential set of the listener/client. While listening to an absorbing story, clients may, with relative ease, temporarily go through one or several specific experiences, which, if therapeutically managed, can assist them in creating personal change. The assistance in creating personal change comes about as clients re-examine perceptions or cognitions, emotions, or potential behaviors in light of a recognition that some *new* experiences, perceptions, or cognitions once thought to be alien actually can be a part of their own personality and experience. In general, it can be said that the usefulness of metaphoric stories in therapy comes into play at any point in therapy where it is advisable or useful for clients to recognize that they can obtain the necessary experiential resources from within themselves rather than having to introject them from an outside authority.

Metaphor is especially useful when brief forms of therapy such as solution-focused therapy, hypnotherapy, family or couples therapy, or grief therapy, are the therapeutic modality of choice. Nevertheless, an additional aspect of the ambiguous nature of metaphor suggests that the use of therapeutic metaphor can have great value in long-term therapies as well.

REDUCTION OF RESISTANCE

Because metaphor offers listeners the ability to apply a wide range or spectrum of potential understandings to what the therapist has said, there is a corresponding reduction in listener resistance. Any therapeutic modality that finds clients to be resistive, possibly due to the nature of the modality itself, will be able to take advantage of metaphoric stories, provided that those stories are constructed and shared in a manner that employs the necessary components.

THE NECESSARY COMPONENTS OF THERAPEUTIC METAPHOR

To be effective, therapeutic metaphor must be perceived and be relevant. It also must engage

listeners and retrieve experience. There are a number of ways these requirements can be fostered in the therapeutic process. There should be a consideration of the relationship of the story to the sensory system primarily used by the listener in order to process data, material that is taken out of sequence to create dramatic engagement or enchantment, and the retrieval and use of experience that is therapeutically relevant.

The Perception and Relevance of the Metaphor

The most important feature regarding relevance of a metaphor or any experience is that it resonates with either clients' current state or clients' anticipated future state. The metaphor should be constructed to hold the attention of clients' conscious minds. This applies to the vast majority of metaphors that therapists will construct and use. Therapists should consider that clients' understandings or representations of problems are likely to be characterized by them in a preferred sensory system. That is, some clients will relate their problem with the majority of their sensory-specific verbs in a preferred representational system: visual, auditory, or kinesthetic (Lankton, 1980/2003). This can be ascertained by listening to clients' presentations of their problems. When such a preference is discovered, it is imperative that therapists attempt to communicate with clients in their preferred manner of thinking and representing. When delivering metaphor the conscious minds of clients will be engaged and consider stories more relevant when this connection is honored. Erickson referred to this as speaking the client's experiential language. Certain portions of a metaphoric story, however, may be strategically represented in a lesser used system for certain purposes. For instance, certain experiences may be more easily retrieved by therapeutic efforts aimed at the lesser used representational systems.

Consider a client who thinks with a predominantly visual set of mental tools. Relating a story that encourages him to see a father and son hugging will have a moving effect of joy or sadness on his conscious mind if he did not receive that type of attention. But then hearing the words spoken (his secondarily used sensory system is auditory) by the father in the story saying "Come here and let me hug you, son. I love you and I'm proud

of you" may more quickly evoke an emotion of tenderness, joy, or sadness. The difference is due to the fact that the client's understanding of his life is primarily a visual "story" in his mind that he can easily navigate. Seeing the images created in the telling of the story, it would be easy for him to quickly compare the ideas to his life and "think" about it. However, thinking with auditory imagery is not as easy for him and the experience attached to the imagery used by the therapist is, in fact, the experience he retrieves with less resistance. Purposeful regulation of this aspect of a story is a matter of training and experience on the part of therapist.

Metaphors that are Parallel to the Problem

There are two major categories of metaphor: those that are parallel to the client's problem and those that are parallel to the anticipated goal. Stories that are parallel to the client's current state or problem are far easier to construct and were the first type of metaphors noticed in the process of attempting to simulate the therapeutic work of experts such as Milton Erickson (Gordon, 1978; Lankton, 1980/2003).

The basic idea of the metaphoric stories that are parallel to the problem can be summarized in the understanding of the term *isomorphism*. Metaphors that are isomorphic have the body of their content in a one-to-one correspondence with the experience (that is, the problem state) of the client. A simple way of understanding this is that for every major person, relationship, and activity in the client's problem there is a corresponding person, relationship, and activity in the story told to the client. Again, the degree of distance or vagueness between the elements in the metaphor and the elements in the client's life will regulate the degree of ambiguity that is introduced, and therefore, determine how likely it is that the client will make the connection between this story and his or her life.

For example, consider the following variation of isomorphic metaphor that matches the problem. Here the husband seeks affection from a wife who ignores him unless blaming him for a fault. The pattern then unfolds as the husband withdraws into depression and the wife becomes angry with him. Table 81.1 lists the situation's components as related by the client, and the two columns show the elements of two different

TABLE 81.1 Isomorphic Construction

Situation	Less Ambiguous	More Ambiguous
husband	lovebird	electric drill
(husband) asks	chirps	(drill) freezes up
needs affection	needs touching	needs oil
wife	girl	mechanic
(wife) ignores	(girl) locks up bird	throws down
(wife) blames faults	(girl) shouts at bird	worries it will burn
(wife) defensive	(girl) recalls messes	brags of skill
(husband) withdraws	(bird) chews cage	(drill) overheats
(husband) depression	(bird) gets ill	(drill) emits smoke
(wife) angry	(girl) sells bird	throws it out

stories that could be told. They illustrate two varying degrees of ambiguity.

It should be obvious that despite the similar isomorphic relationship between parts of the story and the problem, the more ambiguous references may not be an apparent match in the mind of the listener. The solution to the dilemma is not shown in the table, only the components that match to the problem. However, the sketching of part (or all) of the solution would be the next step for the therapist.

There are two important considerations for the use of isomorphic metaphors. First, it must outline the context or heighten the client's awareness for the problem situation in which the solution will be fitted. Second, isomorphic metaphors need to have resolution that provides some metaphoric solution. It is in this second aspect of isomorphic metaphors that beginning therapists may encounter difficulty. There are a few major ways for isomorphic metaphors to be terminated so that they provide a therapeutic conclusion for the problem they have highlighted. The most elegant manner is that which involves the continued and often creative behavior of the protagonist, through whose behavior a solution would be illustrated. A second, less practical method is for the therapist to introduce into the story direct instructions that represent words spoken to the protagonist. This latter example is often called "embedded commands" or "embedded quotes." In this case, the only experience created for the client is that of a verbal idea.

This second option fails to meet the criteria of retrieving experience for a client and often fails to

meet the ambiguity element that prevents resistance in the client. However, it is a very practical method for therapists to deliver clear guidelines, instructions, or directives to a client in a fashion that reduces confrontation and thereby allows a client to save face.

The third and least elegant method to create a goal in an isomorphic metaphor is to introduce a break in the normal flow of the protagonist's behavior owing to some unexpected element such as the protagonist going to therapy, having a dream, or having some sudden sort of epiphany. Although this device within a story will allow the speaker to jump to a solution set, it does so at the expense of the logical flow of the metaphoric content. Yet, it still provides an opportunity for experiences to be retrieved that will help alter perception, behavior, emotion, or attitude—and for the client to experience these needed resources in immediate proximity or conjunction with the problem.

Goal-directed Metaphors

The second major category of metaphor comprises those that are constructed to become parallel to the goal rather than parallel to the problem (Lankton & Lankton, 1986, 1989; Lankton, 2004). It is essential that a basic protocol be followed to address specific goals of changes in attitude, emotion, and behavior, respectively. The content of the metaphors must be so ordered, following a process formula, that the metaphor retrieves specific types of experience-related options that, in turn, may serve as goals for the listener. These protocols

can be streamlined or maximized to facilitate, if not ensure, that the listener's experience will be one of cognitive alteration, emotional alteration, or behavioral sensitizing. In order to illustrate this, the three self-explanatory protocols for emotion, attitude, and behavior metaphors are listed below (Lankton & Lankton, 1986, 1989; Lankton, 2004).

A. Affect and emotion protocol

1. Establish a relationship between the protagonist and a person, place, or thing that involves emotion or affect (e.g., tenderness, anxiety, mastery, confusion, love, longing).
2. Detail *movement* in the relationship (e.g., moving with, moving toward, moving away, chasing, consistently pursuing, orbiting).
3. Focus on some of the congruent physiological changes that coincide with the protagonist's emotion (be sure to overlap with the client's facial and upper torso behavior as he or she listens).

B. Attitude change protocol

1. Describe a protagonist's behavior or perception so it exemplifies the maladaptive attitude. Bias this belief to appear positive or desirable.
2. Describe another protagonist's behavior or perception so it exemplifies the *adaptive* attitude (the goal). Bias this belief to appear negative or undesirable.
3. Reveal the *unexpected* outcome achieved by both protagonists that resulted from the beliefs they held and their related actions. Be sure the "payoff" received by the second protagonist would be considered to be of value to the client.

C. Behavior change protocol

1. Illustrate the protagonist's observable behavior similar to the desired behavior to be acquired by the client. There is no need to mention motives. List about six specific observable behaviors.
2. Detail the protagonist's internal attention or nonobservable behavior that shows the protagonist to be congruent with his or her observable behavior.
3. Change the setting within the story so as to provide an opportunity for repeating all the behavioral descriptions several (at least three) times.

Dramatic Aspects of Metaphor

A client's conscious attention can be held by the addition of dramatic devices in the storyline of the metaphor. By holding the client's conscious attention the therapist ensures that the metaphor can become a vehicle for carrying the interventions that retrieve desired experiences. My definition for the construction of dramatic devices in any oral or rhetoric tradition can be seen as a matter of presenting knowledge or information out of sequence. Information that is in a linear, chronological sequence is simply a documentary. However, when various delivery devices such as tonal inflection are used to stress certain words as if their meaning is deeper than that which is denoted, there is an indication that more than just documentary information is being offered. Furthermore, the hints that are provided by tonal stress in a simple, linear presentation of facts cause the listener to seek that connoted meaning by anticipating *what is to come* in the story or re-evaluating what has been heard so far. However, the actual tactics of creating dramatic hold within a story are more dynamic than simply stressing connoted information.

Looking at Table 81.2, it can be seen that, in the course of a story line, there will be information known to the protagonist (or characters in the story) and information known to the listener (that is, the client). If information known to the protagonist is not known to the listener, mystery arises. For example, in the telling of a story there may be a letter read, a telephone call, or a conversation in a secluded location between protagonists. And the information shared in that exchange can be illustrated as having great importance. However, that information can be withheld from listeners as a secret or private event. Although it has great meaning to the characters of the story, listeners will not know how the protagonists' behavior has been affected by

TABLE 81.2 Creating Drama

Type of Drama	Client	Protagonist(s)
Suspense	Knows info	Does not know
Mystery	Does not know	Knows info
Surprise/ shock/humor	Does not know	Does not know

the information that was concealed from them. As a result, listeners are in a position to try to deduce by anticipation, think back to the character development, or somehow gain a degree of certainty about how the information may affect the outcome of the story or just what the information was.

The element of mystery seems to create a primarily cognitive hold on the listener. It can happen numerous times in a story and it can also be created by means other than dialogues between the characters in the story. An analysis will reveal that the characters have been shown to be privy to some information not known to the listener. In the case of a therapeutic story the listener is the client.

Table 81.2 further illustrates that information known to the client or listener but not known to the protagonists or characters in the story creates the drama of suspense. The “hold” of suspense is a much more visceral or emotional hold of attention compared with mystery. This is often easily created by the storyteller through foreshadowing. In many well-known works of literature, the author will give a glimpse ahead as to how the story is to be framed. This occurs, for instance, when the story begins with comments about how the story will be ended. It is the same in cinema. The motion picture *Gandhi* begins with the assassination of the protagonist. Here we see the archetypal footprint of suspense by means of taking information out of sequence and foreshadowing the later ending of the man’s life. However, in cinema, there are more dramatic devices that can be used, such as sirens and flashing lights or the well-known rhythmical percussion in the movie *Jaws*. In a literary or spoken story, material taken out of sequence that reveals flaws or outcomes about the protagonists to the listener will increase the experience of suspense.

Finally, the drama creation table shows that when neither the listener/client nor the protagonist/character have information about an upcoming event, the result will be surprise, shock, or humor when the event occurs. So, a sudden death in a story, which was not foreshadowed for the listener or expected by the characters, will be a surprise. When surprise or shock occurs in a story, listeners will search facts they have already heard in the story to put the incident in perspective or will examine whether certain information had already existed to predict the surprise. And, too, they will begin to test various anticipated

hypotheses to try to predict how the story will turn out and be fixated on future details to potentially resolve the element of surprise.

Any of these dramatic methods have the effect of capturing attention and *engaging* listeners in the story by means of encouraging them to make sense of it. The visceral or cognitive energy used to sort through past and anticipated futures in a story is the result of the use of drama. The drama does not need to be award-winning or especially creative. It simply needs to be present in the story to help listeners become more consciously absorbed as they make room to entertain the novel experience created by the protocols mentioned before.

Enchantment

As mentioned, one of the devices for understanding the effect of metaphor is the aspect of ambiguity. In addition to drama, ambiguity is one of the major mechanisms that binds the listener to the story. Few words are available for explaining this interpersonal aspect of the phenomenon of ambiguity. Perhaps one of the best terms to refer to it is *enchantment*. Enchantment can be defined as being held spellbound by or as if by irresistible force, words, or charms; or to pique a pleasant mental excitement. It is this last aspect of creating a pleasant mental excitement that is of greatest interest to the therapist constructing a therapeutic metaphor.

Creating dramatic hold in a relevant story with a certain degree of various meanings available maximizes both interest and usefulness of the story for the client. It was mentioned earlier that the degree of ambiguity can be regulated by means of increasing or decreasing vagueness about the connection between events in the client’s life or experiences that will be goals for the client and the elements in the story. That is, the elements in the story can be increasingly mundane or increasingly symbolic and abstract in their denoted content. A degree of skill and practice is necessary to develop the ability to maximize the therapeutic impact and regulate this ambiguity with clients. It requires that therapists continue to have a high degree of observation regarding the impact the story is having upon the listener. Beyond the regulation of controlled ambiguity within the metaphor, there are other devices that create or regulate the experience of enchantment. These include auditory tonal changes in delivery and word-selection that can

create a degree of pathos and highly charged meaning for the listener.

Indications and Contraindications

Contraindications for using metaphor fall into two categories. One category has to do with the experience level of the therapist and the other concerns the type and severity of the client's presenting problem. A therapist who has little skill in the use of indirection techniques and who has limited clinical skill must consider using metaphoric stories with a greatly limited range of clients, problem severity, and diagnostic categories. The beginning therapist can only comfortably use metaphoric stories with individuals who would be considered vocal and intellectual; mildly neurotic, anxious, depressed; and with problems that are not urgent. With such clients, there is more ability to assess impact and ethically evaluate the efficacy of the technique.

Therapists with a greater degree of clinical experience and experience with the use of indirection and ambiguous interventions will find that it is possible to successfully and ethically employ metaphoric stories with a far greater range of individuals, problem categories, and diagnostic types.

Contraindication for diagnostic types includes individuals who are actively psychotic and those who are moderately to severely borderline. This also includes any neurotic individuals who have extreme difficulties with boundary-related issues. The reason for this concern about individuals with cognitive disorders and boundary problems lies in the fact that individuals can and will apply multiple meanings to the ambiguity of the metaphor. When the individual client has demonstrated difficulty retaining cognitive meaning or boundaries in "real-life" situations, the use of any technique that exacerbates a concrete intervention is contraindicated. Similarly, the boundary problem finds its difficulty in those individuals who come to believe that the therapist can read their thoughts by the fact that they have projected meaning into a metaphoric story and failed to realize that it is *their* projected meaning, instead thinking that it is a previously known meaning that the therapist has somehow been able to divine from an extra-ordinary means or from an extraordinary rapport with them.

These extremes do not occur for individuals who do not have boundary or cognitive problems.

However, a third category of contraindication includes those individuals who have a great deal of difficulty establishing rapport and trust. For these persons, regardless of their diagnostic category or presenting problem, the credibility of the therapist is continually being questioned and evaluated. Using metaphoric stories relies upon clients investigating what was said for possible relevant meanings and surrendering a degree of habitual reality testing. As clients become caught up in the relevance, drama, and enchantment of the story, individuals who maintain an analytical distance, and do so while doubting the therapist, are liable to take the ambiguity as a sign that the therapist is to some degree not competent. Again, the clinical experience of the therapist may reduce the number of individuals for whom this type of contraindication is relevant. Therapists with considerable clinical experience are usually skilled at carefully judging the manner in which they need to approach clients in order to engage them in the change process. And, the execution of this type of therapeutic judgment can be referred to as, what this author calls, the "controlled elaboration of ambiguity."

Using Metaphors within the Therapy Process

Using metaphoric stories need not be constrained to individuals in hypnotic trance. Metaphoric stories can be used at any point in the therapeutic process providing the goal is to retrieve perceptual, attitudinal, emotional, or behavior-change goals. Some of the common uses of metaphors even in the early stages of the therapy process are as follows.

- To illustrate a way of using therapy to change problems and arrive at a therapeutic contract
- To help clients relax
- To direct clients' thoughts to the situations that have led them to the office
- To normalize their situation and help them articulate their problems.

All of these goals and more at the early stages of therapeutic contact can not only be accomplished with metaphoric stories but can possibly be accomplished more efficiently by using them. The reason for this is that the degree of choice the listener has in making sense of a metaphoric

story reduces the resistance that can arise from otherwise attempting to be specific with direct communication of statements and questions about how a client is to think, feel, or behave.

During the change process itself, metaphoric stories can enhance any aspect of therapy where increased mental involvement is indicated and where specific experiences brought into the foreground can enhance therapeutic movement. These times are more numerous than can possibly be mentioned and the more experience the therapist has, the more such moments will be apparent.

Summary

Using therapeutic metaphor throughout the therapy process can enhance therapeutic movement as it retrieves the desired experiences clients need for therapeutic movement. Metaphoric stories need to be constructed in a manner that is relevant to clients, holds their attention, and facilitates the retrieval of experience that is helpful to the therapy process. The degree of ambiguity should be carefully regulated by observing the client's responses to the spoken words.

When using metaphoric stories, therapists must continually observe clients during the delivery of each metaphor. The aim of observation is for the therapist to recognize the degree of relevance the story has for the listener by gauging the degree of internal absorption and searching for facial expressions, head nods, changes in breathing, and other ideomotor behavior that the client displays. It is also for the therapist to gauge the degree of achievement that clients accomplish in retrieving desired experiences from the same indicators. Finally, the aim of observation is to gather ongoing diagnostic information as it pertains to the manner in which the client responds to various words and actions that are denoted and connoted within the story.

Because delivering and receiving the metaphor is an individual matter, research on the level of resource retrieval and specific resources that a particular metaphoric story may bring is problematic. Clients will respond in unique

ways depending upon their needs, background issues, and motivation, and also depending upon the therapist's skill in observing and delivering metaphor. Outcomes that are achieved by the use of metaphoric stories are truly co-created. That is, they are a blend of the client's history and motivation coupled with the therapist's ability to provide compelling delivery and meaningful content, as well as therapeutically useful protocol.

Finally, it should be remembered that the listener's achievement of meaning fluctuates with the degree of ambiguity and apparent relevance of the story. Therefore, stories should have some immediate impact upon the listener that is useful within the therapeutic sessions. However, some degree of impact can be expected from certain stories, days or even years later, due to the client's capability to seek useful meanings and project them into the ambiguity provided by a relevant story.

82 Cognitive Restructuring Techniques

Donald K. Granvold & Bruce A. Thyer

From a Cognitive Behavioral (CB) perspective, human functioning is conceptualized as the product of the reciprocal interaction of cognition, behavior, emotion, personal factors (emotion, motivation, physiology, and physical phenomena), and social environmental influences. As social worker Harold Werner put it: "the primary determinant of emotion and behavior is thinking." (Werner, 1982, p. 3), reflecting a perspective similar to that of social worker James Lantz: "The primary concept held by cognitive practitioners is that most human emotion is the result of what people think, tell themselves, assume, or believe about themselves and their social situations" (Lantz, 1978, p. 361). Beck and colleagues also elucidate this point: "The primacy hypothesis reflects the importance we place on cognition by stating that negative cognition and the biased information processing of negative self-referent information can directly influence other behavioral, motivational, affective, and somatic symptoms of depression" (Clark, Beck, & Alford, 1999, p. 157).

From a *behavior analytic* perspective, overt actions, thoughts, and feelings are all seen as forms of behavior, without any causal relations among them. This is in keeping with the definition of behavior provided in the National Association of Social Workers (NASW) *Social Work Dictionary*, "Any action or response by an individual, including observable activity, measurable physiological changes, cognitive images, fantasies, and emotions. Some scientists even consider subjective experiences to be behaviors" (Barker, 1995, p. 33). Although the psychologist John B. Watson claimed that the term behavior should be limited to publicly observable actions, this limited perspective never really was widely endorsed and was replaced by the expansive view of B. F. Skinner who promoted a more

comprehensive definition of behavior, embracing both overt and covert (within the skin) actions, including thoughts and feelings. Unlike the CB perspective, however, behavior analysis does *not* posit that thinking causes behavior, or even has primacy in explaining overt behavior. Rather, the behavior analyst contends that overt actions, thoughts *and* feelings are all largely originating in the person's environmental experiences and biology. This is an important distinction. If one theorizes that thinking causes overt behavior, then to change overt behavior one should focus on changing cognition. This is, of course, the conventional view of most psychotherapies, including cognitive behavioral therapies. However, if one theorizes that thoughts, overt behavior, and feelings are all caused by one's person-in-environment transactions (and biology), the social worker largely will focus on providing new and different environmental experiences in order to bring about changes in thoughts, feelings, and actions. This is much more of an *environmentalist* orientation, as opposed to a mentalist one, and has important treatment ramifications. CB therapy would focus more on office-based consultations and therapies, whereas the behavior analyst would view cognitive change efforts as more real-world based, with change efforts occurring outside the office. Below we will discuss various ways of changing thinking, derived from these two orientations.

TECHNIQUES FOR CHANGING THOUGHTS

Socratic Dialogue

Cognitive restructuring is the term used for a variety of procedures focused on the modification of cognitions and cognitive processing. Many

approaches to cognitive restructuring use the Socratic method to guide the client in the identification, exploration, modification, and elaboration of cognitions. Other approaches use imagery, guided discovery, and in vivo behavioral procedures to “test out” and modify beliefs.

The goal of cognitive restructuring is to guide the client in the exposure of cognitions influencing untoward, unappealing, disconcerting, or dysfunctional outcomes and modify them through further exploration, disputation, or elaboration. Clients are guided in the use of logic or evidence to examine and modify their exaggerated, distorted, or ill-founded beliefs. The first task is to elicit the thoughts, cognitive processing errors, or images contributing to the client’s unhappiness or distress. Wells (1997) recommends a Socratic sequence combining general questions with more specific probe questions. Probe questions are useful in gaining clarification and greater detail. The use of reflection and expressions of empathy and affirmation may promote relationship development and client awareness that the therapist clearly understands. The following dialogue illustrates early intervention with a client experiencing high anxiety.

Therapist: What did you feel in the situation? [general question]

Client: I felt scared and couldn’t stop shaking.

T: When you felt *scared* and *shaky* [reflection] what thoughts went through your mind?

C: I don’t know. I just felt awful.

T: Did you think anything bad could happen when you felt like that? [probe]

C: Yes. I thought I looked stupid.

T: What do you mean by stupid? [probe]

C: I thought everyone would notice and think I was an alcoholic or something (Wells, 1997, p. 53).

Cognitive restructuring is incomplete if the process is stopped at mere identification of operative cognitions. After gaining an understanding of the client’s thinking and associated emotional responses, the focus shifts to modification efforts. The following is a list of questions for use in modifying thoughts.

- Where is the evidence?
- Is there any evidence to the contrary?

- How strongly do you believe that?
- Could you see yourself . . . with more positive views of self . . . having more trust in your partner’s dedication to you . . . having greater purpose in life?
- What is the worst that could happen?
- Could you look at it another way?
- What other meanings can you identify?
- What are the consequences of looking at it this way?
- How do you feel when you think _____?
- Would it be possible to _____?
- What images or sensations do you experience when you think _____?
- What other thoughts flow from that thought (image)?
- Given your current understanding of the impact that our meanings have on the way we think, feel, and are motivated to act, what is your best advice to yourself?
- What if?

Socratic dialogue uses questions like the foregoing to probe for the logic or evidence supporting the client’s thinking and explore the consequences of the belief or beliefs. As beliefs fail to demonstrate validity or viability, cognitive restructuring proceeds with the generation of alternative meanings and their consequences (Beck, 1995; Granvold, 1994).

THERAPIST MODELING ADAPTIVE THINKING

It is important that the therapist model desirable cognitive processing in the questions asked. For example, “How did that make you feel?” promotes external locus of control thinking. Such thinking places the power over one’s well-being with other people or with one’s life circumstances. This violates the cognitive therapy principle that, with a few exceptions, each of us is responsible for our feelings and ultimately our mental health. The question can be rephrased easily as, “How did you feel when . . . ?” Another therapist trap easily avoided is the use of expressions in which information processing errors are evident. For example, to avoid modeling dichotomous thinking the therapist can ask such questions as, “What factors influenced your decision to divorce?” and “When you got angry in traffic, what thoughts were going through your mind?”

CASE EXAMPLE

The following is an illustration of cognitive restructuring with a client who is going through a contentious divorce. By temporary court order, her husband has been given managing conservatorship of their children. Her relationship with her children has been troubled largely due to past episodes of depression and a demanding work schedule. Following the recent separation, she has felt extremely depressed and hopeless, along with feelings of hurt, sadness, loss, and anger. She admits to suicidal ideation but has no plan to do so, nor can she see herself actually committing suicide. Socratic dialogue has identified a web of strong beliefs that undermine her emotional well-being and promote negative views of self. In the following excerpt, one of the most powerful beliefs from this matrix of meanings is identified and explored for change. The probing is focused on uncovering evidence to support or negate her belief.

Client: I have moved out of the house into an apartment. I've lost everything. I don't have my house. My husband doesn't love me. I don't have my kids anymore. I've lost my children [crying].

Therapist: You have experienced a lot of loss with the separation, and I feel badly that you are going through this. You just said that you have lost your children. Could you tell me more about that thought?

C: I don't see them each night when I come home from work. I've lost them. I'm not a mother anymore.

T: When you think the thought, "I've lost my children," how do you feel?

C: I feel empty and sad . . . and hurt.

T: So the thought, "I've lost my children" promotes some pretty unpleasant feelings.

C: Yes [softly crying].

T: You may recall our past discussions about the role our thoughts tend to play in our feelings. You have expressed the thought that you have lost your children. As evidence to support this thought, you indicated that you don't see them each evening as you did prior to the separation.

Let's explore this statement. Have you seen them at all since you moved out three weeks ago?

C: Oh, yes, I see them one or two nights a week and on Saturday or Sunday, sometimes both days.

T: So despite not seeing them daily, you do spend time with them several times a week.

C: Yes, that's right.

T: Although it is not the same as when you were living in the same household with them, are you their mother when you are spending time with them?

C: Well, yes I am, but it doesn't feel the same.

T: In what ways does it feel different?

C: I guess it's different because I know that I am going to my apartment alone, without them.

T: Would you conclude from our discussion that although it isn't the same, you haven't actually lost your children?

C: Yea, I guess that's more accurate.

T: So, you're still their mother, and you are continuing to be actively involved in their lives. Earlier you said that you feel sad, empty, and hurt in relation to the thought that you've lost your children. Would you conclude that shifting your thought from, "I've lost my children" to "It isn't the same" is really a more accurate statement of your situation?

C: Yes, it is, I guess.

T: You have reported feeling sad, empty, and hurt in relation to the thought that you've lost your children. Though it would be unrealistic to expect these feelings to go away completely, can you detect feeling any *less* sad, empty, and hurt as you think, "parenting isn't the same," rather than "I've lost my children?"

C: It's really hard to tell, but I suppose I don't feel as badly.

T: Perhaps you will be able to detect greater change in your feelings over time. Each time you think, "I've lost my children," would you be willing to answer that thought with, "No, I haven't lost my children, it (parenting) just isn't the same?"

C: Yes, I'll try it.

The therapist guided the client in revising a powerful statement presumably influential in promoting strong feelings. The client realized that the evidence contradicted the meaning she attached to the postseparation change in parenting. She arrived at an alternative meaning that was more consistent with her recent experience as a parent. She also considered the connection between her thoughts and feelings. Based on the awareness that effective cognitive restructuring requires repetition, the client was asked to repeat the reframing whenever the faulty thought occurred. This practice was reviewed at several subsequent sessions. As noted earlier, the thought addressed in this excerpt is one of a web of beliefs contributing to her current views about her children, herself, and her emotional state. She also believed that her children no longer cared for her (e.g., "They never call me"; "They could care less whether I call them or not"; "When we are together, it's all about them"). These and other beliefs were similarly isolated for cognitive restructuring with the focus on the identification of supportive evidence and evidence to the contrary.

TERAPIST MODELING OF ADAPTIVE PERFORMANCE

Observing another person engage in desired behavior can be an effective method of inducing behavioral, affective, and cognitive changes (Bandura, 1977). For example, in the behavioral technique of exposure therapy and response prevention, which often is used to treat clients with phobias, a therapist will model all behaviors to be subsequently asked of the client, such as touching a harmless snake, holding it, and verbalizing aloud realistic and adaptive thoughts. Similarly, role playing exercises for nonassertive persons may involve a therapist displaying various ways of acting appropriately assertive with a confederate, while the client observes. The exercises may involve gradually escalating scenarios wherein the therapist/model demonstrates increasingly greater levels of assertiveness.

USE OF SCALING TO ASSESS CHANGE

Cognitive restructuring may not produce a complete change in the client's beliefs. Thoughts and beliefs determined to strongly contribute to distress, disturbance, self-downing, and unrest may remain active following cognitive restructuring efforts. It is more realistic to expect a reduction in the strength of the view, rather than complete eradication of the belief. To evaluate the effectiveness of the specific cognitive restructuring effort, the therapist may ask the client to rate the current strength of the belief under scrutiny.

Therapist: How much do you believe that your husband is trying to take everything from you?

Client: About 50 percent, I guess.

T: How have you managed to drop from 95 to 50 percent?

C: I looked over the proposed property settlement and I can see that he's trying to be fair in that area. I can't let go of the idea completely though, because he's the one with the children [i.e., custody].

T: And now how angry do you feel toward him?

C: Oh, I'm still pretty upset. I guess about a 60 [percent].

T: I see. Although you're still upset, you are making meaningful change in your views and feelings.

Scaling is used in a variety of psychotherapies, including behavioral and cognitive behavioral therapy, solution-focused brief treatment, and many others (see Thyer, Papsdorf, Davis, & Vallecorsa, 1984; Gillaspay & Murphy, 2012; Miller et al., 2003). Apart from being useful to evaluate any changes, the mere act of scaling itself seems capable of inducing some positive changes on the part of the client.

COGNITIVE ELABORATION

Many cognitive restructuring efforts are designed to reframe the cognition under consideration, to replace one thought with another. In some circumstances, it may be undesirable to replace a thought or even to directly attempt to

reduce its strength even though it may stimulate unappealing responses and mood states. Furthermore, a client may be unwilling to abandon a given thought. Cognitive elaboration (Granvold, 2008) is an alternative approach to cognitive restructuring in which the focus is on the generation of alternative thoughts, views, or meaning constructions without the expectation that the original view be abandoned. This approach is particularly useful with clients who are grieving the death of a loved one.

In the illustration that follows, Blake is struggling with the death of his 28-year-old son, James, who was killed a year earlier in a one-car accident. The accident occurred while James was returning from a hunting trip that Blake had originally planned to make with him. James was drunk at the time of the accident. Blake believes that he is responsible for James's death, that had he been with him on the trip, the accident would not have happened. After exploring the belief that "I am responsible for my son's death" and identifying the associated emotional consequences (depression, loss, pain, helplessness, regret) the focus shifted to cognitive elaboration.

Therapist: Because focusing specifically on blaming yourself for James's death appears to result in other problems, suppose you expand your thoughts about James's death in addition to "It's my fault." What other thoughts do you have about James's life or his premature death?

Client: Well, not to be too hard on the kid, but he did have a drinking problem, and, ultimately, I guess that you could say he was responsible for the accident that took his life. He was drunk!

T: Yes, I agree with you that James was responsible for his drinking and the accident. It is somewhat a question of when does a parent quit protecting his child. Blake, can you function with both of these beliefs, "It's my fault" and "James was responsible for his drinking"?

C: Even though they seem contradictory, I think I can.

T: So, it is possible to maintain multiple views or beliefs about a situation.

C: Yes, I think it is.

In this and subsequent sessions, several other meanings were elaborated in relation to James's

death (and life) including (1) James's death will have been a waste if I do not do something in his name that could have a positive impact on the problem of drinking and driving in our society (Blake became actively involved in MADD); (2) I need to be very involved with James's son as James's "representative"; (3) James would want me to get past my intense grief and once again enjoy life (a belief generated through a role reversal exercise); and (4) I can still love James strongly and grieve less.

Challenging Blake's initial belief that his son's death is his fault would have been, I believe, less effective than allowing it to stand as one of many meanings in a matrix of constructs surrounding the loss. The generation of multiple meanings through the process of cognitive elaboration dilutes the strength of a given belief and produces a range of consequences. The position of constructivists is that the client will likely realize greater viability among the various constructs generated.

GUIDED IMAGERY

Guided imagery is a viable alternative approach to cognitive restructuring. An early approach to the use of imagery was developed by Maultsby (1975) in the form of rational emotive imagery (REI). Other Cognitive Behavioral Therapy (CBT) leaders have also employed the use of imagery as a cognitive restructuring method (Beck & Emery, 1985; Beck & Weishaar, 2008; Ellis, 1977). Several imagery techniques have been advanced for use in the process of cognitive restructuring by these and other clinicians. Edwards (1989) notes that "the main techniques for obtaining an image from which to begin are the visualization of a life event or theme, the reinstatement of a dream or daytime image, and feeling focusing" (p. 286). Images, dreams, and fantasies may be drawn from the client's history or current imagination. Alternatively, the therapist may generate content for use in guided imagery. Though not imperative, it may be helpful to teach the client progressive relaxation for use in conducting guided imagery. In the illustration that follows, guided imagery is used with a Vietnam veteran suffering from nightmares about a specific combat experience in which two of his men were killed. The client feels responsible for their deaths and believes he should have

acted to save them. He is a decorated veteran known for his leadership in combat situations. When he awakens from these recurrent nightmares about combat over 40 years ago, he feels extreme sadness and intense self-reproach. On these occasions he acts cold and distant toward his wife and his employees.

Therapist: You said that when you think back on the firefight in Vietnam in which two of your men were killed, you feel responsible, that you should have acted to save them.

Client: That's right. I have vivid dreams about them being torn apart by bullets.

T: Close your eyes. Imagine that you did little to prepare your men for combat and that you are out on patrol. The patrol is attacked, and your men go down beside you. You and your remaining men fight off the enemy and the shooting ends. As you attend to the casualties, how are you feeling?

C: First, I would never act this way. But I'll go along with this thinking. . . . I feel angry with myself, a lot of self-loathing . . . and ashamed for being so irresponsible.

T: So when you think of yourself as failing to prepare your men for combat and casualties result, you feel anger with yourself, self-loathing, and shame. Now this time, imagine that you have prepared your men extremely well for combat. By your instruction, they have become highly skilled soldiers, but you recognize that war is war. Each man knows that he may die in battle. You enter the firefight as before, and men are lost. The patrol is attacked, and your men go down beside you. You and your remaining men fight off the enemy and the shooting ends. As you attend to the casualties, how are you feeling?

C: I feel pretty empty inside over the loss of these men, but I don't feel as upset with myself. I did what I could do . . . but war is war, as you just said.

In this example, the client was asked to consider himself performing his responsibilities unconscionably by failing to prepare his men for battle (a legitimate basis for accepting responsibility for casualties of war). After identifying the associated feelings, he imagined the same combat scene with the awareness that he *had* prepared

his men well for battle. This process resulted in a reduction in the degree to which he felt upset and reinforced the thought, "war is war." The latter thought is one that the client had expressed in an earlier session. The client was a strong candidate for the use of imagery inasmuch as he was experiencing powerful imagery (both nightmares and daydreams) outside therapy sessions.

SKILLS-BUILDING AND REAL-LIFE EXPERIENCES

Behavioral experiments may be used to identify and modify beliefs, assumptions, and expectations. The client and therapist collaboratively develop a plan for the client to "test out" the veracity or viability of his or her views. In the behavioral experiment, the client may "predict an outcome based on personal automatic thoughts, carry out the agreed-upon behavior, and then evaluate the evidence in light of the new experience" (Beck & Weishaar, 2008, p. 286). Ellis introduced his famous "shame attacking" exercises early in the development of REI in which clients exposed themselves to negative attention, typically with little or no actual disconcerting consequences. Several iterations of the experiment often resulted in cognitive and emotive change.

Behavioral experiments may be enacted in vivo or take place in the therapist's office as role-plays. In some cases, the simple gathering of information may suffice (Beck, 1995). The following are illustrations of clients' evaluation of their beliefs in actual life experiences. A client experiencing social phobia tested the hypothesis that "no one will speak to me" at singles' Sunday school class. By attending the class, she disproved the hypothesis and actually experienced a warm reception by many. Another client saw himself as extremely unappealing and consequently no one would be willing to go out with him on a date. He further believed that if he *was* successful, he would not find the woman desirable. We agreed that this experiment might take several iterations. He went online and made contact with several people. After developing ongoing correspondence with several women, he began arranging dates. His first few efforts actually supported his original hypothesis. On the fourth outing, however, he met a woman whom he found to

be highly attractive. They dated for a time. Although their relationship was not sustained, he modified his self-view as a consequence of this experience.

Through behavioral experimentation, clients modify their views as actual life experiences provide evidence that contradicts their conceptualizations. Some clients may approach behavioral experimentation with marked skepticism and strong beliefs that they are “right” in their conceptualizations. For those clients, a review of their personal life experience may be persuasive. Attempt to identify prior life experiences in which anticipation failed to match realized experience (e.g., aerobics classes are for athletic people only). These experiences may serve as useful points of reference in dispelling client reluctance and in developing openness to behavioral experiments.

The second author was once consulted by an older woman who had developed a severe phobia to dogs, following her being savagely attacked by a large dog four years earlier (see Thyer, 1981). She wished to become less afraid of dogs (change her feelings), think less anxious thoughts about them (change her cognitions), and stop unrealistically avoiding them (change her actions). The social worker realized that purely cognitive interventions such as Socratic dialogue, cognitive elaboration, scaling, and guided imagery would likely be less effective at helping her achieve her goals compared with more direct experiences in real life. This is in keeping with Bandura’s admonition that “it is performance-based procedures that are proving to be most powerful for effecting psychological changes. As a consequence, successful performance is replacing symbolically based experiences as the principle vehicle of change. . . .cognitive processes mediate change but . . . cognitive events are induced and altered most readily by experience of mastery arising from successful performance” (Bandura, 1977, p. 191). Accordingly, with full client-informed consent, the therapist arranged a series of real life encounters with live dogs, initially small and cute, then to large and intimidating, with the client in the therapist’s office, using the behavior analytic method known as real life exposure therapy. Although she was initially made highly anxious during these

sessions, with the passage of time within each session she calmed down, felt less anxious, avoided the dogs less, and has less distressing thoughts. Office-based sessions were replaced with real-life interactions with dogs, including a visit to the local humane society. A complete remission of all symptoms, overt behavior avoidance, distressing cognitions about dogs, and fear, was achieved after five such sessions, in about a month. Close contact without anything untoward happening, being repeatedly licked and jumped on, and her mastery of commanding the trained dogs to sit, “speak” and lay down, all worked at inducing not only cognitive restructuring, but also therapeutic changes in feelings and actions. This form of experiential behavior therapy also makes use of therapist modeling desired behavior, which is another valuable way to induce changes in cognitions, feelings and overt actions.

CONCLUSION

Humans are no strangers to the process of cognitive restructuring in some form. We develop and modify beliefs automatically as part of life span development. We are also, however, creatures of habit. Stored and accessible beliefs operate rather inflexibly, and cognitive processing patterns become routine. When modification of these phenomena is indicated, cognitive restructuring procedures like those presented in this chapter provide a methodology for effective change. Clinicians engaged in cognitive restructuring efforts are invited and encouraged to draw on their creativity individually and collaboratively with their clients in developing efficacious cognitive restructuring strategies. More detailed reviews of cognitive restructuring methods can be found via the Internet links provided below, and in Garland and Thyer (2013) and Thyer and Myers (2011).

The Miracle and Scaling Questions for Solution-building and Empowering

Mo Yee Lee

The miracle question and the scaling question is an integral part of solution-focused brief therapy (SFBT), which was originally developed at the Brief Family Therapy Center at Milwaukee by Steve De Shazer, Insoo Kim Berg, and their associates. Solution-focused brief therapy begins as atheoretical with a focus on finding “what works in therapy” (Berg, 1994). Building on a strengths perspective and using a time-limited approach, solution-focused brief therapy postulates that positive and long-lasting change can occur in a relatively brief period of time by focusing on “solution-talk” instead of “problem talk” (De Shazer, 1985; Lee, 2013; Nelson & Thomas, 2007). One definitional characteristic of SFBT is that it equates therapeutic process with therapeutic dialogue, with a focus on what is observable in communication and social interactions, instead of intentions, between client and therapist (Bavelas et al., 2013; McKergow & Korman, 2009). Change happens through the therapeutic dialogue in which the therapist and client co-construct what is beneficial and helpful toward accomplishing the client’s self-determined goals (Lee et al., 2003). Solution-focused brief therapy uses the language and symbols of “solution and strengths” as opposed to the language of “deficits and blame” (Lee, Sebold, & Uken, 2003). Treatment focuses on identifying exceptions and solution behaviors, which are then amplified, supported, and reinforced through a systematic solution-building process (De Jong & Berg, 2013).

Miracle questions and scaling questions, in many ways, synthesize the treatment orientation and practice characteristics of solution-focused

brief therapy. Its conversational- and solution-based characteristics are intimately related to three definitive assumptions and practice principles of solution-focused brief therapy:

1. The power of language in creating and sustaining reality. Solution-focused therapy views language as the medium through which personal meaning and understanding are expressed and socially constructed in conversation (De Shazer, 1994). Because “what is noticed becomes reality and what is not noticed does not exist” (Lee et al., 2003, p. 32), there is a conscious effort for the therapist to help the client stay focused on envisioning a desirable future and finding small steps to actualize the solution-oriented future. Pathology or problem-talk sustains a problem reality through self-fulfilling prophecies and distracts attention from developing solutions (Miller, 1997).
2. A focus on solutions, strengths, and health. Solution-focused brief therapy assumes that clients have the resources and *have the answer*. The focus is on what clients can do versus what clients cannot do. One basic assumption of a systems perspective is that change is constant. No matter how severe the problem, there must be some “exceptions” to the problem patterns. These exceptions serve as clues to a solution and represent clients’ “unnoticed” strengths and resources (De Shazer, 1985). Consequently, the task for the therapist is to assist clients in noticing, amplifying, sustaining, and reinforcing these exceptions regardless of how small and/or infrequent they may be. Once

clients are engaged in nonproblem behavior, they are on the way to a solution-building process (De Jong & Berg, 2013).

3. Solutions as clients' constructions. Solutions are not objective "realities" but are private, local, meaning-making activities by an individual (Miller, 1997). The importance of and the meaning attached to a goal or solution is individually constructed in a collaborative process. Solution-focused therapy honors clients as the "knower" of their experiences and the "creators" of solutions; they define the goals for their treatment and remain the main instigator of change (Berg, 1994).

THE USE OF QUESTIONS IN THE THERAPEUTIC PROCESS

Influenced by these assumptions and practice principles, the primary purpose of solution-focused interventions is to engage the client in a therapeutic dialogue that is conducive to a solution-building process. In this dialogue, the clinician invites the client to be the "expert" by listening and exploring the meaning of the client's perceptions of his or her situation. The use of solution-focused questions is instrumental in this solution-building dialogue. People need useful feedback in the process of change (Lee, 2013). The therapist can provide feedback directly via listening responses, affirming responses, restating responses, and expanding responses (Lee et al., 2003). Instead of directly providing feedback to clients, evaluative questions serve to initiate a self-feedback process within the client. Evaluative questions represent questions that ask clients to self-evaluate their situations in terms of their doing, thinking, and feeling. The therapist abstains from interpreting a client's situation or suggesting any ideas; s/he just asks good questions that help clients evaluate various aspects of their unique life situations (Lee et al., 2003). Questions are perceived as better ways to create open space for clients to think about and self-evaluate their situation and solutions. Evaluative questions operate from the stance of curiosity and convey the message that we believe that clients themselves have the answers and that we, in fact, do not have the answers.

The therapist utilizes solution-oriented questions, including miracle questions and scaling

questions, to assist clients in constructing a reality that does not contain the problem. These questioning techniques are developed by De Shazer, Berg, and their colleagues to utilize fully the resources and potential of clients (De Jong & Berg, 2013; De Shazer, 1985).

LISTEN, SELECT, AND BUILD

The SFBT Treatment Manual endorsed by the Solution-Focused Brief Therapy Association (Bavelas et al., 2013) provides a detailed description of this co-constructive therapeutic process through the steps *listen*, *select*, and *build* (De Jong and Berg, 2013; De Shazer, 1991; 1994; de Shazer et al., 2007). In this dialogue, the therapist first listens for and selects out the words and phrases from the client's language that are indications of some aspect of a solution, including things that are important and salient to the client, past successes, exceptions to the problem pattern, and resources. Building on the client's descriptions and paying attention to the client's language and frames of reference, the therapist composes a next question or other response that invites the client to elaborate the solution picture further. It is through this continuing process of listening, selecting, and building that therapists and clients together co-construct new meanings and new possibilities for solutions (Bavelas et al., 2013).

Miracle Question

The development of the miracle question was inspired by the work of Milton Erickson (the "crystal ball" technique) (De Shazer, 1985). According to Berg (1994), the miracle question invites clients to create a vision of their future without the presenting problem. A major challenge encountered by most clients in social work treatment is that they know when they have a problem but they do not know when the problem has been successfully addressed. When this happens, clients may be in treatment for a long time because there are no clear indicators of health and wellness. Helping clients to develop a clear vision of their future without the presenting problem becomes crucial in successful treatment because it establishes indicators of change and helps gauge clients' progress toward a self-defined desirable future (De Jong & Berg, 2013; Lee, 2003). When defining a future

without the problem becomes a major focus of treatment, accountability for changing one's behavior can be achieved effectively. Defining a desirable future also shifts the focus of attention from what cannot be done to what can be accomplished; it moves clients away from blaming others or themselves and holds them accountable for developing a better, different future (Lee et al., 2003).

The miracle question is intended to accomplish the following therapeutic impact:

1. Allow clients to distance themselves from problem-saturated stories so that they can be more playful in creating a beneficial vision of their future.
2. Facilitate clients to develop a clear vision about a desirable future, given that "what is noticed becomes reality and what is not noticed does not exist" (Lee et al., 2003, p. 32).
3. Because the focus of the miracle question is to identify small, observable, and concrete changes that are indicative of a desirable future without the presenting problem, it establishes indicators of change and progress that help clients to gauge success and progress.
4. Increase clients' awareness of their choices and offer them an opportunity to play an active role in their treatment (De Jong & Berg, 2013).
5. Allow clients to be hopeful about their lives, which can be different than their current problem situation.
6. Empower clients to self-determine a desirable future for themselves. "It creates a personal possible self, which is not modeled after someone else's ideas of what his life should be like" (Berg, 1994, p. 97).

A frequently used version of the miracle question is the following:

Suppose that after our meeting today, you go home, do your things and go to bed. While you are sleeping, a miracle happens and the problem that brought you here is suddenly solved, like magic. The problem is gone. Because you were sleeping, you don't know that a miracle happened, but when you wake up tomorrow morning, you will be different. How will you know a miracle has happened? What will be the first small sign that tells you that the problem is resolved? (Berg & Miller, 1992, p. 359).

Using the process *listen, select, and build*; the therapist carefully *listens* to the client's response to the miracle question and *selects* descriptions that are indicative of the client's goal, desirable future, successes, and resources. The miracle question only initiates the process for clients to envision a desirable future. Paying particular attention and using a client's language and frame of reference, the therapist responds by developing other solution-focused questions or responses that help the client to *build* and expand the solution picture continuously. Note that the focus is on small signs of change. It is also important to invite clients to describe their solution picture in greater detail and to determine how it differs from their current behaviors, feelings, and thinking. The more detailed and refined the description the clearer the indicators of change, which will increase the likelihood that clients will actualize their solution picture, because "what is noticed becomes reality" (Lee et al., 2003, p. 32).

- "Who will be the first person to notice the change? What will they be noticing about you that will tell them that you are different?"
- "How will your spouse, your child (any significant others) know that something is different?" (Relationship question)
- "At what times in your life have you already been doing this?" (Exception question)

The essence of the miracle question is to allow clients to envision a future without problems. As such, social work professionals can be creative in coming up with other versions of future-oriented questions. This can be helpful especially with clients from other cultures or religions who might have their own culture-based interpretation of miracles. Some variations might be:

- "If I were to run into you a year from now, and you had already solved the problem that brought you in today, how would I know that you are different?" What will you be like then?
- If I were to videotape you on a good day, how would you be doing/feeling/thinking differently?
- Five years down the road, what do you want yourself to be like?

Another version is the dream question, which reinforces clients' sense of personal agency, and therefore, is consistent with the goal of empowering clients (Greene, Lee, Mentzer, Pinnell, & Niles, 1998).

Suppose that tonight while you are sleeping you have a dream and in this dream you discover the answers and resources you need to solve the problem that you are concerned about right now. When you wake up tomorrow you may or may not remember your dream but you do notice you are different. As you go about starting your day, what will tell you that you discovered or developed the skills and resources necessary to solve your problem? What will be the first small sign to tell you that you solved your problem?

SCALING QUESTIONS

Scaling questions ask clients to rank their situation and/or goal on a 1-to-10 scale (Berg, 1994). Usually, 1 represents the worst scenario that could possibly be and 10 is the most desirable outcome. People need feedback during the process of change. Therefore, for change to happen, clients will need to be able to self-evaluate their progress and adjust accordingly. Scaling questions provide a simple tool for clients to quantify and evaluate their situation and progress so that they establish clear indicators of progress for themselves (De Jong & Berg, 2013). More importantly, this is a self-anchored scale with no objective criteria. The constructivist characteristic of the scaling question honors clients as the "knowers" and the center of the change process. Scaling can be used to help clients rate their perception of their progress, their motivation for change, confidence to engage in solution-focused behaviors, etc. Scaling questions are also helpful in assisting clients to establish small steps and indicators of change in their solution-building process. Some common examples of scaling questions are:

1. Problem severity or Progress: On a 1-to-10 scale, with 1 being the worst the problem could possibly be and 10 being the most desirable outcome, where would you place yourself on the scale? What would be some small steps that you could take to move from a "4" to a "5"?

2. Motivation: On a 1-to-10 scale with 1 being you have no motivation to work on the problem and 10 being you would do whatever necessary to change the situation, where would you (or your spouse, your boss, your child, etc.) place yourself on the scale? How would your wife (or other significant others) rank your motivation to change on a 1-to-10 scale?
3. Confidence: "On a 1-to-10 scale with 1 being you have no confidence that you can work on the goal and 10 being you have complete confidence that you will continue to work on the goal, where would you place yourself on the scale?" "On a scale of 1 to 10, how confident are you that you could actually do that?" "On a scale of 1 to 10, how confident are you that this will be helpful?"

Similar to using the miracle question in co-constructing change in the treatment process, the therapist carefully *listens* to the client's responses, *selects* and focuses on descriptions that are connected with indications and hints of solutions, and then helps clients to *build* and expand further on desirable change and solutions.

THE CASE OF LINDA

Linda was a 47-year-old woman who suffered chronic back pain after a car accident. The pain also affected her mobility. She was living alone on her own. The therapist (SWR) uses the miracle question to help her envision a more hopeful future.

SWR: Suppose that after our meeting today, you go home, do your things and go to bed. While you are sleeping, a miracle happens and the problem that brought you here is suddenly solved, like magic. The problem is gone. Because you were sleeping, you don't know that a miracle happened, but when you wake up tomorrow morning, you will be different. How will you know a miracle has happened? What will be the first small sign that tells you that the problem is resolved? (*Use the miracle question to engage the client in a solution-building process.*)

Linda: I won't be as cranky as an immovable mountain.

SWR: Instead of being cranky, how do you see yourself being? (*Help client move from a negatively stated description to a positively stated description.*)

Linda: Be a little more upbeat, cheerful, and perky. Get my mind off of it and focus on areas not on the mountain of pain.

SWR: So you want to be more upbeat, cheerful, and perky, and distract yourself from the mountain of pain and do something different? (*Select positive description and use client's language.*)

Linda: So when I am around people they are not affected by it and they are not dragged down by it.

SWR: Let's say you wake up tomorrow after this miracle has happened, what would be the first small thing that you would do and that you are not doing now? (*Build and expand solution-picture.*)

Linda: I don't know. (Pause) Maybe instead of lying in bed staring at the wall, I would get up and open the curtain and turn my computer on, open a book, talk to the cat, anything besides lying in bed and staring at the wall.

SWR: That is what you do now, lie in bed and stare at the wall?

Linda: Yeah.

SWR: When this miracle happens, you would get out of bed, open the curtain, talk to the cat. What else would you do? (*Select and further build solution-picture.*)

Linda: Turn on the computer and get out of bed and do something.

SWR: Do something? (*Invite a more detailed description.*)

Linda: Maybe sweep, dust, or mop.

SWR: Anything else? (*Use presuppositional language that embeds an expectation of change.*)

Linda: Go outside and sit in the sunshine.

SWR: Who in your home would notice the change? Is there somebody else living in your home? (*Relationship question*)

Linda: No, just my cat.

SWR: So what would your cat notice is different about you that you are not doing now? (*Use relationship and difference question to further build the solution-picture further.*)

Linda: I would be up and maybe play with her.

SWR: So you would be up and play with her? How would that make a difference in your day if you were having more fun with your cat? (*Use relationship and difference question to build the solution-picture further.*)

SWR: So who else would notice the change besides your cat? (*Build and expand the solution further using relationship question.*)

Linda: My neighbors, friends.

SWR: What would they notice? (*Invite a more detailed description.*)

Linda: A more positive outlook.

SWR: How would they notice? (*Invite an observable description.*)

Linda: I would respond to them, not giving them dirty looks when it is not their fault. I would run over. I sort of give them a dirty look. It is a major hurdle for me.

SWR: Who would be most affected by this change? (*Invite a description of the expected effect of change.*)

Linda: I suppose that would help other people as well as me.

SWR: How so? (*Invite further elaboration of the effect of change.*)

Linda: You know it would help me because I don't want to be a big drag and that way I won't be dragging people down and it won't be dragging me down because everyone around me is all bummed out, "Oh you poor thing" and all this and I don't want that. I want to get over it. I want to get over it, I want to get over the top of the mountain and go on from here not just hang around the base all the time.

SWR: Tomorrow, meaning the following morning or next morning, you can do this. On a 1-to-10 scale, 10 being likely that you can do this, and 1 being no chance at all, where would you think you are? (*Scaling question regarding feasibility of the change efforts. Good timing to use scaling question because the client has just clearly articulated her desire and motivation for change.*)

Linda: I am at a 6 right now.

SWR: So you are saying getting out of bed in the morning, opening the curtains, turning on the computer, and talking to cat is quite doable because you are at a 6?

Linda: It is doable. I can do that.

SWR: Using the same scale, 10 being you are motivated to do this because it would improve your life, and 1 being you are wishy-washy about it, where would you put yourself on the scale? (*Scaling question regarding motivation of change*)

Linda: I would say an 8, because I don't want to be cranky anymore.

THE CASE OF ELISE

Elise was a 45-year-old Caucasian single mother with three children from 10 to 16 years old. Her husband passed away a year ago and she felt extremely overwhelmed trying to take care of her three children. She became depressed and attempted to commit suicide by overdosing on sleeping pills. She requested that her children be placed in foster homes while she tried to work things out for herself. She received treatment as part of her case plan to reunite with her children. While thinking what might be a helpful goal for her to work on, Elise pondered and struggled. At first, she mentioned developing a better relationship with her children as something she would like to see happen. However, she also felt overwhelmed as a single mother without the support of her husband. The therapist encouraged her to think about what would be personally meaningful and helpful to her at this time. Elise said that she would like to be more productive, although she did not have a clear idea of what a productive life would look like.

Elise: I don't know. I guess I would feel a little different. Maybe just be more productive.

SWR: In what way? (*Invite a more detailed description.*)

Elise: I am not sure. . . I am raising three kids and my husband passed away a year ago, and I am doing nothing myself.

SWR: So life is not cool.

Elise: Yes, not whole lot to do . . . so . . .

SWR: So what would you do differently to be more productive? (*Use client's language; listen and select what is important for the client.*)

Elise: I don't know, but I could be more productive than I am right now. I am reading and doing the seven steps right now. That is about it.

SWR: Do you feel more productive by reading the seven steps and maybe, as you've just said, taking walks? (*Important for the client to evaluate whether she has been more productive*)

Elise: I am thinking about when my kids come home, my relationship with them is going to be more productive. I have to feel like change a little bit. (*Client is still somewhat unclear about what she can do to get herself to be more productive.*)

SWR: Let me ask you this, you wake up tomorrow morning, you do this and whatever it is to make yourself more productive. At the end of the day you look at yourself and said "Man, I am doing well, I really do it now for myself." What do you think that might be? (*This is a different version of the miracle question that helps Elise to be more playful about visioning a future when she is more productive.*)

Elise: Going through the seven steps programs, change my ideas and personality more to be a single woman.

SWR: How will people notice that you stand as a single woman? How will they know that you are different? (*Select what is important to the client and use relationship question to invite elaboration.*)

Elise: The way I am acting.

SWR: What will tell them you changed your attitude and you are different than before?

Elise: Oh, gosh, my weight.

SWR: So your weight will be different. I am curious, pretend that between now and next week, your weight has changed. What will be different for you in your daily life? What will you be doing that you are not doing right now? (*Invite elaboration of the expected effect of change.*)

Elise: If my weight has changed, I will not watch the same TV shows, and I don't want to read the same books, and I don't eat the same junk food.

SWR: You are making big changes in your daily life . . . (*Invite client to self-evaluate the feasibility of the proposed change.*)

Elise: You are right, but this is something that I do want to change.

SWR: What would be the first things that you could possibly do to make this happen? (*Invite client to make a feasible plan.*)

Elise: I've already been walking every day. Maybe I can walk longer and not watch the 8 o'clock show.

SWR: Anything else? (*Presuppositional language that embeds an expectation of change*)

Elise: Don't go to the "snack" aisle when doing my grocery shopping. That'll probably do it.

SWR: So what will you get from the store instead? (*Help client to move from a negatively stated description to a positively stated description.*)

Elise: Maybe more fresh food, like veggies and fish.

SWR: What do you want to see happen when you take walks and eat more fresh food? (*Build and elaborate expected effect of change efforts.*)

Elise: I'll feel as though I'm having more control and being more productive in my life, not just lying around like a couch potato and doing nothing.

SWR: So how confident are you on a 1-to-10 scale that you will be able to take a longer walk and eat more fresh food between now and next time we get together? (*Scaling question regarding confidence about change*)

Elise: Well, I do want to change but you know the temptation. (Pause) Maybe a 3.

SWR: So what are some small things that you can do to move from a "3" to a "4"? (*Use scaling question to establish small steps for Elise to feel more confident.*)

Elise: That's not easy. Maybe talk to my sister so she can remind me once in a while.

SWR: So maybe take it to the next step, and see next week what you do differently as a result of that. I will be very interested to hear what you say next time about how just going through that next step . . . what things you do that make you different and more productive? Is that possible?

Elise: Oh, yes.

SWR: Just pay attention to, "If I would like my life to be better, what small things can I do to make it happen?"

GUIDELINES FOR USING MIRACLE QUESTION AND SCALING QUESTION IN SOCIAL WORK PRACTICE

Knowing *when* to use miracle questions and scaling questions is as important as knowing the questions. Perhaps the most important skill is to pay attention to a client's and our own moment-to-moment communication and responses in the co-constructive therapeutic process. The following are some guidelines for using these questions:

- Use miracle questions to assist clients develop a clear vision of a future without the presenting problem.
 - The miracle question is frequently used during the first session, after the client has shared a description of the problem context and the therapist has an adequate understanding of the problem context.
 - A shift to solution-building by using the miracle question is indicated when client's description of the problem context is getting repetitive and no new information is being offered.
- Scaling questions can be effectively used for the following purposes:
 - Evaluate confidence, ability, and motivation with respect to clients' change efforts.
 - Establish small steps for further change.
 - Help clients gauge their perceptions of problems and goals.
- To fully utilize the constructive effect of scaling questions, use scaling questions when the client has adequately articulated his or her desire for change
 - Avoid inviting clients to scale confidence, ability, motivation early on in the session when there are clear indications that they are not confident or motivated to change; or are hopeless about the problem situation.
- Be patient: Clients do not have the solution in their minds when they seek treatment; it is the responsibility of the therapist to create a safe space for them to slowly "paint" their solution picture.

- Go for details: Assist clients move beyond vague descriptions of the desirable future, to instead describe it in terms of small, observable, specific, or behavioral steps.
- Reinforce client motivation: Assist clients carefully evaluate what may be personally meaningful and useful for them.
- Respect of clients' personal choices and ownership.
- Compliment and acknowledge the client's desire for change.
- Assist clients evaluate feasibility of the solution picture.
- Focus on small steps that can make clients' lives better.
- Assist clients develop clear indicators of change so that they can recognize success.

CONCLUSION

The purpose of the miracle and scaling questions is to help clients establish indicators of wellness and gauge progress toward a desirable future. These self-evaluative questions represent a specific type of conversation in which the therapist talks "with" the client (instead of talking "at" the client) to co-develop new meanings and new realities through a dialogue of "solutions" (Bavelas et al., 2013; De Shazer, 1994; Lee et al., 2003). The challenge for social work practitioners is to work collaboratively with clients so that clients can find a future with which they feel comfortable, as well as feel good about their choices. The therapist cautiously refrains from providing/suggesting any predetermined solutions or desirable future. Through *listen*, *select*, and *build* (Bavelas et al., 2013), the therapist creates a therapeutic context in which both clients and therapists co-construct a solution-building process that is initiated from within and grounded in clients' personal construction of the solution reality and cultural strengths (Lee, 2013). The therapeutic process is collaborative and egalitarian, and one in which the client's self-determination is fully respected (De Jong & Berg, 2013). The ultimate goal of miracle and scaling questions, therefore, is consistent with the goal of empowerment that focuses on increasing clients' personal and interpersonal power so that they can take relevant and

culturally appropriate action to improve their situations (DuBois & Miley, 2013; Gutierrez, DeLois, & GlenMaye, 1995).

84 Improving Classroom Management through Positive Behavior Interventions and Supports

A. M. Thompson

Classrooms are dynamic societies organized for the purpose of teaching and learning. Teachers lead these societies and they organize, deliver, and manage activities to promote student learning. These activities frequently facilitate student interactions that require social, emotional, and cognitive processes (Zins, Payton, Weissberg, & O'Brien, 2007). Conflicts naturally will occur during such interactions. As such, the ability of a teacher to facilitate positive exchanges—with and between students—is related to that teacher's ability to manage conflict and promote positive interactions. When conflicts are not resolved in a constructive and mutually satisfying manner, the results may contribute to an increase in disruptive student behaviors.

Aside from common classroom conflict arising from everyday interactions, many students exhibit above average levels of disruptive behaviors. Studies currently suggest that 20% of students—or three to four students per class—display disruptive behaviors to such a degree that normal functioning is impaired (Brauner & Stephens, 2006; Satcher, 2004). Disruptive behaviors harm everyone in schools, including the students with these behaviors, their

peers, and teachers. Disruptive behaviors are the most common reason students are removed from class—interfering with instruction, exacerbating academic problems, and increasing the likelihood of course failures that lead to dropout (Gresham, Lane, & Lambros, 2000; Nelson, Stage, Duppong-Hurley, Synhorst, & Epstein, 2007; Roderick, 1994). Peers of disruptive students lose about four hours of instruction time per week due to the behaviors—and teachers report disruptive students interfere with teaching and learning on a daily basis (USDOE, 2006; Walker, Ramsey, & Gresham, 2004). Lastly, teachers experience increased stress and burnout from managing disruptive students; a frustration that causes many highly qualified teachers to quit teaching altogether (Brouwers & Tomic, 2000; Hastings & Bham, 2003). A 2005 survey of highly qualified teachers indicated that 53% quit due to disruptive behaviors (USDOE, 2005). Taken together, these issues contribute significantly to an unstable school climate.

To manage the impact of disruptive student behaviors proactively, more than 14,000 schools nationwide have adopted tiered response models known as *positive behavioral interventions and*

supports (PBIS). Though the concept of a tiered response model originated in the late 1950s with the National Institutes of Health (Gordon, 1983), the PBIS model translates the concepts to educational settings. PBIS is explicitly mentioned in the Individual with Disabilities Education Act (IDEA) and No Child Left Behind (NCLB) as a data-driven, school-based model for organizing and distributing a continuum of evidence-based prevention and intervention supports. Although studies indicate that PBIS models are most effective when implemented school-wide, not all school social workers have the luxury of working in settings that use such an approach. Therefore, the purpose of this chapter is to guide school social workers, in consultation with teachers, to implement PBIS strategies at the classroom level. The chapter will first present a brief overview of the research and features of a three-tiered PBIS continuum (e.g., primary, secondary, and tertiary). Next, using each tier as a guide, evidence-based PBIS supports and tools will be described so that school social workers may advise teachers on how to implement the strategies.

OVERVIEW OF POSITIVE BEHAVIORAL INTERVENTIONS AND SUPPORTS IN THE CLASSROOM

On balance, randomized studies indicate that tiered response models have small but significant effects on student- and school-related outcomes. For example, randomized studies suggest tiered response models are associated with improved school safety ($ES = 0.23$), academic achievement ($ES = 0.24 - 0.38$), positive student behaviors ($ES = 0.30$), school climate ($ES = 0.29$), and staff collaboration ($ES = 0.26$) compared to control settings without PBIS (Bradshaw, Reinke, Brown, Bevans, & Leaf, 2008; Horner et al., 2009). Though a large literature details the implementation of a PBIS model (c.f., Lane, Menzies, Bruhn, & Crnabori, 2010; G. Sugai & Horner, 2009), a properly implemented model starts with universal social-emotional and behavioral screening for all students. Based upon these data, primary, secondary, and tertiary supports (i.e., programs and practices) are selected and organized by application intensity.

Primary supports are prevention efforts applied to *all students* to address universal risk factors identified from the screening. For example, packaged curricula like *Second Step* and

Making Choices are research-based programs that address known risk factors such as physical and relational aggression, overt and covert antisocial behavior, and peer rejection (Fraser, Thompson, Day, & Macy, in press; Grossman et al., 1997). Other primary classroom strategies include developing a mission statement, a set of expectations, and behavioral definitions to make the expectations operational; teaching the expectations on a daily basis; establishing a continuum of consequences; and tools to evaluate universal efforts (Sugai & Horner, 2006).

Secondary supports are concentrated and provided to *small groups* of about 20% of students with elevated levels of need. Secondary supports can be divided into selective and indicated prevention. Selective prevention efforts, such as *Check in Check Out* (Cheney et al., 2009) or the *Behavior Education Program* (Crone, Hawken, & Horner, 2010) are delivered to subgroups of students exposed to known risk factors (i.e., free and reduced lunch programs). Indicated strategies, such as the *Self-Monitoring Training and Regulation Strategy* (Thompson, 2012; Thompson & Webber, 2010) are more intensive and apply to students with early signs and symptoms of an oncoming disorder.

Tertiary supports are individualized and provided to *particular students* with an identified condition. In general, tertiary supports follow a referral, a thorough assessment conducted by a multidisciplinary team, and a determination of eligibility—based upon the assessment data—for entitlement services (i.e., special education). Using the data, a multidisciplinary team devises an education plan outlining individualized services (i.e., specific accommodations), performance goals and objectives (i.e., expected benchmarks and levels of achievement), and the defined roles of personnel who provide each service. It is at the tertiary level that “prevention” effectively becomes “intervention”, though tertiary services are intended to prevent further decline of the identified condition. Table 84.1 details the benefits and costs of each level of the three-tiered PBIS model.

APPLYING POSITIVE BEHAVIORAL INTERVENTIONS AND SUPPORTS IN THE CLASSROOM

School social workers can consult with teachers to assess existing primary classroom supports

TABLE 84.1 Benefits and Drawbacks of Each Level of the Positive Behavioral Interventions and Supports Model

PBS Level	% *	Benefits	Costs
Primary (universal)	≈80%	Easy application No iatrogenic effects No contagion effects Focus on context Effective for low at-risk	Impersonal Not individualized May be expensive Potentially wasteful Low effects for high risk
Secondary (targeted: selective & indicated)	≈15%	Accurate with assessment Moderately individualized Efficient dissemination Effective for moderate at-risk	No services just above cut Risk of iatrogenic effects Risk of contagion effects Less focus on context
Tertiary (clinical)	≈5%	Individualized Multi-systemic approach Multidisciplinary approach Effective for high at-risk	Resource intensive No focus on context Risk of iatrogenic effects Risk of labeling effects

* Percentages will vary based upon local norms and expectations.

and identify those that are absent. Undoubtedly, some students will need additional supports, and school social workers can assist teachers to identify and match students with the supports that will meet their needs. Lastly, should some students be unresponsive to primary and secondary efforts, school social workers can assist teachers to implement tertiary level supports—though these supports will involve a team-based approach to meet the student’s needs.

Primary supports. Primary supports broadly address basic human needs (i.e., safety) and narrow in scope to define behaviors that maintain those needs. The process should start by identifying existing risk factors predictive of school failure (e.g., emotional lability, conduct or attention problems, early aggression). Such information can inform early intervention. Other effective primary practices begin with (1) a structured mission statement; (2) clearly worded expectations; (3) explicit rules for each procedure; (4) steps to teach, review, and integrate rules; (5) a range of positive and negative consequences; and (6) an evaluation plan.

Structured mission statement. A classroom mission statement should serve as the underlying rationale for structure. An effective mission statement is clear and broadly enumerates student and teacher duties to maintain safety (Sugai & Horner, 2006). For example:

“In Mr. Thompson’s classroom, students will actively pursue the knowledge and strategies to successfully

achieve desired goals. To accomplish this end, all students have a responsibility to arrive at class prepared to learn, contribute to a safe learning environment, set reasonable goals for themselves, and make socially appropriate choices to achieve those goals. To facilitate student success, Mr. Thompson will prepare activities and lessons that academically challenge all students, listen to the ideas that students have, and help students achieve their goals.”

Clearly worded expectations. Expectations hone the mission statement. Expectations are limited in number (i.e., three to five) and positively describe the behaviors reflected in the mission statement. For example, “Keep Body Parts to Self” suggests an expected behavior. If school-wide rules exist, classroom rules should align with these to communicate seamless expectations.

Explicit rules for procedures. Shown in Table 84.2, rules should operationalize the broad expectations for each procedure. For example, describing the behaviors of a person following the expectation “Being Considerate of Others” for the classroom routine of “Getting Help,” a teacher might expect a student would (a) remain seated, (b) raise his or her hand, and (c) speak when called upon. Procedures are revisited periodically, particularly when new routines are introduced.

Teach, review, and integrate rules. Expectations and rules must be taught on a daily basis. School social workers can assist teachers to translate classroom procedures into lessons that

TABLE 84.2 Translating School-wide Rules into Expected Behaviors for Classroom Routines

School-Wide Expectations Classroom Routines	Keep Body Parts to Self	Complete Assigned Work	Follow Teacher Directions	Be in Assigned Area at All Times	Be Considerate of Others
Entering/leaving room					
Being prepared					
Getting help					
Getting supplies					
Sharpening a pencil					
Whole-group instruction					
Small-group instruction					
Independent seatwork					
Cooperative learning					
Completing work early					

(a) define the skill (i.e., the behavioral rule being taught, the underlying logic, and the corresponding classroom expectation), (b) use examples (i.e., of both desired behaviors *and* undesirable behaviors), (c) model the behavior, (d) include activities to engage students in using the skill, and (e) prompt, remind, and reinforce students to use the skill (Langland, Lewis-Palmer, & Sugai, 1998). School social workers might prepare and teach these lessons, but evidence suggests the concepts are most effective when teachers actually teach, integrate, and reinforce the skills throughout the instructional day (Durlak, Weissberg, Dymnicki, Taylor, & Schellinger, 2011). In addition to direct instruction in classroom expectations, teachers can apply instruction from many packaged evidence-based programs, such as *Making Choices*, to facilitate increased social and emotional awareness among students (Fraser et al., in press).

Positive and negative consequences. Behaviors are shaped by consistent application of effective consequences. Consequences follow and shape a behavior. A positive consequence suggests a behavior is desirable and aims to increase the occurrence of the behavior; a negative consequence suggests a behavior is undesirable and aims to extinguish the behavior. Most importantly, effective consequences (a) never humiliate, (b) link the behavior and consequence, (c) elevate teaching over rewarding or punishing, and (d) rely on a continuum (Oliver, Wehby, &

Reschly, 2011). Table 84.3 depicts a range of positive and negative consequences entailing small and everyday, moderate and frequent, and large and infrequent consequences.

Positive consequences for compliance. Small and everyday positive consequences are brief, free, simple, and offered at a ratio of 4 positive reinforcements to 1 negative reprimand (Reinke, Lewis-Palmer, & Martin, 2007). Moderate and frequent positive consequences are random and connected to specific behavioral expectations (i.e., *turning in all assignments for 1 week before. . .*). Large and infrequent positive consequences are accompanied by prompts and reminders and may be contingent upon individual and group level contingencies (i.e., *all individual work for all students is to be completed before. . .*; Oliver et al., 2011). When shaping positive consequences, look a student in the eye and pair the positive response with a smile and an explanation of *why* you are recognizing the behavior (Goldstein & Brooks, 2007).

Negative consequences for noncompliance. Negative consequences should teach and preserve a student's autonomy and self-worth—imperative when assisting students to integrate positive social behaviors. Because not all students are the same or have the same needs, a school social worker may advise teachers to tailor consequences dependent upon frequency, intent, and harm caused by the behavior. Equity (i.e., what students need) rather than fairness (i.e.,

TABLE 84.3 Example Range of Positive and Negative Consequences

	Small & Everyday	Moderate & Frequent	Large & Infrequent
Positive Consequences	Social praise (“good job”)	Weekly positive home call	Large group project
	Smile, high five, Handshake	Lunch with teacher/principal	Community field trip
	Stickers, stamps, smiley face	Work “escape” ticket	Cooking in the classroom
	Positive home note	Student seat selection	Class sporting event (kickball)
	Select music for seatwork	Computer time	Office helper or hat day
	Free drinking fountain pass	“Buddy” class recess	Class movie day
	Negative Consequences	Non-verbal (proximity, glance)	Instructional modification
Class pre-correction		Seat modification	Reparation
Individual pre-correction		“Buddy” class timeout	Loss of privilege
Individual correction		Student & principal conference	Loss of recess
In-class conference		Parent contact	Working lunch detention
After-class conference		Student & parent conference	Working after school detention

everyone gets the same) is paramount to meet a variety of student needs—and teachers need to be comfortable in dealing out consequences to students equitably (Mendler, 2005). Lastly, if a teacher uses a stepwise sequence of negative consequences, students must be aware the teacher has a duty to implement a “*by-pass*” clause for any acts that threaten the safety of others. When delivering negative consequences, maintain (a) proximity and eye contact, (b) keep a calm voice and remain in control, and (c) teach the expected behavior (Goldstein & Brooks, 2007).

Monitoring primary supports. Efficient means of evaluating student understanding of primary level supports is as simple as providing students with quizzes covering expectations following direct instruction. Another way of monitoring the transfer of primary expectations is to record common behavior problems. Teachers may also use a self-monitoring strategy to count the number of positive reinforcements provided to students to be sure they are acknowledging more positives than negatives and that they are engaging and calling upon a diverse group of students. Another evidence-based strategy for assessing students’ use of behavioral expectations is

to play the *Good Behavior Game*, where points are assigned to student groups when members are observed meeting expectations (Barrish, Saunders, & Wolf, 1969).

Primary support tools. There are many tools available to facilitate universal student screening—and the selection of a screener should be based upon contextual factors. However, the completion of a universal student screening, a brief classroom management self-assessment, and peer classroom observations will assist school social workers and teachers in planning and prioritizing primary supports. Social workers can visit <http://www.pbis.org/> to find these free tools.

- Universal Screening (e.g., *Strengths and Difficulties Questionnaire*; Goodman, 1997) <http://www.sdqinfo.com/>
- Classroom Management Self-Assessment http://www.pbis.org/pbis_resource_detail_page.aspx?Type=4&PBIS_ResourceID=174
- Classroom Observation Tool http://www.pbis.org/evaluation/evaluation_tools.aspx
- Lesson plans for teaching expectations <http://www.pbis.org/training/student.aspx>

- Learning Inventories and Multiple Intelligences Tests <http://www.businessballs.com/howardgardnermultipleintelligences.htm#multiple>
- Good Behavior Game Manual <http://prevention.mt.gov/suicideprevention/goodbehaviorgamemanual.pdf>

Secondary classroom supports. Prior to implementing secondary supports, teachers and school practitioners should assess the fidelity of all primary-level efforts. If primary supports are not faithfully implemented, social workers and teachers should focus on what can be done to implement primary supports fully. When a self-assessment and a classroom management observation reveal that all primary-level classroom strategies are in place and practiced faithfully, but a few students still exhibit challenging behaviors, those students may require secondary supports. Secondary supports generally involve direct instruction with small student groups with similar deficits. The supports should be closely monitored using data to gauge student responsiveness.

The Technical Assistance Center at pbis.org lists the following features of secondary supports: (a) continuous availability; (b) low teacher burden; (c) consistency with primary supports; (d) faculty awareness of secondary efforts; (e) utilization of functional assessment and data to monitor student progress; (f) adequate resources; and (g) students elect to participate (http://www.pbis.org/school/secondary_level/faqs.aspx). Examples of secondary interventions containing the above features include the *Check in/Check out* strategy (CICO), *The Behavior Education Program* (BEP; Crone et al., 2010), or the *Self-monitoring Training and Regulation Strategy* (STARS; Thompson, 2012).

Secondary support tools. Per the Office of Special Education Programs (OSEP) guidelines, most secondary supports will involve assistance from school-based practitioners and should begin with a functional behavioral assessment (FBA). An FBA refers to a range of procedures to assess contextual factors associated with a behavior. An FBA should (a) identify and describe target behaviors, (b) prioritize behaviors based upon characteristics (e.g., frequency, duration, and intensity), (c) identify contextual variables associated with the behavior, (d) develop hypotheses describing the context and the function of the behavior, and (d) result in a suggested

contextual intervention (Goldstein & Brooks, 2007). Indirect and direct FBA can be conducted using the following tools:

- Functional Assessment Checklist for Teachers (FACTS-A) http://www.pbis.org/common/pbisresources/tools/EfficientFBA_FACTS.pdf
- Guess and Check: Teacher Guided FBA http://www.pbis.org/common/pbisresources/tools/Guess_and_Check_version2.pdf
- A direct FBA completed by an educational paraprofessional will supplement a teacher's indirect FBA and across multiple contexts (i.e., playground, cafeteria, classroom, engaged in multiple academic pursuits) using observations, interviews, and behavior protocols. For forms and procedures to complete a direct FBA, visit the OSEP website at http://www.pbis.org/common/pbisresources/publications/PracticalFBA_TrainingManual.pdf

Once FBA data are available, the teacher and paraprofessional should consider relevant accommodations (e.g., academic, social, or environmental adjustments) to intervene in the behaviors. A child who continues to have difficulty—despite such accommodations—may require more intensive strategies such as the CICO, the BEP (Crone et al., 2010), or the STARS program (Thompson & Webber, 2010). The CICO and BEP programs use a daily teacher report card to monitor student behaviors. The STARS program includes elements of the BEP and CICO, but STARS includes direct instructional strategies that teach students a problem solving and decision making model. Following student training, both the student and teacher monitor the student's performance on behavioral goals generated by the student. Prior research and meta-analyses suggest self-monitoring improves classroom behavioral performance for students with a range of internalizing and externalizing behaviors. More specifically, randomized studies of STARS suggest that self-monitoring is associated with teacher-rated improvements in classroom behavior and displays of social competence (Thompson, 2012). A webinar describing the implementation of STARS is available (<https://umconnect.umn.edu/p26217564/>) to describe the implementation of STARS.

Figure 84.1 outlines the basic steps of training students in self-monitoring. Studies suggest that reliability of student observations will

increase if they are trained in self-monitoring (Zimmerman, 1989). Figure 84.2 presents a sample behavioral report card that a student and teacher would use to monitor the student's performance on classroom rules. Using a report similar to Figure 84.1, a student and teacher would monitor the student's behavioral performance on the same goals. After a specified period (e.g., one week), the student and a school practitioner would calculate the daily percentages (dividing the number of "yes" marks circled by the total number [13] of "yes" marks possible for each expectation). The student can also calculate the total performance percentage across all five expectations (summing all "yes" marks circled and dividing the sum by the total [65] possible

across all expectations). It is helpful to visualize the performance over time by graphing those percentages for both the teacher and student data. After the graphs are prepared, the student meets with the teacher and the practitioner to examine the graphs and identify differences between the perspectives. Areas of discrepancy are noted, and new goals can be written to increase the rate of agreement between the student and teacher from the current rate (i.e., 67%) to a level just above current performance (i.e., 70%). Studies suggest STARS is feasible, has low teacher burden, can be implemented with 20% of students at risk, and is perceived by students as socially acceptable and autonomy supportive (Thompson, 2012; Thompson & Webber, 2010).

Purpose: Provide initial training for students to self-monitor behavior goals.

1. Identify and prioritize difficult behaviors
 - a. Functional Behavior Analysis (FBA)
 - i. Indirect Teacher FBA
 - ii. Direct School Practitioner FBA
2. Operationalize behaviors with a definition the student can understand and teach expected behaviors
 - a. Example: "*Being Considerate of Others*" for the classroom routine of "*Getting Help*," a student would: (1) remain Seated, (2) raise your right or left hand, and (3) request help when the teacher calls your name.
 - b. Teach expected behaviors for all procedures
 - c. Check for understanding with student by asking for specific behavior examples
3. Teach Students to Observe Behavioral Performance using a Recording Tool
 - a. Use FBA information to determine
 - i. Priority of goals: intensity, duration, and frequency of behaviors
 - ii. Interval schedule: how often the student should record self-monitoring data
 - b. Define goal statement based upon FBA
 - i. Goals are stated using positive language and is observable, measureable, and realistic
 - ii. Goal specific to problem behavior and may suggest a replacement behavior
 1. Example: "I will increase my 'Following Directions' percentage from 75% to 79% by complying with my teacher's request within 30 seconds after I am given directions from my teacher."
 - iii. Start with few goals; monitor progress and adjust number of goals as needed
 - c. Address strategies to complete record performance
 - i. Strategies for reliable ratings
 1. Watch with timer
 - d. Practice
 - i. Use examples from FBA and ask students to rate themselves
 - ii. Use an internet video and ask students to observe and rate behavior

Figure 84.1 Student self-monitoring.

4. Trial Run
 - a. Observe and rate a short class session with both observer and student completing recordings
 - b. Compare observer ratings with student ratings
 - c. Practice determining goals and completing contract
 - d. Take advantage of this opportune time to talk about the definition of classroom expectations
 - i. The definition of acceptable behavior is determined by the teacher
 - ii. Ask the student to role play the "teacher" and review their data
5. Teach students to calculate percentages and graph percentages. Repeat procedure.
6. Identify and prioritize difficult behaviors
 - a. Functional Behavior Analysis (FBA)
 - i. Indirect Teacher FBA
 - ii. Direct School Practitioner FBA
7. Operationalize behaviors with a definition the student can understand and teach expected behaviors
 - a. Example: "*Being Considerate of Others*" for the classroom routine of "*Getting Help*," a student would: (1) remain Seated, (2) raise your right or left hand, and (3) request help when the teacher calls your name.
 - b. Teach expected behaviors for all procedures
 - c. Check for understanding with student by asking for specific behavior examples
8. Teach Students to Observe Behavioral Performance using a Recording Tool
 - a. Use FBA information to determine
 - i. Priority of goals: intensity, duration, and frequency of behaviors
 - ii. Interval schedule: how often the student should record self-monitoring data
 - b. Define goal statement based upon FBA
 - i. Goals are stated using positive language and is observable, measurable, and realistic
 - ii. Goal specific to problem behavior and may suggest a replacement behavior
 1. Example: "I will increase my 'Following Directions' percentage from 75% to 79% by complying with my teacher's request within 30 seconds after I am given directions from my teacher."
 - iii. Start with few goals; monitor progress and adjust number of goals as needed
 - c. Address strategies to complete record performance
 - i. Strategies for reliable ratings
 1. Watch with timer
 - d. Practice
 - i. Use examples from FBA and ask students to rate themselves
 - ii. Use an internet video and ask students to observe and rate behavior
9. Trial Run
 - a. Observe and rate a short class session with both observer and student completing recordings
 - b. Compare observer ratings with student ratings
 - c. Practice determining goals and completing contract
 - d. Take advantage of this opportune time to talk about the definition of classroom expectations
 - i. The definition of acceptable behavior is determined by the teacher
 - ii. Ask the student to role play the "teacher" and review their data
10. Teach students to calculate percentages and graph percentages. Repeat procedure.

Tertiary Classroom Supports. Tertiary classroom supports work best when both primary and secondary strategies are practiced with fidelity (Crone et al., 2010). Tertiary level supports are individualized, intensive, involve comprehensive assessment, and require a team collaborative approach involving the student’s family. The purpose of a tertiary support plan is

to provide a system of care approach to bridge existing school-based, community-based, and family supports around the child in a seamless intervention plan (Epstein & Sanders, 2002).

The Technical Assistance Center at pbis.org lists the following features of tertiary supports: (a) multidisciplinary team approach; (b) use of comprehensive and multi-domain

assessment; (c) examination of contextual triggers; (d) results in an individualized plan with goals and objectives; (e) involves direct skills instruction; and (e) includes ongoing data to monitor a student's progress (http://www.pbis.org/school/tertiary_level/faqs.aspx). The difference between secondary and tertiary levels of support is defined by the individualized nature of the plan. For students with multiple problem behaviors, an FBA should prioritize complex and competing behaviors according to the frequency, intensity, and duration of such behaviors (Goldstein & Brooks, 2007). An individualized plan should assess and meet the needs of the student across multiple domains, provide classroom modifications, and support a child's family through a wraparound process that identifies existing community-based services.

Tertiary support tools. Tertiary supports include a team approach to examine all data associated with all secondary efforts (i.e., FBA, STARS). Due to their individualized nature, tertiary supports will likely involve "wrap-around" services (Eber, Sugai, Smith, & Scott, 2002). A wrap-around plan should assess strengths and areas of need, and pair those needs with external community resources. A tertiary plan should address problematic behaviors using a behavior intervention plan (BIP) that is based upon existing FBA and classroom performance data. If some of the problematic behaviors include aggression, the BIP should address emergency procedures for managing such behaviors. For more tertiary level supports, including documents to guide the wrap-around process, visit http://www.pbis.org/evaluation/evaluation_tools.aspx to locate the *Educational Information Assessment Tool*, the *Home, School, Community Tool*, the *Student Disposition Tool*, and the *Wraparound Integrity Tool*.

CONCLUSION

The PBIS approach to classroom management provides accessible solutions to the daily challenges faced in schools. When we implement primary classroom strategies with fidelity, studies suggest the majority of students will succeed and fewer students will require more intensive secondary strategies, such as the STARS. However, because significant but modest reductions in disruptive behaviors have been observed for universal ($ES = .21$) and selective programs ($ES = .29$),

linking these supports in a tiered response model will improve student outcomes and, theoretically, reduce reliance upon intensive and individualized supports (Wilson & Lipsey, 2007). For the few students who may require intensive supports, a team-based effort will provide tertiary support services in a process that also identifies existing community supports to supplement existing school-based supports and assist a student and his or her family.

Though studies advise PBIS is best implemented at the school level, the chapter describes how PBIS would be implemented at the classroom level. That said, these efforts will be most successful when conducted in schools with administrative support. In addition, when implementing the model at the school level with district financial support, with full principal and staff buy-in, and community agency collaboration for high-risk students and families, research suggests that five to seven years are required to fully implement a school-wide PBIS model (Sugai & Horner, 2009).

Just as no single intervention works for all children in all settings, school social workers should be aware that the percentages of students who may fall within each PBIS level of support will vary depending upon local classroom, school, and community norms. For practitioners working with students who present complex and difficult behaviors, using the FBA process to prioritize students and difficult behaviors (i.e., based upon behavioral frequency, duration, and intensity) will untangle confounds. Indeed, the research underlying the use of FBA and self-monitoring data is the most widely evaluated and reported data elements of the multi-tiered PBIS model, although these studies largely consist of single subject designs due to the individualized nature of the interventions (Thompson, 2010).

It should also be noted that PBIS is a framework for data driven interventions—that is, the model is meant to be a data-driven context to structure and organize best practices and programs. School social workers should encourage school leaders to develop and maintain systems for collecting and reviewing data. In addition, the types of data used within a PBIS model should include early indicators of problems (i.e., early aggression, peer rejection, student and teacher relations) as well as ongoing mechanisms needed to monitor the progress of selected PBIS supports (i.e., office

referrals, grades). A common mistake made by school practitioners is to rely on ongoing indicators (office referrals, grades, attendance), which only describe the magnitude of existing problems rather than serve as early antecedents of preventable conditions (Bowen, Thompson, & Powers, 2012). It may be argued that significant policy reforms designed to improve academic performance have failed, in part, because schools focus only on the academic progress as measured by standardized tests. A growing body of research continues to suggest schools must do more to prepare students to be contributing members of our society.

85 Best Practices in Parenting Techniques

Carolyn Hilarski

Parenting success is related to parenting competence (Silver, Heneghan, Bauman, & Stein, 2006). “OK . . . but, what is competent parenting? What must I actually *do* to be an effective and skillful parent?” To answer these questions, the following discussion will take an ecological approach and define parenting as *interactions*

with a child in a milieu that embodies respect, safety, and genuineness, while attending to the child’s temperament and level of attachment. Using these parameters, this chapter will describe the current empirical understanding of successful parenting methods that attempt to modify both caregiver and child nonhelpful

behaviors, with the intent of increasing homeostasis in families where imbalance lives. The outcome of this caregiving paradigm is associated with child academic success (Reynolds & Ou, 2004), moral development, emotional regulation (e.g., less anxious or depressed), safe behavior (e.g., child will be more likely to wear a seatbelt or helmet), and social proficiency (Davidov & Grusec, 2006) leading to a reasonable conclusion that competent parenting practices are essential for optimal child outcomes.

PARENT EDUCATION

Parent training appears to be quite effective and available in a plethora of instructional styles and program components (Long, 2007). The key benefits are that caregivers are exposed to a variety of helpful parent/child interactive techniques based on the normal parameters of child development. Educating caregivers about typical child development can be helpful in reducing punitive disciplining methods. Understanding the cognitive and emotional abilities of the child can assist the parent to reframe behaviors that previously might have been perceived as, for example, "spiteful." In the final analysis, parenting practices are most often influenced by perceptions regarding the caregiver/child interactions.

The timing of parent education is critical. It is suggested to be particularly beneficial for caregivers of younger children for several reasons. First, the child's undesirable behaviors tend to be less ingrained. Second, parental interventions are usually more effective because preschoolers tend to lack strong peer influences. Third, a younger child is generally more accepting of changes in behavioral consequences. Finally, young children, even aggressive ones, tend to continue to show affection with their caregivers.

Classes structured in a group format offer parents the added benefit of socialization, while sharing frustrations and childrearing strategies, in addition to increasing supportive networks. However, parenting programs, taken as a whole, are inclined to focus on discipline and behavioral strategies to help parents modify youth behavior¹ and, while successful, the process tends to overlook the caregiver/child relationship influenced by the child's temperament and type of attachment. In families where children have consistent behavioral issues, the

caregiver/child relationship may be stressed on some level and discipline techniques alone may not modify the circumstance (Davidov & Grusec, 2006).

TEMPERAMENT

Caregivers will often describe their infants as either *easy* (e.g., generally cheerful, adaptable, or unproblematic), *difficult* (e.g., often irritable, emotional, and/or highly resistant to change), or *slow-to-warm* (e.g., denoting a relatively inactive or indifferent child who may show moderate resistance to new situations). And these descriptors appear to remain relatively stable, with some moderation owing to the goodness or poorness of fit between the child and his or her environment (Sigelman & Rider, 2006). Families often need help with understanding that their child's temperament can influence the child's level of attachment with the primary caregiver, which can then impact parent disciplining methods (Stovall-McClough & Dozier, 2004). The following case is meant to illustrate this development.

Michael

Both his preschool teachers and parents report that Michael, a healthy Caucasian 4.5-year-old male, is disruptive and antagonistic toward other children at school and in his neighborhood. Michael's parents, Ron and Gail, are expecting a new baby and fearful of how Michael will respond to such a colossal change in their family system. Michael's mother relates that he does not handle change optimistically and will often engage in sullen or tantrum-type behaviors when faced with novel situations. Moreover, they are worried that school peers and teachers will label him a bully and/or troublemaker.

According to his mom, "Michael was *born* irritating people around him." While describing the delivery, Gail recounted, "Once I woke from the anesthesia, I was so excited that my child was born. I asked to see my baby. The nurse replied, 'My gosh, can't you hear him? He's been screaming since he entered the world.'" She went on to say, "Michael is indeed a puzzle and very different from my husband and me. Because I don't understand why he insists on fighting or stubbornly disobeying², I sometimes find it difficult

to sit and play with him and occasionally use a harsh tone, which makes me feel guilty.”

Children with warm, dependent relations in early life are more likely to comply with parental directives. Indeed, the effectiveness of the child’s socialization attempts (e.g., aggressive or nonaggressive peer interactions) are associated with the parent-child relationship and a caregivers’ style of interaction that is *responsive* (e.g., taking the child’s perspective³), *supportive* (e.g., praising and showing affection), *attentive* (e.g., listening and encouraging conversation), *guiding* (e.g., providing information), and *receptive* (e.g., inviting emotional expression) (Grusec & Ungerer, 2003). These parenting practices may provide an environment where the child might develop emotional coping and regulation strategies associated with higher self-esteem and positive life outcomes (see Table 85.1). Keeping this information in mind, what about the following case?

Chevaun

Sixteen-year-old Chevaun is a junior in high school. She lives, in a modest home, with her mother (Mary, a seamstress) and stepfather (George, a factory worker). Her mother remarried when Chevaun was 7 years old, shortly after ending a stormy and abusive marriage with Chevaun’s father.

Several years ago, according to her mom, “Chevaun changed from a brooding and difficult child to a more cheerful young woman.” It was during this time that she asked her parents if she could date. She was given permission, however, with many restrictions on where, when, and with whom she could spend her time. She accepted her parent’s rules until about six months ago. Since then, her relationship with her parents is reportedly, “Almost unbearable. She consistently violates her curfew and arrives home smelling like alcohol or worse, drunk. Her grades are suffering and she did not make the cheerleading squad this year.”

Chevaun and her stepfather allegedly rarely speak and the tension is obvious when they occupy the same space. During a recent home visit, Chevaun seemed quite agitated and asserted that, “He blames me for everything. He says that I’m the reason the family so upset. That just isn’t true! I know he hates me because I’m not his daughter and I won’t obey him anymore. He is so

mean. That is why I sometimes drink and don’t want to come home.”

PARENTING STYLE

Parenting styles are categorized as authoritative, authoritarian, and permissive. These classifications are based on three dimensions: parental control and demands, parental warmth and nurturance, and clarity of parental communication. Both authoritarian and authoritative caregiver styles apply high levels of control in addition to demanding much from their children. However, the authoritarian style often does not include warmth, responsiveness, and age appropriate levels of control; demanding compliance with no excuses (Baumrind, 1967). In contrast, caregivers with an authoritative style of parenting tend to have close emotional relationships with their children, make reasonable age appropriate demands that they enforce, explain reasons for their actions, and request and listen to their child’s points of view (see Table 85.1). Childhood exposure to authoritative parenting is linked to the child’s perceived competence (Steinberg & Blatt-Eisengart, 2006). Yet, parenting practices, born from the caregiver’s style, remain an interactive process and may be strongly influenced by the child’s temperament (Miller-Lewis et al., 2006).

Michael Revisited

Michael’s mom went on to say that, “Michael is very high maintenance! Ron and I have tried everything to make him listen and behave. We just do not know how to handle his outbursts. Sometimes I get so frustrated that I spank him to settle him down.”⁴

During a home visit, Michael was observed interacting with a cousin who was spending the day. He consistently taunted the child; hitting him with a plastic bat, pushing, and taking toys and even his lunch. Michael’s mother ignored the behavior for some time then asked Michael to “stop being so rowdy.” He did not comply. After a few more minutes, his mother spanked him with her hand on his bottom and sent him to his room. He reappeared after a few minutes, at first playing quietly and then beginning the hitting behavior again.

TABLE 85.1 Helpful Parenting

Helpful Parenting Behaviors	Consequences	Parent Education
Listen to your child	Shows respect and caring	Mindfulness: here and now presence that is nonjudgmental http://www.sagepub.com/upm-data/15640_E5.pdf thinking skills
Comfort your child	Children are more likely to feel cared for by a parent who is interested in their emotional responses. Increases positive mental representations and attachment (Nelson & Panksepp, 1998)	Mindfulness: understand the thoughts and motives of your child: “What urges my child to behave in this way?”
Provide structure	Children feel safe knowing there is order to their lives	Structures provide necessary limits, yet, need to be flexible (Popkin, 2007)
Use praise	Your words of praise for the smallest accomplishments bolster the child’s self-esteem	Praise, criticism, and self-esteem Helpful comments: “I need your help”; “Let’s negotiate”; “I need a time-out” (Parent Talk) (Moorman, 1998)
Specify desired behavior/ Communicate	Children feel comfortable knowing the parents’ consistent expectations	Community Education Program (COPE) Designed for use with parents of children ages 3–8 years http://www.fsatoronto.com/programs/counselling/parenting.html http://www.sagepub.com/upm-data/15637_E2.pdf 1. Parents learn give helpful directions, to praise when desired behaviors are presented, and to use timeout for undesired behaviors 2. Parents learn to give reasons for requests and describe the consequences for noncompliance Red Light (undesired behavior) and Green Light (desired behavior) (Moorman, 1998) Parent states circumstance and child decides what to do (Moorman, 1998)
Be consistent	Inconsistent responses to a child’s behavior leave the child confused and cautious regarding how to behave	Establish house rules and boundaries along with consequences (Hieneman, Childs, & Sergay, 2006) Proactive parenting: <i>anticipate</i> an event or interaction and pre-select behavior consistent with family rules (e.g., bring toys or snacks to divert the child’s attention; brainstorm positive responses to the child when feeling angry or frustrated).
Spend play, shared work, and/or reading time with your child	<ul style="list-style-type: none"> • These behaviors encourage caregiver/child attachment. • Play is the principal method by which young children learn and develop. • Sharing chores helps the child to feel needed and embraced in the family system. • Parent/child reading can calm the child and promote bonding. 	PCIT (Parent Child Interaction Therapy) http://pcit.php .ufl.edu/ Play Techniques Designed for use with parents of children age 2–5 years (Hembree-Kigin & McNeil, 1995)
Show affection	Sensitive and nurturing interactions and touch increase oxytocin levels in caregiver and child, which influences attachment and temperament of child.	Intimacy and Feeling (Parent Talk) (see, Moorman, 1998) Use such phrases as, “I love you”; “I see that . . .,” “I am sorry”; “No” Unhelpful phrases: “I was teasing”; “Act your age”; “What I say goes.”

The literature suggests that parents may alter their discipline practices in response to the perceived characteristics⁵ of their children (Lindsey, Caldera, & Colwell, 2005). Indeed, it seems reasonable that parents might experience a certain level of stress when rearing children described as “difficult and/or different” and that these parents might change their parenting strategies (e.g., corporal punishment) in the face of such circumstances. However, corporal punishment, for example, does not teach children self-control (e.g., delayed gratification or compliance for social rewards). Rather, young children may obey out of fear and older children may choose to act out (e.g., delinquent behavior) or act in (e.g., depression). Further, this particular disciplining method does not generalize to other undesired behaviors. An alternative option might be redirecting the young child to a more satisfactory activity. For example, if finger painting the dining room table is not allowed, offer the child a large paper bag to paint on.

In the meantime, Michael’s parents are in need of help to reduce their distress about their family’s future. The following plan was developed as a negotiable strategy for work with family members.

TREATMENT PLAN FOR MICHAEL AND HIS FAMILY

Presenting issue: Michael’s aggressive behaviors (e.g., hitting, pushing, and taking toys)

Long-term goals: Decrease Michael’s aggressive behaviors by 50% (4 weeks)

Short-term objectives:

1. Parents and teachers will develop a systematic plan for discipline (Long, 2007).

1A. Intervention: Parents will agree to read, at a minimum, one section from each item in the following list of parenting education resources specifically focusing on strategies for positive discipline.⁶

<http://www.lifematters.com/step.asp> (STEP Program)

<http://www.loveandlogic.com/> (Love and Logic Program)

<http://www.chickmoorman.com/PTsystem.html> (Parent Talk)

1B. Intervention: Parents will agree to practice,⁷ one time per day, the following

<p><i>Controlled Choices</i> Helpful: ‘Would you prefer to take a walk or read a book this morning?’</p> <p>Not helpful: What shall we do this morning?</p> <hr/> <p><i>I-Statements:</i> ‘I feel sad when I am hit with the plastic bat because it hurts’</p> <p>_____</p> <p><i>Directing Behavior</i> Not Helpful: ‘Stop being so rowdy’</p> <p>Helpful: ‘Those who can follow the rules may play with the plastic bat’</p> <p>_____</p> <p><i>Describe:</i> Describe the undesired behavior: ‘When you hit your cousin with the bat,’</p> <p>Describe the resulting feeling: ‘I feel sad that your cousin is crying’</p> <p>Describe desired behavior: ‘Please do not hit anyone with the plastic bat’</p> <p>Helpful: Parents set enforceable limits without anger</p>

Figure 85.1 Controlled choices.

suggested strategies from the parenting resources: Controlled Choices, Directing Behavior, Describe, and I-Statements [see Figure 85.1] (record progress of

parental practiced behavior as number of Michael’s desired behaviors presented each day [see Knapp, 2005, p. 66]).

- 1C. Intervention: parents and teachers will agree to develop a discipline plan (for home and school) that includes firm limits, reasonable consequences for undesired behavior, and positive reinforcement (encouragement) for desired behavior⁸ (Huebner & Mancini, 2003) and record progress⁹ (number of desired behaviors in a day).
2. Promote bonding in the classroom and at home (Lee, 2006).
 - 2A. Intervention: Parents and child will determine a time of day that they will engage in “together” time (any work or play that includes interaction and no distractions—e.g., sharing family stories or looking at family photos, singing, reading, or coloring in the family life book) (Leckman et al., 2004) and record progress (number of Michael’s desired behaviors presented each day [Knapp, 2005]).
 - 2B. Intervention: Teacher and parents will agree to develop a plan that will enhance Michael’s bonding in the classroom, which may include the teacher and co-teachers engaging in daily chats or greetings, reciprocal smiles, or interactive tasks with Michael, and record the outcome (number of desired behaviors in a day) (Huebner & Mancini, 2003; Hunter, 1998).

Revisiting Chevaun

Her stepfather believes that grounding Chevaun for six weeks is a good way to get her attention and keep her from drinking, becoming pregnant, or hanging with the wrong crowd.¹⁰ He openly admits to hitting her when she is verbally disrespectful to either him or her mother adding that he “has no use for her anymore because she is so hateful to everyone in the family.” (See Figure 85.2.)

Chevaun’s mother is distraught over the continual fighting between her husband and only child. On the other hand, she is worried that her daughter “will come to no good end.” She disclosed that she often feels guilty that her daughter was involved in the violence of her first marriage, which is now being repeated. She reports feeling powerless to solve the problem.

Frequently, youths with *family issues* are drawn to peers with similar environments. There seems to be an unspoken understanding. Moreover, academic failure or underachievement, teen pregnancy, substance use, delinquency, and suicide are not mutually exclusive factors. These variables have a synergy often found within and in the environments of troubled teens. Mary and George’s differing parenting styles, George’s hostility toward Chevaun, and Mary’s depressive withdrawal leave Chevaun in an environment that is unsupportive and non-nurturing (see Figure 85.2). Indeed, she expressed this perception when describing her family’s interactions. The following treatment plan was constructed for negotiable work with this family.

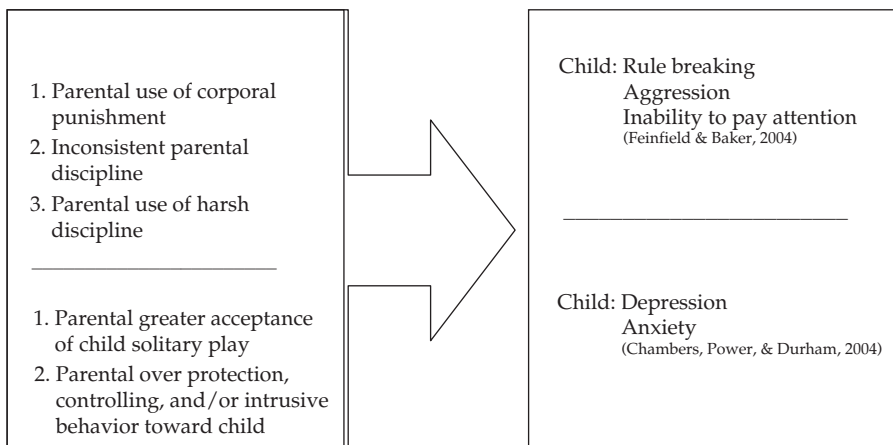

Figure 85.2 Parenting outcomes.

TREATMENT PLAN FOR CHEVAUN AND HER FAMILY

Presenting issue: Chevaun is breaking family/social rules and parents are reporting both overprotective and harsh parenting practices.

Long-term goals: Parents will successfully use positive disciplining methods on a daily basis resulting in a 50% decrease in Chevaun's family/social rule noncompliance (8 weeks).

Short-term objectives:

1. Parents will learn positive parenting practices to increase perceived family homeostasis and bonding.

1A. Intervention: Parents will read the following books: *Your Defiant Teen* (Barkley & Robin, 2008); *Parenting Teens with Love and Logic* (Cline & Fay, 2006); and *Parent Talk* (Moorman, 1998), in addition to journaling and sharing thoughts and feelings regarding the new information with family members and/or counselor/educational group, if involved with that resource.

2. Parents and child will practice various behaviors meant to enable the development of child and parent self-responsibility (see Figure 85.2, and Tables 85.1 and 85.2) increasing the likelihood of family member bonding and family homeostasis. They will also record thoughts and feelings (Best, 2006).

2A. Parents will initiate a daily *family time* (Eaker & Walters, 2002) (e.g., 30 minutes) where the family will talk, share a task (e.g., keep a family journal), or play together, plan future together times, share thoughts and feelings with no distractions (e.g., phone calls or television) and journal thoughts and feelings regarding the new structure to share with family members and/or counselor/educational group.

2B. Intervention: Parents will offer the child an attainable task and allow the child to complete the undertaking without interference, allowing natural consequences to be the learning opportunity (Cline & Fay, 2006; McMahon, 2003). Family members will review the outcome during family time and, if deemed unsuccessful, offer the opportunity again. All family members will journal their thoughts and feelings

TABLE 85.2 Helpful Thinking and Behavior For Parents

-
1. Children are offered choices of potential desired behaviors in a tone that is sensitive and calm.
 2. Consequences for an undesired behavior may be postponed and contemplated with empathy.
 3. Parents do not need to own the problem.
 4. It is the child's responsibility to learn that consequences arise from behaviors and he/she has the ability to ponder possible alternative behaviors for future use (Cline & Fay, 2006).
-

- about this process and share them with one another and/or a counselor or educational group.
- 2C. Intervention: All family members will perform the rewind game (Knapp, 2005, p. 229) to practice *thinking about new ways to solve a problem or behave in response to a circumstance* and share results, thoughts, and feelings during family time and/or with an educational group or counselor.
- 2D. Intervention: Parents will learn the value of supportive statements, such as, "I know you can accomplish this task" (Nelsen & Lott, 2000), and the empowering techniques of listening, power messages, choices, consequences, and permission (Cline & Fay, 2006) They will journal thoughts and feelings about using this new behavior to share with family members and/or counselor/educational group.
- 2E. Intervention: Both parents and child will work together to form a plan for correcting undesired child behavior. All family members will work through the personal problem solving activity (Knapp, 2005, p. 211) and share their results during family time and/or in an educational group or with a counselor.
- 2F. Intervention: Parents will learn about the reciprocal nature of parent and child interactions (e.g., how their response to their child's behavior may reinforce undesired child behaviors) by reading Step Four of *Your Defiant Teen: 10 Steps to Resolve Conflict and Rebuild*

Your Relationship (Barkley & Robin, 2008). They will also journal thoughts and feelings and share these with one another during family time and/or with an educational group or counselor.

CONCLUSION

Parenting can be both a stressful and joyous undertaking that is significantly influenced by parent/child perceptions, goodness of fit, and interactions (Kendler, 1996). Parenting practices have outcomes (see Figure 85.2 and Table 85.1). It is the professional's job to enable frustrated parents to find their own understanding of how to help themselves and their child discover mutually satisfying interactions that strengthen and sustain family homeostasis. All family members must be involved and willing to take responsibility for their contributions to the family dynamics in addition to being open to change. Moreover, schools and communities also have a stake in the health and success of our future generations. Evidence-based responsible and collective caregiving is a significant factor in that outcome.

WEBSITES: PARENTING SKILLS

www.loveandlogic.com
 www.kidshealth.org
 www.healthychildren.org

Notes

1. Low-income parents tend to prefer behaviorally based education (Wood & Baker, 1999)
2. This is a sign of low reflective functioning or a parent who is unable to empathize (see, Slade, 2005)
3. What makes Michael behave in this way? How do I respond when he behaves like this? (maternal state of mind and reflective functioning are associated with child caregiver attachment (Atkinson et al., 2005).
4. Parental stress related to perceived ineffective parenting abilities is associated with the use of corporal punishment
5. For example, "Michael is a disobedient and high maintenance child"
6. Preferably within the first week of seeking advice or counseling
7. Parents will have documented a behavior baseline of at least 3 days (Knapp, 2005).
8. Replacing noncompliance with compliance and cooperation—Exercise IXA (Knapp, 2005, p. 109–110)
9. Behavior baseline documented—Exercise VB (Knapp, 2005, p. 65–66)
10. Grounding is a time-out for teens and not as effective as other parenting methods (see, Barkley & Robin, 2008)

86 Bereavement and Grief Therapy

Elizabeth C. Pomeroy, Kathleen H. Anderson, & Renée Bradford Garcia

Loss is a universal experience that everyone encounters at one time or another during their lives. Loss from the death of a loved one can be especially devastating. Grief resulting from this kind of loss causes significant disruption in

a person's functioning both internally (physically and emotionally) and externally (socially and occupationally). Historically, mental health practitioners have received little in-depth training related to grief and loss interventions. In

addition, only a few theories of grief and loss have been postulated by experts in the field. However, as the topic of grief and loss gains wider acceptance and more visibility, there is a need for an understanding of the grief process that considers the individual within the context of the environments in which he or she functions, rather than just examining the intrapsychic experience of the individual.

Early conceptualizations of the process of grief and loss formed the initial knowledge base of an unexplored area of human experience and helped us understand the problematic symptoms and damaging consequences of grief. They validated that grief is a negative, painful, and disruptive experience for the mourner. Practitioners often misinterpret these models as being grounded in a problem-oriented perspective and consequently often view a person experiencing grief as someone suffering from an illness that must be cured. As a result, the practitioner may de-emphasize the mourner's strengths and resiliencies, which can be brought to bear on his or her unique experience of loss. The strengths-based framework of grief assists practitioners in building on the inherent strengths of the individual while they navigate the grieving process. It encourages mourners to use their positive coping abilities and environmental resources. Furthermore, the strengths-based approach to grief is grounded in the view that grief in response to the death of a loved one is a natural, normal, and potentially health-producing process that aids the individual in adjusting to the absence of the loved one.

THE STRENGTHS-BASED FRAMEWORK FOR GRIEF

The strengths perspective of social work practice developed by Saleebey (2013) and Rapp (1998) views every client as having assets and resources that enhance his or her ability to cope with life events. These assets and resources can be categorized into individual strengths and environmental strengths. Individual strengths include aspirations, competencies, and confidence (Rapp & Goscha, 2012). Aspirations include goals, dreams, hopes for the future, ambitions, and positive motivation to achieve and grow. Competencies are manifested by one's unique ability to use talents, skills, and intellect. Confidence refers to a person's positive self-regard and his or her belief and

tenacity in achieving goals. A person with confidence feels valuable and worthy of positive life events. Strengths are present in every individual. Some people appear to be able to capitalize on their strengths more than others. This phenomenon may be due to a combination of biological, psychological, and social factors. Environmental strengths include resources, social relations, and opportunities. Resources include financial support, access to services, access to information, and other tangible assets. Social relations encompass friends, family, coworkers, neighbors, and others with whom one has interactions. Opportunities refer to the gaps in one's life that are waiting to be filled. They represent positive events that can potentially change one's life. In addition, a person maintains specific niches in life, that is, habitation, job, friends, and leisure activities. According to Rapp (1998), "The quality of the niches for any individual is a function of that person's aspirations, competencies, confidence, and the environmental resources, opportunities, and people available to the person" (p. 42). Together, a person's individual and environmental strengths influence one's sense of well-being, empowerment, and life satisfaction (Rapp & Goscha, 2012).

For clients who are grieving, the strengths perspective is a particularly salient framework. It builds on previous theories of grief with the addition of a lens that emphasizes the health-producing aspects that are intrinsic to the mourner as well as the process of grief. Focusing on client strengths rather than deficits provides the practitioner with a valuable tool that can aid in assessment and intervention. It effectively highlights aspects of the person and his or her environment that can be used and enhanced to assist in the grieving process and promote positive growth. The basic tenets of the strengths-based framework of grief are as follows.

1. Grief in response to the death of a loved one is a natural, expectable, and potentially health-producing process that aids the person in adjusting to the absence of the loved one.
2. The symptoms, emotions, and behaviors associated with expected grief reactions represent a process of healthy adaptation and are not inherently pathological.
3. Mourners benefit by knowing that life-enhancing grief reactions are productive and beneficial. Life-enhancing grief reactions are those responses that facilitate healing within the mourner.

4. All persons have individual and environmental strengths that can assist them as they experience grief. The mourner benefits from the reinforcement of those strengths and the encouragement to consciously employ them during the grief process.
5. Environmental conditions can either help or hinder the mourner's ability to adapt to the loss and enhance the person's life.
6. Many symptoms of grief, although they may be uncomfortable and are commonly regarded as negative symptoms, are healthy coping mechanisms in that they facilitate the process of separation, adaptation to change, and integration of the loss.
7. Life-enhancing grief reactions to loss enable accommodation and adaptation to occur. They facilitate the process of psychological separation from the deceased.
8. Life-enhancing grief symptoms should not be discouraged. Rather, they should be allowed expression while being carefully monitored so that they remain helpful to the mourner's process of adaptation.
9. Grief may be considered life-depleting when the symptoms it produces significantly weaken the mourner's aspirations, competencies, and confidence. Life-depleting grief reactions are those responses and circumstances that act as impediments to the expected grieving process and interfere with the mourner's ability to live a fulfilling life.
10. Life-depleting grief reactions thwart the process of adaptation and lead to entropy.
11. Life-enhancing and life-depleting grief reactions exist on a continuum of intensity.
12. The experience of grief evolves over a person's lifetime and is experienced with varying levels of conscious awareness (Pomeroy & Garcia, 2009).

The outlook for the strengths-based perspective in terms of clinical practice and social work is tempered by the dominant helping modality found in social work and medicine that is molded around the "problems and pathology" framework. Clearer criteria and definition of what strengths-based practice is and testing with more robust research and practice in academia would greatly benefit strengths-based social work (Rapp, Saleebey, & Sullivan, 2005).

**ASSESSMENT OF BEREAVEMENT
ACCORDING TO THE DIAGNOSTIC
AND STATISTICAL MANUAL OF MENTAL
DISORDERS, FIFTH EDITION**

Historically, bereavement has received minimal attention from the American Psychiatric Association and was included in the *DSM IV* and *DSM IV-TR* as a V code (Other conditions that may be a focus of clinical attention). The definition of bereavement included a two-month time period, which was considered a major limitation by the field of experts in grief and loss. Moreover, a diagnosis of Major Depressive Disorder prevented the practitioner from diagnosing bereavement.

Although the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)* recognizes the differences between uncomplicated bereavement, which is still defined as a V code, and Major Depressive Disorder, it also allows for a person experiencing a severe grief reaction and depression to be diagnosed with a Major Depressive Disorder. Although the major symptoms of grief involve feelings of emptiness and loss that come and go in waves, the major symptoms of major depression include hopelessness and persistent depression that pervasively influence the person's mood (APA, 2013). In addition, a person with Major Depressive Disorder will have low self-esteem while the person with a grief reaction may keep their self-esteem intact. However, the authors of the *DSM-5* recognize that there can be significant overlap in symptoms and a bereaved individual can become clinically depressed.

Bereavement is also noted in the *DSM-5* in the Trauma and Stressor-Related Disorders category under Other Specified Trauma and Stressor-Related Disorder. An individual who experiences the death of a close relation (friend or family member) and who continues to long for the deceased, has significant emotional pain, and who is preoccupied with the deceased may have a complicated grief condition that would be classified as a Persistent Complex Bereavement Disorder (APA, 2013). In addition, the individual experiences symptoms similar to a trauma reaction, such as emotional numbing, anger, excessive avoidance of situations that remind one of the death, a desire to die in order to be with the deceased, loneliness, role confusion, and lack of interest in pleasurable activities. A specifier of

“with traumatic bereavement” can be included if the death was of a traumatic nature such as homicide or suicide. Persistent Complex Bereavement Disorder is also being considered as a unique diagnosis; however, presently it is in the Appendix under “Conditions for Further Study.” Therefore, to diagnose a client who is experiencing these symptoms, a practitioner would have to use the “Other Trauma and Stressor-Related Disorder” classification (APA, 2013).

Finally, Uncomplicated Bereavement remains in the *DSM-5* under “Other Conditions That May Be a Focus of Clinical Attention” as a V Code. Uncomplicated Bereavement is considered a normal expression of grief over the loss of a loved one and not a mental disorder (APA, 2013). The duration of a normal grief reaction is not specified in the *DSM-5*, with an acknowledgment that culture may play a significant role in the length of the grief process.

Bereavement can also be found in the *DSM-5* (APA, 2013) under Adjustment Disorders. In the case of the death of a loved one the grief reaction must surpass what is customary in that person’s environment and culture. In addition, the developmental level of the person must be taken into consideration (APA, 2013). For example, a young child who develops behavioral problems after the death of a distant relative might be given a diagnosis of Adjustment Disorder with the specifier, “with mixed disturbance of emotions and conduct.”

STRENGTHS-BASED, EXPECTED GRIEF ASSESSMENT AND INTERVENTIONS WITH INDIVIDUAL CLIENTS

Intervening with bereaved clients from the strengths-based framework of grief involves several skills that originate from a comprehensive understanding of the strengths-based model. The practitioner adheres to the basic tenets of the model while working with the unique situation that the client brings to counseling. Initially, the practitioner allows for the client to present his or her story of the loss and the experience with his or her grief. This story may unfold over many sessions and may be retold from various perspectives. However, the initial presentation of the loss provides the practitioner with information and insight into the client’s present experience. Concurrently, the practitioner listens for information that will complete a preliminary assessment of the client’s internal and external strengths, resources, and

social supports. Some of the skills that the practitioner uses throughout grief counseling include active and empathetic listening, nonjudgmental acceptance of intense emotions, normalizing and educating the client about the grief process, assisting the client with coping skills and resources, and helping the client develop life-enhancing strategies to re-engage fully in life. Finally, the practitioner will assist the client in using his or her experience as fuel for personal growth.

According to the strengths-based framework of grief, the term *expected* grief describes the predictable grief experience that reflects the healthy process of separation from the deceased individual. Although it can take on a wide variety of forms, this type of grief is what the practitioner would expect to see with someone who has lost a loved one. Expected grief leads to health-producing growth. The term *complex* grief describes a grief process that is encumbered with internal and/or external complications that interfere with the health-producing growth process of expected grief. If complex grief is not addressed appropriately, it can lead to life-depleting responses (Pomeroy & Garcia, 2009).

GROUP INTERVENTIONS FOR ADULTS WITH EXPECTED GRIEF

In addition to individual counseling, group counseling has been used as a primary vehicle for working with the bereaved (Worden, 2009). Psycho-educational group interventions have been shown to be effective with caregivers of chronically/terminally ill populations such as Alzheimer’s, oncological, and dialysis patients (Brown, 2011). In addition, psycho-educational groups related to grief and loss have proven to improve well-being and grief resolution, increase social support, and decrease the risk of psychopathology related to unresolved grief issues (Pomeroy & Holleran, 2002). The power of group support and shared, mutual concerns can ameliorate the loneliness and isolation associated with loss. The potential benefit of being with others who share a common experience with grief is tremendous. Group support can effectively minimize the feelings of grief described by Stephen Levine when he writes, “We come to trust ourselves less, we cannot ‘feel’ the world around us as we once did, so we experience ourselves as ‘a bit unplugged’” (Levine, 2005, p. 4).

A STRENGTHS-BASED, PSYCHO-EDUCATIONAL GRIEF GROUP

The authors have found that bereavement groups combining the strengths-based framework with a psycho-educational format can greatly enhance a mourner's feelings of competency in relation to managing grief. The term *psycho-educational* refers to the fact that both information and emotional support are provided and enhanced by each other to alleviate some of the painful symptoms associated with grief. It allows for participants to understand the process of grief in a context that includes not only themselves but others. Upon receiving factual information, group participants are able to dispel some of the myths and unrealistic expectations associated with the grieving process. In addition, the mutual sharing of common experiences creates a community from which each participant can draw strength. Both these dynamics assist mourners in developing the internal and external resources that are necessary for the healing process to progress. Not only are psycho-educational groups effective, they are also economically feasible for clients who cannot afford individual counseling as well as for agencies with limited resources (Pomeroy & Garcia, 2009). Internet-based self-help psycho-educational bereavement groups have been found to be very useful in providing information and support (Dominick, Irvine, Beauchamp, et al., 2009). The following paragraphs outline a psycho-educational group design that uses the strengths-based framework of grief.

THE STRENGTHS-BASED PSYCHO- EDUCATIONAL GROUP DESIGN

Group Goals

The goals for this group are to provide individuals with a safe and structured environment in which to adjust to the absence of the loved one. This is accomplished by facilitating an understanding of the life-enhancing aspects of grief, processing the mourner's adaptation to the loss, promoting awareness about life-depleting grief reactions, and enhancing the mourner's coping skills and resources to engage in a life separate from the loved one. These goals underlie the content of the group sessions (Pomeroy & Garcia, 2009).

Group Structure

Careful consideration should be made when deciding if a grief group should have an open-ended or closed-ended structure. Open-ended groups allow for new participants to join at any time during the process, whereas closed-ended groups limit membership to participants who commit to a specific number of sessions. Although open-ended groups can potentially accommodate a greater number of participants and provide individuals with immediate assistance, the constant flux in membership can prohibit group cohesion, trust, and advanced development (Toseland & Rivas, 2012). When dealing with a highly emotional issue like grief, it can be difficult for members of open-ended groups to progress beyond the storytelling stage of the loss. Closed-ended groups provide a secure environment in which trusting relationships between members can develop, thereby, encouraging more intimate self-disclosure. On the other hand, these groups are limited to a small number of participants and may not be cost-effective for agencies with limited resources. In addition, if some participants drop out of the group, it may become too small to provide members with a meaningful experience (Toseland & Rivas, 2012).

Time-limited psycho-educational groups based on the strengths-based framework of grief have been found to be practical and productive because of the structured discussion topics, the life-enhancing coping strategies that are encouraged between group sessions, and the trusting relationships that develop among members. Although the first two sessions focus on the participants' losses, subsequent sessions guide the participants in the strengths-based coping model outlined earlier. The strengths-based grief group is 6 to 8 weeks in length. This type of structured group is compatible with agencies that specialize in end-of-life care, such as hospice or community outpatient clinics. The facilitator of this type of group also serves as a conduit between participants and community resources (Pomeroy & Garcia, 2009).

Group Participants

In addition to designing the group structure, it is important that potential members be screened for appropriateness. Membership should be composed of individuals who have lost a loved one due to

death, understand the purpose of the group, understand that active participation includes thoughtful listening as well as discussion, and who are able to commit to attending every session. Some individuals are better served by individual counseling rather than group counseling. Bereaved persons whose loss is very recent (0 to 4 weeks) may initially benefit more from the focused attention of an individual therapist. This may also be true for individuals with untreated and severe mental illness, individuals who have many life stresses in addition to the loss, people who are unable or unwilling to share group time with others, or individuals with complex grief (Pomeroy & Garcia, 2009).

Group Content

The content of a grief group will be somewhat dependent on the composition of the group members. For example, if the group is composed of all female participants who have lost their mothers, the discussions may highlight mother–daughter relationship issues. On the other hand, if the group is composed of parents who have lost a child, discussions may focus on the need for communication between the surviving parents. However, regardless of the specific issues that the members bring to the group, there is certain content that is covered in all groups using the strengths-based psycho-educational approach. Topics include adjustment to the loss, navigating transitions, family concerns, using community resources, and engaging in outside activities (Pomeroy & Garcia, 2009).

A STRENGTHS-BASED, COMPLEX GRIEF GROUP INTERVENTION

Group intervention can also be effective for mourners experiencing a complex grief reaction. They can benefit by having a community of people with whom they can share their grief and by being around others who are also grieving. It is particularly useful for mourners with complex grief reactions to be in groups with others who had loved ones die in a similar manner. Interventions for these types of groups are highly specific to the population of survivors. The unique issues related to particular types of death can be explored in depth, and problems related to the mode of death can be shared and managed. For example, survivors of suicide groups provide support to people who have experienced suicide

in their families. Group members may grapple with the anger they feel toward their loved ones as well as guilt they may carry from their inability to prevent the death. Specialized groups such as these also provide a buffer from the stigma associated with the loss and the lack of social support mourners typically receive in their communities. These groups can also provide information and education about topics of particular concern to the group members. Parents of Murdered Children, for example, has support groups that use the psycho-educational approach to helping family members deal with law enforcement and the judicial system in addition to their grief.

In using the strengths-based framework, the authors have found that complex grief reactions can be addressed in a group setting after the mourner has had some individual counseling or has had time to process the trauma associated with the death. Many mourners with complex grief issues can make the best use of group interventions after some time has passed since the death. This time period may range from 2 to 12 months. Assistance by way of individual counseling may be recommended prior to participation in a group. Potential members for these types of groups should undergo an individual assessment prior to entering the group to determine their readiness for group participation. In some cases, their needs would be better served in individual counseling. Some mourners benefit from being in individual and group counseling simultaneously. Assessment for group participation should consider the degree of trauma and level of crisis, as well as the person's overall mental health status (Pomeroy & Garcia, 2009).

ASSESSMENT OF GRIEF AND LOSS IN CHILDREN AND ADOLESCENTS

An accurate assessment of grieving children and adolescents must include information from a variety of sources. Although obtaining detailed information from a young child is unlikely, collaborative resources can provide important and accurate information about the loss and the problems the child may be experiencing. Relevant data can be gleaned from parents or caregivers, medical and school personnel, and other adults who have central involvement in the child's life (e.g., an aunt who provides afterschool child care). Three primary elements in grief assessment of a child were identified by Webb and Doka (2010). The individual child's level of functioning, the factors

related to the death, and the child's support system are all key components of a bereavement assessment (see the Psychosocial Assessment Interview Guide later in this chapter). Initially, the practitioner wants to gather as much information as possible from the youth's parents or caregivers. This may be done over the first few sessions of counseling. Older children and adolescents may also be able to provide salient information.

If the youth is complaining of physical symptoms, a physician's referral is warranted prior to the beginning of therapy. It is recommended that the practitioner form a collaborative relationship with the youth's physician regardless of the presenting problems. If the need should arise for medical intervention, the relationship with the medical professional will have already been established. For example, a young child who presents with encopresis may have a medical problem and should be thoroughly assessed by a physician before determining that it is likely due to regression associated with loss.

Conducting an assessment with children under the age of 13 years most often involves play and activity therapy in order to access and observe the child's feelings and behaviors. Through various activities such as drawing pictures of family, home, or a favorite activity, the practitioner opens the door for conversation regarding the child's experiences and relationships (Webb, 2007). The practitioner may utilize a variety of techniques in eliciting the child's feelings and perceptions. For example, some children are unable to articulate their feelings with words and need assistance developing a vocabulary for emotions. Pictures of faces that display varied emotions as well as stories about feelings may be useful in this regard. Other children need time to direct their own play before engaging in a therapeutic activity. Although some children naturally make use of the available supplies in a therapeutic manner, other children require the practitioner to provide structure and direction. Practitioners should investigate the variety of published play therapy resources such as books on play therapy, games, and art projects.

Older children often possess a great deal of insight and understanding of their experience of loss. However, practitioners must develop a safe working relationship before expecting the older child to share this information. For adolescents, assessment should include perceptions of self-concept, levels of distress, anxiety and depression, degree of loneliness, and presence of

anger responses (Doka, 2013). For older children, practitioners should also seek to know their feelings about seeing a practitioner, their interpretation of the loss, and its impact on their ability to function. When helping adolescents process their grief and loss experience, it is best to build a collaborative relationship because such experiences can intensify current developmental issues and life challenges (Slyter, 2012). In general, older children and teens are better able to express their feelings verbally if the practitioner establishes good rapport. Teens often converse more easily when simultaneously involved with another activity. This may take the form of going for a walk, playing online or video games, making something with their hands, or listening to music. Moreover, when working from a strengths-based perspective, adolescents of both genders strongly self-identified arts-based methods (i.e., music, writing, etc.) as well as utilizing personal relationships and physical activities as preferred methods of coping during times of distress (Slyter, 2012; Tyson, Baffour, & DuongTran, 2010).

Practitioners utilizing a strengths-based perspective can help adolescents to utilize their own talents and abilities in commemorating their bond with the deceased and by engaging in therapeutic rituals (e.g., funeral rituals) to help them move forward from the loss (Slyter, 2012). Adolescents dealing with stressful life events such as illness, loss, and death often utilize the Internet for information seeking, relaxation/stress reduction, mood management, social support, and relationship maintenance (Leung, 2007). Teens are key users of social networking sites and participatory media such as blogs and podcasts as well as virtual worlds (Goodstein, 2007). By utilizing social networking sites and the digital world, adolescents can use their own strengths and resources to express their grief, honor relationships, and process their loss.

GRIEF GROUP INTERVENTIONS WITH CHILDREN AND ADOLESCENTS

As with adults, group intervention with children and teens can be beneficial to youth who are grieving. For adolescents, one particular advantage of group counseling is that the group provides a place for bereaved youth to find relief from the feeling of being different from their peers because of their loss. Group intervention may take many forms, including family counseling, counseling that involves groups of families, groups that are

offered in the community, groups that are hosted in schools, camps that assist youth with their grief in an outdoor setting, as well as the Internet-based support groups. Important components of group intervention with children and teens include sharing the story of the loss, educating and normalizing grief responses, expressing feelings associated with grief, identifying life-enhancing coping mechanisms, addressing feelings of guilt associated with the loss, and memorializing the deceased.

GROUP INTERVENTIONS WITH GRIEVING OLDER ADULTS

According to the Administration on Aging (2012), the population of adults, age 65 years and older has increased by 18% since 2000. And, the population aged 85 years and older is projected to increase from 5.7 million in 2011 to 14.1 million in 2040. The elderly often encounter numerous losses that may come with advanced age, ranging from the loss of loved ones and friends to the loss of mobility due to physical (e.g., illness) and cognitive deterioration (e.g., ability to drive) as well as changing roles within their family (e.g., caregiver to dependent) and community (e.g., worker to retired). Further complicating losses for the elderly is the existence of ageism and the social devaluation that has been identified in many western cultures. Older adults are at high risk for complicated grief, especially when confronted with the death of a loved one. Additionally, chronicity has been associated with physical and mental illness as well as suicidality (Supiano & Luptak, 2013). Older adults can benefit greatly from bereavement support. As with other populations, support groups for bereaved older adults can provide needed social support and outside activities for persons who might be vulnerable to intense loneliness and isolation. For example, one community has developed an organization that specifically focuses on the needs of older widows and widowers for social interaction. The group sponsors monthly events, for which they provide transportation, to engage older people in social activities and opportunities to interact with other widows and widowers. Some of the group's events offer participants opportunities to memorialize their deceased spouse. This organization has grown considerably over the past decade and is well attended by older community members. In addition, groups that focus primarily on issues of bereavement often attract older people who are experiencing either expected or complex grief.

GRIEF AND PERSONS WITH SPECIAL CIRCUMSTANCES

Although there are many commonalities among bereaved persons regardless of the type of loss they have experienced, there are also some deaths that are unique in the way they impact the mourner and the healing process. Counselors require specialized knowledge and understanding to be most effective with these types of mourners. For example, mass violence resulting in traumatic deaths, such as terrorist attacks and school shootings, impacts more than just family/friends; it touches communities and first responders as well. Other examples include the grief experience for persons with disabilities, immigrant populations, divorced families, veterans of war, gay/lesbian/bisexual/transgender populations, mourners of perinatal loss, and victims of crime and domestic abuse. All of these are groups that require specialized knowledge and unique interventions. It would be impossible to detail the unique dynamics of all the various kinds of losses found in our vastly diverse society. In some cases, there are entire books devoted exclusively to the specific circumstances surrounding a particular type of loss. In other cases, there is a dearth of information about a particular life circumstance that a client may present.

The strengths-based framework for grief is particularly germane to populations with special circumstances. Many persons within these groups have developed a reservoir of resiliency due to their encounters with adversity and discrimination. Because their special circumstances often involve additional stigma and ostracism from society, it is even more important that practitioners identify life-enhancing strategies for assisting them through the grief process. In addition, practitioners will want to help clients develop and access environmental assets.

PRACTICE IMPLICATIONS FOR THE PROFESSIONAL

Working with bereaved individuals is a powerful and moving experience. Although practitioners often describe grief counseling as meaningful, rewarding, and profound, there are also moments when it may be experienced as draining, depressing, unsettling, and frustrating. It is also important for practitioners to be able to differentiate normal from complicated grief and the changes made to the *DSM-5* will assist with this delineation.

Despite adherence to professional boundaries between client and counselor, the act of being emotionally present for someone who is mourning a loved one touches the practitioner personally as well. In part, this may be because most practitioners have had personal experience with the death of a loved one and can relate to the experiences of their clients. Additionally, the work of grief counseling involves regular and intimate contact with the prevalence, probability, and impact of death, a reality that society encourages us to ignore. Awareness of how the counseling process affects the practitioner is essential to competent and ethical practice with grieving clients.

Self-awareness, quality professional social work supervision, flexibility, and an ability to cope with ambiguity are all necessary components of being a professional grief counselor. Understanding, implementing, and upholding the National Association of Social Workers Code of Ethics is essential for social workers involved with grieving individuals, groups, and families. Finally, social workers practicing in this area benefit from using positive self-care methods, including professional and personal support when needed. Developing an expertise in grief and loss is a rewarding and worthwhile endeavor because throughout their careers social workers in all areas of practice will have clients coping with these emotions.

WEBSITES

- www.adec.org—The Association for Death Education and Counseling is an international, professional organization dedicated to promoting excellence and recognizing diversity in death education, care of the dying, grief counseling and research in thanatology.
- www.bereavedparentsusa.org—Bereaved Parents of the USA is a nonprofit, nondenominational, self-help support group for bereaved parents, siblings, and grandparents.
- www.childrengrieve.org—The National Alliance for Grieving Children is a national, nonprofit outreach program dedicated to providing educational information and resources to children and teens grieving a death.
- www.compassionatefriends.org—The Compassionate Friends (TCF) is a nonprofit, self-help support organization that seeks to assist bereaved families following the death of a child of any age.
- www.dougy.org—The Dougy Center is a national nonprofit dedicated to providing grief

resources, including support group services, to children, teens, young adults, and their families grieving a death. It also offers training in grief and loss to community agencies.

- www.griefnet.org—GriefNet is a nonprofit, Internet community of bereaved individuals who are dealing with a variety of grief-related issues. Although a small financial donation is requested, it is not required for membership. GriefNet's companion site, www.kidsaid.com, is an online support resource for children.
- www.griefshare.org—GriefShare is a nonprofit, nondenominational organization that uses biblical teachings to help individuals through the grieving process. It offers grief recovery support groups.
- www.friendsforsurvival.org—Friends for Survival is a national nonprofit outreach organization for those who have lost family or friends by suicide, and also for professionals who work with those who have been touched by a suicide tragedy.
- www.taps.org—Tragedy Assistance Program for Survivors is a national, nonprofit organization for those who have lost a loved one who died while serving in the military.
- www.widownet.org—WidowNet is a nonprofit self-help resource for, and by, widows and widowers experiencing grief and bereavement.

87 Motivational Interviewing

Shannon K. Johnson, Kirk von Sternberg, & Mary M. Velasquez

Motivational interviewing (MI) is an empathic, client-entered counseling approach that seeks to elicit behavior change via exploration and resolution of ambivalence around change. MI utilizes a nonjudgmental, collaborative counseling style that focuses on a person's inherent strengths and capacity for change. Put simply, it is a form of collaborative conversation that strengthens a person's own motivation and commitment to change (Miller & Rollnick, 2013). MI addresses the common problem of ambivalence about

making changes in one's life by paying particular attention to client language called *change talk*. In this way, a counselor guides the client in strengthening motivation by eliciting the client's own reasons for change within an atmosphere of acceptance and compassion. While supporting and honoring clients' autonomy and capacity and right to make choices and decisions in their lives, the counselor reinforces strengths, values, and reasons for change by selectively reflecting and reinforcing certain types of change talk.

MI has a strong evidence base, originating with the release of a groundbreaking text by William Miller and Stephen Rollnick over 20 years ago (Miller & Rollnick, 1992). Since the initial publication of this classic text, MI has been used by countless clinicians in diverse settings. It has been cited in over 25,000 articles, and its efficacy has been studied in over 200 randomized clinical trials (Miller & Rollnick, 2013). MI appears effective and appropriate across cultures, populations, settings, and behaviors (Sampson, Stephens, & Velasquez, 2009) and also has been adapted for delivery in a group format (Velasquez, Stephens, & Drenner, 2012; Velasquez, Stephens, & Ingersoll, 2006; Wagner & Ingersoll, 2012).

Two underlying assumptions of the MI intervention are that the decision to change is most powerful when it comes from within and that the responsibility for change is situated with the client. Accordingly, MI adopts a client-centered, respectful, collaborative approach in which client and counselor are co-experts. The MI counselor respects the client as the authority on his or her own life and honors his or her autonomy and right to self-determination. Rather than confronting a client with his or her problems and presuming to assign goals or deliver solutions, the MI counselor's task is to elicit the client's own concerns about and solutions to the presenting problem (Miller & Rollnick, 2013). The counselor can then provide feedback about observations clients have made for themselves (Van Wormer, 2007). Though goal-focused and directive, the MI approach remains nonconfrontational at all times; feedback is not intended to persuade a client to change, but rather is delivered in a way that validates a client's experiences and perspectives and leaves the responsibility for change squarely on the client's shoulders (Sampson, Stephens, & Velasquez, 2009).

THE MOTIVATIONAL INTERVIEWING SPIRIT

In the most recent version of their MI text, Miller and Rollnick (2013) describe the MI Spirit as the underlying set of mind and heart within which MI is practiced. They use the acronym PACE to signify the main components of the MI Spirit: **p**artnership, **a**ceptance, **c**ompassion, and **e**vocation. *Partnership* is the collaborative dialogue in MI in which the counselor, rather than being seen as the "expert," works in accord with the client in

exploring the client's goals, personal strengths, and resources. *Acceptance* is an affirming, empathic recognition that honors and supports the client's autonomy and inherent worth. *Compassion* signifies that the attitudes and actions of the counselor are based on promoting the welfare and best interest of the client. *Evocation* refers to the elicitation of the client's wisdom, goals, solutions, and thoughts about change (Miller & Rollnick, 2013).

PROCESSES OF THE MOTIVATIONAL INTERVIEWING INTERVENTION

Although MI is beneficial for clients at any point in their change process, its nonconfrontational, empathic nature makes it especially appropriate for individuals who are not yet committed to change (Velasquez et al., 2010). Whereas authoritarian approaches often elicit resistance in clients who are not yet ready to change, the MI approach is particularly well-suited for diffusing resistance. In the most recent conceptualization of MI, Miller and Rollnick (2013) explain that the MI intervention is comprised of four processes: engaging, focusing, evoking, and planning. *Engaging* entails involving the client in talking about issues, concerns, and hopes, and establishing a trusting relationship. *Focusing* involves narrowing the focal point of the conversation to habits or patterns that clients want to change. *Evoking* consists of eliciting motivation for change by increasing clients' sense of the importance of change, their confidence about change, and their readiness to change. Finally, *planning* entails developing the practical steps clients want to use to implement the changes they desire. The first two processes are those in which both the counselor and the client establish rapport, build a working relationship, and clarify direction. The latter two elicit the client's ideas about change, develop commitment to change, and formulate a specific plan of action. They can be thought of as stair steps, with each process building upon the ones that preceded it (Miller & Rollnick, 2013). In general, counselors use empathic exploration of ambivalence to highlight discrepancies between the client's behavior and his or her goals and values, thereby enhancing intrinsic motivation and tipping one's motivational balance in favor of change during the early processes (Velasquez, Ingersoll, Sobell et al., 2010). The emphasis then shifts to developing individually tailored change plans, anticipating barriers to change and making

plans to address them, identifying potential support systems, acquiring available resources, and enhancing self-efficacy (Diclemente & Velasquez, 2002; Sampson, Stephens, & Velasquez, 2009).

GUIDING PRINCIPLES

There are four main guiding principles for the MI intervention: expressing empathy, developing discrepancy, rolling with resistance, and enhancing self-efficacy (Miller & Rollnick, 2013). In *expressing empathy*, the MI counselor uses active listening skills to reflect back to the client the meaning and feelings he or she is expressing, thereby conveying understanding and acceptance, which are integral to building rapport in MI. In *developing discrepancy*, the MI counselor creates opportunities for clients to identify and explore areas where their behavior is in discord with their goals and values. Clients are encouraged to consider both the pros and cons of a behavior change with the expectation that ultimately, their recognition of the positive outcomes of a behavior change will begin to outweigh the disadvantages they associate with change. In *rolling with resistance*, the MI counselor accepts resistance as natural and common and recognizes it as a signal to shift strategies. Rather than trying to break down a client's resistance, the MI counselor *rolls with it* by shifting gears when resistance arises. Finally, *enhancing self-efficacy* involves working diligently to build up a client's belief in her or his own ability to achieve and maintain change. MI therapists can do this by expressing their own belief in a client's ability to change and by eliciting input from clients about their previous successes (Sampson, Stephens, & Velasquez, 2009).

CORE STRATEGIES—ASKING OPEN QUESTIONS, AFFIRMING, REFLECTING, AND SUMMARIZING

Four counseling strategies form the foundation of MI and are summarized by the acronym OARS: asking Open questions, Affirming, Reflecting, and Summarizing (Miller & Rollnick, 2013). While a closed question may yield a simple yes or no answer, *asking open questions* involves phrasing questions in a way that encourages clients to elaborate on their experiences and feelings. *Affirming* involves the use of affirmations to highlight a client's strengths and efforts and can be used to build rapport, enhance

client self-efficacy, and strengthen intrinsic motivation. *Reflecting* involves listening intently and conveying back to the client one's understanding of what he or she was saying or feeling. There are several types of reflections. Simple reflections convey understanding of the client's perspectives, goals, and concerns while adding little-to-no meaning or emphasis to what the client has said. Complex reflections, on the other hand, add substantial meaning or emphasis (Moyers, Martin, Manuel, Hendrickson, & Miller, 2005). Double-sided reflections involve acknowledging what a client has said, and then adding to it the opposite side of the client's ambivalence. By capturing both sides of the argument, double-sided reflections mirror the client's ambivalence and can help the client recognize areas in which her or his arguments may be flawed. Finally, *summarizing* involves making a reflective statement that links two or more ideas the client has shared (Miller & Rollnick, 2013). For example, the MI counselor might use the summarizing strategy to recapitulate what a client has shared about his or her perception of the pros and cons associated with change. The four OARS strategies are used in MI to direct clients through a process of exploring and resolving ambivalence and moving toward positive change. Examples of applying the OARS techniques will be provided in a case example at the end of this chapter.

ADDITIONAL MOTIVATIONAL INTERVIEWING STRATEGIES, TOOLS, AND EXERCISES

There are several additional skills, strategies, tools, and exercises that are commonly used in MI. One crucial skill is that of *eliciting change talk*. Miller and Rollnick (2004) note that MI clients literally talk themselves into change. Change talk is comprised of client statements that reflect: (1) a *desire* to change; (2) an *ability* to change; (3) *reasons* to change; or (4) a *need* for change. *Feedback* is also a commonly utilized MI technique. Rollnick, Mason, and Butler (1999) describe the "elicit-provide info-elic" method of providing feedback, in which MI counselors: (1) elicit a client's interest in or knowledge about the topic area; (2) provide personalized feedback based upon results of an assessment or interview; and (3) elicit the client's thoughts or reactions pertaining to the feedback provided. In MI, personalized feedback is provided in a neutral

manner intended to increase client awareness rather than to persuade a client to change (Miller & Rollnick, 2013).

Scaling rulers are often used in MI to assess a client's readiness to change. *Importance rulers* assess the degree to which a change feels important to a client (1 = not at all important; 10 = extremely important), while *confidence rulers* assess clients' belief in their ability to achieve a change (1 = not at all confident; 10 = extremely confident). The balance between one's perceived importance of a change and one's confidence to make that change can be understood as a representation of his or her readiness to change. Scaling rulers can be used to reassess readiness throughout the MI intervention. When used artfully with the application of OARS counseling strategies, they can be used to elicit change talk and enhance intrinsic motivation (Sampson, Stephens, & Velasquez, 2009). See Figure 87.1 for an example of *the importance ruler*.

In MI, the counselor also focuses on *eliciting information* with the goal that the client should ultimately do most of the talking in the session (Rollnick, Mason, & Butler, 1999). The *typical day exercise* and the *values clarification exercise* are both useful exercises for *eliciting information*. In *the typical day exercise* (Rollnick, Mason, & Butler, 1999), the counselor highlights substance use as the focus of the question and then asks the client to describe a typical day in his or her life. Use of this exercise is likely to elicit more information than simply asking how much a client drinks or uses. In *the values clarification exercise*, the counselor can simply ask a client what he or she values in life and then seek elaboration. Alternatively, *a card sorting procedure* can be used in which clients are asked to sort a set of cards, each with a value printed on it (family, health, beauty, sobriety, love, spirituality, etc.), into three piles depending on how important the value is to them (i.e., not important at all, important, or highly important). They then are asked to sort the cards from their "highly important" pile into three new piles based on rank of importance, and to repeat this process

until they have five to eight cards that represent their primary values. The counselor can then explore these values with the client (Sampson, Stephens, & Velasquez, 2009). A ready-made set of cards for this exercise can be obtained from the www.motivationalinterview.org website.

MOTIVATIONAL INTERVIEWING IN GROUPS

Group therapy is one of the most widely utilized intervention modalities in substance abuse treatment settings (Velasquez, Stephens, & Drenner, 2012). Thus, exploring the potential for effective adaptation of MI for delivery in groups is crucial. Velasquez, Stephens, and Ingersoll (2006) reference a growing body of literature that suggests that the MI intervention can be adapted for delivery in groups. Among the promising results cited is a recent application of the Motivational Interviewing Treatment Integrity (MITI) behavioral coding system (Moyers, Martin, Manuel et al., 2005) to an MI-style group treatment for cocaine abuse. The MITI assesses treatment quality by coding counselors' use of MI-adherent (asking open questions, reflecting, affirming, asking permission, etc.) and non-MI-adherent strategies (advising without permission, confronting, arguing), as well as expression of empathy and adherence to the MI Spirit of collaboration, evocation, and support of autonomy. Although this coding system generally has been used to assess counselor performance in individual MI sessions, results of this recent application suggest that an MI-style group for cocaine abuse was highly adherent to MI principles and strategies (Velasquez, Stephens, & Drenner, 2012). These results are promising in that they provide evidence of the adaptability of MI for use in a group format.

Although they caution the MI practitioner to become skilled in practicing MI in individual sessions prior to moving into MI group work, Velasquez, Stephens, and Drenner (2012) provide specific advice for counselors who are prepared for

Figure 87.1 Importance Ruler.

MI group work. They suggest that group work should begin with an introduction of the MI spirit and an explanation of the motivational approach. This introduction should feature an emphasis on the centrality of personal choice and autonomy, nonconfrontation, empathy, and respect. It is critical that the MI counselor(s) work to maintain a nonjudgmental, respectful, collaborative atmosphere and that they provide reminders about the MI spirit and style of respect, nonconfrontation, and support throughout the group process (Velasquez, Stephens, & Drenner, 2012).

When delivering MI in a group format, the counselor adheres to the same principles (expressing empathy, developing discrepancy, rolling with resistance, enhancing self-efficacy) and utilizes the same basic strategies and tools (asking open questions, affirming, reflecting, summarizing, eliciting change talk, providing feedback, etc.) that are used in individual MI. It is important to note, however, that when intervening in a group format, the group is the client; focus must, therefore, be on group processes more so than on the individuals who constitute the group. With two group facilitators, however, one facilitator can focus on group process while the other focuses on applying MI counseling strategies (Velasquez, Stephens, & Drenner, 2012).

HOW TO LEARN MOTIVATIONAL INTERVIEWING

Miller and Rollnick (2009) stress that it takes more than a workshop or training for a counselor to learn to embody MI Spirit. A counselor who wants to practice MI should indeed attend workshops and trainings, but these must be followed by disciplined practice coupled with feedback and coaching from a knowledgeable guide. MI training and workshop opportunities are offered by the Motivational Interviewing Network of Trainers (MINT) and can be found on the www.motivationalinterviewing.org website.

Practitioners who are interested in learning MI will benefit from reading a seminal MI text such as *Motivational Interviewing: Helping People Change, third edition* by Miller and Rollnick (2013). Counselors who are interested in applying their well-honed MI skills in a group format are encouraged to reference a recently published text by Wagner and Ingersoll (2012), *Motivational Interviewing in Groups*. Practitioners who are interested in feedback are encouraged to look into

the aforementioned MITI behavioral coding system (Moyers, Martin, Manuel et al., 2005), which provides very specific feedback about a counselor's fidelity to MI intervention. Finally, Miller and Moyers (2006) provide a useful articulation of eight stages for learning MI.

A CASE EXAMPLE

Counselor: I'm glad you came in today. We have about 45 minutes together, and I'm wondering whether it would be OK with you if we talked for a little about your alcohol use? (*asking permission*)

Client: Sure, but I don't have a drinking problem. I'm only here because my probation officer's making me come.

Counselor: Coming here was not your idea, and it's frustrating to have someone tell you what you need to do. (*complex reflection—expressing empathy*) I want you to know that I'm not going to tell you what to do, and that the things we talk about will be up to you. (*emphasizing choice*)

Client: Good, cuz I don't need to go to AA and all that stuff. I just shouldn't have driven on the night of my DUI. That's all.

Counselor: Well, it's great that you took the step to come in today (*affirming*) even though this wasn't your idea. Since you're here anyway, to help me understand a little how alcohol fits in your life, what are some good things about your alcohol use? (*open question, decisional balance exercise—rolling with resistance*)

Client: Well, all my friends drink all the time, so I always have something to do if I'm drinking. I have fun when I go out with my buddies.

Counselor: So it's important to you to have fun with your friends, and it's easy to fit in if you're drinking. (*simple reflection—expressing empathy*) What else? (*asking open question—encouraging elaboration*)

Client: That's it really.

Counselor: OK, so now that you've told me something good about your drinking, what are some things about your drinking that are not so good? (*open question, decisional balance exercise*)

Client: Well, I only drink with my buddies. It's just to have fun, not every day or anything. Mostly just on Friday nights. I mean, sometimes I drink too many, but other than making my girlfriend angry it really doesn't affect my life.

Counselor: You said that sometimes you drink too many. (*simple reflection*) Tell me more about that. (*asking open question—encouraging elaboration*)

Client: I'll plan on just having a couple beers, and I'll end up drinking more than that.

Counselor: So you drink more than you planned. (*simple reflection*) In terms of drinking with your friends, what does a typical Friday night look like? (*typical day exercise*)

Client: We usually go to a couple bars. We'll start off having beer, but then usually someone ends up buying a round of shots. And then someone else buys another round, and it just goes from there. On a typical night I might have like two beers and six shots. I usually get a ride home, but I couldn't on the night of my DUI.

Counselor: You mentioned that your drinking makes your girlfriend angry. (*simple reflection of change talk*) Tell me a bit about that. (*asking open question—encouraging elaboration of change talk*)

Client: Oh, she's a nag. She gets annoyed when I come home late and starts fights with me. We don't have much money, so she's obsessed with budgeting and says I spend too much going out. She doesn't want me to go out. She's so controlling.

Counselor: It's frustrating to have your girlfriend tell you what to do. (*complex reflection—expressing empathy*) So you've noticed that you've been drinking more than you intend and that you're having conflicts with your girlfriend related to your drinking. And your drinking is taking a financial toll. (*summarizing change talk*) What else? (*asking open question—evoking change talk*)

Client: I just really want to get along better with my girlfriend. That's all.

Counselor: So you desire a better relationship with your girlfriend. (*reflecting change talk*) What would you like to see be different in your relationship? (*asking open question to elicit change talk*)

Client: She used to trust me, but now. . . This DUI is so expensive. I lost my driver's license so I can't have a job, and she has to work extra hours. I don't know why she stays with me—I wish she could trust me again.

Counselor: You feel guilty for the position you've put her in (*complex reflection of change talk*), and you want to regain her trust. (*simple reflection of change talk*) You are really dealing with a lot right

now. (*expressing empathy*) Tell me, how would your life be different if you weren't drinking? (*asking open questions to elicit change talk*)

Client: Well, I wouldn't be on probation. I wouldn't owe so much for my DUI. I'd have my driver's license and job. We'd be moving forward in life. My girlfriend wouldn't be mad at me. I wouldn't feel so guilty, like I messed everything up.

Counselor: So in some ways drinking has made it hard for you to pursue goals, and it seems to be affecting the way you feel about yourself and your relationship with your girlfriend. (*summarizing change talk*) So, IF you were to decide to change your drinking, and you were to take one step to make that happen, what might that look like? (*asking open question to elicit change talk*)

Client: Well, I might have to find something else to do on Friday nights.

Counselor: So a first step would be to make plans to do something on Friday night that doesn't involve alcohol. (*simple reflection of change talk*) OK, let's take a minute, if that's OK (*asking permission*), and think about how important it is right now for you to make that change, let's say on a scale from 1 to 10, with 1 being not important at all and 10 being highly important. (*assessing importance with a scaling ruler*)

Client: I'd say probably a 7 or an 8.

Counselor: That's pretty high. Tell me about why you chose a 7 or 8 instead of, say, a 5 or 6? (*asking open question to elicit change talk*)

Client: I just want to be a reliable man again. I hate feeling like I'm free-loading on my girlfriend while she works so hard to fix my mess.

Counselor: You need to be able to carry your own weight in order to feel good about yourself. (*complex reflection of change talk*) In terms of confidence, I'm wondering how you'd rate yourself on a scale of 1 to 10, with 1 being not confident at all that you could make this first change and 10 being extremely confident. (*assessing confidence with scaling ruler*)

Client: I don't know . . . I guess about a 5.

Counselor: OK, a 5. Can you tell me why not a 4 or a 6? (*asking open question to elicit change talk*)

Client: Well, I can stop if I want to, so I wouldn't choose anything less than a 5. But it's just really hard to not go with my buddies. I get bored easily, and I don't want to be left out.

Counselor: So it's hard for you to deal with the temptation to drink. (*simple reflection to express empathy*) What might help you feel more confident, maybe move you to a 6 or a 7? (*asking open question to elicit change talk*)

Client: I just need some friends who don't drink so much. Or maybe I need to spend more quality time with my family and girlfriend instead of getting drunk.

Counselor: So changing your social circle and shifting your priorities around a bit. (*simple reflection of change talk*)

Client: Yeah, those might end up being good things for me.

Counselor: As we're nearing the end of our time today, let me offer a summary of what we've talked about so we can see if I've captured what you've been saying. On the one hand you have fun drinking with your friends, and on the other hand you feel guilty for how your drinking upsets your girlfriend, and you'd like to be moving along in life, getting a job, being a reliable man, I think you said. (*double-sided reflection to highlight discrepancy*) Some things you've talked about doing are finding new activities for Friday nights and maybe finding some friends to hang out with who don't drink. (*summarizing*) What did I leave out? (*checking in*)

Client: I guess that about says it all—I want things to be different.

Counselor: You are ready for a change. (*simple reflection of change talk*) I know that you can change your drinking if that's what you decide to do (*supporting self-efficacy*), but of course that decision is up to you. (*emphasizing autonomy*) I appreciate your willingness to be so open today, (*affirming*) and I'm looking forward to learning more about you next time we meet.

CONCLUSION

MI is an evidence-based counseling approach that is appropriate across cultures, populations, settings, and behaviors. It strives to tip motivational balance in favor of change for clients who are highly ambivalent, and to provide collaborative problem-solving and coaching for clients who have committed to change. The MI counselor embodies a spirit of collaboration, evocation, and respect for client autonomy and focuses on the grounding principles of expressing empathy, developing discrepancy, rolling with resistance, and enhancing self-efficacy. Core MI counseling strategies include

asking Open questions, Affirming, Reflecting, and Summarizing (*OARS*). Also central to MI are the strategies of eliciting change talk and providing personalized feedback. Scaling rulers can be used in MI to assess a client's readiness to change, while the *typical day exercise* and *values clarification exercise* can be used to maximize the amount of information elicited from clients about their substance use and values. Becoming a proficient MI counselor requires training and disciplined practice coupled with feedback and coaching. Working with Clients Who Have Recovered Memories

Susan P. Robbins

One of the most controversial and divisive issues among mental health professionals and researchers in the past two decades has been the delayed recovery of memories of traumatic events. During the 1990s, major social work journals carried a handful of articles on this topic (see Benatar, 1995; Robbins, 1995; Stocks, 1998). In contrast, well-respected journals in psychology, psychiatry, and law published numerous articles

and special issues dedicated to the debate about the nature, veracity, and accuracy of recovered memories, particularly memories of childhood sexual abuse (CSA). More recently, continued research in this area has focused on laboratory experiments in word memorization, cognitive processes involved in both remembering and motivated forgetting, Vietnam veterans with posttraumatic stress disorder, source monitoring,

the effects of misinformation in real world settings, and neuroimaging of cognitive processes that give rise to true and false memories (Belli, 2012; McNally, 2005). According to McNally, the debate about recovered memory “is unresolved, but not irresolvable” (p. 26).

At the heart of this debate is whether it is possible to repress or dissociate all memory of CSA and later accurately recall the trauma as an adult. Two related questions pertain to the actual prevalence of abused children who completely forget their early abuse and the specific mechanisms responsible for the absence of memory. These became contentious issues because some believe that early memories of traumatic events that are inaccessible to the conscious mind can nonetheless affect one’s social and psychological functioning throughout life.

During the 1980s and 1990s, thousands of people, primarily white middle-class women, were diagnosed by mental health practitioners such as social workers, psychologists, psychiatrists, and substance abuse and other counselors as having been victims of sexual abuse in their childhood, despite a total lack of recall of any such event. Others, who had continuous memories of early abuse, were told that they were victims of additional episodes of CSA, which they did not recall and which were often horrific in nature, such as satanic ritual abuse (SRA). Recovered memories of SRA most typically included being drugged, brainwashed, and forced to watch or participate in satanic rituals that often included murder or rape by multiple perpetrators. Seeking mental health and counseling services for a broad array of problems that included depression, eating disorders, marital difficulties, substance abuse, and bereavement (among others), clients began to allegedly “recover” memories of CSA and SRA with the help of their therapists, spontaneously, or upon reading books for sexual abuse survivors and attending self-help groups.

Clinicians who strongly advocated the use of memory recovery techniques believed that it was necessary for their clients to retrieve their previously forgotten memories of CSA in order to heal and recover from what they believed to be a forgotten but unresolved trauma. Concepts such as repression, dissociation, traumatic amnesia, and multiple personality disorder (MPD) (later renamed dissociative identity disorder [DID]) were used to explain why memory of the alleged trauma was not available to the conscious mind. In the quest to assist clients in recovering these

memories, a variety of therapeutic techniques were used that included, but were not limited to, hypnosis, truth serum, guided imagery, dream interpretation, age regression, free association, journaling, psychodrama, reflexology, massage and other forms of “body work” to recover “body memories,” primal scream therapy, attending survivor’s groups, and reading books on recovering from sexual abuse. Clients were often encouraged by their therapists and self-help groups to believe in the veracity of their newly recovered memories, define themselves as “survivors,” and interpret their present-day problems and symptoms in terms of their early unresolved trauma. Although reports of recovered memories began to wane by the late 1990s, largely due to the refusal of insurance companies to pay for diagnoses that supported its use, recovered memory therapy (RMT) continued to be practiced by those who remained convinced of its utility, despite research that found such techniques to be both questionable and harmful.

Therapy of this sort had consequences not only for the clients, but for their families as well. As the retrieval of recovered memories came to be seen as the path to healing, many clients were also encouraged to confront their alleged perpetrators and break off all contact with anyone in the family who questioned the veracity of their newly recalled memories. Further complicating this issue were criminal and civil charges that clients were encouraged to file against family members as part of their recovery process. Over the years, a large number of cases involving claims of recovered memory reached the appellate courts and raised serious issues related to discovery rules, statutory limitations, and rules of scientific evidence.

Beginning in 1992, a small group of parents who claimed to have been falsely accused joined together with sympathetic professionals to form a support and advocacy organization, the False Memory Syndrome Foundation (FMSF). In addition to sponsoring scientific and medical research on memory, suggestibility, and repression, the FMSF disseminated research to the media, the public, and to the legal and mental health professions. Their final newsletter was published in 2011, as a mounting body of research on memory cast serious doubt on the ability of people to totally forget and later remember traumatic events (McNally, 2005), and new claims of recovered memories dramatically declined. A growing number of people have since recanted their

accusations of abuse, accusing their therapists of pressure, suggestion, and coercion.

More recently, the existence of MPD/DID, one of the underlying mechanisms used to explain repressed memory, has come under serious scrutiny. In a well-researched expose of Sybil, one of the most famous cases of MPD that is credited with launching the multiple personality craze, Nathan (2011) documents the ways in which otherwise well-meaning but misguided therapy led to the total fabrication of Sybil's multiple personality "alters." Supporting this position, Allen Francis (2014), Chair of the *DSM-IV* Task Force, has questioned not only the suggestive therapeutic techniques used to create such alters, but also the validity of the diagnosis itself.

Although this has strongly bolstered the position that such memories are the product of unethical therapy rather than events rooted in reality, recovered memory advocates are skeptical that suggestive techniques can create false memories of CSA. To date, there are no accepted standards for determining the veracity of reports of abuse that are based solely on recovered memories and most agree that it is impossible to determine the validity of recovered memories without external corroboration.

This supports the thorough previous review of the literature on RMT, in which Stocks (1998) examined the various techniques and therapeutic interventions that were commonly used to assist in the recovery of abuse memories as well as the impact of such therapy on client outcomes. Noting the historical ambivalence towards sexual abuse that was prevalent until the latter part of the twentieth century, Stocks also provided a discussion and critique of the initial studies that led some clinicians and researchers to conclude that CSA memories were frequently repressed. In doing so, he cautioned that the reality of abuse should not be confused with skepticism about recovered memories of abuse. This echoed Loftus and Ketcham's earlier position (1994) that the disagreement about memory is not a debate about childhood sexual abuse.

According to Stocks (1998), the research on RMT shows that such techniques are not reliable in recovering valid memories. Although some recovered memories may be accurate, many are partly or totally confabulated, and there is no way to distinguish reliably between those that are real and those that are not. Further, he found no conclusive evidence that memories of this sort have any clinical utility. In fact, the few existing

outcome studies suggest that RMT is likely to lead to deterioration rather than improved functioning. Based on this, Stocks warned that the risks of RMT far outweigh the perceived benefits, discussed the necessity of informed consent for therapy that is unreliable and potentially harmful, and concluded that social workers should avoid using such techniques in their practice. Subsequent letters to the editor in response to his article reflected the professional division concerning the nature of recovered memories and the utility of RMT.

A similar split can be seen in the 1996 final report of the American Psychological Association Working Group on Investigation of Memories of Childhood Abuse. The clinicians in the group differed from the researchers on several points including the mechanisms that are responsible for delayed recall, the frequency of the creation of false memories, and the rules of evidence for testing hypotheses about memory and the consequences of trauma. They concluded that their failure to reach consensus was due in part to "profound epistemological differences" between the researchers and the clinicians. Contentious issues related to recovered memories have not abated and continue, despite attempts at reconciliation (Belli, 2012). This basic disagreement is reflected in the field of social work as well.

There is, however, an underlying professional consensus in four basic areas as summarized in Table 88.1. (Knapp & VandeCreek, 2000, p. 336; APA, 1996).

Despite these significant areas of consensus, ongoing areas of disagreement continue to divide professionals in the field (Belli, 2012). This division is not merely an academic debate inasmuch as it directly affects the theories and practice techniques that are used with clients. By the mid 1990s, most of the major professional organizations issued warnings concerning suggestibility and false memories. One of the strongest cautionary statements came from the American Medical Association (AMA) in its position that, "The AMA considers recovered memories of childhood sexual abuse to be of uncertain authenticity, which should be subject to external verification. The use of recovered memories is fraught with problems of potential misapplication" (AMA, 1994, p. 4).

Most early organizational statements on recovered memory therapy urged the use of caution, with the acknowledgement that recovered memories may or may not be true. Many of the later

TABLE 88.1 Consensus on Recovered and False Memories

Child Abuse	<i>Child abuse is harmful and prevalent.</i> Satanic or ritual abuse is rare.
Memory and the Creation of Memories	Most people who were sexually abused remember all or part of what happened to them. Adults with continuous memories of being abused are likely to have accurate memories. Although it is rare, some memories of past traumas can be forgotten and later remembered. Memories from infancy are highly unreliable. False or pseudomemory memories can be created. Magnification and minimization are better ways to conceptualize memories than the dichotomy of "true" or "false." It is difficult to ascertain the accuracy of memories recovered by suggestive "memory recovery" techniques. It is impossible to distinguish a true memory from a false one without other corroborative evidence.
Diagnosis of and Psychotherapy with Patients with Memories of Abuse	Child abuse, in and of itself, is not a diagnosis. Child abuse cannot be assessed from a set of current symptoms or a checklist of symptoms. Mental illness and mental disorders have many causes. Psychotherapists should ask patients about past childhood abuse if it is clinically indicated. Memory recall of abuse is not necessary for effective therapy to occur. The focus of treatment should be on the current functioning of the patient. Treatments should be tailored to the individual needs of each patient. At times, patients may need to learn to live with ambiguity about the veracity of memory or memory fragments.
Role of Psychotherapists	Psychotherapists need to respect and promote patient autonomy. Psychotherapists need to scrupulously maintain professional boundaries. Psychotherapists need to maintain therapeutic neutrality on the issues of litigation and confrontation. Even though psychotherapists have no primary legal duty to third parties, they should not be oblivious to the impact of their actions on those third parties.

statements more explicitly warn against the use of memory recovery techniques as a method or focus of practice. A good chronology of statements and positions on RMT made by professional organizations can be found on the Internet at: http://www.religioustolerance.org/rmt_prof.htm.

Subsequently, professional concerns focused on informed consent and, as noted by the American Academy of Psychiatry and the Law

(1999, p. 2), in light of the warnings given by most professional organizations, "Few would currently argue against informing patients about the fallibility of memory and the dangers involved with recovering memories of sexual abuse." Given the unproven clinical utility of RMT, coupled with the lack of evidence that the benefits of such therapy outweigh the risks, the issue of informed consent is critical for social

workers inasmuch as this is also mandated by the National Association of Social Workers' (NASW) Code of Ethics (NASW, 1996a).

A specific practice statement addressing the evaluation and treatment of adults with the possibility of recovered memories of childhood sexual abuse, developed by the NASW National Council on the Practice of Clinical Social Work, was published in June 1996. In this statement social workers are cautioned to (a) establish and maintain an appropriate therapeutic relationship with careful attention to boundary management; (b) recognize that the client may be influenced by the opinions, conjecture, or suggestions of the therapist; (c) not minimize the power and influence he or she has on a client's impressions and beliefs; (d) guard against engaging in self-disclosure and premature interpretations during the treatment process; (e) guard against using leading questions to recover memories; (f) be cognizant that disclosure of forgotten experience is a part of the process but not the goal of therapy; and (g) respect the client's right to self-determination (NASW, 1996b, p. 2).

Due to the prevalence of RMT during the 1980s and 90s and the sensationalized media coverage of recovered memories, social workers are likely to encounter clients who were previously, or even recently, subjected to a variety of RMT techniques, abuse survivor groups and literature, or who spontaneously recovered abuse memories. Some clients may still believe in the veracity of these memories, while others may have come to question them. Others may have fully recanted their abuse allegations upon realizing that their memories were inaccurate or iatrogenically induced in therapy. Working with such clients can prove to be a challenge for social workers, because most typically receive little or no formal education regarding the nature of memory or the suggestive techniques that can create false memories.

As noted elsewhere (Robbins, 1997), it is critical that social workers adhere to NASW guidelines when working with clients who have possibly recovered memories of childhood sexual abuse. Neutrality about the veracity of such memories is critical because it is impossible to determine the accuracy of memories without external corroboration. This is especially true when RMT techniques have been used. The NASW guidelines caution that "enthusiastic belief or disbelief can and will have an effect on the treatment process" (NASW, 1996b, p. 2). Personal biases may result in incorrect diagnosis and inadequate or inappropriate treatment.

Social workers should always follow accepted professional standards when diagnosing and treating clients. Information about abuse and other negative childhood experiences should be gathered in the course of obtaining a complete psychosocial history, but this should only be one part of a holistic assessment that includes an evaluation of the client's "total clinical picture including symptoms and level of functioning" (NASW, 1996b, p. 2).

It is also important to remember that CSA is an event in a person's life; it is not a diagnosis and should not be treated as such. In addition, CSA should not be inferred from any specific symptoms or cluster of symptoms (APA Working Group, 1996). Social workers should also be cognizant of the fact that most victims of CSA either completely or partially remember their abuse. Although delayed recall is possible, the frequency of abuse memories that are forgotten and later recalled is not known (Knapp & VandeCreek, 2000; Belli, 2012).

Treatment should always be based on a complete assessment, informed by the scientific literature, and designed to meet the individual client's needs, and the emphasis should be on the client's current functioning (Knapp & VandeCreek, 2000). According to NASW (1996b, p. 2), the social worker's responsibility is to "maintain the focus of treatment on symptom reduction or elimination and to enhance the ability of the client to function appropriately and comfortably in his or her daily life."

In accordance with this, archeological reconstruction of one's past and placing a focus on working through painful emotions should not be the primary goal of treatment. If a client enters treatment with the desire to discuss or examine recovered memories, NASW (1996b, p. 2) recommends that social workers "explore the meaning and implication of the memory for the client, rather than focusing solely on the content or veracity of the report." In addition, it is the responsibility of the social worker to inform the client that their memory may be "an accurate memory of an actual event, an altered or distorted memory of an actual event, or the recounting of an event that did not happen."

Clients who have recanted memories of abuse may need assistance in understanding the dynamics that led them to believe in recovered memories of events that never happened. A psycho-educational approach can assist them in understanding the nature of memory, memory

reconstruction, and the specific techniques that can lead to false memories. They may also need help in resolving issues of guilt and self-blame and in re-establishing relationships within their families. This is particularly true if their abuse memories resulted in accusations, angry confrontation, legal action, or alienation among family members.

Social workers should also be cognizant of legal issues related to recovered memories and be fully informed about issues related to risk management. Although the social worker's primary responsibility is to the client, she or he should also be concerned about the effect of false allegations on the accused, many of whom are family members. The guidelines developed by NASW (1996b) discuss this in detail, with specific recommendations related to record keeping, informed consent, client self-determination, and requisite knowledge of state and federal laws.

Finally, it is incumbent upon social workers to have adequate training, and to maintain current skills and knowledge in the areas of trauma and memory if they are working with clients who have histories of abuse or recovered memories of abuse. Scientific research in this area is constantly emerging and social workers must be able to critically assess new findings and be open to incorporating new evidence-based knowledge into practice.

89 Terminating with Clients

Anne E. Fortune

REASONS FOR ENDING SERVICE

Common reasons for ending social work service include planned ending of time-limited service, ending of open-ended service either unilaterally or by mutual agreement, and unanticipated external factors (Fortune, 1985; Fortune, Pearlingi, & Rochelle, 1991; Westmacott & Hunsley, 2010). The specific reason for ending influences participants' expectations, reactions, and appropriate interventions during the termination phase (Baum, 2005, 2007; Westmacott, Hunsley, Best, Rumstein-McKean, & Schindler, 2010).

Ending Planned, Time-limited Contacts

In time-limited service, participants know how long their contact will last and use that sense of time to frame their work, maintain focus, and motivate participants. Because of the short duration, the foreknowledge of ending and, frequently, the clarity of goals or problems, decisions about when and how to terminate are usually easier than in open-ended service and less preparation is needed.

Ending Open-ended Service by Mutual Agreement

If there are no time limits, ending ideally occurs when clients and social workers agree that service is no longer desirable. The literature suggests eclectic indicators of success to determine when to end, including:

- Meeting goals set by clients, practitioners, or outside arbitrators such as judges.

- Improved behavior, relationships, and intrapsychic functioning for clients.
- In family treatment, improvements in the relationship among family members (e.g., improved interaction and communication) and better family relations with others (e.g., more appropriate boundaries).
- Lack of success. Unless the goal is maintaining functioning in a chronic condition, ethical considerations demand that treatment end: (1) if there is little improvement and little reasonable expectation of improvement, or (2) if further gains are not worth the time and energy required.

The reality of open-ended treatment is that these criteria rarely guide ending. Instead, when termination is mutually agreed, clients may hint—subtly or directly—that things are better and that treatment is no longer needed (Råbu, Binder, & Haavind, 2013). Clients and practitioners then conduct a dance to negotiate termination. Each party is concerned primarily with the feelings of the other, and ending occurs when they “find a way to resolve basic ambivalences concerning ending” (Råbu et al., 2013, p. 19).

Unilateral Client Terminations (Drop-outs)

Clients may decide to end by dropping out without informing their social workers. Although dropping out is often viewed as a treatment failure, as many as two-thirds of dropouts report considerable progress (Westmacott et al., 2010). Many so-called dropouts occur after practitioners miss clients' hints that they are ready to terminate. Practitioners tend to underestimate both clients' progress (especially compared to clients'

estimates) and clients' dissatisfaction with treatment (Westmacott et al., 2010). In extreme cases, practitioners may feel blindsided by a premature ending, but upon reflection recognize the clients' dissatisfaction and their own frustration with treatment (Piselli, Halgin, & Macewan, 2011).

Clients who drop out miss the opportunity to assess the treatment process and solidify gains through planned maintenance interventions, while practitioners also miss the opportunity for reflection and professional growth.

Unanticipated Endings

Many open-ended cases end partly or wholly because of unexpected situational factors. Unanticipated or unplanned reasons for ending include:

- Practitioners leave an agency or become ill.
- Students end their social work internships.
- Schedule changes, transportation problems, expenses
- Parents remove children from treatment.
- Agency constraints, such as excessive caseloads or demise of a program.

In unanticipated endings, progress is rarely optimal, although again practitioners are often more cynical than clients (Westmacott & Hunsley, 2010). Despite limited progress, gains can be consolidated by conducting termination-phase interventions, including dealing with disappointment or anger, assessing gains, and suggesting how clients may continue progress. Practitioners should also consider transferring clients to other service providers.

Transfer to Another Service Provider

Clients may transfer elsewhere when service is cut off—for example, if the social worker leaves the agency, more appropriate service is available elsewhere, or the client and worker do not get along. Termination of the relationship between initial social workers and clients is similar to other situations, with social workers also facilitating linkages with new social workers.

Ending in Managed Care

Managed care and insurance-supported services usually have standard time limits imposed by the service provider (Cuffel et al., 2000). Extension

beyond the time limits requires administrative review and approval. Most social work providers consequently plan time-limited treatment with specified goals. Termination is “built in” and handled as for other forms of planned time-limited treatment. The provider rarely ends service, but if an extension is requested the uncertainty about continuing service may complicate termination. There may be dashed hopes, anger, and an inability to use the positive effects of time limits. Nevertheless, whenever possible under managed care, the formal interventions of the termination phase should be conducted, especially after a denied extension.

CLIENT' REACTIONS TO TERMINATION

Although much of the literature describes termination as a gloomy process of mourning, most clients have more positive reactions than negative feelings (Baum, 2005; Fortune, 1987; Knox et al., 2011; Roe, Dekel, Harel, Fennig, & Fennig, 2006; Siebold, 2007). The ending of service usually means accomplishments as well as losses and new beginnings and independence for clients. A wide range of reactions is “normal” with individual expressions and cultural variations in what emotions are appropriate and how they may be expressed. Common reactions during the termination phase include:

- Clients naturally evaluate their progress and goal attainment, summarize their work in treatment, and review the treatment process itself.
- In intrapsychic and existential treatments, the focus shifts to concurrent and future outside activities, with clients expressing a growing sense of autonomy.
- Clients are proud of their accomplishments, excited at ending, and satisfied.
- Clients express ambivalence about ending, including sadness, a wish to continue the relationship, and ambivalence about whether progress is sufficient. Ambivalence may show itself actively in lateness or missed sessions.
- Clients may re-experience previous losses or recreate earlier treatment experiences, often as part of integrating therapeutic growth.

Less commonly, clients experience negative reactions that must be handled separately from

normal termination reactions. These negative reactions include:

- In successful long-term treatment, mourning the loss of an intense relationship, with stages of denial, anger and loss, depression, and finally acceptance
- Anger or bitterness
- Regression to previous inappropriate behaviors or acting out
- Extreme negative emotions like depression, feeling “destroyed,” or loss of self-esteem.

Factors Affecting Reactions to Termination

Several factors affect clients’ reactions to termination.

Reason for Termination

- When service ends unexpectedly, reactions are more negative: more anger, problematic behaviors, mourning, mood disturbances, and a sense of unfinished business (Baum, 2005).
- When the ending is mutually agreed upon, there is more pride and excitement (Roe, Dekel, Harel, & Fennig, 2006).
- Dropouts are less satisfied than those who end by agreement, but are more satisfied than the practitioner thinks (Westmacott et al., 2010).

Outcome

- The more successful the outcome, the more positive clients’ reactions (pride, accomplishment, sense of independence, etc.) (Cuffel et al., 2000; Kacen, 1999; Knox et al., 2011; Roe, Dekel, Harel, & Fennig, 2006).
- The more successful the outcome, the more temporary anxiety or hurt, as well as greater distancing from the therapeutic relationship as clients prepare for the end (Baum, 2005).

Therapeutic Alliance

- The stronger the therapeutic relationship or working alliance, the more positive clients’ feelings at ending (Knox et al., 2011; Roe, Dekel, Harel, Fennig, et al., 2006). However, during the termination process, such clients often have stronger negative reactions,

anxiety, and sense of loss than clients with less attachment to the practitioner (Kacen, 1999).

Preparation for Ending

- Early preparation (including setting time limits at the beginning) has important benefits: (1) introduction of affective content can be managed to allow therapeutic processing; (2) clients have time to work through their reactions; and (3) clients are less likely to act out during termination (Fortune, Pearlingi, & Rochelle, 1992).
- Systematic processing during the termination phase is associated with positive reactions and appropriate transitions (Baum, 2005; Knox et al., 2011; Roe, Dekel, Harel, Fennig, et al., 2006). Fruitful processing may include assessment of outcome, review of the therapeutic process, and focus on both positive and painful or frustrating aspects of the relationship.

Previous Loss

- Clients with unresolved loss may go through mourning reactions as they re-create the previous loss experiences (Zilberstein, 2008). In some theoretical approaches, treatment generally and termination in particular is viewed as a corrective experience that enables clients to learn new, better ways of coping with relationships and loss.

Other factors such as type of service or modality may affect reactions to termination, but studies are lacking. One rarely studied factor is culture, or race and ethnicity. We know that minority clients end treatment prematurely more often than others (Snowden & Yamada, 2005), but we do not know if reactions are similar or culturally defined. The *meaning* of ending may differ among cultures. Urban adolescents who were more engaged in mental health services were *more* likely to drop out without acknowledging termination than less engaged adolescents (Mirabito, 2001, 2006). Elsewhere, in tight-knit rural and in ethnic urban communities, once practitioners provided service, they and their resources were considered part of the community; the concept of ending did not exist (Graham, Shier, & Brownlee, 2012). In general, our knowledge of different definitions and reactions to termination is based primarily on anecdotes, rather than systematic study (see, for example, Gutheil, 1993; Walsh, 2007; Wayne & Avery, 1979).

SOCIAL WORKERS' REACTIONS TO TERMINATION

Social workers, too, experience a range of emotions at ending with each client. Typically, reactions are less intense mirrors of clients' reactions. They include pride in clients' accomplishments and in their own therapeutic skills, ambivalence, sadness, a sense of overview of the treatment process, and sometimes hurt at abandonment, doubt, disappointment, and guilt about the limits of their helping abilities (Fortune et al., 1992; Piselli et al., 2011; Westmacott et al., 2010). Factors related to practitioners' reactions are also similar to those that influence clients' reactions. For example, practitioners whose clients dropped out unilaterally had more negative emotions than those with mutually agreed upon terminations (Baum, 2007; C. Gelman, Fernandez, Hausman, Miller, & Weiner, 2007; C. R. Gelman, 2009). Practitioners whose clients had better outcome reported more pride in their clients' successes and in their own skills (Baum, 2007; Fortune, 1987).

Social workers should be aware of their own reactions for several reasons:

- Social workers' reactions affect their ability to recognize when to end or how to intervene. For example, they may enjoy a client, be reluctant to admit they are not helpful, or miss warning signs that the client is dissatisfied.
- Countertransference (attributing one's own feelings to the client) may lead to inappropriate interventions.

INTERVENTIONS FOR THE TERMINATION PHASE

Termination interventions should be an integral part of treatment planning. Interventions during the termination phase differ from change interventions in earlier phases of treatment, although they require the same good therapeutic relationship, planning, and implementation skills. The termination interventions are designed to help clients (1) assess progress and the treatment process, (2) generalize gains to other settings and situations, (3) develop skills and strategies to maintain gains, (4) make the transition to no service or to another service, and (5) deal with emotional reactions to ending. We also mention practitioners' self-development interventions

that can enhance their personal and professional growth.

Assessing Progress and Process

A primary task during termination is assessing the status of goals and clients' problems (Fortune, 1987; Roe, Dekel, Harel, Fennig, et al., 2006). Purposes of the progress review are to:

- Provide data to confirm (or disconfirm) tentative decisions to terminate.
- Assess progress realistically and solidify the clients' learning during treatment.
- Increase clients' sense of mastery and ability to cope, which are important to continued functioning.
- Provide information to shape other termination interventions, for example, clients' strengths for future problem-solving efforts.

Clients and social workers also review the treatment process, emphasizing the problem-resolution steps and skills clients can use in the future. The review helps bring closure by giving an overview of the course of treatment.

Generalizing Gains

Unless deliberate efforts are made to broaden gains, clients' use of new skills may be limited to circumscribed areas—for example, improved communication at work but not with family members. Some termination activities are designed to expand the use of new cognitive or interpersonal skills (generalization) and to improve their durability after ending (maintenance) (Fishman & Lubetkin, 1980). Activities to extend client gains to other areas include:

- Learning general principles about dealing with problems—for example, problem-solving skills, anger management, or family communication
- Transferring skills from treatment sessions to clients' natural environments through homework assignments or tasks, for example, trying out "I statements" learned in group treatment at home with family members
- Systematically transferring skills from one situation to another, for example, a child sharing activities with others first in the classroom, then at recess.

Maintaining Gains

Another concern is how long clients' gains last after treatment ends. Interventions that help maintain gains include:

- Increasing clients' sense of mastery through realistic praise and highlighting their role in creating and maintaining change
- Internalizing the "voice" or persona of the practitioner so the memory of the practitioner remains as a guide for clients after ending (Råbu, Binder, et al., 2013; Zilberstein, 2008). Råbu, Haavind and Binder (2013) talk about "the co-creation of metaphors" regarding the therapeutic alliance as a way to create memories for clients to draw on in the future. For example, metaphors about cleaning may convey how practitioners and clients together have cleaned up and sorted things out.
- Discussing general principles that underlie coping and change
- Ensuring that newly learned skills are appropriate for the clients' normal environments.
- "Fail-safe planning" (Fishman & Lubetkin, 1980) or how to deal with future difficulties, such as handling potential conflict around a child's report card
- Ensuring that the new skills are supported in the client's environment, such as:
 1. Bringing clients' support systems directly into treatment, for example, inviting a spouse to termination sessions to discuss maintenance, or including a schoolchild's friends in treatment designed as a "club."
 2. Creating new support networks through joining existing organizations, such as Alcoholics Anonymous, church groups, or social interest groups (cards, classes to learn new skills, hunting, etc.)
 3. Teaching clients how to elicit support from significant others
 4. Conducting follow-up booster sessions that include maintenance interventions such as reinforcing what clients are doing well, reviewing principles, discussing coping strategies, and planning for the future.

Making the Transition

If clients are not prepared to function without treatment, all the gains can be lost quickly.

To ease the transition, practitioners reduce any overdependence and assure that clients are ready to function on their own (or with different services). Interventions that help accomplish the transition out of treatment include:

- Within the content of treatment sessions, a systematic shift in time focus from past activities through present functioning and then a future orientation, for example, from childhood trauma to current handling of emotional triggers to means of responding in the future
- Increased attention to outside treatment activities and supports through:
 1. Discussing events in clients' lives
 2. Maintenance and generalization activities such as homework assignments and fail-safe planning
 3. Activities that take place away from the normal context, such as a trip to a park for youngsters.
- Using natural breaks like vacations to test readiness for clients to function on their own, or deliberately increasing time between sessions (fading) so clients get used to being on their own (C. Gelman et al., 2007).
- Having clients take as much control over the ending process as possible (Fragkiadaki & Strauss, 2012; Råbu, Binder, et al., 2013)
- In groups, reducing cohesion by decreasing the cooperation and interaction required from group activities—for example, boys playing table tennis (an individual game) instead of soccer (a teamwork activity), or adults developing homework tasks in pairs rather than in full groups
- When clients are transferring to service elsewhere, interventions to smooth the transition to new agencies or social workers include:
 1. Linking clients to referral agencies by providing thorough information about contacting the agencies, making an appointment for the clients, or accompanying the clients to the agencies
 2. Ensuring that new providers are prepared for the clients by consulting with the providers, explaining expectations, and sharing information (with clients' permission)
 3. Following up with clients and new providers after their initial meetings to ensure that the connections are made

4. To minimize clients' feelings of rejection, discussing openly the reasons for termination/transfer and exploring clients' feelings and expectations of the new services.

Dealing with Clients' Emotional Reactions to Ending

Expressing feelings is an important part of the ending phase. Acknowledging the emotions makes them acceptable, validates the clients' experiences, and provides models for handling both affect and termination. Interventions to elicit reactions and build on them for therapeutic purposes include:

- Encouraging clients to talk about their feelings by:
 1. Exploring expressions of ambivalence (as well as other expressions of emotion)
 2. Modeling self-disclosure by introducing the social worker's own reactions (this also helps shift the therapeutic relationship to greater collegiality)
 3. Describing in words the emotions clients seem to express nonverbally, such as angry gestures, evading discussion, or hesitant pride
- Once clients express emotion, build on these reactions for other treatment or termination interventions. For example:
 1. Build on positive feelings (such as pride in accomplishments) to reinforce clients' sense of mastery.
 2. Label ambivalence and sadness as normal, healthy expressions of ending.
 3. Handle strong negative reactions as intensive grief reactions that can be resolved through stages of mourning.
- Introducing activities designed to elicit clients' reactions and to provide opportunity for other termination interventions. For example:
 1. Artistic activities such as individualized coloring books that include highlights of children's treatment, such as "memory books" (Elbow, 1987). Such activities encourage review of the treatment process and help solidify gains (assessing progress and process). The artistic products themselves are mementos for clients (ritual markers).
 2. In educational groups, a "toast" to each person about what members learned from them reinforces learning and a sense of mastery, as well as celebrates ending.
- Introducing formal termination rituals. Such rituals help clients deal with conflicting emotions, give a sense of specialness and make connections between past and future. Appropriate rituals include:
 1. Culturally defined good-bye markers like hugging and shaking hands
 2. Complex exchanges of mementos with special meaning, such as photographs, certificates of completion, or gifts that convey the essence of a person
 3. Elaborate events, such as graduation ceremonies or status elevation ceremonies. Such celebrations may also serve other purposes, including demonstrating individual accomplishments and reviewing the treatment experience. For example, in a group to increase self-esteem, a potluck (covered dish) supper with each person contributing his or her ethnic specialty (Wayne & Avery, 1979).
 4. Encouraging clients to choose special or symbolic activities that will help them organize and remember the therapeutic experience, such as a client and practitioner walking together in the park (Walsh, 2007).

Managing Practitioners' Reactions during the Termination Phase

Done well, termination is a mutually beneficial interaction, a partnership or dance (Råbu, Binder, et al., 2013; Siebold, 2007). Because practitioners' reactions and interventions affect clients' termination, practitioners' professional responsibility requires understanding those reactions and using them to benefit clients. But, for practitioners, as for clients, the termination phase offers opportunities for professional development (Baum, 2007; Fragkiadaki & Strauss, 2012; C. Gelman et al., 2007). Termination is viewed as a transition, not as a loss of clients. Reviewing cases allows social workers to assess the treatment process: what worked, what was overlooked, what were potential mistakes. Assessing their own skills will, one hopes, generate a sense of pride, but even doubts are catalysts for future improvements. It is hoped, too, that social

workers will affirm their self-identities as helpers and recommit to helping people.

Not all cases go well. Clients dropping out often upsets practitioners, especially those who are introspective and honest enough to recognize mistakes and acknowledge their own roles in such drop-outs (Piselli et al., 2011). Even good cases can have bad endings, if practitioners mishandle the termination phase. To aid constructive personal growth when cases end distressingly, Schaeffer and Kaiser (2013) offer a structured approach: honor the practitioner's initial reaction to the termination; appraise possible causes; determine the most probable cause, take appropriate responsibility; mourn; perform reparation for current and future clients; evaluate their own well-being and sense of self-efficacy; and take a broader perspective for the future.

Social workers may give short shrift to termination; with that in mind, it is worth noting that experienced (presumably good) practitioners not only process ending sensitively during the termination phase, but are also continually aware of termination and its implications from the very beginning of service (Baum, 2007; Fragkiadaki & Strauss, 2012).

Is Ending the End?

Traditionally, the end of service was considered an absolute, and professional pride dictated that social workers manage their boundaries and be definitive in ending. Contemporary views are not so black-and-white. As mentioned earlier, some communities or cultural groups do not recognize the concept of ending in the way western service providers do (Graham et al., 2012), leading Mirabito (2001) to recommend intermittent service and open-door policies. Most social work services are no longer thought of as "cures" but as assistance with identifiable but recurring difficulties. Managed care has required and indeed normalized short-term treatments. Theoretically, too, ideas about practitioners' roles have changed. Attachment theory suggests creating transitional objects—memories of practitioners—that stay alive in clients' minds after termination (Siebold, 1992; Zilberstein, 2008). Răbu, Binder, and colleagues (2013) suggest that the possibility of future contact creates a sense of safety for clients that aids ending.

Opinion has similarly shifted about parting gifts and mementos. Previously viewed

as boundary violations and a breach of ethics, mementos are now viewed as symbolic markers representing multiple meanings to participants.

In short, termination may or may not be the last time practitioners and clients interact professionally. Aside from ethical prohibitions on transforming professional relationships into personal ones, there are few absolutes about termination ending all therapeutic relationships. Services should not continue if clients are not benefiting. Otherwise, the immediate context and professional ethics should guide decisions about irrevocable terminations and gift exchanges.

SUMMARY

Termination is as important to ethical social work practice as engagement, assessment, and treatment planning. Whatever the reason for ending, early preparation and careful interventions during the termination phase helps clients maintain gains and deal with the practical and emotional reactions to ending.

Specific Interventions*

Transtheoretical Model Guidelines for Families with Child Abuse and Neglect

Janice M. Prochaska, James O. Prochaska, & Judith J. Prochaska

In the child abuse field, caseworkers often use compliance with case plans as a proxy or indicator of change. Thus, parents who attend parenting classes or go to counseling are seen as changing—even if those same parents continue to deny abuse and neglect. Compliance with a court-ordered program of services or classes is, however, not the same as psychological readiness to change or actual change in behavior.

The transtheoretical model of behavior change offers a more reliable, valid, and complex assessment of change than a simple recording of compliance. The model assumes that changing behavior is a dynamic process and that one progresses through a series of stages in trying to modify behavior—precontemplation, contemplation, preparation, action, and maintenance. Over thirty-five years of research on a variety of behaviors have identified interventions that work best in each stage to facilitate change (Prochaska, Norcross, & DiClemente, 1994; Noar, Benac, & Harris, 2007).

DEFINITIONS OF STAGES

Each of the five stages represents a period of time, as well as a set of tasks needed for movement to the next stage. Although the time an individual spends in each stage may vary, the tasks to be accomplished are assumed to be invariant.

Precontemplation is the stage at which there is no intention to change behavior in the foreseeable future. Most individuals in this stage are unaware or underaware of their problems. Family, friends, or neighbors, however, are often

well aware that the precontemplator has a problem. When precontemplators present for help, they often do so because of pressure from others. Usually they feel coerced into changing by a spouse who threatens to leave, children who threaten to disown them, or courts that threaten to punish them. They may also be demoralized from having tried to change and failed.

Measures that identify where clients are in the change process (i.e., their stage of change), ask individuals if they are seriously intending to change the problem behavior in the near future, typically within the next six months. If not, they are classified as precontemplators. Even precontemplators can wish to change, but this is quite different from intending or seriously considering change. Items that are used to identify precontemplation on a continuous stage of change measure include, “I have done nothing wrong and resent child welfare getting involved in my life” or “I guess I have faults, but there’s nothing that I really need to change.” Resistance to recognizing or modifying a problem are the hallmarks of precontemplation.

Contemplation is the stage at which people are aware that a problem exists and are seriously thinking about overcoming it but have not yet made a commitment to take action. People can remain stuck in the contemplation stage for long periods. Contemplators struggle with their positive evaluations of their dysfunctional behavior and the amount of effort, energy, and loss it will cost to overcome it. Individuals who state that they are seriously considering changing in the next six months are classified as contemplators. These individuals also would endorse such items

as, “I have a problem and I really think I should work on it” and “I’ve started to think I haven’t been caring for my kids as well as I could.” Serious consideration of problem resolution is the central element of contemplation.

Preparation is the stage that combines intention and behavioral criteria. Individuals in this stage are intending to take action within the next month and have taken some small steps. As a group, individuals who are prepared for action also report some small cognitive changes, such as, “I have questions for my caseworker about taking care of my kids” and “If I don’t change, I will never be the kind of parent my children need.” Although they have made some reductions in their problem behaviors, people in the preparation stage have not yet reached a criterion for effective action, such as not hitting their children or regularly providing supervision and appropriate food and shelter.

Action is the stage at which individuals modify their behavior, experiences, and/or environment to overcome their problems. Action involves the most overt behavioral changes and requires considerable commitment of time and energy. Individuals are classified in the action stage if they have successfully altered the dysfunctional behavior for a period ranging from 1 day to 6 months. Individuals in the action stage endorse statements such as, “I am really working hard to change” and “I am doing things about the problem that got me involved with child welfare.” Modification of the target behavior to an acceptable criterion and significant overt efforts to change are the hallmarks of action.

Maintenance is the stage at which people work to prevent relapse and consolidate the gains attained during action. For abusive behaviors, this stage extends from six months to an indeterminate period past the initial action. For some behaviors, maintenance can be considered to last a lifetime. Being able to refrain from abusive behavior and being able to engage consistently in a new positive behavior for more than six months are the criteria for considering someone to be in the maintenance stage. Representative maintenance statements are, “I may need a boost right now to help me maintain the changes I’ve already made” and “I sometimes feel nervous that when child welfare is out of my life, I will fall back on old behavior.” Stabilizing behavior change and preventing relapse are the hallmarks of maintenance.

Spiral Pattern

As is now well known, most people taking action to modify chronic dysfunctional behavior do not successfully maintain their gains on their first attempt. Relapse is the rule rather than the exception across virtually all chronic behavioral disorders. Accordingly, change is not a linear progression through the stages. Most clients actually move through the stages of change in a spiral pattern. People can progress from contemplation to preparation to action to maintenance, but most regress to an earlier stage. Some relapsers feel like failures—embarrassed, ashamed, and guilty. These individuals become demoralized and resist thinking about behavior change. As a result, they return to the precontemplation stage and can remain there for extended periods of time.

PRESCRIPTIVE GUIDELINES

Assess the Client’s Stage of Change

Probably the most obvious and direct implication for risk assessment is the need to assess the stage of a client’s readiness for change and to tailor interventions accordingly. Stages of change can be ascertained by asking the client a series of simple questions to identify his or her stage, for example, “Do you think behavior X is a problem for you now?” (if the answer is, “yes,” then contemplation, preparation, or action stage; if the answer is “no,” then maintenance or precontemplation stage) and “When do you intend to change behavior X?” (if the response is, “some day” or “not soon,” then contemplation stage; if “in the next month,” then preparation stage; if “now,” then the action stage).

Beware of Treating All Clients as Though They Are in Action

Professionals frequently design excellent action-oriented treatment and self-help programs but then are disappointed when only a small percentage of people attend or when large numbers drop out of the program after coming once or twice. The vast majority of clients are *not* in the action stage. Aggregating across studies and populations, we estimate that 10%–15% are prepared for action, approximately 30%–40% are in the contemplation stage, and 50%–60% are in the precontemplation stage. Thus, professionals who approach clients only with action-oriented

programs are likely to underserve or mis-serve the majority of their target population.

Assist Clients in Moving One Stage at a Time

If clients progress from one stage to the next during the first month of treatment, they can double their chances of taking effective action within the next six months. Treatment programs designed to help people progress just one stage in a month can increase the chances of participants taking action on their own in the near future.

Recognize that Clients in the Preparation Stage Are Far More Likely to Achieve Better and Quicker Outcomes

The amount of progress clients make during treatment tends to be a function of their pretreatment stage of change. This has direct implications for assessing risk and selecting and prioritizing treatment goals.

Anticipate Recycling

Most clients will recycle through the stages before achieving long-term maintenance. Accordingly, intervention programs and personnel expecting people to progress linearly through the stages are likely to produce discouraging results. Be prepared to include relapse prevention and recycling strategies in treatment, anticipate the probability of recycling, and try to minimize caseworker guilt and client shame over recycling.

Conceptualize Change Mechanisms as Processes, Not as Specific Techniques

Literally hundreds of specific psychotherapeutic techniques have been advanced; however, a small and finite set of change processes or strategies underlie these techniques.

Change processes are covert and overt activities that individuals engage in when they attempt to modify problem behaviors. Each process is a broad category encompassing multiple techniques, methods, and interventions traditionally associated with disparate theoretical orientations. Consciousness raising, for example, is the most frequently used process across systems of psychotherapy. But different systems apply this

process with very different techniques, including observations, classifications, interpretations, confrontations, feedback, information, and education. Change processes can be used within treatment sessions, between treatment sessions, or without treatment sessions.

Although there are 400-plus ostensibly different psychotherapies, we have been able to identify only 10 different processes of change based on principal components analysis. Table 90.1 presents the 10 processes, along with their definitions and representative examples of specific interventions.

STAGES OF CHANGE

Do the right things (processes) at the right time (stages). Over thirty-five years of research in behavioral medicine, self-change, and psychotherapy converge in showing that different processes of change are differentially effective in certain stages of change. In general terms, change processes traditionally associated with the experiential, cognitive, and psychoanalytic persuasions are most useful during the earlier precontemplation and contemplation stages. Change processes traditionally associated with the existential and behavioral traditions, by contrast, are most useful during action and maintenance.

In the transtheoretical model, particular change processes are optimally applied at each stage of change. During the precontemplation stage, individuals use the change processes significantly less than people do in any of the other stages. Precontemplators process less information about their problems, devote less time and energy to re-evaluating themselves, and experience fewer emotional reactions to the negative aspects of their problems. In treatment, these are the most resistant or the least active clients.

Individuals in the contemplation stage are most open to consciousness-raising techniques, such as observations, confrontations, and interpretations, and are much more likely to use bibliotherapy and other educational techniques. Contemplators are also open to emotional arousal, which raises emotions and leads to a lowering of negative affect if the person changes. As individuals become more conscious of themselves and the nature of their problems, they are more likely to re-evaluate their values, problems, and themselves both affectively and cognitively. Both movement from precontemplation to contemplation and movement through

TABLE 90.1 Titles, Definitions, and Representative Interventions of 10 Processes of Change

Process	Definition: Interventions
1. Consciousness raising	Increasing information about self and problem: observations; confrontations; interpretations; videos and bibliotherapy on parenting skills
2. Self re-evaluation	Realizing that the behavior change can enhance one's identity: imagery; corrective emotional experience
3. Dramatic relief	Experiencing and expressing feelings about one's problems and solutions: psychodrama; grieving losses; role-playing
4. Social liberation	Realizing that social norms and environments support the behavior change: see alternatives as opportunities rather than coercion; policy interventions
5. Environmental re-evaluation	Realizing the impact of changing or not changing troubled behavior on other people: family value clarification, notice impact on the children
6. Self-liberation	Choice and commitment to act and belief in ability to change: decision-making therapy: New Year's resolutions; commitment-enhancing techniques
7. Counter conditioning	Substituting alternatives for problem-related behaviors: relaxation, anger management; assertion; positive self-statements; parenting skills
8. Stimulus control	Avoiding or countering stimuli that elicit problem behaviors: restructuring one's environment (e.g., removing alcohol); avoiding high-risk cues, fading techniques
9. Reinforcement management	Rewarding oneself or being rewarded by others for making changes: contingency contracts; overt and covert reinforcement; self-reward, feeling better about self
10. Helping relationships	Seeking and using social support to encourage or help with behavior change: therapy; Parents Anonymous

Source: Adapted from Prochaska, DiClemente, & Norcross, 1992.

the contemplation stage entail increased use of cognitive, affective, and evaluative processes of change. Some of these changes continue during the preparation stage. Individuals in preparation begin to take small steps toward action, create a plan, build their confidence, and make commitments to bigger steps.

During the action stage, people are putting into practice self-liberation or commitment. They increasingly believe that they have the autonomy to change their lives in key ways. Successful action also entails effective use of behavioral processes, such as counter conditioning (substituting healthier alternatives) and stimulus control, to modify the conditional stimuli that frequently prompt relapse. Reinforcement management, especially self-reinforcement, also comes into frequent use here.

Just as preparation for action was essential for success, so is preparation for maintenance. Successful maintenance builds on each of the processes that came before. Specific preparation for maintenance entails an assessment of the conditions under which a person would be likely to relapse and development of alternative responses for coping with such conditions without resorting to self-defeating defenses and pathological responses. Continuing to apply counter conditioning, stimulus control, reinforcement management, and helping relationships is most effective when based on the conviction that maintaining change supports a sense of self that is highly valued by oneself and significant others. Figure 90.1 lists appropriate interventions for workers to use based on the processes for each stage.

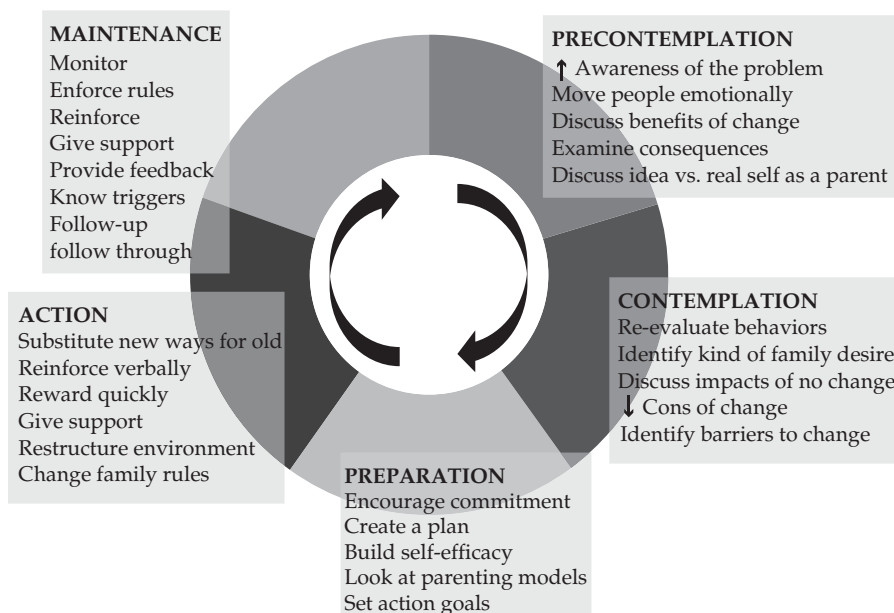

Figure 90.1 Interventions for the five stages of change.

MORE ABOUT PRECONTEMPLATORS

Most parents in abusive situations experience themselves as being coerced into receiving help. They do not see themselves as in need of change, probably want to change others, and tend to defend their behavior intensely. Without help from others, precontemplators can remain trapped in this stage. Often, a first step by the caseworker is to enable the parent to become conscious of the self-defeating defenses that get in the way of looking at change. Becoming conscious of their defenses and how they operate can help clients gain a measure of control over them. Does the precontemplator make the least of things (denial and minimization); have excuses (rationalization); turn outward (projection and displacement); or turn inward (internalization-depression). Once precontemplators are aware of how they defend themselves when they feel threatened, they can work at getting control over their defenses rather than having the defenses control them.

Environmental forces can also help a precontemplator to become unstuck. A child welfare investigation, an arrest, or a school official calling can demonstrate that the environment no longer supports their lifestyle. The precontemplator can progress if they can identify with the environmental forces urging them to change. What not to do as a worker is to push precontemplators to immediate action, nag them, give up on them, or

enable them (avoid discussions and confrontations, or make excuses).

HELP FOR CHRONIC CONTEMPLATORS

Contemplators can see changing as too difficult to decide to take the first step, or they may get sidetracked and become discouraged and disappointed in their efforts. They may also be ambivalent and say to themselves, "When in doubt, don't change." Chronic contemplators substitute thinking and ruminating for acting. Conflicts and problems hang suspended, decisions are never finalized, and action is avoided. Contemplators need help with seeing the benefits of changing ("I will get to keep my kids," "My kids will benefit," or "I will feel better about myself.") and help with reducing the cons ("It's hard to do all that child welfare wants," or "I will miss getting high," or "Doing things differently will create problems between me and my partner."). Contemplators using self re-evaluation can begin to imagine how life would be substantially improved if they were free from their problem behavior.

RISKS AND STAGES OF CHANGE

Gelles (1996) combines the dimensions of stages of change and degree of risk and lays out

TABLE 90.2 Two Dimensions of Risk Assessment for Child Abuse and Neglect

Stage of Change	Severity of Risk		
	High	Medium	Low
Precontemplation	No reunification High likelihood of terminating parental rights		Parent education classes Project early start
Contemplation		Comprehensive Emergency Services	
Preparation		Parent aide Mother for mother Volunteer support	Family preservation
Action	Family preservation only with close monitoring		Family preservation
Maintenance			Reunification recommended

Source: Adapted from Gelles, 1996.

appropriate programs to offer abusive parents according to risk and stage of change (Table 90.2). According to Gelles, intensive family preservation programs are most appropriate for families who fit the lower right cell—those where the level of risk is low and the stage of change is action. Family preservation could be used with close monitoring for higher risk families but only those who are in preparation or in action. Family preservation is clearly inappropriate for high-risk families who are in precontemplation and contemplation.

RECENT CHALLENGES AND SUCCESSES

As with all major theories, the transtheoretical model has undergone challenges and criticisms. In the child welfare field, the model has been criticized for oversimplification (Littell & Girvin, 2004; Corden & Somerton, 2004); yet, the critical reviews have not considered the model in its full entirety, instead evaluating only stage of change as a single construct.

As detailed earlier, the transtheoretical model includes 14 constructs in addition to stage of change: self-efficacy (confidence and temptations), decisional balance (pros and cons), and the 10 processes of change. Intervention trials

tailored on all 15 transtheoretical model constructs have demonstrated wide application and relevance to child welfare, including with regard to adoption readiness, bullying prevention, partner abuse treatment, teen dating violence prevention, and sex offenders. For example, Prochaska et al. (2005) found that the transtheoretical model helped conceptualize and assess emotional readiness to be an adoptive parent and paved the way for future efforts to develop an intervention that guides professionals in their work with prospective parents. Evers, Prochaska, Van Marter, Johnson, and Prochaska (2007) found that a computer-based individualized and interactive transtheoretical model intervention for bullying prevention in schools, given at three time points over one semester, led to significant reductions in bullying, passive bystander, and victim events. In the middle schools, approximately 22% of the treatment group progressed to action or maintenance (always acting with respect) compared with 5% of the control group. In the high schools, approximately 29% progressed to action or maintenance compared with 10% of the control group.

Levesque, Ciavatta, Castle, Prochaska, & Prochaska (2012) developed a multimedia computer expert system program for male domestic violence offenders as an adjunct to traditional mandated treatment. In a randomized clinical

trial, the transtheoretical intervention group was significantly more likely to be in the action stage (54% vs. 24%) for using healthy strategies to stay violence-free. Babcock, Canady, Senior, and Eckhardt (2005) applied the Transtheoretical Model to female and male perpetrators of intimate partner violence and found that the model applies to female perpetrators as equally well as to male perpetrators. Tierney and McCabe (2005) encourage the use of the model in the treatment of sex offenders and provide a practical description of the use of all the constructs in the treatment. The Teen Dating Violence Prevention program is a computerized stage-based intervention designed to help high school students develop and use healthy relationship skills to prevent dating violence (if dating) and peer violence (if not dating). In a randomized trial, the program significantly reduced physical and emotional peer violence victimization and perpetration among daters and nondaters (Levesque, 2011).

These studies strongly support the application of the transtheoretical model to reduce abusive relationships. One of the challenges for the future would be how to disseminate these promising interventions from research centers to treatment centers most effectively.

91 Play Therapy with Children in Crisis

Nancy Boyd-Webb

Many adults tend to think that children are like the three monkeys who see no evil, hear no evil, and do no evil. Unfortunately, the very opposite is true of most children, who pick up cues and take notice whenever trouble is brewing, whether or not the adults in their lives tell them about what is occurring. When children do not receive logical and truthful explanations of the happenings around them, they often create fantasies in their imaginations that may far exceed the magnitude and impact of the actual crisis. Because we live in a world in which violence, terror, and danger are everyday occurrences in families, schools, and communities, no one of any age is immune to the possibility of exposure and to the subsequent stress and anxiety related to perceived threats about one's personal safety.

PLAY THERAPY

Play therapy refers to a theoretically based helping interaction between a trained adult therapist and a child that aims to relieve the child's emotional distress through deliberate use of the symbolic communication of play. Play therapy is the treatment of choice in working with children because it encourages them to communicate through child-friendly play rather than verbally. Just as adults talk out their worries, children express their fears and anxieties by playing them out. The child identifies with the toy doll or other object and displaces his or her feelings onto the toy. The assumption is that when children understand that the therapist's role is to help them, they will then express their emotional conflicts and find more adaptive solutions within the metaphor of play. Often play therapy not only alleviates the presenting symptoms (important as this may be to parents and child) but also may

help remove impediments to the child's continuing development, so that the prospects for the child's future growth are enhanced (Crenshaw, 2006; Webb, 1996; Webb, 2007). In other words, the child's relief from anxiety frees him or her to proceed with his usual activities at home and at school. In summary, the primary purpose of play therapy is to help troubled children express and obtain relief from their conflicts and anxieties symbolically through play in the context of a therapeutic relationship.

Some of the specific elements inherent in play that make it valuable in therapy have been identified as its communication power, its abreaction power (permitting the review of past stress and the expression of associated negative emotions), and its rapport-building power (Reddy, Files-Hall, & Schaefer, 2005). Each child's situation is unique; therefore, therapy with individual children will have different emphases, depending on the specific assessment of the child's problem situation and the child's particular reactions.

DEFINITION AND HISTORY OF CRISIS

INTERVENTION PLAY THERAPY

Crisis intervention play therapy is a specialized form of play therapy that aims to help children who have become anxious and symptomatic following a stressful crisis (or traumatic) experience. It uses the broad range of play therapy methods for the purpose of relieving the child's reactions of fear and helplessness. This approach is usually short-term and directive. It relies on the safety of the therapeutic relationship to permit the child to deal with stressful memories, either symbolically or directly, using play materials. Crisis intervention play therapy is especially recommended for single-event and recent traumas, referred to as

Type I trauma (Webb, 2007; James & Gillibrand, 2008). Numerous reports attest to the treatment effectiveness of this form of play therapy in helping traumatized children (Brohl, 1996; Shelby, 1997; Webb, 2003, 2004, 2007). When the child has experienced multiple or chronic traumas (Type II trauma), a more extended treatment approach is recommended. See James and Gilliland for more discussion of Type I and Type II traumas.

The historical roots of crisis intervention date to the second deadliest fire in American history, the Coconut Grove fire in Boston in 1942, in which 493 people lost their lives. Eric Lindemann and his colleagues studied the relatives of the victims over time to document cases of acute and delayed grief reactions (Lindemann, 1944). The findings showed the importance of a mourning period, called "grief work," following a tragic loss. People who were able to undergo a period of mourning made a better adjustment than did those whose grief was delayed or denied (Roberts, 2005). This appeared to argue for timely intervention following a trauma so that feelings are not brushed aside or ignored. Lindemann's work was later adapted for use with WW II veterans who were suffering from what was then referred to as "combat neurosis" (Roberts, 2005). It was subsequently widely adopted by suicide hotlines, as well as rape and domestic violence crisis programs, and continues to be used with clients of all ages in a variety of problem situations (Parad & Parad, 1990). A 32-chapter *Crisis Intervention Handbook* (Roberts, 2005) demonstrates the broad application of this method with victims of natural disasters, various kinds of violence, medical conditions, drug abuse, and suicide in both individual and group formats.

Roberts's model of crisis intervention begins with an assessment and the establishment of a positive relationship, then moves to dealing with feelings and emotions, followed by exploration of alternatives and an action plan and later follow-up. Roberts says "effective crisis intervention should be active, directive, focused, and hopeful" (p. 157).

The use of crisis intervention play therapy with children facilitates their ability to deal with the emotions of the crisis by displacing and projecting them onto a toy or drawing, thereby decreasing their fears. According to Lenore Terr (1991), it is not necessary for the child to openly acknowledge the parallel between the play activity and his or her own life in order for it to be effective. However, most play therapists do look

for ways to establish this connection without creating undue anxiety in the child.

Another therapy method for use with children after traumatic exposure, namely, trauma-focused cognitive behavior therapy (TF-CBT), has been referred to as a "hybrid model" (Cohen, Mannarino, & Deblinger, 2010), which also incorporates some methods similar to those of crisis intervention play therapy. This approach emphasizes the importance of play re-enactment of the stressful/traumatic experience, as well as the mental reworking or cognitive restructuring of the event. Rooted in the belief that it is crucial for the individual to be able to review his or her crisis/traumatic experience and develop a narrative about it, this verbal review involves repeated guided interactions in which the therapist directs the child to imagine and describe a different desired outcome to the stressful event. After teaching the child some relaxation skills the therapist then guides the child gently in giving details of what happened, including the "worst moment." Subsequent sessions encourage the child to process this experience with the goal of putting it in the wider context of the child's whole life, and to reframe it as "something bad that happened." This brings about a changed outlook regarding the experience. Conjoint parent-child sessions are held later in which the child shares the story and receives support from the parent. In summary, some specific methods in this cognitive approach include the use of calming and relaxation techniques, guided imagery, psycho-education, positive self-talk, and instruction that the child should rely on parents and other competent adults in dangerous situations. There is a complete discussion of this method in Cohen, Mannarino, Deblinger, & Berliner (2009).

DIRECTIVE VERSUS NONDIRECTIVE PLAY THERAPY

Often children (and adults) do not want to remember their frightening crisis experiences. Avoidance is typical following a crisis or traumatic event (American Psychiatric Association [APA], 2000), and the child's understandable reluctance to review anxiety-evoking memories presents a challenge to the therapist who knows that pushing worries away does not cause them to disappear. In fact, the prevailing practice wisdom recommends that for traumatic experiences to be resolved, some form of retrospective review is usually necessary. With directive, crisis/trauma-focused play

therapy, a child can gradually process anxious feelings and learn methods to put them in the past so that they no longer hold center stage in the child's present emotional life. The key is to move at the child's pace and not insist that the child talk about the crisis before he or she is ready to do so. Crisis intervention play therapy consists of a mixture of cognitive-behavioral, supportive, and psychodynamic approaches. A primary goal is to help the child achieve an understanding that the crisis situation was in the past and is no longer a current source of threat in the child's present life.

THE ASSESSMENT PROCESS

It is essential for the social worker who is doing play therapy to take a history related to the child's reactions to the crisis/traumatic event. Although an extensive psychosocial history usually is not feasible because of the pressure of time, the worker needs to have a general sense of how the child was functioning prior to the crisis/trauma, as well as a description of the child's current symptomatic behaviors and how they are interfering with his/her current life.

There are three parts to any assessment of a symptomatic child. I refer to this as "the tripartite assessment" (Webb, 2007). The specific groups of factors in each part are:

- Factors related to the individual child
- Factors related to the support system
- Factors related to the nature of the traumatic or crisis event

The first set of data refers to the nature of the child's pre-crisis adjustment; the second part describes the nature of the surrounding environment; and the third set of data relates to the nature of the crisis/traumatic event itself. The play therapist must obtain pertinent information from the parents and other sources regarding these matters to establish appropriate treatment goals. Space does not permit full discussion of the assessment process here, and readers who wish more detailed information about using this assessment tool should consult Webb (2004, 2007, 2011).

SETTING GOALS

The focus of treatment following a crisis or trauma is to return the child to his or her pre-crisis adjustment. Sometimes the child actually becomes emotionally stronger after a

crisis because he or she now identifies herself as a survivor. The treatment goals flow directly from the assessment. For example, if a child is waking up every night and going into the parents' room for comfort, the goal may be to help the child feel comfortable enough to stay in his or her own bed. It is important to involve the child in setting the goals to increase his or her willingness to achieve them. Depending on the child's age, it is often desirable to have the parent involved with the assessment process and also with the treatment, as will be illustrated in the case of Anna.

CASE EXAMPLE: ANNA

[NOTE: A brief discussion of this case appears in Webb (2003)]

This case illustrates the value of timely play therapy intervention following a traumatic event. Anna, age 5 years, became preoccupied and inattentive in school following a fire that caused a middle-of-the night evacuation from her apartment. She was waking every night, and during the day when at home she always wanted to be in her mother's presence. Although Anna, her parents, and her brother had been safely relocated to a new apartment, the child was disconsolate because she had lost her beloved stuffed bunny with which she used to sleep every night. Her mother did not comprehend the meaning and degree of her daughter's loss and Anna's need to mourn.

In play therapy over four sessions with the mother and child together, the therapist encouraged Anna to re-create her traumatic experience in drawing and in play with blocks and toy furniture. Typically, the play therapist tells the young child that she intends to help him or her with any troubles or worries and then invites the child to relate specific concerns either verbally or in play or drawings. The therapist may then ask the child to "show me what happened" with the puppets or dolls or in a drawing. During this process with Anna the therapist acknowledged the child's loss in her mother's presence, and validated the child's pain, thereby stimulating the mother's awareness of her child's grief. After four sessions, the child's symptoms of anxiety and accompanying school inattention resolved.

Specific Play Therapy Interventions

The play therapist began by telling Anna that she intended to help her with any troubles or worries

and then invited Anna to relate specific concerns either verbally or in play. This conveyed to Anna that it was not necessary to talk. The play therapy with Anna consisted of several drawing and block play activities in which the child re-created the traumatic event and revealed her ongoing fears of the possibility of a fire in her new apartment.

Initially, the therapist asked Anna to draw a picture of her present room and after she had done so the therapist invited her to use blocks to duplicate this. As Anna created her room, using a toy bed and tiny bendable dolls she said "Behind the wall is the kitchen, and there is a fire in the stove." After questioning further and with the mother's in-put it became evident that Anna was referring to the pilot light in the stove, which she worried could cause a fire. Their previous apartment had had an electric stove so the pilot light was a new factor that was contributing to Anna's present fears. Both the mother and the therapist assured Anna that the light in the stove was "only for cooking" and that it would not spread and burn down this new apartment. In the first session the therapist invited Anna to draw a picture of her old apartment before the fire. Anna drew the apartment and spontaneously inserted a drawing of her bunny in the corner of the paper. The picture of the bunny was quite distorted, and as she drew it, Anna kept talking about how much she missed her bunny. In response to this, the mother said rather dismissively, "I'll get you a new bunny." The play therapist said in response that there will never be another bunny like the one Anna had before. Subsequent sessions included more block play and drawings; in the third session the therapist believed that Anna was sufficiently comfortable, so she asked her to draw a picture of her apartment in the fire. As the child did this she kept repeating her wish that they had been able to save her bunny. The therapist then suggested that Anna write a letter to her bunny stating her feelings. With Anna's permission the therapist wrote the child's message on the drawing. Her message was brief and said only "I love you and miss you." The therapist suggested that she add the word "good-bye" to help Anna realize that she would not see her bunny again. This activity seemed to have great meaning for Anna. Her mother reported in the next session that Anna had stopped her nighttime waking and was behaving more appropriately in school. At this point the therapist asked Anna to draw a picture of how she wants to remember her bunny

now. Anna drew an intact bunny with a smile on its face, which was in sharp contrast to the disjointed drawing she had made before.

Obviously, a number of factors contributed to Anna's rapid alleviation of anxiety. First, there was clarification about the child's current safety once the reassurances about the "fire in the stove" were made. Secondly, the mother picked up from the therapist the need to acknowledge the pain of Anna's loss. Most importantly, the therapist acknowledged the child's feelings of sadness, which the mother had tended to dismiss. Finally, Anna was able to "say goodbye" to her bunny, thereby acknowledging that she will not see it again.

Treatment Goals

As previously stated, the focus of treatment following a crisis or trauma is to return the child to his or her precrisis adjustment. The ultimate goal of crisis intervention play therapy is for the child to gain some feeling of mastery over the crisis event or traumatic experience through the realization that it will no longer continue to impact his or her life. This appeared to happen in Anna's case, and she was able to return to her usual routine at school and at home after having said her farewells to her beloved bunny and having received acknowledgment from the therapist and her mother about her loss.

Specific Intervention Techniques

Play therapy methods cover a wide range of activities, including the following:

- **Art activities**—Including drawing, painting, and use of clay and Play-Doh®. See Malchiodi (2006) for more information about art therapy.
- **Doll play**—Using bendable family dolls, doll furniture, army dolls, rescue personnel, fantasy figures such as witches and fairies, stuffed animals, and dinosaurs. See Webb (2007) for cases involving the use of dolls in play therapy.
- **Puppet play**—With a variety of friendly and wild animals; family puppets; and worker puppets in the form of both hand puppets and finger puppets. Provision of several adult puppets and child puppets of the same species encourages displacement of family dynamics onto the toys. See Baggerly (2007) for an

illustration using puppet play with children following a natural disaster.

- **Storytelling**—Sometimes the therapist initiates this by beginning a story and asking the child to complete it. See Gil (1991) for examples.
- **Sand play**—This involves making scenes in a sandbox, using a variety of miniature toys. See Carey (2006) for an example of sand play therapy with a traumatized boy.
- **Board games**—These may be either specifically “therapeutic” games or regular games that the therapist selects because of themes that resemble the child’s experience. See Schaefer and Reid (2001) for numerous examples of the use of board games in play therapy.

The assumption in the use of these materials is that the child identifies with the toy and projects and displaces his or her own feelings onto the play figures. The therapist’s responses may include curiosity (so the child will give more details), or expression of feelings (so the child feels validated), or statements of closure and conclusion (so the child can put the experience behind him or her).

Research has not been able to produce definitive conclusions about whether directive or non-directive approaches bring more favorable results in therapy with symptomatic children following crisis or traumatic events. Shelby and Felix (2005) comment that throughout the history of child trauma therapy, there has been debate about how best to intervene. In view of the lack of agreement (and lack of conclusive empirical research findings), it seems understandable that few child therapists currently rely on either a *purely* directive or nondirective treatment approach. One can hope that future research will lend light on this important topic; until then, methods that combine both directive and nondirective treatment will continue to be used to relieve children’s distress following crisis or traumatic experiences.

GUIDELINES FOR CRISIS INTERVENTION PLAY THERAPY

The following guidelines should be followed in providing this type of treatment.

- Obtain specialized training and participate in ongoing supervision.

- Conduct a brief assessment to determine the child’s previous level of functioning.
- Establish a supportive therapeutic relationship with the child.
- Teach the child some relaxation methods to help keep anxiety in check.
- Provide toys or drawing materials to assist the child in re-creating the traumatic event.
- Move at the child’s pace; do not attempt too much in one session.
- Emphasize the child’s strength as a survivor.
- Repeat that the traumatic experience was in the *past*.
- Point out that the child is safe in the present.

CONCLUSION

Social workers who plan to do crisis intervention play therapy should be well grounded in child development, play therapy, trauma therapy, and grief counseling. All should seek ways to obtain ongoing support and supervision for themselves in order to avoid what has been called vicarious traumatization. This refers to the personal reactions of therapists who become overwhelmed and traumatized themselves in the course of their work with trauma survivors.

We know how to help traumatized children. It is most gratifying to observe a child’s reduction of symptoms and return to precrisis functioning. This work, though very challenging, is also very rewarding and well worth the struggle to help children overcome and cast out the demons of fear that develop after crisis and traumatic experiences.

92 Social Skills Training and Child Therapy

Craig Winston LeCroy

An important part of the socialization of children can be facilitated by offering social skills training. Social skills therapy or classes teach prosocial skills that substitute for problem behaviors, such as aggression or withdrawal. Interpersonal skills can be taught to enhance communication with peers, parents, and authority figures. Stress management and coping skills can be taught to help prevent future problems. Numerous opportunities exist for the implementation of various skills-based programs that can help facilitate the successful socialization of children. For a unique gender-specific application with adolescent girls see LeCroy & Daley, 2001. Social skills training groups are frequently used in school settings to address a wide range of problem behaviors (LeCroy, 2013).

Research strongly suggests that social competence is essential for healthy normal development (Ashford & LeCroy, 2013). It is through a child's interactions with peers that many of life's necessary behaviors are acquired. For example, children learn sexual socialization, control of aggression, expression of emotion, and caring in friendship through their interaction with peers. When children fail to acquire such social skills, they are beset by problems such as inappropriate expression of anger, friendship difficulties, and inability to resist peer pressure. It is this understanding that has led to the present focus on changing children's interpersonal behavior with peers. Because many of a young person's problem behaviors develop in a social context, the teaching of social skills is one of the most promising approaches in remediating children's social difficulties.

DEFINING AND CONCEPTUALIZING SOCIAL SKILLS

Social skills can be defined as a complex set of skills that facilitate successful interactions between peers, parents, teachers, and other adults. The "social" refers to interactions between people; the "skills" refers to making appropriate discriminations, such as deciding what would be the most effective response and using the verbal and nonverbal behaviors that facilitate interaction (LeCroy, 2008).

Social skills training uses two key elements in addressing social adaptation of children: knowledge and skilled performance. In order to respond appropriately to situational demands a child must have knowledge of appropriate interpersonal behavior. However, that knowledge must be translated into skilled performance or social skills. Social skills training programs or therapy use methods to enhance a child's knowledge of social situations and enhance effective performance in those situations. An additional consideration is to plan for generalization so that any new skills learned are adaptable to different environments such as playgrounds, schools, and neighborhoods.

The conceptualization of social skills as training suggests that problem behaviors can be viewed as remediable deficits in a child's response repertoire (King & Kirschenbaum, 1992). This focuses on building prosocial responses or skills as opposed to an emphasis on the elimination of excessive antisocial responses. Children learn new options to problem situations. Learning how to respond effectively to new situations produces

more positive consequences than past behaviors used in similar situations. This model focuses on the teaching of skills and competencies for day-to-day living rather than focusing on the understanding and elimination of defects. It is an optimistic view of children and is implemented in an educative remedial framework.

DEVELOPING PROGRAM OR THERAPY GOALS AND SELECTING SKILLS

Social skills training can be conducted as a program of skills using a group format or as a treatment plan for an individual child. The first step in the development of a successful social skills training program is to identify the goals of the program based on the needs of the target population or individual. What specific skills does the child need to learn? For example, a program goal for withdrawn children is to be able to initiate positive social interactions. Once the goals of the program are clearly defined, the next step is to select the specific skills that need to be learned.

For example, a 5-year-old boy is referred to a child therapy clinic. The teacher reported his behavior as “mean” and “sadistic,” explained that he had no friends, and saw him as uncooperative. His mother reported he had engaged in numerous fights, described him as being uncooperative, and complained about the use of swearing and about noncompliance when directed to do things. In order to develop a social skills training therapy program for him, we will need to determine what constitutes the opposite of these negative behavior patterns. For example, he would benefit from learning the following types of skills: how to get along with others without fighting, frustration tolerance, and compliance. Learning how to translate problems into skills is an essential part of providing a skills-based model of treatment. Table 92.1 presents examples of how problems can be conceptualized as skills needed to learn.

After skills are selected for the treatment, the practitioner selects a method to promote acquisition of the skills. For example, common methods might include: behavior modification, use of supportive empathy, dramatic play, and storytelling. Also, group methods using behavioral rehearsal are popular methods for teaching social skills.

The process of social skills training requires continual attention to refining each skill that is to be taught. After identifying the broad social skills, it is important to divide each broad skill

into its component parts so that it can be more easily learned. For example, LeCroy (2008, p. 136) breaks down the skill “beginning a conversation” into six component parts:

1. Look the person in the eye and demonstrate appropriate body language.
2. Greet the person, saying one’s own name.
3. Ask an open-ended question about the person. Listen attentively for the response.
4. Make a statement to follow up on the person’s response.
5. Ask another open-ended question about the person. Listen attentively to the response.
6. Make another statement about the conversation.
7. End the conversation by letting the person you have to leave.

A classic social skills training study by Oden and Asher (1977) sought to improve the social skills and peer relationships of third and fourth grade children who were identified as not well liked by their peers. The social skills program taught the following four skills: participation, cooperation, communication, and validation/support. The intervention consisted of a five-week program whereby each skill was (1) described verbally, (2) explained with examples, (3) practiced using behavior rehearsal, and (4) refined through feedback, coaching, and reviews of progress. The results of this study found that the children increased their social skills and that they had improved more significantly than a group of elementary school children who did not participate in the program. Particularly impressive was the finding that the children showed gains in how their classmates rated them on play and peer acceptance at a one-year follow-up.

Guidelines for Using Social Skills Training Methods

After program goals are defined and skills are selected, various methods can be used for teaching social skills. These methods of influence are the ways in which the learning of such skills is promoted. There are three main methods of influence used in social skills training: (1) skills-based play therapy, (2) group-based social skills treatment, and (3) behavior modification. Many variations exist within these three main methods. For example, using reinforcement of selected skills during spontaneous play therapy sessions,

TABLE 92.1 Translating Problems into Skills

Problem	Skills
Withdrawn, moody, and irritable	Being aware of one's feelings Getting pleasure from interaction with others Controlling one's mood Doing more
Impulsive behavior "Acting out"	Complying with demands Concentrating, maintaining attention Following through, showing persistence Delaying gratification
Anxious, dependent behavior Separation difficulties	Relaxing, putting one's body at ease Separating from others Accepting disapproval of others Handling rejection
Feeling unloved, showing no outside enjoyment in life, bored	Getting pleasure from loving acts toward others Getting pleasure from exploration Anticipating pleasure and fun from activities Celebrating one's accomplishments and successes Accepting compliments from others Getting pleasure from positive attention
Substance abuse	Identifying problem situations Using effective refusal skills Making friends with non-using friends General problem solving for risky situations

eliciting stories from the child and using them to reinforce selected skills, conducting spontaneous mutual dramatic play that focuses on selected skills, using conversation and fantasies as a means of rehearsal and reinforcement of skills, and playing games designed to teach social skills (LeCroy & Archer, 2001). For this chapter, two of the main methods are described: skills-based play therapy and group-based social skills treatment.

SKILLS-BASED PLAY THERAPY

Although play therapy is often associated with more dynamic approaches to treatment, it can be an excellent method for teaching social skills. However, rather than a focus on the catharsis of feelings in play therapy, the focus is on learning new skills to address problematic feelings. In skills-based play therapy this is accomplished by using scripted modeling plays, reading stories

that model skills, encouraging selected skills from the child's spontaneous play, and designing plays and stories that are specific to the child's needs.

A primary method is the use of dramatic play where the practitioner models the skills the child needs to learn through manipulating play material. It is important to provide multiple opportunities to practice skillful patterns of behavior. This is accomplished by conducting modeling "plays" that allow the child to experience the skill being demonstrated vicariously through the play.

When conducting plays or designing stories (as described below) practitioners should follow the basic principles established in modeling theory. Strayhorn (1988) summarizes the principles concisely.

1. Use multiple characters to provide exposure to multiple models.
2. Have a role model experience reinforcing consequences of his or her action.

3. Design a character who is seen as desirable and appropriate to the cultural context.
4. Use a coping model whereby the character struggles some but then overcomes those initial difficulties.
5. Use characters who engage in self talk demonstrating good coping skills.

In this way, skills-based play therapy is very goal-directed play, which can be linked directly to the skills needed to be learned by the child. For example, a sample modeling play like the following might be performed for the child.

Sample modeling play. This play is designed for a child who is having difficulty sharing and ends up fighting with other children over what to do. The social worker would need to set the play scene: This example uses a play about two boys and how they share when one boy comes over to the other boy's house. A wind-up toy is used as the object that the boys will share. Prior to conducting this play, make sure the child has seen the toy so he is not preoccupied with learning about the toy. Materials needed for the play include two boy action figures and one wind-up toy. The social worker begins by focusing the child's attention on the play, "I'm going to put on a play; you watch and then after I'm done you can play with these toys."

Parent: I'm glad you could come over to play Robert! I have something you two might like to play with.

Robert: What is it?

Skylar: Yea, mom what did you get?

Parent: It's a Godzilla gorilla that spits fire when you wind it up!

Robert: Wow, let me see.

Skylar: I want to wind it up, let me wind it up.

Skylar: I know, Robert. Would you like to take turns?

Robert: OK, you can do it first, but then I get to do it right after.

Parent: Great sharing Skylar; I like how you worked out a good way to share with Robert.

Skylar: Thanks Mom. Robert was really nice to let me play with it first. Look! I'm winding it up, look at the fire! (Sparks come out of its mouth)

Robert: Wow! That is really cool.

Skylar: OK, now it's your turn, Robert.

Robert: Thanks, Skylar. I'll wind it up again. Look, fire is coming out everywhere. OK, it's your turn again, Skylar.

Skylar: Thank you (takes the toy and begins winding it up again).

Parent: (re-enters the room) You two are doing a great job sharing and playing together. Can I get you a snack?

When conducting plays like the one above, the practitioner should have play material to enact the different scenes; for example, action figures (a dad, mom, and several children), a house, a play yard, play equipment, a school bus, and miniature toy items like food, televisions, and computers. The play is conducted with great animation, figures are picked up when talking, and used in a puppet-like fashion. Different characters have different voices and the action sequence is fast, matching the attention span of the particular child. After conducting a modeling play, many children will immediately imitate the play, "rehearsing" the skills that the practitioner is trying to teach the child.

STORYTELLING: MODELING SKILLS THROUGH READING

An additional method for teaching children social skills is the careful design or selection of stories that model the desired skills. Young children are drawn to storytelling and stories can be used to demonstrate and model skills they need to learn.

For example, if a target skill is anger management, a story can be constructed where the main character gets frustrated but does not get angry. Another character can provide reinforcement and support, "You just walked away and did not get angry—that's a great skill." Or if the target skill is friendship abilities, the story might enact a scene where the target child joins the play of others. For example, "Hi guys, looks like a great soccer game. I'd like to play, too." This character also says to himself, "I'm glad I asked to play soccer with those guys. It's a lot more fun."

The process of using skills-based storytelling can take several venues. First, stories can be told or read to children in play therapy sessions. This provides good variation to the additional methods that should be used in individual sessions with children. Stories can also be given to parents to read to the child. The goal should be many repeated exposures of the stories—children like

familiar stories and each repetition provides increased vicarious learning of desired skills.

Group Based Social Skills Treatment

Social skills training is often conducted in a group format, which provides support and a reinforcing context for learning new responses and appropriate behaviors in a variety of social situations. The group is a natural context for social skills training because of the peer interactions that take place as the group members work together. Additionally, the group allows for extensive use of modeling and feedback that are critical components of successful skills training.

The following seven basic steps delineate the process that group leaders can follow when conducting social skills training (based on LeCroy, 2008). These guidelines were developed for social skills groups with middle school students. Table 92.2 presents these steps and outlines the process for teaching social skills. In each step there is a request for group member involvement. This is because it is critical that group leaders involve the participants actively in the skill training. Also, this keeps the group interesting and fun for the group members.

1. Present the social skill being taught.

The first step for the group leader is to present the skill. The leader solicits an explanation of the skill, for example, "Can anyone tell me what it means to resist peer pressure?" After group members have answered this question, the leader emphasizes the rationale for using the skill. For example, "You would use this skill when you're in a situation where you don't want to do something that your friends want you to do and you should be able to say 'no' in a way that helps your friends to be able to accept your refusal." The leader then requests additional reasons for learning the skill.

2. Discuss the social skills. The leader presents the specific skill steps that constitute the social skill. For example, the skill steps for resisting peer pressure are: good nonverbal communication (includes eye contact, posture, voice volume), saying "no" early in the interaction, suggesting an alternative activity, and leaving the situation if there is continued pressure. Leaders then ask group members to share examples of when they used the skill or examples of when they could have used the skill but did not.

3. Present a problem situation and model the skill. The leader presents a problem

TABLE 92.2 A Summary of the Steps in Teaching Social Skills Training

-
1. Present the social skills being taught
 - A. Solicit an explanation of the skill
 - B. Get group members to provide rationales for the skill
 2. Discuss the social skill
 - A. List the skill steps
 - B. Get group members to give examples of using the skill
 3. Present a problem situation and model the skill
 - A. Evaluate the performance
 - B. Get group members to discuss the model
 4. Set the stage for role playing the skill
 - A. Select the group members for role playing
 - B. Get group members to observe the role play
 5. Group members rehearse the skill
 - A. Provide coaching if necessary
 - B. Get group members to provide feedback on verbal and nonverbal elements
 6. Practice using complex skill situations
 - A. Teach accessory skills (e.g., problem solving)
 - B. Get group members to discuss situations and provide feedback
 7. Train for generalization and maintenance
 - A. Encourage practice of skills outside the group
 - B. Get group members to bring in their problem situations.
-

situation. For example, the following is a problem situation for resisting peer pressure:

After seeing a movie, your friends suggest that you go with them to the mall. It is 10:45 and you are supposed to be home by 11:00. It is important that you get home by 11:00 or you will not be able to go out next weekend.

The group leader chooses members to role play this situation and then models the skills. Group members evaluate the model's performance. Did the model follow all the skill steps? Was his or her performance successful? The group leader may choose another group member to model if the leader believes the group member already has the requisite skills. Another alternative is to present videotaped models to the group. This has the advantage of following the recommendation

by researchers that the models be similar to the trainee in age, sex, and social characteristics.

4. Set the stage for role playing of the skill.

For this step the group leader needs to construct the social circumstances for the role play. Leaders select group members for the role play and give them their parts to play. The leader reviews with the role players how to act out their role. Group members not in the role play observe the process. It is sometimes helpful if they are given specific instructions for their observations. For example, one member may observe the use of nonverbal skills, another member may be instructed to observe when “no” is said in the interaction.

5. Group members rehearse the skill.

Rehearsal or guided practice of the skill is an important part of effective social skills training. Group leaders and group members provide instructions or coaching before and during the role play and provide praise and feedback for improvement. Following a role play rehearsal the leader usually will give instructions for improvement, model the suggested improvements, or coach the person to incorporate the feedback in the subsequent role play. Often the group members doing the role play will practice the skills in the situation several times to refine their skills and incorporate feedback offered by the group. The role plays continue until the trainee’s behavior becomes more and more similar to that of the model. It is important that “overlearning” take place, so the group leader should encourage many examples of effective skill demonstration followed by praise. Group members should be taught how to give effective feedback before the rehearsals. Throughout the teaching process the group leader can model desired responses. For example, after a role play the leader can respond first and model feedback that starts with a positive statement.

6. Practice using complex skill situations.

The last phase deals with more difficult and complex skill situations. Complex situations can be developed by extending the interactions and roles in the problem situations. Most social skills groups also incorporate the teaching of problem solving abilities. Problem solving is a general approach to helping young people to gather information about a problematic situation, generate a large number of potential solutions, evaluate the consequences of various solutions, and outline plans for the implementation of a particular solution. Group leaders can identify appropriate problem situations and lead members through

the above steps. The problem-solving training is important because it prepares young people to make adjustments as needed in a given situation. It is a general skill with large scale application. (For a more complete discussion on the use of problem solving approaches, see Gresham, 2002).

7. Train for generalization and maintenance.

The success of the social skills program depends on the extent to which the skills young people learn transfer to their day-to-day lives. Practitioners must always be planning for ways to maximize the generalization of skills learned and promote their continued use after training. Several principles help facilitate the generalization and maintenance of skills. The first is the use of overlearning. The more overlearning that takes place, the greater the likelihood of later transfer of skills. Therefore, it is important that group leaders insist on mastery of the skills. Another important principle of generalization is to vary the stimuli as skills are learned. To accomplish this, practitioners can use a variety of models, problem situations, role play actors, and trainers. The various styles and behaviors of the people used produces a broader context in which to apply the skills learned. Perhaps most important is to require that young people use the skills in their real life settings. Group leaders should assign and monitor homework to encourage transfer of learning. This may include the use of written contracts to do certain tasks outside of the group. Group members should be asked to bring to the group examples of problem situations where the social skills can be applied. Lastly, practitioners should attempt to develop external support for the skills learned. One approach to this is to set up a buddy system where group members work together to perform the skills learned outside the group.

SUMMARY

As social workers work toward the goal of enhancing the socialization process of children, methods for promoting social competence, such as social skills training, have much to offer. Social workers can make an important contribution to children, families, and schools through preventive and remedial approaches like those described in this chapter. As we have seen, children’s social behavior is a critical aspect of successful adaptation in society. The strategy of social skills training provides a clear methodology for providing

remedial and preventive services to children. This direct approach to working with children has been applied in numerous problem areas and with many child behavior problems. It is straightforward in application and has been adapted so that social workers, teachers, and peer helpers have successfully applied the methodology. It can be applied in individual, group, or classroom settings. Research supports the efficacy of social skills training; it is perhaps the most promising new treatment model developed for working with children and adolescents.

93 Guidelines for Chemical Abuse and Dependency Screening, Diagnosis, Treatment, and Recovery

Diana M. DiNitto & C. Aaron McNeece

Nearly 15% of English-speaking household residents of the United States aged 18 years and older have met the criteria for a substance (alcohol or drug) use disorder during their lifetime (Kessler et al., 2005). Nearly

9% of U.S. household residents aged 12 years and older met these criteria in the past year (Substance Abuse and Mental Health Services Administration [SAMHSA] (2011). Others do not meet these diagnostic criteria but use

alcohol or drugs in risky or harmful ways. Tobacco use is also prevalent. Approximately 27% of U.S. household residents aged 12 years and older used a tobacco product in the last month (SAMHSA). Social workers need knowledge of these problems because they work in many settings that serve people who have alcohol and drug problems.

The major categories of drugs of abuse are (1) central nervous system (CNS) depressants, such as alcohol, barbiturates, methaqualone, benzodiazepines, and inhalants; (2) CNS stimulants, such as cocaine and amphetamines; (3) opioids or narcotics, such as heroin, morphine, and codeine; (4) hallucinogens, such as LSD, PCP, psilocybin, mescaline, and peyote; (5) cannabis or marijuana; (6) anabolic steroids used to build muscles and improve appearance; (7) tobacco (nicotine); and (8) various over-the-counter drugs used to treat insomnia, coughs, colds, and other maladies, including some herbal preparations and dietary supplements intended to increase energy, sexual performance, appearance, or provide other effects. New substances or designer drugs that can be abused often become available. The National Institute on Drug Abuse (NIDA) and the Drug Enforcement Administration continually update their websites on drugs of abuse.

The causes of alcohol and drug problems have been widely debated. There is growing evidence that genetic and brain chemistry factors are involved (Wilcox & Erickson, 2005). There is also evidence that social and environmental factors influence substance abuse and dependence (McNeece & DiNitto, 2012).

SCREENING

A number of quickly and easily administered and scored instruments are available for social workers to use in screening individuals for alcohol and drug problems. Instruments may be self-administered (i.e., the client answers questions using pen and paper or on a computer) or the social worker administers the instrument by asking the client questions. Among the brief screening instruments most commonly used with adults are the:

- Alcohol Use Disorders Identification Test (AUDIT) (available in many languages)
- Substance Abuse Subtle Screening Inventory (SASSI).

Selection of screening devices and the method used to administer them should be based on the clientele served (e.g., age, reading level). Some screening instruments have been developed specifically for use with adolescents, such as the Problem Oriented Screening Instrument for Teens and the adolescent version of the SASSI, or with older adults, such as the MAST-Geriatric. The T-ACE and the TWEAK were developed for use in screening for risk drinking during pregnancy. Allen and Wilson (2003) contains many of the aforementioned instruments, as well as other instruments for screening, diagnosis, assessment, treatment planning, and measuring outcomes, including descriptive, psychometric, and copyright information and sources for obtaining the instruments. The SAMHSA-Health Resources and Services Administration (HRSA) Center for Integrated Services website also provides a page on screening tools. Winters (1999) provides information on screening adolescents for substance use problems. Though some instruments have undergone psychometric testing with members of various racial, ethnic, and cultural groups, the field lacks instruments that may improve screening among specific racial, ethnic, and cultural groups. An exception is the Drug and Alcohol Assessment for the Deaf, which was developed and tested in American Sign Language (available through the South Southwest Addiction Technology Transfer Center).

Screening has been increasingly used in health settings to identify individuals who drink at risk levels. Risk may be defined for men under age 65 years as no more than four drinks on any day *and* no more than 14 drinks in a week ("Rethinking Drinking," n.d.). Risk may occur at lower levels if an individual has health or other risk factors. Because women tend to metabolize alcohol more slowly than men and may experience alcohol-related problems at lower drinking levels than men, limits for women are lower—no more than three drinks per day *and* no more than seven per week. Because alcohol metabolism slows with age, everyone aged 65 years and older is advised to observe these lower levels.

Evidence-based brief interventions can help individuals who drink at risk levels cut down or stop drinking. These short education, advice, or counseling interventions can be delivered

- CAGE (the four-item CAGE is one of the briefest tools)
- Michigan Alcoholism Screening Test (MAST)
- Drug Abuse Screening Test (DAST)

in sessions as short as a few minutes (“Brief Interventions,” 2005).

DIAGNOSIS

Screening is often the first step in the assessment process, but it does not substitute for a diagnostic evaluation made by a qualified clinician such as a social worker. The *Diagnostic and Statistical Manual of Mental Disorders* (DSM) (American Psychiatric Association, 2013), used extensively in the United States, contains criteria for two major categories of substance-related disorders—substance-induced disorders and substance use disorders.

- Substance-induced disorders include intoxication, withdrawal, and substance-induced mental disorders (psychotic, bipolar, depressive, anxiety, obsessive-compulsive, sleep, sexual, delirium, and neurocognitive) that result from intoxication or withdrawal from abused substances. Medication (prescribed or over-the-counter)-induced mental disorders result from use at suggested doses. Substance/medication-induced mental disorders usually resolve within a month of cessation or withdrawal but may persist. In crisis situations, it can be difficult to distinguish whether alcohol, other drugs, or other factors are the cause of these mental disorders. Diagnoses can also be difficult to make because some people have more than one substance use disorder or they have both mental *and* substance use disorders (Kessler, Chiu, Demler, Merikangas, & Walters, 2005).
- Substance use disorders are “a problematic pattern of” substance “use leading to clinically significant impairment or distress” (APA, 2013, [see, for example, p. 490]). This diagnosis generally requires that at least 2 of the following 11 criteria have occurred within a 12-month period:
 1. Using greater amounts than intended
 2. Continued desire or unsuccessful attempts to control use
 3. Spending substantial time getting, using, or recovering from the substance
 4. Craving or strong desire to use the substance
 5. Recurrent failure to meet major responsibilities due to substance use
 6. Recurring social/interpersonal problems due to substance use
 7. Curtailing work or other important activities due to substance use
 8. Continued use in physically hazardous situations
 9. Continued use despite related physical and/or psychological problem(s)
 10. Tolerance (The same amount of the substance produces less of an effect or more of the substance is needed to produce the desired effect.)
 11. Withdrawal (The signs or symptoms of the substance’s withdrawal syndrome occur or the substance or a closely related one is used to prevent or relieve withdrawal.) This criterion is not present for every drug class (e.g., hallucinogens, inhalants).

A substance use disorder is “mild” if two or three symptoms are present, “moderate” if four to five are present, and “severe” if six or more are present. Specifiers are “early remission” if no criteria are met for at least 3 months but less than 12 months, and “sustained remission” if no criteria have been met for at least 12 months. However, an individual may meet the craving or desire criterion and still be in early or sustained remission. Other specifiers indicate whether an individual has restricted substance access (e.g., they are in jail or locked inpatient treatment), and for some substances, whether the individual is on maintenance therapy (medications to prevent substance use).

With release of the DSM’s fifth edition in 2013 (APA, 2013), tools are becoming available to help clinicians apply the revised criteria for substance-related disorders (e.g., Nussbaum, 2013). Clinicians are more confident in their diagnoses of substance use disorders when they have multiple sources of information on which to rely, such as a diagnostic interview, laboratory tests, and information from collateral sources (e.g., family members, other professionals, and client records).

Screening and diagnosis are best done (Skinner, 1984) when the:

- Client is alcohol- and drug-free and mentally stable
- Person doing the assessment builds rapport with the client
- Client knows that corroborating information will be used

- Client is assured of confidentiality.

In many cases, drug courts, probation or parole officers, or child protective service agencies refer clients to qualified professionals expressly to determine the existence of a substance abuse or dependence problem and the need for intervention. Though these clients may be under duress, they often consent to release of information (i.e., waive confidentiality and allow the information to be released) to the referring agency.

ASSESSMENT

The Addiction Severity Index (ASI) is a widely used standardized instrument for conducting assessments of adults with substance use disorders. (Allen and Wilson [2003] describe this and other assessment tools.) The ASI contains seven domains: medical, employment, alcohol, drug, legal, family/social, and psychiatric, which provide substantial social history information. This type of multidimensional assessment is consistent with social workers' bio-psychosocial perspective. The ASI includes three types of scores (composite scores based on answers to several questions, interviewer-rated severity scores, and client-rated severity scores) that indicate the extent of the clients' problems in each of the seven domains.

Social workers are generally well versed in taking social histories. Because most do not work in chemical dependency treatment programs but encounter clients with these problems, McNeece and DiNitto (2012) provide information and a guide for taking clients' social history in cases where information on alcohol and drug problems is needed. This book is also a basic text on chemical dependency for social workers and other helping professionals and contains information on treatment and on populations such as women, adolescents, older adults, members of minority racial and ethnic groups, people with mental and physical disabilities, and gay, lesbian, bisexual, and transgender persons. The social history guide addresses 10 areas: education, employment, military history (if applicable), medical history, drinking and drug use, psychological or psychiatric history, legal involvement (if applicable), family history, relationships with significant others, and reasons the individual is seeking help. As with diagnosis, assessment can be facilitated when multiple sources of information are available.

TREATMENT PLANNING

Once the nature of the client's substance abuse or dependence and related problems is understood, treatment planning may begin. The American Society of Addiction Medicine (ASAM) (Mee-Lee, 2013) publishes a guide for treatment planning in the chemical dependency field. The placement criteria are in the form of a two-dimensional crosswalk. One dimension of the adult admission crosswalk contains five levels of care that form a continuum:

1. Early intervention
2. Outpatient services
3. Intensive outpatient/partial hospitalization services
4. Residential/inpatient services
5. Medically managed intensive inpatient services.

The second dimension contains six factors that suggest the level of recommended care:

1. Acute intoxication and/or withdrawal
2. Biomedical conditions and complications
3. Emotional, behavioral, or cognitive conditions and complications
4. Readiness to change
5. Relapse, continued use, or continued problem potential
6. The individual's "recovery environment."

The crosswalk makes it clear that treatment should be based on the individual client's needs.

A client's readiness for change, and the services needed based on this level of readiness, is often assessed using the transtheoretical model (TTM) of change (Prochaska, DiClemente, & Norcross, 1992). The TTM is also an approach to delineating the stages an individual goes through in changing a behavior like alcohol or drug abuse or dependence. This change process has been conceptualized in five stages (Prochaska et al., 1992; DiClemente, 2003):

1. Precontemplation (individual is unaware a problem exists)
2. Contemplation (individual becomes aware of problem and starts to think about making changes)
3. Preparation (individual intends to make changes soon)

4. Action (individual successfully changes his or her situation)
5. Maintenance (individual makes continued changes to avoid relapse).

The stages do not necessarily progress in a linear fashion. People may relapse and return to some earlier stage in the change process, necessitating a change in treatment or service approaches that will help them move forward.

EVIDENCE-BASED TREATMENT

The ASAM crosswalk indicates that several modalities are used in treating alcohol and other drug problems. Among the residential services clients may need are therapeutic communities and halfway houses, which vary in their level of client supervision and monitoring and in the length of stay allowed. Insurance-supported treatment for many people has become briefer, and long stays in intensive inpatient treatment programs are rare. Most clients receive outpatient services.

The literature often discusses treatment for alcohol problems separately from treatment for other drug problems even though these problems often co-occur. Historically, approaches for addressing alcohol problems and other drug problems developed separately. The U.S. Department of Health and Human Services (DHHS), National Institutes of Health houses the National Institute on Alcohol Abuse and Alcoholism (NIAAA) and NIDA, which cooperate with each other and fund treatment studies. SAMHSA, another DHHS agency, works to improve treatment quality and availability.

NIDA (2012a) describes principles of effective drug addiction treatment.

- No single treatment is appropriate for all individuals.
- Treatment should be readily available.
- Effective treatment should address the individual's multiple needs.
- Remaining in treatment for a sufficient time is essential.
- The most common treatments are individual and group counseling and other behavioral therapies.
- Medications can be an important treatment component.
- Continual assessment and modification (when needed) of an individual's treatment/service plan is necessary.

- Individuals who have substance use disorders and coexisting mental disorders should receive treatment for both.
- Medical detoxification is generally the first treatment stage (alone it is unlikely to change long-term drug disorders).
- Treatment does not have to be voluntary to be effective.
- To prevent relapse, possible drug use during treatment must be monitored continuously.
- Treatment programs should provide assessment for infectious diseases and counseling to change risk behaviors.

Many approaches, including medications (pharmacotherapies), have been used to treat alcohol or other drug problems. The evidence-based practices social workers use usually have a cognitive and/or behavioral basis. Some of the evidence-based approaches to alcohol and drug addiction treatment for adults NIDA (2012a) has identified are:

Cognitive-behavioral therapy is based on the theory that learning processes play a critical role in the development of maladaptive behaviors such as drug abuse. Treatment techniques include exploring the consequences of continued drug abuse and self-monitoring to recognize cravings and how to address them.

Contingency management interventions/motivational incentives (CM) principles involve giving tangible rewards to reinforce positive behaviors such as abstinence. CM includes the use of vouchers and other "prize" incentives.

Community Reinforcement Approach plus vouchers uses a variety of recreational, familial, social, and vocational reinforcers, along with material incentives, to make a drug-free lifestyle more rewarding than substance use.

Motivational Enhancement Therapy uses motivational interviewing principles to strengthen motivation and build a plan for change. Coping strategies for high-risk situations are suggested and discussed with the client.

The Matrix Model helps clients learn about issues critical to addiction and relapse, receive direction and support from a trained therapist, and become informed about self-help programs. Clients are monitored for drug use through urine testing.

12-Step Facilitation Therapy is an active engagement strategy designed to increase the likelihood that a substance abuser will become involved in 12-step mutual-help groups. The key principles are acceptance, surrender, and active 12-step recovery group participation.

Family Behavior Therapy involves the client and at least one family member in applying behavioral strategies to improve the home environment. It combines behavioral contracting with contingency management. Clients are involved in treatment planning and choosing specific intervention strategies. The evidence-based behavioral therapies primarily used with adolescents that NIDA (2012a) has identified include Multisystemic Therapy and Multidimensional Family Therapy. Both target interactions within the family and the relationships between the client, the family, and external networks, such as schools, peers, and the neighborhood.

NIDA (2012a) provides more information about these treatment modalities for adults and adolescents. The Cochrane Collaboration and the Campbell Collaboration provide systematic reviews of specific treatment approaches. Social workers will also find the SAMHSA National Registry of Evidence-based Programs and Practices helpful. Notable themes among efficacious treatments appear to be a focus on building clients' skills and self-efficacy, increasing motivation, and inclusion of significant others (Miller & Wilbourne, 2002). Although evidence supports the inclusion of significant others in promoting and sustaining recovery, treatment programs may pay insufficient attention to doing so, perhaps due to funding constraints. Assisting families is a strong suit of social workers. Family members need education and counseling to help them cope, whether or not the individual with the substance use disorder desires help.

MEDICATION-ASSISTED TREATMENT (PHARMACOTHERAPIES)

Another evidence-based approach to substance dependence treatment is medication, generally used as an adjunct to cognitive/behavioral (also called psychosocial) treatment. A few medications have been approved for longer-term opioid,

alcohol, and tobacco use disorder treatment. No medications have yet been approved for treating stimulant (e.g., cocaine, amphetamine) use disorders. Social workers may work with clients taking these medications. They may also refer clients to physicians who can help the client consider whether such medications may be helpful to them.

Opioid Treatment

Methadone, a long-acting synthetic opioid agonist medication, has long been used in preventing withdrawal symptoms and reducing craving in individuals addicted to opioids. It is taken orally and can also block the effects of opioids. Buprenorphine is a synthetic opioid medication that acts as a partial agonist for other opioids. It does not produce the euphoria and sedation caused by illicit opioids and can reduce or eliminate withdrawal symptoms associated with opioid dependence. Naltrexone, a synthetic opioid antagonist approved for treating opioid addiction, prevents the euphoric effects of illicit opioids, and has been used for many years to reverse opioid overdose.

Tobacco Treatment

The commonly used nicotine replacement therapies (NRTs) include the transdermal nicotine patch, nicotine spray, nicotine gum, and nicotine lozenges. Bupropion, originally marketed as an antidepressant (Wellbutrin), produces mild stimulant effects by blocking the reuptake of certain neurotransmitters. Some patients who were prescribed bupropion for depression reported that the medication was also effective in suppressing tobacco craving. Varenicline, the most recently FDA-approved medication for smoking cessation, acts as a partial agonist/antagonist on nicotinic receptors in the brain thought to be involved in the rewarding effects of nicotine.

Because tobacco use is a major cause of cancer, heart disease, bronchitis, emphysema, and stroke and is a common cause of preventable death, social workers should be available to assist clients with effective smoking cessation treatments such as cognitive behavioral therapy (NIDA, 2012a) and self-help or mutual help programs such as telephone "quit lines" and the Quit for Life program (NIDA, 2012b).

Alcohol Treatment

Naltrexone blocks opioid receptors that produce the rewarding effects of drinking and the craving for alcohol. For some problem-drinkers it may reduce the chance of relapse. An extended-release injectable version, Vivitrol, is also FDA-approved for treating alcoholism, and increases patient compliance. Acamprosate does not prevent the immediate withdrawal symptoms people may experience when they stop drinking alcohol, but it acts on certain neurotransmitter systems to reduce symptoms of protracted withdrawal (e.g., insomnia, anxiety, restlessness, and dysphoria). It helps the brain work normally after an individual has drunk a large amount of alcohol. It may be more effective than other medications for patients with severe dependence. Acamprosate is used (with counseling and social support) to help people who have stopped drinking large amounts of alcohol to avoid drinking alcohol again. Disulfiram (Antabuse) use results in the accumulation of acetaldehyde, which produces extremely unpleasant reactions (flushing, nausea, and palpitations) if alcohol is ingested. Disulfiram's effectiveness is considered limited because compliance is often poor, but it can be useful for highly motivated patients. Some use it effectively for high-risk situations (e.g., social occasions where alcohol is served).

12-STEP PROGRAMS AND OTHER MUTUAL-HELP RESOURCES

The first 12-step program was Alcoholics Anonymous (AA). Similar groups developed to help people with other drug problems, such as Narcotics Anonymous (NA) and Cocaine Anonymous (CA). They are considered spiritual programs, though agnostics and atheists have recovered in them. These programs offer a wealth of literature through their national offices and websites, including information directed to professionals.

Groups such as AA and NA have "open" meetings to help family members of people with alcohol and drug disorders, helping professionals, and other interested individuals learn about them. These groups are usually listed in local phone directories and online and can be contacted for information on attending meetings. The groups are often different than what visitors (and new

members) imagine they will be. Professionals should be knowledgeable about them in order to help clients consider their suitability for helping them in the recovery process. Participation in mutual-help groups is fully compatible with professional treatment and can be an especially good source of aftercare. Others may not utilize professional treatment and use these groups as their primary recovery resource.

The 12-step program for family members and friends of alcoholics is Al-Anon and for families and friends of addicts is Nar-Anon. Groups for children and adolescents are Ala-tot and Alateen (contact information is the same as for Al-Anon). Other groups for family members have emerged such as Adult Children of Alcoholics groups.

Other mutual-help programs for those recovering from alcohol and drug problems are SOS, an alternative to the spiritual programs, and Women for Sobriety, dedicated to empowerment and other aspects of women's recovery.

OUTCOME MEASURES

Measuring individual client outcomes in clinical practice is often done informally, but tools specific to the substance abuse and dependency treatment field can be used to assist with this task. Allen and Wilson (2003) contain many of them (along with tools for measuring agency- or program-level outcomes). For example, the ASI has a follow-up version that can be used to measure client outcomes following treatment, and the Drinker Inventory of Consequences (DrInC) can also be used in treatment planning and in evaluating treatment outcomes. Several chapters in this volume focus on measuring and evaluating outcomes in health and mental health settings.

Best Practices in Social Work with Groups

Mark J. Macgowan & Alice Schmidt Hanbidge

Social work with groups should be based on best practices within the profession gained through a career-long commitment to a systematic process of critical reflection, inquiry, application, and practice evaluation, defined as evidence-based group work (EBGW, Macgowan, 2008). EBGW is a process of judicious and skillful application in group work of the best evidence using evaluation to ensure desired results are achieved (Macgowan, 2008). It is operationalized through a critical four-stage process model in which group workers (a) formulate an answerable practice question; (b) search for evidence; (c) undertake a critical review of the evidence for rigor, impact, and applicability yielding “best available evidence”; and (d) apply the evidence in practice with concern for relevance and appropriateness for the group and its members, utilizing evaluation to determine whether desired outcomes are achieved. EBGW is a process that can incorporate various theories and models of practice, as long as there is best evidence that these will be helpful to group members. Failure to engage in this process can lead to stagnation in practice, reliance on what is popular and not effective, and group processes and outcomes that are iatrogenic but avoidable. EBGW incorporates (a) empirically supported group interventions and processes, (b) evidence-supported guidelines, and (c) practice evaluation.

EMPIRICALLY SUPPORTED GROUP INTERVENTIONS AND PROCESSES

Empirically supported *group interventions* (including preventive interventions) (ESGIs) have been shown to be efficacious for specific diagnostic groups (e.g., depression, anxiety) or populations through randomized clinical trials and meta-analyses. ESGIs are typically well-defined, often manualized, and structured. Group workers would use such interventions if they are determined to be “best available evidence” as defined above.

Empirically supported *group processes* are what research has demonstrated to be associated with positive outcomes in groups. One example is cohesion, which is “the therapeutic relationship in group psychotherapy emerging from the aggregate of member-leader, member-member, and member-group relationships” (Burlingame, Fuhrman, & Johnson, 2001, p. 373). A meta-analysis reported that cohesion was significantly associated with reductions in symptom distress or improvements in interpersonal functioning across various settings and diagnoses (Burlingame, McClendon, & Alonso, 2011). Although the research is not as extensive as that of cohesion, engagement is also a predictor of retention and positive outcomes in groups

(Macgowan, 2006; Macgowan & Newman, 2005). According to Macgowan (1997), engagement in groups is a multidimensional construct where group members connect to their groups in seven areas: Attendance, verbal contribution and/or participation in group activities, support for the work of the leader, interaction with members, adoption of the contract, work on own problems, and assisting members in their work on their problems.

EVIDENCE-SUPPORTED BEST PRACTICE GUIDELINES

The second element that EBGW critically incorporates is evidence-supported group work standards and practice guidelines that have been developed by panels of experts to promote appropriate and effective practices (“best practice guidelines”). All group workers must become familiar with the standards and guidelines, and particularly those within their professions. Such standards and guidelines incorporate the best practices, values, and ethics of the respective professions. There are practice guidelines from the American Group Psychotherapy Association (AGPA, 2007; Burlingame et al., 2006; Leszcz & Kobos, 2008) and best practice guidelines and standards from the Association of Specialists in Group Work (ASGW, 2000, 2008).

Within social work, there are standards for the practice of social work with groups developed by the International Association for the Advancement of Social Work with Groups (IASWG, 2006; formerly the *Association for the Advancement of Social Work with Groups*) (Cohen, Macgowan, Garvin, & Muskat, 2013). The Standards “represent the perspectives of the [IASWG] on the value and knowledge and skill base essential for professionally sound and effective social work practice with groups and are intended to serve as a guide to social work practice with groups” (IASWG, 2006, p. 1). A reliable and valid measure has been developed to assess group workers’ perceptions of the importance of the items in the Standards and their confidence in doing them (Macgowan, 2012, 2013; Macgowan & Vakharia, 2012). Using the measure, one study (Macgowan, 2012) identified the top items in the Standards that respondents ($n = 426$) thought they were least confident in doing. Three of the top items were: (a) using special skills in working with mandated members; (b) promoting group

exploration of nonproductive norms when they arise; and (c) helping members mediate conflict within the group. This chapter will include specific practice ideas/techniques to manage those three issues. Knowing how to practice the IASWG Standards is an essential foundation for social work with groups.

In addition, ASGW (2012) developed best practice principles with respect to multicultural group work and social justice. The multicultural and social justice competence principles fall into three areas: (a) awareness of self and group members; (b) use of strategies and skills that reflect multicultural and social justice advocacy competence in group planning, performing, and processing; and (c) social justice advocacy (Singh, Merchant, Skudrzyk, & Ingene, 2012). In working with increasingly culturally diverse populations, it is essential for group workers to become familiar with these guidelines, in addition to the best practice guidelines of their own professions.

PRACTICE EVALUATION

The third area of EBGW is practice evaluation. According to the IASWG Standards, group workers should include in their practice “monitoring and evaluation of success of group in accomplishing its objectives through personal observation, as well as collecting information in order to assess outcomes and processes” (IASWG, 2006, p. 9). Practice evaluation needs appropriate assessment measures and a suitable research design.

Assessment. Assessment may focus on (a) member-related outcomes, (b) group-related outcomes, and (c) group processes. Assessing *member-related outcomes* focuses on the original concern that led to the member’s referral (e.g., aggression, depression, social competence). An excellent resource for member-related assessment instruments is Fischer and Corcoran’s *Measures for Clinical Practice and Research* (2007). Assessing *group-related outcomes* focuses on collecting information about the group experience from group members. Examples of such measures include the Post-Session Questionnaire (Rose, 1984) and Evaluation of the Group Experience (Corey, Corey, & Corey, 2010). Assessing *group processes* emphasizes areas such as cohesion and engagement, which are related to positive group outcomes. The Cohesiveness Scale (Burlingame, et al., 2006) and the Group Engagement Measure (Macgowan, 1997, 2006; Macgowan & Newman,

2005) may be used (for additional group outcome and process measures see Burlingame et al., 2006; Garvin, Tolman, & Macgowan, 2015; Sodano et al., 2014). It should be noted that assessment instruments should be carefully selected for their rigor, impact, and applicability (Macgowan, 2008). In particular, they should be appropriate for the racial and ethnic group with which they will be used (Macgowan, 2008; Singh et al., 2012).

Research design. To determine whether the group work service actually helps group members, assessment is accompanied by a suitable research design. There are various approaches to evaluating whether an intervention is successful (Garvin et al., 2015). One informal approach is to use Goal Attainment Scaling (Kiresuk, Smith, & Cardillo, 1994; Toseland & Rivas, 2012). Goals may be a change in the problems of individual group members (member-related outcomes), or a change within the group itself (group-related outcomes), such as level of cohesion or engagement. A more formal approach is to use a single-case design (Macgowan & Wong, in press). A basic A–B single-case design can be used, consisting of taking several baseline measurements (“A”) before the group begins, followed by repeated measurements over the course of the group (“B”). If baseline measurements cannot be done, a simple B design of repeated measures over the duration of the group may be used. In addition to the quantitative single case design, group workers may use a qualitative method, such as a focus group to gather detailed information about the group work service (Toseland & Rivas, 2012). For additional designs for group work, see Garvin and colleagues (2015).

All three elements of EBGW, empirically supported group interventions and processes, evidence-supported best practice guidelines, and practice evaluation are incorporated in this chapter. We describe how social work with groups incorporates the best available evidence through a generic developmental stage model of group work of planning, beginnings, middles, and endings. In addition, because group workers are often least confident working with mandated members, we will incorporate ideas for working with mandated members throughout this entry.

PLANNING

Northen and Kurland defined planning as including “the thinking, preparation, decision-making,

and actions of the social worker prior to the first meeting of the group” (2001, p. 109). Best practice guidelines (AGPA, AGSW, IASWG) and much empirical research (Burlingame, Strauss, & Joyce, 2013) refer to the importance of pregroup planning and preparation, although it is often neglected (Kurland, 1978). The IASWG Standards (2006) include 15 tasks and skills that group workers should master in the planning stage related to recruiting, screening and selecting members, provisions and limits for informed consent, and identifying group purposes and goals. Of the fifteen areas, three which social workers have felt least confident in doing were how to (a) select the group type, structure, processes, and size that will be appropriate for attaining the purposes of the group; (b) select members for the group in relationship to principles of group composition (assuming one has a choice); and (c) prepare members for the group (Macgowan, 2012). These areas will be addressed in the following sections on screening, purpose, composition, structure, and content. We will also include a section on planning for group work with mandated members.

Screening

Best practice guidelines (AGPA, ASGW, IASWG) recommend that group members should be selected and screened to assess their suitability for group work and to determine how the proposed group work may meet those needs. The first consideration is to determine whether the prospective member is suitable for group work. There are research-based screening tools that can be helpful, such as the Group Readiness Questionnaire (Baker, Burlingame, Cox, Beecher, & Gleave, 2013) and the Group Therapy Questionnaire (GTQ) (Burlingame et al., 2006; MacNair-Semands, 2004). The GTQ may be used to evaluate client expectancies for group work, which “may identify clients that could be ‘at risk’ for premature dropout, allowing more effective preparation of the client prior to group participation” (Burlingame, Cox, Davies, Layne, & Gleave, 2011, p. 71). Although these measures are research-based (rigorous), they should also be evaluated by each group worker for their applicability for intended group members (Macgowan, 2008).

Purpose

The group’s purpose determines many factors about the group, such as “the group type,

structure, processes, and size" (IASWG, 2006, p. 10). A clear statement of purpose reflects member needs and agency mission and goals (IASWG, 2006). It is essential to have a preliminary purpose statement that is succinct and that captures the essentials of the group work service. So that it is clearly understood, the purpose statement should ideally be one sentence, such as "to help sixth-grade pupils make a satisfactory adjustment to junior high school," followed by goals that "would be related clearly to the needs of particular members of the group" (Northen & Kurland, 2001, p. 125).

In going over the purpose of the group, group workers should ideally meet in person with prospective members. Although it may not always be feasible, the meeting is recommended because it (a) helps prepare members for the group service; (b) can establish the empirically supported therapeutic alliance that lays the foundation for group cohesion (Burlingame, Fuhriman, & Johnson, 2002); and (c) may improve retention (Burlingame, Fuhriman, & Mosier, 2003; Piper & Ogradniczuk, 2004), particularly for persons with alcohol and other drug problems (Joe, Simpson, & Broome, 1999; Simpson, 2004). Sometimes such sessions are done in an orientation group session, where suitability for the prospective group can be assessed *in vivo*. This orientation session would also include (a) obtaining informed consent, which aids group member commitment; (b) a discussion of member rights and a professional confidentiality disclosure outlining the limits of confidentiality; and (c) dealing with any potential concerns or questions.

Composition

The function of screening is to determine members' suitability to participate in the life of the group and to not distract others from that ability. Composition in groups is the planned mix of individuals who have already been screened. Unlike screening where there are clearer guidelines, the research on how to compose groups has mixed findings: "The diversity of findings regarding composition suggests that there is no simple rule to follow, requiring group leaders to be conversant with relevant research findings" (Burlingame, et al., 2013, p. 669). Thus, what follows are tentative guidelines for composition. In many cases composition cannot be predetermined, but where it can, members should be selected based on principles of group composition, which is part of the IASWG Standards.

The first and foremost principle is that the group's purpose will guide who should be included (Klein, 1972; Northen & Kurland, 2001; Toseland & Rivas, 2012). All members must share the common purpose, though not necessarily common objectives. A second principle is that composition is less important with groups that are briefer and more structured, such as task- and training-oriented groups, rather than groups that are relationally oriented and interactional (Yalom, 1995). A third principle is if the group work is focusing on particular issues, group members should be similar with respect to that issue. This is particular so with group interventions that may be specifically related to race and culture ("culture-specific groups," see Merchant, 2009), such as bicultural skills training with Latino immigrant families (Bacallao & Smokowski, 2005). A meta-analysis (Griner & Smith, 2006) reported that interventions provided for same-race participants were four times more effective than interventions provided for mixed-race groups. Interventions delivered in clients' own languages were twice as effective as interventions delivered in English. A fourth general principle is to avoid having one person with little in common with other members (Garvin, 1997; Northen & Kurland, 2001). For example, Levine (1979) suggested that children in groups should be able to identify with at least one other child in the group, in terms of age, gender, culture, or other areas that are important for the child. A fifth principle is that even in groups where there is homogeneity with respect to certain variables (e.g., race, ethnicity), heterogeneity with respect to life experience, level of expertise, and coping skills is desirable so that members may benefit from one another's different strengths. Such differences "can provide multiple opportunities for support, validation, mutual aid, and learning" (Toseland & Rivas, 2012, p. 173).

Structure

Structure includes many things, but two are group size and length. The length and size of a group varies depending on the purpose of the group and the population involved. For example, closed groups that are long (over 12 sessions) and involve nonmandated involuntary clients may need to have larger group sizes to compensate for attrition. However, as a general guide, cohesion is strongest when a group has over 12 sessions and includes five to nine members (Burlingame,

McClendon, et al., 2011). With respect to length, there are different standards depending on the type of group. The ideal length for a psycho-educational group is 12 to 16 sessions and from 10 to 15 sessions (or more) for counseling groups (DeLucia-Waack & Nitza, 2014). To effectively have time to integrate therapeutic factors into adult groups, psycho-educational and counseling groups are typically 1 to 1½ hours in duration (DeLucia-Waack & Nitza, 2014). Groups for mandated members often vary in length and are focused on the development of skills. Anger management, problem-solving, or offender groups are often 8 to 12 sessions (Morgan, 2004).

Content

ESGIs have been shown to be efficacious for persons with specific diagnoses through randomized trials, meta-analyses, or through consensus of experts based on a critical review of the best research evidence. Systematic reviews over the years support the efficacy (tightly controlled studies) and effectiveness (real-world settings) of small group interventions (Burlingame et al., 2003; Burlingame et al., 2013). A systematic review of more than 250 studies across 12 problem areas/client populations concluded that there is “clear support for group treatment with good or excellent evidence for most disorders reviewed (panic, social phobia, OCD, eating disorders, substance abuse, trauma-related disorders, breast cancer, schizophrenia, and personality disorders) and promising for others (mood, pain/somatoform, inpatient)” (Burlingame et al., 2013, p. 664).

With respect to particular change theories, there is very good to excellent evidence that

- Cognitive-behavioral group therapy (CBGT) is effective with social phobia and comorbid depression, bulimia nervosa, binge-eating disorders, panic disorder, schizophrenia, trauma symptoms, and secondary outcomes.
- Psycho-education, time-limited therapy, and support groups are effective for cancer patients.
- CBGT and dialectical behavior therapy are effective for treating suicidality, parasuicidality, depression, and hopelessness associated with borderline personality disorder;
- A range of models (e.g., behavioral, motivational, contingency management,

psycho-educational, integrative group therapy, interactional, 12-step) are effective for reducing substance use. (Burlingame et al., 2013; Burlingame, Whitcomb, & Woodland, 2014)

Group workers should obtain the particular studies in the review (Burlingame et al., 2013) and critically review them for rigor, impact, and applicability to ensure they are the best available evidence (Macgowan, 2008). An ESGI may be “efficacious” but it may not be appropriate for the group. This is particularly important when considering the use of ESGIs with populations that are culturally different than those in the original studies. Such interventions may need to be adapted or tailored for race and ethnicity to be more effective (Benish, Quintana, & Wampold, 2011; Chen, Kakkad, & Balzano, 2008; Macgowan & Hanbidge, 2014). To be a skillful multicultural group worker (ASGW, 2012), it is important to develop “a repertoire of culturally relevant group work interventions” (DeLucia-Waack, 2004, p. 167).

Mandated Members in the Planning Stage

During the planning phase, there are special considerations in working with clients who are involved in the criminal justice system (offenders) and those who are legally required to attend treatment (mandated). Involuntary members may be mandated or have nonlegal pressure from others to attend a group (Rooney, 2009). Group work can be effective with offenders, mandated clients, and involuntary clients. A systematic review reported that group work with such clients can reduce anger, anxiety, and depression, as well as improve interpersonal relations, locus of control, and self-esteem (Morgan & Flora, 2002). Coviello and colleagues (2013) found that clients who were mandated to community treatment (which included group work) were higher treatment completers than those who were not court-ordered to attend. Additionally, mandated offenders were 10 times more likely to complete treatment than voluntary participants.

Group members who are mandated may not be prepared to acknowledge problems that others have identified. Understanding the nature of change through the stages-of-change model (Connors, Donovan, & DiClemente, 2001; Prochaska & DiClemente, 1984) can help

workers facilitate the change process with clients who are mandated to service. The five stages include precontemplation (no recognition of problem), contemplation (identify problem, not willing to act), preparation (ready to make first step), action (taking steps), and maintenance (maintain change) (Miller & Rollnick, 2002). Designed particularly for those in the precontemplation and contemplation stages, motivational interviewing (MI) is “a client-centered directive method for enhancing intrinsic motivation to change by exploring and resolving ambivalence about change” (Miller & Rollnick, 2002, p. 23). MI is an efficacious communication style, which includes the following five elements: express empathy, avoid argumentation, roll with resistance, develop discrepancy, and promote self-efficacy (Miller & Rollnick, 2002; Miller & Rose, 2009). MI often also includes providing personalized feedback on behaviors presented in a person-centered, nonconfrontational way to help persons explore their behaviors. The technique often includes discussing the pros and cons of the behaviors and highlighting discrepancies (for applications of MI in group work, see Sobell & Sobell, 2011; Velasquez, Maurer, Crouch, & DiClemente, 2001).

In the planning stage, when mandated and involuntary group members may be in the precontemplation and contemplation stages of change, Rooney (2009; 2004) recommends the following actions when meeting with members or when composing the group:

- Clarify non-negotiables
- Reframe from resistance to ambivalence
- Clarify rights, choices, and limits on choices
- Expect oppositional behavior
- Identify current motivations and attempt to link to them
- Identify positive skills and knowledge to be gained in group
- Include positive role models, such as successful former members, in the group.

Morgan and colleagues (2014) recommend the following ESGIs as effective with offenders and mandated clients: (a) cognitive-behavioral group work; (b) structured group work (i.e., clearly defined goals and objectives, clear rules and expectations); and (c) out-of-group homework exercises, which improves outcomes compared with groups not utilizing such exercises (Morgan & Flora, 2002).

BEGINNINGS

The beginning of a group is often characterized by caution and tentativeness and it is common for group members to enter the group with mixed emotions; excitement and hope that the group can be beneficial mixed with concerns about trusting strangers with personal information and fears that the group could be a negative experience. The role of the group worker in establishing the group is central at this time. There are many areas that must be addressed at this stage and the IASWG Standards (2006) include a number of tasks and skills related to beginnings. We focus on what the Standards highlight as important; namely, cultivating mutual aid and building cohesion. We also continue the theme of how to work with mandated members.

Cultivate Mutual Aid

One of the early tasks as the group begins is for the worker to invite members to introduce themselves and to say what brought them to the group. This activity helps members to begin to share mutual concerns and interests in a trusting environment to develop universality (“all in the same boat”) which is an essential ingredient of mutual aid (Shulman, 2009; Steinberg, 2010). Creating mutual aid is a core part of social work with groups (IASWG, 2006). Schwartz defined mutual aid as “an alliance of individuals who need each other, in varying degrees, to work on certain common problems” (1961/1994, p. 266). This supportive, working group does not simply happen, but is facilitated by the group worker in a “mediating” professional function (Schwartz, 1976) in which the worker connects individuals with each other and with the worker to create a helping system.

The IASWG Standards (2006) includes numerous items related to helping build mutual aid in the group, such as “helps members establish relationships with one another”; “highlights member commonalities”; “encourages direct member to member communication”; “clarifies and interprets communication patterns among members, between members and worker, and between the group and systems outside the group”; “models and encourages honest communication and feedback among members and between members and workers”; and “links members to one another.” In particular, linking is an important technique for fostering mutual

aid. Middleman and Wood (1990) discuss two ways in which members may be linked; a feeling link and an information link. A feeling link asks members “to connect with a feeling being expressed” (p. 120), whereas an information link asks members “to connect with a statement or question that someone has expressed” (p. 122). Reaching for an information link not only connects members but also allows the worker to “give back their assumed power to others by signaling that they are the ones best able to respond to their issues out of their own experiences” (Middleman & Wood, 1990, p. 123).

Build Cohesion

Cohesion is an essential part of effective group work. Research studies have reported a number of factors related to cohesion: (a) it is most strongly associated with client improvement in groups using an interpersonal, psychodynamic, or cognitive-behavioral orientation; (b) group leaders who facilitate member interaction have higher cohesion-outcome links than groups that focused less on process; and (c) it contributes to outcomes regardless of inpatient and outpatient, or diagnostic classifications (Burlingame, McClendon et al., 2011). To build cohesion, the group worker should (Burlingame et al., 2001)

- Conduct pregroup preparation to establish treatment expectations
- Introduce structured activities in early sessions, which reduces anxiety and leads to higher levels of disclosure and cohesion later in the group (but reduce structure over time)
- Model effective interpersonal feedback, and maintain a moderate level of control and affiliation
- Time the delivery of feedback based on the developmental stage of the group and the readiness of members
- Effectively manage his or her own emotional presence to be warm, accepting, and empathic, which not only affects relationships with individuals in the group but all group members as they see the workers’ way of relating with others
- Facilitate group members’ emotional expression (e.g., empathy, support and caring, acceptance), and the responsiveness of others to that expressiveness.

Ongoing assessment of group processes is essential for measuring the optimal functioning of the group and for moving the group toward desired outcomes. Best practice guidelines (AGPA, 2007; Burlingame et al., 2006) recommend assessing group processes such as cohesion to determine whether strategies are needed to improve processes linked to positive outcomes. Group workers can monitor the effectiveness of the cohesion-building strategies above using the Group Psychotherapy Intervention Rating Scale (Chapman, Baker, Porter, Thayer, & Burlingame, 2010).

Mandated Members in the Beginning Stage

In the beginning stage, mandated and involuntary group members may still be in the precontemplation and contemplation stages of change. Best practices (Rooney, 2009; Rooney & Chovanec, 2004; Toseland & Rivas, 2012) recommend that the group worker

- Provide an opening statement addressing members’ initial concerns and ambivalence about accomplishing the group’s work and reassure them that they are not alone (linking members)
- Help members collaboratively recognize where points of ambivalence may occur. Rather than ignoring, playing down, or attacking the ambivalence, the group leaders can help the group members work through it.
- Reclarify non-negotiable and negotiable issues
- Help members recognize the range of choices, including constrained choices
- Support positive choices, identifying positive self-motivating statements
- Provide emotional support
- Present facts in nonblaming fashion
- Review choices and consequences of decisions
- Initiate discussion of pros and cons of deciding to change
- Emphasize self-assessment of severity of problems
- Enhance self-attribution (acknowledgment that change is in members’ best interest)
- Use tactful experiential confrontation (highlight discrepancy) when behaviors are inconsistent with stated goals

- Negotiate group rules and clarify expectations for each session
- Solicit member goals and link these to group goals.

MIDDLES

The journey to the middle stage may not be smooth. The group may go through what has been described as a time of “uncertainty-exploration” characterized by “storming” or “power and control” (Garland, Jones, & Kolodny, 1965; Northen & Kurland, 2001; Tuckman, 1965). During that time, workers help the group discuss and manage negative expressions of feelings, hostility, and conflict that might occur. Encouraging members to express negative feelings creates an environment of openness and gives an opportunity to address behaviors that are incongruent with the group’s purpose.

The middle (or working) stage of the group is often characterized by an increased level of self-disclosure, cohesion, mutual aid, problem-solving, a willingness to work on personal issues, and individual and group growth (Toseland & Rivas, 2012; Zastrow, 2009). The leader’s role shifts from active to less directive, encouraging greater group ownership and shared leadership within the group (an important value of the IASWG Standards). There are many areas that workers attend to in the middle stage, including maintaining cohesion, empowering group members, acknowledging cultural diversity, assessing progress, continuing to promote the process of mutual aid and to “use that process as a vehicle for work on personal, interpersonal, group, and environmental problems” (Northen & Kurland, 2001, p. 353). The IASWG Standards include 21 tasks and skills in the middle stage. Two skills that group workers find most challenging (Macgowan, 2012) are dealing with conflict in the group and managing disruptive norms, which will be discussed in this section, along with the theme of working with mandated members.

Manage Nonproductive Norms

The IASWG Standards note that unproductive norms and conflict are to be explored with the group, rather than addressed exclusively by the group worker. Processing interpersonal and group-related factors with members “is a major source of learning for both members and leaders”

(Ward & Ward, 2014, p. 40) and an essential part of social work with groups. Norms are shared expectations about ways to act in the group; these may be explicit or implicit, and develop through the interactions of group members (Toseland & Rivas, 2012). A single action is not usually evidence of a norm, but the repeated pattern of actions (behavior) over time and/or by a number of members. Given that they are developed through group interactions, the group must be involved in the process to manage norms. Group workers have the primary responsibility of guiding the group to create and reinforce productive group norms in the planning and beginning stages, and the responsibility to guide the group to explore nonproductive norms when they arise in any stage (Bernard et al., 2008; IASWG, 2006). Some examples of nonproductive norms include group members using “You” and “We” language, speaking in the third person, resisting, rescuing, and challenging the leader (Sklare, Keener, & Mas, 1990).

The IASWG Standards note that group members are to participate in the process of change. The group worker points out the unproductive norm and puts it back to the group to work it out, such as, “How have we let the repeated tardiness continue to today?” If successful, this may lead to the group managing other norm disruptions without prompting (Bernard et al., 2008). Some techniques for promoting group exploration of nonproductive norms as they arise include (partly based on Toseland & Rivas, 2012):

- Solicit group members’ feedback on the norm
- Discuss or demonstrate how the norm will affect the group’s ability to fulfill its purpose
- Help the group to develop a new productive response
- Help members reflect on the process of norm adjustment.

If these measures fail, the worker may need to intervene directly or have an external member work with the group to change its norms.

Work with Conflict

Conflict is “behavior in which there is disagreement between two or more persons” and “is a natural, necessary, and important component of group process” (Northen & Kurland, 2001, p. 214). A worry of group workers, particularly those with limited group work education and training, is that conflict will spiral out of control and ruin

the group experience (Northen & Kurland, 2001; Steinberg, 1993). As with exploring unproductive norms, the IASWG Standards expect that group workers help “members mediate conflict within the group” (2006, p. 19), rather than resolving it unilaterally or solving it exclusively outside the group. The role as mediator “resolves disputes, conflicts, or opposing views within the group or between a member and some other person or organization; takes a neutral stand and helps members arrive at a settlement or agreement that is mutually acceptable” (Toseland & Rivas, 2012, p. 285). The most important task of the group worker is to help group members work through the conflict in a constructive manner: “When conflict is constructively discussed, members learn that their relationships are strong enough to withstand an honest level of challenge, which is what many people want to achieve in their outside relationships” (Corey & Corey, 2006, p. 187). The role as mediator in the group, described earlier as part of the function of the group worker (Schwartz, 1976), helps model for group members the effective management of conflict.

A number of practices can help members mediate conflict within the group. The first is to help members understand the role of mediator as someone who works with and among the persons involved in conflict, rather than someone who serves as a unilateral decision maker responsible for solving the conflict. Toseland and Rivas (2012) offer a number of suggestions for handling conflict in groups:

- View conflict as normal and helpful
- Identify conflict
- Encourage members to listen to the entire group discussion before judging
- Help members to avoid personal differences and to stick to facts and preferences
- Promote consensus
- Pre-plan a problem-solving model and follow it, using agreed-upon decision criteria
- Clarify and summarize discussion regularly, while remaining neutral in the conflict
- Remain sensitive to group members’ preferences and concerns.

Mandated Members in the Middle Stage

The working stage assumes that members have moved to the contemplation if not the action

stage (Rooney & Chovanec, 2004). Working with mandated and involuntary members in group requires assisting members with assessing the costs and benefits of change, providing information about choices, helping members in their plans to change while emphasizing responsibility for choices (Rooney, 2009; Rooney & Chovanec, 2004).

ENDINGS

The ending stage is an essential but often neglected part of group work. Best practice guidelines (AGPA, ASGW, IASWG) discuss the critical importance of preparing members in advance for endings (also known as termination, adjourning, separation, transition). An ending should be viewed as a “unique stage with its own goals and processes.” (AGPA, 2007, p. 64) The work on endings should ideally begin in the planning stage, when the parameters for termination are initially discussed (Yalom & Leszcz, 2005). Endings also occur each session as individuals leave open groups, and with the entire group if the group is closed. If the group is closed, the work on endings should occur a few sessions before the final session (Toseland & Rivas, 2012). Workers should be attuned to any cultural variations among members regarding endings (ASGW, 2012). Rituals, such as ceremonies and celebrations may be used, “which aid the members in learning through the leave taking process.” (AGPA, 2007, p. 64)

The group worker manages both instrumental and affective tasks related to endings. Instrumental tasks relate to assessing problem reduction and goal achievement, discussing maintenance of gains, and reducing reliance on the group. The group worker should complete the following instrumental tasks (AGPA, 2007; Bernard et al., 2008; IASWG, 2006; Northen & Kurland, 2001; Toseland & Rivas, 2012):

- Review and reinforce individual and group change (preferably through systematic evaluation methods. See Practice Evaluation above.
- Discuss unfinished individual work.
- Help members apply knowledge and skills to environments outside of the group.
- Anticipate situations that might be stressful and practice coping skills developed in the group.

- Refer members to other services and, if appropriate, involve significant others in referral decisions.
- Prepare record material (e.g., progress notes, see assessment above) as required.

The group worker also helps members manage their feelings about endings and separation. The amount of time spent doing this will depend on the structure and type of group. For example, in unstructured therapy and support groups, feelings about endings may be more intense than in educational or task groups. Both positive and negative feelings are solicited, and both direct and indirect signs of member's reactions to endings are monitored and discussed. Indirect expressions may be tactics to delay or avoid discussing endings, such as late or missed sessions, denial, acting out, and changing topics (IASWG, 2006; Toseland & Rivas, 2012). Feelings of transference, countertransference and "unfinished business" may arise in the final phase of group work for both the worker and the group members and sharing these feelings in the group is encouraged. Best practice guidelines and the literature (AGPA, 2007; ASGW, 2012; Bernard et al., 2008; IASWG, 2006; Northen & Kurland, 2001; Shulman, 2011; Toseland & Rivas, 2012) identify the following tasks the group worker should complete in dealing with emotional aspects of endings:

- Be aware of and manage one's own feelings related to separations.
- Share own feelings about endings with the group.
- Explore, support, and clarify the range of emotional expressions related to endings.
- Appreciate the wide range of possible emotions that may be expressed, remaining aware of cultural differences in endings.
- Use empathy as members struggle to share feelings related to success, loss, or failure.
- Particularly in therapy groups, help members "resolve conflicted relationships with one another and the leader." (AGPA, 2007, p. 64)

Mandated Members in the Ending Stage

Using the stages-of-change model, group members move from the action stage into maintenance in endings (Connors et al., 2001; Prochaska & DiClemente, 1984). The endings techniques

noted above are valid in working with mandated members in groups, but areas that are emphasized include helping members to (a) solidify behavior changes so that they become automatic (e.g., awareness of triggers and how to deal with them); (b) develop relapse prevention skills that generalize to other settings, often using role-playing; and (c) join or lead other groups (Connors et al., 2001; Rooney, 2009; Rooney & Chovanec, 2004). It is particularly important that group workers help members to support others who are at risk of relapse, because those who relapse but have had a positive attachment to group "will more likely return to the group following a lapse." (Connors et al., 2001, p. 141)

95 Supported Employment

Marina Kukla & Gary R. Bond

BACKGROUND TO SUPPORTIVE EMPLOYMENT

Supported employment refers to rehabilitation services that assist clients with severe mental illness obtain and maintain competitive employment in the community through an individualized approach that emphasizes rapid job search and de-emphasizes a stepwise approach of

intermediate employment prior to placement in a competitive job. It helps to compensate for the challenges presented by mental illness, such as psychotic symptoms, cognitive dysfunction, and a lack of social skills that make obtaining and maintaining employment more difficult. Supported employment services are especially crucial given the finding that the majority of people with severe mental illness want to work, yet

most are unemployed (Becker & Drake, 2003). Supported employment programs are present in a variety of settings (e.g., Veteran Affairs medical centers, university-run outpatient clinics), but are most often found in community mental health centers, which provide mental health counseling, medication management, case management, housing assistance, and other services.

HISTORY

Community-based psychiatric rehabilitation services began in the mid-1950s. This era included the deinstitutionalization movement, in which large numbers of people with severe mental illness moved out of inpatient hospitals into the community. One of the earliest forms of community-based psychiatric rehabilitation was the “clubhouse,” where people with severe mental illness could go during the day and socialize. Clubhouses fostered the idea that an individual could work and should have an opportunity to work, if they so desired, even if they had spent many years in the hospital and suffered from debilitating psychiatric symptoms. The desire to participate in meaningful, productive activity ultimately led to the provision of specific employment services for this population (Becker & Drake, 2003).

The earliest formulation of supported employment was the “place–train” approach first used in the developmental disabilities field (Wehman & Moon, 1988). The place–train approach assumed that rapid placement into a competitive job in the community with appropriate training and support thereafter would lead to better outcomes for people with even severe disabilities than the traditional “train–place” approach requiring clients to receive pre-employment training prior to placement. Pre-employment training was ineffective because of the lack of generalizability of job skills training and the unrealistic nature of the pre-employment training situation (clients know that it is not the “real world”).

Given the shortcomings of the train–place approach, the principles of Wehman and Moon’s (1988) more successful place–train approach began to be adopted by the mental health field in the late 1980s. The most widely studied, used, and standardized supported employment approach for people with severe mental illness is the Individualized Placement and Support (IPS) model (Becker & Drake, 2003).

THEORETICAL PERSPECTIVE

Supported employment is an evidence-based practice based on the recovery model. Recovery from mental illness has several definitions, but a commonly used definition is “a deeply personal, unique process of changing one’s attitudes, values, feelings, goals, skills and/or roles. It is a way of living a satisfying, hopeful, and contributing life even with limitations caused by the illness. Recovery involves the development of new meaning and purpose in one’s life as one grows beyond the catastrophic effects of mental illness.” (Anthony, 1993; p. 17) It is widely accepted that work is a crucial part of recovery, as individuals with Serious Mental Illnesses (SMI) engage in meaningful, personally satisfying roles, such as employment, in the community.

PRINCIPLES

The IPS model is an evidence-based vocational model. It uses the following research-based principles (Bond, 1998; 2004; Drake, Bond, & Becker, 2012):

- *Principle of Zero Exclusion.* IPS programs serve anyone with severe mental illness who professes an interest in working, regardless of symptoms, work history, lack of skills, strange appearance, or any of the myriad of reasons often given for excluding people from vocational services.
- *Principle of Goal of Competitive Employment Only.* Employment specialists do not place clients in noncompetitive jobs such as work crews or sheltered workshop positions in which jobs are reserved for those with severe mental illness.
- *Principle of Focus on Client Choice and Preferences.* Client job preferences, needs, and abilities, are given paramount importance in identifying jobs during the job search as well as in determining what kinds of help will be provided. For example, if the client prefers not to disclose his/her psychiatric disability to the employer, the supported employment team accommodates this preference.
- *Principle of Ongoing, Informal Assessment.* Based on direct observation and conversations with clients and employers, the employment specialist continuously assesses

the fit between the client preferences and capabilities and the environmental demands. Skills needed to perform job duties are only one aspect of this assessment; relationships with supervisors and coworkers are usually crucial. Other life circumstances, including housing and family situations are also considered.

- *Principle of Systematic Job Development.* Employment specialists build an employer network based on clients' interests, developing relationships with local employers by making systematic contacts. Job development involves cultivating a relationship. Usually the IPS specialist plans the first employer contact to introduce herself/himself to the employer and request another meeting. The second contact is to learn about the employer's business. Future contacts are to discuss potential employees when there might be a good job match.
- *Principle of Rapid Job Search.* The job search begins as soon as the client enters an IPS program. There is no prevocational training or lengthy vocational assessment. Standardized assessment tools are mostly of little value in identifying who is able to work or what jobs to pursue.
- *Principle of Time-unlimited, Individualized Follow-Along Support.* Ongoing follow-along support provided by the employment specialist may include a variety of interventions, including assisting clients in mastering job duties, consulting with the client's coworkers and supervisors to enhance interactions with the client, and suggesting modifications in the work environment to accommodate client's needs. Once a client is successfully employed for a period of time (e.g., one year), employment specialists typically taper off support to once a month or less, transitioning the bulk of support to the clinical treatment team.
- *Principle of Benefits Counseling.* IPS programs provide clients with personalized information regarding the consequences of employment earnings on their Social Security and Medicaid payments.
- *Principle of Integration of Employment Services and Mental Health Treatment.* Staff from IPS programs work closely with mental treatment teams and attend treatment team meetings. Integration of supported

employment services and mental health treatment is characterized by employment specialists providing mental health information to mental health clinicians and mental health clinicians providing vocational information to employment specialists. For example, in the case example of Tim, Tim's employment specialist provides information to mental health clinicians about new symptoms Tim experiences on the job or medication side effects that affect his ability to work. Mental health clinicians (i.e., case managers) provide information to Tim's employment specialist about other aspects of his life, such as changes in his residential status or transportation that could affect Tim's vocational status.

Another important component of the IPS model is that employment specialists carry small caseloads (i.e., usually no more than 20 clients). In addition, employment specialists provide employment services only and do not have responsibilities for nonvocational services, such as crisis intervention, housing, or other case management tasks.

STEPS FOR IMPLEMENTING SUPPORTED EMPLOYMENT

The following is a step-by-step description of the IPS supported employment process. Although the steps may vary somewhat in temporal sequence and nature dependent upon the individual circumstances of each client, this represents the rudimentary process for a typical client.

1. The client expresses a desire to work competitively to their mental health team or the client comes into the community mental health center seeking help with employment.
2. An employment specialist begins to work with the client, identifying important factors, including the client's preferences, needs, and individual circumstances (e.g., transportation) in regards to employment. If the client is receiving disability benefits, the client receives specific information on the financial implications of earnings from employment, both prior to the job search and after a specific job offer is made. The employment specialist and client discuss options regarding disclosure of mental illness to employers.

3. Although not a requirement for enrollment in supported employment, supported employment programs often receive funding from the state–federal vocational rehabilitation system. Consequently, employment specialists typically work closely with this agency on behalf of their clients, initiating contact before the client obtains a job.
4. Usually within a month’s time, the employment specialist and the client together begin the job development process and search for a suitable job.
5. When the client obtains the job, the employment specialist often works with the supervisor and coworkers to work out a suitable work environment for the client. This role will depend on the client’s preferences, including whether the client discloses his/her psychiatric disability.
6. The employment specialist makes routine visits to the client at the job site or in the community and intervenes when issues and problems arise throughout the client’s tenure at the job. In some instances, the employment specialist is in regular contact with the client’s supervisor. Employment specialists also meet often with clients outside the work place. The job support plan is individualized.
7. If employment ends or the client desires a new job, the employment specialist works with the client to find another job matching his/her job preferences and needs.

WHAT’S THE EVIDENCE?

Vocational Outcomes

Research has found that supported employment is superior to other employment approaches in improving competitive employment outcomes (Bond, Drake, & Becker, 2012). Fifteen randomized controlled trials have compared the IPS model of supported employment with various other approaches, finding a significant advantage in competitive employment rates for IPS, as shown in Figure 95.1.

These studies have also found that clients receiving supported employment services obtain their first competitive jobs 50% faster and have significantly longer job tenure as compared with clients receiving services in alternative approaches. Studies of day rehabilitation programs that have converted to supported employment programs have found that they have been able to do so successfully, with improved competitive employment outcomes for clients (Becker, Bond, McCarthy, Thompson, Xie, McHugo, & Drake, 2001). Moreover, long-term studies indicate that the vocational benefits of supported employment are long-lasting (Becker, Whitley, Bailey, & Drake, 2007).

Nonvocational Outcomes

Participation in a supported employment program does not itself lead to improved nonvocational outcomes. However, research has indicated that clients who obtain employment realize other

Figure 95.1 Competitive employment rates in 11 randomized controlled trials: Individual placement and support.

benefits, including improved self-esteem (Bond, Resnick, Drake, Xie, McHugo, & Bebout, 2001; Mueser, Becker, Torrey, Xie, Bond, & Drake, 1997), fewer symptoms (e.g., Bond et al., 2001; Mueser et al., 1997; Burns, Catty, White, Becker, Koletsi, & Fioritti, 2009; Kukla, 2010), better general functioning (e.g., Mueser et al., 1997; Burns et al., 2009), improved social networks (Kukla, 2010), and higher quality of life (e.g., Twamley, Narvaez, Becker, Bartels, & Jeste, 2008).

ASSESSMENT AND EVALUATION

Supported employment studies have typically used objective indicators of competitive employment, such as rates of obtaining employment, time to first job, job tenure, and hours worked per week. Supported employment researchers have often used rigorous research designs, with careful training of clinicians and monitoring of implementation (*efficacy* methods), conducting these in real-world settings with clients from heterogeneous backgrounds (*effectiveness* methods) (Bond et al., 2008a). Studies have been conducted in a multitude of settings, including urban and rural areas, and in countries outside the United States with differing labor conditions (e.g., Australia, Canada, Hong Kong, and several European countries).

It is standard practice in IPS studies to assess *fidelity*, that is, adherence to the IPS program model using a well-validated fidelity scale (Bond, Becker, Drake, & Vogler, 1997). The IPS fidelity scale is comprised of 15 items rated on a 1 to 5 behaviorally anchored scale, with higher scores indicating better fidelity. Fidelity is assessed at the level of the IPS program and fidelity items cover the primary tenets of the IPS model, such as “rapid job search for competitive jobs,” “agency focus on competitive employment,” and “zero exclusion criteria” (Becker, Swanson, Bond, & Merrens, 2011). Assessing IPS fidelity and making adjustments to practice is also important, given findings that better fidelity to the IPS model leads to better employment outcomes for clients (Bond, Becker, & Drake, 2011).

IMPLEMENTATION ISSUES

As noted above, systematically assessing and monitoring supported employment fidelity is a crucial implementation strategy. Several other components of effective implementation that

relate closely to fidelity include the following (Bond, McHugo, Becker, Rapp, & Whitley, 2008b):

- Discontinuing non-evidence-based vocational services (e.g., sheltered workshops, train-place vocational approaches).
- Improving the integration of employment services with clinical and mental health services, via supervisor leadership.
- Changing relevant organizational and structural tasks to be compatible with the supported employment model. These may include things such as changing billing processes and procedures, training staff, endorsing the supported employment philosophy organization-wide, and changing documentation in client records.
- Implementing supported employment programs at exemplary sites that can be models and opportunities for training of later sites.
- Obtaining support and consensus from all stakeholders (i.e., clients, family members, state authorities, practitioners, and administrators).

In addition, studies have found that supported employment may be implemented successfully and is widely generalizable and applicable across community settings (rural and urban) and across various ethnic and minority groups (including African-Americans, Hispanic-Americans, and Asian-Americans), among both young and older adults, and with clients with co-occurring substance use (Bond, Drake, & Becker, 2010).

PROVIDER COMPETENCIES

Although several provider competencies of employment specialists exist that are necessary for successful supported employment services, little research has been conducted in this area. However, some of the most important provider competencies that should be emphasized in practice include:

- Hopeful attitudes and the belief that clients with severe mental illness *can* work (Gowdy, Carlson, & Rapp, 2003)
- The ability to form a good “working alliance” or relationship with the client (Kukla & Bond, 2009)

- Job development skills, or the ability to locate and secure numerous and diverse jobs matching client preferences and needs
- Skills encompassed within each specific phase of employment services (e.g., appropriate on-going job support to the client) (Bond & Kukla, 2011)
- Employment specialist motivation and interest in the field of supported employment
- Employment specialist focus on working in the community in all phases of employment services, rather than in the agency office

Importantly, these are skills and behaviors that can be taught. The research suggests that appropriate supervision, feedback, and leadership provided to the employment specialist by team leaders and other supervisory-level staff make a difference.

FUTURE DIRECTIONS

Several areas of future research are needed in the supported employment arena, given the paucity of research conducted thus far and/or the need for improvement of supported employment services in various areas to result in improved client outcomes. Such areas include the following (Drake & Bond, 2008):

- Provider competencies
- Ways to increase job tenure of clients
- Understanding the overall costs of supported employment and better ways to finance and organize supported employment services
- Better job development strategies
- Ways to enhance career trajectories of supported employment clients
- Effective ways to address lack of motivation to work

In addition, in recent years, studies have begun to examine adjuncts to supported employment that are designed to compensate for deficits associated with mental illness. For instance, studies have investigated cognitive remediation and social skills training delivered along with IPS-supported employment. To address the educational needs of people with SMI, research suggests that supported education services delivered along with supported employment results in promising outcomes, especially for young adults (Nuechterlein, Subotnik, Turner, Ventura, Becker,

& Drake, 2008). These are fairly new domains of research, however, and future studies should focus on these important areas.

Elizabeth M. Tracy & Suzanne M. Brown

The role of supportive relationships is central to the mission of social work and its practice. Assessing and working with social support systems are considered requisite skills for social work practice, as the following case examples illustrate.

- A teenage mother receives home visits and attends a parent support group to build a supportive social network as she transitions into the role of parent.
- A man who has completed a substance abuse treatment program attends Alcoholics Anonymous and works with his sponsor and case manager to build a social network supportive of sobriety.
- Family members participate in a psycho-educational support group so that they get the support and help needed to cope with a family member with a mental disorder.

Social support refers to the actions that others perform when they render assistance. There are several different types of social support, such as:

- Emotional support—having someone listen to your feelings, comfort you, or offer encouragement
- Informational support—having someone teach you something, give you information or advice, or help you make a major decision
- Concrete support—having someone help in tangible ways, loaning you something, giving you information, helping with a chore, or taking you on an errand.

Social support can take place within naturally occurring helping networks of family, friends, neighbors, and peers, or in groups and organizations that have been specifically created or contrived for this purpose. Formal support includes services delivered by paid human service professionals. Informal support, which is the focus here, can be delivered by kinship networks, peers, including peers from treatment programs, volunteers, or local community groups.

People with access to social support resources are in better physical and emotional health and are better equipped to adapt to and cope with life changes. Thompson (1995) has identified several key functions of social support that may reduce or protect against the negative effects of stressful events:

- Emotional sustenance and a sense that you are not alone
- Counseling advice and guidance in dealing with challenging life events
- Access to information, services, material resources, and tangible assistance
- Skills acquisition and training
- Social monitoring and social control of behavior.

Social networks are the primary mechanism through which support functions are made available. The term *social network* refers to a set of individuals and the ties among them. The study of whole networks examines the pattern of relations within a group bounded by geography or some characteristic, such as all the clients in a treatment program. A personal social network focus examines the relations surrounding a focal

person, such as an individual client or family. A personal social network approach to assessment and intervention, which is the focus of this entry, considers the behavior of individuals in the context of the people with whom they directly interact.

Personal social networks consist of several dimensions. Compositional network qualities include:

- Size—the total number of people in the network
- Relationships of network members to the focal person—friends, family, professionals
- Characteristics of network members—for example, alcohol/drug users
- Frequency of contact—how often people in the network interact with one another
- Duration—how long people in the network have known one another
- Reciprocity—the amount of give and take.

Structural network qualities include such features as:

- Density—the percent of ties that exist in a network out of all those possible
- Components—network members who are connected to one another directly or indirectly
- Multiplexity—the extent to which network relationships serve more than one function or provide more than one type of support
- Centrality measures—degree to which a network is organized around one or a few people.

Sometimes composition and structure can be combined, such as identifying whether the most structurally central person is supportive of the client's recovery.

The terms *social network* and *social support* do not necessarily refer to the same concept. People may be surrounded by large social networks but may not feel supported or perceive support from others. They may also not be receiving the types and amount of support that they need. A social support network refers to the set of people who do provide various forms of social support for one another.

Likewise, not all social ties are supportive because interpersonal relationships may be sources of support as well as stress (Lincoln, 2000). Patterns of negative social networks may

be evident. For example, social network members may be overly critical or demanding of one another, or members may reinforce or encourage harmful or antisocial behavior, such as drug abuse or gang violence. Social networks may also fail to support efforts to change behaviors or maintain changes in behavior, such as a parent changing from punishment approaches to more positive forms of child management. Additionally, social network members may offer both positive forms of support in one area of an individual's life while at the same time preventing change in other areas of the individual's life. One example may be a network member who, while providing concrete support such as money or housing, also encourages an individual with a history of alcoholism to continue to use substances (Brown, Tracy, Jun, Parks, & Min, under review).

Finally, several related concepts are important to note. Enacted support refers to the actual utilization of support resources. Perceived support refers to the extent to which an individual feels that his or her support needs are or would be fulfilled. Network orientation refers to beliefs, attitudes, or expectations concerning the usefulness of network members in helping cope with a problem. Some people may have adequate social networks but may not make use of or access their network in times of need owing to a negative network orientation. Another barrier to use of one's social network may be inadequate social skills in requesting help, developing network relationships, and maintaining supportive social ties over time. Networks can also be negatively or positively influenced by the resources and climate of the larger social and physical environment in which they are situated.

SOCIAL SUPPORT ASSESSMENT GUIDELINES

Given the complexity of social support, a necessary first task is to complete an accurate assessment of social network resources and the functional qualities of social network relationships. The following questions serve as guidelines for social support assessment.

1. Who is in the network? How are they related to the client? Who could be potential members?
2. What are the strengths and capabilities of the social network? Among the

strengths that need to be examined are the number of supportive relationships, variety of supportive relationships, types of support available (emotional, concrete, and informational), and reciprocity among helping relationships.

3. What are the gaps in social support needs? Is there a lack of fit between the types of support network members are willing or capable of providing and the types of support the client needs or desires?
4. What relationships in the network are based on mutual exchange? Does reciprocity seem to be an issue for the client? Is the client always giving to others and thereby experiencing stress and drain? Or does the client appear to be a drain on the network, with the result that network members are stressed and overburdened?
5. What network members are identified as responsive to requests for help, effective in their helping, accessible, and dependable? Do sufficient numbers of network members meet these conditions?
6. What network members are critical of the client in a negative or demanding way? Is the client surrounded by a network that is perceived as negative, nonsupportive, and/or stress-producing?
7. What obstacles or barriers to using social network resources exist? Does the client lack supportive resources or skills in accessing them? Are network members unable to provide more assistance owing to lack of skills or knowledge? Or have they provided support in the past and are now unwilling or unable to continue to do so? Overwhelming family stressors, such as homelessness or substance use, may be present that interfere with the provision of support (Kemp, Whittaker, & Tracy, 1997).
8. Are there internal traits or emotional states such as shame, fear, or difficulty trusting others that may be barriers to help seeking or barriers to effectively creating and utilizing network supports?

INTERVENTION STRATEGIES

Social network interventions are typically directed toward either structural changes in the social network itself or functional changes in social network relationships. Structural

interventions aim to create a new network or supplement one that already exists. Some examples of structural changes include:

- Increasing or decreasing the size of the network, as in increasing the number of friends
- Changing the composition of the social network by facilitating new connections, as in introducing a new cluster or re-establishing network relationships that have been lost
- Increasing or decreasing the frequency of contact with particular social network members—for example, highly negative network members.

Functional interventions seek to improve or enhance the quality and nature of relationships within a network. This might include increasing or mobilizing various types of support (e.g., concrete emotional or informational support, as in respite care services for a family) or teaching network members new skills for interaction. Some examples of skill-enhancing interventions to facilitate more social support include:

- Developing or increasing skills in making friends
- Decreasing negative beliefs about self (if this is a barrier to developing/maintaining supportive relationships), increasing positive self-statements, and increasing the ability to identify personal strengths
- Developing strategies for handling criticism from others
- Increasing assertive skills (if this is a barrier to developing or maintaining supportive relationships)
- Increasing communication skills (if this is a barrier to developing or maintaining supportive relationships)
- Teaching reciprocity skills (if this is a barrier to developing or maintaining supportive relationships) to ask for help (Kemp et al., 1997).

The overriding purpose of the social network intervention should be kept in mind. Changes in social support may be desired for a variety of reasons: first, to support maintenance and generalization of treatment efforts, as in building social networks supportive of change (Tracy & Biegel, 2006); second, to serve as a protective factor, as in increasing supportive bonds for children at risk of

juvenile delinquency or substance abuse (MacNeil, Stewart, & Kaufman, 2000); and third, to provide a coping mechanism, as in social support provision due to a crisis or life transition (Cameron, 2000).

Examples of Social Network Intervention Strategies

- Network facilitation through network meetings—for example, family group conferencing (Crampton, 2007); network therapy for alcohol problems (Copello, Orford, Hodgdon & Tober, 2009)
- Additional network clusters, through referral to formal or informal organizations (e.g., referral to self help programs)
- Additional individual network members through a social networking intervention (Biegel, Tracy & Corvo, 1994)
- Peer support programs and mutual aid or self-help groups (Moore, 2005); peer education and modeling to promote changes in behavior throughout a social network (Latkin et al., 2013)
- Natural helper intervention (Gaudin, 1993)
- Social and communication skills training (Richey, 1994)
- Extended family support and psycho-educational approaches—for example, teaching family members how to deal with psychiatric symptoms (Mueser, Noordsy, Drake, Fox, & Barlow, 2003).

See Kemp et al. (1997) for further descriptions of these and other intervention strategies.

IMPLEMENTING FOR SUCCESS

A network intervention is not a panacea. Many clients still require professionally delivered services, with social network interventions as a supplement. There are a number of implementation issues to consider.

- Pay close attention to the type of support desired or needed by the client (e.g., informational or emotional) and match the intervention to that need.
- Ensure that *reciprocal* relationships are established.
- Focus on the relationship quality and functioning of network relationships, not just size of network.

- Recognize that not all networks are supportive and attend to negative or stress-producing network relationships; intervene to enhance these relationships.
- Monitor the effect of interventions on network members to ensure that the network is not overburdened.
- Attend to perceived as well as enacted support.
- Teach skills needed to elicit and maintain supportive relationships, both to the client and network members, as skill deficits may contribute to lack of support.
- Recognize that advocacy may be needed to build supportive resources at the community level.
- Focus on change from the client's perspective of their network relationships. Clients may be aware of ways in which some network members may be more supportive than we are aware. For example, while professionals may assess relationships with children in a network as one directional, mothers may receive support from their children and perceive these relationships as reciprocal and not burdensome.
- Recognize that social factors such as poverty and lack of education may limit an individual's capacity for network change due to limited geographic mobility and limited housing or neighborhood options. In these cases, the goal may be to increase interpersonal skills to manage network relationships that cannot be changed.

Social support interventions are challenging to evaluate owing to their complexity and diversity. Hogan, Linden, and Najarian (2003) conclude in a review of 100 intervention studies that although there is some support for the usefulness of social support interventions, there is an insufficient research base to conclude what type of intervention works best for what presenting problem. It may be difficult to see immediate results of network interventions. People may perceive supportive interventions differently depending on the source of support. The timing of the intervention may be an important consideration as well. Networks may change over time and attention to network structure, composition, and support are important to assess at initial intake as well as at time points post treatment or services (Min et al., 2013). In spite of the limitations of our current knowledge, social support

interventions hold promise, and the skills of assessing and mobilizing support are important for every practitioner to acquire.

Eye Movement Desensitization and Reprocessing with Trauma Clients

Tonya Edmond & Allen Rubin

Eye movement desensitization and reprocessing (EMDR) was developed in 1987 as a procedure for alleviating stress-related symptoms connected to traumatic memories. Its founder described it as “an interactive, intrapsychic, cognitive, behavioral, body-oriented therapy” that aims “to rapidly metabolize the dysfunctional residue from the past and transform it into something useful.” (Shapiro, 1995, pp. 52–53) Within this description and subsequent publications is the assurance that EMDR can be effectively employed by practitioners who draw from a variety of theoretical orientations, including, but not limited to, cognitive-behavioral, psychodynamic, and systemic approaches (Shapiro & Laliotis, 2011).

Although EMDR was not originally theoretically derived, which has been a source of criticism, the Adaptive Information Processing (AIP) model has been developed as a working theory to help explain both symptom development and the observed treatment effects of EMDR on those symptoms (Shapiro & Laliotis, 2011; EMDR International Association [EMDRIA], 2012; Schubert & Lee, 2009). The AIP model is viewed as the framework guiding case conceptualization, treatment planning, and implementation of the eight phases and three prongs that make up EMDR (Shapiro & Laliotis, 2011; EMDRIA 2012; Schubert & Lee, 2009). In brief, the AIP model posits that human beings have an innate information processing mechanism that facilitates integration of life events into existing memory networks that can generate new learning.

During particularly distressing experiences, information may not be adequately processed or integrated, resulting in maladaptive encoding

of the memory, which is dysfunctionally stored in a neural network, similar to the fear network proposed by Foa and Kozak (1986) (Shapiro & Laliotis, 2011; EMDRIA 2012; Schubert & Lee, 2009). Because the core elements of the distressing experience—feelings, thoughts, body sensations—have not been sufficiently processed and integrated, present-day reminders can trigger the distress, impair functioning, and potentially lead to the development of significant mental health conditions. The eight phases and three prongs of the EMDR protocol are employed to activate the neural network where the memory is dysfunctionally stored and to re-engage information processing to facilitate adaptive resolution of the distressing experience (Shapiro & Laliotis, 2011; EMDRIA 2012; Schubert & Lee, 2009). For a more detailed review of research on the AIP model and a comparison with other models of posttraumatic stress disorder (PTSD), see Schubert and Lee (2009).

EIGHT-PHASED, THREE-PRONGED TREATMENT APPROACH

According to Shapiro and Laliotis (2011), the eight phases of EMDR are implemented within the context of the three-pronged approach, which uses past, present, and future elements to guide the treatment process. The therapist works with the client to identify pertinent experiences from the past that are related to the problems the client is having in the present; triggers that are being activated in the present; and future actions the client can take to respond adaptively to new life experiences.

In the first phase, a thorough client history is obtained, preferably with the inclusion of standardized diagnostic tools, and, from that, a treatment plan is developed. The clinical evaluation during this phase should be comprehensive and include a determination of whether there are indications that the client is likely to benefit from EMDR treatment as well as any contraindications for the use of EMDR with the client. Using the presenting issues, the therapist should help the client identify past events affecting current functioning, triggers currently being activated, and potential future needs. Both positive and negative life experiences are identified and incorporated into the treatment plan.

In the second phase, the client is prepared for the EMDR procedure and client goals and expectations regarding treatment are established. Preparation includes building a therapeutic relationship and educating clients about their symptoms or diagnoses, as well as the EMDR procedures that will be employed. During this process, data on the effectiveness of EMDR is shared, along with possible negative reactions to it, so that client fears and safety issues can be addressed and informed consent for treatment ensured. Emphasis is placed on fostering the development of self-soothing and affect regulation skills to ensure stabilization during and between sessions. Metaphors, guided imagery, and other techniques are used to develop adaptive resources before trauma processing work is initiated. This is recognized as especially important for clients with histories of complex trauma.

In the third phase, an assessment is conducted to determine what target issue and what components thereof are to be addressed. Target components include the presenting problem, the memory associated with the presenting problem, a mental image of that memory, identification of a currently held negative self-belief associated with the memory, identification of a desired positive self-belief with which to replace the negative one, the emotions associated with the memory, and any physical sensations the client notices when picturing the traumatic memory. During this phase, the client focuses on a mental picture of the traumatic memory, identifies the negative self-belief about the experience, identifies a positive self-statement with which the client would like to replace the undesired one, reports unpleasant emotional sensations connected with the image, notes where in the body the emotional unpleasantness is felt, and provides a subjective

rating of the severity of the distress they feel and how true their preferred self-belief seems to them. That is, the client holds the mental image of the memory while simultaneously thinking of the desired positive self-statement and is then asked to rate how true the desired self-belief feels on a scale from 1 to 7. The client is also asked to think of the emotions evoked by the image in the here and now and the negative self-belief and to rate on a scale from 0 to 10 how disturbing the emotions currently feel when holding the image and negative self-statement in mind. Depending on the level of these two ratings, the therapist may decide to proceed to the next phase or stay in Phase three and seek to identify alternative issues or components that are more problematic.

In the fourth phase, the desensitization process is implemented. The target memory is activated by asking the client to hold all of the identified target components in mind while the therapist induces alternating bilateral stimulation (visual—eye movements, auditory—sounds from head phones, or tactile—hand taps). During this time, the therapist encourages the client to simply notice the experience and to report whatever observations they noticed about the target image, memory, thoughts, feelings, or bodily sensations. The processing and reporting that occur is often likened to free association. With each set of bilateral stimulation, the client will spontaneously move from a body sensation, to an image or an emotion or insight without describing a coherent narrative as is commonly expected in gradual or prolonged exposure during trauma processing work.

If eye movements comprise the bilateral stimulation, the client is asked to visualize the distressful scene and keep in mind the identified cognitions and feelings while visually tracking the therapist's fingers moving rapidly and rhythmically (about 18 inches in front of the client's face) back and forth, up and down, or diagonally. The speed is about two back-and-forth movements per second. The direction and number of movements varies on an individual basis, but is around 24–36 passes. The average duration of each set of bilateral stimulation is approximately 30 seconds. After each set, the client discusses with the therapist what thoughts, feelings, or images came up during the set, and then reports changes in the degree of distress felt. If not much changed, the therapist likely will repeat one or more sets of bilateral stimulation, targeting the same stressful memory, feelings, and cognitions.

If the client seems stuck or processing seems stalled, the therapist will use a cognitive interweave to interject adaptive information. If new material comes up, the next set(s) will target that new material. This process will then be repeated throughout the treatment session, with each successive set of bilateral stimulation typically targeting the new material that comes up each time. The aim is to reach a point when the client's level of disturbance rating drops considerably (ideally to a level of 0 or 1 on the 10-point scale). Additional sessions can be used as needed to deal with the same or other sources of distress. The three-pronged approach is particularly important during this phase, working to process past distressing experiences, current triggers, and potential future challenges.

In the fifth phase, which commences after successful processing during the desensitization phase, additional sets of bilateral stimulation are used to install the desired cognition (i.e., a positive self-belief). The positive cognition is considered to have been successfully installed when the client rates how true the desired self-belief feels as a 6 or 7 on the 7-point validity of cognition scale.

In the sixth phase, the client is asked to hold the target image or memory in mind along with the desired positive belief and to scan their body to determine whether there are any positive or negative residual physical sensations from the target issue present. If any such physical sensations are identified, this is a signal that there is unresolved material that needs to be processed further, in which case Phases three through five are reapplied until the client indicates that only positive or neutral physical sensations are present.

The seventh phase involves closure, in which the clinician employs relaxation techniques (such as guided imagery) to alleviate any lingering distress experienced by the client. The objective in this phase is to ensure client stability, both at the end of a given session and in-between sessions when additional processing may occur. The need for additional desensitization sessions may be identified during this phase, and clients are asked to maintain a log of any distressing emotions or cognitions they experience between sessions. Clients are encouraged to use guided imagery or other self-soothing, affect-regulating skills as needed to facilitate stability in-between sessions.

The eighth phase involves client re-evaluation to assess treatment effectiveness. This begins by

checking whether anything new emerged after the previous session. The three-pronged protocol is used to determine whether there is any residual distress related to past experiences, current triggers, or future challenges that still needs to be targeted. If there is any indication of residual distress related to any of these areas, they are targeted for treatment and Phases 3–8 are implemented again.

The number and length of the sessions required to achieve meaningful change vary from client to client. Some studies have reported clinically meaningful and stable changes with as few as one to three sessions, typically for a single traumatic event (Shapiro, 1996a,b; 2010). For clients who have complex trauma histories, the length of treatment is longer and varied. According to the EMDR International Association (2012), "EMDR treatment is not completed in any particular number of sessions. It is central to EMDR that positive results from its application derive from the interaction among the clinician, the therapeutic approach, and the client." (EMDRIA's Definition of EMDR, 2012) Ninety minutes is the recommended session length for adults and adolescents. Most of the time is taken up by discussion before and after each set. The actual cumulative amount of time the eyes are moving (or other forms of bilateral stimulation are occurring) will be several minutes.

The EMDR procedure is implemented in the context of an ongoing therapeutic relationship, after a therapeutic alliance is established with the client. It is intended to be used by experienced psychotherapists, in conjunction with other clinical approaches they employ, only after they have received formal EMDR training. Also, therapists are advised to apply EMDR only to target problems that they already are competent to treat.

Although literature pertaining to the use of EMDR with children and adolescents is much less than that which exists for adults, there is emerging evidence of EMDR's effectiveness with those populations, particularly for treatment of posttraumatic symptoms and PTSD (Adler-Tapia & Settle, 2009; Field & Cottrell, 2011; Ahmad, Larsson, & Sundelin-Wahlsten, 2007; deRoos, 2011; Rodenburg, Benjamin, deRoos, Meijer, & Stams, 2009). Recently, the California Evidence-Based Clearinghouse for Child Welfare (CEBC) listed EMDR as one of only two trauma-focused treatments for children that has received a Level 1 rating, which indicates that it is well supported by evidence. The

only other modality to receive that rating was trauma-focused cognitive behavioral treatment (CEBC, 2013).

In addition to having been trained in both the basic EMDR protocol and the Advanced Training in using EMDR with children, it is also recommended that any clinician treating traumatized children have training in trauma treatment, as well as prior experience working with children and adolescents. Furthermore, to ensure treatment fidelity the AIP model and the full EMDR protocol with the three-pronged approach should be used with children and adolescents with the recognition that there will need to be treatment adjustments to accommodate the child's developmental stage and specific presenting problem (Adler-Tapia & Settle, 2009; Adler-Tapia, 2011). Nevertheless, although clinicians are able to incorporate into each of the eight phases of the EMDR protocol useful techniques and strategies employed in other child and adolescent treatment approaches (e.g., play and art therapy), the guiding framework should continue to be the AIP model.

Adler-Tapia and Settle (2009) highlight some examples of age appropriate modifications and creative ways to integrate other techniques across each of the eight phases of the EMDR protocol. During the preparation phase, relaxation skills and recognition of emotions are taught. Metaphor and fantasy may be used with sand trays, play therapy, clay, or drawings during the assessment phase to help the child communicate his or her feelings and thoughts to identify the treatment target.

In the desensitization phase, it is recommended that in order to facilitate continued interest and engagement, the therapist use shorter sets of eye movements (<24) and vary the type of bilateral stimulation provided. The therapist might start with a set of eye movements and then the next round of bilateral stimulation could involve audio signals, followed by hand taps. Fun alternatives for bilateral stimulation include having the child drum, clap, or march. Alternatives for visual bilateral stimulation include the use of puppets or stuffed animals. In between sets of bilateral stimulation, the child can verbally describe what she or he noticed or if needed, the child can draw, use clay, or a sand tray to describe what occurred internally. This process may move more quickly to a point of resolution in children because they have lived for a shorter time and may have a smaller number of adverse events associated

with their presenting problems than is common among adults.

In the installation phase, the therapist would revisit the original drawing or sand tray work with the child and ask him/her how true the desired positive cognition felt. With the body scan, a therapist might use a magnifying glass and a toy to make the notion of a body scan more concrete. During the closure phase, the relaxation skills developed during the preparation phase would be employed both in the session and as an out-of-session resource for the child and parents to support affect regulation. In addition, drawing could be used to create containers to place painful feelings, thoughts, and memories in between sessions and for developing the future template. In addition, any drawings developed over the course of treatment can be reintroduced during the re-evaluation phase with the child to review progress.

As with many other children-focused interventions, inclusion of parents or caregivers is important, beginning with education about trauma, child development, and the EMDR treatment process. Parents/caregivers also serve as an important resource in providing information about the child's developmental and attachment history, experiences of trauma, current symptoms, and problems of concern. As treatment progresses, parents/caregivers can also provide information on external indicators of distress or signs of improvement in the child (Adler-Tapia & Settle, 2009). Dr. Adler-Tapia has written extensively about using EMDR in the treatment of children. For a more comprehensive description, see *EMDR and the Art of Psychotherapy with Children* (Adler-Tapia & Settle, 2008).

Despite having received a great deal of rigorous outcome research supporting its effectiveness in treating adults with noncombat, single-trauma PTSD, EMDR is still viewed by some as controversial. One reason is that its proponents historically touted it as being effective not only with trauma and fear-based disorders, but also with virtually every area of psychopathology—areas in which there is much less supportive research. Another reason is the initial extreme claims that were made about it by its proponents, such as suggesting that only one session is needed to resolve trauma symptoms or calling it a “breakthrough” therapy (Shapiro & Forrest, 1997). Although there is evidence that for some single-incident traumas one to three sessions of EMDR can be effective in reducing or eliminating trauma

symptoms or PTSD, chronic or complex trauma typically requires a longer course of treatment with EMDR or any other evidence-based trauma treatment (Edmond, Rubin, & Wambach, 1999; Ironson, Freund, Strauss, & Williams, 2002; Jaberghaderi, Greenwald, Rubin, Dolatabadim, & Zand, 2004). For example, in comparison studies of EMDR and Prolonged Exposure, six to nine sessions were provided with comparably effective outcomes (Ironson, Freund, Strauss, & Williams, 2002; Lee, Gavriel, Drummond, Richards, & Greenwald, 2002; Rothbaum, Astin, & Marsteller, 2005). It should be noted that the EMDRIA definition of EMDR treatment states that length of treatment is driven by the client's needs and circumstances and not by a prescribed number of sessions.

Some have portrayed EMDR as a pseudo-scientific movement that promotes an intervention that merely tacks an unnecessary treatment gimmick (dual attention stimulation) onto imaginal exposure techniques (Olatunji, Parker, & Lohr, 2005–2006). Its detractors have also criticized the fact that its development was not based in theory and that attempts to connect it to theory have been speculative and mutable over the years. The AIP model described above is the most current iteration. The same detractors have argued that EMDR proponents keep changing the criteria used for judging the fidelity of EMDR treatment with each outcome study that produces findings that its proponents dislike (Rubin, 2003, 2004).

Despite these claims, there have now been nearly 50 randomized, controlled trial (RCT) studies and several meta-analyses that have demonstrated the effectiveness of EMDR (Bisson et al., 2007; Bradley, Greene, Russ, Dutra, & Westen, 2005; Davidson & Parker, 2001; Seidler & Wagner, 2006; Van Etten & Taylor, 1998). Moreover, the first decade of research on EMDR led Division 12 (Clinical Psychology) of the American Psychological Association to deem EMDR one of three empirically validated treatment approaches probably efficacious in treating PTSD (Chambless et al., 1998). The other two validated treatment approaches were exposure therapy and stress inoculation therapy. Since that time, several studies have been conducted that included direct comparisons of EMDR with Prolonged Exposure that found both treatments to be effective, but with EMDR achieving results in fewer sessions with less homework (Ironson, Freund, Strauss, & Williams, 2002; Lee, Gavriel,

Drummond, Richards, & Greenwald, 2002; Power, McGoldrick, Brown, Buchanan, Sharp, Swanson, & Karatzias, 2002). These results indicate that although EMDR may not be more *effective* than other evidence-based trauma treatments, it may be more *efficient* in achieving comparable results in a shorter period of time, requiring less out-of-session work by the client.

In 1999, EMDR was designated in the treatment guidelines of the International Society for Traumatic Stress Studies as an effective treatment for PTSD (Chemtob, Tolin, van der Kolk, & Pitman, 1999). Subsequently, it was also recognized as an effective treatment for PTSD in the Cochrane Database, The California Evidence Based Clearinghouse, Substance Abuse and Mental Health Services Administration (SAMHSA's) National Registry of Evidence Based Programs & Practices, the American Psychology Association, the American Psychiatric Association, and the Department of Veteran's Affairs & Department of Defense. In addition, EMDR has been endorsed in several international treatment guidelines in the United Kingdom, Ireland, France, Israel, Sweden, and the Netherlands.

The early evidence supporting the effectiveness of EMDR in treating traumatized children was based primarily on several quasiexperiments and other studies with relatively weak controls for various threats to internal validity (Rubin, 2003). But although there is less research evidence supporting the effectiveness of EMDR in alleviating the trauma symptoms of children than is available on adults, the evidence is growing and showing promise. Several small RCTs have been conducted, along with two systematic reviews and a meta-analysis, all indicating that use of EMDR in treating trauma in children is effective. Chemtob, Nakashima, and Carlson (2002) tested a brief three-session course of EMDR treatment against a wait-list control with elementary school children ($n = 32$; aged 6–12 years) who had experienced a hurricane and found it to be effective in reducing PTSD symptoms, anxiety, and depression. Jeffres (2004) found that up to five 60-minute sessions of EMDR alleviated PTSD symptoms among children (ages 8–12 years) who had suffered one or more traumas. Ahmad and associates (2007) conducted an RCT with children ($n = 33$) diagnosed with PTSD comparing EMDR to a wait-list control and found significant differences in outcomes on all measures except the hyperarousal symptom cluster.

Kemp and associates (2010) compared EMDR to a wait-list control with children between 6 and 12 years of age with PTSD symptoms ($n = 27$) following a motor vehicle accident. Those who received EMDR experienced a 25% reduction in PTSD symptoms, while the wait list did not experience any reductions. Each of these studies would have been strengthened by comparisons with established effective treatments.

Jaberghaderi and colleagues (2004) compared EMDR to cognitive behavioral therapy (CBT) with a group of Iranian girls ($n = 14$) who had been sexually abused. Both treatments produced effective outcomes in reducing PTSD and behavior problems, but EMDR achieved the results in half the number of sessions (6.1 vs. 11.6) needed for similar results in the CBT group. Recently deRoos (2011) conducted an RCT comparing the effectiveness of EMDR + parental counseling to CBT + parental counseling in children ($n = 52$) between the ages of 4 and 18 years exposed to a disaster. Both treatments were effective in reducing key trauma symptoms—PTSD, depression, and anxiety—but as seen in adult sessions, results were achieved in fewer sessions (3 vs. 4). It is worth noting that deRoos codeveloped the CBT intervention used in that study; consequently, if one were to be concerned about bias it would be presumably toward the CBT condition.

Rodenburg and colleagues (2009) conducted a meta-analysis of seven RCTs involving the use of EMDR to treat children who had experienced a variety of traumas. They found EMDR to have an overall significant medium effect size of $d = .56$ and concluded that EMDR is an efficacious treatment for children and adolescents with trauma symptoms. Adler-Tapia and Settle (2009) conducted a systematic review of the efficacy of EMDR with children and adolescents that included 19 studies that met their inclusion criteria. Four of the studies included RCTs with children who had PTSD or posttraumatic symptoms, all of which are mentioned above. They concluded that the available evidence suggests that EMDR is a promising practice for treating trauma in children and adolescents, but its efficacy with other behavioral problems and disorders has not yet been established.

Three experimental studies raised questions about the effectiveness of EMDR in treating children whose symptoms were not clearly trauma-based. Two of these experiments compared the efficacy of EMDR with that of in vivo exposure in the treatment of spider-phobic

children. One found positive effects for EMDR, particularly on self-report measures, but also found that in vivo exposure had superior effects in reducing avoidance behaviors (Muris, Merckelbach, Holdrinet, & Sijsenaar, 1998). It concluded that in vivo exposure is the treatment of choice for this type of phobia and EMDR added nothing of value to it. In the other experiment, in vivo exposure produced significant improvement in behavioral as well as self-reported outcome measures, whereas EMDR produced significant improvement only on self-reported spider fear. Also, providing EMDR before in vivo exposure did not enhance the effectiveness of the in vivo exposure treatment (Muris, Merckelbach, van Haften, & Mayer, 1997).

One randomized experiment (Rubin et al., 2001) raised doubts about the effectiveness of EMDR when treating children whose emotional and behavioral problems are not connected in a narrow fashion to a specific trauma or whose very young ages or clinical problems require improvisational deviations from the standard EMDR protocol.

In addition to the need for more evidence regarding the effectiveness of EMDR with children, questions remain unanswered regarding its effectiveness with other target populations and problems. The evidence is mixed, for example, regarding its effectiveness in treating combat PTSD among military veterans (Rubin, 2003; Albright & Thyer, 2009). Likewise, there is a shortage of evidence supporting its effectiveness in treating victims of multiple traumas who experience complex PTSD (Rubin, 2003). Also needed is more evidence to support the claims of some that EMDR is effective in treating a wider range of problems, including less circumscribed ones that may not be caused by trauma, such as self-esteem issues, agoraphobia, somatic disorders, smoking cessation, chronic depression, obsessive-compulsive disorder, and eating disorders (Rubin, 2003; Shapiro, 1995).

Although EMDR incorporates various cognitive-behavioral techniques, its most distinguishing feature is the use of bilateral stimulation. Eye movements usually comprise the bilateral stimulation. Other forms of stimulation include alternating right and left hand taps or alternating sounds in the right and left ears for clients with vision problems or who have difficulty thinking about stressful material while concentrating on tracking the therapist's rapidly moving fingers with their eyes. Some

critics consider EMDR to be nothing more than traditional cognitive-behavioral therapy with an added component of bilateral stimulation (Rosen, 1999; Nevid, Rathmus, & Greene, 2008). Others, however, claim that what distinguishes EMDR is not just the bilateral stimulation, but a unique and systematic treatment sequence that incorporates other components thought to be effective in most types of effective trauma treatments such as mindfulness, relaxation, cognitive restructuring, and some degree of exposure (Lee & Cuijpers, 2013).

Perhaps the most controversial unanswered question pertains to whether the bilateral stimulation component of EMDR is really necessary. Some randomized experiments have offered limited support to the notion that the distinctive bilateral stimulation component enhances the effects of EMDR and that EMDR is more effective than exposure therapy (Maxfield, Lake, & Hyer, 2004). Still other experiments reached the opposite conclusions and questioned whether the beneficial effects of EMDR can be attributed exclusively to its imaginal exposure aspects (Olatunji, Parker, & Lohr, 2005–2006; Rothbaum, Astin, & Marsteller, 2005).

In a recent meta-analysis, Lee & Cuijpers (2013) analyzed 14 clinical EMDR studies and 10 laboratory studies evaluating the effect of eye movements. In the clinical studies, EMDR with eye movements was compared to EMDR without eye movements and a significant and moderate effect size was found for the additive effect of the eye movements (Cohen's $d = 0.41$). Likewise, in the laboratory studies where subjects were asked to think about a distressing memory with and without the use of eye movements, a significant and large effect size was found for the use of eye movements ($d = 0.74$). An interesting finding in the laboratory studies was that the largest effect size was in a measure of vividness ($d = 0.91$) indicating that the use of eye movements reduced the vividness of the distressing memory, which has important implications for treating trauma symptoms like intrusive images and flashbacks.

The debate as to the necessity of the bilateral stimulation component of EMDR pertains to the need for a more persuasive theoretical explanation as to why and how that component makes a difference. The primary theoretical model currently used is the AIP model described above. According to Schubert and Lee (2009), there are four hypotheses regarding the underlying mechanisms of EMDR that are congruent with

the AIP model and have some empirical support: (1) working memory, (2) orienting response, (3) REM-like state, and (4) increased hemispheric communication.

Working memory hypothesis suggests that the dual attention aspect of any of the forms of bilateral stimulation employed in EMDR, which involves attending to the external stimulus and one's internal experience of the trauma memory, taxes attentional capacity. Essentially, during the trauma processing work that takes place during the desensitization phase "the quality of the [trauma] image deteriorates, presumably because it gets pushed out of working memory and integrated into long-term memory, where the memory then becomes less vivid and less emotional." (Schubert & Lee, p. 127, 2009)

The orienting response is thought to be activated through the eye movements, which induce a relaxation response that reduces stress in a way that makes processing the trauma more tolerable (Elsofsson et al., 2008; Sack et al., 2008 as cited in Schubert & Lee, 2009). The eye movements have also been found to produce physiological responses that resemble a "REM like state" that "through repeated orienting responses, may 'push-start' memory processing in the brain by inducing a physiological and neurological state that is akin to REM sleep that aids in the transfer and integration of memories." (Schubert & Lee, p. 126, 2009) Another hypothesis is that horizontal eye movements in EMDR increase hemispheric communication in the brain, strengthening traumatic memory recall without arousal (Christman et al., 2003 as cited in Schubert & Lee, 2009).

Regardless of the theoretical explanation, there appears to be ample empirical evidence supporting the efficacy of EMDR in treating PTSD symptoms among traumatized adult clients. There is growing evidence supporting its efficacy with traumatized children. Although this review has focused on EMDR, its authors are aware of substantial empirical support for the effectiveness of trauma-focused cognitive behavioral therapy (TF-CBT) with children (Cohen, Mannarino, & Deblinger, 2006; Cohen, Berliner, & March, 2000). Consequently, clinicians treating traumatized children are advised to also consider TF-CBT as a possible alternative to EMDR.

Additional research will be required to explain why EMDR works. More studies are needed regarding its efficacy in treating a wider range of problems less narrowly connected with PTSD

symptoms resulting from a specific trauma, the debate as to whether the bilateral stimulation is really necessary, and the comparative effectiveness of EMDR versus other evidence-based trauma treatments (TF-CBT, Prolonged Exposure, and Cognitive Processing Therapy). While awaiting those studies, clinicians treating traumatized adults can be encouraged to use EMDR or any of those other evidence-based treatments.

98 Educational Interventions Principles for Practice

Kimberly Strom-Gottfried

Many settings and interventions require that the social worker act as an educator. In this role, professionals may lead educational groups, train volunteers, provide professional or community education workshops, create podcasts, guide new workers through educational supervision, or teach new skills as part of their interventions with clients. Often, however, practitioners may not consider these activities

as teaching, and therefore, may overlook valuable frameworks to assist in their practice. In order to encourage systematic attention to this role, this chapter summarizes the key elements of an education framework. It is intended to help social workers in a variety of settings to consider the educational aspects of their practice and to use teaching interventions more effectively.

Effective educational practice relies on six essential components:

1. The development of clear and appropriate objectives
2. An understanding of the learners' needs and abilities
3. An atmosphere that is conducive to learning
4. Knowledge of the material to be conveyed
5. The skill to select and use teaching methods appropriately
6. The ability to evaluate one's performance and the learners' acquisition of educational outcomes.

Whether one is teaching parenting skills to an individual teenager, conducting a psycho-educational group for mental health consumers, or presenting a course on crisis intervention to a group of volunteers, these steps comprise the necessary components of an effective educational program. Steps 1–6 are ongoing, but typically begin well before the worker and learners come together. Step 6 should take place throughout the duration of educational contact, and be done retrospectively as well.

DEVELOPING CLEAR AND APPROPRIATE OBJECTIVES

“No wind is favorable if you don't know your destination.” This quote, attributed to the Roman philosopher Seneca, aptly addresses the first step in any form of social work intervention. Workers must be clear about their purpose in using an intervention or technique, and the goals they hope to accomplish or the intended outcomes their clients expect. Specific to educational interventions, the worker should have some sense of what the learners need or what skills, knowledge, or attitudes they hope the learners will have as a result of the intervention (Anastas, 2010). Because a program's marketing, participant recruitment, location, topic selection, teaching methods, and evaluation all flow from its purpose, it is imperative that the goals be clearly articulated and appropriate for the needs of the end users.

Goals are sometimes an outgrowth of existing work with a client or group (Johnson & Johnson, 1997). For example, it may be apparent that clients diagnosed with HIV, diabetes, or other conditions can benefit from education about the

course and management of their diseases and strategies to manage daily activities and relationships in light of the illness. At other times, educational programs are developed independently, after which participants choose (or are chosen) to participate. The development of web-based continuing education to meet the needs of professionals desiring continuing education credits in ethics would be one such example.

Planning becomes more complex when a need or service gap is believed to exist, but has not yet been documented. In this case, needs assessment strategies should be used to determine the type and nature of the educational need. Needs may be determined through formal surveys, past enrollment data or program evaluations, interviews with service providers from social work and other disciplines, and from meetings or focus groups with potential consumers or representative groups.

Learning objectives typically fall into three broad categories: those geared to achieving knowledge or understanding, achieving skills or abilities, or achieving insight or attitudinal change (<http://www.oucom.ohiou.edu/FD/writingobjectives.pdf>). Within a given content area, interventions may have one focus (“Learn about diabetes and the diet plan to manage the disease”—*a knowledge goal*) or several (“Learn about the diabetes diet plan and be able to plan meals that fit in the plan”—*knowledge and skills goals*). Clarity about the type of learning expected is especially important when workers select their teaching methods, given that teaching strategies are better suited to some educational goals than others. For example, skill building is better done through simulations or role plays than a strictly lecture-based teaching format; experiential exercises can effectively lead to understanding and self-examination; webinars or podcasts address knowledge goals (Ko & Rossen, 2010). In creating continuing education or staff development programs, administrators may consider whether growth in knowledge, skills, or attitudes is most needed. Some learning objectives (improving sensitivity to cross-cultural differences, developing empathy, understanding countertransference) may be better handled through educational supervision than group processes (Kadushin & Harkness, 2014).

Clear objectives are also important when marketing an educational program. The dangers of advertising a program with an ambiguous purpose include drawing participants with

too-diverse a range of abilities or interests or discouraging appropriate people from enrolling at all because they cannot determine whether the program is “for them.” And finally, particularly in programs where learners and teachers are evaluated on the outcomes they have achieved, goals must be clearly specified in order to assess attainment adequately (Johnson & Johnson, 1997).

UNDERSTANDING LEARNERS’ NEEDS AND ABILITIES

Determining the need for and the purpose of an educational endeavor requires consideration of the prospective learners. Actually developing the educational intervention requires taking this understanding a step further and examining the particular life space of the learners, including their abilities, knowledge, and attitudes, as well as what motivation or reluctance they may possess with regard to the content. It involves “tuning-in” to the “feelings and concerns that the client may bring to the helping encounter” (Shulman, 1992, p.56). It may also involve understanding ethnocultural, developmental, and other issues and the way that teaching dynamics are affected by differences among teachers and learners (Anastas, 2010). An accurate understanding of learners will facilitate the selection and sequencing of content and the training methods used. Inadequate tuning-in may lead to learners’ resentment and resistance, may affect enrollment and attendance, and may lead to the selection of material that is variously rudimentary, irrelevant, or too complex (Anastas, 2010; Bain, 2004).

A number of teaching principles are predicated on “knowing the learner” both as an aggregate group and as individuals. These include understanding sources of intrinsic and extrinsic motivation, making the material relevant and meaningful for each individual, building on the learner’s existing knowledge, sequencing material from the familiar to the unfamiliar, identifying learning styles, and expressing appropriate confidence in the learner’s abilities (Kadushin & Harkness, 2014). The ability to individualize learning makes it more potent, as does forging a relationship in which the participant feels known and valued. Both require actively anticipating and understanding the individual-as-learner.

DEVELOPING A LEARNING-CONDUCTIVE ATMOSPHERE

This component of teaching refers to both the physical environment and the emotional environment in which learning is to take place. Clearly, all learning opportunities carry with them the risk of mistakes or failure. As Kadushin has noted regarding educational supervision, “We learn best when we can devote most of our energies in the learning situation to learning. Energy needed to defend against rejection, anxiety, guilt, shame, fear of failure, attacks on autonomy or uncertain expectations, is energy deflected from learning.” (1985, p. 149)

In keeping with this admonition, educators should inform learners about the purposes, processes and structures for the learning activity. Learners must know what will be expected from them and what they can expect from the teacher (Lemov, 2010). The teacher should acknowledge and support the learner’s risk-taking in pursuit of change and establish a climate of trust and safety. When teaching in a group format, guidelines should be established and articulated that will yield a supportive environment for all involved, and the leader should be aware of any dynamics that are impinging on an individual’s participation (Brooks, 2011; Gregory, 2013; Ko & Rossen, 2010). Some class members may pose challenges to the safety and efficacy of the learning environment. Hostile, monopolizing, inattentive, unprepared, or fawning participants may alienate both the instructor and the fellow class members (Royse, 2001). It is up to the leader to determine the basis for the problematic behaviors and craft an effective response. Some problems arise from poorly specified expectations or norms, and thus the resolutions may be structural in nature. Problems that arise from behavioral, psychological, or interpersonal issues will likely require an individualized intervention (McKeachie & Svinicki, 2014). As with other challenges arising in social work practice, supervision and consultation are essential to assist the worker in managing his or her personal responses to the difficulty and the difficulty itself.

The physical climate is also important for effective learning, though generally it is less in the leader’s control. Ideally, the facilities should be well-suited for the purposes and characteristics of the learners. The literature on group work is relevant here as we consider, for example, the needs of a group of adults in a didactic presentation as

compared to those of teenagers in an experiential learning program. The very setting of the educational program should be determined with the purpose and audience in mind. The location, accessibility, safety, parking, available hours, and “reputation” or message carried by the site will influence learner attendance. Keeping the nature of the training and trainees in mind, attention must also be paid to room size, temperature, arrangement, the use of tables or chairs without tables, other furnishings, and the availability of audio visual equipment, rest rooms, and refreshments. Creating the appropriate levels of physical and emotional comfort for learners is a planning task, and an ongoing management responsibility for the educator.

KNOWLEDGE OF CONTENT

Implied in accepting the role of educator is the notion that one has some knowledge that can be taught to or shared with another. Yet a stumbling block for many would-be educators is the fear that they do not have a sufficient command of the material to put themselves forth as instructors. This section addresses how much knowledge of content is needed, what sources can be used to enhance or supplement the instructor’s knowledge, and how the fear of not knowing enough can be overcome.

How much knowledge is required depends on the needs of the learners and the purposes and structure of the educational program (Anastas, 2010). A single fact about normative child development may be sufficient to inform a client in an intervention around parenting, but a good deal more knowledge will be required if providing an adult education course on the subject. As noted earlier, clarity about the goals of the educational program will be a vital guide. As educators begin to tune in to the program and learners, they get a sense of the depth and breadth of information needed. Reviewing curricula for similar programs or discussing ideas with colleagues and clients will help further identify content needs even prior to the training. These steps often remind facilitators that they know more than they think they do. Where further knowledge of content is needed, presenters can supplement their knowledge through traditional sources such as texts and journals, interviewing subject experts, or viewing videos and films. In the classroom, presenters can augment the content they have to offer by using

educational media, handouts, bibliographies, videos, or outside speakers.

Despite these steps, educators often feel vulnerable about their command of the course content. Such feelings may stem from the mistaken impression that the teacher must be “the sage on the stage” rather than “the guide on the side.” This misconception not only places an unrealistic burden on the worker, but can deprive all participants of the richness that comes from shared responsibility for learning. Sometimes referred to as student-centered learning, this model encourages the instructor to set the stage and provide the foundation through which all class members can contribute and learn from one another. This approach is consonant with theories of adult education, mutuality, and empowerment-based practice. Even if instructors cannot wholly utilize such a model, they must address the fear of not knowing. Learners do not expect that instructors will have all the answers, and in fact, will have a greater respect for those who are able to say “I don’t know, I’ll check and get back to you.” or “I hadn’t heard about that. What do you know?” Similarly, the ability to catch and acknowledge mistakes conveys important messages about the authenticity of the instructor and the acceptability of errors. Conversely, the need to be right or know it all often sets up an adversarial learning environment, in which genuine learning is sacrificed for gamesmanship and defensiveness (Lang, 2012).

Although there is no definitive answer to, “How much content is enough?” there are multiple strategies for adjusting content in the event of over- or underestimation. When planning a program, instructors should anticipate the amount of time they will devote to certain material, and think about how they might be able to cut or add as necessary. In multisession groups, instructors can retool between sessions as content needs become apparent. Discussions, experiential exercises, and case studies can be used to take content to a deeper level of application if presenters move through their material more quickly than anticipated. If too much material has been planned, instructors can re-examine the objectives and eliminate less crucial information or outside work or reading can supplement in-class time. In addition, the dilemma can be shared with learners, and their input used to prioritize the content to address with limited time.

SELECTING AND USING TEACHING TECHNIQUES

Many people teach the way they have been taught. Unfortunately, many people have been taught in ways that stifle learner involvement, enthusiasm, and critical thinking. Having sat through mind-numbing lectures, tangential discussions, and fun-but-pointless exercises, they may believe that these are the only available means of conveying information. In fact, there exists an array of teaching approaches; the challenge is not only in finding them, but in selecting them to appropriately meet the needs of the learners and the objectives of the intervention.

Certain structures and teaching techniques are particularly well-suited for different teaching goals (Davis, 2009; Knowles, 1975; Strom-Gottfried, 2006):

Lectures

- Convey complex material
- Highlight important facts and concepts
- Create a cognitive map for future applications

Exercises, Demonstrations, Role Plays and Simulations

- Provide ice-breakers
- Build group cohesion
- Foster skill acquisition and rehearsal
- Generate empathy
- Model techniques and concepts
- Facilitate problem-solving

Cases, Discussions, and Debates

- Develop insight
- Foster new perspectives
- Apply concepts

Web-based and Other Instructional Technologies

- Convey complex material
- Allow self-paced and self-timed learning, review, and repetition
- Are convenient
- Content, assignments, and discussions can be archived for sharing or future use.

Each teaching method has its own promises and pitfalls. Suggestions for effectively using instructional strategies include (Carnes, 2011; Christensen, Garvin, & Sweet, 1991; Davis, 2009; Filene, 2005; Kadel & Keehner, 1994; McKeachie & Svinicki, 2014; Royse, 2001; Sweet, 2010):

Lectures

- Limit length or break up with discussions, examples, question and answer sessions, or activities.
- Vary vocal intonations, facial expressions, gestures, and movement about the room.
- Initiate with a compelling question or scenario to be addressed by the lecture content.
- Do not read the lecture but do read the audience.
- Provide scaffolding for content in outline form through handouts or Power Point presentations.

Exercises, Demonstrations, Role Plays and Simulations

- Link to learning goals or course material
- Choose judiciously
- Clearly explain the objectives and directions
- Be alert to emotional reactions among participants
- Prompt skill development with modeling, videotaped examples, or discussion of strategies for effective practice
- Demonstrate support for risk and enthusiasm for the exercise
- Debrief to identify strengths, weaknesses, and links to learning objectives.

Cases, Discussions and Debates

- Create a supportive, caring, and respectful atmosphere
- Develop clear learning points
- Establish ground rules for discussions
- Allow time for participants to think before responding
- Encourage or structure alternative perspectives
- Summarize key outcomes

Web-based and Other Instructional Technologies

- Carefully sequence educational modules
- Make sure materials and directions are clear, thorough, and accurate
- Design should be visually compelling and user-friendly
- Anticipate technological glitches
- Incorporate varied teaching strategies, including real time meetings, discussion boards, video clips, question and answer sessions and other interactive opportunities.

When selecting strategies to support various learning objectives, educators must also keep in mind their learners' capacities, the size of their group, and the amount of time they have for instruction. Such variables will affect the mix of teaching strategies employed, the time needed to carry them out, the learners' ability to benefit from the technique, the facilities needed, and the sequencing of material (Anastas, 2010).

EVALUATING TEACHING PERFORMANCE AND LEARNERS' ACQUISITIONS

Most evaluations address two questions: "Were the learning objectives achieved?" and "How effective was the instructor in helping them to be met?" Both elements of evaluation are important. Evaluating satisfaction without having some measure of the benefit of the content is referred to as "popularity polling" (Davis & McCallon, 1974, p. 275). Evaluating attainment without determining what was effective and what was not in terms of delivery does not help the instructor generalize the effort to future situations. A variety of measures can be used for each form of evaluation, and to some extent, the measure chosen depends on how the information gleaned will be used (Unrau, Gabor, & Grinnell Jr., 2007). If the information will be quantified, for example to give the learner a grade or to rate the instructor, precise numerical measures will be called for. For other purposes, less precise measures are adequate and sometimes preferable. For

example, in measuring what people learned in a social skills training program, observed change or self-reported change may be adequate, whereas a CPR training program would require more definitive measures of competency.

Used alone or in combination with quantifiable ratings, open-ended questions or narrative evaluations can provide feedback with valuable depth and context (Davis, 2009). For example, the instructor may find that the structure or timing of an exercise was ineffective, not the exercise itself, or the learner may get feedback about particular areas of strength within a specific content area.

In addition to the form of evaluation, timing is another consideration. In general, periodic formal or informal check-in types of evaluation will help both learners and educators reassess their progress toward achieving the objectives and reprioritize material or alter teaching strategies accordingly (Davis, 2009; Unrau, Gabor, & Grinnell Jr., 2007). Methods for this include brief self-reports at the end of a session about insights and information achieved or "minute cards" where participants provide written feedback on the meeting.

Effective and ethical instruction arises from the conscientious use of various forms of evaluation to inform practice. In addition to utilizing incremental and cumulative verbal and written feedback from participants, social workers can utilize peer observers, coaching, and video-taped sessions to continually improve and refine teaching performance.

CONCLUSION

Teaching is an integral part of social work practice, done in a variety of settings with a range of populations. This chapter offers guidance for the creation and delivery of educational interventions and offers resources for further study. It encourages the examination of social work activities from an education framework, advocating that as this function is better defined, models can be further developed, teaching challenges examined, and the necessary knowledge and skills for effective practice specified.

99 Divorce Therapy

The Application of Cognitive-behavioral and Constructivist Treatment

Donald K. Granvold

Divorce is one of the most distressing transitions one can undergo. Whether the decision is unilateral or shared, or one is the initiator or the one being left, the process is painful and disruptive. The change following divorce is pervasive, extending across many domains of the individual's life. For most, coming apart carries with it extreme emotional consequences. Divorce is simultaneously an ending punctuated by loss, estrangement, and detachment and a new beginning characterized by fear of the unknown; challenging novel roles, responsibilities, and behaviors; and promising future possibilities. Client treatment goals can be expected to fluctuate. The desire for a sense of closure regarding the past may prompt a focus on the estranged or ex-mate and the associated family and social networks. Alternatively, the focus may be on the development of novel or expanded selves to meet current and evolving demands and possibilities (Granvold, 2010).

STAGES OF THE DIVORCE PROCESS

The divorce process can be conceptualized as being composed of three overlapping stages: (1) decision making, (2) transition, and (3) postdivorce recovery (Granvold, 2000a, 2000b, 2010). Each of these stages poses unique challenges to the individual and each is replete with crisis potential.

Decision Making

I believe that therapists are challenged most greatly in helping individuals/couples with the

decision to divorce. Specific methodologies are least well developed in this area. Typically, one or both partners continue their marriage in a state of high dissatisfaction and protracted indecision before ultimately arriving at a decision to divorce. The state of indecision is stressful in itself, characterized by high levels of frustration, anxiety, uncertainty, fear, worry, insecurity, distrust (particularly for the mate who is more greatly committed), hurt, resentment, depression, hopelessness and impending doom, and feelings of disempowerment. There is often erosion in feelings of love, intimacy, sexual desire, and sexual satisfaction. Individuals who are emotionally fragile, highly dependent on the mate, and/or lack self-esteem often experience situation-specific crises as the couple moves toward a final decision. This individual, typically more committed and less likely to decide to leave the relationship, is far more vulnerable to crisis responses.

The following are examples of therapeutic goals during the decision-making stage:

- Specify factors eroding the relationship
- Optimize relationship functioning (specify and implement strategic change)
- Promote frustration tolerance for indecision (i.e., combat low frustration tolerance)
- Limit impulsive decision making
- Carefully determine and weigh the factors of satisfaction and dissatisfaction
- Clarify values and life goals related to coupling

- Clearly identify perceived advantages and disadvantages of divorce relative to remaining married
- Consider structured marital separation to interrupt maladaptive patterns of interaction, re-evaluate the relationship from an altered perspective, and move more gradually to singlehood (a treatment of choice only for select couples) (Granvold, 1983).

The gravity of the decision and its effect on the lives of the couple, their children, extended family, and friends creates great pressure on the decision maker(s). Typically, both the decision maker and the rejected partner experience intense and protracted pain. It is noteworthy that divorce appears far more likely to be the consequence of a loss of intimate connectedness than the result of intense conflict (Stanley, 2001). The absence of overt signs of disagreement and dissatisfaction may be confusing to both partners and those close to the couple, particularly offspring.

Transition

Once a decision to divorce is made, the couple enters the transition phase of the divorce process. For many, divorce is largely a consequence of an erosion of love, a shift from feeling “in love” to simply “caring.” Despite this shift, interpersonal attachment tends to persist. There is a sense of comfort in the relationship and in the shared physical environment. Dissolving the relationship and physically separating may well have a concomitant profound sense of loss even for those who are no longer in love and who *want* the divorce.

Physical separation and the initiation of legal action are characteristically periods of extreme stress (Wang & Amato, 2000). Clients should be carefully evaluated for their ways of dealing with stress in the event they are putting themselves or others at risk or alternatively, are experiencing significant maladjustment. Of further concern are those who have endured violence in marriage. Separation has been found to instigate additional assaults by abusive partners and first-time violence in previously nonabusive mates. The following are examples of therapeutic goals during the transition phase:

- Assess and treat suicidality and homicidal ideation and planning
- Assess death wishes (passive suicide)
- Assess and develop strategies for postseparation domestic violence
- Assess alcohol use and prescription and illicit drug use
- Complete strengths and resiliency assessment
- Strategize informing children, family, and friends regarding the divorce
- Promote the expression of loss (emotionally, cognitively, behaviorally)
- Develop adaptive strategies for stress management during transition (e.g., limit alcohol/drug use, check excessive investment in work, explore deep muscle relaxation, engage in healthy exercise)
- Facilitate effective relationships with children, family, and friends
- Address effecting legal action to dissolve the marriage contract
- Address child custody and parallel parenting issues
- Promote a collaborative property settlement agreement.

The transition phase also requires attention to the specifics of the division of property, physical relocation, child custody, and child support—all of which stimulate emotional reactions. These considerations pose remarkable opportunities for conflict, divorce decision doubt, uncertainty regarding the future, and intense feelings of loss.

Postdivorce Recovery

Postdivorce recovery, as identified earlier, involves pervasive change. In addition to dealing with losses of a physical and emotional nature, the individual is challenged with redefining self and re-envisioning his or her life. Now, it is necessary to establish a monadic identity, independent of the self that evolved and was forged through years of intimate connectedness with the ex-mate. The path of life that had been relatively established and known no longer fits the novel territory in which one now travels. The transition process to postdivorce recovery is replete with pervasive change. Among the changes being experienced are new role relationships with children (for example, single parenting), workmates, extended family, and friends. The development of friendship and intimate relationships as well as participation in network groups (for example, church, interest groups, support groups) have been found to be positively associated with

postdivorce adjustment (Krumrei, Coit, Martin, Fogo, & Mahoney, 2007). Although a positive association exists between social support and postdivorce adjustment, the quality of these relationships promotes or undermines well-being (Krumrei et al., 2007).

The clinical and research findings on the effects of divorce are inconsistent. Some individuals experience positive change in the form of relief, a renewed sense of freedom, joy, enhanced self-esteem, increased happiness, greater life satisfaction, greater sense of responsibility, and a sense of renewal, whereas others experience such untoward consequences as extreme loss, hurt, depression, social isolation, unhappiness, financial problems, increased risk of health problems, single parenting challenges, reduced life satisfaction, and diminished self-esteem (Baum, Rahav, & Sharon, 2005; Sakraida, 2005). Vulnerability to greater postdivorce maladjustment appears to reside with older versus younger women (Sakraida, 2005), noninitiators of divorce, and those lacking social support (Krumrei et al., 2007). Furthermore, divorce is likely to exacerbate the emotional instability of those with a predivorce history of mental health problems. A substantial number of divorced individuals fall into this category, given the predisposition of poorly adjusted people to divorce.

Literature on the effects of divorce has predominantly reflected a deficit model, emphasizing the negative psychological, social, and health consequences to adults and children. Recent studies have given greater attention to positive short- and long-term consequences in which the divorce process is viewed as a potential personal development opportunity (Hilton & Kopera-Frye, 2004).

Common maladaptive coping strategies involve the excessive use of alcohol and drugs (prescribed and illicit), oversleep, overexercise, and overinvestment of time and energy in work. Though grieving is a necessary, adaptive process and is unique from person to person, it may become debilitating to those who allow it to become all-consuming.

The following are examples of therapeutic goals during postdivorce recovery:

- Delineate and dedicate efforts to the evolution of “possible selves” consistent with the re-envisioning of one’s life
- Establish a quality relationship with children as a single parent (attend to their emotional

needs and their need for structure in the reconstituted family)

- Develop an effective parallel parenting relationship with the ex-spouse
- Gain closure on the marriage (grieve and seek to accept emotionally that the marriage is over)
- Promote efficacy expectations regarding present and future life satisfaction
- Generate rejuvenation goals across various categories of life (career, education, hobbies, interests, relationships, lifestyle, geographic and environmental circumstances)
- Seek intimate connectedness with others through clear delineation of partner/relationship qualities, active pursuit, deliberate relationship evaluation, and proactive decision making to terminate or maintain the relationship(s) (Krumrei et al., 2007; Wang & Amato, 2000)
- Develop and rejuvenate sexuality
- Activate a lifestyle in which physical health and exercise are priorities.

INTERVENTION

The proposed treatment model incorporates behavioral methods, orthodox cognitive treatment methods, and constructivist conceptualizations and methods (Granvold, 2000a, 2000b, 2008, 2010). The unifying factor is the view that cognitive functioning plays a central role in the human condition and human change. Although cognitive functioning plays a crucial role in the development and regulation of human behavior, it is recognized that behavioral activation strategies used in combination with cognitive change represent the most powerful and resilient forms of intervention.

There is remarkable empirical support for the application of cognitive-behavioral treatments (CBTs) to an array of psychological disorders (DeRubeis & Crits-Christoph, 1998). Many empirically supported psychotherapy treatments (ESTs) use a wealth of cognitive and behavioral intervention procedures in various forms and combinations. Divorced clients can be expected to present with problems and concerns suitable for treatment with methods proven to be efficacious. As noted earlier, there are many psychological consequences of divorce. Among the most typical are depression, anxiety and panic disorders, anger control, posttraumatic stress disorder

(particularly relevant for survivors of domestic violence), obsessive-compulsive disorder, alcohol abuse and dependence, and substance abuse and dependence. CBT has been applied successfully in treating each of these problems. CBT interventions continue to be scrutinized and evaluated through extensive ongoing empirical research.

Postmodern conceptualizations of divorce provide an alternative (albeit in many ways compatible) perspective on the process of coming apart and transitioning to single life. Divorce is viewed as necessarily disruptive to the self system with a concomitant array of emotional consequences. A primary treatment goal is the generation of multiple meanings of specific events in the process of divorcing and adjusting to singlehood. Emotional expressions are evoked and processed through an array of cognitive and behavioral methods. Attention is given to the client's redefinition of self and the modification and expansion of intimate and social relationships. Emphasis is placed on the client's strengths and the positive change possibilities inherent in this major life transition (Granvold, 2008, 2010).

The constructivist aspects of the intervention are represented in the following enumeration.

1. Conceptualize divorce as a self-system perturbation.
2. Seek to access self-schemata activated by the divorce process with the objective of modifying core ordering processes through construct elaboration.
3. Explore primary attachment relationships as they relate to views of self and the world, including the attachment relationship with the ex-spouse.
4. Promote a view of self as a multifaceted and ever-changing system of identity meanings, rather than a singular, fixed self.
5. Promote emotional expressiveness through guided discovery, imagery, imaginary dialogues (empty chair technique), and therapeutic rituals.
6. Use personal narratives and journaling as change mediums.
7. Accentuate client strengths, personal and social resources, creativity, coping capacities, and resiliency.
8. Collaborate with the client in constructing change mediums, models, and techniques with which the therapist has an expertise and which suit the client.

Although the therapist has expertise regarding both the process of divorce and human change processes, a nonauthoritarian role is assumed in relation to the client. The intervention is strategically the co-construction of the client and therapist. See Chapter 40 for detailed information on constructivist theory and practice.

CLINICAL EXAMPLES

The following are exemplars covering each stage of divorce.

Decision Making

Penny and Jason presented for therapy undecided whether to divorce or remain married. As part of the intervention, the couple used journaling to clarify their expectations of a mate and marriage. They traced their relationship from its inception and noted the evolution of their partner and marriage expectations. In therapy sessions, they were guided in the use of their journaling to make specific comparisons of their expectations with their "experience" of the relationship. The process helped them realize that although their marriage had closely aligned with early expectations, they had evolved divergently and no longer found the relationship satisfactorily viable. They reported feeling as if they had made a collaborative decision to divorce, and they shifted their focus to the emotional and practical requirements of coming apart.

Transition

The divorce decision was imposed on Marla by her husband, Mark. Although the relationship was amicable, Marla had been having extreme difficulty with the transition. She drank several glasses of wine each night, had withdrawn from family and friends, and had discontinued her aerobics workout routine that she had done for years. The couple was childless. Having effectively coped with the loss of her father (with whom she was close) five years earlier, Marla was prompted to compare and contrast her ways of coping with the two losses, her father and Mark. She identified differences in the losses, specifically noting that Mark had been there for her during her grief over her father's death. She concluded, however, that she could implement some of the same coping strategies this time.

She decided to limit her drinking to one glass per night, do something “social” at least one occasion per week, and resume a four-day-a-week workout regimen. Therapist actions included Socratic questioning, gentle encouragement, and strong verbal support for her plans.

Postdivorce Recovery

Greg presented for therapy a year after his divorce was legally final. His primary goal was to let go of the relationship with his ex-wife, Laurie, and to “feel” divorced. After several sessions, it was apparent that Greg was emotionally ready to let go. An implosion strategy was discussed and planned in the session (Granvold, 1994). The following Saturday, he dedicated eight hours to grieving the loss of his relationship with Laurie. He looked at pictures and memorabilia, played their music, ate Chinese food in the middle of the bed as they had done many times, smelled a pillow laced with her perfume, and freely cried with no goal to stop the crying. In three to four hours, the tears dried up. Although it was an emotionally painful experience, at the following session Greg reported a greater sense of closure, as if an emotional connectedness had been purged, a connectedness that could no longer be.

CONCLUSION

Although much has been written about divorce, there is a paucity of information focused on treatment. This gap in the treatment literature is particularly alarming given the relatively high divorce rate and the emotional trauma associated with coming apart. This chapter has provided treatment guidelines and a limited view of the application of CBT and constructivist methods to treat clients during divorce decision making and beyond.

100 Primary Prevention Using the Go Grrrls Group with Adolescent Females

Craig Winston LeCroy & Nicole M. Huggett

Female adolescents today face a multitude of risks such as cigarette and drug use, body dissatisfaction and body image disorders, problems associated with sexual behaviors, and high rates of depression and unhappiness. Gender specific programs can address the unique issues that adolescent girls face. Universal primary prevention models offer a method of providing girls with necessary skills and protective factors to combat a wide array of risky behaviors before these behaviors lead to more serious consequences.

Girls face unique biological, psychological, and social changes during adolescence. Gender-specific programs are able to address these issues. For example, physical maturation can be a negative experience for girls (Benjet & Hernández-Guzmán, 2002), and early maturation, in particular, is a significant risk factor. Studies have found early maturation to be related to multiple risks including eating problems and body image disorders (McCabe and Ricciardelli, 2004), depression and low self-esteem (Kaltiala-Heino, Kosunen, & Rimpela, 2003), and delinquency (Negri, Fung, & Trickett, 2008). All these factors support the reasoning that gender-specific prevention programs are ideal to support a healthy transition for girls from adolescence into adulthood.

One factor that should be considered in the development of a universal primary prevention program for adolescent females is the multitude of negative messages about women in the media. The negative consequences of gender stereotypes in traditional media such as music, television, and advertising have long been recognized by researchers (Simmons & Blythe, 1987). However,

adolescents today are also bombarded by these images on websites and in social media outlets like Facebook and Instagram, where there are pages dedicated to thinspiration (or “thinspo”) and proponents of anorexia (“pro-ana”). These websites depict pictures of very thin women to provide inspiration to girls who are trying to lose weight, information regarding how to hide an eating disorder from loved ones, and opportunities for girls with body image disorders to form a network to connect with others. Unfortunately, this network often becomes isolating and encourages the continuation of these unhealthy behaviors (Tantillo, 2006).

Girls are also at risk for cyberbullying, including online sexual harassment. Some studies have found that anywhere from 20% to 40% of adolescents have been victims of cyberbullying, with girls being as likely as boys to be bullied (Gamez-Gaudix, Orue, Smith, & Calvete, 2014). Being a victim of cyberbullying is associated with low self-esteem, symptoms of depression, substance abuse, and Internet addiction (Ybarra, Mitchell, Wolak, & Finkelhor, 2006; Gamez-Gaudix, Orue, Smith, & Calvete, 2014). These risk factors may interact with stressors associated with adolescence and lead to an unhealthy and difficult transition into later adolescence and adulthood.

Considering the multitude of risk factors for adolescent girls, interventions are most effective when they promote a broad concept of well-being and positive development. Several researchers (e.g., Elliott, 1993; Millstein, Petersen, & Nightingale, 1993; Johnson & Roberts, 1999) have recommended movement away from interventions for single problems, and

have instead suggested interventions that focus more generally on positive adolescent growth and good health. These efforts have grown out of the understanding that specific problem behaviors can be better understood as a constellation of problems that are interrelated.

This research highlights the importance of the creation of a developmentally based gender-specific program for adolescent girls. The empowering adolescent girls program, or Go Grrrls curriculum, (LeCroy & Daley, 2001a) is informed by understanding the timing of the intervention, selection of relevant issues, and a focus on reducing identified risk factors. In this manner the program is both developmentally appropriate and gender specific, because it addresses some of the unique aspects of adolescent development. Table 100.1 describes the developmental issue, developmental process, and the program objectives for the Go Grrrls curriculum.

An evaluation of the Go Grrrls curriculum shows promising findings. Compared to a control group, Go Grrrls participants showed greater increases in their perceptions of body image, self-reported assertiveness, perceptions of attractiveness, self-efficacy, and self-liking and competence immediately following the end of programming (LeCroy, 2004). Additionally, the curriculum provides participants with a link to new friends as well as personal and community resources.

GO GRRRLS CURRICULUM

Program Structure

The Go Grrrls program is a psycho-educational program delivered in a group format to middle school girls. The group structure is practical for reaching a large number of girls, as well as being developmentally appropriate due to the fact that adolescents tend to place a high value on social interaction with their peers. The curriculum is intended to be delivered in a community setting such as a school, community center, or library. It is designed to be delivered in 90-minute sessions weekly in an optimal group size of eight to ten girls. The success of the sessions relies heavily on the energy level and participation within the group. For this reason, facilitators with certain attributes are preferred: enthusiasm, organization, interpersonal sensitivity abilities, and good social skills. Co-facilitation is also recommended

so that the facilitators can model role play with each other, as well as take turns facilitating to maintain momentum and high levels of group energy.

The curriculum includes a participant workbook, *The Go Grrrls Workbook* (LeCroy & Daley, 2001b), which provides exercises and information that reinforce the material learned in the group sessions and serves as a journal for the girls to record their thoughts and feelings. For example, each workbook chapter includes a slumber party dialog, a quiz, a "Did you know?" section, a "Check it out," section, and a journal assignment that is aligned with each group session. A parent workbook to aid parents or guardians is also used to facilitate parental engagement with the program material. The parent workbook provides an overview of each session and suggests ways to talk about the topics with daughters. This is especially useful in the sessions that discuss sexual health, when parents may find it more difficult to talk to their daughters about these topics. This also serves to get girls to talk to their parents about household rules, values, and expectations.

When recruiting participants for the Go Grrrls curriculum, girls are most receptive to hearing the program referred to as the Go Grrrls Club. A club seems more fun than a prevention program. When girls are excited about being a part of the Go Grrrls Club, this energy is translated into the group sessions, which is critical to the success of the activities.

Ensuring Successful Group Sessions

As previously emphasized, the success of the curriculum depends on participation and engagement. With energetic facilitators and the consideration of a few key factors for successful group facilitation (see e.g., Schiola, 2011), sessions will be fun and engaging for the participants, rather than feeling like a classroom atmosphere.

Active pacing. An active pace is necessary in sessions to keep girls' attention. Additionally, there is a lot of material to cover in each session, and active pacing is often necessary to ensure that all of the material is covered. Each session includes recommended time allowances for the various activities. Facilitators are encouraged to map out the session beforehand so that they know exactly what time transitions should be made in order to keep the session moving. Facilitators also should feel comfortable in keeping group members on-task, especially when dealing with more

TABLE 100.1 Developmental Issues, Developmental Processes, and Related Program Empowerment Objectives

Developmental Issues	Developmental Process	Program Implementation: Empowerment Objectives
Gender Role Identification	At puberty, gender-intensification theory suggests gender-related expectations influence behavior.	Enhance positive messages about gender roles; promote a more positive sex-role self-image.
Body Image	Adolescent girls are at risk to develop a negative body image, which leads to low self-esteem, depression, body image disturbance, and eating disorders.	Promote understanding of the changes that take place during puberty. Promote positive body image and body acceptance.
Self-Acceptance	In early adolescence girls have a drop in self-esteem and this is accompanied by increased self-criticism, negative mood states, and for some girls, depression.	Promote a positive self-image in response to the biological, psychological, and social changes girls confront. Reduce self-criticism and promote positive mood states.
Peer Relationships	Membership in the peer group is a major developmental task. Adolescents who fail to develop positive peer relationships are at greater risk for developing problems like substance abuse and depression. Conformity and peer pressure can lead to bad choices made by young people.	Promote positive peer relationships. Build on the relational quality many girls have in friendships to strengthen positive reasons for friendship. Build sharing and mutual understanding for enhanced companionship, support, and empathy.
Responsible Decision Making	Most adolescents in today's society will confront decisions that could have lifelong if not lethal consequences. The cognitive development of young people has important implications for adolescent risk taking.	Promote responsible decision making by teaching problem solving skills. In conjunction with decision making encourage personal assertiveness.
Sexuality	Girls' sexuality is a major issue because of the potential consequences associated with high risk behaviors. As girls develop sexually they need information and skills to prevent unwanted sex, unwanted pregnancies, and STDs.	Promote awareness and understanding of sexuality issues. Enhance responsible decision making and safe sex. Broaden girls understanding of sex so it is not seen only as intercourse. Address the special risks for younger girls.
Accessing Resources	Adolescent girls face multiple risks and a full one-third are estimated to be at high or very high risk. Along with girls' "invisible" problems (like depression) adolescents vastly underutilize systems of care.	Reduce barriers to services and help prepare girls to find and accept professional help when they need it.
Planning for the Future	Adolescent girls often experience a "crisis in confidence" that undermines their educational and career decisions for later life.	Enhance girls' achievement motivation. Build their confidence for educational and vocational aspirations. Teach a "mastery orientation" as opposed to a "learned helplessness" orientation.

verbose participants. A simple reminder that the group needs to stay on schedule and an offer to continue the discussion after group is a gentle way to move the group forward if a participant begins to digress.

Honest and open communication. Most people, adolescents included, have a good sense of when people are being honest with them. In order to foster a trusting environment, it is important that facilitators be open and honest with the participants. This will be particularly important at the end of the program, when girls may be attached to facilitators and expect to be able to stay in touch with them. Facilitators should always speak truthfully and tactfully without oversharing personal or inappropriate details.

Frequent contribution. It is important that facilitators elicit participation from all members of the group. This can be done by calling on participants by name. Also, rather than having the girls share by going around the circle, facilitators can keep girls on their toes (and engaged) by calling on them randomly by name. It is also important that facilitators keep their own comments during discussion to a minimum to encourage input from participants.

Use of praise. Facilitators are trained to use a great deal of praise during group sessions to foster confidence and assertiveness in group members. This praise should be specific about the individual's behavior, as opposed to a general comment about the individual as a person.

Use of names. A name game is utilized in Unit 1 to help participants remember each other's names—and also help facilitators in remembering names. Using names frequently in the group helps to foster a more intimate feeling, and will help the girls feel comfortable in a new setting.

GO GRRRLS SESSIONS

Unit 1. Introduction to Girls' Issues

The goals for the initial session are (1) to create a supportive atmosphere and begin building cohesiveness within the group; (2) to collect baseline data for program evaluation; (3) to introduce participants to group standards such as confidentiality and respect for others; and (4) to introduce the program content. To begin, facilitators warmly welcome participants and wait for them to get settled before beginning the assessment, which will inform the evaluation of the program. The

assessment measures girls' self-reported depression symptoms, self-esteem levels, and confidence in problem-solving, among other things.

A "name game" is played to loosen everyone up and to help with introductions. Following the game, we help the girls to establish group standards by asking them to suggest their own rules for the group. If the group-generated rules do not include important areas (such as confidentiality and its limits), then the group leaders bring up these subjects. Finally, we introduce the program content by displaying a large poster with the "Go Grrrls" puzzle, and encourage each member to read one of the topics aloud (see Figure 100.1). Finally, we distribute Go Grrrls workbooks, which the girls are instructed to use to complete brief assignments for the group and to express themselves in any way they wish. The journals/workbooks are a tool for helping the girls incorporate what they learn into their personal lives and provide a mechanism for encouraging them to continue their self-growth and discovery after the group ends. Facilitators ask the girls to complete the "All About Me" assignment for the next meeting. The first session ends with playing "Two Truths and a Lie." Table 100.2 shows all components of Unit 1 demonstrating the structure that the program uses for each session.

Unit 2. Being a Girl in Today's Society

This session helps girls call attention to the stereotypes and gender roles that are ubiquitous in modern society through the media. Once the girls are aware of the many negative images of women in popular media, they can begin to challenge these stereotypes critically. Additionally, this unit provides the participants with basic information about what is considered sexual harassment.

The largest part of this session focuses on helping girls identify stereotypes in the media. In the media message exercise, girls listen to popular music while creating collages of pictures from magazines and the Internet that depict stereotypes of femininity or what it means to be a woman. Facilitators draw the girls' attention to the unattainability of these stereotypes, and stress the importance of nonphysical factors such as intelligence and honesty. The girls also begin to notice that these negative messages are prevalent in the music they hear.

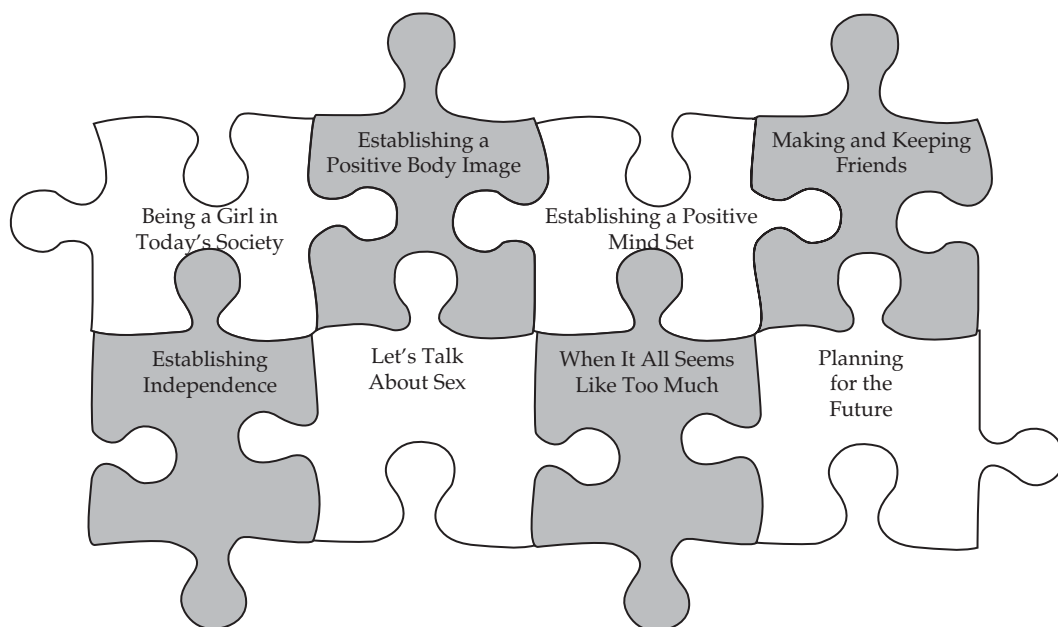

Figure 100.1 Go Grrrls Puzzle.

TABLE 100.2 Unit 1 Activities

Activity	Time
Introduction	5 minutes
Play the Name Game	20 minutes
Go Grrrls Assessment	25 minutes
Establishing Group Rules	10 minutes
Go Grrrls Puzzle	10 minutes
Distribute Workbooks and Parent Curriculum	10 minutes
Closing—Two Truths and a Lie	10 minutes

Unit 3. Establishing a Positive Body Image

The goals of this session are (1) to help girls accept their bodies as they are and develop a positive body image; (2) to teach girls that attractiveness is based on factors other than physical traits; and (3) to encourage girls to appreciate their unique qualities, talents, and skills. During the course of the meeting, the focus will shift from physical qualities to personal qualities, abilities, skills, and talents. We begin the group by asking participants to discuss the reasons that developing a positive body image is important for girls. We then embark on a series of image-boosting

activities. In one such activity, girls are asked to list five things they like about themselves, and then share this list aloud in the group. Group leaders construct a chart of these responses as they are offered. The chart includes categories for physical aspects, social/personality traits, special skills and abilities, and cognitive abilities. Discussion then centers around the fact that each girl has a unique set of strengths in these different categories.

Unit 4. Establishing a Positive Mind Set

An important part of our program is teaching girls about the relationship between self-esteem, self-criticism, and depression. As mentioned previously, girls entering the seventh grade show a significant decline in their overall self-esteem. This session is designed to teach girls how they can avoid setting unrealistic standards for themselves and can instead give themselves positive messages to facilitate realistic goal achievement.

Participants complete fill-in-the-blank handouts listing their unrealistic "I should" messages. We then help them to change these messages to "I want" statements that are more constructive. For example, "I should be liked by everyone" versus "I want to have good friends." Finally, we describe how negative thoughts tend to generate

even more negative thoughts in a sort of downward spiral, while positive self-messages tend to lead to increased confidence, in an upward spiral. An example follows:

Downward Spiral	Upward Spiral
<i>I should be liked by everyone.</i>	<i>I want to have good friends.</i>
<i>Nobody likes me.</i>	<i>I can make friends with people.</i>
<i>I must be a horrible person.</i>	<i>I am a good friend to other people.</i>

Unit 5. Making and Keeping Friends

Navigating social groups in middle school can be very challenging for girls, because pressure to be popular and well-liked mounts during these years. This session encourages girls to focus on developing healthy friendships rather than concerning themselves with popularity. Facilitators then help girls realize that the traits one seeks in a close friend are often the same traits one seeks in a significant other. This discussion supports healthy romantic relationships for the participants and stresses the importance of good relationships for a person's well-being.

The main activities during this unit include developing a friendship "want ad," doing a "dating values game," and learning friendship social skills. For the friendship want ad girls individually write friendship "want ads," but they do not put their names on their profile. After the girls finish writing, the facilitator collects the want ads, shuffles them, and passes them back out to the group (ensuring that no one gets their own ad back). The girls then highlight or underline what they really like or what they have in common with the person who wrote the profile. They then read the profiles out loud and try to guess who wrote it. During this exercise, the facilitator writes these qualities on a flipchart. At the end, the girls reveal which profile they wrote. This unit also focuses on conversation skills and uses role plays for teaching friendship skills.

Unit 6. Establishing Independence

The point of the Go Grrrls curriculum is not to tell girls how to act, but rather how to make the right choices for themselves. Often, adolescents make decisions impulsively without considering

the impact of their choices. Their decisions represent "experimental" attempts to acquire skills for dealing with new situations, but unfortunately these attempts may lead to serious consequences. Unit 6 is truly a skill-building session, as we teach group members a method for solving problems and then ask them to practice this method.

Girls practice this procedure in the large group, and then split into two smaller groups to practice further. Finally, they play the Choices and Consequences board game as a fun way to continue using their new skills.

Because girls in our society are often socialized to be passive and accommodating, some girls may not develop the skills to be assertive in certain situations that call for standing up for themselves. This unit also teaches girls the difference between assertive, aggressive, and passive, and emphasizes the importance of being assertive.

Unit 7. Let's Talk About Sex

The Go Grrrls curriculum places an emphasis on pregnancy prevention within a broader program context that is both educational and skill based. The program includes two group meetings devoted specifically to the topic of sexuality, but it is the cumulative effect of the entire curriculum that is most likely to make a difference in a young person's behavior. The skill-building sessions included in the curriculum (assertiveness, problem solving, making and keeping friends, positive self-talk, and setting reachable goals for the future) all serve as important components in reducing a teen's likelihood of engaging in early, unhealthy sexual activity. Psycho-educational components of the curriculum (confronting media messages and establishing a positive body image) boost girls' understanding of the effects of broader cultural trends on their individual lives.

During this session we review myths and facts about sexual activity. Leaders display posters depicting male and female reproductive organs, explain the physical act of intercourse, review what goes on during the menstrual cycle, and cover other basic sexual information. Participants are then asked to place their questions about sexuality, or myths they may have heard about sex, into an anonymous "question can." This is the highlight of the group, and most times, after the initial round of anonymous questions have been answered, girls continue to toss new questions in, or to simply ask aloud as they become more comfortable with the process.

After the questions have been answered, participants discuss reasons why some teens choose to have sex and some do not. Next, girls play the Handshake Game, which demonstrates how sexually transmitted diseases (STDs) can spread. Role play activities give girls practice in using refusal skills, and community resources for obtaining birth control information and supplies are identified.

Unit 8. When It All Seems Like Too Much

By this point in the curriculum girls have learned a number of helpful skills to empower them to handle difficult situations independently and with confidence. Unit 8 serves to show girls that not all problems can be solved alone, and that asking for help when you need it can be a sign of strength rather than weakness. When conducting this session, facilitators have found that after building rapport with the participants, some girls share sensitive stories and concerns during this session. For this reason, it is important at the outset of this session to review the limits of confidentiality.

The first part of this session teaches girls to identify when they can solve a problem on their own and when they might need help to solve a problem. This is done by discussing various scenarios and what girls would do if they were in any of these situations. For example, one scenario might be: *Annalise has been worried about her friend McKenzie lately. McKenzie has not been acting like herself; she seems tired all the time and never wants to hang out with Annalise. McKenzie is even starting to look different. She has lost weight and hardly ever smiles. Should Annalise solve it or seek help?* The girls lead the discussion while facilitators draw out the reasoning behind why the girls came to the conclusion they did.

During this session girls also begin to create a personal yellow pages directory. This is a place where they write down different people and places they can go for help.

Unit 9. Planning for the Future

This session helps girls learn to set achievable goals for themselves so they can work toward

a bright, directed future. In this session, we encourage girls to set long-term educational, career, and adventure goals for themselves, and teach them how to create short-term objectives to help them achieve those goals. The majority of the session is spent playing the Planning for the Future Game. This game is like Pictionary. Each girl takes a turn drawing her goal, and the other girls try to guess what it is. The person whose goal is guessed in the shortest amount of time wins the game.

Unit 10. Review and Closure

The last session is often difficult for both facilitators and participants. It is important in this final session that the facilitators are honest and forthright about their ability to keep in touch with girls. If a participant says to a facilitator that she will miss the facilitator, it is important that the participant has her feelings acknowledged. Group leaders should give specific compliments to girls about the great work they did in the program and any progress they have made. After a brief review of what was covered during the program, girls complete the post-assessment. All participants receive a certificate of completion and receive praise from group leaders. Girls then are free to hang out, eat, and say their goodbyes.

CONCLUSION

Adolescent girls live in an environment that is often toxic to their healthy development. They present unique challenges and the Go Grrrls curriculum is designed to help these girls confront those challenges and prepare for a healthier and happier lifestyle. This psycho-educational skills training program was designed with regard to empirical studies that identify the developmental issues that impact early adolescent girls the most. Based on practical instruction and skill building, the program provides a fountain of knowledge and skills to help girls cope with the pressures of growing up in contemporary culture. It promotes adolescent girls' positive assets and addresses relevant developmental issues. When girls are given the tools to access resources, both internal and external, they are empowered to make lifelong healthy decisions.

101 Cyberbullying and the Social Worker

Michelle F. Wright & Diane L. Green Sherman

INTRODUCTION

Youths' rapid uptake of electronic technologies has led to many conveniences in their daily lives, such as having access to an endless amount of information and being able to communicate with just about anyone they want (Espinosa, Laffey, Whittaker, & Sheng, 2006; Kaara, Brandtzaeg, Heim, & Endestad, 2007; Subrahmanyam & Smahel, 2011; Williams & Merten, 2011). A darker side to these conveniences is that they offer youths additional ways to harm one another. One such consequence of electronic technology use is cyberbullying. Although various definitions of cyberbullying exist in the literature, researchers generally define it as the utilization of electronic technologies through which individuals engage in repeated, aggressive online acts (Hinduja & Patchin, 2009; Smith, Mahdavi, Carvalho, Fisher, Russell, & Tippett, 2008; Tokunaga, 2010).

This chapter draws on research from social work, psychology, public health, criminology, and sociology in order to review bullying behaviors in the cyber context. The first section provides definitions, alternative terminologies, describes various forms of these behaviors, and explains the similarities and differences between cyberbullying and face-to-face bullying. In the second section, the prevalence rates of cyberbullying within the United States are discussed, along with details about the sample and measurement of these behaviors. Section three describes the predictors and consequences associated with cyberbullying involvement among American youths. The fourth section discusses prevention and intervention programs aimed at reducing cyberbullying. The fifth section presents recommendations for future research on cyberbullying

and suggestions for social workers. The concluding section summarizes the chapter and lists suggested websites.

WHAT IS CYBERBULLYING?

This section defines cyberbullying, lists the electronic technologies utilized to harm others, describes examples of these behaviors, and summarizes the differences between face-to-face bullying and cyberbullying. Distinct from more deviant forms of cyber activities (e.g., cyber harassment, flaming, cyberstalking), cyberbullying is difficult to define due to disagreement over which behaviors constitute cyberbullying (Ybarra & Mitchell, 2004; O'Sullivan & Flanagan, 2003; Spitzberg & Hoobler, 2002). Despite these difficulties, researchers agree on the media through which cyberbullying occurs, such as mobile phones, the Internet (e.g., e-mail, social networking sites, YouTube), and gaming consoles (Fenaughty & Harre, 2013; Gorzing & Olafsson, 2013; Pujazon-Zazik & Park, 2010). Examples of cyberbullying behaviors include cruel teasing, intimidation and threats of violence, spreading malicious rumors, exclusion, and ignoring (Dooley, Pyzalski, & Cross, 2009). Like face-to-face bullying, cyberbullying also includes direct and indirect forms (Brenner & Rehberg, 2009). Direct cyberbullying behaviors have an immediate effect on victims, with perpetrators using instant messaging, text messaging, multimedia messaging, or e-mail to harm victims. On the other hand, indirect cyberbullying is harming others by proxy. These bullies post insults on Facebook, specifically created websites, or some other public area of cyberspace without directly targeting victims.

Cyberbullying is difficult to define because terminologies vary based on country (e.g., cyber-mobbing in Germany; Virtual-bullying in Italy; online harassment in the Czech Republic; Kowalski & Limber, 2007; Nocentini et al., 2010; Sevcikova & Smahel, 2009). Regardless of terminology differences, researchers do agree on the definition of face-to-face bullying. Face-to-face bullying is a form of aggressive behavior intended to cause harm through repeated actions carried out over time by targeting an individual who is not able to defend himself or herself (Olweus, 1980). Core components of this definition include repetition of the act, intention to cause emotional harm, power imbalance between victim and perpetrator, and malicious harm. Extrapolating the face-to-face bullying definition to the cyber context, the definition of cyberbullying typically includes repeated, aggressive online acts perpetuated via electronic technologies.

Some researchers (e.g., Grigg, 2010; Modecki, Barber, & Vernon, 2013; Pornari & Wood, 2010; Runions, Shapka, Dooley, & Modecki, 2013; Schnurr, Mahatmya, & Basche, 2013; Schoffstall & Cohen, 2011; Wright & Li, 2013) utilize the terminology of cyber aggression to describe maliciously harmful acts through electronic technologies. As a broader form of cyberbullying, cyber aggression encompasses negative acts that do not necessarily include repetition or an imbalance of power, but still are intentional and perceived as offensive, derogatory, harmful, and unwanted (Grigg, 2010; Dooley et al., 2009). Cyber aggression includes happy slapping (e.g., hitting or slapping someone and recording the assault), outing (e.g., public display or forwarding of personal communication), cat fishing (e.g., setting up a fictitious online profile to lure another into a fraudulent relationship), and flaming (e.g. sending angry, rude, or obscene messages) (Hinduja & Patchin, 2009). This chapter will not attempt to reconcile differences in the definitions and the measurement of cyberbullying and cyber aggression, but interested readers may refer to research (e.g., Langos, 2012; Menesini et al., 2012; Nocentini et al., 2010; Wingate, Minney, & Guadagno, 2013; Ybarra, Boyd, Korchmaros, & Oppenheim, 2012) focused on synthesizing definitions and providing recommendations for the measurement of these behaviors.

Some characteristics separate cyberbullying from traditional face-to-face bullying. First, perpetrators of cyberbullying may inflict harm

anonymously using masked identities, whereas face-to-face bullies usually make their identity known (McKenna & Bargh, 2000). Cyberbullies can create an almost endless number of fake instant messenger or e-mail accounts, and use these fake identities to insult others, without victims being aware of the aggressor's identity. Although some face-to-face bullies can harm others anonymously (e.g., placing an insulting note in someone's locker), there are more opportunities for engaging in anonymous, harmful behaviors via the cyber context (Wright, 2013). Second, cyberbullying can reach a larger amount of potential victims and it can take place at any time as compared with face-to-face bullying (Kowalski & Limber, 2007; Slonje & Smith, 2008). Not only can cyberbullies target many victims at one time, but their aggressive acts may be witnessed by an almost endless audience. Third, in the face-to-face context, bullies can experience victims' reactions, whereas cyberbullies may not necessarily witness these reactions (McKenna & Bargh, 2000). Being unable to witness victims' reactions may encourage more impulsivity and aggressive behavior via the cyber context (Postmes, Spears, & Lea, 1998; Teich, Frankel, Kling, & Lee, 1999). Another difference between cyberbullying and face-to-face bullying is that the former can occur using relatively permanent electronic media, such as pictures or videos, which may be perceived as worse than face-to-face bullying and can significantly impair victims' emotional well-being (Dooley et al., 2009; Wright, 2013).

There are also similarities between face-to-face bullying and cyberbullying. Cyberbullying may happen more than once, inflict both psychological and emotional harm, and is intentional, just like face-to-face bullying (Dehue, Bolman, & Vollink, 2008). Next, psychosocial (e.g., depression, loneliness, anxiety) and school difficulties (e.g., school dropout, failure) are reported by both face-to-face victims and cyberbullies (Gradinger, Strohmeier, & Spiel, 2009; Grills & Ollendick, 2002; Kochenderfer-Ladd & Skinner, 2002; Kupersmidt & Coie, 1990; O'Moore & Kirkham, 2001; Ybarra & Mitchell, 2004). Regardless of the similarities and differences between face-to-face bullying and cyberbullying, it is important that educators, researchers, parents, and law makers quickly find common ground so that we can more thoroughly understand the impact of cyberbullying and how to deal with it appropriately.

HOW FREQUENTLY DOES CYBERBULLYING OCCUR?

The first part of this section reviews research on the prevalence rates of cyberbullying involvement. In the second section, studies focused on understanding gender differences in cyberbullying are also discussed. We reviewed only those studies conducted among youths, ages 10 through 18 years, in the United States. Much of the research on the prevalence rates of cyberbullying has examined youths' victimization, but some research has focused on understanding the rates of cyberbullying perpetration. One of the earliest studies, which was conducted in the year 2000, revealed that 12% of surveyed youths (ages 10–17 years; 48% female) reported that they had perpetrated aggressive behaviors online, including making rude or nasty comments to someone on the Internet and using the Internet to harass or embarrass others (Ybarra & Mitchell, 2004). Five years later, Hinduja and Patchin (2008) found that 16% of the 1,500 adolescents (ages 13–18 years; 53% female) they surveyed admitted to having cyberbullied others. In another study conducted two years later, Kowalski and Limber (2007) utilized a large sample of 3,767 youths (51% female; grades sixth through eighth) to further understand rates of cyberbullying perpetration. Only 11% of the surveyed participants admitted that they were involved in cyberbullying as the aggressor. Dempsey, Sulkowski, Dempsey, and Storch (2011) found similar rates as Kowalski and Limber, such that 10% of the 1,672 adolescents (48% male; ages 11–14 years) in their study admitted that they had perpetrated cyberbullying within the past 30 days. In 2010, Bauman (2010) found that 1.5% of the surveyed intermediate school students ($N = 221$; fifth through eighth grades) in her study admitted to cyberbullying others, a much lower frequency rate when compared with other studies (e.g., Dempsey et al., 2011; Hinduja & Patchin, 2008; Kowalski & Limber, 2007; Ybarra & Mitchell, 2004). Recognizing that adolescents may be biased in reporting their perpetration of cyberbullying, Wright and Li (2013) utilized a peer-nomination measure to assess these behaviors among 261 adolescents (ages 11–14 years; 58% female) in the Midwestern United States. Not only did they find that it is possible to assess cyberbullying at the school level with peer-nomination measures, but their findings also revealed that 38%

of adolescents were nominated at least once as a cyberbully.

In one of the earliest studies to document the prevalence rates of youths' experiences with cyberbullying, Finkelhor, Mitchell, and Wolak (2000) found that 6% of the youths ($N = 1,501$; 10 to 17 years of age; 53% male; 73% White) they surveyed had experienced threats and negative rumors, with a smaller percentage (around 2%) reporting that they had suffered distressing harassment (i.e., been very or extremely upset or afraid because of the incidence). Following up their study a few years later, Ybarra, Mitchell, Wolak, and Finkelhor (2006) found that 9% of youths ($N = 1,500$; 10 to 17 years of age) reported that they experienced some type of electronic harassment. Also utilizing data from 2005, Hinduja and Patchin (2008) found that 33% of the 1,500 youths (ages 13–18 years; 53% female) they surveyed reported being victimized online, with most reporting that they were disrespected (41%), followed by being called names (19%), and threatened physically (12%). A few years later in 2008, Hinduja and Patchin (2009) sampled 2,000 middle-school students in the Southeastern United States. Their findings indicated that 10% were cyberbullied within the past 30 days, while 17% reported that they were bullied at least once in their lifetime. In a study conducted a few years later, Dempsey, Sulkowski, Nichols, and Storch (2009) found similar patterns of victimization as Hinduja and Patchin. In their study, Dempsey and colleagues found that 15% of their sample reported that they had received mean or threatening messages via mobile phones, instant messenger, and e-mail. Later research by Bauman (2010) revealed that only 3% of surveyed intermediate school students in grades fifth through eighth ($N = 221$; 54% males) reported being victimized in the cyber context. Research from 2012 revealed that 77% of adolescents ($N = 261$; ages 11–14 years; 58% female) reported that they had experienced insults, rumor spreading, and threats via instant messenger, social networking sites, e-mail, and mobile phones within the last school year (Wright & Li, 2013).

Just as many studies document the frequency rates of cyberbullying involvement, researchers have also extensively examined gender differences in order to provide insight into the characteristics that put youths at risk for these behaviors. Some of the available research indicates that boys are more likely to perpetuate cyberbullying (e.g., Wang, Iannotti, & Nansel,

2009) and be the victims of these behaviors (e.g., Bauman, Toomey, & Walker, 2013), whereas others (e.g., Dehue et al., 2008) find that girls are more often the aggressor and the victim (e.g., Dempsey et al., 2009; Hinduja & Patchin, 2008; Kowalski & Limber, 2007; Mesch, 2009; Sontag, Clemans, Graber, & Lyndon, 2011; Ybarra, Diener-West, & Leaf, 2007). However, other researchers have found no gender differences in cyberbullying involvement as victims (e.g., Bauman, 2010; Kowalski & Limber, 2007; Schoffstall & Cohen, 2011; Varjas, Henrich, & Meyers, 2009) or perpetrators (e.g., Bauman, 2010; Hinduja & Patchin, 2008; Raskauskas & Stoltz, 2007; Williams & Guerra, 2007; Wright & Li, 2013). Variations in the prevalence rates and inconsistencies regarding gender differences in cyberbullying involvement reflect differences in the sampling, methodology, and measurement of these behaviors. Despite the discrepancy in these rates, it is clear that American youth experience and engage in cyberbullying. Furthermore, youths also report greater frequency of cybervictimization when compared with cyberbullying perpetration. Such differences may reflect self-report biases or indicate that a small group of cyberbullies perpetrates most of the aggressive acts via the cyber context.

PREDICTORS AND CONSEQUENCES OF CYBERBULLYING INVOLVEMENT

In this section, predictors of American adolescents' involvement in cyberbullying are discussed, followed by the consequences associated with experiencing and engaging in these behaviors. Researchers have examined how youths' utilization of electronic technology places them at risk for cyberbullying. Youths' risky online behaviors (e.g., sharing private information and passwords) and greater technology usage each predict cyberbullying involvement (Bauman, 2010; Hinduja & Patchin, 2008; Mesch, 2009). Other researchers (e.g., Bauman, 2010; Hinduja & Patchin, 2008; Kowalski & Limber, 2007; Raskauskas & Stoltz, 2007; Ybarra et al., 2007) have focused on the behavioral profiles of cyberbullies and cybervictims. In this research, face-to-face bullying and face-to-face victimization are consistently related to the involvement in cyberbullying, as perpetrators and aggressors. In other research, Sontag and colleagues (2011) found that reactive and proactive face-to-face

aggression each related to cyberbullying. In addition, cybervictimization is linked to cyberbullying, further indicating that there is significant overlap between youths' face-to-face and digital environments (Wright & Li, 2013; Ybarra et al., 2007). Other characteristics relate to cyberbullying perpetration, such as beliefs about the acceptability of aggression (i.e., normative beliefs), frustration, hostility, less remorsefulness, and moral approval of bullying (Burton, Florell, & Wygant, 2013; Low & Espelage, 2013; Patchin & Hinduja, 2006; Sontag et al., 2011; Williams & Guerra, 2007).

Cyberbullying is not only perpetrated by anonymous bullies, but also by youths' peers at their school. Therefore, researchers have investigated the role of peers and the school environment in cyberbullying involvement. Results from this research revealed that school problems and being the victim of physical assaults perpetrated by peers related to cyberbullying and cybervictimization (Hinduja & Patchin, 2008). In addition, adolescents' social standing among their peers is also related to cyberbullying, such that perceived popularity (i.e., based on social reputation) and peer-rejection were each associated with the perpetration of these behaviors (Wright & Li, 2013; Wright, in press). Furthermore, peer-rejection was associated with cybervictimization. Another important direction in this research is the focus on school climate (i.e., the quality and character of school life). Like face-to-face bullying, researchers (e.g., Brighi, Guarini, Melotti, Galli, & Genta, 2012; Hinduja & Patchin, 2012; Williams & Guerra, 2007) have found that youths' lower perceptions of school climate related to greater rates of cyberbullying among peers at school. Thus, it is not surprising that lower attachment toward peers and school were related positively to both cybervictimization and cyberbullying (Burton et al., 2013; Schneider, O'Donnell, Stueve, & Coulter, 2012). In addition, youths, who believed that their peers engaged in cyberbullying, perpetrated increased levels of these behaviors (Hinduja & Patchin, 2013).

Relationships with parents also have an impact on cybervictimization and cyberbullying. In this research, parents' use of coercive discipline, along with fewer emotional bonds with their children and poorer quality of family relationships, each predicted cyberbullying perpetration (Beran & Li, 2007; Ybarra et al., 2007). Furthermore, feelings of alienation and loneliness from parents

correlated positively with bullying acts in the cyber context (Brighi et al., 2012). Youths' beliefs about their parents' sanctions against online aggressive acts also related to cyberbullying, indicating that youths with fewer such beliefs engaged in more of these behaviors (Hinduja & Patchin, 2013). In addition, family violence and lower levels of parental monitoring predicted cyberbullying among adolescents (Low & Espelage, 2013). Mesch (2009) found that victims of cyberbullying had parents who set fewer rules on which websites to visit, what information to share, and the time they could spend online. Thus, he argued that there is a need for more parental participation in youths' electronic technology usage, given that parents may be able to reduce their children's negative experiences in the cyber context. It is important that parents stay involved in their children's online activities, especially in adolescence, given that parents usually underestimate their involvement and monitoring of these activities.

Researchers have thoroughly documented the consequences of cyberbullying and cybervictimization. Ample research has revealed that cyberbullying involvement is related to depression and anxiety (Bauman et al., 2013; Schenk & Fremouw, 2012; Sontag et al., 2011). Many of these studies do not control for face-to-face bullying and face-to-face victimization, which are highly correlated with both cyberbullying and cybervictimization (Bauman, 2010; Hinduja & Patchin, 2008; Kowalski & Limber, 2007; Mesch, 2009; Schneider et al., 2012; Sontag et al., 2011; Ybarra et al., 2007). In one of the few studies to control for gender, and youths' involvement in face-to-face bullying, Dempsey and colleagues (2009) found that both cybervictimization and cyberbullying predicted depression and anxiety. When compared with nonvictims and nonbullies, cyberbullies and cybervictims were six times more likely to report emotional disturbances as well as increased anger and sadness (Patchin & Hinduja, 2006; Ybarra & Mitchell, 2004). In addition, victims and perpetrators of cyberbullying also reported more suicide attempts and suicidal ideation when compared with nonvictims and nonbullies (Bauman et al., 2013; Hinduja & Patchin, 2008, 2009; Schneider et al., 2012). Furthermore, cyberbullying involvement is related to substance use (i.e., drugs, alcohol) and delinquency (Hinduja & Patchin, 2008, 2009; Hinduja & Patchin, 2008; Low & Espelage, 2013). Cybervictims and cyberbullies also reported

lower school performance, declining self-concept and self-esteem, worsening grades, poorer concentration in school, and increased absences, truancy, detentions, and suspensions (Beran & Li, 2007; Didden et al., 2009; Katzer, Fetchenhauer, & Belschak, 2009; Schneider et al., 2012; Varjas et al., 2009; Ybarra et al., 2007). Taken together, it is clear that cyberbullying perpetration and cybervictimization each have short-term and long-term consequences, warranting the need for promoting and executing programs dedicated to reducing youths' involvement in these behaviors.

REDUCING CYBERBULLYING

Many schools throughout the United States have implemented antibullying programs (Ferguson, Miguel, Kilburn, & Sanchez, 2007). Given that cyberbullying is conceptualized as a new form of an old behavior (i.e., bullying), there is much debate about using existing antibullying programs to address cyberbullying (Stauffer, Heath, Coyne, & Ferrin, 2012). Such a debate is important because some of the characteristics of cyberbullying (e.g., anonymity, ability to reach a larger audience, unable to witness victims' emotions) are unique to the cyber context (Kowalski & Limber, 2007; McKenna & Bargh, 2000; Slonje & Smith, 2008; Wright, 2013). Given that cyberbullying often occurs outside of school hours, school officials are often reluctant to take action against students perpetrating these behaviors while not in school (Franek, 2006; Shariff & Hoff, 2007). However, it is not only important that antibullying programs be adapted to the specific needs and attitudes of the entire school, but that they should also be modified to address cyberbullying as a distinct behavior, separate from face-to-face bullying. Targeting youths' involvement in bullying may not lead to an enduring reduction in these behaviors because parents and teachers may affect the success of the program. Parents and teachers may question the effectiveness of the antibullying program, potentially erasing the effects of the program and wasting staff members' time and training. Thus, whole-school programs are most effective for reducing bullying when they target the school level, the home level, and the individual level (Rigby & Slee, 2008; Smith, Ananiadou, & Cowie, 2003; Stevens, Bourdeaudhuij, & Van Oost, 2001; Vreeman & Carroll, 2007). Such programs reach not only the bullies, but the bullied, and the bystanders,

as well as foster sustainability (Michaud, 2009). A recent meta-analysis (i.e., Ttofi & Farrington, 2011) revealed that the most effective programs for reducing victimization are those that use videos, disciplinary methods, parent training/meetings, and cooperative group work. Regarding the reduction in the perpetration of bullying, programs should implement the previous components for victimization as well as improve playground supervision, increase the number of school assemblies, provide information for parents, implement classroom rules, and improve classroom management.

Despite the newness of cyberbullying, a number of effective strategies have been developed to combat and subsequently reduce such behaviors. Several cyberbullying prevention strategies involve addressing these behaviors in antibullying programs, setting clear rules and consequences, raising awareness about cyberbullying, increasing the supervision of students, having youths understand acceptable user policies, involving youths and school personnel as well as parents in Internet safety programs, and showing youths that messages they believe are anonymous can be traced (Campbell, 2005; Chibnall, Wallace, Leicht, & Lunghofer, 2006; Franek, 2006; Willard, 2007). In addition, Migliore (2003) recommended adult monitoring of youths' online activities and called for school personnel to participate in service programs in order to learn and understand effective intervention procedures. At home, it is recommended that home computers be placed in common areas, rather than in youths' bedrooms (Snider, 2004). Parents should also carefully monitor youths' electronic technology consumption. However, parents and teachers are advised to talk to youths about the dangers of cyberbullying and to take immediate action if it occurs as well as ask youths to sign contracts about appropriate electronic technology usage. Similarly, teachers need to support youths who report witnessing bullying behaviors and to take immediate action against those responsible for harming others. Although contracts about appropriate electronic technology usage may not reduce or prevent cyberbullying, contracts may heighten awareness of this issue. Youths can also sign anti-teasing pledges and practice effective conflict resolution strategies (Osher & Fleischman, 2005). Such pledges may empower students and potentially help cyberbullies understand what they have done, which is critical to cyberbullying prevention (Kraft & Wang, 2009). Awareness over the consequences of one's actions

is especially important because the perceived anonymity of cyberbullying may be especially attractive (Slonje, Smith, & Frisen, 2013).

There is limited research available regarding anti-cyberbullying programs. Some programs (e.g., Character Counts; Olweus Bullying Prevention Program) have recently been implemented in schools and their effectiveness is currently being evaluated. One program utilized the KiVa Antibullying Program to reduce cyberbullying among Finnish school-aged youths (Williford, Elledge, Boulton, DePaolis, Little, Salmivalli, 2013). Results indicated that the lowest frequencies of cybervictimization and cyberbullying were reported by students who participated in the program, revealing that KiVa may be effective for reducing the involvement in these behaviors. Currently, Williford and colleagues at the University of Kansas are implementing a similar program with American youths. Another program utilized a Quality Circle in which students work in small groups to find out information about a problem, use structured discussion techniques, and come up with solutions (Paul, Smith, & Blumberg, 2012). These solutions are then presented to teachers. Such a program allows teachers to keep up-to-date on the fast moving changes in the kinds of cyberbullying that youth experience. Thus far, the effectiveness of this program has not been evaluated and, therefore, its long-term effects on cyberbullying are currently unknown. Other programs have utilized youths' immersion in electronic technologies to help reduce cyberbullying. One of these programs uses online peer support, called CyberMentor, to provide guidance to victims of cyberbullying (Slonje et al., 2013). Youths who need to talk can log on and chat with trained Cybermentors, who are able to refer mentees on to counselors for further support if necessary. The CyberMentors program has been evaluated positively for providing quality support and help to cybervictims (Banerjee, Robinson, & Smalley, 2010; Thompson & Smith, 2011). There is also a CyberMentors mobile phone application, which focuses on building self-esteem, confidence, and helping victims feel safe. It is currently unknown whether the mobile application is beneficial to youths. Other researchers (Liang, 2010; Moore, Nakano, Enomoto, & Suda, 2012) have also recommended automated ways of dealing with cyberbullying. As increasing attention is given to cyberbullying, and researchers thoroughly identify the risks and consequences associated with

these behaviors, it is likely that additional programs will be developed.

FUTURE DIRECTIONS AND RECOMMENDATIONS FOR SOCIAL WORKERS

In the cyberbullying literature, there is a lack of understanding regarding the impact these behaviors have on youths' long-term behaviors, their relationships, and subsequent psychosocial adjustment. Although some research (e.g., Barlett & Gentile, 2012; Del Rey, Elipe, & Ortega-Ruiz, 2012; Low & Espelage, 2013; Sticca, Ruggieri, Alsaker, & Perren, 2013; Wright & Li, 2013) has included longitudinal designs, additional research is needed to further understand the temporal ordering of cyberbullying involvement, depression, anxiety, and the relationship these variables have to later academic engagement among youths. Such designs should also provide insight into youths' social cognitive processes (i.e., attributions, normative beliefs, response evaluation and decision) as these processes increase (or decrease) their subsequent involvement in bullying (Perren, Gutzwiller-Helfenfinger, Malti, & Hymel, 2012). Concurrent research designs (e.g., Bauman, 2010; Pornari & Wood, 2010) have focused on social cognitive processes and their relation to cyberbullying, but, to our knowledge, longitudinal research has yet to be published on these variables. Investigations of the relationship between social cognitive processes, such as attributions, and cyberbullying is important because some antibullying programs include attribution retraining to reduce hostile attributional biases in an effort to reduce face-to-face bullying (Bugental, Ellerson, Lin, Rainey, Kokotovic, & O'Hara, 2002; Sukhodolsky, Golub, Stone, & Orban, 2005).

Many times social workers are expected to make decisions about youths' cyberbullying on the basis of nonexistent, unclear, or nonspecific policies. Although social workers may be aware of cyberbullying on their school campus, they may be unsure how to deal with such behaviors. In one of the few studies assessing social workers and cyberbullying, Sing and Slovak (2011) found that half of their sample agreed that cyberbullying is more harmful than traditional bullying, but almost all (93%) were unsure about their ability to intervene. They recommend that additional training for social workers,

based on the type of school they are serving (i.e., elementary vs. middle or high school), is necessary. Such training will increase social workers' ability to create a school atmosphere conducive to students' disclosure of cyberbullying involvement. In these training programs, social workers should learn about identifying and explaining technologies that could be used for cyberbullying (Mason, 2008; Smith et al., 2008). With this knowledge, social workers can conduct training sessions for teachers, staff, administrators, parents, and students on cyberbullying. Other strategies may include inviting officers from local police departments to talk with school personnel, students, and families about the effects of these behaviors. Officers could discuss with students both the emotional and legal implications of cyberbullying. Social workers should address the problem of cyberbullying, as well as face-to-face bullying, using an ecological approach that includes family, the whole school, and community involvement. Instead of a zero-tolerance response to cyberbullying, social workers and other school personnel should recognize the needs of those involved in this form of behavior. Helping to create and then maintain a culture of respect, social workers should carefully observe and engage youths in conversation about cyberbullying.

SUMMARY AND CONCLUSIONS

As a topic of increased concern in recent years, cyberbullying is not yet completely understood or sometimes even recognized as a problem among youths. In this chapter, we discussed the problems facing researchers regarding defining, explaining, and conceptualizing cyberbullying. Such limitations have implications for educators, youths, and parents, given that it is difficult to make recommendations for reducing cyberbullying when we are limited in our basic understanding of this phenomenon. Despite these problems, it is clear that cyberbullying involvement has detrimental effects on youths' behavioral, psychological, and academic functioning. As our knowledge increases, we are better able to recommend the best practices for reducing cyberbullying. Although we acknowledge that the problem of cyberbullying is growing faster than our ability to respond to these behaviors, we are confident that the field is developing in the right direction.

Our lack of knowledge of cyberbullying will not make the problem disappear, because electronic technology usage among youths is not likely to decrease any time soon. Thus, it is important for educators, researchers, parents, and policy makers to understand that cyberbullying is a separate issue, albeit related, from face-to-face bullying. There is great need for researchers to come to a consensus on the terminologies, definitions, and theoretical frameworks for cyberbullying. By addressing these important directions, we are better able to recommend the best practices for combating cyberbullying.

102 Empirically Supported Treatments for Borderline Personality Disorder

Jonathan B. Singer

Borderline personality disorder (BPD) is one of 10 personality disorders in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)* (American Psychiatric Association [APA], 2013). Personality disorders are characterized by inflexible and maladaptive personality traits that cause significant functional impairment or subjective distress in social, occupational, or other areas of functioning (APA, 2013). BPD is one of three personality disorders (along with histrionic and narcissistic personality disorders) that are characterized by dramatic, emotional, or erratic individuals. The essential feature of BPD is “a pervasive pattern of instability of interpersonal relationships, self-image, and affects, and marked impulsivity that begins by early adulthood and is present in a variety of contexts.” (APA, 2013, p. 664) Prevalence rates for BPD are 1% to 2.5% in the general population, 20% in outpatient settings, and up to 50% in inpatient settings (Soloff & Chiappetta, 2012). Women account for 75% of those diagnosed with BPD (APA, 2013). BPD most commonly co-occurs with other personality disorders, depression, bipolar disorder, substance use disorders, and posttraumatic stress disorder (PTSD) (Miklowitz, 2012). BPD is a severely disabling condition. Nearly 80% of people diagnosed with BPD report suicidal thoughts and behaviors, and BPD has a higher suicide rate than any disorder other than schizophrenia (Soloff & Chiappetta, 2012). The challenges posed by BPD, and the professional lore that has grown up around the disorder, has resulted in it being perceived by professionals and the public alike as the most difficult and problematic of all disorders to

assess and treat (Howe, 2013). Recent research, however, has suggested that BPD is neither as intractable, nor as impossible to treat, as was once believed. Retrospective studies have suggested that after 10 years, 50% of people with BPD will no longer meet criteria, and by 27 years only 8% will meet criteria for the disorder (Paris & Zweig-Frank, 2001; Zanarini, Frankenburg, Reich, & Fitzmaurice, 2010). For those who cannot wait 27 years, there are a number of psychotherapy interventions that have been shown to be effective in reducing, and in some cases eliminating, symptoms associated with BPD (Stoffers et al., 2012). This chapter presents an overview of empirically supported and promising approaches to the assessment and treatment of BPD.

ASSESSMENT OF BORDERLINE PERSONALITY DISORDER

Assessment of BPD is notoriously difficult (Biskin & Paris, 2012). There is no standard assessment protocol for BPD, no established genetic markers, no laboratory or imaging tests, and no self-report measures that will provide an accurate diagnosis (Biskin & Paris, 2012; Calati, Gressier, Balestri, & Serretti, 2013; Carpenter, Tomko, Trull, & Boomsma, 2013). There is significant symptom overlap between BPD and other personality disorders (PD), and similar clinical presentation with bipolar disorder and PTSD (Biskin & Paris, 2012). Diagnosing adolescents with BPD is controversial, in part because of the stigma associated with the diagnosis, beliefs that some of the symptoms (such as difficulties in

interpersonal relationships) are normative during adolescence, and because until recently guidelines have discouraged diagnosis (Laurensen, Hutsebaut, Feenstra, Van Busschbach, & Luyten, 2013). These diagnostic challenges, along with a widely held belief that personality disorders should be conceptualized as occurring along a continuum rather than as a binary category, led to a proposed change in the conceptualization of all personality disorders for *DSM-5* (Morey & Skodol, 2013). For various political and empirical reasons, however, the proposed changes were not adopted in *DSM-5*, but can be found in Section III (Emerging Measures and Models) (APA, 2013). Consequently, the clinical interview remains the most reliable method for diagnosing BPD.

The clinical interview should identify at least five of nine specific criteria in order to diagnose BPD (APA, 2013). Symptoms are generally clustered in four domains: interpersonal functioning, cognitive, affectivity, and impulse control (Biskin & Paris, 2012). Because problems associated with BPD are inherently social, assessment should establish how *interpersonal instability* manifests in interpersonal behaviors and affects relationship quality. For example, people with BPD tend to misinterpret neutral situations, experience rejection in inclusive situations, and have difficulties repairing cooperation after experiencing disappointment (Lis & Bohus, 2013). Assessments should also establish which types of symptoms result in the most significant impairment or distress: *cognitive symptomatology*, *affect dysregulation*, or *lack of impulse control*. Possible assessment questions could include “How do you deal with conflict? Who can you rely on for support? Tell me about a long-term friend whom you feel is ‘in your corner.’ Do you often feel empty inside? What do you do when someone makes you mad? Describe to me your ideal relationship.”

TREATMENT OF CLIENTS WITH BORDERLINE PERSONALITY DISORDER

Until the 1990s, few if any treatments demonstrated effectiveness in reducing core symptoms of BPD. Since then, a number of treatments have demonstrated success in addressing specific features of BPD. According to a recent systematic review (Stoffers et al., 2012) the most commonly used empirically

supported treatments are dialectical behavior therapy (DBT), mentalization-based treatment (MBT), transference-focused therapy (TFP), schema-focused therapy (SFT), and the systems training for emotional predictability and problem solving (STEPPS). These treatments have demonstrated better outcomes than treatment-as-usual (TAU) in randomized controlled trials (RCTs). Two treatments have demonstrated efficacy over other empirically supported treatments: DBT performed better than Client-Centered Treatment at reducing core BPD symptoms and associated psychopathology (Turner, 2000), and SFT performed better than TFP at reducing BPD symptom severity and retention (Giesen-Bloo et al., 2006). The following is a brief review of empirically supported and promising treatments for BPD.

Dialectical Behavior Therapy

Marsha Linehan and colleagues originally developed DBT as a treatment for women who engage in self-harming behaviors, but they found that a significant number of their clients met criteria for BPD (Linehan, 1993a). DBT is the treatment for BPD with the most empirical support (Stoffers et al., 2012). In the past 20 years, DBT has demonstrated efficacy in reducing or eliminating core BPD symptoms in self-harming adult women with BPD; adolescents with BPD, comorbid substance use disorders and BPD, and PTSD and BPD; binge eaters; depressed elderly patients; and even families of people with BPD (Bloom, Woodward, Susmaras, & Pantalone, 2012; Harned, Korslund, Foa, & Linehan, 2012; Hoffman, Fruzzetti, & Buteau, 2007; Stoffers et al., 2012). In response to criticism that existing research on DBT simply reflects the benefits of having small caseloads, targeted supervision, and a controlled environment, Linehan and colleagues tested DBT against six expert treatments in a community setting (Linehan et al., 2006); DBT proved more effective than expert community care in reducing the frequency and severity of suicide attempts, outpatient crisis services, inpatient hospitalization, and client retention.

DBT is a combination of Cognitive Behavior Therapy (CBT) and Zen mindfulness training (Linehan, 1993b). Unique features of DBT include (1) interventions based on mindfulness and acceptance (e.g., finding a balance between emotion and rationality, known as “wise mind”); (2) emphasis on the dialectic (i.e., reality is

comprised of ever-changing opposing forces); (3) focus on emotions and the bio-psychosocial model (i.e., BPD is understood to be a dysfunction of the emotional regulation system, which is part of a bio-psychosocial system); and (4) addressing five specific processes of therapy (Chapman, 2006). The five processes and their corresponding treatment modalities are (1) motivating the client to change and rehearsing cognitive and behavioral skills that help clients regulate their emotions in 1-hour weekly individual therapy; (2) enhancing behavioral skills: mindfulness, interpersonal skills, regulation of emotions, and distress tolerance in 2-hour weekly skills training groups; (3) ensuring the generalization of these skills to activities of daily living using as-needed phone consultations with outpatient treatment or milieu therapy for inpatient programs; (4) enhancing therapist capabilities and motivations in 1-hour weekly DBT consultation team meeting; and (5) structuring the treatment environment to support client and therapist capabilities (Linehan, 1993b). DBT is a highly structured treatment. As with all manualized treatments, the empirical support for DBT relies on clinicians delivering DBT with fidelity (i.e., according to the manual). However, one study found that in a typical outpatient setting, incorporating the DBT skills training group with non-DBT individual therapy was effective in reducing BPD symptomatology (Harley, Baity, Blais, & Jacobo, 2007).

Mentalization-based Treatment

Peter Fonagy and Anthony Bateman developed MBT as a day hospitalization treatment for people diagnosed with BPD (Fonagy & Bateman, 2008). Five studies have demonstrated that adult patients who receive MBT, and adolescent patients who received MBT-A, demonstrated significant and enduring changes in mood states and interpersonal functioning, such as significant reduction in suicidal behavior, diagnostic status, service use, use of medication, and increase in global functioning (Bales et al., 2012; Bateman & Fonagy, 2013; Jørgensen et al., 2013; Rossouw & Fonagy, 2012; Stoffers et al., 2012). These improvements remained clinically and statistically significant at 8-year follow-up (Bateman & Fonagy, 2008). As with other BPD treatments, MBT has failed to improve general social functioning (Bateman & Fonagy, 2008).

MBT is a psychodynamic developmental model for understanding BPD in which

“mentalizing” is the key to treatment. According to Fonagy and Bateman (2008), “Mentalization is the capacity to make sense of each other and ourselves, implicitly and explicitly, in terms of subjective states and mental processes.” (p. 5) The model assumes that people with BPD cannot understand the thoughts and feelings associated with the behaviors of self and others because (1) their own infant mental states were not understood by their caregivers (i.e., early disrupted attachment) and (2) experiences of trauma resulted in neurobiological changes that impeded the development of emotional regulation skills. MBT targets three higher order social cognitive functions that are important in attachment contexts: affect representation and regulation, attentional control, and mentalization. The challenge for the clinician is to help the client develop emotional regulation without stimulating the attachment system. One way MBT achieves this is by eschewing the role of insight and minimizing affective exploration in therapy. The developers contend that therapists can do harm to clients who have poor conceptions of self and others and who have significant difficulty regulating emotion by insisting on using traditional insight-oriented, psychodynamic treatment and emotion-focused techniques.

Cognitive Behavior Therapy

Two CBT treatments have been investigated in the treatment of BPD (Davidson et al., 2006; Morey, Lowmaster, & Hopwood, 2010; Weinberg, Gunderson, Hennen, & Cutter, 2006). The first clinical trial compared TAU with TAU plus CBT in a typical outpatient community mental health setting (Davidson et al., 2006). The CBT condition sought to change patient’s beliefs and behaviors that impair social and adaptive functioning, in order to reduce suicidal thoughts and behaviors. Results suggested that participants in both conditions showed reductions in suicidal ideation and hospitalization. The TAU + CBT group also showed reductions in dysfunctional beliefs, state anxiety, and distress caused by psychiatric symptoms (Davidson et al., 2006).

Manual-assisted Cognitive Treatment (MACT) incorporates elements of DBT, cognitive therapy, and bibliotherapy in a six-session treatment (Weinberg et al., 2006). Each session centers on chapters from a workbook that covers specific topics such as emotion regulation, problem solving, negative thinking, suicidal thoughts

and behaviors, and substance use and relapse prevention (Schmidt & Davidson, 2004). MACT has been evaluated in two studies (Morey et al., 2010; Weinberg et al., 2006). Although there is some evidence that MACT can be effective in reducing suicidal ideation and attempt, and holds promise in reducing affective instability and BPD symptoms, more research needs to be done.

Schema-focused Therapy and Transference-focused Psychotherapy

A recent study compared a cognitive-based treatment (schema-focused therapy; SFT) and a psychodynamic treatment (transference-focused psychotherapy; TFP) in a three-year randomized trial of 82 men and women with BPD (Giesen-Bloo et al., 2006). SFT combines psychodynamic and behavioral theories to help people identify self-defeating core schemas and maladaptive coping styles in adulthood. TFP uses processing of transference material to transform primitive object relations to advanced ones by modifying defenses and resolving identity diffusion (Stoffers et al., 2012). Giesen-Bloo and colleagues (2006) noted that whereas treatments such as DBT, CBT, and MBT target specific symptoms, such as self-harm behavior or interpersonal functioning, both SFT and TFP were developed to restructure clients' personalities. Results of the study indicated that participants from both treatments improved significantly on all *DSM-IV* BPD criteria, all effects were apparent after the first year, and there was significant improvement in the quality of life for the majority of participants. SFT reported greater effectiveness in reducing core BPD symptoms and keeping patients in treatment (Giesen-Bloo et al., 2006). A recent meta-analysis of SFT for BPD suggested that it holds promise, but more research needs to be done (Sempértegui, Karreman, Arntz, & Bekker, 2013).

Systems Training for Emotional Predictability and Problem Solving

Systems Training for Emotional Predictability and Problem Solving (STEPPS) is a group treatment based on Minuchin's structural family therapy model. Three RCTs have found that as an adjunctive treatment to usual care, STEPPS is effective at reducing impulsivity, negative affectivity, and depressive symptoms, and at improving mood and global functioning (Black, Blum,

McCormick, & Allen, 2013; Blum et al., 2008; Bos, van Wel, Appelo, & Verbraak, 2011). STEPPS has not been found to reduce suicidal thoughts and behaviors or hospitalizations, except in a study of prisoners (Black et al., 2013). An adaptation of STEPPS, Emotion Regulation Therapy for Adolescents (ERT-A), has been found to be effective in reducing severity of BPD symptoms, general psychopathology, and improving quality of life (Schuppert et al., 2012).

Promising Treatments

Promising treatments include those with a single study, no control group, or equivocal evidence. These interventions hold promise for addressing specific symptoms, populations, or for specific treatment settings (listed in alphabetical order):

- *EMDR*. Brown and Shapiro (2006) presented a case study of treating BPD using eye movement desensitization and reprocessing (EMDR), a recognized trauma therapy. This individual treatment holds promise in addressing trauma issues for people with BPD using a treatment that has some empirical support in other populations.
- *Intermittent-continuous eclectic therapy (ICE)*. ICE is a group approach developed in Chile. Menchaca, Pérez, and Peralta (2007) described a one-year pilot study of men and women ages 15 to 40 years in an outpatient setting. The authors reported improvement in self-aggression and general symptoms.
- *Interpersonal psychotherapy (IPT-BDP)*. IPT is an empirically supported individual treatment for people with moderate-to-severe depression that focuses on the bidirectional influence of interpersonal problems and depressive symptoms. IPT-BDP targets the interpersonal instability and depressed affect commonly encountered in people with BDP. Results of an RCT suggested efficacy in reducing core BPD symptoms and depression (Bellino, Rinaldi, & Bogetto, 2010).
- *Pharmacotherapy*. Despite recent advances in addressing core symptoms of mood, anxiety, and childhood disorders, pharmacotherapy is not recommended in the treatment of BPD. Treatment guidelines recommend the use of medications to address temporary psychosis and other discrete symptoms (Oldham, 2004), but the evidence to support the use of

medications alone, or in combination with psychotherapy is equivocal (Belli, Ural, & Akbudak, 2012).

- *Supportive therapy.* Supportive therapy is a nondirective, humanistic treatment that relies on the therapist demonstrating unconditional positive regard, empathy, and genuineness, and assumes these are necessary and sufficient conditions for client change. Supportive therapy has been evaluated as a standalone treatment (Aviram, Hellerstein, Gerson, & Stanley, 2004) and as the “control” condition in clinical trials of BPD (Jørgensen et al., 2013). In both settings, supportive therapy has been found to be efficacious in engaging people with BPD, minimizing the frequency and intensity of self-harming behavior, and reducing core BPD symptomatology.

IMPLICATIONS FOR THE FUTURE

There is cause for hope among clinicians and clients that effective treatment of BPD is possible. Recent empirical findings have challenged the long-held belief that BPD is treatment-resistant and follows a chronic disease model (Zanarini et al., 2010). The growing evidence-base suggests that most manualized treatments address core BPD symptoms more effectively than TAU, and some manualized treatments are better than others (e.g., MBT and SFT are superior to SCM and TFP, respectively) (Budge et al., 2013). Clinicians with cognitive behavioral, psychodynamic, or humanistic practice perspectives can find empirically supported treatments that are consistent with their orientations.

Despite the advances in the evidence-base and the breadth of treatment for BPD, there are notable gaps in our understanding of BPD assessment and intervention. First, there continue to be unanswered questions regarding the fundamental nature of PDs, diagnostic criteria and thresholds, the value of categorical versus dimensional diagnosis, and the most valid and reliable method of assessing BPD (Morey & Skodol, 2013). It was widely assumed that the proposed changes to PDs in *DSM-5* would address some of these concerns. This proposal would have reconceptualized PDs as having both dimensional and categorical features, reduced the number of disorders, and changed the organization of core symptoms. Because this proposal was not adopted, these

questions remain. The good news for clinicians is that everything they knew about PDs remains the same, except that they can no longer refer to their PD clients as “Axis II” due to the elimination of the multiaxial coding system (APA, 2013).

Second, although empirically supported treatments (ESTs) have demonstrated efficacy reducing core BPD symptoms, reducing suicide risk, reducing hospitalization and treatment dropout, they have been ineffective in improving psychosocial functioning. Consequently clients can no longer meet criteria for BPD and continue to have significant functional impairment. The next generation of interventions should target clients’ social and vocational functioning in addition to addressing BPD symptomatology (Soloff & Chiappetta, 2012).

Third, ESTs with the strongest support (e.g., DBT and MBT) are highly specified manualized treatments that require extensive provider training, and require frequent client contact over 1–3 years, all of which place a significant burden on clients, providers, and the health service system. The next generation of interventions should identify how and when the least intensive of two treatments (e.g., structured case management vs. intensive individual therapy in a partial hospital setting), might be as effective in addressing BPD (Bateman & Fonagy, 2013; Davidson & Tran, 2013).

A final and related issue is that, as with most mental health problems, clinical intervention research for BPD has focused on answering the question, “are there effective treatments and if so, which treatments are most effective?” rather than “which treatments work best for whom?” (Goldman & Gregory, 2010). For instance, there is compelling evidence that DBT is effective in addressing self-harm behavior and other core BPD symptomatology in adults and adolescents with BPD only, as well as with co-occurring substance use or PTSD (Stoffers et al., 2012). But no treatment, no matter how effective, is effective for every client (Rizvi, 2011). In response, some have recommended an integrative or modular approach to treatment, which would match symptom presentation to specific techniques, client expectations with treatment approach, and the “best of” specific ESTs (Koerner, 2013; Livesley, 2012). To that end, Livesley (2012) proposed a two-component integrated model for treating BPD, “1. a system for conceptualizing borderline personality disorder based on current empirical knowledge about the structure,

etiology, and stability of borderline pathology that serves as a guide when selecting and delivering interventions; and 2. a model of therapeutic change based on the general literature on psychotherapy outcome and specific studies of PD treatments." (Livesley, 2012, p. 47) Although leaders in the field have voiced support for integrated approaches (Paris, 2013), and similar efforts have demonstrated efficacy in the treatment of other mental health problems (Weisz et al., 2012), empirical support is needed before integrated or modular approaches can be considered "best practices."

103 The Interface of Psychiatric Medications and Social Work

Kia J. Bentley & Joseph Walsh

Psychiatric medications are regularly used to help treat clients at mental health agencies who present with a variety of mental, emotional, and behavioral symptoms and challenges. Social workers, representing the largest number of professionals in outpatient mental health settings, and who may have the most extensive face-to-face interactions with clients, are increasingly called upon to be a resource for clients with respect to issues related to medication use. However, social workers *across settings*, including those in private practice, schools, child welfare agencies, and jails and other forensic settings, as well as in hospitals, clinics, hospices, and other health care settings, also work closely with clients using these medications. This suggests that social workers who truly want to be responsive to the complex and comprehensive concerns of clients need to develop a competence and comfort in addressing their medication-related dilemmas. That is, social workers should learn how to both use what they already know, as well as develop new skills and strategies to partner with clients to help them. Such skills and strategies might include, for example, making informed decisions about psychiatric medication use, dealing with accompanying issues of meaning and identity, designing strategies to assist with adherence problems when relevant, building referral highways, and advocating for access to affordable medications. This chapter provides a brief context and overview of the five classes of medication, reviews two overarching goals with respect to the interface of psychiatric medications and social work, offers six specific role categories through which to meet those goals, and further identifies several

complex issues that may emerge as important for social workers in the near future.

The introduction of chlorpromazine (Thorazine) in the 1950s is most often associated with stimulating the modern era in psychopharmacology. More recently, however, the explosion of brain research, and the renewed emphasis on etiological models of mental illness emphasizing genetics and neurotransmission, have been the defining influences on pharmacological research and development. In the past 20 years, medications have even been characterized by some as actually “fixing” chemical imbalances in the brain. Others have harshly criticized simplistic explanations such as that and pointed to what they see as serious flaws in the clinical research arena as we know it, not to mention highlighting the powerful sociopolitical forces that seem to bias the psychiatric enterprise. Indeed, while psychopharmacologists theorize a great deal about why psychiatric medications “work,” precise causes of action are typically now fully known. And the influences of the medical model and profit motive are undeniable. Nevertheless, experiences of hundreds of thousands of people suggest that even in the face of bothersome (or worse) side effects, for many these medications can help improve functioning and contribute to a higher quality of life. Psychiatric medications, similar to other medical interventions, are generally thought to be about 70% effective for consumers. Listed below are the five classes of medications with some specific examples of each, although it must be emphasized that there is much overlap among categories when it comes to actual use.

1. **Antipsychotics.** Conventional or first generation medications include fluphenazine (Prolixin), haloperidol (Haldol), and thioridazine (Mellaril). Atypical or second generation medications include risperidone (Risperdal), Olanzapine (Zyprexa), aripiprazole (Abilify), and Ziprasidone (Geodon). Some authors are calling Aripiprazole a third generation antipsychotic, because it is thought to be sufficiently different in its action on the neurotransmitters serotonin and dopamine.
2. **Antidepressants.** Three different types of antidepressant medications include the monoamine oxidase inhibitors like phenelzine (Nardil) and tranylcypromine (Parnate); cyclic drugs such as amitriptyline (Elavil), nortriptyline (Pamelor), doxepin (Sinequan), and imipramine (Tofranil); the selective serotonin reuptake inhibitors (SSRIs) including fluoxetine (Prozac), citalopram (Celexa), paroxetine (Paxil), sertraline (Zoloft) and fluvoxamine (Luvox). Other antidepressants include bupropion (Wellbutrin), and duloxetine (Cymbalta).
3. **Mood Stabilizers.** Lithium has been the most widely prescribed medication for the treatment of bipolar disorder but anticonvulsant drugs including valproate (Depakote), lamotrigine (Lamictal), and others have emerged since the late 1970s as alternatives.
4. **Antianxiety Medications.** Benzodiazepines are the largest category of antianxiety drugs, including diazepam (Valium), alprazolam (Xanax), and triazolam (Halcion), but caution surrounds their use due to their abuse and dependence potential. Increasingly the SSRI medications are effectively used to treat anxiety. Bupirone (Buspar) represents another type of antianxiety drug.
5. **Stimulants.** The stimulants and other medications for attention difficulties include amphetamine (Adderall), atomoxetine (Strattera), pemoline (Cylert), and methylphenidate (Ritalin, Concerta).

TOWARD RESPONSIVENESS AND COLLABORATION

As we noted earlier, almost all social workers work at least occasionally with clients who use psychotropic medications as part of their intervention plans. In many service settings, social

workers assess mental status and inquire about psychiatric medication use as a part of a client's bio-psychosocial assessment. However, social workers have recently begun to elaborate a more complete range of professional roles with regard to psychiatric medication. They are more frequently expected by clients and other providers to possess sound knowledge of medications and their consequences for clients' lives, not merely to complement the physician's role, but because they bring important insights, techniques, and a special appreciation of client self-determination. A social work perspective includes a person-in-environment perspective (seeing people within a larger context of systems and in cultural and historical context), a social justice perspective (awareness of sociopolitical dimensions of situations with a special sensitivity to inequities in the distribution of rights and privileges), and a strengths and empowerment perspective (putting client desires and goals at the center of practice and using client capacities to reach them). Contemporary practice requires the social worker to strive for two related goals with respect to psychiatric medication:

GOAL 1. Be an effective collaborator with clients, families, and other providers.

To do this well, social workers should subscribe to the following philosophical practice principles:

- Embrace a client-centered "partnership" perspective around the range of medication-related dilemmas and issues that emerge in practice. This suggests working toward a nonthreatening collaborative alliance, a demystification of the helping process, and a mutual sharing of respective expertise. Contemporary models of social work practice call for decreased distance with clients; an explicit, unconditional affirmation of their humanity; and nonjudgmental empathy about the dilemmas they present.
- Maintain a balanced perspective about psychiatric medication in the face of admittedly complex issues related to human rights and professional roles, and the "costs" and "benefits" of medication use. This means rejection of any "cheerleader" role or "naysayer" role.
- Work toward the successful integration of psychosocial interventions and psychopharmacology, and recognize the intrinsic power of combined treatments.

- Work toward interdisciplinary relationships characterized by equality, flexibility, decreased professional control, mutual understanding, and shared goals. Appreciate the challenges that emerge in managing parallel care and treatment.
- Appreciate both the strengths and the limits of clients and their families. Interventions should center on clients and families' unique strengths and aspirations and away from symptoms or weaknesses. This calls for a more radical reorientation to practice than most social workers seem to realize. Yet, admittedly, barriers to progress such as a lack of skills, inadequate resources, or other situational limits must also be appreciated. The trick is to reject blaming the client, or making automatic assumptions of diminished capacities or poor judgment, for example.

GOAL 2. Be a meaningful resource to clients, families, and other providers around medication-related issues and dilemmas.

Social workers can do this by engaging in a range of general activities:

- Focus first on assessing and clarifying medication-related issues, which can occur on psychological, social, strategic, practical, and informational levels.
- Be a valuable source of whatever information, support, or "supplies" are called for in reaching specific "wants" and goals of clients with respect to their medication. These "supplies" range from providing emotional support, information and guidance, help with problem-solving and decision-making, or connection to concrete resources, to name a few.
- Be creative in applying clinical skills and techniques drawn from evidence-based practice theories and models to medication-related issues, and emphasize the use of both individual, group, and environmental supports and resources.
- Encourage the client and family to share their own experiences and emotions about medication use. Provide input to the helping process, generate and weigh options, negotiate, and offer feedback as decisions are made.

Roles and Competencies in Medication Management. Six specific and often overlapping

contemporary roles for social workers with relevance for psychopharmacotherapy include:

1. *The consultant.* The social worker takes on an active role while maintaining a nonadversarial position with the provider. The social worker performs preliminary screenings to determine clients' possible need and desire for medication, makes referrals to prescribers, assists in information-sharing and shared decision-making, and consults with clients and providers as needed. The social worker prepares clients for active participation in the medication assessment by helping clients anticipate their meetings with prescribers. Related responsibilities might include articulating the rationale for the referral, addressing the client's attitude toward psychiatrists, discussing the client's expectations and fears about medications, assessing the client's ability to pay for medication, and addressing issues of adherence. The social worker monitors the client's subjective experience as well, particularly the meaning and impact of the referral to the client and validates their experiences.
2. *The counselor.* The social worker helps clients articulate goals, see options, weigh alternatives, plan and practice tasks, and take action steps to solve problems and reach personal goals related to psychiatric medication. Counseling can also involve giving accurate information about medication and offering advice based on the literature and professional experiences. The counselor recognizes the importance of empathy, especially around the client experience of side effects or impatience with therapeutic effect. Toward this end, listen to the lived experiences of clients, providing opportunities for clients to share the impact of medication on their sense of self and identity. Social workers need to listen deeply to how medication, both positive effects and adverse effects, and self-definitions of mental illness or emotional distress are intertwined.
3. *The advocate.* Social workers perform two essential tasks that relate to their ethical mandate to advocate for clients: (1) advocating directly for clients and families and (2) empowering and facilitating clients to advocate for themselves. Examples of advocacy in psychopharmacotherapy

- include trying to increase client access to the newest types of medication, obtaining free medication from a drug company when needed, discussing potential overmedication with client's physician, challenging a hospital's termination of a clinical trial, or appealing an insurance company that declines coverage of a psychiatric drug. Advocacy is linked with client and family rights, particularly regarding access to quality treatment.
4. *The monitor.* The social worker helps the client keep track of both positive and negative effects of medication so that prompt prescriber action may be summoned when indicated. This requires that social workers have an understanding of basic pharmacokinetics (effects of the body on a drug) and pharmacodynamics (effects of a drug on the body). In addition, monitoring adverse psychological effects involve watching for any changes in the client's self-image and identity that emerge as a result of using medications. For example, a few clients may come to view themselves as "sick" or become overly dependent on medication as a solution to problems. Adverse social effects include any potentially negative consequences that go beyond the individual to consider how medication use affects one's employment and standing with certain social institutions. Finally, social workers in some settings may be creative in using existing measures or devising systematic procedures to evaluate each medication's effectiveness and a client's response over time.
 5. *The educator.* The social worker performs as a teacher and coach for clients, families, and perhaps other providers regarding issues including drug actions, benefits, risks, common side effects, dosing regimens, routes of administration, withdrawal, toxicity, and adherence. This might occur in individual meetings with clients or as part of psycho-educational programs that exist in many agency settings. In addition, social workers teach and practice the steps in problem solving, and in collaboration with nurses, pharmacists, and others offer practical suggestions to help clients take medication appropriately. Teaching clients skills in assertiveness and negotiation can help clients maximize their relationship to the prescribing physicians.
 6. *The researcher.* Using case reports, single-case designs, or more elaborate designs, the social worker documents how medications impact the lives of clients and families, how medications interact with other interventions, and how interdisciplinary relationships can be best coordinated. Social workers design and implement research about use of medications and other psychosocial interventions with special populations (e.g., children in foster care or with older adults in residential care).

Below is a diagram (Figure 103.1) that summarizes the social worker's application of the roles described above, followed by a clinical illustration.

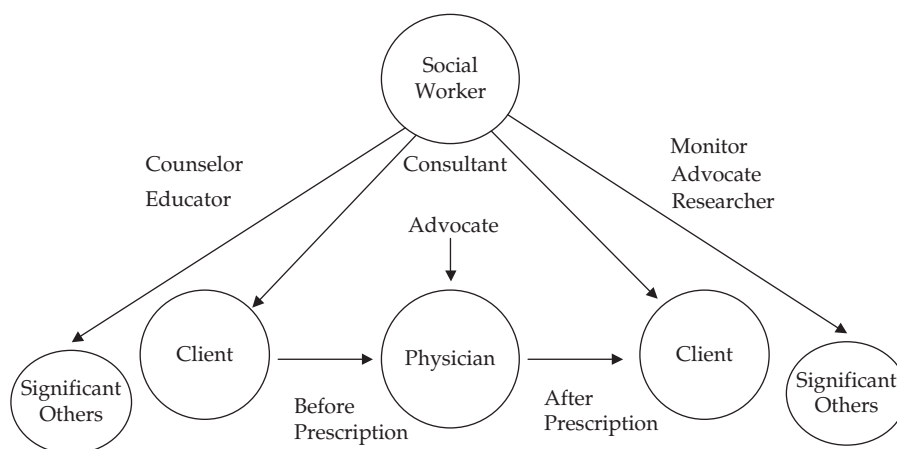

Figure 103.1 Roles and Competencies in Medication Management.

ILLUSTRATION OF THE SOCIAL WORKER'S ROLES

Rebecca was a 40-year old divorced attorney with no children, living alone, with a diagnosis of schizoaffective disorder, characterized by delusions of persecution and agitated behavior. While representing her law firm overseas she confronted associates about their inappropriate "spying" on her, and threatened lawsuits in retaliation. She was hospitalized against her will by her parents and sister. Although she took injectable medication and quickly stabilized in the hospital, she remained angry and paranoid, and declined to take medication as an outpatient, threatening to sue the social worker if he tried to convince her otherwise. The family was concerned about additional acting out on Rebecca's part, which could ruin her already damaged legal career.

The social worker learned during his assessment that the client perceived medication use as evidence that she was "crazy," and taking it would have a devastating effect on her self-image as an independent woman succeeding in a primarily male profession. Further, Rebecca felt that the medication represented efforts of others to "control her mind" and "sabotage" her important legal advocacy work. Clearly, the idea of medication had strong, negative implications for Rebecca's self-image. Rather than refer her directly to a physician, the social worker spent several weeks getting to know the client, validating her successes and empathizing with her trials, and not "pushing" her use of medications (counselor role). The client gradually developed trust in the worker, and agreed to a trial of "minimal-dose" medications that would serve to "help me relax and deal with the stress of my persecution." The social worker met with the physician before Rebecca's first session to let him know of her history and her attitudes about medication (consultant). He also arranged for Rebecca to receive free medications for three months from the agency's funding pool, even though she did not strictly qualify for it (advocacy). The client admitted that, with her level of ambivalence, she would not take medications if she had to pay for them. With the social worker's encouragement, the physician also validated Rebecca's concerns about the medications and agreed to be

available, through the social worker, should her ambivalence become more pronounced (monitor). With the social worker's patient intervention, Rebecca eventually accepted the medication and benefited from it. The social worker continued to emphasize its role in helping her remain calm (educator), and the client took it regularly. He also maintained contact with the client's family, with Rebecca's permission, to inform them of the effects and possible limitations of the medication (educator).

Future Directions. Issues of importance to the fields of psychopharmacology and social work practice in the coming years include:

- Although new drug treatments may appear, perhaps with a more precise spectrum of producing drugs without unwanted side effects, there also exists a general belief that pharmaceutical companies will curtail the development of new psychiatric drugs.
- The discovery of and experimentation with unique delivery routes like brain implants, skin patches, or sublingual (under-the-tongue) medications
- More findings regarding the differential physical and psychological effects of medications on people of different ages, genders, races, and ethnicities
- More inquiry into the placebo effect and the additive or interactive effects of combining psychosocial interventions
- Uncertainties about the lasting popularity of herbs, vitamins, and holistic alternatives
- Expanding prescription privileges among nonphysician health care providers
- Increased public scrutiny and criticism of psychiatric medications, clinical drug trials, drug companies, and advertising agencies
- Greater mandate to learn how to evaluate information from websites, and maintain up-to-date knowledge base through professional development offerings
- New models of health care financing that may influence drug availability and use, as well as greater access to psychosocial interventions.

Ideal practices for social workers with regard to psychiatric medications will always feature a collaborative helping environment in which the

work is comfortably paced but action-oriented, and relationships are characterized by honesty, genuineness, and warmth. There is, and should be, more attention paid to the ethical dimensions of medication management such as avoiding subtle coercion of clients, respecting client decisions not to take medication, being vocal about concerns related to over- or undermedication, and long waiting lists for medication evaluation. Although a medical model of intervention suggests that the goals of care are symptom reduction and compliance, the goals of care in a social work focused partnership perspective are quality of life, self-determination, and collaborative care. Social workers should maintain a critical perspective on medication use in society, but also an appreciation of the power of integrated treatment to improve the quality of lives of people dealing with mental illnesses, behavioral problems, or emotional distress.

WEBSITES

www.mentalhealth.gov

National Mental Health Information Center

Site run by the federal government's U.S.

Department of Health and Human Services which provides free one-stop access to information via internet, phone & publication to public.

www.nimh.nih.gov

National Institute of Mental Health (NIMH).

Public information on specific disorders, diagnosis, and treatment with a section on NIMH research activities.

www.nami.org

National Alliance on Mental Illness (NAMI).

NAMI is a national advocacy group with a strong consumer and family member perspective, focusing on serious mental illnesses. This page leads to a number of NAMI articles focusing on disorders, medications, and research.

www.mentalhealthamerica.net

Mental Health America

This site offers access to fact sheets, pamphlets, merchandise, and position statements on a wide variety of mental health topics including disorders, medications, and suicide. This is the new name of the National Mental Health Association founded in the 19th century by Clifford Beers.

www.mentalhelp.net

Mental Health Net

A very comprehensive site linking to information on disorders and treatments, professional resources, and journals. The site is stated to be a public service of CenterSite.Net, a provider of website services and educational content to behavioral health and employee assistance organizations.

www.dr-bob.org/tips

Dr. Bob's Psychopharmacology Tips

A unique site that allows users to search for tips (edited by Dr. Robert Hsiung of the University of Chicago) on psychopharmaceutical use from physician postings on the Interpsych discussion list. Although not scientific, this site allows users to see direct opinions from prescribers on their experiences with psychopharmaceuticals.

www.medicinenet.com/medications/article.htm

Medicine Net

Site run by a "network of doctors" who want to provide up-to-date comprehensive health information to the public. This page offers access to the alphabetical pharmacy index.

www.pdrhealth.com

Physicians' Desk Reference

For more than 50 years, doctors have relied on the "PDR" for up-to-date, accurate drug information. The information on this site is written in lay terms and is based on the FDA-approved drug information found in the PDR.

PART X

Case Management Guidelines

104 An Overview of the *NASW Standards for Social Work Case Management*

Chris Herman

The roots of case management and social work are intertwined in the late 19th and early 20th centuries (Stuart, 2008). Though social work has evolved greatly since that time, the practice of case management remains integral to the profession (Whitaker, Weismiller, & Clark, 2006). In 2013, the National Association of Social Workers (NASW) revised its standards for social work case management, last published two decades earlier (NASW, 1992). The standards reflect the many changes within both case management and the social work profession over this 20-year period.

CHANGES IN SOCIAL WORK CASE MANAGEMENT

Numerous factors have influenced social work case management over the past two decades and continue to shape practice. Service delivery systems have grown in both size and complexity, resulting in greater fragmentation of services. Thus, the need for interdisciplinary and inter-organizational coordination and collaboration is now greater than ever, especially during transitions between service providers and settings (Golden & Shier, 2012–13; National Transitions of Care Coalition, 2010).

The client role in social work case management also continues to evolve. Client-directed services have become more common—and expected—in a number of practice specialties, such as aging, disabilities, and behavioral health (National Center for Participant-Directed Services, 2013; Substance Use and Mental Health Services Administration, 2010; University of Minnesota, 2009), and health care practice has become more person and family centered

(Institute for Patient- and Family-Centered Care, 2011a, 2011b; U.S. Department of Health and Human Services, 2013). Similarly, practitioners are encouraging clients to assume increasingly active roles in the case management process (see, for example, Coulter, 2012). This shift reflects a deepening twofold recognition: one, that clients are their own best experts; and two, that service delivery is ineffective, and change is impossible, without consistent client engagement. Consequently, case management reflects a social worker–client partnership, rooted in and drawing on clients’ goals and strengths.

As the client role in social work case management has evolved, so, too, has the need for clear outcomes. Social workers across specialties face growing pressure to demonstrate that the services they provide are effective (Social Work Policy Institute, 2010) and guided by evidence, even as shrinking resources require all service providers to do more with less. Technology can help case managers achieve these aims, even as it creates new challenges (Powell & Fink-Samnack, 2013; Stricker, 2012).

Over the past 20 years, both case management and the profession of social work have also become more specialized (Federal Interagency HIV/AIDS Case Management Work Group, 2008; Stuart, 2008), though generalist social work practice remains strong (McNutt, 2008). At the same time, case management and related practices are increasingly performed by a variety of providers, such as nurses and other health care professionals, paraprofessionals within both health care and social service settings, and peer counselors. Such diversity compels social workers to understand, articulate, and demonstrate

the perspectives and activities that distinguish social work case management.

STANDARDS REVISION PROCESS

Numerous social workers contributed to the revision of the NASW case management standards. An advisory panel of 10 NASW members provided substantive input throughout the revision process.¹ The panelists had expertise with diverse clientele across multiple specialties, including aging, child and family services, disability work, health, mental health, substance use, and veterans' services. Moreover, the expert panelists worked in the public, nonprofit, and for-profit sectors in rural, suburban, and urban locations throughout the United States. All had years of direct practice experience, and most were still engaged in direct practice. Furthermore, each panelist had demonstrated professional leadership on a national level, whether through social work education, research, or leadership within NASW, other professional associations, or federal agencies.

Using a consensus-based process, NASW staff collaborated closely with the advisory panel to develop the draft standards. The Association then posted the draft standards for public review and comment. NASW, other organizations, and the expert panel publicized the two-month comment period using a wide variety of print and electronic media. Following the comment period, NASW staff and the expert panel reviewed and integrated the feedback received. The NASW board of directors then approved the standards, which were published in early 2013 (NASW, 2013).

OVERVIEW OF NASW STANDARDS

The standards publication includes not only the standards themselves, but also introductory material—such as historical background and definitions of key terms—relevant to social work case management. The primary goals of the NASW standards are (1) to enhance social work case management with any population and in any employment sector, service setting, or practice specialty and (2) to educate the public about the professional social work role in case management.

In keeping with the growing diversity of program models and job titles, the standards apply to all social workers whose primary function is

either case management or a related practice, such as care management or care coordination. At the same time, the publication highlights the principles that distinguish and guide social work case management:

- Person-centered services
- Primacy of the client–social worker relationship
- Person-in-environment framework
- Strengths perspective
- Collaborative teamwork
- Intervention at the micro, mezzo, and macro levels (NASW, 2013, pp. 17–18).

These principles infuse the 12 standards that follow:

1. *Ethics and values.* Standard 1 relates the core values of the social work profession to case management practice and underscores the need for social work case managers to adhere to NASW's *Code of Ethics* (2008). This standard also reflects some of the ethical challenges and responsibilities inherent in case management.
2. *Qualifications.* Standard 2 identifies the minimum qualifications for social work case management practice: (a) a social work degree from a Counsel on Social Work Education (CSWE)-accredited school or program; (b) adherence to state laws and regulations governing social work licensure or certification; and (3) relevant skills and professional experience.
3. *Knowledge.* Standard 3 summarizes the foundational knowledge needed for effective social work case management practice. Such knowledge includes an understanding of human behavior, growth, and development; behavioral and physical health; family relationships (as defined by each client); resources and systems; and the role of the professional social worker.
4. *Cultural and linguistic competence.* Standard 4 emphasizes that culture—which, similar to the concept of *family*, is defined quite broadly—is a source of resilience. The standard underscores the importance of cultural and linguistic competence in both service delivery and organizational functioning, noting the pervasive effects of systemic oppression and privilege.

5. *Assessment.* Standard 5 links ongoing bio-psychosocial assessment with other aspects of practice and stresses client engagement in the assessment process. This standard also details multiple domains that may be included in the assessment process.
6. *Service planning, implementation, and monitoring.* Standard 6 illustrates a variety of micro-, mezzo-, and macro-level social work interventions that may be incorporated in social work case management service plans. Furthermore, this standard addresses service coordination and termination.
7. *Advocacy and leadership.* Standard 7 illustrates how social work case managers exercise leadership through advocacy at the micro, mezzo, and macro levels. Such advocacy is done both with and on behalf of clients and communities.
8. *Interdisciplinary and interorganizational collaboration.* Standard 8 focuses on the role of interdisciplinary and interorganizational communication and teamwork in promoting clients' goals and improving service delivery. The standard also notes that social worker–client collaboration infuses both the case management process and the other 11 case management standards.
9. *Practice evaluation and improvement.* Standard 9 outlines an array of evaluation activities, both internal and external, that social workers may use to assess and enhance case management services. Such input focuses not only on outcomes, but also on processes of care.
10. *Record keeping.* Standard 10 addresses the content of social work documentation and its role in facilitating communication with other service providers on behalf of case management clients. This standard also addresses confidentiality in the storage and release of client-related information.
11. *Workload sustainability.* Standard 11 emphasizes that establishing and maintaining appropriate workloads is the shared responsibility of social workers, management staff, and organizations. The standard describes some of the factors that influence case management caseloads and workloads, noting that the latter includes any social work function that supports case management services.
12. *Professional development and competence.* Standard 12 illustrates the role of ongoing professional development in maintaining and enhancing competence in case management practice. The standard delineates an array of professional development activities and encourages social work case managers to impart their knowledge and skills to their social work colleagues.

APPLYING THE STANDARDS IN PRACTICE

The case example included in this chapter illustrates how one social worker applies, in practice, the guiding principles of the *NASW Standards for Social Work Case Management* (2013). When Juan's adult children approach the social work case manager with a request to influence their father's treatment plan, the social worker responds empathetically while supporting Juan's self-determination. In this way, she gently reminds the family that her primary goal is to uphold Juan's choices. The social worker maintains this person-centered approach throughout her work with Juan by following his lead in conversation and offering information and resources that address his concerns. She also helps Juan understand how factors in his bio-psychosocial environment influence his personal experiences.

Recognizing the centrality of Juan's relationship with his children, the social work case manager supports Juan in communicating his feelings and goals to his children, thereby strengthening that relationship. Similarly, the social worker uses her professional alliance with Juan to facilitate his communication with both the Social Security Administration and the hospice team. These collaborative efforts expand Juan's support network and reaffirm his strengths. Following Juan's death, the social worker's response to Juan's adult children demonstrates her knowledge of, and support for, systemic advocacy. This advocacy complements the social worker's micro- and mezzo-level interventions during the last months of Juan's life.

The case example also exemplifies application of many of the 12 case management standards. The social worker's actions are consistent with social work ethics and values and demonstrate a solid knowledge of case management practice and relevant resources. She provides culturally and linguistically appropriate services and advocates for her client to obtain such services from other

organizations. As Juan's circumstances change, she engages him in reassessing his goals and developing a plan to realize those goals. She collaborates with other organizations and Juan's adult children on his behalf and, following his death, responds

to the family's desire to engage in macro-level advocacy.² Visit www.socialworkers.org/practice/naswstandards/CaseManagementStandards2013.pdf to download the *NASW Standards for Social Work Case Management* (2013).

Case Example: Juan

A social work case manager works in a community-based agency serving older adults and families. One of her long-standing clients, a 61-year-old man named Juan, has recently been diagnosed with inoperable bladder cancer. Juan, who smoked as a young adult, blames himself for his illness and has withdrawn from social contact. Though the oncologist has informed Juan and his adult children the prognosis is poor, the children have encouraged their father to undergo chemotherapy and radiation. They ask the case manager to convince Juan not to "give up."

The social work case manager acknowledges the family's distress while reminding them that their father has the right to make his own decisions. The first time she visits Juan following the diagnosis, he avoids the subject of cancer. During the next visit, however, Juan acknowledges his dread of being repeatedly asked about his current or past smoking habits. The social worker normalizes this reaction, helping Juan understand the societal dynamics at the root of his shame. She also reaffirms the many positive steps Juan has taken over the years to maintain a healthy lifestyle and reminds him that environmental factors beyond his control may have contributed to his cancer risk.

By the following conversation, Juan is ready to talk about his medical options. The social worker asks what is most important to him right now. Juan explains that he would rather forego chemo and radiation and live a shorter amount of time than to deal with the side effects of those treatments. "I'm not afraid to die—I just want to feel as well as I can in the time I have left." The social worker explains to Juan that palliative care can help him in this respect. Juan wants to ask his doctor about it but knows his children aren't ready. He accepts the social worker's offer to facilitate a family conversation. With the social worker's support, Juan is able to communicate his feelings to his children, who eventually accept his decision.

During the family discussion, Juan also verbalizes his fear of being a financial burden on his

children; because of his cancer symptoms, he has been unable to work lately and anticipates retiring, but is a year too young to qualify for early retirement benefits under Social Security. The social work case manager explains that, given the severity of Juan's diagnosis, he would probably be approved for Social Security Disability Insurance very quickly under the Social Security Administration's Compassionate Allowances program. Juan is relieved but overwhelmed by the prospect of completing a written application in English, which is his second language. The social worker tells Juan that he can apply by phone in Spanish. Still uncertain, Juan asks if the social worker will make the first call with him. Together, they call the Social Security Administration to begin the process. After a few minutes, Juan's confidence grows, and he talks freely.

Juan then meets with his oncologist, who refers him to a hospice program. After Juan enrolls in hospice, he is reluctant to accept visits from anyone but the hospice nurse. The social work case manager explains the value of the hospice team and obtains a signed release to talk with the hospice social worker. The hospice social worker appreciates the information and affirms the value of Juan's continued relationship with the social work case manager. The two social workers discuss their respective roles and agree to propose a joint visit with Juan. Following this meeting, Juan is more receptive to the hospice social worker and even agrees to meet the hospice chaplain the following week. Juan and his family are closely involved with both the hospice team and the social work case manager during the last few months of Juan's life.

Several months following Juan's death, the adult children contact the social work case manager. While describing their participation in a bereavement support group, they ask how they can get involved in advocacy to help other people affected by cancer. The social worker refers them to a local chapter of a cancer organization that sponsors such activities.

105 Clinical Case Management

Joseph Walsh & Jennifer Manuel

Clinical case management is an approach to human service delivery that integrates elements of clinical social work and traditional case management practices. It is used primarily with clients having serious mental illnesses, such as schizophrenia, major depression, bipolar disorder, personality disorders, and substance use disorders. The range of client needs within this population includes social relationships, housing, income support, medical care, job training, recreation, life skills development, counseling, and medication. Interventions are usually provided in mental health agencies.

Clinical social work practice is the application of social work theory and methods to the diagnosis, treatment, and prevention of psychosocial dysfunction, disability, or impairment in individuals, families, and groups (NASW, 2005). It is based on an application of human development theories within a psychosocial context. Case management somewhat differently emphasizes the development of a client's growth-enhancing environmental supports, both formal and informal, using resources that may be spread across agency systems. Case managers work independently or as members of teams, and their traditional activities include assessment, planning, linking, monitoring, and advocacy.

Social work recognizes the importance of one's physical and emotional environment in

facilitating growth throughout the life cycle, and clinical case management is a professional specialization characterized by an understanding and integration of the relationships among the range of internal and external factors that influence the course of development (Wong, 2006). In clinical case management, the social worker combines the sensitivity and interpersonal skill of the psychotherapist with the creativity and action orientation of the environmental architect (Surber, 1994). The practice gives priority to the quality of the relationship between the client and social worker as a prerequisite for the client's growth. Those who support clinical case management argue that substituting nonclinicians for appropriately skilled clinicians often leaves consumers in need of holistic interventions with staff who are ill equipped to meet their needs (Essock, Covell, & Drake, 2006). Furthermore, due to the inherent problems with role confusion and authority in traditional case management, the client is best served if the worker is encouraged to function as the primary therapeutic resource.

Storey (2009) has summarized a perspective first articulated by D. W. Winnicott that is instructive in identifying how clinical case management bridges the modalities of psychotherapy and social casework. Winnicott believed

that the psychotherapist starts from the client's "inside" and is concerned with inner conflicts that hamper social development. The social (case)worker starts off as a "real" person concerned with external events and people in the client's life (the "outside"), and in the course of intervention brings harmony between those two worlds.

Clinical case management includes the following 13 activities within four areas of focus (Kanter, 2011, 1996):

- Initial phase—engagement, assessment, and planning
- Environmental focus—linking with community resources, consulting with families and caregivers, maintaining and expanding social networks, collaboration with physicians and hospitals, and advocacy
- Client focus—intermittent individual psychotherapy, independent living skills development, and client psycho-education
- Client–environment focus—crisis intervention and monitoring.

Clinical case management may be implemented within many program models. For example, Floersch (2002) differentiates five models of case management supported by federal, state, and private research monies, including psychiatric rehabilitation, broker, assertive case management, recovery, and strengths. Clinical case management can be practiced in all but the broker model.

TASKS AND ACTIVITIES

Harris and Bergman (1988) have summarized the therapeutic tasks of clinical case management practice as follows:

- Forging a relationship, or making a positive connection with a client. This may unfold in a variety of ways depending on a particular client's characteristics, and may range from high levels of interaction to the maintenance of interpersonal formality and distance.
- Modeling healthy behaviors to facilitate a client's movement from a position of dependency to one of greater self-direction. When this is successful, the client comes to understand that he or she has unique needs, goals, and skills, and that focused actions can influence the course of events.

- Altering the client's physical environment through processes of creation, facilitation, and adjustment.

THE WORKER–CLIENT RELATIONSHIP

The clinical case management relationship is the sustaining link between the client with mental illness and the external world (Walsh, 2000a). It provides an environment of safety for the client. Within that context, the client can:

- Experience structure as an antidote to disorganization
- Appreciate the significance of internal and external limits as a guard against poor impulse control
- Learn that help is available for most problems
- Improve reality testing
- Experience cognitive and experiential learning
- Enhance self-esteem through success experiences.

The worker–client relationship provides a context for positive outcomes in all clinical practice situations, including those involving clinical case management. This alliance consists of a positive emotional bond between the parties, mutual comfort, and a shared understanding of goals and tasks. It develops over time in unpredictable ways from the expectations, beliefs, and knowledge that each person brings to the relationship. Hewitt and Coffey (2005) conducted a meta-analysis of studies on the significance of the therapeutic relationship with clients who have schizophrenia and concluded that clients who experience an empathic, positive, and facilitative relationship have better outcomes. Additionally, Miller, Duncan, and Hubble (2005) concluded from their literature review that the two elements of the therapeutic alliance and the practitioner's ongoing attention to the client's attitude about the intervention account for positive outcomes more than anything else.

Walsh (2000b) asserts that the social worker's management of relationship boundaries in clinical case management is a more complex process than in other forms of intervention. Boundaries include the spoken and unspoken rules that case managers and clients observe about the physical and emotional limits of their relationship. Special

boundary challenges in clinical case management include:

- The possibility of dual relationships with the client or his or her significant others (for example, serving as a client's payee)
- Unwelcome or inappropriate intrusions into the client's home environment
- Unclear assumptions about self-disclosure for both parties
- The social worker's use of coercion in the relationship
- Managing issues of reciprocity (including material transactions and also a client's frequent desire to be the social worker's friend).

CLINICAL SKILLS

In addition to relationship-building skills, the clinical skills needed for long-term work with clients having mental illness include the ability to (Harris & Bergman, 1988; Kanter, 1996, 1995):

- Make ongoing judgments about the intensity of one's involvement with a client
- Assess and recognize a client's fluctuating competence and changing needs
- Titrate support so as to maximize a client's capacity for self-directed behavior
- Differentiate the biological and psychological aspects of mental illness
- Help family members cope with their troubled relative
- Appreciate the effects of social factors on a client's sense of competence
- Understand how clients both shape and internalize their environments
- Appreciate a client's conscious and unconscious motives for behavior
- Develop a longitudinal view of the client's strengths, limitations, and symptoms.

Many community-based program developers are reluctant to support clinical case management because of concerns that social workers may focus on psychotherapy in lieu of the full range of case management interventions. Neugeboren (1996) suggests that environmentally focused practice (advocacy and monitoring) requires "sociopolitical" skills, in contrast to "socioemotional" skills required for relationship development, assessment, and planning. This perspective underscores

the need for ongoing professional development in all areas of clinical case management practice.

OUTCOME RESEARCH

Researchers have attempted to compare case management models with regard to effectiveness. It is difficult, however, to isolate particular models because of intervening variables that confound the relationship between program philosophy and actual practices. A recent systematic review of 38 randomized clinical trials concluded that clinical case management, which emphasizes high intensity services and manageable caseloads, ensures that more people remain in contact with psychiatric services, improves general functioning, and shortens the length of hospitalization, especially among those who are frequently hospitalized (Dieterich, Irving, Park, & Marshall, 2010). An earlier meta-analysis included a greater range of studies evaluating 44 mental health case management programs over a 20-year period and found that both assertive case management and clinical case management were effective with regard to measures of family burden, family service satisfaction, and cost of care (Ziguras & Stuart, 2000). The two approaches were equally effective in reducing symptoms, increasing client contact with services, reducing dropout rates, improving social functioning, and increasing client satisfaction. Another study also found that clients of clinical case managers made comparable gains to those receiving assertive community treatment (Essock et al., 2006). A systematic review by Smith and Newton (2007) found that case management models emphasizing assertive engagement and clinical case management shortened hospital stays and improved treatment engagement, adherence, independence, and client satisfaction. In a 10-year review of a large care program in the United Kingdom, it was observed that the introduction of clinical case management was associated with an increasing focus on clients with the more severe mental disorders (Cornwall, Gorman, Carlisle, & Pope, 2001).

One gap in the research is that individual case manager effects (as opposed to program effects) on client outcomes have rarely been examined. In one such study of a nationally known community support program, strong support was found for the differential effectiveness of case managers (Ryan, Sherman, & Judd, 1994). More recently,

research has indicated the benefit of client-case manager ethnic matching. One such study by Ziguras, Klimidis, Lewis, & Stuart (2003) found that ethnic minority clients who were matched with bilingual clinicians were more engaged in treatment and had less frequent contact with emergency services. Other studies, however, did not find such benefit in ethnic matching (Ortega & Rosenheck, 2002; Chinman, Rosenheck, & Lam, 2000). Additional research of the characteristics or effectiveness of individual case managers could more clearly evaluate the practice of clinical case management.

CONCLUSION

Two national consensus panels, sponsored by the Center for Mental Health Services and the Center for Health Care Strategies, have identified 11 core competencies for the effective treatment of persons with serious mental illnesses, including the clinical tasks of developing a therapeutic relationship, conducting reliable symptom assessment and diagnoses, and integrating psychosocial and psychopharmacological treatments (Lieberman, 2005). Among the issues to consider in developing the therapeutic aspects of clinical case management are worker roles, authority, status, training, caseload, and supervision. These may be addressed in the following ways.

- Program developers should acknowledge that case managers provide therapeutic interventions and direct their recruitment and supervision policies accordingly.
- Because they are the focal point of the client's intervention milieu, clinical case managers must be given authority to assume overall case responsibility.
- Administrators must develop career paths for clinical case managers so that turnover based on low status and pay is not so endemic.
- Caseload size should be controlled so that clinical case managers can realistically attend to the needs of their clients. Caseloads of approximately 20 to 30 clients per worker appear to facilitate effective intervention.

Supporting clinical case management will provide another positive consequence for clients—namely, reduced stigmatization. Among the benefits of acknowledging the therapeutic nature of case manager–client relationships is

the implied belief that all persons are capable of psychological growth.

106 Assertive Community Treatment or Intensive Case Management

Phyllis Solomon

Assertive Community Treatment (ACT) and Intensive Case Management (ICM) are services designed to serve persons with severe mental illness. Although there is no clear operationalization of what severe mental illness (SMI) is, it is

commonly accepted that there are three dimensions that identify members of this group: diagnosis, disability, and duration. The diagnostic categories often employed are schizophrenia spectrum disorder and major affective disorders

with increasing inclusion of personality disorders. Disability refers to “dangerous or disturbing social behaviors, moderate impairment in work and non-work activities and mild impairment in basic needs” (Dieterich, Irving, Park, & Marshall, 2011, p. 7). Duration refers to persistent and long-term history and treatment of the illness of at least two years or more (National Institute of Mental Health, 1987). This chapter will provide background on the development of ACT and its evolution over time into the basic staple of case management as a core service for persons with SMI, its establishment as an evidence-based practice, its international spread and its relationship to recovery. Furthermore, some suggested guidelines will be offered.

BACKGROUND HISTORY AND EVOLUTION OF ASSERTIVE COMMUNITY TREATMENT

ACT was developed at Mendota State hospital in Madison, Wisconsin by Marx, Test, and Stein (1973) in the early 1970s in response to the needs created by deinstitutionalization of public psychiatric hospitals. It was originally named Training in Community Living (TLC) because it was designed to take the hospital’s interdisciplinary team into the community and to train patients being discharged from the hospital into community settings in which they were intending to live. This approach was found to be necessary due to the fact that patients had limited ability to generalize the skills they learned in the hospital to the new settings in which they were to reside. Later, it was renamed Program in Assertive Community Treatment (PACT) and eventually, it was shortened to Assertive Community Treatment (ACT).

ACT was designed as a fully comprehensive, self-contained program that was to provide for all of the treatments, services, supports, and rehabilitation needs of the patients and to be available 7 days a week, 24 hours a day. The services and supports are proffered by a multidisciplinary treatment team minimally comprised of a psychiatrist, nurse, therapist/clinician, and case managers who are to serve as the coordinating resource for the team. Professionals with greater specialization are added to the team contingent upon the needs of the population served. For example, a substance abuse counselor would be included should the clients have a comorbid substance abuse disorder, or an employment specialist would be added if the team targeted employment for the

population being served. Over time, these teams have been designed to serve a variety of specific populations, including forensic clients (Forensic Assertive Community Treatment [Cuddleback, Morrissey, Cusack, & Meyer, 2009]), clients with borderline personality disorder (Horvitz-Lennon, Reynolds, Wolbert, & Witheridge, 2009), and transitional age youth (McGrew & Danner, 2009). Recently, teams have begun to include peer support specialists and family members as team members to make these teams more recovery oriented (Schmidt, Pinninti, Garfinkle, & Solomon, 2013). Recent research on including a peer as a team member is showing positive effects, while at the same time demonstrating that the integration of these members is a slow process (van Vugt, Kroon, Delespaul, & Mulder, 2012).

ACT services are delivered *in vivo* with high intensity wherever a client lives, works, and recreates, and are to engage in assertive outreach. These latter were important features because these services are to be reserved for those who are most in need, not for all persons with an SMI diagnosis. This program is to serve those most disengaged from the mental health treatment system, who are homeless, who have a number of hospitalizations and crisis episodes, who are sometimes referred to as heavy users of services, or specialized populations like those with substance abuse disorders or criminal justice involvement. In other words, those who are most costly to the system, because they frequently choose to enter the mental health system at crisis points rather than engaging with mental health services and treatments on an ongoing basis. It is estimated that ACT is the service of choice for about 20% of those with a severe mental illness, but not for all with a SMI diagnosis (Schmidt et al., 2013). From its inception, ACT was established to reduce the need for hospitalization, increase the client’s independence from the service system, and increase his/her integration into the community settings of his/her choosing.

The core features of ACT are:

- Multidisciplinary team approach
- Small caseloads (1:10–12)
- 24–7 crisis support
- Individualized care
- Team members sharing caseloads
- *In vivo* delivery
- Monitoring of medication
- Assertive outreach
- No-discharge policy

ACT teams are to serve no more than 120 clients at any given time and are to meet daily in order to ensure all team members are aware of the current status of all clients. This increases the likelihood of continuity of care should the primary therapist or case manager designated for a client not be available. However, a no-discharge policy has been found to be nonsustainable; teams quickly reach their maximum caseload with no discharges and are unable to serve new clients needing the service. Research has found, however, that there are no negative consequences from transferring clients if done in a highly planned way (Phillips et al., 2001; Salyers et al., 1998) and with allowances for clients to return if deemed clinically beneficial. Consequently, these findings have resulted in a relaxation of this feature.

Intensive case management over time really evolved from both broker and clinical case management models and from ACT. Like ACT, broker case management was identified in the early 1970s with the big push for deinstitutionalization. Basic case management, which was referred to as broker case management, functioned to coordinate resources, supports, and services needed by individuals being released from public psychiatric hospitals. These functions and supports were not particularly new to social work, given that they had been inherent to the practice of social work since the emergence of the profession (NASW, 2013). It was soon recognized that a more intensive service was needed for discharged patients. Clinical case management emerged, and broker case management essentially merged with it. Clinical case management was not particularly well defined, but this service incorporated more clinical aspects, such as supportive counseling and had small caseloads and was usually delivered by those with some advanced training, frequently social workers. As research on ACT began appearing that demonstrated its effectiveness, some of the elements of ACT came to be incorporated into intensive case management. These elements could include assertive outreach, small caseloads (usually fewer than 20 clients per case manager), *in vivo* service delivery, and working in teams or pairs of case managers. Agency back-up of crisis services, as well as medication administration and monitoring by a psychiatrist could also be included. What is referred to as case management currently often means intensive case management, but there is no consistency in exactly what this service is in practice. This term is used interchangeably with ACT, but it does not contain all

of the elements of ACT (Dieterich et al., 2011). In addition, such a case management service may be called targeted case management, because this is what case management is designated by the Centers for Medicare and Medicaid Services, which sets policy for payment of these services. During the past 10 years these two original models (ACT and Intensive Case Management) have been modified and merged, with resultant difficulty in distinguishing the differences between them. Consequently, Cochrane abandoned the recent review of ACT and combined the research on the ACT model with the systematic review of intensive case management. One finding of this review was that the effectiveness of intensive case management relies on the extent to which the service is faithfully implemented consistent with the elements of ACT and contingent on a high use of hospital beds (Dieterich et al., 2011).

EFFECTIVENESS OF ASSERTIVE COMMUNITY TREATMENT AND INTENSIVE CASE MANAGEMENT

ACT is currently considered an evidence-based practice. Reviews of ACT compared with other case management models, or to standard care, consistently have found reduced hospitalization and shorter lengths of stay when clients are hospitalized, decreases in homelessness and in crisis services use, high degrees of satisfaction by both clients and their families, and increased engagement with services. Clients engaged in ACT were also better at maintaining contact, thus reducing service drop outs and increasing housing stability. Furthermore, ACT has been found to be a cost-effective service due to its less frequent use of hospitalization (Schmidt et al., 2013).

However, given the changing environment, in which hospitalization has become more infrequent and when it does occur, is much shorter, and the concurrent increased comprehensiveness and incorporation of such major elements of ACT into what has become the standard of care in case management, the effectiveness of ACT has diminished when reduction in hospitalization as an outcome is compared with the standard of care in low hospital use environments. In other words, in these environments, it is difficult to further reduce hospitalization.

In the most recent Cochrane ICM review, it was found that for those hospitalized ICM did reduce length of stay, but so did standard care. The

advantage of ACT/ICM seemed to be for those who had spent a good deal of time in the hospital in the past two years. Consequently, these reviewers concluded that there is no evidence that ICM substantially affects the cost of psychiatric hospital care. This review included more European and Australian-based studies, whereas prior reviews were mostly North American studies. Yet, these studies are predominately from countries that have already undergone deinstitutionalization. This Cochrane review lacked studies from low-income countries and countries that have limited or almost no community-based mental health care systems (Dieterich et al., 2011). For example, ACT in Japan did find positive outcomes for hospitalization, but then Japan is a country that still relies heavily on hospitals and is just beginning to develop a community mental health system of care (Ito, Oshima, Masaaki, & Kuno, 2009; Ito et al., 2011; Nishio et al., 2012). In a short period of time, since its initial experiment with J-ACT, Japan has successfully implemented ACT throughout the country.

Botha and colleagues (2010) noted that there is “a worldwide focus on assertive community interventions in an attempt to address some of the repercussions of the implementation of deinstitutionalization. Although these interventions have often been implemented under different names such as assertive outreach, intensive case management, and assertive community treatment, essentially they have had the same core characteristics” (Bortha et al., 2010). These researchers conducted a randomized controlled trial of an assertive intervention with high frequency service users in Cape Town, South Africa and found the intervention to be effective in reducing readmissions and improving psychopathology and level of functioning. Furthermore, these investigators concluded that these interventions do not necessarily have to be as comprehensive and as expensive as in the developed countries to produce such positive outcomes.

RECOVERY AND ASSERTIVE COMMUNITY TREATMENT

There has long been a concern that ACT is a coercive service, given its orientation toward adherence to treatment, specifically to prescribed medication. The current trend toward a recovery orientation emphasizes consumer choice, empowerment, and self-determination, and recognizes

client expertise, rather than the clinician as the expert. This approach to practice requires full partnership between consumers and providers in developing individualized treatment plans. Furthermore, a recovery-oriented practice must be inculcated into the “norms, attitudes, and values that emanate from the shared culture of the ACT team,” whereby hope and believing in oneself are communicated to clients served (Salyers & Tsemberis, 2007). Thus concerns emerge as to the extent to which ACT is consistent with this mode of practice. Two experts in ACT did an analysis as to the extent to which ACT can incorporate a recovery orientation (Salyers & Tsemberis, 2007) and concluded that while there are some aspects of ACT that make it a challenge to achieve this goal, with proper training, supervision, and monitoring as well as the inclusion of consumers as equal team members a recovery orientation within ACT can be achieved.

Guidelines for Assertive Community Treatment/Intensive Case Management

Although ACT is currently considered by many to be an evidence-based practice (EBP), the evidence is continually evolving. Not only is fidelity of ACT important to securing positive outcomes, but the environment in which the study is conducted also impacts the outcomes produced by this intervention. What we see is that as the crucial elements of ACT migrated into standard care, and as the postinstitutionalization period began, the advantages of ACT waned in the United States and other developed deinstitutionalized countries. However, ACT with modifications for culture continues to maintain advantages in countries that are just beginning to deinstitutionalize and where there are few community-based mental health services. Investigators in these countries have also found that it is possible to modify ACT to reduce its cost, but yet be able to retain its positive effects. What emerges from these recent studies and reviews are the following guidelines for policy makers, program managers, and clinicians.

1. ACT/ICM is a model that makes good clinical sense for persons with severe mental illness who are frequent users of hospital services. It is a comprehensive high-cost service model that should be reserved for heavy users

- of costly services, particularly high use of hospitals. It is not as likely to be beneficial for other persons with severe mental illnesses.
2. ACT/ICM is a flexible model that can be adapted, supplemented, and modified for emerging new populations. It is a comprehensive service and its core features are essential for good clinical care for a diversity of mental health populations beyond those with severe mental illness for whom it was originally designed. Because of its flexibility, other EBP's, such as cognitive behavioral treatment, Individual Placement and Support (IPS), as supported employment program, or Illness Management and Recovery (IMR) can be merged within an ACT program.
 3. In environments where deinstitutionalization is just beginning, the advantages of ACT/ICM are maintained. However, careful modifications may be made without reducing effectiveness. These modifications need to be based on empirical evidence and clinical needs.
 4. A decision to use ACT/ICM in places where there are fully developed community-based mental health systems of care and hospital use is limited cannot be made on the basis of cost-effectiveness. At this point, it cannot be determined whether this service model is cost effective (Dieterich et al., 2011). Cost effectiveness may be a greater driver in countries where hospitals are the major sites of mental health care. However, even this cannot be stated with empirical confidence.
 5. In order for ACT/ICM to maintain its effectiveness, the service needs to be faithful to the critical elements of ACT, including assertive outreach, *in vivo* service delivery in a site of client's choosing, low caseloads (a ratio of 1:20), team approach, shared caseload, 24–7 access to the team, daily team meetings, team supervisor devotes at least half of his or her time to client contacts, either through supervision of team members or in contact with team clients, and no expectation of transferring clients (Dieterich et al., 2011). However, having a psychiatrist and a nurse on the team does not seem to be essential (Dieterich et al., 2011).
 6. Implementation of ACT/ICM requires training in the model. Substance Abuse Mental Health Services Administration (SAMHSA) has a toolkit available for implementing ACT, which is downloadable from the SAMHSA website. Alternatively, a boxed toolkit can be obtained for the cost of mailing. The package includes DVD, CD-ROM, brochures in English and Spanish, and a Power Point presentation. A fidelity assessment measure is also available, which should be used to monitor the implementation, given that faithfulness to ACT is essential for positive outcomes.
 7. Clinicians should be knowledgeable regarding the essential components of ACT/ICM even if they will not be implementing it. Clinicians need to be aware of what ACT/ICM is and what it is not.
 8. Because Intensive Case Management derives from Clinical Case Management, it seems essential that intensive case managers need to be clinically trained, preferably with a master's degree in social work, counseling, or psychology. Bachelor's level social workers or psychologists may be employed if well supervised by a clinically trained individual, particularly a social worker.

CONCLUSION

ACT/ICM is a service that has been around for over 40 years. It emerged with the beginning of deinstitutionalization to meet more appropriately the needs of those with severe mental illness. It is currently considered an EBP, but changes in the environment have diminished its effectiveness in some places. It seems to maintain its strengths, however, in settings and locations that are similar to the environment in which it was originally created. ACT/ICM remains important for a particular subset of clients, but it is not intended for everyone diagnosed with a severe mental illness. Given that it is an extremely costly service, it needs to be judiciously used, where it will have the greatest benefit.

WEBSITES

ACT Center of Indiana provides up-to-date information and technical assistance and training. Their mission is to help integrate research and practice to promote best practices, such as ACT, for persons with severe

mental illness. <http://psych.iupui.edu/ACT/index.html>

Substance Abuse and Mental Health

Services Administration provides a toolkit and other information regarding ACT. <http://store.samhsa.gov/product/Assertive-Community-Treatment-ACT-Evidence-Based-Practices-EBP-KIT/SMA08-4345>

Assertive Community Treatment Association holds annual conferences and has done so since 1984. It also provides trainings and advocates for the dissemination of ACT. It is a nonprofit membership association comprised of mental health providers, mental health peers and their families, government officials and others committed to spreading ACT. <http://www.actassociation.org/>

107 Case Management Practice in Psychosocial Rehabilitation

David P. Moxley

INTRODUCTION

Although case management emerged in human services as a generalist approach to serving people experiencing a multiplicity of needs and life issues, its diffusion was shaped by the search for service continuity within a diversity of human service domains. Originally, case management was seen as a means to rectify systems-level problems, such as service integration, plaguing community-based and institutional forms of human service. Brokering forms of case management, for example, sought the creation of bundles or packages of services for consumers whose needs, influenced by medical, physical, and psychosocial issues and characterized by complexity and long duration, required different types of care and support. Brokering, coordination, and other systems approaches to case management proved to be limited because they often were too general in their focus, failed to specify appropriate recipient populations or intended beneficiaries in rigorous ways, did not specify strategy and methods, and failed to align organizational resources with the role requirements that case management demanded. In addition, given overwhelming case loads, case management personnel found it difficult to personalize the support of the people they served.

Insight into case management effectiveness, largely derived from systematic evaluation of various approaches, indicated that good case management incorporated a specific purpose and set of goals, made explicit the target population that could benefit, and specified relevant methods based on its purpose and the issues potential recipients faced in their daily lives. In addition, good case management aligns requisite resources

case managers need to effect meaningful change in the lives of recipients with purpose and aims of service.

DISTINCTIVENESS OF PERSON-CENTERED CASE MANAGEMENT IN PSYCHOSOCIAL REHABILITATION

Recovery Focus

Case management in psychosocial rehabilitation recognizes the importance of such context and input factors consonant with good service delivery. The distinctiveness of case management is found in the person-centered nature of the field of psychosocial rehabilitation in which the management of illness has yielded increasingly to the facilitation of recovery. The concept of recovery envisions recipients becoming more engaged in the achievement of outcomes that bring them life satisfaction while learning to actively manage the psychological, behavioral, physical, and social consequences of psychiatric disability (Anthony, Cohen, Farkas, & Gagne, 2002). Good case management in psychosocial rehabilitation recognizes how psychiatric disability creates numerous barriers to effective functioning, and it also recognizes that recipients likely value life outcomes common to all human beings, including good health, employment, education, reliable and adequate income, and decent housing (Moxley, 2011).

The focus of case management in psychosocial rehabilitation on the fulfillment of such common human needs infuses this approach with practicality combined with recognition of how serious mental illness can frustrate recipients' pursuit and realization of these aims. Case management in psychosocial rehabilitation emphasizes the

(1) fulfillment of positive human needs (the psychosocial aspect) manifested in helping people plan actively for a lifestyle and situation they find satisfying, and (2) modification of environments, particularly barriers that frustrate the pursuit and realization of life satisfaction (the rehabilitative aspect; Anthony et al., 2002).

Importance of Person-Centered Practice

Person-centered practice is salient when case managers help recipients identify and frame a central outcome with the realization of what they will find satisfying. The ensuing process of planning helps recipients understand their own process of recovery, identify barriers to the achievement of the outcomes they value, and formulate strategies to overcome barriers through personal and environmental change. Joining these two aspects within case management literally integrates the psychosocial and the rehabilitative practice approaches. Such joining moves case management in psychosocial rehabilitation away from an exclusive preoccupation with illness and functioning to incorporate human aspirations and positive psychology as important advanced organizers of practice.

One can further frame person-centered practice through the specification of three elements. Recognition of what the author refers to as “in spite of” ensures that case management personnel help people identify the barriers to life satisfaction they face while those barriers are framed as factors that the person with serious mental illness and the case manager can overcome, particularly through advocacy (Moxley & Washington, 2009). Identifying and enacting factors of support (what the author refers to as “through”) that counteract barriers people with serious mental illness experience increases the chances of overcoming those barriers and achieving what they wish for themselves. And, by specifying “what I want to achieve” the person with serious mental illness can focus on what they seek for themselves. This element constitutes the aim of life satisfaction.

Thus, person-centered practice in psychosocial rehabilitation involves a process of change: “In spite of X, through S, I can bring about Y.” X stands for barriers, S involves support, and Y involves the desired object or aim the fulfillment of which contributes to a person’s realization of a satisfying life. In psychosocial rehabilitation, “S” or support involves social support through social networks (Tracy, 2009), team support and

support from rehabilitation personnel and peers, and community assets. It can involve organizational arrangements and the creation of supportive communities and group life (Sandfort, 2010). In other words, person-centered practice is ecological in the full meaning of that word. Figure 107.1 captures the sequence of person-centered case management and its various components.

PRECURSORS

The evolution of case management in psychiatric rehabilitation parallels the growth and development of case management in the broader field of human services. One form of case management emerged within the community mental health movement as a means of integrating a range of outpatient-based services, but this approach placed more emphasis on getting people services than on achieving outcomes that recipients found practical and desirable, including a decent standard of living and a good quality of life. Although coordination of services was seen as important within this approach, management of medication and symptoms of those individuals labeled as seriously mentally ill was a central aspect that makes this approach within the community mental health movement an extension of community psychiatric care.

The failure of the community mental health movement to address fully the demands of deinstitutionalization in the 1970s and the needs of those individuals coping with the most serious and complex forms of psychiatric disability ushered in another form of case management. Influenced by the service integration movement of the 1970s and early 1980s, case management was seen as a way of achieving within local service systems single points of entry, unified needs assessments, and unified client pathways—tactics thought useful to the movement of people through complex community-based systems of care. This form of case management, characteristic of community support systems for people with serious mental illness, sought the integration of medical, social, psychosocial, and behavioral domains.

Unlike the community mental health model, this approach extended its reach beyond services offered by various human service agencies to incorporate resources embedded informally in social and community networks charging case management with the challenging responsibility of incorporating all forms of community support into assessment, planning, and action. The

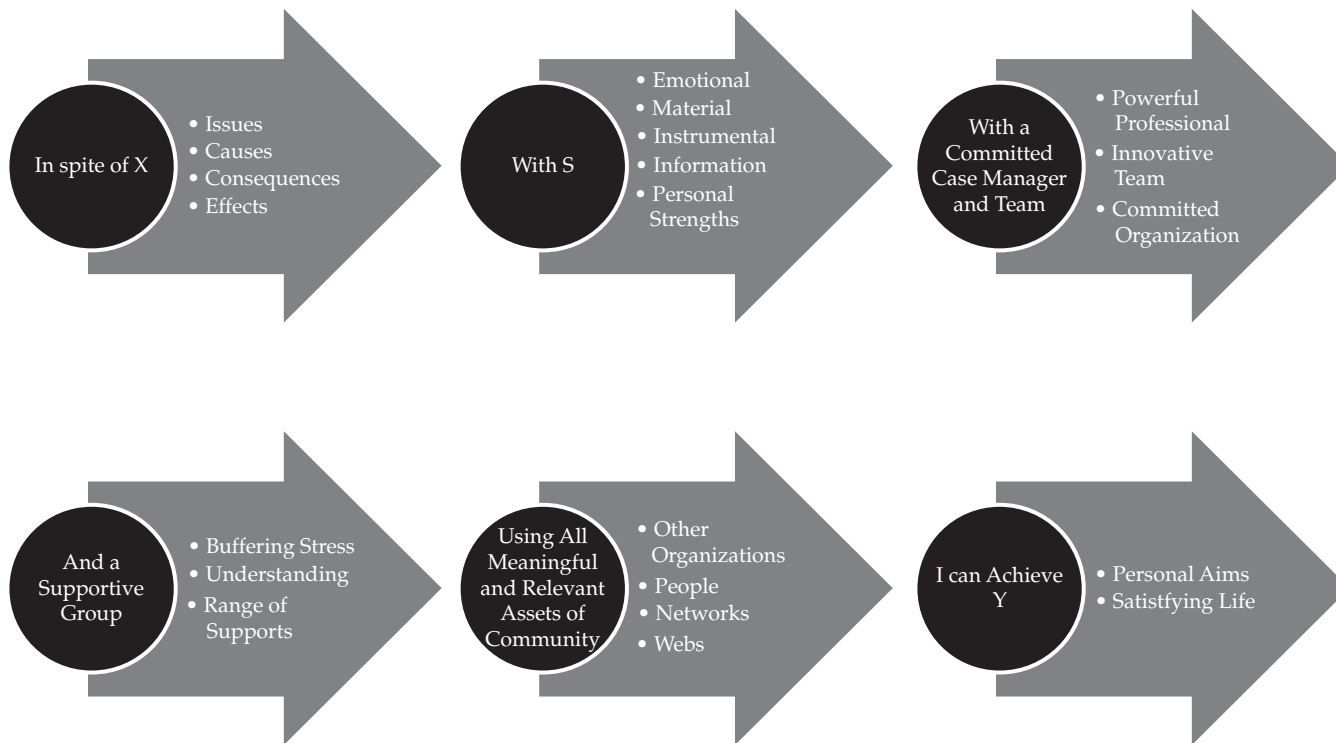

Figure 107.1 Person-centered practice in case management and psychosocial rehabilitation.

National Institute of Mental Health Community Support Model (NIMH, 1980) gave case management a central and expansive role in systems of care without augmenting professional standing of case managers, the resources they had available to serve a population facing a broad spectrum of serious issues and unmet needs, or the infrastructure to assist individuals adequately. Through outreach, home-based services, and the provision of community-based follow-along services case management within community support systems was intended to extend practical assistance into the daily lives of people experiencing deinstitutionalization. Integration was seen as a principal virtue of this kind of case management, manifesting unification of direct assistance, resources to support daily living, skill development opportunities, and social support.

However, the management of the actual illness and related disability found in symptoms and deficits in self-care served as the principal aim: case management sought to respond to the immediate community living needs of people and combat recidivism, particularly the revolving-door syndrome in which recipients oscillated between periodic short-term hospital stays and residence in community situations. Nonetheless, as a result of the community support model, case management today is an essential component of local systems that now integrate medical care, social services, mutual support among consumers, rights protection and advocacy, rehabilitation, housing, and employment support.

As deinstitutionalization progressed in the ensuing decade of the 1980s, other forms of case management took root, including the team-based approaches found in assertive community treatment. An increasing number of state and local service systems adopted this approach, which emerged in the 1970s as a significant innovation in care, and clinical case management, a form of practice that reasserted the importance of a diagnostic perspective, psychotherapeutic interactions, and clinical management in service planning and delivery omitted from community-based forms of case management.

With all of these variants of case management, practitioners tended to view recipients as impaired individuals who needed to accept the limitations their illnesses created. Although case managers encouraged the involvement of recipients in joint planning of services and supports, the principal focus of care was on recipient self-acceptance of illness and management of both the primary

aspects of the illness and their psychological, behavioral, and medical consequences, placing case management within a paradigm in which medical response was dominant. Case management reflects this paradigm when it focuses mainly on medication and symptom management or relief, a form of service that persists today. The variant of case management found in assertive community treatment offers intensive hands-on services to foster successful community living among people who would otherwise engage in high levels of utilization of potentially expensive care whether inpatient, restrictive, or crisis-oriented. However, using such a variant team-based management of the trajectory and consequences of the illness prioritizes medical aspects of psychiatric disability. As one examines the expanse of case management that emerged over a period of almost 50 years, case management sought to manage the person rather than manage the situations in which those persons found themselves, ones mostly deficient in nurturing resources. The instrumental nature of case management emphasized person management rather than a strategy of person-centered support.

CASE MANAGEMENT IN PSYCHOSOCIAL REHABILITATION

Case management in psychosocial rehabilitation legitimates the medical trajectory and consequences of serious mental illness, but this kind of management seeks to identify, organize, and implement broad-based supports that address and fulfill not only people's immediate and concrete needs for community living but also their needs for growth and development, imbuing it with the qualities of positive psychology, including humanization, hope, and optimism. Case management in psychosocial rehabilitation sought to offset the frequent dehumanization of people coping with psychiatric disabilities. Conversely, it sought to humanize the rehabilitation experience by forming strong partnerships between service providers and recipients, collaborating to advance the quality of life of people coping with the causes and consequences of psychiatric disability. Discerning the strengths of individuals, both internal and external, is a central quality of case management in psychosocial rehabilitation (Rapp & Gocha, 2006).

Rehabilitation case management emerged during a time of rehabilitation pessimism in community psychiatry, and was relatively unrecognized during the 1960s through the early 1980s,

only to emerge later as a best practice. Case management based on psychosocial rehabilitation principles and practices introduced a new teleology into the care of those with serious mental illness, one asserting hope and optimism for the progress they could realize. Previous generations of case management required professionals to specify what a person needed and should receive through the process of service brokering, an approach that proved largely ineffective. Case management based on psychosocial rehabilitation frames human needs from the perspective of the person, not the illness. It asks fundamental questions like, “What direction do people coping with psychiatric disability want to take in their lives? What outcomes do they value? What opportunities do they want and, as a consequence, what supports do they see as important in order to take advantage of the opportunities they value? What barriers do they feel that they must overcome to achieve what they want for themselves? How satisfied are they with the supports they obtain and what those supports produce in terms of practical changes in daily life?”

Such questions are not alien to social work given the profession’s commitment to self-determination and empowerment as central values of practice. The questions themselves underscore the importance of relationship and its role in helping recipient and practitioner form an alliance useful in the achievement of recipient identified aims (Brun & Rapp, 2001). The questions themselves suggest an assumption that case management is a catalyst for helping recipients find their voice and articulate their desires in the face of the tremendous personal demands and challenges of serious mental illness. The questions link directly to humanistic and phenomenological dimensions of social work: while a person is struggling with mental illness, the struggle must be understood as an expression of someone traveling a unique and distinctive life journey. The transformational impact of serious mental illness in which a person will not likely return to their premorbid state needs to be understood in terms of how the experience of mental illness can influence life direction and the individual’s goal set.

Thus, the correspondence between social work values and case management in psychosocial rehabilitation is strong, as both are founded in a respect for individualization and personalization of the process of care and support and operationalized through a process of humanization. The idea of humanization indicates that the person coping with serious mental illness is still a

person who possesses interests, desires, and aims. Case management in psychosocial rehabilitation, therefore, amplifies the importance of these strivings, and the case manager’s recognition of the potential for a person’s growth and development is a central idea of practice.

ADVANCED ORGANIZERS

Producing the distinctiveness of case management in psychosocial rehabilitation are those advanced concepts that help organize the manner in which practice is undertaken in the field of psychiatric disability. Particularly important are those advanced organizers involving consumer-centered values, narrative and the lived experience, and positive psychology.

Consumer-centered Values

The idea that people coping with psychiatric disabilities should influence (if not direct) the rehabilitation process as much as possible was introduced in the 1970s and 1980s by a growing consumer and ex-patient movement (Moxley & Mowbray, 1997). Psychosocial rehabilitation was responsive to these consumer-based values by introducing practices legitimating consumer-professional collaboration, self-help alternatives, and mutual support opportunities (Mowbray, Moxley, Jasper, & Howell, 1997). Influenced by an emergent consumer movement, psychosocial rehabilitation sought to make the person (as opposed to the illness) central, not ancillary, within the process of service and support, particularly in making key decisions about care.

Rather than requiring the person coping with serious mental illness to be a passive recipient of service, this form of case management required the individual to be an active participant with ownership over the process and outcomes of rehabilitation. Case management in psychosocial rehabilitation values a recipient’s assertiveness and seeks to empower them as decision makers even in the face of the pervasive challenges serious mental illness can create in judgment and self-agency.

The active involvement of recipients is a legacy of psychosocial rehabilitation and within the process of case management involvement itself is beneficial because recipients make informed choices about their present and future circumstances using their own values and desires. The

act of framing life goals based on humanism, optimism, and hope for the future using practical solution-focused practice makes this form of case management distinctive given psychosocial rehabilitation's emphasis on person-centered rather than service-centered aims.

Over the course of two decades, the 1970s, and the 1980s, psychosocial rehabilitation expanded to incorporate a range of supports, including professional services, peer support, and consumer-operated rehabilitation and community living options. The 1990s witnessed the emergence of the support model as a best practice (Carling, 1995), a model prioritizing concrete assistance to help people choose and achieve practical outcomes in areas like housing, employment, education, recreation, and social involvement. A recipient's subjective sense of quality of life as a principal outcome of case management became increasingly salient within psychosocial rehabilitation. To facilitate this outcome, the recovery-based practitioner in psychosocial rehabilitation makes use of environmental specificity in which well-desired supports are positioned to strengthen functioning of a person who learns to perform a specific role in a given environment, such as someone who is learning a job in an employment setting or performing as a student in an educational setting.

Narrative and the Lived Experience

Given the importance of person-centered values within psychosocial rehabilitation, narrative forms of practice figure into case management in important ways. Diagnostic interviewing focuses on symptom identification and clarification and situational considerations of how a person functions given the influence of the label assigned by a psychiatric professional. A narrative approach, however, involves deep listening and the amplification of the person's story with the professional discerning during the story telling process those experiences, situations, strengths, assets, and challenges identified as important (Washington & Moxley, 2008, 2009a). The narrative itself, replete with central themes that can come to define the direction and strategy of case management, gives the ensuing management plan a personalized profile. People coping with psychiatric disability, for example, whose onset of mental illness was in late adolescence or young adulthood may come to amplify how their educational and vocational aims were frustrated or derailed. "Getting back on track" and "investigating

educational or vocational training opportunities" may become salient in the storytelling that engages the psychosocial rehabilitation professional and recipient in discerning direction.

A traditional practitioner, one more tied to the medical paradigm, may think (or even say), "this direction isn't possible. He needs to back off and lower his expectations." A psychosocial rehabilitation professional will likely continue the dialogue, finally reaching a point where a miracle question is asked: "What will go well with your health to help you get back on track with the education you seek?" The achievement of health can become an enabling outcome of a higher level outcome—the pursuit of education. In this example, narrative drives the process and is legitimate within the person-centered paradigm of psychosocial rehabilitation.

Four types of narrative can emerge during the dialogue between recipient and practitioner (Moxley, Washington, & Crystal, 2013). Those types can reveal a person's vulnerability and resilience (Moxley, Washington, & Feen-Calligan, 2012). One is the "narrative of plight," in which the recipient frames what isn't and what hasn't gone well over the life course. The narrative of plight may express itself as a form of grieving or mourning—opportunities lost, frustration, and setbacks may be prominent (Washington & Moxley, 2009b). Another type is the "narrative of efficacy," in which the recipient reveals strengths, assets, enabling conditions, and opportunities, particularly ones that are on the horizon. These two narratives may conflict or even contradict one another and they may compete for ascendance within the dialogue. However, careful listening (by both practitioner and recipient) can reveal a structure within which action can be taken, consistent with the rehabilitation framework. Barriers are appreciated in relationship to an outcome that the person seeks, and strengths and assets (including other people who can assist) are seen as enabling conditions of a desired outcome. Within the narrative of efficacy, strengths can be discerned, and even within the narrative of plight, both practitioner and recipient can appreciate strengths (e.g., tolerating setbacks, coping with stress, getting back on track).

A third form of narrative involves the story of hope each person may offer. Hope is not elusive even when people find themselves in despair. A person may communicate what they want for themselves, what they consider important in terms of life aims. Still, a fourth type of narrative

involves the recovery, one in which people communicate their efforts to “get well.” Using appreciative inquiry, case management personnel can ask questions about what has gone well in the past to encourage recovery as the professional and consumer work together to craft such supportive conditions.

A narrative strategy highlights the humanistic posture of psychosocial rehabilitation found in the personalization of the recipient, who is seen as striving, purposeful, and goal-oriented. The narrative reflects the lived experience: “Here is how I have lived with serious mental illness. Here is how I have changed, suffered, triumphed, endured and my experience has made me stronger as an individual.” The appreciation of the recipient’s lived experience can certainly reframe how assessment is undertaken, emphasizing phenomenology in service to the creation of an idiographic profile of the individual’s assets, strengths, capacities, and abilities. Successful case management can help recipients produce new narratives, ones populated with new opportunities, new capacities (e.g., good health), valued achievements, and the realization of desired outcomes. The new narrative may hold a special position for the case management professional whose own narrative of efficacy (found in helping the recipient achieve valued outcomes) is intertwined with the recipient’s given the collaborative features of case management in psychosocial rehabilitation.

Positive Psychology

Increasingly psychology, social sciences, and the health and human services are balancing concepts of deficit, disease, disorder, and impairment with those that are positive in their orientation to human development (Lopez, Snyder, & Rasmussen, 2003). Positive psychology is emphasizing research and findings on how concepts and qualities such as faith, spirituality, and social capital, or virtues like endurance and courage, optimism, well-being, and hope ascend within helping frameworks (Washington, Moxley, Garriott, & Crystal-Weinberger, 2009). These ideas and the research they have fostered suggest that people confronting life-threatening and life-challenging situations may exhibit signs of stress and strain, but they can also exhibit virtues that strengthen their resolve and ability to cope (Wright & Lopez, 2002). A person who experiences numerous setbacks in health may muster cognitive and

emotional strategies, helping them reframe the possibility of success in a given situation by modifying adaptive approaches and augmenting coping. Recognizing that people experiencing adversity bring to bear hardiness and resilience is central to positive psychology.

Such a positive psychology is well rooted in psychosocial rehabilitation, so case management recognizes that constructs like hope (anticipation of a positive future) and optimism (an immediate attitude that frames current circumstances in a positive way) figure into the process of support in important ways. The case management plan can play off of a person’s resolve to pursue opportunities (such as valuing education and the work ethic) they find fulfilling.

“Okay,” says the case manager, “you have been ill, but you are very hopeful. What drives your hope?”

“I just know that I can handle college if I can change my living situation and wade into school slowly,” the client replies.

“You sound so hopeful. What will help you get ready?”

“Maybe I can visit a community college and talk with counselors. Can you come with me?” the recipient asks.

“Certainly, let’s schedule it.”

This brief dialogue shows how hope and optimism can link to action. This recipient is getting ready for a new undertaking, and the social worker senses this immediately. Acting on this readiness moves the recipient a little closer to the valued outcome. The case manager as ally is part of the system of optimism and hope that has formed, indicative of the collaborative framework of psychosocial rehabilitation.

The Person-centered Paradigm

The paradigm formed by the intersection of the advanced organizers of consumer-centered values, narrative, and positive psychology produces an interesting model of case management practice in psychosocial rehabilitation. The model emerging from this paradigm is as follows.

VALUE ASSIGNED TO THE RECIPIENT’S PERSPECTIVE →
 NARRATIVE AS A TOOL TO HIGHLIGHT DESIRE AND
 DIRECTION → NARRATIVE TO IDENTIFY STRENGTHS/
 ASSETS, ISSUES, BARRIERS → PERSON-CENTERED
 PLAN → COLLABORATIVE ACTION TO ACHIEVE
 PERSON-CENTERED OUTCOMES → EMERGENCE
 OF A NEW NARRATIVE

THE EMERGENCE OF PERSON-CENTERED RECOVERY-BASED CASE MANAGEMENT

As psychosocial rehabilitation continued to evolve during the decade of the 1990s, Anthony (1994) suggested that recovery could become the principal aim of the field, a perspective that has increasingly expanded in scope and research (Davidson, Harding, & Spaniol, 2005). The idea that recovery was possible infused a new idealism about the possibilities for the rehabilitative support of people coping with serious mental illness. Recovery-based psychosocial rehabilitation establishes a framework for the practice of a new form of case management, one founded on the best consumer-centered traditions of the field.

Recovery within the context of psychosocial rehabilitation does not mean the person's return to a premorbid state, a view more suggestive of a medical than a rehabilitation model. Many people coping with psychiatric disability would say that their experience was so distressful and challenging that a "return" to the lives they led prior to the onset of their illnesses was not possible or even desirable. Many people who label themselves as "survivors" (to emphasize that they literally outlived horrific experiences and mistreatment) are mindful of how their identities were altered substantially by their negative personal experiences, ones induced by inappropriate or iatrogenic service responses and stigmatizing social reaction.

Recovery requires people coping with serious mental illness to contemplate and answer two questions that appear on face contradictory: How do I live with the illness and its consequences? How do I live without the illness? In answering the first question, people must address how they will respond to stress, symptoms, grief and loss, anger about injustice and deprivation, and the management of morale and positive outlook. In answering the second question, people will address setting a life direction, identifying new roles they want for themselves, obtaining enabling resources, and achieving a lifestyle that brings personal satisfaction and fulfillment.

Psychiatric disability can encapsulate individuals in networks that reinforce their identities as ill individuals and leave few (if any) other options for them to develop identities based on other conceptions of self. Helping people discover how to manage their situations while they learn how to emerge out of the illness, leave it behind, and reformulate their identities based on new

lifestyle choices they find satisfying together form the essence of recovery. Although practitioners may think of recovery as a discrete outcome, for many survivors, it is a process requiring a personal practice of a "lived experience" involving health promotion and the pursuit of personal meaning. A person's practice of recovery can demand vigilant self-management, self-help, and mutual support. It can require sanctuary, as well as opportunities to witness mistreatment or inadequate support and to provide support to others (Paynter, 1997).

Recovery can involve the creation of new identities based on personal transformation in which people overcome the psychological, behavioral, biological, and social consequences of illness and disability (Moxley & Washington, 2001). Social workers practicing recovery-based case management in psychosocial rehabilitation are mindful of the need to help clients focus on what recovery means for them. These practitioners refrain from defining recovery for recipients because they understand that people must come to learn what recovery means in the context of their own lived experience.

The personal process of defining recovery, exploring the outcomes and consequences of recovery, and practicing recovery can help individuals make decisions about how to reduce the centrality of serious mental illness in their lives. Overcoming the illness through the achievement of new roles and lifestyles that bring personal satisfaction, even though a person may need to learn to live with particular symptoms, gives recovery-based case management a transcendent quality (Washington & Moxley, 2001). To paraphrase Victor Frankl (2000), people learn to transcend their situations when they understand the meaning and direction their lives can take.

ASSUMPTIONS AND PROCESS OF PERSON-CENTERED RECOVERY-BASED CASE MANAGEMENT

Principal implications of a recovery orientation to case management are as follows.

1. Recovery-based case management values a nondirective approach in which practitioners collaborate with recipients to discover what recovery means to them and actualize supports that contribute to their realization of recovery.

2. The practice of recovery helps people dealing with serious mental illness gain control over each aspect of the case management service process. A basic assumption of this form of case management is that individuals coping with psychiatric disability often lose control of the service process because professionals come to dominate their lives as principal decision makers. Most people coping with serious mental illness use this control responsibly and typically select outcomes they find most personally relevant and pragmatic given their aims and desires. When freely chosen and realized by the client, these outcomes can produce personal fulfillment that, in turn, contributes to satisfaction as the person defines it. In choosing what outcomes to pursue, people are selecting how to invest their creative energies, giving recovery-based practice an existential flavor.
3. To establish a rehabilitation direction, a case manager who engages in a recovery assessment may work with an individual to answer an important existential question, one that the social, psychological, and biological experience of mental illness can undermine: "How will I direct my creative energies to find fulfillment in my life?" A recovery-based case management plan can help individuals identify the supports, experiences, and opportunities that will help them illuminate answers to this important question. Recovery-based case management will also help people address another important question: "What help do I need to develop and direct my creative energies?"
4. These two existential questions were never central to other forms of case management because these other forms assumed that the illness would be chronic and pervasive, and as a consequence, people needed only adequate or appropriate medical and social services. For recovery-based case managers, however, helping people find answers to these questions is crucial to the growth and development of recipients.
5. Recovery-based case management assumes an active consumer—that people coping with serious mental illness can and will reflect on what they experience, evaluate their experience, and make decisions to change the process, products, and outcomes of rehabilitative support. So recovery-based case managers collaborate with the people they

serve as active decision makers who want to stake out and achieve directions in which they find substantive importance.

6. Recovery-based case managers assume communities are repositories of a great number and variety of supports. In collaboration with the people they serve, case managers discover the ones that recipients find most relevant to the fulfillment of their aims.

CONCLUSION: AN EYE TO THE FUTURE

Shaping the case management in psychosocial rehabilitation will be forces emanating from how the field frames the paradigm of serious mental illness, organizes supports, and responds to the politics of mental health coverage within health care. The achievement of parity between health and mental health services will likely bring the care of serious mental illness into primary health care centers and clinics in which family practice physicians and other generalists are increasingly involved in medical management. New pharmaceutical and diagnostic approaches will likely equip such practitioners with more powerful tools for the management of the primary symptoms of serious mental illness.

Networks of care linking medical clinics to psychosocial rehabilitation options will place physicians in central referral roles and innovations in medical education will make these practitioners more mindful of the benefits inherent in combining medical care, social services, and psychosocial rehabilitation options. Parity itself will legitimate the provision of case management services that are outcome-focused and health-oriented in their aims. The further integration of serious mental illness into a neomedical model, one that emphasizes community-based care, health promotion, prevention, and cost-effectiveness (achieved by reducing relapse) can further legitimate a recovery framework within medical care and psychosocial rehabilitation, particularly as positive psychology becomes more dominant within models of care.

Enhanced medical care can assist recipients in considering the next steps in their wellness including a consideration of how best to advance their life satisfaction and quality of life. Feeling better physically and mentally can help recipients invest new found energy in planning their

living situations and investing in their realization of hopes and dreams. Here psychosocial rehabilitation can play an important role. Its distinctiveness and expertise lie in helping recipients move forward through the articulation of plans that recipients find relevant and meaningful. Thus, the future of case management in psychosocial rehabilitation is synergetic within a framework of positive psychology and strengths-based practice. Though it can stand alone, it is probably most potent when combined with other care approaches that incorporate a similar worldview.

108 Case Management and Child Welfare

Jannah H. Mather & Grafton H. Hull, Jr.

Case management, a process by which complex situations are managed by social workers, plays a major role in child welfare services today. Case management, as noted by Woodside and McClam (2013) is a creative and collaborative process, involving skills in assessment, communication, coordination, consulting, teaching, and modeling, resulting in positive outcomes for the agency (Commission for Case Manager Certification, 2009). Glissen and Green (2006a, b) estimate that some 3 million children receive child welfare and juvenile justice case management each year. In the field of social work, case management has grown from a vague definition regarding the organization of services for clients to the development of various models of practice incorporating specific theories, skills, and values. These elements are, in turn, dependent on the situation or field of practice in which social workers find themselves.

Rothman (1992) notes that case management in the child welfare service area began as a response to increased disorganization of families, growing numbers of divorces, and mounting abuse situations. These conditions created an environment in which children and families were in need of increased aid, and few programs could organize their services around these growing numbers. Case management was designed “to counter long-term problematic client conditions, and a community service system that was uncoordinated, ever shifting, and increasingly restrictive” (Rothman, 1992, p. 3). The consequences of these conditions produced a new service concept, one that Rothman says had two central functions: (1) providing individualized counseling services, and (2) linking clients to services and supports in both the formal and informal contexts of the client’s life.

In many ways, case management as just defined offered a generalized approach to intervening with clients in child welfare situations. In this definition, the child welfare case manager was expected to work with both the individual and relevant environmental conditions. The belief that case management could produce different results by structuring these processes in a standardized manner had considerable impact on child welfare programs. Child welfare workers could relate intimately with the concept of poorly operating community service systems as described by Rothman (1992). However, the question in case management that was most important to child welfare workers was: How effective are case management models for chronic and complex client systems? The evidence to date has been mixed. On the one hand, Burns, Phillips, and Wagner (2004) found that case managers frequently failed to recognize serious mental health needs of the children they served. Too often, children ended up in out-of-home placements that might have been prevented had case managers adequately screened children for mental health concerns. Treggeagle and Mason (2008) found that "case management did not result in relationships which consistently informed the service" (p. 391). Additionally, Dauber et al. (2012) found that intensive case management had minimal benefits. On the other hand, Glissen and Green (2006a) studied the experience of over 1,200 children needing specialized case management services. Their findings suggest that when the mental health needs of children are carefully assessed by their case managers and those services are provided, a substantial reduction in out-of-home placements occurs. Another study by the same authors noted that the organizational culture in which the case managers practiced had a major impact on how well these individuals performed their jobs (Glissen & Green, 2006b). Blair and Taylor (2006) found that case management services were crucial to and wanted by kinship caregivers of children placed outside the home. Blair et al. (2009) also found, "Most caregivers and their families possess significant strengths that can be used in a strengths-based approach to case management" (p. 431). Johnson and Wagner (2005) found that providing case managers with a structured decision-making tool significantly increased reunification and permanency planning of children in Michigan's foster care system.

Child welfare workers see case management as a strong response to the horrendous issues

surrounding foster care. As an essential component of permanency planning, case managers perform tasks and functions involved in negotiating and coordinating services, referring clients to agencies, using community services, managing visitations, and assisting families and children with the development of support services (Pecora, Whittaker, Maluccio, Barth, & Plotnick, 1992). As part of permanency planning, as well as other specific areas of service for families and children, case management is an integral component of child welfare practice. Specialized models of case management in child welfare have developed primarily as a response to families who are facing multiple challenges and consequently using many different, uncoordinated services, accompanied by a lack of follow-up regarding service outcomes. The focus of these initial models produced a planned method for following a family and child through the maze of services offered and accounting for the resources used. As the role of case management has become more important in child welfare, it has highlighted the need for a knowledge and skill base that reflects the specialized components of child welfare.

KNOWLEDGE AND SKILLS NEEDED IN CHILD WELFARE CASE MANAGEMENT

To produce models of case management practice appropriate to child welfare, delineation of a knowledge and skill base related to child welfare has been offered by several different authors (Mather, Lager, & Harris, 2007; Sallee & LeVine, 1999). The following areas have been seen as consistently relevant.

1. *Human development.* Knowledge of children, adults, families, agencies, and institutions. An ability to understand and apply interviewing skills, data collection assessment, planning, intervention, referral, evaluation, termination, and recording. Knowledge of and competence to work with culturally diverse children and families through a value system that is open and reflective.
2. *Child welfare practice.* Basic knowledge of the mission of child welfare services and child welfare policies and practices. Understanding of outcome data regarding the application of agency, state, and federal policies on families and children.

3. *Agency functioning.* Knowledge of administrative and structural issues affecting the operation of the child welfare agency and the employees who work within that agency. Understanding how agency functioning affects the family and child and the infrastructure needed to create change.
4. *Interdisciplinary understanding and collaboration with professionals from multiple disciplines.* Understanding and recognition of the importance of multiple disciplines in the delivery of services. Knowledge of how to access services from a diversity of disciplines to ensure positive case outcomes. Knowledge of medical and mental health issues, educational aspects, and judicial rules and laws. The understanding of how to integrate multiple disciplines into the case management process for the child and family.
5. *Holistic practice perspective.* Recognizing that the services for the client must be addressed through a holistic view of the person within his/her family. This perspective takes into account the health, mental health, educational, and spiritual aspects of the person within the environment. Much of the knowledge and skill needed in case management is incorporated into the basic education of all social workers. These include social work roles, purposes, values, and ethics. Mather et al. (2007) note that case managers in child welfare must:
 - Engage all systems and individuals to be involved in a mutual and positive manner
 - Quickly establish the roles of the various systems within case management
 - Work together toward a mutual treatment plan
 - Contract for responsibilities in the process and case
 - Meet on a regular basis to review goals and outcomes
 - Agree with all systems involved on time for termination
 - Always evaluate the case management process as well as the outcome.

Vourlekis and Greene (1992) added to the knowledge base in case management and produced a definition of processes for the social worker. They noted the following characteristics:

1. A trusting and enabling worker–client relationship
2. A focus on understanding the person in the environment
3. Provision of a continuum of care to clients with complex multiple problems
4. Intervening to ameliorate the emotional problems causing a loss of function
5. Using the skills of brokering and advocacy in service delivery
6. Targeting clients who require a range of community-based and long-term services
7. Providing services in the least restrictive environment
8. Using assessment of the client’s functioning capacity and support network
9. Affirming the social work values of self-determination, dignity, and mutual responsibility.

Though these perspectives provide an understanding of the knowledge and skill base, as well as the processes that a child welfare worker must employ to engage in effective case management practice, the issue of the underlying goals of system management of the case cannot be overlooked.

DIVERGENT PARADIGMS

1. Different underlying goals in case management appear to be related to the field of practice in which they are used (child welfare, disabilities, aging, etc.). The knowledge (or lack thereof) of these goals often drives the outcome of the case management model. These goals can be part of one or both of two demanding paradigms from which case management developed. Moxley (1996) notes that case management can be either systems-driven or consumer-driven (pp. 15–20). *Systems-driven case management* is in direct response to the call for efficiency and accountability in social welfare practice, whereas *consumer-driven case management* focuses on providing the best organized practice for clients in complex and chronic situations. From these differing paradigms come a variety of case management models that resemble one another in some ways but can never really be conceptualized in a broader, more standardized perspective of practice.

The relationship of this discussion to child welfare becomes important when the emphasis in case management models is not based on both underlying paradigms but rather on one or the other. In the public child welfare system, a focus that looks only at efficiency and accountability is not necessarily helpful to the family and child, whereas a model of case management that focuses only on client needs ignores the realities of the system and will not survive within this setting. The differences in these underlying goals can be seen in the identification of steps applied in case management. Steps in case management, such as (1) problem identification; (2) formulation of goals and objectives; (3) contracting an agreement; (4) implementation and monitoring; and (5) case closure, reflect more of a systems-driven approach to case management. Steps such as (1) outreach, referral, client identification, and engagement; (2) a biopsychosocial assessment of the client; (3) the development of a service plan; (4) implementation of the service plan; (5) coordination and monitoring of service delivery; and (6) advocacy on behalf of the family and child denote more of a consumer-driven base of practice. Although neither of these models of case management practice appears to be based on specific underlying paradigms, the terminology in each reflects differing foci. In child welfare, the lack of a specific model of practice that incorporates both paradigms will not provide the best services needed, nor will it reflect the best model of practice for case management.

MODELS OF CHILD WELFARE CASE MANAGEMENT

The following four models of case management practice provide examples of how a solid knowledge and skill base along with a focus on both systems-driven and consumer-driven paradigms can produce effective models.

Community-based Case Management

Community-based case management is a model of practice that has proven effective within the child welfare setting when the issues being addressed involve many different community systems and agencies. For example, The Homebuilders Model of intensive family preservation services (Booth & Leavitt, 2012) found that intensive, time-limited, home- and

community-based family preservation services met the goals of clinical objectives as well as case management needs. Community models were first identified during the early 1970s as part of a reform promoted by the National Institute of Mental Health for the support of persons with severe mental illness living in the community. This model was later expanded to be more inclusive of other populations in need. The community model has always included case management, but more clearly began to be defined as a model of its own when case management began to establish its own practices and designs. There is general agreement among authors and practitioners that the responsibilities of case management in the community model include the assessment of client needs, referral to services, assurance by case managers that clients have access to services, service coordination, analysis of whether these services are meeting client goals, and the continuing provision and accountability of the services within the community.

Strength-based Case Management

Strength-based case management (East, 1999) is another model that provides a perspective of both the system and consumer-driven paradigms. In strengths-based case management the underlying premise for child welfare workers is that the family and child have the skills and talents to make changes in their lives. This model provides an opportunity for families to focus on their strengths rather than their deficits. A project focused on providing services to grandparents raising their grandchildren found that when case management services focused on the grandparents' strengths and natural skills, the services were more readily utilized and fostered a sense of independence and self-assurance.

Strength-based case management is strongly linked to the strength-based or empowering approach of social work practice. In this model, clients or client systems are empowered to make changes in their own lives through their own goals and decisions. In this model of case management, control of the situation is placed in the client's hands. A study by Blair et al. (2009) found that most caregivers and their families have enormous strengths that can be used in a strength-based approach. Huebner, Jones, Miller, Customer, and Critchfield (2006) found similar positive outcomes when this model was used. Although many child welfare

clients have little control over their involvement with services, the greater opportunity for choice given to them, the more likely they will involve themselves in services and have positive outcomes.

Integrated Case Management

Integrated case management involves the participation of various professions in providing services to a client through the organization of those services around the client's needs, rather than those of professionals. Cigno and Gore (1999) provide an example of an integrated case management approach in their study of a multi-agency children's center. This center provided the opportunity for each family and child to receive services from various agencies and professions within the same facility. The results of the study indicate that clients who aid in the management of their own services, work closely with a variety of agencies and professionals, and have a more holistic approach given to their case, feel more positive about the results.

Hubberstey (2001) found similar outcomes looking at integrated case management services in her study of the Canadian child welfare system. She concludes:

"When the focus is on the well-being of the child, parents can learn to set aside their own disagreements with each other or with their worker in order to achieve something positive for their child(ren);

Clients appreciate the more holistic approach that emphasizes their strengths and capacities, not just their problems and deficits;

By working together, parents and practitioners can develop more appreciation for what each has to offer and for each other's roles;

Through their ongoing participation, parents acquire new skills, such as problem-solving, anger management and priority setting that they can apply to other areas of their lives;

When everyone has a written copy of the service/care plan, there is a greater likelihood of successful implementation of the service/care plan;

Allocation of resources is more realistic and better suited to client needs." (p. 96)

In a related study, Christensen and Todahl (1999) found case management was used by different disciplines in relapse prevention for multiple cyclical reluctant clients. The study identified how case management and planning could be used by a group of various professionals

to target specific behaviors and reduce relapse for individual clients. In child welfare services, case management provides a model of care for not only the child and family but also for the variety of professionals who work in the service continuum.

Intensive Case Management

Intensive case management (ICM) is a model of practice that involves the social worker's intervention in a very concentrated way over a four to eight week period. ICM is used in "working with families to prevent children from being placed in foster care" (Frankel & Gelman, 2012, p. 43). The idea behind ICM is that clients are immediately connected with all community resources and the case manager stabilizes the client as quickly as possible. This requires lower caseloads, exhaustive knowledge of community services, and a skill of coordinating services in a short matter of time. It is reflective of both paradigms through its rigorous use of systems and its intensive engagement of clients.

TRAUMA-INFORMED PRACTICE

Trauma informed practice is now being used across the country when intervening in child welfare situations. Although based primarily in treatment, it is having an impact on case management within child welfare. The National Child Traumatic Stress Network, in conjunction with other organizations, has developed a Training Toolkit (2008) that can assist case managers in approaching their child welfare cases with a comprehensive view. Trauma informed practice focuses on the knowledge, skills, and values needed when working with children with traumatic stress. These components are then used to "support children's safety, permanency, and wellbeing through case analysis" (NCTSN, p. 1). Case analysis then uses the systems and consumer paradigms to place trauma factors at their core.

RECOMMENDATIONS

The material developed related to case management suggests that it can produce both effective processes and outcomes. In child welfare services, a model must be definitive as to its knowledge and skill base. Beyond this, it then becomes important

to study and understand which models are most effective and with which populations. The four models presented herein all have merits for child welfare practice and yet appear to have decided differences according to their focus. As the evidence base for case management services with different populations increases, it will be possible to identify those practice approaches showing the greatest promise. Social workers will increasingly consult resources (such as the Campbell Collaborative) to identify effective interventions with specific client populations. This will be critical to social workers committed to interventions most likely to produce positive outcomes. At the same time, as we learn that our similarities outweigh our differences, there will be increased attention to models and applications drawn from international research.

109 Case Management with Substance-abusing Clients

W. Patrick Sullivan

Among the host of social ills that confront American society, most would agree that alcohol and drug abuse remains a prime concern. Mark, Levit, Vandivert-Warren, Coffey, and Buck (2007) estimate that a staggering 9.4% of the U.S. population suffers from a substance abuse disorder. As a result, the price tag for treatment alone reached \$20.7 billion in 2003. When direct and indirect costs are considered, the fiscal impact of substance abuse, by any measure, is staggering.

Simply put, substance abuse is a major public policy issue and a condition that impacts service delivery and criminal justice systems, the workplace, and the day-to-day lives of citizens. Given these issues, it is not surprising that the value and effectiveness of treatment services are under constant scrutiny. Indeed, nearly two decades ago, Barber (1994) argued “by any set of performance indicators, it is hard to resist the conclusion that our current treatment methods are not working” (p. 521). Undoubtedly, this sentiment remains in force today. For this reason alone, the search for innovative methods to improve performance is ongoing. Alcohol and drug abuse is commonly viewed as a chronic, relapsing condition. Success, it follows, comes only after years of hard lessons, increased self-awareness, available natural supports, and the use of appropriate treatment services. Recovery, as research and personal accounts can attest, is not easy.

Recent developments in health care policy offer the possibility that the view of substance abuse and treatment may shift, and thereby alter the landscape of treatment services. Understanding substance abuse as an episodic personal problem

leads to the development of time-limited and acute models of care. In contrast, understanding substance abuse as a chronic *health* condition suggests the need for new long-term approaches that emphasize continuing care, and underscores the importance of services that target the whole person. Additionally, when providers take clinical *and* fiscal responsibility for an entire population of enrollees they must remain sensitive to the total cost of care, prompting the search for less expensive alternatives to traditional practice while maximizing positive outcomes. Within this evolving social policy context it is likely that case management will no longer be treated as an auxiliary or novel service, but rather a primary component in an increasingly integrated health care environment.

THE ROLE OF CASE MANAGEMENT IN ALCOHOL AND DRUG TREATMENT

Over the last 20 years, case management became a standard service offering in comprehensive treatment systems (Benshoff & Janikowski, 2000; R. Rapp, 1998; Siegal & Rapp, 1996; Sullivan, Wolk, & Hartmann, 1992; Vanderplasschen, Rapp, Wolf, & Broekaert, 2004). There are many definitions of case management and a plethora of case management models. Darnell (2013) posits that in the era of the Affordable Care Act, two emerging case management roles are navigator and assister. Yet, for our purposes case management is described as a direct service function that involves skill in assessment, counseling, teaching, modeling, and advocacy that aims to enhance the social functioning of clients. This service is

poised to amplify traditional treatment offerings by impacting those facets of consumers' lives that account for much human misery—and the lion's share of total costs incurred.

Therefore, the rise of case management in drug and alcohol treatment is consistent with efforts to develop more comprehensive service programs that address all aspects of a client's life (Evenson, Binner, Cho, Schicht, & Topolski, 1998; Humphreys & Tucker, 2002; Institute of Medicine, 1990; McLellan, Weinstein, Shen, Kendig, & Levine 2005). Indeed, the growing popularity of case management also signaled the adoption of a different view of addiction and, hence, a new approach to treatment. Vanderplasschen and associates (2004) argue that case management became a viable service as substance abuse problems became "increasingly recognized as multifaceted, chronic and relapsing conditions that required a comprehensive and continuous approach" (p. 913).

Current policy initiatives, culminating in the passage of the Patient Protection and Accountable Care Act establish a framework to move addiction services into a chronic care and recovery oriented framework. Notable among these trends is the rise of Accountable Care Organizations, Patient Centered Medical Homes, and the movement to integrate behavioral and physical health care (see Druss & Maurer, 2010; Pating, Miller, Gpolderud, Martin, & Ziedonis, 2012). Each of these service delivery models rely on some form of case management. Many of these initiatives feature bundled payments methods that will afford providers more flexibility than a fee-for-service approach, while the projected expansion of Medicaid should stimulate increased use of treatment services and provide a reimbursement mechanism for case management (Barry & Huskamp, 2011; Busch, Meara, Huskamp, & Barry, 2013).

McKay and Hiller-Sturmhofel (2011), endorse the adoption of the chronic care model for substance abuse, noting that long-term interventions, particularly those that make a concerted effort to reach out and engage people in treatment, enjoy greater success. Accordingly, case management is a vital ingredient in a continuous and integrated care model.

Noel (2006) argues that the "purpose of a case management program determines the focus of case management activities" (p. 312). Nevertheless, among a range of choices the strengths-model has emerged as a popular choice in alcohol and drug programs (Rapp, 2006; Rapp & Goscha, 2006; Sullivan, 1996; Sullivan et al.,

1992). This model is predicated on the principle that behavior is partly influenced by the resources available to people (C. Rapp, 1998; Rapp & Goscha, 2006). Here the definition of resources is broadly construed, targeting the availability of supportive friends, family, recreational activities, a stable residence, and meaningful activities, including work and education. The ability of case managers, working alongside consumers to secure these resources, is posited to improve the effectiveness of treatment. Indeed, a review of outcome research indicates that factors associated with social stability improve the resilience of the treatment effect (Sullivan et al., 1992). Barber (1994) also observes that "the best predictors of treatment success are all social factors" (p. 529).

Unquestionably these observations can be criticized on a number of fronts, particularly given the inability of such research to ascertain the direction of causality. Certainly we would expect people who are clean and sober to perform better socially. Nonetheless, it still stands that case management services geared to address the problems in living faced by consumers, regardless of the nature of the association, can be an important addition to the traditional array of services.

THE PRACTICE OF CASE MANAGEMENT

The practice of strengths-based case management follows the common template that guides most intervention in human services. The difference in strengths-based case management is reflected in the points of emphasis, the nature of the professional–consumer relationship, and the locus of care.

Assessment

Standard assessment procedures gauge such factors as types of substances abused, the frequency of use, and other measures that ascertain physical and emotional dependence. In the strengths model, assessment is seen as an ongoing activity that focuses squarely on consumer functioning, both past and present, in key life domains, including work, leisure time, health, finances, relationships, and living arrangements; specific assessment instruments have been designed for this purpose (Rapp & Goscha, 2006).

Given the impress of substance use, it presents little challenge to decipher the presence of difficulties and uncover the litany of failures that have marked the life of many consumers. The task from this perspective is different. Here, the purpose is to also expose areas of success, both past and present, and support or rekindle interests that the consumer may still hold. Hence, the professional must look behind the malady and dysfunction to see areas of health and strength, for these are the building blocks for the work to follow.

Goal and Case Planning

The process of strengths discovery allows one to view the client as a unique individual, not simply a typical drug abuser or an alcoholic. The assessment process should reveal the whole person and their specific life goals, dreams, and aspirations. With the strengths assessment as a guide, the work phase begins, but with one important proviso: the consumer is viewed as the director of the process.

A vexing problem in substance abuse treatment is that for recovery to begin, individuals must suspend activities that while problematic, ordered their day, provided some purpose, and offered a level of gratification. Furthermore, common treatment programs, though perhaps well grounded, are rarely based on consumer choice. In the strengths model, consumers identify the goals important to them; consistent with the functions of case management, these goals are tied to the key life domains addressed in the assessment process.

The process described here is rarely linear. Consumers often fail to follow through or suggest overall goals that may be beyond their current capacity. Skilled case managers are adept at helping clients break even the largest and seemingly the most unrealistic goals into a series of manageable, measurable, and documented steps. This process provides a model for addressing life problems in a proactive, organized, and incremental fashion—and learning this skill alone can help consumers avoid relapse when life demands overwhelm them.

Resource Acquisition

If success and recovery are functions of the resources available to people, then it follows that a key function of case management, in

conjunction with consumers, is to identify and secure the resources needed to realize case goals.

The development of case goals, and ultimately the resources that are targeted in the care plan, should flow logically from the strengths assessment. This phase of helping requires a measure of creativity and “out-of-the-box thinking.” Often professional views of resources are restricted to those specialty services and providers that constitute the human service network. Case managers operating from the strengths model view the community as an unlimited source of resources for consumers preferring to access those supports and services used by all citizens.

Aggressive Outreach

The ability of case managers to be successful in the art of resource acquisition and helping consumers realize their goals pivots on aggressive outreach. Creative case planning requires managers who are keenly aware of the formal and informal resources a community offers, and this is best learned while “on the street.” These case managers develop relationships with employers, landlords, recreation directors, and other gatekeepers to those nontraditional resources vital to true recovery.

The ability of a case manager to observe consumers in real-world settings also provides insights on what life is like in their host environment. For example, case managers can uncover problems that consumers have heretofore masked, such as illiteracy, while simultaneously providing a glimpse of the strengths individuals possess. By remaining in constant contact with consumers, the case manager can detect signs of impending difficulties and the possibility of relapse.

The natural environment is also the most appropriate site for the consumer to try the skills learned in treatment settings, be it the will to resist contact with troublesome actors or tangible items, like learning to ride the bus or hold a job.

IMPACT OF CASE MANAGEMENT

As case management grows in popularity, there is more urgency to assess the efficacy of this service. One pioneer in this area is the Wright State University School of Medicine. Their initial work underscored the important role of case management in improving treatment retention and

engagement (R. Rapp, 1998). This remains one of the most robust findings in case management services for those facing addiction (Kim, Saitz, Cheng, Winter, Witas, & Samet, 2011; Krupski, Campbell, Joesch, Lucenko, & Roy-Byrne, 2009; McLellan et al., 2005; Morgenstern, Bianchard, McCrady, McVeigh, & Morgan, 2006; Soson & Durkin, 2007; Vanderplasschen et al., 2004; Vanderplasschen, Rapp, Wolf, & Broekaert, 2007; Winn, Shealy, Kropp, Felkins-Dohm, Gonzales-Nolas, & Francis, 2013). The importance of this outcome cannot be minimized, because retention is one of the key variables in overall treatment success is a key mediating variable in a wide array of important client goals from abstinence to employment (Hartmann, Wolk, & Sullivan, 1993; Morgenstern et al., 2009; Rapp, 2006; Vanderplasschen et al., 2007), and can impact the cost of care by reducing the necessity for more intensive services and/or emergency care (Kirk, Di Leo, Rehmer, Moy, & Davidson, 2013; Kumar & Klein, 2013; McLellan et al., 2005).

The ability to engage and retain individuals in treatment is a particularly powerful outcome, given that case management appears to be useful in a wide range of settings and populations including those who are homeless (Soson & Durkin, 2007), veterans (Winn et al., 2013), individuals in methadone maintenance programs (Coviello, Zanis, Wesnoski, & Alterman, 2006), women applying for or involved in public assistance (Morgenstern et al., 2009) and adolescents (Noel, 2006).

A consistent finding in studies of strengths-based case management has been the success of the goal planning method. The results derived from this method, as demonstrated in a host of settings and with a variety of clientele, are admirable, with goal attainment rates consistently around 70% or higher across life domains (C. Rapp, 1998; Rapp & Goscha, 2006). This positive outcome appears to hold in alcohol and drug treatment (R. Rapp, 1998, 2006).

For integrated health care to be efficacious, early detection and treatment of substance abuse problems is a necessity. Individuals present with substance abuse issues in every social service setting, and in particular, primary medical care. The goal, as Pating, Miller, Gpolderud, Martin and Ziedonis (2013) suggest, is that there should be no wrong door for a person to receive needed care. Likewise, once a substance abuse problem is identified, engagement and retention in treatment is

critical to good outcomes. Engaged clients are less likely to rely on high-end care, a vital issue to providers operating in an at-risk or shared risk fiscal environment. Given the impact of case management in these areas, there appears to be a robust future for case and care management.

CHALLENGES AND CONTROVERSIES

Though the rationale for case management in alcohol and drug treatment may be evident, the introduction and implementation of the services faces a number of stern challenges. For many years, the disease model of alcohol and drug abuse has shaped our understanding of this problem and the treatment designed to help. Case management practice can be viewed as at odds with the disease model, both conceptually and in practice. Much of the work of case managers, particularly resource acquisition and relapse prevention, can be viewed by disease model adherents as professional enabling (Sullivan, Hartmann, Dillon, & Wolk, 1994). From this standpoint, the case manager protects clients from the consequences of their actions, thus delaying, not expediting, recovery. These differing viewpoints can dramatically impact how case management services are accepted and implemented. It is not uncommon for staff in treatment programs to have experienced addiction personally and to have benefited from classic treatment methods. In contrast, case management positions may be filled by those holding college degrees but without direct experience with substance abuse. Consequently, when case management services are introduced to a traditional treatment agency, a clash of cultures may ensue. For case management services to be seamlessly introduced in many settings requires strong leadership, particularly at the middle management level. In truth, the entire substance abuse treatment world may be at the point of a sea change, with an increased emphasis on credentials and the adoption of practices and procedures more akin to the world of medicine on the horizon (Roy & Miller, 2012).

It also remains difficult to untangle the respective contribution of particular models of case management on client outcomes apart from the potential power of the basic case management relationship. In fact, successful execution of the role may mimic what has been referred to in therapy circles as the *real relationship* (Angel & Mahoney, 2007; Gelso et al., 2005). Case

managers work alongside consumers in day-to-day situations and on basic life problems. They are there when clients succeed and fail. Case managers serve as advocates, coaches, cheerleaders, and the person who points out how alcohol and drug use impedes progress toward cherished goals. Clearly, case managers become key persons in the lives of those struggling with recovery, and first-person accounts affirm this (Brun & Rapp, 2001). Boundaries are still important and must always be monitored carefully.

It is also obvious that by virtue of the addiction process and/or the necessities of survival, denial and deceit are interpersonal issues confronted by professional helpers on a regular basis. In classic treatment, confrontation is used to counter these issues when they arise. However, case management practice is predicated on professional–client relationships marked by partnership and trust. Can this apparent dilemma be resolved? Some argue that the success of strengths-based practice in addiction treatment is inextricably tied to the capability of case managers to forge a mentoring relationship with consumers that is characterized by genuineness and warmth (see Brun & Rapp, 2001; Rapp & Goscha, 2006).

Although case management has been used effectively in a wide range of practice settings, there are specific concerns germane to addiction programs. Many clients in treatment have extensive criminal backgrounds and a history of failed treatments. Taking advocacy roles in such areas as employment and housing, for example, comes with some risk. Key issues to consider are the selection of clients for case management and the timing of services. To date there appears to be no prevailing model to suggest which consumers can benefit from case management or for whom it is contraindicated (Rapp, 1998; Sullivan & Maloney, 1992).

However, one large question continues to loom over the field. Is case management effective? Although there is some evidence that case management directly improves client outcomes in addiction services, the results are, at best, modest (see Gurewich, Sirkin, & Shepard, 2012; Hall et al., 2009). Thus, it is dangerous to oversell the power of case management. Vanderplasschen et al. (2004), drawing from an extensive review of outcome studies, argue that “case management for substance use disorders is no panacea, but it positively affects the delivery of services that can help stabilize or improve an individual’s complex situation” (p. 920). Therefore, case management is best conceptualized as an important aspect of a

well-integrated and organized system of care—not as a standalone service. In many ways, the introduction of case management is consistent with the evolution of drug and alcohol treatment. If substance abuse represents a long-term and relapsing condition, an acute model is inappropriate. Therefore, the true impact of this method may be assessed only in the long run and within the context of the system in which it is embedded (Saleh, Vaughn, Fuortes, Uden-Holmen, & Hall, 2006). To date, longitudinal studies that measure the impact of case management in addiction service are rare. Future research must explore the effectiveness of case management against other standard offerings in addiction programming, as well as the independent contribution the service makes.

110 Case Management with Older Adults

Daniel S. Gardner & Dina Zempsky

INTRODUCTION AND BACKGROUND

Medical and public health advances over the last half-century have reduced the burden of disease, extended life expectancy, and significantly accelerated the aging of the population. In 2011, over 41 million people—approximately 13% of Americans—were aged 65 years or older. By 2050, this number is expected to more than double to 84 million, representing over 20% of the population (U.S. Census Bureau, 2012). Although older adults are living longer, healthier lives, over two-thirds live with chronic illnesses or conditions such as diabetes, cancer, cardiovascular disease, depression, or dementia (Centers for Disease Control and Prevention [CDC], 2013).

The growing prevalence of chronic and disabling conditions in later life poses considerable challenges for older adults, their families, and caregivers. Chronic conditions typically require

ongoing medical monitoring and care, diminish quality-of-life, and increase disability, medication use, hospitalizations, and mortality in older adults (Benjamin, 2010). Over one-third of elders report some type of disability (i.e., difficulties with walking, hearing, vision, or self-care) that requires assistance from others in order to live independently (Administration on Aging, 2012). Over 44 million Americans—representing 19% of all adults—care for someone aged 50 years or older with a chronic, disabling condition. An estimated 15 million adults, for example, care for a family member living with Alzheimer’s disease or other dementias (National Alliance for Caregivers/American Association of Retired Persons [NAC/AARP], 2012).

The costs associated with these changes are substantial. In 2010 approximately 93% of all Medicare fee-for-service spending on beneficiaries, or \$279 billion, was spent on caring for chronically

ill elders (Centers for Medicare and Medicaid Services [CMS], 2012). Informal caregiving costs family caregivers and employers approximately \$34 billion each year (MetLife, 2010); the economic value of this uncompensated care is estimated to be over \$450 billion (Feinberg et al., 2011). In response to ever-increasing expenditures, Congress passed the Omnibus Budget Reconciliation Act of 1981 (Public Law no. 97-35, Sec. 2176), authorizing the funding of demonstration projects under the Medicaid Home and Community-based Waiver that integrate health care, personal care, and case management for community-dwelling older adults and people living with disabilities who might otherwise require institutionalization (Duckett & Guy, 2000; Austin & McClelland, 2009). To further support older adults in the community and control Medicare and Medicaid costs, Title III of the Older Americans Act funds geriatric case management programs across the country through the Aging Services Network (i.e., State Units on Aging and Area Agencies on Aging).

Despite the complex health and service needs of older adults, home and community-based long-term services and supports are often fragmented and difficult to access (Naleppa, 2006). Geriatric case management responds to these barriers by providing client-centered assessment and care planning, facilitating access to critical resources, and coordinating health, mental health, and long-term services and supports that enhance quality of life and promote the health and functional independence of community-dwelling elders. The geriatric case manager's specific role is shaped by agency function (e.g., assisting with financial, housing, health, nutritional, or mental health needs), care setting, and population served (Naleppa, 2006; Wodarski & Williams-Hayes, 2003). The case manager's professional discipline (e.g., social work, nursing, or rehabilitative medicine) and expertise further frames the focus of practice. An array of case management approaches has emerged in the past several decades, including care coordination, patient navigation, and transitional care models. While these terms are often used interchangeably, they have distinct definitions, goals, and functions. Two common goals of case management models—improving the quality of client care and containing costs through service coordination—can, at times, conflict with each other and pose additional barriers to the development of appropriate care plans (Gallagher et al., 2002; Wodarsky & Williams-Hayes, 2003).

Case management has been a core method in clinical social work dating back to the roots of the profession in the late nineteenth century (Frankel & Gelman, 1998; National Association of Social Workers [NASW], 2013). Social work case management is grounded in professional values of enhancing individual autonomy and dignity, advancing social justice, and effecting change in both micro- and macro-level systems (NASW, 2013). Although their goals and functions vary by setting, social work case managers share a commitment to client- and family-centered practice, maintain a strengths perspective, and attend to the sociocultural and relational contexts of individual and social functioning (Austin & McClelland, 2009; Darnell, 2013).

COMPONENTS OF GERIATRIC CASE MANAGEMENT

Geriatric case managers work independently or as members of interdisciplinary teams in a variety of institutional, home, and community based settings—including Aging Service Network agencies, hospitals, home health care organizations, long-term care institutions, and other public or private human service organizations (Naleppa, 2006). Recently, private case management with older adults—often referred to as geriatric care management—has emerged to meet the growing demand of families seeking information, assistance, and advocacy around accessing resources, coordinating services, and making current and long-term care decisions (Morano & Morano, 2006).

Although operationalized differently by practice setting and professional background, geriatric case managers share a set of core service components that include:

- 1) *Community outreach*: Identifying and targeting at-risk older adults in the community who lack access to case management services or community resources and supports.
- 2) *Comprehensive geriatric assessment*: Conducting thorough, multidimensional assessments of older adults and their home environments. Being a core service component of all case management with older adults, comprehensive geriatric assessment (CGA) is the foundation of a care plan that addresses the older client's

unique needs, strengths, and challenges. CGA addresses the following domains:

- **Activities of Daily Living (ADLs):** Ability to perform daily self-care (i.e., bathing, toileting, ambulating) within one's place of residence. ADLs represent a well-documented measure of client's functional status and capacity to live independently.
- **Instrumental Activities of Daily Living (IADLs):** Tasks that, when performed independently, enable the adult to live in the community. Includes shopping, housekeeping, and medication management.
- **Pharmacological profile:** Medication list (prescription and over-the-counter) and daily protocols. Helps identify and address gaps in care, drug interactions, adverse effects, medication adherence, and use of herbal remedies or alternative treatments.
- **Cognitive, psychological, and psychiatric functioning:** Diagnostic work-up, including evaluation of mental status, memory loss, signs of delirium or dementia, impairment in judgment or decision making. Includes assessing client's psychological state, mental health history, signs of depression or anxiety, and interpersonal functioning, as well as making referrals for further evaluation and treatment when indicated.
- **Home environment:** Adequacy of living situation and extent of person:environment fit. Assessment of home safety, risk of falls, adequate nutrition and hygiene. Assessment of need for in-home supports or alternative living situation.
- **Long-term care planning and legal concerns:** Client's care preferences and goals, including views about medical treatment, settings of care, and the decision-making process. Facilitating client–family and client–provider conversations about care preferences and advance care planning, client income and assets, and securing legal assistance with wills, power of attorney, guardianship, and advanced directives.
- **Family/caregiver supports:** Client's social functioning, social and familial supports, and family functioning. Identifying

social isolation and loneliness, and assessing whether client has adequate caregiving and other supports to live independently.

- 3) *Benefits and entitlement navigation:* Educating older adults and their families about the continuum of community-based services, and helping them navigate complex health systems and benefits (e.g., Medicare and Medicaid, assistance with income subsidies, housing, and utilities). Identifying and accessing personal care services, assistance with chores, homemaking, medical care and chronic illness management, nutritional services and home-delivered meals programs, transportation services and escorting older clients to appointments, financial management and budgeting, and legal assistance.
- 4) *Advocacy and interagency coordination:* Facilitating communication between the institutions and systems with which clients interface, to ensure continuity of care and address lack of clear communication or care coordination. Plan, facilitate, and monitor care transitions, for example, between hospital and home, home and assisted living, or hospital and nursing home.

PRACTICE CONSIDERATIONS AND ESSENTIAL COMPETENCIES

Research evaluating the effectiveness of geriatric case management has been limited by the lack of shared definitions, goals, and outcomes of different case management models (Austin & McClelland, 2009; Peikes et al., 2009). Although there is evidence that case management reduces hospitalizations and health care costs for frail elders, these findings have not been consistent. A recent survey of Medicare-funded demonstration programs, for example, found that only 3 of 15 care coordination projects were successful in reducing re-hospitalization rates (Peikes et al., 2009). The lack of evidence may reflect the high degree of need among case management-eligible elders (Ferry & Abramson, 2006). Successful case management programs share several components, including targeted outreach to at-risk elders in the community (e.g., those who were recently hospitalized or had multiple emergency room visits), personal contact (including face-to-face and telephone) between the case manager

and client, and the use of interdisciplinary teams where nurses focus on health promotion and illness management, and social workers facilitate and coordinate supportive services and resources (Brown et al., 2012).

Based on established geriatric competencies in social work (Naito-Chan et al., 2005), the authors consider the following knowledge, skills, and attitudes essential to working effectively with older adults and their families:

- 1) *Bio-psychosocial and spiritual needs of older adults:* Knowledge of age-related physical, functional, and cognitive changes, and the impact of comorbid chronic illnesses, geriatric syndromes, frailty, and medication effects in later life. Understanding developmental concerns and tasks of older adults and family caregivers, normative life events and stressors (e.g., retirement, widowhood, and multiple losses), and family life cycle development is essential. Awareness of cultural differences regarding aging, and understanding the bio-psychosocial and economic effects of institutional oppression and disparities on African American; Latino; immigrant; lesbian, gay, bisexual, and transgender (LGBT); and poor and economically insecure elders.
- 2) *Comprehensive geriatric assessment:* Skills in conducting initial and ongoing assessments, identifying at-risk clients, prioritizing needs, and evaluating cognitive and functional status, person:environment fit, and the home environment. Familiarity with standardized measures of geriatric health, mental health, and physical functioning, and skills in developing care plans with measurable, mutually established goals.
- 3) *Continuum of community-based supports:* Familiarity with range of supportive services for older adults, from home and community-based health and social services to institutional long-term care settings, and up-to-date eligibility requirements for accessing benefits (e.g., income supports, health insurance, and services). Skills in negotiating multiple complex support systems (i.e., medical, long-term care, housing), and advocating to best meet the needs of vulnerable older adults and their families.
- 4) *Client and family-centered interventions:* Skills in providing crisis intervention

when needed, and ensuring access to short- and long-term psychotherapeutic and psychopharmacological treatment for older adults coping with stressful life events, or mental health or substance use disorders.

Knowledge of evidence-based interventions for older adults (e.g., cognitive-behavioral and interpersonal therapy for elders with depression; Functional Adaptation Skills Training [FAST] for elders with severe mental illness) and caregivers. Family treatment skills in working with family members and caregivers to improve client supports, alleviate caregiver burden, and access supportive services.

- 5) *Interdisciplinary team care:* Valuing interdisciplinary collaboration as an essential component of efforts to assess the needs and enhance the health and well-being of older adults and their families (Shortell, 2004). Skills in collaboration, advocacy, and leadership with other team members or supportive contacts around meeting the bio-psychosocial and spiritual needs of older clients and their family caregivers. Skills in educating and advocating on behalf of clients in order to ensure access to essential supportive services.

As is clear in the case of Miss A. (see Box 110.1), engaging with older clients and establishing a good working relationship is critical for geriatric case managers. Older adults are often wary of “strangers” and choose to interact with smaller circles of friends and family (Carstensen, Isaacowitz, & Charles, 1999; Lang, 2000). Some elders present with psychosocial concerns that can create barriers to service, such as prior mental and behavioral health concerns, a history of difficulties with service providers, or family conflict and dysfunction (Ferry & Abramson, 2005). Geriatric case managers must demonstrate authentic empathy and respect for client autonomy, take the time to establish trust, and be persistent while respecting boundaries in order to develop successful working alliances with older case management clients.

THE CHANGING CONTEXT

Over the past several decades, the trend toward community-based services, consumer direction,

Box 110.1 Case Narrative: Miss A.

Miss A. is an 81-year-old African-American woman who lives alone with her beloved cat, “Pumpkin,” in a tidy studio apartment in East Harlem, New York. Miss A. describes herself as “a loner,” only visiting with a friend once a week and occasionally hanging-out at the diner downstairs. Miss A. is diagnosed with osteoarthritis, obesity, hypotension, depression, and poor mobility. She is very independent, wishes to continue living alone, is deeply untrusting and suspicious of strangers, and somewhat resistant to accepting outside assistance. At the time of her referral, she agreed to accept a visit by a case manager only because it is required for her to participate in a home-delivered meals program. Her case manager, a 24-year old white woman named Rachel, enrolled her in Meals-on-Wheels and helped Miss A. access available benefits and services including rental assistance (SCRIE), transportation to and from medical appointments and church (Access-a-Ride and reduced fare MetroCard), and SNAP/Food Stamps. These services supported Miss A. in maintaining her autonomy and independence, but

Rachel was concerned that Miss A. needed additional help in maintaining her home and living independently. Despite her assessment, she was unable to convince Miss A. to accept additional support with her daily needs beyond meals.

Rachel, who has now worked with Miss A. for over five years, eventually persuaded her to try out Medicare-funded home care, which she receives two days/four hours each week. Happily, Miss A. loves her personal care attendant and, with growing trust, has allowed the aide to assist her with housework, cleaning, laundry, and shopping. Rachel also persuaded her to use an emergency alert bracelet, which Miss A. wears dutifully on the days when the aide is not present. Although Miss A. has limited the amount of help she will accept, the systems of care Rachel has been able to put in place, her understanding of the client’s preferences, and deep respect for her strengths have helped them to create a distinctive safety net that maintains Miss A. in her long-standing home and community.

and care coordination have been significant drivers of the field of geriatric case management (Austin & McClelland, 2009). In the coming decades, sweeping changes set in motion by passage of the Patient Protection & Affordable Care Act of 2009 (ACA; Public Law 111 - 148) will have a far-reaching impact on older adults, caregivers, and case managers. In addition to extending insurance coverage to an estimated 27 million uninsured people (Nardin, et al., 2013), the ACA will expand and broaden Medicaid coverage to millions of individuals living near the poverty line, encourage greater use of home and community-based services, and incentivize the use of case management and care coordination to increase access to and use of home and community-based long-term care services for older adults and people with disabilities (Andrews et al., 2013; Darnell, 2013).

Building on the successes of Medicare demonstration projects that integrated medical and social services for community-dwelling older

adults (e.g., Program for All-inclusive Care of the Elderly [PACE], social health management organizations [social HMOs]), the ACA promotes the development and dissemination of several models of care, including patient-centered medical homes (PCMHs) and Accountable Care Organizations (ACOs). Despite different approaches, both programs aim to organize and integrate services around primary care providers and provider networks; providers will, in turn, have more latitude and bear more responsibility in ensuring the quality, coordination, and costs of care. The ACA creates incentives for greater use of electronic medical records to cut down on medical error and increase systems communication, and models new payment structures that seek to reward efficiency and quality. The goal of these reforms is to reduce health care costs and fragmentation of medical and social services and supports, and promote health, function, and independence among community-dwelling elders. Although it is difficult to predict the

ultimate effects of these reforms, the ACA has already enhanced case management and service coordination for older adults and their families (Darnell, 2013).

CONCLUSION

Case management with older adults has grown in response to critical demographic, epidemiologic, and economic changes of the past half century: a rapidly aging population, the growing prevalence of chronic illnesses in later life, systemic changes in health care financing and delivery, and an increasingly fragmented, inefficient, and expensive system of health care and social service supports for vulnerable elders. Our ability to better meet the needs of older adults and their families is constrained by a critical shortage of social workers, nurses, and other direct service workers who are trained in the competencies of working with older adults and their families (Institute of Medicine [IOM], 2008). As the Baby Boom generation ages and life expectancies grow over the next several decades, there will be an increasing need for all social workers to be skilled in working with older adults and their families. Social workers will be called upon to evaluate and advocate for innovative health and long-term care policies and services that more effectively meet the needs of community-dwelling elders. And geriatric case managers will continue to enhance their clients' physical, emotional, cognitive, and social functioning, while ensuring autonomy, choice, and dignity for older adults and their caregivers.

111 HIV/AIDS Case Management

Brian Giddens, Lana Sue I. Ka'opua, & Evelyn P. Tomaszewski

Social work case management with/for Persons Living with HIV (PLHIV) optimally is guided by the *NASW Standards for Social Work Case Management* (National Association of Social Workers [NASW], 2013). These standards uphold the profession's strengths-based perspective, value the consumer-provider partnership, promote collaborative relations across professional disciplines and organizations, and endorse purposeful intervention at the micro, mezzo, and macro levels. HIV case management (HCM) is customized to address the bio-psychosocial and spiritual needs of PLHIV in their respective social environments, with strong consideration of changing conditions caused by treatment advances, public policies, and other systemic factors.

Despite variation in programs, four types of activities are common across almost all programs. Common services in both generic and HIV-specific case management include: consumer advocacy, service brokerage, services coordination, and provision of informational, emotional, and tangible support (NASW, 2013; Murphy, Tobias, Rajabiun, & Abuchar, 2003). Across the trajectory of the HIV epidemic, these services have evolved continuously to address the emergent needs of PLHIV.

In the early years of the HIV epidemic, HCM programs were developed in urban epicenters to meet the medical and psychosocial needs of PLHIV. Because HIV disproportionately affected groups already disenfranchised, case managers found themselves intervening in situations imbued with social stigma and discrimination (Brennan, 1996). Interventions were aimed at facilitating access to benefits, care, housing, legal, and other resources vital to consumer well-being.

With the advent of highly active antiretroviral therapy (HAART) in the mid-1990s, HCM evolved to emphasize support for living with HIV as a chronic condition. HCM innovations included assessment of an individual's capacity to adhere to complex HAART regime, support for management of medication side effects, and assistance in coping with the psychosocial consequences of chronic disease management (Giddens & Ka'opua, 2006; Ka'opua & Linsk, 2007). In the first decade of the 21st century, HIV incidence has stabilized, a fact generally attributed to biomedical advances and public health education.

Despite this very positive development, factors such as continued stigmatization, discrimination, and lack of access to care influence delays in HIV testing and treatment, potentiating disparities in mortality and morbidity (AIDS Healthcare Foundation, 2012; Tomaszewski, 2012; Lambda Legal, 2010). Persons identifying as ethnic and/or sexual minorities continue to be disproportionately burdened by HIV infection; particularly affected are Men who have Sex with Men (MSM) and African-Americans (Centers for Disease Control and Prevention [CDC], 2012). Notably, these challenges coexist alongside newer ones, namely, that of an aging, seropositive population vulnerable to non-AIDS defining cancers and other disease conditions associated with older age, diminished funding for health and human services, shifting health policies, and transitioning health care service and insurer systems (Coates, Richter, & Caceres, 2008; Deeken et al., 2012; Emler, Gerkin, & Orel, 2009; Lambda Legal, 2010; Sankar, Nevedal, Neufeld, Berry, & Lurborsky, 2011). This chapter provides a concise review of the scope and role of HCM in addressing persistent challenges, as well as newly emerging ones.

Also provided are key considerations for practice application, focused segments on confidentiality, cultural competency and quality improvement, and resources for more in-depth perusal.

EVIDENCE BASE FOR HIV CASE MANAGEMENT

Published research suggests that HCM positively influences consumer- and service systems-related outcomes.

Risk Reduction

- *HCM programs guided by a behavioral change theory* (e.g., Social Cognitive, Social Learning) are most efficacious in reducing HIV risk (Lyles et al., 2007).
- *HCM programs integrating case management and motivational counseling* reduce HIV risk behaviors among Hispanic persons using injection drugs (Robles et al., 2004).

Service Utilization

- *HCM is associated with entry and sustained use of health services.* A longitudinal, case-control study involving a representative sample of urban-dwelling PLHIV adults indicated that:
 - HCM and other ancillary services are associated with increased entry and retention to care, thereby offering the prospect of increased medication adherence (Messeri, Abramson, Aidala, Lee, & Lee, 2002).
 - HCM providers offering tangible support in obtaining stable, adequate housing is crucial, with housing predictive of entry and retention outcomes, regardless of sociodemographic characteristics and physical/behavioral health variables (Aidala, Lee, Abramson, Messeri, & Siegler, 2007).
- *HCM structured on a brief counseling model* and strengths-based in approach promotes entry into care and may be particularly effective with newly diagnosed persons (Craw et al., 2008; Gardner et al., 2005).
- *Integrative HCM models promote entry to care and sustained engagement* in medical/behavioral health care across the HIV illness

trajectory. Models that include capacity for intensive HCM, outreach, navigation-like activities, and training on life skills and health literacy improved HIV-care retention of consumers from five socioeconomically disadvantaged, culturally diverse communities (Gardner, McLees, Steiner, del Rio, & Burman, 2011).

Cost-effectiveness

- *Research on cost-effectiveness of HCM yields mixed results.* When HCM provides access to services that enhance health status and functioning, cost-effectiveness is promoted (North Carolina Department of Health and Human Services, 2011). Preventative HCM may be less cost-effective than outreach to MSM, condom distribution, or needle exchange in high-prevalence communities (Cohen, Wu, & Farley, 2006).

Direct application of research to practice is cautioned due to general lack of agreement on “what” components comprise the HCM “gold standard,” as well as methodological limitations. However, findings may offer helpful considerations for HCM practice and development of innovations. In reviewing research to inform practice, it is important to assess critically the evidence on types of services influencing a specific HIV-related outcome, as well as the socioeconomic and cultural characteristics of the consumer population for whom an intervention is intended. Customizing evidence-based practice is indicated.

WHAT IS CASE MANAGEMENT?

Case management (CM) is a service that utilizes assessment, planning, facilitation, coordination, evaluation, and advocacy to meet an individual’s health needs (Case Management Society of America, 2013). The term CM has been used by several disciplines and institutions to describe coordination activities for clients and patients. *Insurance/Utilization CM* starts with the payer of services, focusing on monitoring and advocating for efficient and appropriate use of resources. *Medical CM*, centered within the health care system, concentrates on achieving improved patient outcomes, based on specific treatment interventions. *Social CM* often incorporates the

psychosocial and spiritual factors affecting care, as well as tangible support and resource needs that can lead to improvements in care. Increasingly, as states are implementing health care reforms and creating or expanding systems, case managers will need to have a general understanding of all aspects of the medical, social, and payer realms.

In addition to the varied “case manager” roles, similar services have emerged, such as “care coordinators” and “patient navigators” (Bradford, Coleman, & Cunningham, 2007; NASW, 2013). Some of these services can assume aspects of case management activities. For example, a patient navigator may focus on specific tasks, such as coordinating a person’s medical appointments or arranging transportation.

Setting can also differentiate the role of the case manager (Barney & Duran, 1997). For example, hospital-based programs may allow for a more medically focused style of case coordination, whereas the community-based case manager may be able to work closely with clients in their home setting, incorporating a more holistic assessment. With the implementation of the Patient Protection and Affordable Care Act (ACA), the HCM has the opportunity to provide care coordination and skill expertise through HIV-specific programs, patient-centered medical homes, and/or as a member of the community based prevention and wellness programming integrated into the newly defined health care systems. Access to medical treatment should be supplemented with ongoing case management services to facilitate continuity of care. Supportive services such as transportation, legal assistance, nutrition services, mental health services, substance use treatment, and child care are essential for certain populations facing difficulties with everyday needs.

For the purposes of this chapter, we will utilize an integrated model of HCM. An integrated model is interdisciplinary, incorporates the medical and psychosocial aspects of case management, and is client/patient centered. HCM is built on collaboration between providers and systems and removes barriers to care. Thus, HCM minimizes service duplication and contributes to cost-effectiveness.

ACTIVITIES AND ROLES IN HIV CASE MANAGEMENT

The integrated HCM model reflects the ecological view of the profession, a commitment to

fostering productive relations with other professionals on behalf of the client, and approaches to service delivery that are client-centered, empowerment-based, and culturally responsive. HCM aligns with the National HIV/AIDS strategy of increasing access to care, improving health outcomes, and reducing health disparities (Office of National HIV/AIDS Policy, 2010). This specific variation of social work CM is unique in several ways. First, HCM models recognize that living with the disease poses bio-psychosocial and spiritual challenges. The implications of HIV-related stigmatization are underscored, and at the broadest level of intervention, HCM services are optimally delivered in a relationship characterized by acceptance and unconditional positive regard. The social worker providing HCM services is often one of the first gatekeepers in the service delivery system, and being a safe, confidential, and respectful contact is emphasized. Second, because crises may occur across the illness spectrum and client needs may vary over time, HCM often uses a triage system that prioritizes involvement on crucial points in disease progression. Triage takes into account various acuity factors, such as basic needs, substance abuse, physical and mental health, and cultural or linguistic differences (Thompson, 1998). Third, prevention, adherence, and risk reduction are components of HCM; the social worker may take on the role of educator/counselor, as well as the more generic roles of service broker, advocate, and monitor. The case manager also assumes roles that are linked to the core activities of the initial interview/intake, assessment, and development, implementation, and monitoring of the service plan.

INITIAL INTERVIEW/INTAKE: CASE MANAGER AS SAFE CONTACT, CRISIS COUNSELOR, SERVICE BROKER

The process of HCM begins with the initial interview and in many settings is combined with the intake. In the initial interview, the primary goal is to establish a comfortable rapport that facilitates the development of a collaborative working relationship and establishes the social worker as a safe point of contact. In the first encounter, the role of crisis counselor may be important because entry into the service delivery system is often precipitated by crises that require immediate intervention. Information about the scope of services available is integrated into the initial interview.

During the intake, a preliminary assessment of client needs is made with a view toward bridging the gap between service needs and system resources. Client rights, grievance procedures, and responsibilities are reviewed, and informed consent to enroll the client in the service delivery system is obtained. Information that may be necessary to register the client includes confirmation and date of initial HIV/AIDS diagnosis or first positive HIV antibody test, health insurance status, HIV disease progression, source of exposure to HIV, CD4 count, housing status, active substance use, mental health status or psychiatric diagnoses, and tuberculosis (TB) status. Due to persistent HIV-related stigmatization, it is vital that social workers explain why information is collected, who will have access to the information, and how that information will be documented. The ACA provisions promote increasing use of electronic medical records to increase efficiency and improve coordination between providers (U. S. Department of Health & Human Services, 2013).

**ASSESSMENT: CASE MANAGER
AS CLINICIAN, SERVICE BROKER,
LINKER, EDUCATOR**

The needs assessment is optimally conducted as a collaborative effort with both case manager and client identifying treatment and service needs, client strengths, psychosocial resources, and areas in which service linkage is needed. The assessment is key to establishing a baseline profile for initial service referrals, development of the service plan, and criteria for evaluation of service outcomes. Data collected in the assessment process can include a variety of information, depending on setting and client situation, and can include questions related to living situation, perception and understanding of illness, relationships and social support, psychosocial functioning and mental status, functional status, service needs and issues, and legal issues (NASW, 2013). Case managers are increasingly taking on the functions of conducting risk assessments and assessing the ability of the client to adhere to treatment. Assessing HIV transmission risk includes identifying barriers for the client in reducing transmission risk and involves educating clients about HIV transmission and ways to reduce risk. When risk behaviors are identified, these can be addressed through the service plan and monitored within

the context of the ongoing HCM relationship. The other function of determining capacity for adherence should be done in conjunction with the interdisciplinary team. The role of the case manager is not only to identify and help resolve the psychosocial barriers to adherence but also to advocate for access to treatments that better fit the client's lifestyle and resources.

Various competencies are required for completion of the comprehensive assessment, including the technical capacity to gather clinical information and the cultural and linguistic competency to collect culturally relevant information. The case manager should work closely with the interdisciplinary team to ensure that client goals are congruent with treatment goals. Key indicators of mental health distress and disorder should be identified and referred for follow-up by a licensed mental health provider.

**DEVELOPMENT OF THE SERVICE
PLAN: CASE MANAGER AS PLANNER,
COLLABORATOR, ADVOCATE**

The service plan is central to the HCM effort and builds on the information gathered in the assessment. The case manager and client collaborate to create an inventory of needs and to formulate long- and short-term objectives that support the overall goals of health maintenance and independence. Specific planning, guided by realistic objectives, is required to prioritize activities and identify how services will be obtained, monitored, and coordinated among the providing agencies and health care systems. Responsibilities of all parties and a realistic timeline should be clearly delineated for accomplishing objectives and relevant activities. When service options are not available to meet identified needs, the case manager may need to consider either advocating for options or designing interim solutions. This is more likely to occur when clients' cultural values or practices are dystonic with that of existing programs, when clients have co-occurring diagnoses, such as substance abuse or a mental disorder, or when clients reside in rural areas with relatively few HIV-specific services. Service plans should be clearly documented in the client's chart along with copies of written correspondence and application forms for entitlement programs, experimental drug protocols, and the like. It may be helpful to offer the client an abbreviated version of the plan along with contact information.

IMPLEMENTATION/ MONITORING: CASE MANAGER AS BROKER, COORDINATOR, SERVICE MONITOR, COACH

In the implementation phase, the social worker and client take action to accomplish the service plan. Once consent to refer has been obtained, the case manager may employ a number of roles to facilitate the client's receipt of services, including that of broker, monitor, advocate, and coach. As broker, the case manager contacts other providers to pave the way for client referral and may also arrange for ancillary services, such as transportation to appointments. To ensure linkage with services, the case manager maintains regular client contact to monitor that services have been received and rendered in an acceptable way. On occasion the case manager may need to advocate on behalf of the client to ensure necessary services are received. As coach, the case manager encourages the client to anticipate barriers to access and utilization and, when necessary, works with the client to address these issues. Service plans are usually implemented in increments with careful documentation of client progress, including dates of contact, information on who initiated contact, and any action that resulted from the contact. Obstacles to implementation should be noted, as well as client satisfaction, modifications to the plan, and progress toward specified goals and objectives. Professional social work supervision, peer support, and inter- and intra-agency case conferences are often helpful in addressing implementation difficulties.

The aging of PLHIV will require increased coordination with community agencies and the long-term care system. The prevalence of HIV among older adults (persons ≥ 65 years) is growing and in comparison to other age cohorts represents the greatest increases (CDC, 2011). As a PLHIV ages, it is more likely that the individual will experience other medical conditions that require coordination with primary care providers and health systems. For case managers, this will require expertise in the broader health care spectrum.

CONTINUOUS QUALITY IMPROVEMENT

Ensuring the quality of a HCM program, including the evaluation of outcomes, is becoming increasingly important. Funding agencies

increasingly require proof that their programs are making a tangible difference for their client base, and that services are being provided as efficiently as possible. Traditional evaluative activities, such as assessment of client satisfaction with services provided, determination of whether the affected population in a geographic area is aware of the availability of services, and assessment of medical provider satisfaction with HCM continue to be helpful. However, funders are increasingly requiring outcome-based evaluation (Health Resources and Services Administration [HRSA], 2009).

Examples of outcome evaluation can include whether CM is helping clients adhere to treatment (i.e., tracking health outcomes, completed medical visits) or whether clients actually engaged with referred services (i.e., tracking not only the number of referrals made to community services but whether the client followed through with the linkage). Quality improvement processes can monitor both the micro and macro level of service provision, ensuring that the needs of the client and the community are met. For example, identification of an unmet need in the community could involve bringing together the system of care for the affected population and brainstorming how to build the needed resource into the fabric of the community.

CONFIDENTIALITY

From the initial encounter with a client, the case manager should be transparent about what information may be shared, under what circumstances it will be shared, and with whom it is shared. The Health Insurance Portability and Accountability Act (HIPAA), as well as specific state and federal privacy regulations, are counters to concerns about managing client records in the digital age; service providers will need to stay current on such regulations. The advent of electronic provider/client communication via web portals and provider/client e-mail, as well as the burgeoning use of mobile devices hold promise for enhanced communication, but pose risks for privacy and confidentiality (West, 2012; Schickedanz et al., 2013). Additionally, as part of patient/client-centered medical homes, Accountable Care Organizations (ACOs) must collaborate with "neighborhood" or community-based prevention and wellness

programs, thus increasing the standardized use of electronic medical record systems (Collins, 2011). To ensure support for privacy and confidentiality, a periodic review of institutional policies and workflows (i.e., sequence of procedures and standards within an organizational system) is indicated.

CULTURAL COMPETENCY

Discrimination and stigmatization have been directed at PLHIV, as well as the ethnic/racial, gender, sexual, and other minority groups with whom PLHIV identify (AIDS Healthcare Foundation, 2012; Lambda Legal, 2010). Cultural misunderstanding often is woven into this fabric of intolerance and the social work profession has been at the forefront of continuous advocacy for cultural competence (Ka'opua, 1998). The *NASW Indicators of the Achievement of Standards for Cultural Competence* (NASW, 2007) endorse culturally competent and linguistically appropriate policies, programs, services, evaluation, and research across practice settings. HCM providers may benefit from a review of these standards. In addition, cultural competence training on specific minority groups may be helpful.

The "graying" of PLHIV is of particular concern in the 21st century (Administration on Aging [AOA], 2012; CDC 2013). The CDC estimates that by 2015, older (≥ 50 years) adults will comprise about 50% of the seropositive population, thereby necessitating attention to culturally competent HIV practice with older adults. AOA recommends collaboration of HIV and aging networks, with attention to combating age discrimination, recognition of diverse strengths and needs of aging PLHIV, as well as cultural values reflective of their respective age cohort and/or other groups with whom they identify.

CONCLUSION

Since their earliest beginnings, social workers providing HCM have adapted their practices to meet the changing needs of their HCM populations. Over time, HCM has moved from a primarily social case management model to one that incorporates treatment adherence and other medical issues. HCM providers have adapted to changing contexts by gaining knowledge of resources and funding streams to sustain and

increase services for PLHIV. Continuing shifts in the social and medical contexts of the disease will necessitate continuous evaluation and concomitant changes in the ways HCM is provided. HCM providers will need to adapt their practices to meet the evolving person- and systems-related conditions.

Case managers will also have to learn the language and culture of other disciplines, especially nursing, medicine, and pharmacy. As various forms of CM, managed care and disease management models proliferate, greater coordination will be needed between systems of care. Reducing redundancies and creating efficiencies will preserve more dollars for patient care and help avoid funding duplicative programs. This will require collaboration among programs and providers. With collaboration comes the need for skills in negotiation, systems thinking, problem solving, and communication. Given that skills such as these are what social workers practice every day, the profession is poised to take a prominent role in the HCM field of the future.

112 Social Work Case Management in Medical Settings

Candyce S. Berger

There is no standardized definition of case management, nor one accepted approach (National Association of Social Workers [NASW], 2013). Many health care professionals claim dominion over case management, including social work. Social work's involvement in case management can be traced to the turn of the 20th century and the social casework approach. Social casework processes parallel the steps described in the case management process: assessment, diagnosis, intervention, and follow-up. Social work case

management is rooted in the problem-solving process and incorporates biological and developmental understanding, systems theory, and/or ecological theories that balance personal and environmental determinants in understanding illness and health. Social work leaders in health care have emphasized the importance of this bio-psychosocial approach in working with patients, dating back to Ida Cannon at the turn of the 20th century. Cannon emphasized the need to reach out into the community to link hospital and community-based care in

a holistic approach to health care delivery. Though the term “case management” may not have appeared in these early writings, the descriptions of services included similar terms, such as screening for high risk, assessment, intervention, brokerage, linkages, evaluation, and follow-up (Berger, 1996). Several factors contributed to the rapid growth of case management in health care settings.

1. *Health care inflation.* As the costs of health care exceeded the ability of individual, organizational, and governmental payers to keep pace with its growth, people began looking for ways to contain costs. Although the rate of growth in health care spending has slowed since the 1980s, it is still growing faster than the national income. The recent economic recession has added to the burden of health care costs as more individuals fall into unemployment or lower paying jobs. These conditions have continued the U. S. focus on containing health care costs, while making health care more accessible to the country’s citizens. (www.kaiseredu.org/issue-modules/us-health-care-cost/background-brief/aspx). Case management continues to be embraced as an effective approach to cut costs, and a multitude of studies have shown improved efficiency and effectiveness, including research on the intervention strategies utilized (Atteberry, 2009; Bierman, Dunlop, Brady, Dubin, & Brann, 2006; Coleman, Austin, Brach, & Wagner, 2009; Dorr, Wilcox, McConnell, Burns, & Bruner, 2007; Felt-Lisk & Mays, 2002; Kolbasovsky, Zeitlin, & Gillespie, 2012; Laramee, Levinsky, Sargent, Ross, & Callas, 2003; Peikes, Chen, Schore, & Brown, 2009; Riegel et al., 2002; Rodgers & Purnell, 2012; Shea et al., 2009; Sweeney, Halpert, & Waranoff, 2007; Vourlekis, Ell, & Padget, 2005).
2. *Legislative initiatives.* Legislation soon followed that extended the breadth of case management services. For example, the Health Maintenance Act of 1973 encouraged comprehensive health services over the continuum of care, including preventive, acute, chronic, and terminal care services. Case management became a primary vehicle to facilitate integration of services. Passage of the Omnibus Budget Reconciliation Act in 1981 and the subsequent Consolidated Omnibus Budget Reconciliation Act in 1985 encouraged the expansion of case

management services to the Medicaid population. According to Mason and Gammonley (2012), starting in the 1980s, home health care services continued to struggle with insecure funding and was characterized as an adjunct to medical care. The rapid changes in health care financing in response to cost-containment priorities began to shift the focus of care to community-based settings where case management services received increased attention, particularly case management teams. However, The Patient Protection and Affordable Care Act (PPACA) of 2010 has expanded the emphasis on community-based care even further with several components that extend the use of case management approaches (see section below).

3. *Employer benefits.* Employers quickly followed by incorporating case management programs into their health benefits plans. This expanded the role and visibility of case management, particularly in the medical claims arena, with a priority for cost containment.
4. *Chronicity as a leading health problem.* A new set of patient care challenges emerged as chronic illness became a major focus in health care delivery. Rather than the controlled environment of an acute, inpatient unit, much of health care delivery moved to the community. This move required intensive coordination of service delivery across multiple venues of care (e.g., medications, physician office visits, long-term care, and wraparound services). Case management offered an approach that was capable of coordinating multiple systems of care to enhance quality while reducing fragmentation and costs.

Chronic disease has surpassed acute episodes of care as the greatest cause of death and disability. A major factor accounting for this is the rapid growth of the elderly population, who are living longer, often with multiple chronic conditions (Mason & Gammonley, 2012). According to Coleman, Austin, Brach et al (2009, p.75), chronic diseases account for 59% of all deaths and 46% of the global burden of disease. This shift to treating chronic illness can lead to overutilization of health care services, increasing costs, and poor health outcomes if disease is poorly managed.

One of the biggest challenges to the management of chronic disease is patient adherence to medical recommendations (Felt-Lisk & Mays, 2002; Laramée et al., 2003; NASW, 2007; Vourlekis & Ell, 2007). The World Health Organization (2003) estimates that medical adherence in developed countries is 50%; and even less in developing nations. Poor adherence not only compromises the quality of life of patients but also negatively impacts health economics. Case management strategies are increasingly used to address management of patient care, particularly in the area of adherence, because of the perceived positive influence on efficiency and effectiveness. Over the past decade, evidence-based studies have provided increasing data to substantiate these claims.

5. *Prevention.* As rising health care costs associated with acute care placed greater emphasis on prevention as a more cost-effective approach, case management was used to coordinate and monitor patient compliance with prevention strategies. Under the PPACA, this focus will rise in importance.

DEFINING CASE MANAGEMENT

Case management has been defined in many ways by a variety of professions and organizations. The American Case Management Association defines it as a, “collaborative practice model.... [that] encompasses communication and facilitates care along a continuum through effective resource coordination” (Standards of Care, p.1) for hospitals and health settings. The Case Management Society of America defines it as, “a collaborative process of assessment, planning, facilitation, care coordination, evaluation, and advocacy for options and services to meet an individual’s and family’s comprehensive health needs through communication and available resources to promote quality, cost-effective outcomes” (<http://www.cmsa.org>). Finally, NASW defines it in their Standards for Social Work Case Management (2013) as, “A process to plan, seek, advocate for, and monitor services from different social services or health care organizations and staff on behalf of a client” (p. 13). Although these definitions vary, there are commonalities that shape the models, interventions, and goals of case management. Five models of case management continue to be relevant today

in health care settings, particularly hospitals (Rose, 1992; Berger, 1996). These models include the following.

1. *Primary Care Case Management.* The primary care physician is responsible for coordinating the care for all of the patients assigned to him or her, mostly associated with health maintenance organizations and more recently with the “medical home” or “health home” contained within the PPACA. It is characterized by having a physician responsible for overseeing all of the patient’s health care interventions and synthesizing the medical information (e.g., laboratory, specialist consultations, radiology) to reduce fragmentation and duplication of care. Most health maintenance organizations use this approach by requiring authorization from the primary care physician for all health care services provided and holding him or her fiscally responsible for coordination of services (e.g., capitation).
2. *Medical Case Management.* This approach focuses on a select group of patients in whom severe illnesses and/or injuries require intensive coordination and monitoring of services. The approach requires a good understanding of medications, medical information (e.g., medical diagnosis and interpreting laboratory data), and medical equipment and supplies. The goal is to prevent medical crisis or exacerbation of health status. Nurses typically assume the role of case managers, though social workers may also fill these roles, particularly in the area of mental health.
3. *Social Case Management.* This approach emphasizes coordination and monitoring of nonmedical aspects of the patient’s environment that impinge on his or her ability to maximize health care services (e.g., social and economic factors that interfere with a patient’s ability to follow medical requirements). Non-acute, community-based patients (e.g., frail elderly, severely mentally ill) typically fall into this category. Social workers and nurses are the primary providers of this approach to case management services.
4. *Medical-social Case Management.* Medical and social case management are integrated to provide a more holistic approach to managing health care delivery. This is premised on an ecological approach in which

medical, social, economic, and cultural factors are synthesized to frame the case management process. It is this model of case management in which the greatest conflict over professional domain occurs, with nurses and social workers often competing for dominance. Team approaches are increasingly being used to maximize opportunities rather than competition for turf.

5. *Benefit Case Management.* This approach focuses exclusively on health care benefits, emphasizing the most appropriate use of health care resources. It often combines the dual focus of ensuring appropriate use of benefits (e.g., utilization review) and making benefits more flexible to achieve cost-effective services. It is used primarily within the insurance industry, though hospitals have incorporated aspects of this model. For example, a hospital may pay to have a ramp built in a patient's home (a service that may not be covered by one's insurance) in order to discharge the patient earlier. Also, many of the care management protocols used in inpatient settings are premised on effective and timely utilization of resources.
6. *Case Management Team.* A more recent model is the case management team (Kraft, 2009; Ruggiano et al, 2012). A case management team is defined as a multidisciplinary team, typically consisting of up to six different professions and health support personnel; the team composition is usually driven by patient-specific issues and needs. Team members combine their knowledge and information about the patient to gain group consensus in designing the best approach to the delivery of care in order to achieve the most positive outcomes for the patient. One member of the team assumes the role of a "lead" in order to collect, organize, and disseminate information; do patient scheduling; and facilitate team communication.

Although the various models presented above may differ, they all share a common approach that relies on the sequencing of activities to ensure efficiency and effectiveness in the delivery of health care services. They suggest that all the steps can be collapsed into two key ingredients: facilitating high quality of care and achieving cost-effectiveness. The steps involved in the

case management process have been described in many fields of practice, including health care. Although different terms may be employed, these descriptions share a common set of generic steps that emanate from a problem-solving approach to intervention (Berger, 1996; Dorr et al., 2007; Felt-Lisk & Mays, 2002; Kane, 1992; Kirton, 1999; Laramée et al., 2003; NASW, 2007; Sangalang, Barth, & Painter, 2006; Schmuttermaier et al, 2010; Sweeney et al., 2007; Vourlekis et al., 2005). These steps include:

1. *Case Finding.* Potential recipients of case management services are identified through a standardized process using formalized screening criteria. Identification can be based on the type, nature, or extent of an individual's illness/disease (i.e., catastrophic, terminal, chronic, preventive) or the anticipated costs of care (Kane, 1992). As the boundaries between the sites of care (e.g., hospital, nursing home, and home health care) blur in response to a series of legislative initiatives that encourage cross-boundary collaboration, case finding has expanded to allow other providers to cross boundaries to identify high-risk clients. Kolbasovsky, Zeitlan, and Gillespie (2012) emphasize the importance of identifying clients for case management at the "point of care." This facilitates early connection to both the patient and to the health care providers, ensuring more accurate collection of patient and medical information and promoting more effective communication among all the providers of care. For example, Kolbasovsky (2008) describes community-based case managers initiating enrollment activities while the patient is still in the psychiatric hospital. Home health care agencies have implemented similar partnerships with hospitals to achieve earlier identification and engagement of patients to participate in case management.
2. *Assessment.* Once identified, recipients of case management services receive an evaluation that can range from a comprehensive, bio-psychosocial evaluation to a more focused evaluation of a specific aspect of care (e.g., pattern of resource utilization or eligibility determination). The case management model employed (e.g., social-medical vs. benefits case management) and the time perspective (e.g., relevance of information drawn from an individual's past, present, and future situation) will

define the scope of the assessment. Care must be taken during the assessment process to ensure the adequacy and reliability of information, because subsequent steps in the case management process are based in the interpretation of these data. A variety of validated risk assessment tools are available to assess substance abuse, mental status, and adherence to treatment (Cutler & Everett, 2010).

3. *Intervention.* This stage can also span a wide range of activities, varying in scope and intensity. Interventions can be as simple as flexing one's benefits package or providing information and referral to a comprehensive set of interventions that might include several or all of the following services: information and referral, coordination of service delivery through linkages, brokerage of client services, advocacy, provision of concrete services (e.g., arranging transportation), education, and therapeutic counseling. This last intervention is still a source of much debate as to whether a case manager should also serve as the client's therapist. For example, professionally trained case managers may employ motivational interviewing to address medication or medical issues. Careful review and consideration should be given before agreeing to provide this type of care, and should be restricted to case managers who hold a professional degree. Patient education is another intervention that may be incorporated into the case manager's role. Education is focused on the identification of symptoms and the appropriate response by the patient or caregiver if symptoms become more severe (Kolbasovsky, 2008). Regardless of the mix of interventions, each is linked to a measurable outcome or goal, mutually defined by the case manager and the client.

A primary intervention of the case manager is to facilitate communication. Without effective systems to promote communication with all the health care providers and community support systems, most of the other interventions associated with case management are likely to fail or at least be compromised in both efficiency and effectiveness (Kraft, 2009).

4. *Monitoring.* This set of activities focuses on reviewing the process of case management to ensure appropriateness and timeliness

of intervention, and patient compliance. Regardless of how thorough the plan of intervention, problems can occur. An effective case manager regularly reviews the process of care to identify "breakdowns" in the plan.

The newest approach to monitoring home-based or community-based patients is the use of telemedicine technology (Atteberry, 2009; Britton, Engelke, Rains et al (2000 in Atteberry, 2009; Shea, Weinstock, Teresi et al, 2009; Suter, Hennessey, Florez et al, 2011). Telemedicine has been found to be particularly effective in monitoring community-based home care settings with homebound patients, those with chronic disease, and patients who require more frequent intervention to achieve health behavior changes. The goal is the early identification of symptoms or risk factors that can produce complications to the patient's health status. Home telemedicine units are placed within a patient's home to monitor physiological symptoms through the patient's uploading of self-monitoring data (e.g., glucose levels, blood pressure, etc.). These units also may have web-based cameras that enable video conferencing. The advantages of these units include increased involvement of the patient in self-monitoring activities, the ability to gather patient information, and face-to-face video conferencing with a case manager or a specific health care provider based on patient need. Economic benefits include reduced hospital and emergency room visits and reduction in home visits by home care personnel. Monitoring also covers the communication and collaboration across health care providers, community agencies, and members of a case management team (Kraft, 2009).

With the increasing reliance on computerized data systems (e.g., electronic patient records, computerized information systems, and telemedicine), monitoring activities can be more thorough and timely, promoting more effective and efficient care. However, sole reliance on these sources of information may give a skewed picture. The case manager should not underestimate the importance of direct contact with the client to get a thorough understanding of not only *what* has occurred but also *why* (i.e., what factors in the home or the community may be contributing to the problem).

5. *Evaluation.* As with any intervention, a practitioner evaluates the impact of his or her work. Evaluation combines a focus on both the process (e.g., number of contacts, types of services provided) and outcome (e.g., goal achievement, health indices) of case management. Outcome measures might also include population-based indices, such as changes in health status, quality of life, or financial impact. If clear goals and objectives for the interventions have been identified in Step 3, evaluation becomes an easier task.

The steps in case management have been presented as if they represent a linear process. It is important to emphasize that this is a dynamic process; movement can go forward or backward and steps may occur simultaneously, particularly when there are multiple problems being addressed.

CONTEXTUAL FACTORS RELATED TO CASE MANAGEMENT IN HEALTH CARE

Developing and implementing case management in health care is neither a simple nor easy task. Many factors shape the practice to create a mosaic of models, providers, and services. This complexity often presents challenges and conflicts that plague its use. This chapter concludes with a set of factors to be considered when developing or implementing a case management program (Berger, 1996).

1. *Case Management Goals.* What is the primary purpose or focus of the case management program? This will often define the appropriate model of case management (e.g., medical, social, or benefits case management), which professional(s) is most likely to fulfill the role of case manager, and the size of the case manager's caseload.
2. *Location of Case Management Services.* Where will case management be provided? Will it be provided in the hospital, in the community, or spanning both locations of care? Hospital-based services more often use the medical case management model and typically employ nurses or teams of social workers and nurses as case managers. Utilization review can be structured as a

benefit or medical model and is also prevalent on inpatient units.

Community approaches tend to use more of a social, medical-social, or team approach, though "benefits case management" is also evident. Providers are typically nurses, social workers, or case management teams that may consist of nurses, social workers, occupational therapist, physical therapist, speech therapist, other health care support providers, and/or consumers. Benefits case management may or may not employ practitioners from health disciplines. Thompson (1998) suggests that community approaches may require interactive case management that uses street-based, hands-on interventions rather than having the client come to the worker's office. Creating teams that include public health professionals is an excellent option for achieving this level of case management, particularly when spanning inpatient and outpatient arenas. Several studies have validated the positive impact of community-based case management on patient, organization, and system outcomes (Bierman et al., 2006; Dorr et al., 2007; Felt-Lisk, & Mays, 2002; Laramée et al., 2003; Riegel et al., 2002; Sweeney et al., 2007; Vourlekis et al., 2005). An example of this is the Chronic Care Model (CCM) that has been piloted over the past decade (Coleman, Austin, Brach et al, 2019; Schumuttermaier, Schmitt, King et al, 2011). CCM involves six areas: self-management support, decision support, delivery system design, information systems, health care organization, and community resources; but no standardized approach exists. The Centers for Medicare and Medicaid have been piloting the CCM approach in community-based settings.

A more recent development is the use of "transitional case management" programs (Kilgore, 2010). Transitional support is defined as, "a broad range of time-limited services designed to ensure health care continuity, avoid preventable poor outcomes among at-risk populations, and promote the safe and timely transfer of patients from one level of care to another or from one type of setting to another" (Naylor, Aiken, Kurtzman et al, 2011, p.747). Services are typically initiated in an institutional setting and then follow the patient's care into the community for

a brief period of time to ensure compliance with medical recommendations. Many of these transitional programs are based on Dr. Coleman's Care Transition Intervention (CTI) model (Coleman, Parry, Chalmers et al, 2006) that combines traditional hospital care management with case management within the community.

3. *Auspices of the Program.* Is the case management program internal to the service delivery system (e.g., a hospital has a case management program for its patients) or external to the system of care (e.g., a payer implements a case management program that crosses organizational boundaries)? Internal and external programs are inversely related in terms of their advantages and disadvantages. For example, although internal programs can have greater potential influence based on their formal and informal relationship with key decision makers and providers, they may lack the objectivity and autonomy that are characteristic of external programs when choosing interventions and services for the patient. Several studies have shown the importance of the need for the case manager to be closely related to health care and/or demonstrating expertise in the disease(s) being managed (Laramee et al. 2003; Vourlekis & Ell, 2007).
4. *Who the Client Is.* Although this has the illusion of an easy question, the waters become quite murky when one recognizes that health is embedded in an economic, political, and social constellation of players. The "patient" would seem the immediate response and clearly the priority according to NASW standards for case management (2013), whereas the real client may be the hospital, the payer, or society. This becomes a source of major confusion and potential conflict. For example, what happens when an organizational goal and a client goal conflict? Case managers must clarify who is the primary customer of the services and examine the various contextual factors that define the client's goals and objectives. For example, when working with women, the client may be more than the individual woman; the "client" often encompasses the family system, and a broader base of need will shape the goals and objectives. A distinguishing characteristic of social work case management is the emphasis on advocacy as a primary role.
5. *Professional Training of Case Managers.* Who is the case manager? Should it be a nurse, a social worker, a physician, or some other provider? Some case management programs have employed indigenous providers (e.g., Community Health Workers) to be individual case managers or to serve as members of the case management team (Nemcek & Sabatier, 2003; Norris, Chowdhury, Van Le, et al, 2006). Previous consumers of care are often in a position to enhance outreach services, as well as provide insights into the assessment of client needs. Issues also emerge regarding functional training in case management (e.g., certificate programs) and the credentialing of case managers through state and national programs. Several accrediting bodies for case managers now exist. The American Case Management Association offers credentialing exclusively to social workers and nurses. Professional domain may be less of an issue if one begins with an understanding of the model of case management to be employed. The development of a case management team is an effective alternative to a single-discipline practice, particularly when social and environmental determinants are significant to a patient's health (e.g., social-medical model). These teams have been used with both inpatient (e.g., care maps and utilization review) and community-based approaches (e.g., prenatal care, AIDS).
6. *Caseload.* Goals, intensity of services, duration of contact, and sophistication of the service delivery network will influence caseload size. If management of benefits is the sole objective of case management, caseloads can be extremely large (e.g., one case manager per 10,000 clients). Comprehensive case management may use caseloads that are smaller, and the size will vary according to the intensity of services provided (e.g., one per 20 clients for intensive case management; one per 100 cases where clients are more capable of mobilizing resources independently).
7. *Breadth of the Service Delivery System.* Case managers typically have a broad definition of the service delivery system (e.g., hospital, outpatient, community agencies, and churches). They should also have a good understanding of cultural determinants of health and health behavior, including awareness of different customs and health

care practices. Competency in culturally sensitive practice may lead one to incorporate nontraditional providers into the network of care, such as spiritual healers, herbalists, and other complementary and alternative treatment providers.

8. *Power and Influence of the Case Manager.*

If the case manager does not have the authority or institutional influence to change the environmental factors that inhibit the delivery of health care services, case management will ultimately fail to achieve significant improvements for the patient. Authority will be influenced by such factors as ownership of the case management program (e.g., insurance companies, agencies, government), auspices (e.g., internal or external), and professional discipline of the case manager. This can determine whether the authority exists to change rules or regulations that present barriers to care.

9. *Ethical Challenges.* There is not sufficient space to allow a thorough discussion of the ethical issues that will influence case management practice. Issues of confidentiality, client autonomy, and justice will each surface in a health care delivery system that relies more heavily on health care networks, computer technology, and cost-containment goals (Berger, 1996). Practitioners will need to continuously monitor their practice for ethical dilemmas and draw on the assistance of institutional and/or professional ethical committees to help guide their practice.

FUTURE ISSUES AND DIRECTIONS

As we look to the future, several issues or mandates emerge that are relevant to social work practice and education.

1. *The Patient Protection and Affordable*

Care Act (PPACA) passed in 2010 is heralding a new era in health care reform. It is the boldest step to date in health care reform, bringing the United States closer to universal access to health care services. Several elements within this new legislation directly impact the use of case management approaches. Naylor, Aiken, Kurtzman et al (2011) delineate six different sections within the legislation that specifically address the use of transitional care services:

- Section 3026: establishes the Community-based Care Transitions Program, which offers funding to health systems and community agencies that offer at least one transitional care interventions for Medicare recipients.
- Section 3012: the Centers for Medicare and Medicaid funding for innovative care programs including transitional care
- Section 2602: Federal Coordinated Health Care Office to foster integration of care for dual-eligible recipients (Medicare and Medicaid beneficiaries)
- Section 3022: Accountable Care Organizations will be required to submit data on their performance measures, including data related to transitions across sites of care
- Section 2703: Health Homes will provide comprehensive care management, including transition services, to chronically ill individuals
- Section 3023: a national pilot program to bundle payments across the continuum of care, including institutional care, physician care, and home care into a single payment.

The research to date on transitional care programs has found them to be efficient and effective (Naylor, Aiken, Kurtzman et al, 2011). However, the majority of the research does not include populations considered to be targets of the PPACA legislation: dual-eligible recipients, cognitively impaired, and the medically underserved. Another drawback is that much of the research focuses on coordination and collaboration across health care providers, and does not include community services that often address the wraparound services necessary to support the patient's quality of life.

As discussed earlier, the move to community-based services has advanced the delivery of case management services, especially the development of case management teams. The PPACA includes a variety of financial incentives to encourage the use of community-based services as an alternative to the traditional use of nursing homes for long-term care (Reinhard, Kassner, & Houser, 2011). These include:

- Community First Choice: increases the federal match for Medicaid by 6% for states promoting person-centered home and community-based settings

- **Balancing Incentive Payment Program:** offers financial incentives to states that have relied on institutional long-term options to encourage the development of community-based long-term care. This program also stipulates the use of conflict-free case management systems, in which there are no financial incentives for referrals to specific providers.
- **Accountable Care Organizations:** defined as, “a group of providers who are willing and able to take responsibility for improving the overall health status, care efficiency, and health experience for a defined population” (p. 41). Devore and Champion (2011) add that financial incentives are created to promote seamless networks of providers across the continuum of care from institutional settings to community-based care.

Embedded in each of these programs, as well as the establishment of Health Homes, is the imperative to provide case management that facilitates this seamless delivery of care, encourages adherence to medical recommendations, and encourages self-management and behavior change that promotes improved health status and quality of life. Throughout the PPACA documents, references are made to the use of “patient navigators.” Rogers and Purnell (2012) describe their duties, which appear to be almost identical to activities performed by case managers: guide patients to needed services; assist with identifying insurance/exchanges and assist with completion of applications; assist with prescription costs; identify and refer to wraparound services; appointment scheduling; and client education. Natale-Pereira, Enard, Nevarez et al (2011, p. 3548) describe how patient navigators address four key areas to reduce health disparities: prevention and early detection, health care access and coordination, insurance coverage and continuity, and diversity and cultural competency. The legislation also stipulates the use of patient navigators to staff state exchanges (Gardiner, 2012).

2. *Advances in Information and Communication Technology.* NASW (2013) establishes face-to-face contact as the standard of care. However, studies have substantiated positive outcomes with the use of telephonic interventions for community-based case

management (Laramee et al., 2003; Riegel et al., 2002). As discussed previously, the use of computerized technology for patient monitoring is increasing. Though research on this new technology is still evolving, it is garnering significant attention from providers, health care administrators, and payers. Incorporating e-mail and web-based cameras on home computers, or attached to the telemedicine units, promotes interactive discussions, and the video conferencing may resolve the need for face-to-face contact., Ruggiano, Shtompel, Hristidis et al. (2002) suggest that information technology is an essential tool to maximize the communication and collaboration necessary to achieve patient health care goals. Social workers will need to develop proficiency in these new technologies to enhance case management processes.

3. *Future Direction for Social Workers in Health Care:* From its earliest roots, social work has played a major role in providing case management services to clients and patients. Although medical social work began within ambulatory and community settings, it has spent the majority of practice within institutional settings, especially hospitals. For the past several decades, health care has been moving from hospital to community-based programs, elevating home health care from its “second class” status as a health care provider to a major player in the network of care (Mason & Gammonley, 2012). Social work will need to parallel this move, increasing its presence in community-based health care programs. Under the provision of the PPACA, social work increasingly will play a role in the provision of geriatric services to address the growing elderly population, especially those struggling with multiple chronic illnesses. This growing demand for geriatric practitioners should produce a growth in funding to educate social workers to provide case management services to this population. Gardiner (2012) points out that the PPACA will “expand initiatives to increase racial and ethnic diversity in the health care professions, strengthen cultural competency training for all health care providers and require health plans to use language services and community outreach in underserved communities” (pp. 3550–3551). Social workers are uniquely qualified to fill these roles of patient navigators.

Case management in health care settings is a complex and dynamic intervention. Effective implementation will rely on a thorough understanding of the purpose, goals, and contextual factors that shape its practice. Attention should be given to advances in communication technology to facilitate case management processes, as well as evidence-based research to demonstrate practice efficiency and effectiveness. As health care increasingly moves into the community settings of care, team case management models may hold the greatest promise for the efficient and effective management of patient care.

PART XI

Community Practice

113 An Integrated Practice Model for Community Family Centers

Anita Lightburn & Chris Warren-Adamson

Family centers are an exceptional resource for disadvantaged families, who struggle with survival, often living in traumatic situations, in need of safety and a place to heal and grow. Immigrant families, isolated and beleaguered single parents, grandparents parenting troubled children, military families in the shadow of war, and young families who need more than child welfare services can provide, all benefit from responsive community-based family support. Family centers are an indispensable resource providing a system of care through connections to services in the community, with a caring community to be part of, a family center “home” that makes a difference for families, program staff, and their larger community.

As community programs, family centers reflect wide variation in structure and auspices. Some are mandated by legislation, others are supported by nonprofit organizations or sponsored by county, state, and federal funding, such as school-based family support centers and the court-mandated family relationship centers in Australia. Often associated with early child programs, multifaceted family centers are also referred to as family resource centers, child and family centers, or family support centers. These community centers, with a grass roots history, have developed over the past decades in neighborhoods, community centers, clinics, schools, early childhood programs, churches, and military bases. Prevention, early intervention, support, and empowerment focus the array of integrated services and methods of practice that are offered. The friendly neighborhood center is a place for parents, grandparents, children, and youth, joining with local helpers to connect and be helped to cope with crises, meet social and educational

needs, and access community resources. In important ways, these centers are a local system of care, connecting families to needed resources, often through co-located services.

COMMUNITY-BASED FAMILY CENTERS

Cultural traditions influence the family center, blending an interdisciplinary group of professionals with natural helpers, including parents, as shown in the evolving character and service of the Center for Family Life’s 30 years of work in the Sunset Park Community in Brooklyn, New York (<http://sco.org/programs/center-for-family-life>; Hess, McGowan & Botsko, 2003). Promoting cultural understanding and community empowerment, as demonstrated by this center and the Community Family Centers of Houston, Texas, shows the unique role centers have in developing community in beleaguered neighborhoods (<http://www.communityfamilycenters.org/>). Parents describe centers as a safe haven, where they experience a family-like environment, a place to belong. Friendly walk-in centers welcome families to join in programs, with flexible offerings that respond to local needs and preferences. These centers are unique because they frequently manage to integrate child protective work with a host of other therapeutic, educational, and supportive services. Efforts are made to emphasize family strengths, with creative approaches to engage those who have been referred by protective services because their children are at risk for abuse or neglect. Centers often play a role in family reunification, supporting trial visitations and preparation for children to come home to a more stable, safe environment.

Parents have an opportunity to be part of a community that works, where they can receive and provide help to others through a complex array of structured and creative offerings, such as parent support groups and family play sessions, parent education, and social action committees, with opportunities for individual, group, and family work. Community building and empowerment practice involves promoting parental strengths, ideas, and roles in a host of activities, such as providing play groups, recreation, and celebrations with advocacy that benefit the family center and local community. The centers that thrive do so because in formal and informal ways they are a community of learners where capacity building is a shared goal for staff and participants to enhance and build resilience. Capacity building takes many forms: staff development for effective service provision, building connections for developing social capital within the family center and local community through strengthening partnerships, and providing opportunities for parents to take meaningful roles in supporting and running the center's programs. Service provision varies because it depends on auspices and funding, center leadership, and the collaboration between professional and local helpers. For example, some centers emphasize group programs over individual counseling, including parenting groups that provide support and use evidence-based parent training curricula, and skill-building groups focused on such topics as budgeting, nutrition, skills for job hunting, opportunities to complete high school education, and coping with substance-abusing family members.

For staff there is the challenge of meeting parents' personal needs while balancing the needs of the whole community. For many parents who are survivors of traumatic experiences because of violence in their community and homes or because of military service, a safe family center needs to have essential program characteristics that aid their recovery. A trauma-informed program can become critical in a family center, as advocated by SAMSHA (2013), exemplified in the Full Frame Initiative (www.fullframeinitiative.org; Huebner, Mancini, Bowen, & Orthner, 2009). There is both an art and science to making it all work, with a good measure of humor and excellent management! Family centers are noted for having a unique synergy that contributes significantly to the helping experience and positive outcomes for children, parents, and center staff (Hess et al.,

2003; Lightburn & Warren-Adamson, 2006; Warren-Adamson & Lightburn, 2010; Tunstill, Aldgate, & Hughes, 2007).

EVIDENCE FOR AN INTEGRATED PRACTICE MODEL

Lessons learned about what works in family centers follows, with a theoretical understanding of how development and change occur in these complex community programs (Warren-Adamson & Lightburn, 2006; 2010). A brief highlight of major findings, including case studies and a number of empirical studies, suggests that family centers are an important resource contributing to a range of valuable outcomes for parents and children. Case studies of family centers across the globe report outcomes of enhanced family stability, parent and child development, and parents' progress in attaining self-sufficiency (Hess et al., 2003; McMahon & Ward, 2001; Tunstill et al., 2007; Warren-Adamson, 2002; Warren-Adamson & Lightburn, 2010). Although more empirical studies are needed, there is evidence that family centers successfully provide a continuum of services with good outcomes for fragile families (Comer & Fraser, 1998; McCroskey, 2006). Findings from a national study of 665 family support programs showed that these programs produce positive effects for children's cognitive and social development and parent's behavior and attitudes. Positive outcomes were heightened when an early childhood education component was included, parent groups were provided rather than home visits, peer support opportunities for parents were provided, parent self-development was a program goal, and professional staff were used rather than paraprofessional (Layzer & Goodson, 2001). Research also indicates that collaborative learning in support groups is particularly valuable for parents (Berry, Cash, & Hoge, 1998; Ireys, Divet, & Sakawa, 2002; Whittaker & Cowley, 2012).

Practice in family centers requires an understanding of how the family center community contributes to family and child well-being, because these communities can be integral to belonging, identity, and achieving personal goals. We introduce an integrative model of family center practice based on a theory of change developed from cross-national examples of family centers, with support from current research cited, developmental theory, and

prevention and developmental science (for elaboration of this practice model, see Lightburn & Warren-Adamson, 2006; Warren-Adamson & Lightburn, 2006; 2010).

A WORKING THEORY OF CHANGE

In Figure 113.1, an integrative model of practice based on our proposed working theory of change is a guide for practice in family centers. To meet parents' complex needs, it is useful to have a flexible model of practice that takes into account the realities of parents' daily lives, as well as the potential for change that a family center supports through their staff and relationships with community service providers. This integrative model of practice necessarily includes building the family center community as well as using individual, family, group, and case management methods. In addition, these centers are systems of care; hence, an important aspect of this integrative model of practice includes work that strengthens collaboration and connection with service providers and community resources (Brandon, 2006). Because family centers are often seen as beacons in their communities, there is the added work of influencing and shaping what happens there, such as working to decrease neighborhood violence (Huebner et al., 2009; Whittaker & Cowley, 2012).

Historically, an enduring problem for family center practice is the absence of a theory of change, despite the fact that different models of intervention have been adopted. A theory of change is a working framework that explains the relationships between the family center program components and desired outcomes. The theory of change presented in Figure 113.1, based on knowledge of human behavior, the process of psychosocial development, and ecological systems, and the role of social capital in community capacity building, helps practitioners and family center leadership understand what interventions will be important and the pathways that staff and participants need to take to work toward their goals. The outcome goal is a community that serves as a dynamic resource for vulnerable families based on an understanding of how preventive services buffer stress and reduce risk so that learning, growth, and healing can occur (Warren-Adamson & Lightburn, 2006; 2010). This theory of change for family center practice guides mapping of goals and objectives. These

are followed by connections to strategies and resources that are essential to support intended outcomes. Developed and implemented in collaboration with stakeholders in a family center, the theory of change can assist program developers, staff, and families focus on what is most important and also help describe personal, program, and family center community steps along the way in the process of development and change.

The theory of change presented describes an integrated family center model. The basic resources, goals, objectives, and strategies of the model, along with anticipated outcomes, follow.

FAMILY CENTER RESOURCES

The critical resources on which the change process depends are described in the left column of Figure 113.1. A host of resources make it possible to reach family center goals; some of the most indispensable are described. For example, the importance of place is highlighted as one of the key resources for the family center that includes a building, an accommodating place that becomes an important place of connection for families, both in the here and now, and a place to hold in their minds. The center can become as important as a family home, welcoming and familiar, with reminders of staff and friends, a place to belong, where achievements are experienced, and possibilities entertained that have yet to be explored.

Family center leadership, a critical resource, promotes, encourages, and manages the range of formal and informal roles, activities, and internal and external connections needed to fulfill the center's mission. Leadership builds the family center community around a mission that can be valued by all. Most centers benefit from a multidisciplinary staff, including social workers with community-building, clinical, and case management skills; family therapists; and early education specialists, who work in tandem with natural helpers/volunteers and parents in supporting center programs, as they take increasingly active roles in day care programs, working with reading groups, organizing food and clothing donations, and holiday celebrations.

Funding challenges and maintaining financial support requires the creative involvement of all stakeholders, including advocacy and grant seeking to garner support for center programs (Tunstall et al., 2007; Warren-Adamson & Lightburn, 2006; Huebner, et al., 2009). Special

programs are frequently developed through imaginative collaborations with community service providers, including negotiations that result in co-located services. When there are limits to a family center's space for co-locating services, good coordination and links with community resources become essential (Tunstall et al., 2007, Brandon, 2006).

FAMILY CENTER GOALS

The goals outlined in the second column of Figure 113.1 represent those commonly held in family centers that will vary according to each center's purpose and mandate. These include (1) building a community, (2) meeting family needs for safety and protection, (3) nurturing psychosocial development of parents and children, (4) supporting family attachment bonds, (5) reducing the need for child placement, and (6) promoting the mental health and well-being of all family members.

Meanings that we have attached to these goals are as follows.

- Community describes both a family center community where all who participate have a role and a culture of care that is a product of this community.
- Meeting protection needs means responsibility to protect children along with the wider notion of safety for parents and the community.
- Nurturance is a complex notion that assumes an actual and symbolic parenting role for the community and parents over time. Nurturance is essential for positive psychosocial development of both parents and children.
- Supporting attachment bonds develops Bowlby and others' idea of the importance of diverse and multiple attachments, such that the center in its complexity can encourage and provide some of these attachments over time (McMahon & Ward, 2001; Warren-Adamson & Lightburn, 2006, 2010). At the same time, attachment bonds between parents and their children are critical to a child's development, and therefore, also an important goal for the center's programs.
- Influencing out-of-home placement means that the center's integrated services are focused on working toward achieving the goal of preventing out-of-home placement,

and when this is not possible, it means the better management of foster or residential placement through supporting visitation and transition plans to reunite the family; or it can mean negotiating and sustaining kinship care instead of foster care, and so on.

- Helping parents meet mental health needs means promoting well-being as well as addressing mental health concerns, such as depression and posttraumatic stress disorder that influence parents' ability to nurture their children.

Objectives with Strategies to Guide Family Center Practice

The objectives designed to support achievement of the model's goals, with possible strategies for success, are defined in the center column of Figure 113.1.

Staff Development

Investment in building the capacity of a multi-disciplinary team is central to the family center's success including collaborative practice, supported by a clear mission, supervision, training, and team meetings important to a dynamic, evolving center. Local needs and traditions should be represented in the center's mission, which is shaped by stakeholders (parents, providers, community members) and leadership. For example, the mission of an integrated family center may be to ensure nurturance and protection of children and parents with a culture of care that includes access to needed resources and services. Leadership oversees ongoing investment in the family center staff through capacity building for a vital learning organization promoting competence and use of best practices (Brandon, 2006; Hess et al., 2003; McMahon & Ward, 2001).

Creating and Maintaining a Culture of Care

A crucial objective in the family center practice model is the development of a culture of care that makes it possible to meet parents' diverse agendas (their hopes, purpose, and investment in coming to the center). Strategies that create the culture of care include activities that result in containment, protection, mutuality, and support (Warren-Adamson & Lightburn, 2010). The culture of a family center, like that of a school,

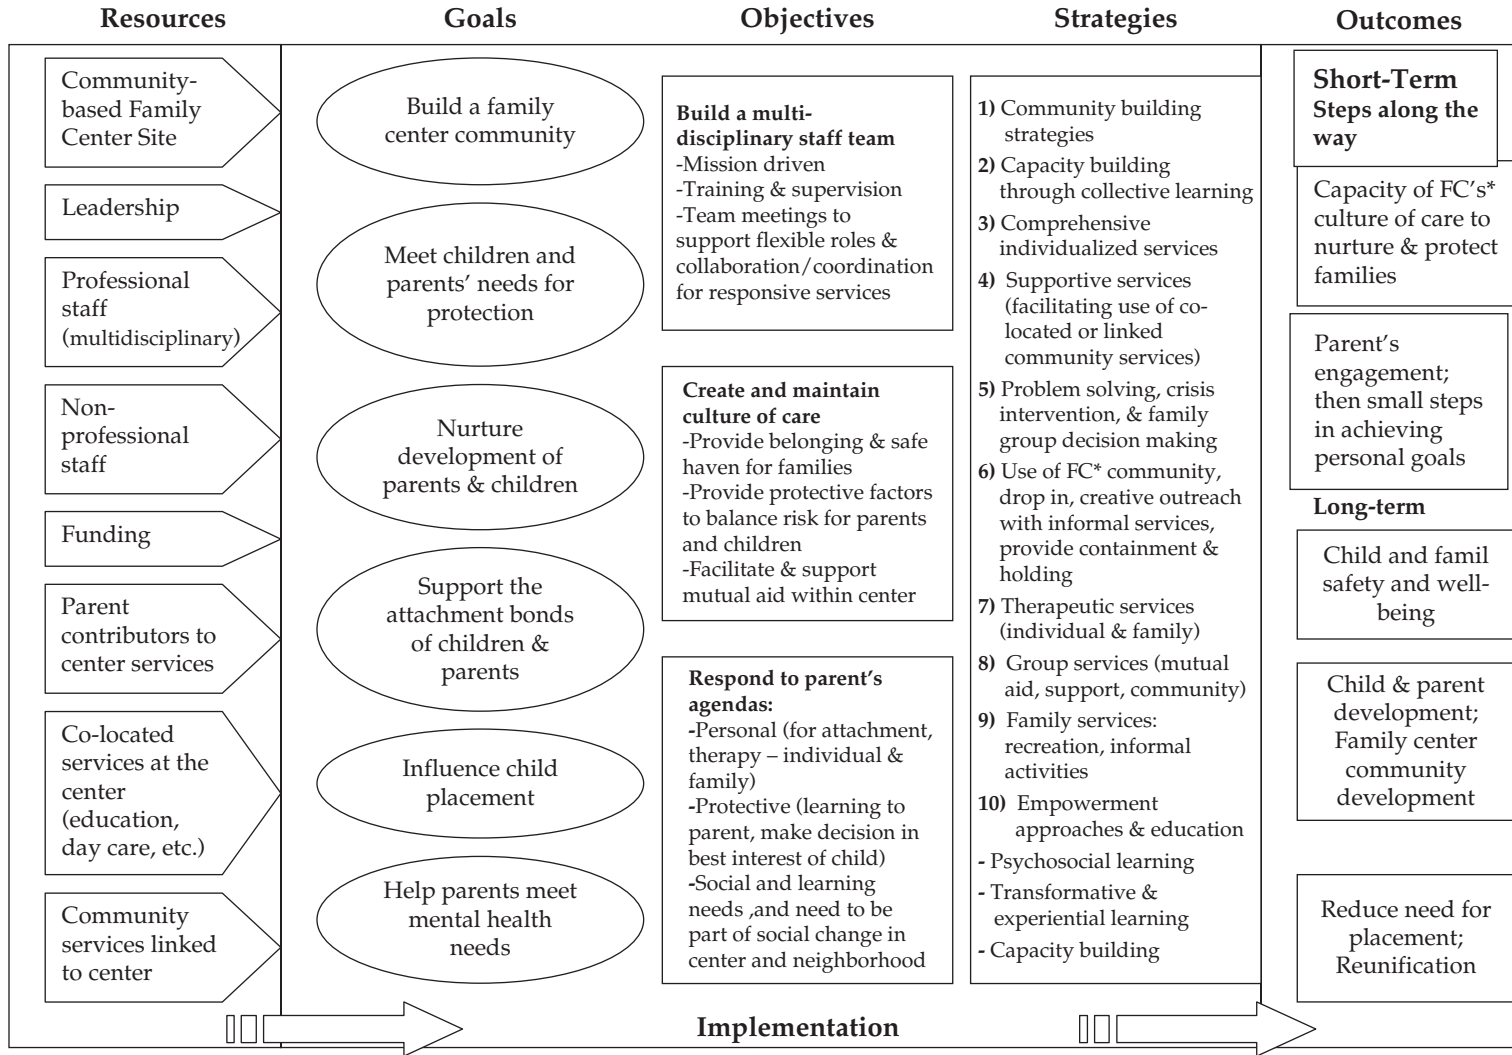

Figure 113.1 Theory of change.

contributes to the psychosocial development of its participants by shaping communication, experience, and identity. A culture of care is evident in the center community's shared values. Development of a culture of care includes trauma-informed program principles that promote safety for children, families, and staff. This involves recognizing and attending to risk and abuse as well as educating community members in alternative problem-solving strategies, rather than tolerating or denying dangerous situations. Mandated supervision of children is part of this culture, wherein the best interests of children are seriously attended to with the support of protective services. At the same time, a clear message is given that the family center will work collaboratively to keep parents and children together. This may be a new experience for most families, who have often failed to work well with service systems that are child-focused, where parents feel blamed and there is limited flexibility in the way services are provided. The family center's culture of care is in significant contrast to the culture of neglect and abuse many families know, where isolation, loneliness, anxiety, and fear rob children and parents of love and nurturance (Warren-Adamson & Lightburn, 2006; 2010).

A key to how the family center culture shapes outcomes is found in the use of time. Parents need opportunities to experience relationships that nurture through acceptance and continuity with flexible responses when there are unexpected and repeated crises. For parents, this community becomes a family—the nurturing, accepting family that many have never known. A strong commitment to families communicates understanding when they are not yet able to grasp how their lives can change. This culture of care provides an important holding environment (McMahon & Ward, 2001; Warren-Adamson & Lightburn, 2006; 2010). As such, it supports development and growth, using parents' strengths and promoting new abilities, where parents' development is as important as their children's.

The values of family-centered practice and family empowerment are enacted through the cultural norms and helping relationships in the family center community, which promote protective factors that buffer risk and support parents' coping skills. For example, community building is vital where staff work to engender positive norms that hold center life together, such as mutual aid, hope, kindness, and positive expectation. The change process depends on promoting

this positive strengths-based culture, which benefits from a learning organization approach that works for the best interests of all.

PARENTS' AGENDAS

The strategies listed in the fourth column in Figure 113.1 build on all that is best, diverse, and challenging in our knowledge about effective interventions and are derived from several traditions of practice: child welfare, and therapeutic and community care, including capacity and community building and advocacy. Effective strategies in implementing family center practice goals and objectives include problem solving, crisis intervention, individual and family therapy, mutual aid groups, parental education, empowerment practice, as well as social action groups and educational opportunities with informal activities.

AN INTEGRATED MODEL OF THE PROCESS OF FAMILY CENTER PRACTICE

An integrated model of the process of family center practice is represented in Figure 113.2. The model integrates four different areas that identify a focus for practice based on a parent's different agendas. This framework responds to the spoken and unspoken, known and yet to be recognized needs, reasons, and hopes that parents bring to the family center. Agenda is the term used to describe family center staff and parents' collaboration to identify a focus for their participation in center programs. Agenda is used instead of contract or treatment plan. It is important to respond to parents' needs and priorities as their personal goals/agenda evolve with their involvement in the center. Practice in family centers is based on collaborative, family-centered principles that recognize parents as active contributors in all outcomes. Parents are contributing members of the community, not cases to be treated and managed.

The parents' agenda as depicted in the model in Figure 113.2 includes the following four domains.

1. *Personal agenda*, reflecting parents' desire to connect and bond with others, be guided and mentored, and gain resources. Personal agendas can be met in a variety of

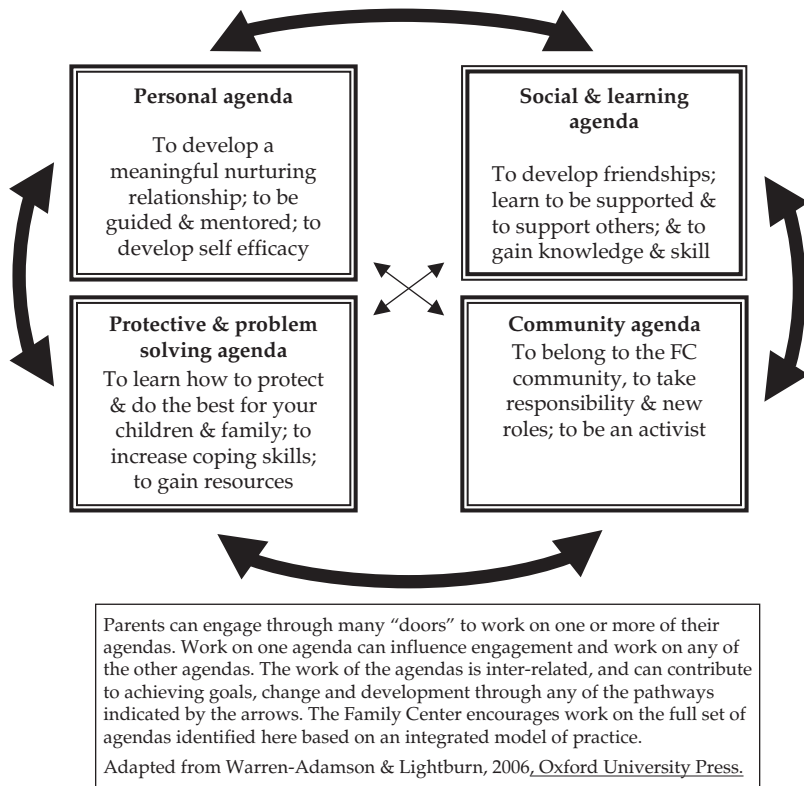

Figure 113.2 Parent's agenda.

- ways, including work with case managers to facilitate use of a range of possible opportunities and services, work with a mentor (parent peer) or guide on steps to self-sufficiency, or work with a therapist to meet interpersonal and mental health needs. Mental health needs are normalized with a focus on building relationships and learning and developing coping skills in a supportive environment.
2. *Protection and problem-solving agenda*, including learning how to protect and nurture one's children and one's self, as well as gain competence in parenting. Many parents have to fulfill mandated requirements to prove they are competent; others want to meet basic needs and find their way out of poverty, domestic violence, or substance abuse. This domain can include learning to solve problems at points of crisis and later develop problem-solving skills to work with family parenting and personal concerns. Of primary importance is the need to establish safety plans that ensure children are protected and nurtured in their families

and communities. This includes recognizing the effects of trauma and understanding the path to recovery, with appropriate parent education opportunities.

3. *Social and learning agenda*, which includes developing friendships, learning to be supported, and supporting others. The experience of mutual aid and being valued as a member of the family center community is an essential contributor to parents' development and self-efficacy, as friendships and support are invaluable in raising children in impoverished or dangerous neighborhoods. Parents are usually interested in group programs, as they share many concerns and can mutually benefit from working on issues with one another, such as managing family life, budgeting, and preparing for employment. Parents often need help identifying what they need to learn and how this can best happen.
4. *Community agenda*, which involves learning to belong and take responsibility, including new roles in the family center community, and to be an activist. Parents' membership

as part of the community reinforces their belonging and provides opportunities for them to join with other parents and staff. Experience as an active community member can increase parents' authority and sense of efficacy because they have roles as citizens to influence and shape the center's community and to advocate for change.

Comprehensive programs offered in many family centers make it possible to meet multiple social and mental health needs described in the parents' agendas. As Figure 113.2 indicates, parents can be engaged to work on one or more agendas. A parent's progress in meeting goals with one agenda can influence his or her desire to work on other agendas. A parent's work on different agendas may influence the progress made overall, as indicated by the directional arrows in Figure 113.2. The challenge for family center practice is imagining and understanding how to facilitate the working of the whole while also focusing on specifics. For example, integration of comprehensive services that aim to meet requirements of mandated protection includes a focus on development for parent and child. Some parents have been victims of violence and for them to grow in competence as a parent they need help with their own recovery and healing. Services must be individualized, responding to a parent's main concern, while maintaining awareness of challenges and abilities. Service integration happens over time, in response to a parent's needs, priorities, and abilities to engage in the work of the agenda, and is similarly based on the capacity of the family center to provide various forms of help.

WORKING WITH OUTCOMES

The diverse and complementary avenues for development and change described in the theory of change sets us on the road to identify outcomes that include familiar long-term outcomes—such as well-being, protected children, more intact families, community development, and so on—alongside what we describe as steps on the way. Outcomes as steps on the way have a particular resonance for practitioners and they are twofold. First, there are those small steps that can include parents meeting personal goals, such as skills in building relationships and exercising personal authority to ensure safety for

oneself and one's children. Second, practitioners in particular contribute to outcomes that define the community of care in developing mutuality, modeling behaviors, and providing containment through parenting behaviors, creative activity, and conviviality. Such outcomes construct a community of care and contribute to change that cannot be fully explained by the traditional names we attach to intervention. The outcomes column should become a valued representation of what is expected and hoped for, as well as a realistic statement of what is possible.

Concluding Thoughts

Centers for families, like many social welfare initiatives, are barometers of economic, political, and ideological change. Over the past 30 years they have waxed and waned in number and the recent economic crash has taken its toll. Nonetheless, a healthy momentum continues in this decade and readers can take note of particular contemporary features of family center activity that enhance our understanding of practice. For example: models of leadership for community development of integrated centers (Whalley, 2006); engaging fathers (Fletcher & Visser, 2008); parent education that is based on evidence, and sensitive to culture and context (Aldgate & Rose, 2012; Petersson et al., 2004); child participation and children centers as versions of family centers; centers directly mandated by courts, as in the Australian family relationship centers (Moloney, 2013); and protection (Warren-Adamson & Lightburn, 2010).

The current decade also brings new theorization about community-based family centers with ideas about sensitive and proximal outcomes described above that connect with the growing interest in complexity theory and the transformational nature of complex systems. For example, complexity theory's synergy principle refers to "the whole as greater than the sum of the parts," where a diverse and complex center system described above generates change in families unexplained by individual component parts (Lightburn & Warren-Adamson, 2012). Other creative center examples—in mental health communities, medical centers, and community work resource centers, for example—suggest goals outlined in the "possible" personal agenda's for parents and the focus on building community, rather than in the reductionist trend for single interventions, should be to create centers

of synergy and complexity. Each complex center would have its own distinctive transformative characteristics but would be replicable in its commitment to synergy generated by a rich level of activity.

SUMMARY

This chapter described an integrated practice model for community-based family centers by explaining a step-by-step logical approach to building such a center, illustrating possible pathways for engagement, development, and change. The framework for practice in Figure 113.1 was developed in response to the goals set out in the theory of change. We suggested intervention in centers involves working with parents' different agendas (see Figure 113.2), with flexible, responsive helping strategies and a broad tradition of intervention supported by a theory of change to meet a variety of goals, and something special that, when it is put all together with energy and commitment, results in a culture of care, providing the "glue" for service integration. Family centers are exceptional because they are more than a system of care; they are a special community that makes a difference for families, staff, and the larger community.

114 International Perspectives on Social Work Practice

Karen M. Sowers

Although our world is becoming easier to navigate, the complexity of social issues and their impact globally demands that social workers respond. International social work practice, an evolving and exciting area of practice, which is gaining increasing interest (Elliott & Segal, 2012; Midgley, 1981) may hold the key to solutions for a peaceful, thriving, and sustainable environment for future generations. This chapter addresses social work practice in the global arena and provides an understanding of the interconnectedness of social work and social development across the globe. Some examples provide illustrations of ways international social work is making a difference to empower people, communities, and organizations.

Social work practice was primarily developed in response to local needs—most often to serve the powerless and disadvantaged and address

issues in managing the developmental challenges of everyday living. As populations expanded and immigration and migration grew, it became clear that the challenges facing people in achieving their individual and collective goals were in many ways more similar than they were different (Sowers & Rowe, 2007). For some social workers, the events of 9/11 emphasized the increasing importance of recognizing a broader economic and cultural context of globalization (Elliott & Segal, 2012).

The increased impact of globalization over the past few decades has highlighted the similarities of social problems. The initial response was a presumption that social work practices in developed countries were the most desirable and effective and needed only simple cultural adjustments to be applied to human and social problems everywhere. However, it became clear that no single

location or country has the preferred methods for all, although various countries may have exemplar programs or best practices that can be instructive to others (Sowers & Rowe, 2007).

INTERNATIONAL SOCIAL WORK

The definitions and conceptualizations of social work differ greatly across cultural contexts. Initially, international social work was concerned with comparing social work as it exists in different cultures and countries. The view of the social worker as one who primarily provides individual clinical services originated in Western industrial countries. Most societies, however, have always had a role for individuals who worked to improve conditions for community members. Clinical practice is more characteristic of industrialized countries, and community organizers in Western countries have learned many of their strategies and practices from their peers in developing countries (Rowe, Hanley, Moreno, & Mould, 2000). Although *social work* is the term most commonly used in the United States and other industrialized countries, *social development* or *developmental social welfare* is often used in developing nations (Elliott & Segal, 2012).

Over the decades, social work has grown and matured worldwide. Currently an effort is being made to address social work from a global perspective—as one profession practicing in many different countries. This effort is led by two international organizations, the International Federation of Social Workers (IFSW) and the International Association of Schools of Social Work (IASSW). In 2001, the IFSW and IASSW jointly agreed on an international definition of social work. That definition has evolved over time. The current definition on international social work can be found on the IFSW website (www.ifsw.org/policies/definition-of-social-work) (IFSW, 2012a). In March 2013, the IFSW and IASSW crafted a “point-in-time” Draft International Definition of Social Work (IFSW, 2013a). This draft, endorsed by both organizations is open for feedback and comment until December 2013 (go to <http://ifsw.org/get-involved/global-definition-of-social-work> to view and add your voice). The current draft definition of social work is below:

The social work profession facilitates social change and development, social cohesion, and the empowerment and liberation of people. Principles of

social justice, human rights, collective responsibility and respect for diversities are central to social work. Underpinned by theories of social work, social sciences, humanities and indigenous knowledges, social work engages people and structures to address life challenges and enhance wellbeing (IFSW, 2013a).

INTERNATIONAL SOCIAL WORK PRACTICE

Global social work practice is based on the values of human rights and social justice. The most universal beliefs that characterize social work globally include the principle of social inclusion as core to the alleviation of poverty and the promotion of self-determination and self-sufficiency of disenfranchised and vulnerable people and the inherent value of people and the responsibilities of societies to create conditions in which people can thrive (Morales & Sheafar, 2001).

In 2013, the IFSW, the IASSW, and the International Council on Social Welfare (ICSW) solidified a global agenda for social workers, educators, and social development practitioners (IFSW, 2013b). The Global Agenda outlines and specifies commitments to action to ensure the dignity and worth of the individual, the promotion of sustainable communities and environmentally sensitive development, the promotion of well-being through sustainable human relationships, and ensuring an appropriate environment for practice and education. Social workers interested in or engaged in global social work practice should also be familiar with and practice within the international standards and guidelines for social work practice. These include the Global Qualifying Standards for Social Work Practice (IFSW, 2012b), the International Code of Ethics (IFSW, 2012c), the IFSW campaign for real rights (IFSW, 2013c), the Universal Declaration of Human Rights (United Nations, n.d.).

Practicing within the Cultural Context

Social and cultural realities can create both challenges and opportunities in global social work practice. Global social work practice requires that social workers become aware of their own values, biases, and beliefs and value and respect differences as well as understand the dynamics of difference (Matsuoka & McCubbin, 2008; Sowers-Hoag & Sandau-Beckler, 1996).

For example, in 1986, New Zealand restructured its social welfare department in response

to growing criticism that it was too bureaucratic, emphasized individualized casework services, neglected local needs, and failed to respond to cultural needs of specific groups. The new model adopted by New Zealand allowed for joint decision making and resource sharing with communities. The model particularly targeted indigenous communities, using community as provider within the delivery system. Changes in social work practice included the development of culturally sensitive practice with strong links to indigenous communities. The promotion and funding of preventive, community-based services were determined by local communities. (For more information, see Baretta-Herman, 1994.)

As can be seen from this example, the most effective approaches to advancing human rights require cultural sensitivity and responsiveness and embrace inclusive strategies that encompass culture and religion and the roles played by local power structures and institutions (United Nations Population Fund, n.d.). Because societies and cultures are increasingly complex and changing, social workers practicing in a global context must be lifelong learners and willing to change, adapt, and use strategies that are relevant and specific to differing situations (Sowers & Rowe, 2007).

Today, poverty, inequality, and human distress are issues to which social workers respond everywhere in the world. Certain social issues, including population aging, immigration and migration, substance abuse, human-made and natural disasters, and health and mental health, transcend nation-states. The following provides some examples of worldwide social problems addressed by social workers.

Substance Abuse and HIV

In many cities around the world HIV disease has reached epidemic proportions. On the basis of global 1992 data, the World Health Organization (n.d. a) estimated that "over 5 million people injected drugs, that between 150,000 and 200,000 drug injectors died every year, and that at least half of those deaths were associated with HIV." By 1996 the United Nations estimated that seven persons per million were infected by HIV as a result of injectable drug use and that the 1996 rate increased to 248 persons per million in 2000 (World Health Organization, 2005). Global efforts are needed to support safe behavior among HIV-infected substance abusers and among drug

abusers in general. Because of the critical need to support safer behavior, particularly in cities with a high prevalence of HIV, cities, governments, nongovernmental organizations, and other groups are implementing harm reduction programs (Sowers & Rowe, 2007; World Health Organization, 2007). Harm reduction is defined as "policies and programs which attempt primarily to reduce the adverse health, social and economic consequences of mood altering substances to individual drug users, their families, and their communities" (International Harm Reduction Association, n.d.). This new global approach is especially useful in the prevention of HIV/AIDS.

In contrast to a punitive approach to drug abuse, the harm reduction model views addiction as an adaptive response to a wide cross-section of individual and collective variables that may influence behavior. Practitioners using the harm reduction perspective develop interventions that reduce drug-related harm without necessarily promoting abstinence as the only solution. Harm reduction for injection drug users primarily aims to help them avoid the negative health consequences of drug injecting and improve their health and social status. These approaches recognize that for many drug users total abstinence from harmful substances is not a feasible option in the short term. It focuses on helping users reduce their injection frequency and increase safety. To be effective, harm reduction strategies must be embedded into comprehensive prevention and intervention packages for injection drug users (World Health Organization, 2005). The following are typical components identified by the World Health Organization (2005) that have a significant potential to reduce individual risk behaviors associated with drug injection:

- Needle-syringe programming provides drug users with access to clean injection paraphernalia, including needles and syringes, filters, cookers, drug containers, and mixing water. These interventions may also collect used needles and syringes. These programs serve as information points for drug and HIV disease education and provide referral for treatment services. Their ability to break the chain of transmission of HIV and other blood-borne viruses is well established.
- Drug substitution treatment involves the medically supervised treatment of individuals with opioid dependency. The primary goal

of drug substitution treatment may be abstinence from illicit drug use but many patients are unable to achieve complete abstinence. There is clear evidence that some drug substitution treatments, such as methadone maintenance, can significantly reduce unsafe injection practices of those who are in treatment and at risk of HIV infection.

The application of harm reduction principles to other problematic substances, such as ecstasy, tobacco, and alcohol is a fairly recent event but has shown widespread effectiveness and public acceptance in many places across the globe.

In Argentina, 39% of those diagnosed with HIV acquired the virus through intravenous (IV) drug use. Past harm reduction activity efforts had little effect. In response, a specific harm reduction approach with poor populations in Buenos Aires using a community-based outreach approach with specific emphasis on drug users, their sexual partners, and children was developed with the participation of 23 pharmacies. This approach proved successful, reaching 900 drug users with preventive messages in a 3-month period. In location-specific areas, preventive materials were distributed by drug users, former drug users, and local pharmacies (Rossi et al., 2001).

Mental Health

Mental health problems are common to all countries. They are the cause of immense human suffering, disability, social exclusion, and poor quality of life (Davis & Jung, 2012; Sowers, Rowe, & Clay, 2008). Across the globe, about one in every four persons going to health services has at least one mental, neurological, or behavioral disorder. Mental and behavioral disorders are estimated to account for 12% of the global burden of disease, yet the mental health budgets of the majority of countries constitute less than 1% of total health expenditures. Unfortunately, even in countries with well-established mental health services, fewer than half of those individuals needing care make use of available services. This is related both to the stigma attached to individuals with mental health and behavioral disorders and to the inadequacy of the services provided (World Health Organization, 2001).

According to the World Health Organization (World Health Organization, 2001), good mental

health care flows from the following basic principles:

- Diagnosis
- Early intervention
- Rational use of treatment techniques
- Continuity of care
- Availability of a wide range of services
- Consumer involvement
- Partnership with families
- Involvement of the local community.

Integration of mental health treatment into primary health. The prevalence of mental disorders is worldwide, and many persons suffering from mental and behavioral disorders are first seen in primary care settings. This is probably because mental health problems are often associated with physical disease. But because many primary care providers do not have specialized training in mental illness, these disorders are often not detected. A global trend has been the integration of mental health care into basic primary health care by training primary care and general health care staff in the detection and treatment of common mental and behavioral disorders. The World Health Organization stresses the importance of the development of community-based mental health and social care services and the integration of mental health care and treatment into general hospitals and primary care (World Health Organization, 2013). With appropriate information, training, integration, and continuity of care between providers patients discharged from psychiatric facilities can be effectively followed up in primary health care settings. This is a particularly important initiative in countries where community-based mental health services do not exist. In many developing countries, well-trained health care workers have been able to provide treatment effectively and efficiently for persons with mental illnesses. In fact, experiences in some African, Asian, and Latin American countries indicate that adequate training of health care workers in the early recognition and management of mental disorders can reduce institutionalization and improve clients' mental health outcomes (Sowers & Rowe, 2007).

There are an estimated 4 million people with schizophrenia in India. It is estimated that this impacts approximately 25 million family members. Recognizing that outcome of the disorder is strongly influenced by social factors, especially

family, the Indian government developed a system of support to people with schizophrenia. According to the World Health Organization (n.d.b) components effecting outcomes included:

- A manual for family intervention produced in local languages
- Training of the local health workers. Training focused on the appropriate identification, management, and referral for mental health problems and how to implement actual interventions.
- Brief psycho-educational interventions were provided to 1,500 families. Content included information about mental illness, basic training in daily living, problem solving, and communication skills. Pharmacological treatment was provided to patients. Day centers were opened for people with mental disorders.
- Nongovernmental organizations were mobilized and actively involved in the project. Emphasis was placed on awareness-raising events and information dissemination about mental health problems and their management.

Natural and Human-made Disasters

Recent events around the world underscore our lack of preparedness and ability to respond to the aftermath of disasters. Disasters may be natural occurrences such as floods, hurricanes, or volcanic eruptions. Human-made disasters include technological disasters, terrorism, armed conflicts, and war. Man-made disasters may also result from environmental degradation such as overcultivation, erosion, severe deforestation, or overgrazing of marginal lands. Natural and human-made disasters often strike communities with little or no warning. Although social workers have a long history of responding to disaster trauma, few have knowledge or experience in dealing with the sort of disasters that have occurred with increased frequency and intensity. As disasters occur more frequently and with greater intensity, disaster response, relief, and recovery efforts have become more complex. To respond in a timely and appropriate manner to the likely psychological distress experienced by trauma survivors, social workers must understand the nature of the problems survivors may experience, the types of help they may need, and

the level of preparedness of the health and human service delivery systems in place to respond to those needs (Sowers & Rowe, 2007).

The World Health Organization's Department of Mental Health and Substance Dependence (2001) provides important lessons learned from responses to catastrophes:

- Intense emotional reactions in the face of these events are expected and normal
- There is a trajectory of response over time, most often starting early and subsiding within weeks and months. For some people, however, the onset of response may be delayed. For others, the reactions may become long-term, leading to considerable disability.
- Responses will be highly individual in nature, often quite intense, and sometimes disputatious
- The range of feelings experienced may be quite broad. People may describe intense feelings of sadness followed by anger.
- There may be temporary disruptions in normal coping mechanisms for many people, and some may develop problems with sleep, nightmares, concentration, intrusive thoughts, and a preoccupation with reliving the events.

The Department of Mental Health and Substance Dependence (2001) offers the following guidelines for providing help in the aftermath of a catastrophe:

- Create opportunities for people to talk and share experiences in supportive groups.
- Provide accurate and practical information, especially concerning the larger recovery efforts.
- Give particular consideration to the needs of special groups such as children, those who have been most intensely exposed, or those with a history of previous trauma.
- Children and adolescents will need the support of their caregivers.
- As many as 30% of people who experience the most direct exposure to the events may go on to develop more serious mental health concerns and may need to be referred for services.

Promising new approaches are focusing on risk reduction from natural disasters. One such

innovative approach is the “sustainable livelihoods” model. This approach analyzes the range of vulnerabilities in poor communities and outlines specific assets within the community. Vulnerability and capacity analysis is a valuable new field tool currently being used to assess communities’ disaster resilience and mobilize risk reduction (International Federation of Red Cross and Red Crescent Societies, 2002).

Since the attacks that rocked the world on September 11, 2001, some global leaders have noted that disasters have the potential to increase poverty and hunger, increase infectious diseases, and effect primary education for children. Disasters can have particularly devastating effects on the development of poorer nations. Disasters have the potential to destroy farmland, animals, and other forms of livelihood. Even small disasters that are recurrent can affect family resources and resilience. All of these effects can take a toll on health and wellness.

CONCLUSION

Increased recognition of the importance of international social issues has spurred a growing demand for social workers. As welfare, economic, and foreign policies become ever more globally interdependent, there is a need for global social work practice. We can hope that the future will see a reduced tendency for social work to dichotomize between global and domestic social work issues. The fostering of mutual exchanges of experience and information between social workers in different societies can only advance our practices. We have much to learn from each other.

115 Community Organizing Principles and Practice Guidelines

Terry Mizrahi

This chapter is based primarily on my own experiences over 40 years. It is also informed by the literature reflected at the end, and validated by the cumulative field experiences of hundreds of community organizing students at the Silberman School of Social Work at Hunter College (formerly Hunter College School of Social Work).

I address the reader as “you” and assume that you are reading this as you initiate or are being called upon as a student or experienced organizer to respond to an issue, address an agency or community need, or as you are training and teaching others these principles. The phrase “target of change” is used to mean whichever body (a person, agency,

or a system) you are trying to influence. These principles are not laid out in a linear order. Several of them need simultaneous consideration before taking action; others are interactive and overlap.

**PRINCIPLE 1: EFFECTIVE ORGANIZING
BALANCES PROCESS AND PRODUCT**

A key assumption is that there is never sufficient time, staff, and other resources to involve people in making change (the process) and accomplishing a specific goal or task (the product). Both are important, so the question is how to operationalize and balance them. Process means that there must be enough discussion to achieve a consensus to move ahead and keep the participants engaged. This does not mean unanimity, but rather a “sense of the body,” informally or formally (by vote) determined. Where there is disagreement, there must be a mechanism to ascertain its intensity, and to determine whether moving ahead means a permanent division or dissolution. How much dissent is inevitable and acceptable? You need enough process to gauge people’s interest in and commitment to the task. Involvement of people creates a sense of investment and can ultimately lead to a sense of ownership of the product as well as a transformative process of working together in its own right. You need time to build trust between the group and you as well as among participants. That can be done by working on the task while reflecting periodically on the process: “How we are doing?” “Whose voices do we still need to hear?”

The solutions to managing time so that you achieve the product without sacrificing the process are to (a) calculate a more complete and realistic timetable; (b) modify expectations if necessary; (c) prioritize what is essential with those involved; and (d) ascertain who else can assist with the project. Organizing means planning for contingencies, allowing more time than appears necessary, following through, and paying attention to detail.

**PRINCIPLE 2: PLANNING IS
A COMPLEX VALUE-BASED,
SOCIOPOLITICAL AND TECHNICAL
PROCESS**

Planning is not just about data collection, goals, and timelines or who can write a clear, internally consistent proposal. Rather, planning, as a part of

organizing is a sociopolitical as well as a technical process. Power and resources inform the way you and your constituency define the problem and select the solutions. But underlying planning is a value base or ideology, which includes basic assumptions about why a problem exists, why needs are not being met, why conditions are not optimal, and also includes ascertaining who or what is to “blame” for the problems identified. Social work values are informed by social and economic justice and democratic, participatory decision-making. Power means understanding that *somebody* (with a small or capital B), that is, some individual or group has the ability to make decisions about how resources are allocated and whether to implement the program or change a policy. Resources include creating, increasing, or redistributing assets (social and economic capital) that address the planning outcomes. Hence, the strategies you select for influencing the decision makers to achieve your goal are done within a sociopolitical and value-based context.

Here are some examples: Substance abuse was identified as a national problem in the 1960s when it spread beyond the ghetto to middle-class America; mental retardation “came out of the closet” when President John F. Kennedy disclosed that he had a mentally retarded sister. Although middle-class parents had been organizing and planning services for their children throughout the 1950s, mental retardation became a national priority because the president used his office to create funding opportunities for additional facilities and programs. On the other hand, HIV/AIDS did not become a national priority when first detected because President Ronald Reagan did not publicly address the problem until enough visibility and pressure was placed at his doorstep in 1986. It took organized social action of groups like ACT-UP, together with publicity about a Caucasian boy, Ryan White, who contracted AIDS because of a blood transfusion, to lead to additional funding for prevention, education, and treatment with the involvement of consumers and providers.

**PRINCIPLE 3: THERE IS NO
SUCH THING AS “RATIONAL”
AND “IRRATIONAL” FROM THE
PERSPECTIVE OF HOW PROBLEMS ARE
DEFINED OR RESOURCES ALLOCATED**

Many times, as part of the process of identifying problems, someone may say that a particular

system, structure, or policy needs to be changed because it does not make sense; “It’s irrational.” When someone makes such a statement, consider reframing the question by instead asking that person or group: “To whom does it make sense?” “For whom is it functional and working?” “Why hasn’t that policy been changed, if it isn’t working for your constituency?” You will usually uncover reasons why conditions or attitudes have remained in place, why a need was not met, why people have resisted change, or why a new program was not implemented.

Usually the case does make sense from the perspective of those who maintain that system or oppose the change. It is essential to consider reasons for the resistance to change. For example, a new program can be an implied criticism of the existing system. It may mean that a group perceives they will lose power if that program is created. In other words, it is not irrational for groups that may be affected adversely to attempt to maintain the status quo. Understanding this allows you to identify the covert as well as overt reasons for resisting change and to develop strategies to decrease resistance. This does not mean that there are not instances where situations do not change because of mistakes, arbitrariness, inertia, time or cultural lag, or misinformation. Not everything is deliberate and conscious. Analyzing the seemingly irrational status quo can be done by “peeling the onion,” addressing the stated reasons one at a time until perhaps the underlying rationale, whether coherent or not, becomes evident.

Understanding that there is no such thing as value-free planning and organizing provides an opportunity to identify and explore the values and beliefs that inform the problem definition, which, in turn, shapes the proposed solutions that emanate from that definition. It allows you to understand why your group’s beliefs and proposals may seem irrational to others.

It is important to understand that “rationality,” when it means utilitarian, is itself an ideology, one that is usually associated with capitalism and pragmatism. Often the term “rationality” is invoked in contrast to “ideology,” as, for example, when opponents of a plan will state that the proposers are not being rational. You need to consider whether evoking “rational” solutions is being used to prevent deliberations that include values such as fairness, equality, and justice, or if it is being used to divert or discredit those who have a progressive value base. Nevertheless, you

need to be open to listening to opposing viewpoints and understand and explain their attitudes and behaviors without necessarily excusing or exonerating their conclusions. To take the example of homelessness, the problem was ignored by government and the public until a combination of deinstitutionalization of mental hospitals and gentrification of formerly abandoned and neglected neighborhoods resulted in hundreds of thousands of people without a place to live in the 1970s. However, the solutions to homelessness are informed by values and ideology, not just on the basis of need or data alone. Those who perceived it as a housing problem advocated for the right to shelter and housing; those who perceived it as a mental health problem advocated for services; those who perceived it as a civil liberties problem advocated for personal choice and the right to be left alone; and those who perceived it as a criminal justice and morality problem advocated for incarceration, involuntary commitment, forced work, and other social control measures. These were all “rational” solutions from the perspective of the proposers.

Nevertheless, political and ideological arguments about rationality should not obfuscate your need to be logical, systematic, and problem-focused. It is necessary to anticipate the steps, activities, people, and resources needed to produce a coherent plan from beginning to end, implement it, and evaluate it, as well as to identify contingencies beyond your own and your constituency’s control. Analytical skills as part of “rational” planning are essential.

PRINCIPLE 4: KNOW AND MAKE YOUR CASE

Assessments are a critical part of community organizing and planning practice. It is essential to ask the questions: “How do you know there is a problem?” “How do you know there is a need for a particular intervention?” “Who asserts that there is a problem/need?” “Who is defining the problem/need?” “Why at this time?” “How serious and pervasive is the problem?”

As noted in Principles 2 and 3, defining the need has an ideological as well as factual component. For example, if it is reported that 30% of the students in a particular school or community did not complete high school, the questions to be posed should include: “Is that a problem?” “For whom is that a problem?” “What are the

solutions?" Answers to those questions will depend on several factors and values: whether the norm in that community (however defined) is to complete high school, whether it is desirable to complete high school, whether that figure has gone up or down in the last several years, how that figure compares to other schools, and the alternatives to and consequences of not completing high school. Remember, the way a problem is defined will determine the proposed solution(s). If you report that 30% of the students dropped out of school last year, there is already an implied causation. "Drop out" implies a willful act on the part of the student or neglect on the part of parents or the community. Consider the difference when you say that 30% of the students were "pushed out" or "turned out" last year. The latter implies the problem lies primarily with the school system.

Once you define the problem, the next step in the planning process is to document the problem. This entails gathering quantitative and qualitative data, sometimes called empirical (objective) and perceptual (subjective) information. The needs assessments that use both are most effective; they present statistics as well as humanize the issue. Documentation includes identifying assets and deficits. Prepare the materials using multiple methods and media—written, verbal, and visual. In making your case, use numbers, narration, surveys, interviews, case studies, anecdotes, and secondary data analysis. Language matters. How one phrases a term also affects how it is received; for example, when homeless people are welcomed as "guests" rather than identified as "the homeless," it makes a difference. Calling someone an "ex-con" versus a "formerly incarcerated person," makes a difference in how the message is perceived.

Next, consider the ways in which to convey that information to make the strongest, most convincing case. First, you need to identify the various audiences who need to know about the problem. How do you reach the various communities and constituencies? How do they best receive information? Communicating with the decision makers may be different than communicating with supporters and allies. To reach the public at large, you may need different means and messages from the ones used for reaching clients and constituencies. Here are just a few of the many steps to consider: Will it be in the form of a letter, a report, or an article in a community newspaper? Should it be a story on an ethnic

radio station? Who writes and signs it? Who will review the format and content? Remember, presentation is as important as the content. *Pithy* and *poignant* are key words in persuasive communication. Make it brief with emotion! Lengthier background information pieces should be available without inundating the various publics. Is there a public or private forum where the data should be presented? Who will be there? Who else should be invited or know about the event? What materials should be presented (e.g., fact sheets, photos, or videos of the conditions; testimonies of people directly affected; experts and influential people in the field)? Who will follow up? Outreach is a strategic campaign of many steps, not just an activity.

For example, several years ago, a director of a public health clinic helped create additional funding for dentistry for low-income adults by making the case about the depth and breadth of the problem. He launched a public awareness campaign showing enlarged photographs of decayed mouths of adults. He took these to many public forums in that community and then to the press. When asked the age and country of the people with this severe dental disease, no one could guess that they were New York City residents 20 to 40 years old. This created public sentiment for increasing coverage of preventive dental care for low-income populations, which was communicated to the decision-makers, the City Council, and the Mayor.

PRINCIPLE 5: THE "COMMUNITY" IS NOT MONOLITHIC

In engaging in a change effort, or in trying to build the influence of your constituency, the organizer must pay attention to historic tensions, intra- and interpersonal conflicts, and interorganizational and interdisciplinary differences, as well as structural inequalities that prevent people from working together. Community has multiple definitions (geographic, symbolic, identity, interest/issue-based). The tension is that for some political and strategic purposes it is important to identify a general constituency (e.g., Latinas, seniors, Asian Americans); for other purposes, it is important and almost inevitable to recognize that within that large category there usually are differences according to other identities such as gender, country of origin, culture, and other attributes, which can divide the group if unaddressed. Organizers must balance unity and diversity.

If the aim of organizing is to build a diverse constituency or coalition that is multicultural or includes segments of a community that have been excluded, additional time and thoughtfulness must be brought to the fore. Historical and current differences by class, race, gender, ethnicity, status, or sexual orientation have to be factored in from the beginning. Experience has shown the difficulty of including excluded groups after a process of building an organization or coalition already has begun. Consider the groundwork that has to be done “on the way to the first meeting.” Acknowledge and anticipate heightened sensitivities if new partners from different backgrounds are coming together for the first time, or if groups that distrust each other are returning to a new table.

The relationship between an organization that is leading a campaign (whether at a grassroots or coalition level) and the constituencies it wishes to reach are the important factors. Is the organization trustworthy? Is there a track record of competency? As you begin outreach, the reputation of your organization counts. Are the organization and organizer from that community (however defined) or from outside it? The organizer is not a free agent. The auspices and background of the organizer are critical factors in the role he/she plays in organizing a campaign.

There are benefits and limitations to both the insider and outsider position. An inside organization has a track record and already has its allies and (most likely also) detractors; an outside organization (e.g., a university, a foundation, a corporation) especially if it is mainstream and powerful, may or may not have a positive track record with that community. A person with the same identity (or one or more identities—e.g., gender, race, education) as the constituency may be accepted more easily, but an outside person with a different background may bring new ideas and connections, along with a fresh perspective, and may be able to bridge internal divisions.

**PRINCIPLE 6: KNOW THE
DECISION-MAKING STRUCTURES OF
THE TARGET SYSTEM: WHO HOLDS
FORMAL POWER (AUTHORITY) AS
CRITICAL ACTORS AND WHO HOLDS
INFORMAL POWER (INFLUENCE) AS
FACILITATING ACTORS**

Understanding and utilizing the concept of power; that is, which *body* (person) or *Body*

(group, structure) can make the change you want, is an essential component of organizing. It is important to analyze the two faces of power—authority and influence. The “critical” actors are the actual legitimate decision makers, those with the sanctioned formal authority to grant the request, make the change, and allocate the resources. The facilitating actors are those who can influence the critical actors because of their relationship to them. Many times, people do not know who has the formal power because it is hidden, or because the system is complicated. The best approach is to do a power analysis beforehand. Who are the people and organizations who control the systems you want to influence? For example, the authority in a hospital may be vested in the board of trustees and the medical boards. State health departments, which have the authority to grant or suspend an operating license to that hospital, have the ultimate formal power over the hospital—although they may not readily use it. The authority to evict a tenant rests with a landlord, but the local or state government may create regulations to curb a landlord’s absolute power through regulations or the courts.

The formal system of authority is usually found on some version of an organizational chart. These are usually in the form of a diagram that shows the chain of command, who reports to whom in the hierarchy, who controls certain activities, and to whom they are accountable internally. Do not be surprised if the organizational chart is difficult to obtain, even within your own organization. Many organizations do not want to reveal the formal authority; they may conceal differences between those designated to make decisions and those who actually make them. Often, groups will be told that the organizational table is in transition or not current.

Knowing someone’s formal position can help decide the level of intervention in the system. If someone says they cannot make a certain decision, you want to ascertain whether they are being accurate or “buck passing.” It is essential to ask that person, “Who can make that change or grant the request?” Those persons you initially approached may become a facilitating actor in the process of making change if they reveal their relationships to the critical actor(s). There are many instances where organizers and their constituencies are at the wrong door as a result of ignorance or deceit.

There is also a need to know and use the informal structures of influence. Influence is power acquired by people when they do not have the authority to make decisions. Clearly people are able to amass power to make change by virtue of being able to influence the decision-making bodies. There are many ways groups can be powerful when they are not in a position to command, “Just do it!” People have power through the positions they hold, their past history of action, longevity in a system, perceived effectiveness and expertise, connections to the decision makers, ability to control a large constituency, characteristics such as persistence and willingness to take risks. There are powerful “subordinates” in organizations because of certain functions they perform or access they could provide (e.g., janitors, secretaries, and technical staff).

Organizing power by using strategies of influence is an essential skill set. Organizers use these strategies to bring pressure to bear on the structures of authority to convince them to make the needed changes, fund programs, reallocate resources, and so on. Different tactics will be needed for confronting public/government and private/corporate power. Depending on the issue, many changes can be made at lower levels in both public and private bureaucracies. It is not always necessary or wise to start with or go to the top.

PRINCIPLE 7: DO NOT ASSUME THAT THE TARGET YOU WANT TO INFLUENCE IS A UNIFIED, MONOLITHIC SYSTEM

Whether you are on the inside or outside, look for internal strains, divisions, and vulnerability within the system, organization, or institution your group wants to influence. Seek friends and allies from within. Most organizations try to create a culture of unity; at the very least, they attempt to present a unified front to the public. However, that does not mean that there is unanimity among staff regarding their positions, policies, or programs, especially in large bureaucracies. In analyzing the system you are trying to influence, it is essential to ascertain who on the inside of that system (besides you, if you are part of that system) feels similarly about the issue as does your group/constituency? Those inside people can provide important pieces of information, including the identification of the critical and facilitating actors. They know about

the organization’s past and current policies, procedures, and culture.

Conversely, those insiders may need your (outside) group for support, legitimacy, and resources, and even want you to pressure them to do their job more effectively (Principle 12 provides more detail for those on “the inside”). The model of exchange is pivotal. You provide them with the capacity to be more influential on the inside, and they can become an ally.

The exposé of the conditions at Willowbrook State Institution for the Mentally Retarded in New York City in the early 1970s provides a case in point. It was a long struggle and went public after several years of professional staff and families trying to convince those in charge to improve the horrendous conditions. Many courageous social workers, resident psychiatrists, and other staff inside the institution worked with advocacy and family groups on the outside by providing necessary information to them and eventually to media and elected officials. When—then young—investigative reporter Geraldo Rivera turned his cameras on the site, it was because people on the inside obviously had blown the whistle. This resulted in a transformative change in the system of care. Working behind the scenes is tantamount to Principle 10.

Some caution must be exercised in attempting to exploit the complexities or tensions within an agency or target system. Although outsiders initially may rally staff (and clients), this may create difficulty in negotiating later on in the process, because the conflict has been escalated and become widespread. It may prevent at least some on the inside from cooperating for fear of antagonizing their leaders and managers. You may need to protect their cover and also respect their need for a low profile. Clients may fear losing their program even if it has deficiencies. The principle is to proceed deliberately, allowing time for the people on the inside to persuade others of the need to grant the request or meet the demand (further discussed in Principle 9).

PRINCIPLE 8: ASSUME NOBODY KNOWS ANYTHING, ANYTIME

For political and strategic purposes, you must work from the assumption that those in charge of the systems you are attempting to change are ignorant of the problem or need. Therefore, your first step is to define and document the need in a

way that gives the decision makers a chance to respond, even if you believe that those in control already have the requisite information on which to act. For example, assume the mayor of a large city does not know that thousands of homeless people live on the streets every night. In reality, that information has appeared in various media. Nevertheless, it apparently has been ignored or dismissed. So, once you present the problem and possible solutions, the ball is in their court. If they really did not know the extent or seriousness of the problem, then this is a genuine opportunity to influence and negotiate change by presenting the necessary information and making a cogent argument as discussed in Principle 4.

If they already knew about the problem but did not act, they are more apt to respond when the need is directly presented in an organized and persuasive manner. You may have given them a chance to save face if the need was hidden. Do not underestimate the value of this human principle. In the best scenario, they will do something about the issue (i.e., clean up the park, fund a program, pass legislation, allocate staff time for an activity, etc.). In the worst scenario, they will delay or oppose the solution openly. If they do not respond, your group has greater legitimacy for moving ahead and escalating the pressure—from presenting additional information to using more intense and persistent persuasive tactics including taking the issue public or threatening later actions. The important point is to document all the steps taken in this process, and keep the relevant people, constituencies, and organizations informed and involved. This should include the constituency itself, as spokespersons, leaders, and as representatives of the population.

This principle also applies to the constituency itself without being patronizing. Educating them about the root causes, the power structure, and the gaps between their knowledge and actions is an important role for the organizer. It must be done in a way that respects their views even if misinformed. Presenting data from real life can counter stereotypes and myths.

**PRINCIPLE 9: ASSUME GOODWILL
AND COMMON CAUSE ON THE PART
OF THOSE WHO CONTROL AND
OPERATE THE SYSTEM**

This may seem to contradict Principle 7, but in reality, both tensions have to be managed at the

same time—both are truths. There are unhappy employees who may be willing to provide “inside information” and even speak out, but experience has shown that line and support staff, professionals included, are usually loyal to their place of employment. Assume that most people want to do a good job most of the time (based on the human relations theory of management). The reasons for loyalty are many. It may be because of the pride they take in their own work or because they understand the many obstacles impeding major changes inside their system. It could be out of a sense of vulnerability, or their fears of being outspoken, or their uneasiness with proposed alternatives. They may have been co-opted, or they may have made the system work for them. Certainly a need for stability and predictability may outweigh change and uncertainty.

Even if you uncover disillusionment, fear, or inertia among certain staff, caution must still be exercised in publicly criticizing the whole agency or system. Staff or clients may agree with the issues being raised; however, they may not necessarily want those problems uncovered in public. Time and again, organizers have underestimated the sense of workers’ and clients’ feelings of hurt or anger at perceived attacks on their system or agency. Even when the outside group attempts to separate or not blame all workers or supervisors equally, there may be resistance to aligning themselves with an outside or even inside activist group.

As noted in Principle 6, it is vital to gauge the tacit or active support of at least some people on the inside and identify the extent of their loyalty. This will help you assess whether those in control of the institution/agency have the power to use a “we/they” division to create rifts between those on the outside and those on the inside. To use one case example: when a neighborhood health organization began criticizing a local hospital for inadequate care, the organizers assumed the hospital workers, most of whom were from the same background or came from the same neighborhood, would join in their public meetings or issue a statement of support. Private conversations afterward revealed that many staff were angered that no one had asked them their opinions about the issues or strategies in question. A “divide and conquer” strategy ensued, with the hospital director firing the few sympathetic workers who joined with the health organization while promoting a few others who were then co-opted. The rest of the staff remained silent.

This came as a total surprise to the organization seeking change and undermined its effectiveness.

Therefore, in beginning any campaign with an organizational target, it makes sense to assume that the system is not intentionally out to harm or hurt the clients/constituency, but rather is attempting to do the job it was given. Hence the value of framing the problem in consensus terms, at least initially. It should not be presented or perceived as a “win/lose” scenario (see Principle 8). The goal of a campaign can be stated in ways that recognize that all involved have a similar mission; for example, they want to help children, provide quality health care, have a clean environment, keep a neighborhood safe, and so on. Alternatively, your group could convey its understanding of the difficulties that the agency/system has in meeting the needs of its clients or constituency. Then your strategy becomes one of demonstrating and documenting to the leadership, staff, the public, and clients, how the agency/system is interfering with or defeating its own goals or mission. Where possible, appeals should be made to their self-interest as well as to their altruism. “What we are asking is good for you and good for the community!”

Assuming common cause does not mean letting people off the hook or giving them a “pass.” As conveyed in Principle 8, it means alerting them to the inadequacy or deleteriousness of their program or policy in a systematic sustained manner.

PRINCIPLE 10: ASSUME THE PRINCIPLE OF LEAST CONTEST. ESCALATE THE PROCESS ONLY AS NEEDED

Following from Principle 9, in order to have credibility and to gain the broadest support, your group should not antagonize the targets prematurely or unnecessarily. Intervene just high enough to gain recognition and ultimately to achieve your goals. Strategies of influence exist on a continuum of social change from consensus to contest tactics. These range from presenting information in persuasive ways, to negotiation and bargaining processes, to offering incentives, to more conflictual tactics including threats, and, finally, to using social action strategies of mass mobilization, protest, resistance, and disruption.

In general, and in accordance with Principle 8, you should not begin with adversarial and confrontational tactics until those with authority

have been given a chance to change voluntarily. On the other hand, you cannot assume that information alone will be sufficient to produce major change. A strategic question to answer is: “What will it take to have the issue seriously addressed?” A well-thought-out strategy will determine the process and timing of moving from the least- to more-conflictual strategies, assuming you have some control over these factors. The cogent questions are: “How long have you been waiting for change to occur?” “How long can you wait; that is, how serious are the consequences of inaction?” “What is your group prepared to do next?” “What resources and contributions would be needed to move to the next step?” “What are the consequences of escalating the tensions?” “Who will you lose and gain along the change continuum?”

In intensifying and escalating the pressure on those with authority, you must pay attention to ethical considerations. You will need to build support for your effort, preferably before, and not just during, a campaign, so you do not alienate (again, unnecessarily or prematurely) potential allies who are either on the inside or on the outside. You need to build your credibility before your group goes above or around someone or exposes someone publicly (the principle of “no surprises”). It is essential to have factual information and ethically engage in a democratic decision-making process with your group and its allies. Among the essential ethical practices based on social work values, is whether your constituency is informed about the tactics in which they are being asked to engage. If there is a chance of provocation or serious repercussions, participants should have the ability to make an informed choice in advance, even at the risk of losing some of them, to the extent that the risks can be anticipated. As noted in Principle 11, the organizer’s role is to anticipate the consequences. A key question to pose is: “What’s the worst that could happen if...?” Organizers cannot promise their constituencies immunity from the consequences of their actions; for example, you should never use absolutes, “Your landlord can’t evict you” or “Your boss can’t fire you.” Even when this may be legally correct, a person can still be harmed emotionally, financially, and even physically from confronting powerful targets of social change. Collectively, people need to know the consequences of moving from lawful protest to civil disobedience. This is especially important around tactics that have legal ramifications, for

example, events that need police permits, confront trespassing laws, and so on.

Saul Alinsky wrote in his “means and ends” essay that an end justifies the means. Organizers informed by social work principles need to seriously weigh using undemocratic deceitful tactics—and never without consulting colleagues, constituencies, and allies. The related principle should be “no surprises!”

PRINCIPLE 11: THERE WILL ALWAYS BE OPPOSITION TO CHANGE AT SOME LEVEL, BE IT ACTIVE OR PASSIVE RESISTANCE

It is essential to assume that *somebody/Body* will always be opposed to the change your group wants to make, and therefore, to anticipate a range of responses to your actions. You may hear such things as “It can’t be done,” “We’ve tried it before and it can’t work,” “We can’t afford it,” and so on. Identify the opposing side’s arguments by playing out alternative responses to the problem and by testing the waters with the facilitating actors who can influence the decision makers. As much as possible, analyze in advance who may be opposed to the identified solutions, and why they may be opposed.

Effective organizers develop strategies to counter or neutralize opposition where they can, as well as identify those elements in the change process that they or the group cannot control. In identifying supporters, it is essential not to write off potential allies, even if they have been adversaries on other issues. Short of those intense ideological battles where there is little room for compromise (e.g., abortion rights, affirmative action), appeals for support can be made to most sectors of society. Arguments used will usually vary among different groups. You may appeal to such factors as reputation, pride, and professional expertise to gain or keep people on the side of your proposed change. Ask supporters for their advice or would be adversaries to put themselves in your constituencies’ shoes.

Sometimes the opposition may not be apparent because the implications of the change may not be visible until the change process is under way. Do not assume that all the opposition is external or conversely that it is being orchestrated from the target of change. Remember that communities and systems are not monolithic. There may be as much division and difference

within a community as between “the community” and the target of change (see Principles 5 & 7). Sometimes the opposition may be passivity or inertia rather than visible and articulated differences. They may delay or avoid a response in hopes of outlasting your group.

To the extent possible, your group should have one or more responses, anticipating resistance. For example, one tactic of the opposition is to ask, “So how would you fix it?” or “What would you do if you were in charge?” Understand that groups engaged in social change are not obligated to come up with solutions because they identify an issue. In a democratic society, citizens have the right to raise questions, make demands, and hold those in charge accountable for outcomes. The latter have the authority, resources, and expertise to run the show. Your group has a right to point out that things are not working and that there must be a better way.

However, you are more likely to be credible and effective if you have thought through the arguments for why the current situation has to change and how it can be changed. If the response to your request is, “We don’t have the funds,” your group may be able to counter with “We know where you can get them,” or “We know from where they can be taken.” When the response is, “We can’t do that” your group has to ask “Who says?” Ask for the written policies and procedures when the rejection is a legal or regulatory one.

There may be circumstances in which your group may be strong and invested enough to pose alternatives to the current situation and even strive to replace those in control or create an alternative entity. This takes a long-term commitment with its own set of limitations when you are “in charge” as opposed to holding those with the authority accountable for their actions.

Another tactic of the opposition is to divide and conquer or discredit a group. This has happened when groups left out of the decision-making process begin to challenge the authority of those in control. Those in charge may question your own or your group’s credibility and representativeness. It may attempt to exploit differences within a community or coalition, or “play favorites,” bribe, or isolate. Hence, out of range of the opposition, your group should strategize the range of alternatives available. It is important to identify who your spokesperson will be and what message you want to convey, even if you cannot always control all the events.

Establishing some procedures and protocols in advance is essential. It is always helpful to have some counter-expertise, meaning trustworthy allies and supporters who are willing to use their professional knowledge or political experience to challenge the opposition on its own terms. Given the elitism and privilege of those in positions of authority, having professional or powerful people on your side lends weight to your arguments, although relying on this strategy does little to change the structural inequalities of a system. You must come to agreement on the following: Is your group willing to negotiate? What is the bottom line? What happens if the target says no? What happens if the target says yes? What happens if they ask your group to come up with a proposal or to join a task force? There is no one right or wrong answer, except the principle of anticipating opposition and being prepared for differential outcomes.

**PRINCIPLE 12: IN MAKING CHANGE
FROM INSIDE, ASSESS RISKS
REALISTICALLY—IDENTIFY AND
WEIGH COSTS AGAINST GAINS**

You can engage successfully in major change efforts from within your own system or agency, if you strategically assess your role and are prepared for possible controversy and consequences. All the Principles in this document apply here. There are several positive aspects to initiating or participating in change from within. By being on the inside, you already have a foot in the door. You have the legitimacy to ask for and obtain information; you know who makes decisions and how the system “really” works, that is, its informal, as well as formal, structure. You know the history of past efforts to engage in change, and most importantly, presumably you have some credibility, longevity, and allies within that structure. Working to improve an organization from within is not disloyal. As noted in the NASW Code of Ethics, it may be the only ethical course to pursue. Timing and tactics are part of the equation as to when and how to act—not whether. There are, however, two conundrums in working from within. Those on the outside may not know of your efforts behind the scenes and might assume you have been co-opted; on the other hand, working with others outside the system or going outside (i.e., whistle-blowing) may

produce reprimand or worse. The seriousness and pervasiveness of the issue will help guide your actions.

Therefore, it is essential to play out for yourself and with your constituents the generic question posed above: “What’s the worst that can happen if...?” You have to ascertain the support you have and to anticipate the amount and intensity of the opposition to minimize your isolation or ostracism. There are times when hard choices have to be made as to how far to take a social change project. To determine the type and extent of action to be undertaken, you should consider pragmatic things such as feasibility of success, and factors such as the seriousness and pervasiveness of the situation. Is there an imperative to act? Is there a sense of urgency? Is the timing right? Is there a window of opportunity? What are the consequences of inaction?

There will be some risk to every action taken. It is important to anticipate actual or perceived repercussions (as per Principle 11) from peers, line or support staff, supervisors, managers, and clients. Therefore, if a major change that affects a department or the whole agency is needed, or if the required action includes an implied criticism of your agency or system, you need to employ Principles 8, 9, and 10.

Note that there is a long continuum from doing nothing to getting fired. The importance of keeping your own house in order cannot be stressed enough. Rarely will you be directly sanctioned for your organizing activities. You are more likely to be called to task for not doing your paid job. Pay attention and do not be caught off-guard when engaged in internal organizing, no matter how justified. Staff members are reprimanded for not turning in reports on time, for leaving early, for not following up. To minimize any criticism directed at you, consider taking on additional responsibilities. Demonstrate your value to your employer and the clients.

If you are advising, or are part of a group of people working on the inside, it is essential neither to overpromise protection nor to underestimate repercussions. Organizers can never assert that nothing untoward will happen to those participating in a change process. On the other hand, it is essential to uncover any perceived fears, even if not grounded in reality, so they can be addressed by you or the group. People are often caught short when they have not thought through Principle 11.

PRINCIPLE 13: RECORDKEEPING AND NOTE-TAKING ARE POLITICAL, NOT CLERICAL FUNCTIONS

If information is power, then obtaining and recording information is a political process. The persons or group in charge of those processes may be the most powerful players in their organization or system. Experienced organizers always want to be involved in those processes, although what and how records are kept should be identified and decided by the group's leaders. Documentation includes taking minutes, corresponding with people, recording actions and inactions, keeping people on track, and reminding people of past decisions through letters, memos, e-mail, and written records. Technology allows for myriad methods of storing data, but the bottom line is to have them available in multiple ways and permanently stored. Taking minutes is a critical skill, value, and process. Minutes help gauge and set the tone for the way a group makes decisions as well as what decisions were made and by whom. Documents are accountability tools; they help keep processes and outcomes transparent, and keep the people involved focused and honest. They also provide a historical account, preserving the institutional memory, and their availability allows disputes about past actions to be resolved. Therefore, the role of archivist should be identified to organize and store and help determine access.

You can assess the seriousness, effectiveness, and cohesiveness of a group/organization by whether minutes are taken and reviewed and how participants are engaged in their production and review. Experience has demonstrated that if there are no minutes of a meeting or group process, chances are nothing will change. Experience has also shown that those in charge of a system or the target of change (the critical actors) will often resist the formal recording of or sharing of minutes. In those instances, you must create a paper trail that includes agreements and timetables and note-taking shared among all constituencies.

Minutes can also be a diagnostic tool to assess an organization's culture, structure, and history. When organizations spend an inordinate amount of time refuting minutes, you can infer that there is distrust and dissention that will result in an inability to move ahead. When minutes are viewed as *pro forma* without much attention paid to them, you can infer that there is not much investment or involvement of its participants in the organization.

It is important to prepare someone in the group to take notes of strategic meetings, regardless of whether the person in charge agrees to have notes taken. If possible, at least two people should attend all important meetings or be conferenced-in and be ready to report on the session verbally and in writing. If there are no minutes taken, those who attended should debrief and designate someone to write a letter or send an e-mail thanking them for meeting and stating their understanding of what took place and what was agreed to by attendees. Any disagreements and next steps should be highlighted. The same thing applies with strategic phone calls. If there are minutes taken by those who called the meeting, those attending should ensure that they receive a copy and have the ability to review and comment on them. It should not be surprising that there are memory lapses (intentional or not) and different interpretations with regard to issues addressed and promises made. Without a record, there will be little or no progress.

PRINCIPLE 14: THE MEDIA ARE UNPREDICTABLE AND AMORAL. PROCEED WITH CAUTION

Given the importance of communicating with a variety of constituencies and publics, understanding the role of the media as a powerful sector of society, and knowing the types and functions of various media outlets, is an essential part of the organizer's job. The variety of media outlets active today are growing in number and changing rapidly—electronic media, blast e-mails and faxes, and blogs, in addition to the more traditional print media (newspapers, magazines, mainstream, and alternative presses), plus broadcast media—TV (network, cable, public), and radio. Organizers and designated leaders in the group need to know the basic tools of these various outlets and the functions they play in society, in your community, and in the sectors you wish to influence. Given the importance of outreach campaigns in creating awareness and action for your issues, and the role technology plays in making, as well as recording, “news,” your group may want to retain a media consultant for a fee or on pro bono basis. If there is a college nearby, chances are they have a media studies or journalism department, or film and video studies department, for you to consult. Communication is an essential skill and facet of an organization's life today.

As part of an outreach campaign, the first step is to identify whom you want to reach and then decide how they are best reached. You need to know how the constituencies you want to influence receive their information. What mass media do they read, watch, or listen to? What ethnic and community media do they value? How do they use the Internet and social media? Who are the media personalities that influence them? Second, is to identify and cultivate a person in each of those outlets used (*outlet* is a generic term for all the different types of media). Who writes or talks about your topic or issue? Be proactive with them. Send them background materials about your organization. Invite those reporters or opinion-makers to your organization. Ask them to meet with your constituency. Become their expert on the issues and know who else is. Determine who may be “more friendly” and who less friendly to your organization and/or issue.

How do you craft a message so that the media important to your organization will want to publish or cover the issue? How do you convey your story in compelling ways? At this juncture, organizers and most media part ways; hence, the “amoral assertion.” Organizers (social workers, human rights and social justice advocates) usually want to publicize stories that are serious and pervasive. The story you want told probably involves many people who are in that circumstance, for example, people who are suffering from what the government or a corporate body is doing—or not doing—to them. The target of change may be providing inadequate services or denying them; they may be cutting back on opportunities and pathways, limiting resources, and so on. You usually want to show universality of an issue and convey the numbers of people affected. For example, “Ms. Jones is one of millions of people losing her food stamps.”

Most media, on the contrary, regardless of political bent, want to show just the opposite. They cover the unusual, the bizarre, and the extreme. If there are thousands of people collecting an inadequate amount of public assistance, or if the child welfare system discriminates against parents of color, they will feature the “welfare queen” or the one tragic case of major child abuse. Journalists, regardless of whether they are liberal or conservative, whether the outlet is a tabloid or an intellectual magazine, do not generally portray the usual or typical. They do not cover the good news as

often as they do bad news. They are prone to exaggeration and hyperbole; they like to cover conflicts and dissension. The slant is usually toward the sensational. This does not suggest that the media are nonideological. Different outlets have their political slants reflected in their editorials and opinion sections. Experience has shown, however, that regardless of the reputation of the station or newspaper, they may not cover “your story” the way you want it to be conveyed. Therefore, the organizing principle when the media come knocking is that you cannot control the outcome. So the decision your group must make is whether to reach out to the media and still make every effort to educate them in advance where possible. It helps to provide succinct background material; easy to read, but substantive at the same time (see Principle 4).

The media as a sector of a society has the same biases as other institutions in the United States. They usually reflect the “isms” in some fashion regardless of their politics. Recognition of this fact will temper expectations of the outcomes. There are many examples of media coverage that reflect institutional inequalities. In general, with few exceptions, they will generally focus on the professional rather than on the client or constituency. They will seek out males more than females; they will gravitate more to the Caucasians than to people of color. Therefore, practically speaking, if you want to downplay those disparities and ensure a unified and accurate message, prepare spokespersons in advance. Agree to channel the media to designated people and provide everyone with a few sound bites, should they ask. If relevant, try to pair professional and indigenous leaders so that new and undervalued (by the media) voices are up front and visible. Learn to handle the pressure and avoid the seduction of becoming an instant celebrity.

If the coverage you receive portrays the story differently from what you wanted, write a letter to the editor and to the author and publisher or owner of the outlet. Let your own constituency and allies know what you attempted to convey. Research has shown that letters to the editor are the second most-read section of a newspaper (after sports) and are highly read in magazines as well. It may be difficult to get an article into the *New York Times* or a story on national network TV, but there are hundreds of smaller outlets in your community.

CONCLUSION

These principles are meant as guides to action and will apply differentially, depending on the auspices of your agency, the goals identified, the political and economic context of the community, the issues in question, and the system driving the organizing. Organizers cannot control all the variables, but acquiring these competencies along with your commitment to the long haul will go a long way. Remember to incorporate these four H's into your work, which reflect critical social work values and traits: humanity, humility, honesty, and humor.

116 Contemporary Community Practice Models

Marie Overby Weil & Dorothy N. Gamble

Throughout the history of social work, community practice has been a prominent method, one which embodies the profession's empowerment tradition and social justice values (NASW, 1996; Simon, 1994). With the complexities of current societies; rapid technological, social, and economic change; political unrest in many parts of the world; and the globalization of trade and communication, community practice at local, regional, national, and international levels is an even more essential element to revitalizing democracy in the United States and encouraging democratic societies internationally to build and nurture inclusive, supportive, nonracist, and nonsexist communities and institutions (Weil & Gamble, 2013). Societies across the world are becoming more multicultural, and globally there are now more internally displaced persons than at any previous time. With these global changes and the realities of both internal and cross-national conflicts, protection of human rights, particularly the rights of women and girls, becomes increasingly critical in efforts to build and maintain socially just communities. Serious political divides in the early decades of the 21st century revolve not only around differing conceptions of national common good, but also around the different paths to and conceptions of the common good in international and global terms. Currently, in several areas of the world fledgling, as well as established, democracies now face internal political challenges and external threats to ongoing development (Weil, Reisch, & Ohmer, 2013). Community practice in its essential forms of organizing, planning, development, and progressive work for social change is increasingly needed within and across communities and nations (Weil & Gamble, 2013).

The moral, political, and economic equation for human development requires an understanding of global social and economic interdependence. Vandana Shiva describes the "Declaration of Interdependence," sponsored by the Democracy Collaborative, as growing from the recognition that "we are earth citizens and have earth identities which are both the particular identity of place, and the global planetary identity. As members of communities, we have multiple community identities. ... These diverse, multiple identities shape our sense of self and who we are. And these diversities are not inconsistent with our common humanity. Without diversity, we have no humanity" (2005, p. 142). These issues of democratic development, revitalization, sustainment, and transformation are the central purview of community practice in all its forms; the skills and knowledge for building and rebuilding community are critical for those who work to achieve positive and sustainable development and pluralistic, multicultural societies in a global economy.

Community practice encompasses a broad scope, ranging from grassroots organization and development to human services planning and coordination. It employs multiple methods of empowerment-based interventions to strengthen participation in democratic processes, reform human service systems, and assist groups and communities in advancing their concerns and organizing for social justice. This chapter presents community practice models that are widely identifiable in interventions employed in the first quarter of the twenty-first century. They are rooted in traditions evolving from the settlement house movement, the charity organization

society movement, the rural development movement, and from the organizing and development histories and cultures of diverse ethnic and racial groups (Betten & Austin, 1990; Rivera & Erlich, 1998; St. Onge, 2013, 2009).

MODELS OF COMMUNITY PRACTICE FOR THE 21ST CENTURY

Eight basic models of community practice are described. They illustrate approaches widely used in many parts of the world and they are expected to persist. Community practice efforts focus primarily on the following general purposes.

Community Practice Purposes

- *Improving quality of life:* Work to support well-being, decrease poverty and respond to basic human needs, such as food and shelter, security, opportunities for education and basic health; promote freedom from violence; build opportunities to organize and participate in community goals and decisions. Work for well-being can focus from local to global issues.
- *Extension and implementation of human rights:* Build inclusion through participatory structures; respond to needs and promote rights of marginalized groups who are discriminated against, are political or economic refugees, or are internally displaced; end slavery and human trafficking; and support enforcement of full human rights for women and girls.
- *Advocacy:* Conduct research; document policies, practices and behaviors that limit opportunities of groups and individuals; promote egalitarian political leadership, policies, and work to build human capabilities and community capacity for the most marginalized groups; form groups and coalitions to press for human rights and provide “voice” and opportunities for vulnerable groups at multiple levels; advocate for full human rights, education, and equality of opportunity from local communities to national and global venues. Examples include lobbying for improved services for children with severe emotional problems; campaigning for human rights for women; working for rights of lesbian, gay, bisexual, and transgender (LGBT) groups; or passing legislation to fund minority group economic development projects through such structures as the Community Reinvestment Act.
- *Human social and economic development:* Create opportunities for people and groups to gain knowledge and skills thus enriching their capabilities and building community capital; establishing well-being through education and training for viable livelihoods; work with communities to preserve their natural resources and develop assets through economic cooperatives, microenterprise, or development programs. Economic development can be fostered by national governments or international nongovernmental organizations (NGOs), and can function regionally—most importantly it can function at grassroots levels to grow local economies and develop leadership among the poor. In combination, social and economic development should ensure social support, and economic viability and sustainability for marginalized rural and urban groups by promoting participation and leadership development—locally, regionally, and globally.
- *Service and program planning:* Work with local people to assess the strengths and needs of a whole community or specific populations and the development of plans, resources, and structures to meet those needs. Employ appropriate technology that can assist in building capacity as well as provide needed services. Services may be adapted for specific interventions, and evidence-based interventions may be adapted to fit context and local population and culture.
- *Service integration:* Establish a range of services and link them so that a continuum of care is in place for the broad needs of community members. Examples include building the continuum of family support, preservation, and child welfare services; establishing a network of well-connected services for both healthy and frail senior citizens; or providing food, protection, relocation opportunities, and services for new starts for refugees and internally displaced persons from international or national conflicts.
- *Political and social action:* Engage in the political process to change existing problematic policies, establish new

progressive legislation, or change legislative policy makers. Activity in political and social action is direct, open, and nonviolent. It requires free spaces in which people can gather, organize, and speak out, especially those who have been excluded from political involvement in the past. Political and social action seeks to foster institutional change for inclusion and equity, and increase participatory democracy and equality of opportunity in local, regional, and international institutions. Organizing for the rights, protection, and welfare of children by the Children's Defense Fund and Amnesty International's efforts to prevent torture and secure release of political prisoners worldwide are examples of political and social action that is nonpartisan.

- *Social justice*: Involves building toward human equality and opportunity across race, ethnicity, gender, and nationality. Examples are working to ensure basic education for girls in all countries, full political participation for women, making reparations to people who have endured systematic oppression in the past such as Native Americans, African Americans, and Japanese Americans, and building the fabric of civil and human rights laws both nationally and globally.

The value base of community practice not only respects the dignity of the individual but also focuses on the interdependence of families and communities and the development of legislative, political, and distributive justice. Community practitioners work with competing perspectives on issues, using multiple strategies to solve problems that inevitably arise within and among diverse groups in communities. America's reality as a pluralistic society where communities of color are still struggling for inclusion increases the need for skilled multicultural organizing and development of multicultural human service organizations (Gutierrez, Lewis, Dessel, & Spencer, 2013). The eight models depicted in Table 116.1 are analyzed in terms of outcome, change targets, constituencies, scope of concern, and primary social work roles through lenses of globalization, human rights, and multiculturalism (Gamble & Weil, 2010). Though the models are described as particular entities in the chart for analytic clarity, elements of the models are often observed in interaction—being mixed or phased

as organizations and groups respond to new challenges or shifts in the environment (Rothman, Erlich, & Tropman, 2008).

Neighborhood and Community Organizing

Much of community organizing depends on the face-to-face opportunities available to people in geographic proximity, such as a neighborhood, rural community, or county, though increasingly, digital media are employed to support communication. Community organizing focuses on activities to increase the leadership, planning, and organization-building skills of ordinary people to help them develop power at the neighborhood or village level and increase community well-being. It is the bedrock of democratic institutions. When people at the grass roots of society learn how to organize their efforts, be inclusive in organization building, employ democratic decision making, set priorities, access resources, and reach their goals, they have learned basic lessons of democracy. Increasing their capacity to work on basic community problems makes it possible for citizens to change conditions to improve the quality of life for all residents. This model of community practice can be seen in a variety of forms across the globe, in the democracies that have been working at neighborhood organizing for hundreds of years yet still tend to exclude the most vulnerable groups in society, as well as in the newly emerging democracies of Eastern Europe, Africa, Asia, the Middle East, and South America.

Organizing in communities almost always carries aspects of both consensus building and contest or conflict (Mondros & Staples, 2013). Within neighborhood groups conflict will occur over what strategies to adopt and even in external contest focused organizing—such as seeking a change in state policy, organizers look for allies in powerful positions. As Gutierrez and Lewis (1994) have discussed, organizers most often will strive to help groups achieve internal consensus to plan for work within their community and plan for more social action oriented strategies when external forces are oppositional. Indeed, community groups work to solve internal conflicts and develop a cohesive and coordinated strategy for external work. Where possible, community organizations will first work externally, using educational and collaborative approaches, adopt persuasion and campaign tactics where needed with the public and officials, and when

TABLE 116.1 Models of Community Practice in 21st Century Contexts

Comparative Characteristics	Neighborhood & Community Organizing	Organizing Functional & Communities of Interest	Social, Economic & Sustainable Development	Inclusive Program Development	Social Planning	Coalitions	Political & Social Action & Policy Practice	Movements for Progressive Change
Desired Outcome	Develop capacity of members to organize; Direct and/or moderate the impact of regional planning and external development	Action for social justice focused on advocacy and on changing behaviors and attitudes; may also provide service	Promote grassroots plans; Prepare citizens to use social and economic resources without harming environments; Expand livelihood opportunities	Expansion, redirection and new development of programs to improve service effectiveness using participatory engagement methods	Neighborhood, citywide or regional proposals for action by (a) neighborhood groups (b) elected body; armor (c) planning councils	Build a multi-organizational power base to advocate for standards and programs, to influence program direction and draw down resources	Action for social justice focused or changing policies or policy makers	Action for social, economic & environmental justice that provides new paradigms for the healthy development of people and the planet
Systems targeted for change	Municipal/regional government; external developers; local leadership	General public; government institutions	Banks; foundations; external developers; laws that govern wealth creation	Financial donors & volunteers to programs; beneficiaries of agency services	Perspectives of (a) neighborhood planning groups (b) elected leaders (c) human services leaders	Elected officials; foundations; government policy and service organizations	Voting public; Elected officials; Inactive/potential participants in public debates and elections	General public; Political, social and economic systems that are oppressive and destructive
Primary constituency	Residents of neighborhood, parish, rural community, village	Like-minded people in a community, region, nation, or across the globe	Low-wealth marginalized, or oppressed population groups in a city or region	Agency board & administrators; community representatives	(a) neighborhood groups (b) elected leaders (c) social agencies and interagency organizations	Organizations and citizens that have a stake in the particular issue	Citizens in a particular political jurisdiction	Leaders, citizens, and organizations able to create new visions and social structures
Scope of Concern	Quality of life in geographic area; Increased ability of grassroots leaders & organizations to improve social, economic & environmental conditions	Advocacy for particular issue or population (examples: environmental protection; women's participation in decision making)	Improve social, economic and environmental wellbeing; Employ equality, opportunity and responsibility to guide human behavior	Service development for a specific population (examples: children's access to health care; security against domestic violence)	(a) neighborhood level planning (b) integration of social, economic & environmental needs into public planning arena; (c) human services coordination	Organizational partners joining in a collaborative relationship to improve social, economic & environmental conditions and human rights	Building the level of participation in political activity; Ensuring that elections are fair and not controlled by wealth	Social, economic and environmental justice within society (examples: basic human needs; basic human rights)
Social work/Community Practice roles	Organizer Facilitator Educator Coach Trainer Bridge Builder	Organizer Advocate Writer/Speaker Facilitator	Negotiator Bridge Builder Promoter Planner, Educator Manager Researcher Evaluator	Spokesperson Planner/Evaluator Manager/Director Proposal Writer Trainer Bridge Builder Visionary	Researcher Proposal writer Communicator Planner Manager Evaluator	Mediator Negotiator Spokesperson Organizer Bridge Builder Leader	Advocate Organize Researcher Candidate Leader	Advocate Facilitator Leader

Adapted from Gamble, D. N., & Weil, M. (2010).

necessary move to social action approaches of contest and conflict (Brager, Specht, & Torczyner, 1987; Mondros & Staples, 2013).

Neighborhood and community organizing has the dual focus of building the capacity of individuals to lead and organize while accomplishing a task that will enhance the quality of life for the geographic area. Elements of this model are found in settings in which people can come together to create needed change. One example is the Center for Participatory Change (2013), which works to help people in small rural communities in Western North Carolina “recognize their own power, work together, and transform their communities” (<http://www.cpcwnc.org/>). Community organizing that has expanded from work in Los Angeles into a national network, PICO (www.piconetwork.org) works on building social capital, developing local leaders in many communities, and in organizing campaigns for needed social change. Current efforts include work by “Dreamers,” citizenship-seeking Latino youth who were brought to the United States as young children by undocumented parents; health reform; and an overarching focus on economic health and well-being for families and communities.

Organizing Functional Communities—Communities of Interest and Identity

The essence of this model is its focus on communities of interest—functional communities—rather than geographic. The focus in organizing communities of interest or identity is advocacy for social justice and policy change to promote acceptance and inclusion of the chosen issue or group. In their efforts toward social justice, functional communities also seek to change general attitudes and behaviors and may develop services for their specific population that have not been adequately addressed in the mainstream service system. Examples are development of alternative service systems for women, evolving from feminist organizing, consisting of rape crisis centers and domestic violence programs, and more recently expanding to deal with women’s employment and economic development issues. Functional communities typically engage in community education, as is illustrated in the LGBT community’s earlier work to educate others about HIV/AIDS—and to press for appropriate health care

and supportive health policy. More recently this community of identity and allies has advocated for nondiscrimination in employment, and the same social, economic, and civil rights that others take for granted.

As communities of interest/functional communities organize, build internal capacity, and conduct research about their issues, members may move from mutual support to become strong advocates and leaders, as have parents of children with severe emotional disturbances through the Alliance for Mentally Ill Children and Adolescents. Leaders have also emerged among the groups that have organized in many parts of the nation to work against toxic waste sites.

Examples of communities of interest include the ARC, which functions in many localities and as a national group to improve services and advocate for the rights of children and adults with developmental disabilities; environmental groups such as Resourceful Communities/Conservation Fund, which is a “grassroots network that implements the triple bottom line low-wealth communities by building capacity and a statewide movement that advocates for sustainable economic development, social justice, and environmental stewardship” (www.resourcefulcommunities.org); and groups such as Amnesty International, which documents human rights violations and seeks protection and justice for political prisoners worldwide through local advocacy groups.

Social, Economic, and Sustainable Development

Providing opportunities for people to increase their social and economic security has been a central focus of social work. To be effective, social and economic development projects must work together within a context of sustainable development (Gamble & Hoff, 2013). Development efforts are currently framed under four rubrics:

- *Human development*, the focus of the United Nations Human Development Index, which measures progress using a composite focused on life expectancy at birth, knowledge (based on literacy rate and school enrollment), and adjusted per capita income in purchasing power parity (UNDP, 2011)
- *Social development*, focused on basic life skills and livelihood education (especially for

the poor), promotion of gender equality, and most critically, short-term amelioration and long-term eradication of poverty through policy investments in marginalized groups and communities, expanding their capacities, building social capital, and providing programs that can improve well-being and create economic opportunity (Midgley & Conley, 2010)

- *Economic development* that invests in meeting human needs and building adequate incomes and assets by employing empowerment strategies to move families and communities out of absolute poverty (Rubin & Sherraden, 2005; Friedmann, 1992)
- *Sustainable development*, described initially in *Our Common Future*, the 1987 report of the World Commission on Environment and Development as “development that meets the needs of the present without compromising the ability of future generations to meet their own needs” (www.un-documents.net/wced-ocf.htm; p.43. Sustainable development encompasses social and economic development that restores and protects the natural environment (Estes, 1993; Gamble, 2013; Hart, 1999).

Historically, many community development programs emphasized either economic development or social capacity building. In recent years, there has been a growing focus on integrated development strategies combining human capacity building, popular education, and locally controlled economic development (Freire, 1970; Nussbaum, 2011; Sen, 1999). Some current programs are designed to build personal assets. Individual development accounts (IDAs) and individual training accounts (ITAs) are local, statewide, and national programs that match the savings of a low-wealth person who is saving for a training or educational program, the startup of a small business, or the purchase of a home (Sherraden, 2013). IDAs and ITAs are seen as individual ladders to help people climb out of poverty (Schreiner et al., 2001). Coupled with other workforce strategies, they may be especially helpful to those people who have been on the poverty borderline for many years. Though individuals need these kinds of programs to develop creative entrepreneurial skills, individual strategies are insufficient without companion programs that focus on broader human investments in health and education, and policies that improve minimum wages and fairness in taxes.

Community development corporations (CDCs), of which there are thousands across the United States, often combine efforts to change the community by decreasing barriers to economic and social resources (e.g., Bethel New Life; Murphy & Cunningham, 2003). These corporations often combine increasing the availability of resources to broad groups of people in the community (e.g., community reinvestment funds and community development block grants) with individual training to help people take advantage of such resources (e.g., home buyers’ clubs and microenterprise loan circles) and with increased social and economic infrastructure (e.g., increasing affordable housing stocks, and developing health clinics, day care, and after-school programs). In this strategy, it is not just the individual who is changing; it is the whole landscape of the community that is changing with visible infrastructure and options for social support and economic advancement.

Inclusive Program Development

In community-practice focused approaches to program development, there is growing recognition that it is important to have active participation of potential consumers and community members (Dominelli, 2007; Patti, 2009). Planning that is fully inclusive will engage agency staff with potential participants and community representatives in all aspects of the process from creation of the vision through the evaluation and adaptation needed to refine the program. Such efforts are intensive but can help to embed the program in the community and promote support. Inclusive planning requires ongoing intentional processes of engagement with diverse aspects of the community. Perspectives on inclusive engagement are provided by Chambers (1997), and Netting, O’Connor, and Fauri (2008). The approach is grounded in participatory and empowerment perspectives and strategies.

Involvement in the planning process gives community members a stake in the program and its success. Inclusive planning can be carried forward in nonprofit or public settings. A well-known example of major systems change was the engagement over time of the Maori community of New Zealand with the Child Welfare System. From the intensive work to make services fit appropriately with Maori culture—of extended families and extended family responsibility for children—the entire structure of the

New Zealand Child Welfare Services was refocused to employ family group conferencing with all clients.

In the United States, a somewhat similar process was used to build a network of family preservation services in Contra Costa County. The innovative service approach was developed focused on family-centered, neighborhood-based services through inclusive planning with community members and the multiple agencies that were members of the County Youth Services Board. These organizations worked to expand an interagency family preservation program that had proven successful into a county-wide model. This effort involved major system change. The planning process utilized five agency–community interactive processes: (1) Developing a strategic plan; (2) learning about targeted neighborhoods and involving residents in planning; (3) including staff and community members in family-centered service integration teams; (4) negotiating waivers with the state to support the new model; and (5) negotiating with potential clients and other community members throughout the planning process (Armstrong, 2001). Commitment and hard work was required of all participants—but they made the project work and developed services that were truly community-based and family-centered.

Agencies considering a new community-based program should emphasize participatory processes to strengthen planning and build staying power for the effort (Minkler & Wallerstein, 2008). Using intensive outreach, planners can identify community members' concerns and interests and build on these ideas in the needs assessment process. Although secondary data and official community data will be used in a needs assessment, it can be strengthened by surveying potential program participants and community residents about their interests, concerns, and hopes for the community. Focus groups of citizens, as well as the surveys, can be used to enlighten and expand staff understanding and strengthen the plan through information received directly from potential participants and community members.

Evidence-based practice strategies build the “science” of intervention; however, programs that are adapted appropriately to community culture, contexts, and interests are likely to have long-term staying power and to be perceived as community assets. Participants should be involved in program evaluation through more

than surveys of satisfaction. For programs to be responsive and relevant to the communities they serve it is important to have program participants involved in the evaluation and to collect qualitative outcome data and program improvement recommendations. This full-circle process of engagement with community members, clients, and potential clients will enable staff to make the program more responsive to changing issues and community needs (Noponen, 2002).

Social Planning

Social planning operates at a range of levels and focal issues. Two major approaches are primary in current practice: planning *with* communities at local levels and larger scale planning, which can take place at four levels: (1) as planning for services in specific sectors such as mental health, or child welfare; (2) as community-wide social planning as carried out by social planning councils; (3) within city and regional planning departments or other government agencies; and (4) in agencies engaged in international, multinational, and global service and planning efforts (Sager & Weil, 2013). In all these venues for social planning, community social workers will strive to see that the planning process is inclusive and that people “living with the problems” or “living in the neighborhood or region” are seriously engaged in multiple aspects of the planning and implementation process (Weil, 2013).

The scope of planning encompasses community renewal, combining social and economic development, and/or coordinating social services and community programs. Such work often involves community revitalization and seeks to redress problems in rural communities or urban neighborhoods; it also can involve work to rebuild communities after natural disasters. The Dudley Street Initiative in Boston is one example of community-based comprehensive neighborhood planning (Medoff & Sklar, 1994; www.dsni.org).

In service or service sector planning, practitioners are involved with designing new services, or refining older services and approaches to render them more responsive to current and emerging populations. For example, in a federally funded initiative to improve preventive services to families, North Carolina initiated a Family Support and Family Preservation program that engaged communities in 33 counties in local-level service planning. Work was accomplished through new

planning groups composed of citizens and local service providers. Counties were successful in developing model programs that could provide primary prevention support and intensive intervention to preserve families experiencing crises (Gamble & Weil, 2010).

City-wide nonprofit sector planning councils such as those affiliated with the National Association of Planning Councils typically conduct needs assessments and target one to three major issues over several years. These councils and service sector planning efforts strengthen services for particularly vulnerable populations, such as children with disabilities or the elderly. The long-established Jacksonville, Florida Community Council, for example, has carried forward major research and service initiatives in several areas. A recent project developed a multi-site program plan designed to reduce teen pregnancy. The research reported in the *Jacksonville Quality of Life Progress Report 2006* indicates very positive results with lowering pregnancy rates and keeping young women in school (see Gamble & Weil, 2010, pp. 298–303).

Community development corporations engage in constant planning and program refinement as they seek to respond effectively to changing community needs in low-wealth communities. Two exemplary CDCs with multiple economic, housing, business development, and service and support programs are Bethel New Life in Chicago (www.bethelnewlife.org/) and Chicanos por la Causa in Arizona (www.cplc.org).

In a government-funded San Francisco program, Margaret Brodtkin worked with an advocacy organization and citizens' and agency groups to establish a model children's service system that resulted in multiple positive outcomes for children and families. In this public/nonprofit partnership, the ingenuity and energy of the advocacy organization and planning groups made the change happen (Brodtkin, 2013). At city-wide planning levels, both Seattle, Washington and Austin, Texas have been engaged in multiyear neighborhood-based planning with citizens' groups and provide models that would be beneficial in many cities (Weil, 2013).

Because planners engage with a variety of individuals and groups, they need excellent communication, facilitation, and management skills, as well as technical skills in research, needs assessments, participatory planning, evaluation, and proposal development. Planners increasingly organize community meetings to gather

ideas and educate the public about directions for services and development. They engage community leaders in effective development strategies for fundraising, evaluation, and modification of programs.

Several useful resources are available to assist planners working with citizens and organizations for local planning. The Vancouver, British Columbia Social Planning and Research Council provides an excellent *Citizen's Guide to Community Social Planning* (1993). *A Community Planning Handbook*, compiled by Nick Wates for communities in the UK provides generalizable strategies for local planning within neighborhoods; and the Aspen Institute provides a planning workbook that incorporates environmental, economic, and social planning.

Coalitions

Coalitions have been defined as "complex inter-organizational entities that require partners to commit to collaborative efforts toward a specific goal" (Alter, 2008, p. 528). The interdependence of coalitions makes it possible for separate groups to work together for collective social change.

To be effective, whether voluntary or mandated, members of coalitions need to commit to agreed-upon methods and processes for work (Ivery, 2008). Mizrahi, Rosenthal, and Ivery (2013) emphasize that coalitions come together for the pragmatic reason of achieving their shared goal. Social movement theory indicates that the choice to "coalesce" is based on shared values and commitment to a cause or social issue (Mizrahi, Rosenthal, & Ivery, 2013). The dynamics of interorganizational relationships are explained through exchange theory, which emphasizes mutual benefit and reciprocity (Roberts-DeGennaro, 1987). Increasingly, some coalitions establish themselves as long-term organizations, such as the Coalition for the Homeless in Los Angeles and the Domestic Violence Coalitions, located in many states, dedicated to assisting women and ending family violence.

Coalitions may focus on the needs of a specific population, on service development or integration, or on social change advocacy. The desired outcome for social-change coalitions is to build multiorganizational power bases large enough to influence social program direction, with the potential to garner resources to respond to the

common interests of the coalition. Problematic public policies or elected officials are often the systems targeted for change as citizens press for more favorable policies. Government institutions that may have the authority to respond to a particular social concern, but not the readiness to do so, are also the targets of coalitions' advocacy, education, and action strategies.

Coalition building typically requires a major time commitment; for this reason, only organizations that have a stake in the particular issues will engage in longer term involvement. Examples of coalitions found in many communities are those organized for affordable housing, against the increase in teen pregnancy and teen violence, for service programs for the elderly, and for environmentally safe economic development. A coalition of major human service, child advocacy, and professional groups has successfully lobbied for federal support for family-centered, community-based services over the past two decades. This coalition with leadership from the Children's Defense Fund, Child Welfare League, Family Impact Seminar, and National Association of Social Workers (NASW), among others, successfully lobbied for implementation of the 1993 Family Support Act (P.L. 103-66). Coalitions for the homeless have been successful in many urban areas in establishing shelters and services, and some are also concerned with development of low-income housing. To stay together, coalitions develop complex exchange relations and find ways to balance their commitment to the issues that hold them together with the individual agendas and perspectives of member organizations (Roberts-DeGennaro & Mizrahi, 2005). Mattessich, Murray-Close, Monsey, and Wilder Research Center (2001) have analyzed 40 studies of collaboration and identified six major domains and related factors that contribute to establishing and maintaining successful collaborations: positive environment, cooperative membership, flexible processes and structures, effective communication, shared purpose, and sufficient resources.

Social workers are likely to be leaders and spokespersons in human service coalitions, using mediation and negotiation skills to balance internal tensions and maintain the coalition's focus. In coalitions of advocacy groups focused on alternative services, such as coalitions against domestic violence, social workers may also have roles that emphasize group and interorganizational facilitation, teaching and coaching, leadership

development, conflict negotiation, and skills in organizational relations and planning.

Political and Social Action and Policy Practice

This model embodies action for social, political, or economic justice with a focus on changing the agenda of policy makers, changing policies, or changing policy makers. When public agendas and policy directions become so skewed as to cause harm and decrease opportunities for human development, political and social action becomes the means to redress wrongs and put forward a progressive agenda. Social and political action campaigns conduct research and document a problem, select a target and change strategy, generate the power to effect a solution, and use effective communication and direct action to implement promised changes.

Social action seeks progressive change through building powerful local community organizations that can counter the status quo with a visible agenda and a critical mass of people advocating openly for change. Groups use social action and organizing strategies to "change conditions that are injurious to their members or on behalf of others who cannot organize for themselves" (Mondros, 2013, p. 347). Political action can be as simple as handing out leaflets or as complex as running for office. It focuses on enlarging democracy and especially assisting and promoting voting among those who are disadvantaged or oppressed by current policies. Social and political action efforts can change the power relations in a larger community, make people aware of their own power through consciousness raising and group solidarity, and engender personal changes so that people recognize and use their own power more effectively. Collective action can stimulate a sense of community and activate community power.

Mondros (2013, p. 350) makes the case that there is much in common among social, political, and legislative approaches to action: all three seek to "transfer power and resources"; persistence is required in each approach along with disciplined action; and community practitioners may be working at different or multiple levels from neighborhood to state or national. Social and political action can be seen in areas as varied as Appalachia, where citizens trained by the Highlander Center conducted research, documented toxic waste, and were successful in

closing a waste dump (You Got to Move, 2008); to Wisconsin where citizens have been demonstrating a number of years in opposition to the Governor's unfair new policies toward public employees.

Social action organizations may join with other local groups or form coalitions that can apply pressure at national levels. In the South, black farmers have been involved in long legislative struggles to rectify discrimination in federal loan procedures, and across the nation many organizations have been involved in "living wage," "school reform," voter registration, and civic participation efforts. The goal of progressive social and political action is to shift the balance of power so that those who have been excluded in earlier decision-making processes become players in future decisions. This goal is grounded in processes for strengthening participatory democracy and building social justice. For work in both social action and policy practice Brager, Specht, and Torczyner (1987) recommend three types of tactics that escalate in intensity: (1) Collaborative Tactics (Education, Persuasion, and Pooling Resources); (2) Campaign Tactics (Bargaining, Negotiation); and (3) Contest Tactics (Direct Action, Disruption).

Policy practice has been defined by Jansson (2008) as "efforts to change policies in legislative, agency, and community settings" through development of new policies or defeating the policies of others. In policy advocacy, social workers support the rights and concerns of less powerful people and work to help them improve their "resources and opportunities" (p. 14). This work can focus on "case advocacy" or "cause advocacy." Schneider and Lester (2001) define social work advocacy as "the exclusive and mutual representation of a client(s) or a cause in a forum, attempting to systematically influence decision-making in an unjust or unresponsive system(s)" (p. 64). Advocacy is a primary responsibility of social workers and serves as the foundation for political, social, and legislative action.

Movements for Progressive Change

Progressive social movements, focused on economic and social justice and more recently human rights, have occurred when large groups seek to change harmful social and environmental conditions. Wood and Jackson (1982) define social movements as groups "that attempt to produce or prevent radical or reformist types of change"

(p. 3). Social movements promote action for social change that provides a new paradigm for the way we respond to a particular population group or social issue. For example, the growing number of states in the United States that have legalized gay marriage, along with new federal and military policies that provide protections and benefits for married same-sex couples, are significant social change markers. While the struggle of the lesbian, gay, bisexual, and transgender (LGBT) community has been long and arduous—and is not over—these changes have engineered a tipping point through which education and advocacy by the LGBT community and allies, coupled with generational shifts in attitudes and beliefs, and some political shifts, provided momentum for continued change toward extension of civil and legal rights for this New Social Movement (NSM). Other NSMs focus on human rights, identity, and critical consciousness (Reisch, 2013). The major systems targeted for change are the general public and especially political systems. The abolitionist movement in the United Kingdom is credited with being the earliest mass movement for human rights. To be progressive, movements must support both human rights and social justice. In the United States, the civil rights movement is perhaps the best known and most far-reaching example of a social movement; it created conditions and expectations that fostered civil and social rights work in other groups, including La Raza, the women's movement, and the disabilities rights movement (Parish et al., 2006; MacNair, Fowler, & Harris, 2000). New paradigms related to these groups emerged with the success of the movements. Both legislation and attitudes have begun to focus more on abilities than disabilities; women increasingly exercise equal rights and move into leadership positions. Members of the LGBT community are pressing to achieve full equality. Latinos, African Americans, and Native Americans have legal civil rights but must continue to fight discrimination and prejudice as they work toward social and economic equality (National Association for the Advancement of Colored People [NAACP] [www.naacp.org/]; American Indian Movement [AIM] [www.aimovement.org/]). In the United States and many parts of the world, immigrants' rights are contested or denied. In social movements, social work roles are typically those of advocate and facilitator. Social workers, in keeping with the values of the profession, are allied with social movements that support democracy, individual

dignity, the rights of minorities, the needs of the poor, sustainable development, and the broad goals of human development and liberation.

Social movements often occur when protest erupts as a result of intensifying oppression or when great and inequitable changes in the political or social system occur. Localized protests may call attention to widespread oppression; when those protests engender widespread support and mass empathy, a social movement emerges. Piven and Cloward (1979) analyzed four different American social movements and conclude that “both the limitations and opportunities for mass protest are shaped by social conditions” (p. 36). There may be only a small window of opportunity for change provided by the temporary relaxation of the social order brought about by widespread social protest. They suggest that the best strategy to achieve sought-for change through social movements is to extend that window of opportunity through organizing and action.

Social movements that maintain momentum can achieve significant change. The election of Nelson Mandela as President of South Africa was the outcome of a social movement and long-term struggle to end the system of apartheid and to establish civil and social rights for Black South Africans. The efforts toward human rights in Latin America, Africa, Asia, Eastern Europe, and other parts of the world continue. As a social movement succeeds, the ideals that it has advanced are accepted as legitimated political and social norms.

CONCLUSION

The descriptions of these eight models, coupled with the historical and value discussion that places community practice in its social work context, provide some guidance for those working in a wide range of community efforts. One value of examining these models is to realize the multiple roles social workers have to play in facilitating individual, group, organizational, and community development toward democratic institution building. Social workers are called on to be organizers, teachers, coaches, advocates, facilitators, negotiators, mediators, planners, researchers, managers, proposal writers, spokespersons, promoters, and political candidates (Weil & Gamble, 2013).

Community practice at all levels is influenced by local, national, and global changes. Citizens the

world over are no longer leaving initiatives for social change just to governments and business. Social workers who are knowledgeable and have skills to contribute to this process will coach community members to become change agents in their communities. There will always be a role for social workers in the area of neighborhood and community organizing. The technology exists to communicate across the globe in seconds, but we still do most of our community building in face-to-face groups and organizations. The new communication technologies are particularly helpful for organizing functional communities, and these communities can benefit from social work’s knowledge of social action, need and asset assessment, service and program development, and leadership.

There will be a tremendous need for social workers skilled in community social and economic development in the next several decades. As societies recognize the need to incorporate the lessons of sustainable and human development into the equations for economic progress, social workers can facilitate the dialogue to help local and regional groups create new paradigms for sustainable development. The work of social planning will focus on developing more humane and inclusive social and economic systems for communities. Communities no longer will accept development that squanders the environment, tramples the vulnerable, and unjustly divides the profits. Application of social work’s value and knowledge base, to new theoretical concepts for inclusive, comprehensive, and participatory work can make a significant contribution to social planning. Program development, community liaison, and service coordination will be the primary foci of organizations’ administrators and managers as they seek to involve the consumers of human services as partners in planning and providing human services in all their variety. Political and social action will always be in the purview of social work as long as one of the strong values of the profession is social justice. The *NASW Code of Ethics* makes it very clear that “social workers should engage in social and political action that seeks to ensure that all people have equal access to the resources, employment, services, and opportunities they require to meet their basic human needs and to develop fully” (1996, p. 27).

Because social workers are skilled in the facilitation of groups and organizations, they will be key actors in building the coalitions needed in the coming decades. Though social workers are not typically major leaders of social movements, their

skills as advocates and facilitators are critical for preparing groups and organizations to participate in progressive social movements. In all these models there is a need for high levels of interpersonal, process, task, and technical skills. A particular skill needed by those working in community practice will be for facilitation methods using popular education and participatory planning (Chambers, 1997; Freire, 1970). Community practice workers will need to understand that the work they do is often long and arduous; however, the rewards in contributing to development of a more just and democratic society are enormous.

117 Legislative Advocacy to Empower Oppressed and Vulnerable Groups

Michael Reisch

INTRODUCTION

Legislative advocacy focuses on promoting the common welfare or securing and protecting the rights, benefits, or services for a specific population, which cannot speak on its own behalf, by supporting or opposing laws or items in governmental budgets. During the past century, many significant policy achievements, such as Social Security, Medicare, and Medicaid at the federal level, and housing, public health, and employment regulations at the state and local levels were the product of legislative advocacy by social workers and their allies (Stern & Axinn, 2012; Jansson, 2011). Since the early 1980s, however, as a consequence of policy devolution and fiscal cutbacks, the focus of legislative advocacy has largely shifted to the state and local arenas on issues such as health care, public assistance, Affirmative Action, services for homeless persons, marriage equality, and immigrant and refugee rights (Luhby, 2011; Jenkins, 2011; Barber, 2011; Fessler, 2010; Squillace, 2010). This is significant because research suggests that considerable differences exist among legislative advocacy practice at the national, state, and local levels, and that these even vary considerably across different states and municipalities (Hoefler, 2013). Many examples cited herein come from such efforts, where social workers often have more opportunity to exercise their skills and influence.

THE PURPOSES OF LEGISLATIVE ADVOCACY

Legislative advocacy is a means to mobilize people, raise political consciousness, and accentuate

the shortcomings of societal institutions and structures, while working to improve the quality of life or expand the rights and benefits of specific populations, particularly those who are in a position of power and resource disadvantage. It attempts to influence the decisions and perspectives of legislators, stakeholders, executive department heads and key staff, the media, and other influential advocates (Hoefler, 2012). The work of organizations like the Michigan League for Human Services, Philadelphia Citizens for Children and Youth (PCCY), and Health Care for the Homeless in Maryland is an example of this type of advocacy. Legislative advocacy also requires the mobilization of constituents' resources so that they can be focused on a specific policy goal through collective action (Richan, 2006). The recent successes in Maryland of efforts to pass marriage equality and a "Dream Act" illustrate how this can be done effectively.

During the past three decades, however, most advocacy efforts by social workers and their allies have been defensive in nature. Advocacy groups in diverse states—New York, Michigan, Maryland, Texas, and Pennsylvania—have resisted budget cuts that would disproportionately harm low-income groups. A statewide alliance in Oregon defeated a well-funded anti-gay ballot measure. Broad-based coalitions in California defeated ballot propositions that would have eliminated funding for HIV/AIDS services, slashed welfare benefits, or banned the use of demographic data about race and gender to target resources to vulnerable populations. Unfortunately, many of these efforts have not succeeded, as the recent passage of anti-Affirmative Action initiatives and legislative restrictions on

voting rights demonstrates. Yet, even during politically and fiscally conservative times like the present, offensive advocacy is possible (Shaw, 2001). In the past year alone, advocacy groups have passed laws that have enhanced immigrants' rights, increased funding for domestic violence programs, established marriage equality, protected workers' rights, and abolished capital punishment.

In addition, legislative advocacy can serve a variety of purposes beyond passing or blocking a particular bill. Often, it is a means to strengthen one's organization or coalition or expand its membership. It can complement the service delivery objectives of participating organizations by providing increased funding for agency programs. Even unsuccessful advocacy campaigns increase public awareness of clients' issues and enable service providers to enhance their reputations and fundraising efforts. They can also strengthen interorganizational relationships among potential allies and help build grassroots leadership. By speaking out for welfare recipients, the Kensington Welfare Rights Organization in Philadelphia kept the issue alive in the media and the public consciousness at a time when their needs were being ignored in the political arena.

In sum, legislative advocacy can serve the following purposes for social workers:

- ***It can increase client competence by educating them to testify before legislative committees or advocate with individual legislators.*** For over 15 years, Coleman Advocates for Children and Youth in San Francisco has been particularly effective in training the parents of low-income children, through a group called Parent Advocates for Youth, and youth themselves, through a group called Youth Making a Change, to engage in such activities. Other advocacy organizations are substantially increasing the level of civic participation among youth, particularly within racial and ethnic minority communities, by addressing issues that specifically concern them (Checkoway & Gutierrez, 2006).
- ***It can encourage one's organization to be more responsive to clients' needs and to be more aware of the conditions that affect their lives.*** The ongoing work of the Los Angeles Roundtable for Children is a good example of this effect.
- ***It can facilitate intracommunity or interagency cooperation by requiring participating organizations to channel their efforts through a structured, disciplined, and cooperative process.*** Annual report cards on legislators, a tactic pioneered by such organizations as Children Now and the Children's Defense Fund, are now widely used.
- ***It can stimulate needed organizational changes by the very demands it creates for improved information, extensive public education campaigns, greater political sophistication, and stronger ties with constituents and their communities.*** Numerous state chapters of the National Association of Social Workers (NASW) have become more effective and more efficient in their operations as they became more involved in legislative advocacy.
- ***It can be a catalyst for the redistribution of resources and power within an agency, a community, and an advocacy coalition itself.*** A Maryland statewide coalition, Maryland Hunger Solutions, is a good illustration of this phenomenon.
- ***Finally, it externalizes clients', workers', and agencies' problems by focusing them on a mutually selected target.*** This helps them cope more effectively with the daily stresses in their lives and practice. For decades, welfare rights organizations and advocacy groups such as the National Alliance on Mental Illness (NAMI) and Health Care for the Homeless have noted such effects.

COMPONENTS OF LEGISLATIVE ADVOCACY

The major tasks of legislative advocacy can be summarized as follows:

- Applying substantive expertise and technical assistance to draft legislation or make budget recommendations.
- Organizing support for legislators to enable them to take political risks on an issue of concern to one's organization and its constituents.
- Monitoring all legislation and budget items that are relevant to one's constituents, including all committee and caucus votes that influence the course of particular bills.

- Developing ongoing cooperative professional and personal relationships with other legislative advocates and with legislative staff.
- Creating and using media contacts and developing a media advocacy strategy to complement work in the legislature itself (McNutt & Menon, 2008).
- Using the legislative advocacy process to organize, educate, train, and empower constituents through phone trees, listservs, social media, Twitter, and existing advocacy networks; orchestrating letter writing, fax, e-mail, text, Twitter, Facebook, and phone campaigns; and participating in legislative hearings and other key legislative events.
- Using the legislative advocacy process and complementary media activities to spotlight particular issues, educate the public and legislators, arouse popular support for policy alternatives, and provide legislators with the opportunity to test public reactions to their positions on new or controversial policy issues (Kanter & Fine, 2010).

In sum, legislative advocacy is a political process that combines conflict, negotiation, cooperation, and compromise. Some of its activities are considered “inside” tactics because they take place within well-established routines and affect policymakers directly. Others are considered “outside” tactics because they work to influence policymakers through means other than the established legislative process. More than other forms of advocacy, however, the need to compromise in the legislative arena often generates ethical conflicts among social workers. Although each ethical dilemma that emerges in the legislative advocacy process must be resolved on its own terms, it is generally useful to keep in mind that legislative advocacy is not an end in itself but one of several complementary strategies to achieve particular policy goals. One must consider, therefore, both the short-term and long-term needs of constituents when engaging in such advocacy efforts.

THE ROLES OF LEGISLATIVE ADVOCATES

Legislative advocates play multiple roles depending on the needs of their constituents, organizational imperatives, and the political culture and climate of their circumstances (Hoefer, 2013). At times, local advocacy groups like Coleman

Advocates and Philadelphia Citizens for Children and Youth, and national organizations such as the Children’s Defense Fund, Children Now, and the National Association of Child Advocates focus on a specific population, such as children in poverty. Other groups have recently focused on displaced workers, undocumented youth, or homeless veterans. At other times, legislative advocates play the role of ombudsperson or broker. In the former role, they help articulate clients’ or agencies’ needs to policymakers or assist clients and constituents in making their voices heard through community forums, blogs, Twitter, and other forms of social media. As brokers, legislative advocates work with legislative staff to negotiate compromises in legislative or budgetary language that affect their constituents.

On occasion, as the author has experienced in his work, they can become directly involved in shaping the budgets of key government departments. Sometimes, as a favor to a sympathetic legislator, advocates can be catalysts for compromise even though they have no direct interest in a proposed law. In return, the legislator may agree to sponsor or “carry” a bill promoted by the advocates. These diverse roles underscore the importance of developing expertise on a range of substantive issues, as well as the legislative process itself, to increase advocates’ visibility and political viability.

STRATEGIES AND TACTICS OF LEGISLATIVE ADVOCACY

Although the overall goal of legislative advocacy is to influence the policy-making process on behalf of clients and constituents, the paths to attain this goal vary considerably depending on the presenting issue, the political climate and culture, and the relative influence of advocates and their allies in a particular context. Often when advocates have little prior experience in legislative work or the issue is relatively new, the major focus of legislative advocacy is to obtain, organize, and present data to illuminate the scope of a problem for which a legislative solution is sought. As advocates acquire a reputation for reliability in their area of expertise, they are often called on to prepare more focused reports or presentations for a legislative committee or a particular legislator who is a potential sponsor of a bill. In such instances, advocates may be asked to conduct research, write or present

expert testimony, or help draft the legislation itself. This requires advocates to balance their interest in acquiring visibility with their need to obtain critical political support. It also potentially jeopardizes the role of advocates as forces outside of the political process who speak for the people. Once advocates “win”—that is, play an insider’s role in key legislative or fiscal processes—they risk jeopardizing their ability to criticize the actions of governments with which they are now cooperating. They also risk changing the perception of the public, organizational allies, and constituents regarding their integrity and trustworthiness. As the author learned from his work in San Francisco, Baltimore, Philadelphia, and Southeast Michigan, weighing the trade-offs of such situations is critical; it requires assessing the trustworthiness of the legislators and administrators involved and the long-term implications of decisions.

Advocates should answer the following questions prior to testifying before a legislature:

- Do we possess sufficient knowledge of the subject and adequate presenting skills?
- Can we provide supporting data—statistics and case examples—for value-based appeals?
- Would testifying on a particular issue advance the long-term goals of our constituents?
- Would our testimony add anything new and constructive to policy debates?
- Is it important that we take an independent position on this issue?

Occasionally, an effective tactic for legislative advocates is the use of electoral campaigns—ballot initiatives or candidate elections—to advance their issue. Although advocacy organizations must be careful to remain nonpartisan (i.e., not back a particular candidate or party) or risk losing their nonprofit status, they can and often do get involved in educating the electorate about the central issues of a campaign. In 2012, the Maryland chapter of NASW, for example, played an active role in a successful campaign to pass marriage equality in the state.

After a bill has been introduced, advocates often engage in a broad range of public educational activities in cooperation with allies, including town meetings, press conferences, speak-outs, demonstrations, and, most recently, social media campaigns. Research on successful legislative advocacy (Hoefler, 2005) has identified

the following determinants of success: (a) consistent and continuous involvement of constituents; (b) well-established and varied means of communication; (c) ongoing positive relationships with legislative targets; (d) skills in consensus building and the mobilization of public opinion; and (e) the establishment of credibility on a focused set of issues. Efforts that reflected the diversity of constituency groups were also more likely to gain recognition and obtain access to key decision makers.

GUIDELINES FOR LEGISLATIVE ADVOCACY

Healy and Sofer (2013) make the following comments about legislative advocacy at the federal level:

1. ***Politics is a process, and just about anyone can master it...*** Many people find the procedures arcane, but that is only true for those who never try to learn them.... Mastery is crucial to success, particularly for nonprofit advocates who must rely on knowledge to overcome other disadvantages, such as lack of funds.
2. ***Winning requires both inside- and outside-the-Beltway strategies.***
3. ***Successful campaigns require a lot of different skills***—a leader who is willing to be a tough taskmaster and keep pressure on people to make sure they are engaged and helpful; ... lots of resources, money, and in-kind contributions; ... allied organizations to lend staff and provide other assistance; and [most importantly] ... a core group of members in the coalition who bring different strengths to it.
4. ***It helps to have villains.***
5. ***There is strength in numbers.***
6. ***Persistence pays off.***
7. ***It is crucial to target efforts in Congress, because not all members of Congress are equal.***
8. ***Education of legislators and their staff members is critical.***
9. ***It is crucial to bring disparate groups together to present a united front.***
10. ***Media coverage greatly influences the process.***
11. ***Support from the Executive Branch is incredibly helpful.***

12. *Work both sides of the political aisle, and never take your supporters for granted.*
13. *Do not give up on members who have opposed your program in the past.*
14. *Segment the market.*
15. *Get people who directly benefit from the programs to help out.*
16. *Recognize and reward friends and supporters* (pp. 252–255).

Beyond these valuable suggestions, effective advocacy at the state and local level requires additional ingredients. At the state level, Teater (2009) found that the most effective groups were locally based and maintained regular contact with their constituents. Legislators also report that the groups they find most effective have clear plans, a focused mission, specific goals, and an involved membership, which results from ongoing two-way communication and accountability between leaders and members, and which enhances a group's legitimacy.

In sum, effective legislative advocacy at all levels requires advocates to:

- Be consistently and continually engaged in the legislative process even when the legislature is not in session. This is particularly important in states where it meets for only a few months (as in Maryland) or every other year (as in Texas).
- Research the orientation and priorities of the legislators they are seeking to influence. The distribution of regular publications to legislators and department heads and frequent updates to organizational websites, blogs, Facebook pages, or Twitter feeds are effective means for advocates to make their presence felt (Kanter & Fine, 2010).
- Provide technical assistance and political information to legislators and their staff members even on issues that are of indirect concern to advocates. Doing so builds trust and credibility that can be tapped during efforts on behalf of difficult or unpopular issues.
- Develop personal and political relationships with legislators and their staff members, often through informal contacts at fundraisers, conferences, and workshops.
- Be clear about their long-term goals, even as advocacy tactics shift, through ongoing communication with allies, constituents, the media, and the public.
- Be sensitive to the views of legislative opponents, particularly those who hold key committee posts.
- Recognize that legislators and their staffs have unexamined and unquestioned prejudices and learn how to confront these prejudices directly without alienating potential supporters.
- Develop the ability to take risks despite the overriding ethos of compromise in the legislative arena and the appearance of insurmountable partisan divisions.
- Convince others that one's objectives are socially worthy and not self-serving.
- Support efforts of coalition partners on issues that are not directly of concern to one's organization or constituents.
- Frame policy issues in terms that are consistent with the worldviews of legislators and learn when to refrain from advocacy that might produce resentment among them.
- "Change their tune" from time to time so that their message continues to be heard in a chaotic environment dominated by today's 24/7 news cycle.
- Save scarce resources and energy for another day by recognizing when the political climate is hostile to their message.
- Be sensitive to the egos of legislators and the political pressures they experience and shape advocacy arguments around their political and personal imperatives.
- Develop diverse mechanisms to influence the legislative process that include traditional means, such as action research committees, focus groups, and training sessions for constituents and supporters, as well as tech-savvy social media and wikis (Libby, 2012).

BARRIERS TO SUCCESSFUL LEGISLATIVE ADVOCACY

Obstacles to successful legislative advocacy fall into three broad categories: those created by the political-economic environment; those inherent in the legislative process; and those intrinsic to advocacy itself. Legislative advocacy is both partisan and political—roles that may produce some discomfort among many social workers. Social workers need to recognize, however, that the profession has been involved in legislative advocacy almost since its emergence.

The most obvious obstacle to successful legislative advocacy is the presence of a generally

unfavorable political environment for social welfare programs, particularly those on behalf of low-power and stigmatized groups (Haynes & Mickelson, 2010). Attempts to influence traditional centers of power, such as legislatures, increasingly encounter overt and covert hostility from opponents and even skepticism from potential allies. Sometimes, advocates can be distracted by the presence of “wedge” issues (e.g., efforts to roll back reproductive rights or expand gun rights) that, because of their urgency, compel advocacy organizations to shift from an offensive to a defensive posture. Recently, recurrent fiscal crises (which most states have experienced since the onset of the Great Recession) make it more difficult for advocates to adopt a proactive agenda (Oliff, Mai, & Palacios, 2012; Chantrill, 2012; Barnett, 2011).

Another obstacle is the difficulty of sustaining a “conflict posture” in a legislative setting. Legislative advocacy is a time-consuming and expensive strategy that can drain the resources and energy of even the strongest individuals and their organizations. Organizations that operate on a shoestring budget and rely primarily on volunteers often cannot sustain their efforts over time. Groups that are engaged in a wide range of initiatives sometimes have trouble maintaining a high degree of mobilization among supporters and constituents. The growing influence of external funders, particularly foundations or corporations, has restricted the activities of advocacy organizations or compelled them to focus on issues their financial supporters, rather than constituents, have defined as critical. In such cases, advocates must choose their battles very carefully.

A third barrier is the increasing fragmentation of the policy-making process within legislatures as a consequence of the growing specialization of committees, budgets, and proposed legislation. As legislative advocates, social workers may become frustrated by the need to reframe broad issues within the narrow requirements of the legislative process. An additional complication in this regard is the competition among legislative committees for jurisdiction over policy initiatives. Here, the importance of developing and sustaining personal relationships with legislators is critical. Unfortunately, the imposition of term limits in many jurisdictions has complicated the development of such relationships. A related obstacle is the difficulty of identifying the locus of accountability for policy decisions. A partial solution

to this problem is to make additional efforts to strengthen ties with media contacts, officials in the executive branch, and legislative staff, who often have longer tenures than the politicians for whom they work.

Advocates also experience ongoing tensions between the time and effort involved in expanding the participation of community-based constituents and the persistent time constraints of the policy-making process. Such constraints are usually the result of legal or constitutional procedures or the politics of the legislative process. Recently, the greatest constraints on effective advocacy have been the limits placed on legislative initiatives by economic conditions and the need for fiscal cutbacks, the imposition of constitutionally mandated balanced budget requirements, voter spending initiatives (at the state and local level) that can restrict or target funding in heavily prescribed ways, and the resource disadvantage of social work advocates in comparison with wealthier groups. Some advocacy groups, however, have found solutions to these dilemmas. These include creative framing of the issues (e.g., demanding higher wages for low income workers to strengthen families [Gordon, 2006]); developing innovative tactics (e.g., Coleman Advocates taking over City Hall with a “baby brigade” [Brodkin, 1993]); and using patriotic language to promote the rights of “dreamers,” undocumented immigrant youth (American Civil Liberties Union, 2012).

At the local level, additional barriers exist. These include:

1. The way information is disseminated by both City Hall and the media.
2. The control of public-space and political messages by wealthy individuals and corporations.
3. The idea that heroes are “chosen” rather than the outcome being decided by people making a series of decisions to do the right thing.
4. The structure of political parties and elections, which are designed to decrease activism rather than encourage it (Meslin, 2011, cited in Hoefler, 2013).

Within the social work profession itself, four problems stand out: (1) inadequate preparation of social work graduates, (2) practical barriers

(time pressures, lack of organizational resources devoted to advocacy, proximity to state capitals, especially in large states), (3) negative attitudes about politics, and (4) misinformation about the laws regulating advocacy by government or nonprofit organizations (Council on Social Work Education [CSWE], 2008; Hoefler, 2001, 2005, 2012; Cochran, Montgomery, & Rubin, 2010; Teater, 2009; Smucker, 1999).

THE FUTURE OF LEGISLATIVE ADVOCACY

Since the late 19th century, legislative advocacy by social workers has transformed the social landscape of the United States and led to improvements in the material well-being of millions of Americans. It has shaped the domestic policy agenda of the nation, altered the balance of power at the state and local level, facilitated the emergence of leaders at the community level, and enhanced the status of the social work profession. Over the past three decades, however, much of that advocacy has been defensive in nature, involving efforts to minimize spending cuts or prevent the elimination of long-standing social protections. Hoefler (2013) predicts that advocacy organizations at the state and local levels will expand their use of electronic tools and social media (McNutt & Menon, 2008; Dunlop & Fawcett, 2008), will increasingly see the connections between advocacy efforts and fundraising (Daigneault, Davis, & Sybrant, 2011), and that social justice battles will intensify at the state and local level.

Despite today's conservative political and fiscal climate, several recent trends produce guarded optimism about the future of legislative advocacy. A notable development is the growing emphasis on expanding the civic participation of clients and constituents, particularly youth (National Center on Civic Literacy, 2013; Checkoway & Gutierrez, 2006). A related trend is the growing power of the Internet and social media to help advocates and their constituents develop increasingly sophisticated databases and communication networks, share ideas and advocacy strategies, and develop rapid tactical responses to rapid changes in the policy environment. Finally, in response to the consequences of economic globalization, legislative advocates are increasingly incorporating regional and international perspectives into local advocacy efforts and building

transnational alliances on such diverse issues as poverty, immigration, civil rights for gays and lesbians, trafficking in children and women, and the impact of climate change (Reilly, 2007; Cullen, 2001).

118 Community Partnerships to Support Youth Success in School

Dennis L. Poole & Aidyn L. Iachini

INTRODUCTION

A *community partnership* is an alliance between citizens and practitioners to bring about planned change for the public good (Poole, 2002, 2008). *Community* stems from the Latin word *communis*, which implies something shared and public. The term *partnership* derives its meaning from its derivative, *partner*. A partner once referred to a piece of timber used to buttress the deck or mast of a wooden sailing ship. This is a fitting analogy for this chapter. Community partners strive together to achieve community goals that are above and beyond the reach of any one partner—in the context of this chapter, namely, promoting the healthy development and educational success of young people in school.

IMPORTANCE OF COMMUNITY PARTNERSHIPS

Many youth thrive in school and graduate with plans to enter the workforce or apply for postsecondary educational opportunities. An increasing number of others, however, experience barriers and challenges that significantly affect their potential. Unmet mental health needs, substance abuse issues, family conflict, bullying, unsafe neighborhoods, and other conditions are just a few of the individual, peer, family, school, and community factors that can negatively affect a young person's ability to learn in the classroom and succeed in school.

A powerful consensus has emerged over the past decade that no community institution alone can address all of these barriers and challenges. Advocates continue to call on schools and

community agencies to work together to provide an array of services and supports designed to (1) address the multiple and varied needs of students and (2) promote students' overall healthy development. In response, partnership-oriented models are being promoted that replace fragmented, uncoordinated services for youth with integrated, collaborative networks of services and supports (Anderson-Butcher, Lawson, Iachini, Bean, Flaspohler, & Zullig, 2010a; Anderson-Butcher, Lawson, Iachini, Flaspohler, Bean & Wade-Mdivanian, 2010b; Dryfoos, 2005; Poole, 1997; Taylor & Adelman, 2000). Full-service community schools, community collaboration models for school improvement, school mental health systems, and comprehensive systems of learning supports are common examples of these models that prioritize the importance of community partnerships (Anderson-Butcher et al., 2010a; 2010b; Dryfoos et al., 2005; Weist, 1997).

Community partnerships are important and beneficial for several reasons. First, developing community partnerships can result in blurring or removing previously fixed institutional boundaries between schools and agencies (Epstein, 2002; Poole, 1997). For example, schools and agencies usually each have their own set of rules, regulations, and customs that inhibit or prohibit the sharing of information. Through community partnerships, new agreements (e.g., memoranda of understanding) can be reached that allow for information sharing across agency and school settings. Community partnerships also can minimize interorganizational competition, reduce fragmentation in service delivery, and increase efficient use of organizational resources. Finally,

another important benefit of community partnerships is that they often lay the groundwork for agency services to be linked with and/or co-located and delivered in the school setting (Anderson-Butcher & Ashton, 2004; Taylor & Adelman, 2000). For example, Iachini, Dorr, and Anderson-Butcher (2008) describe a partnership between one school district, three mental health agencies, and other community and school stakeholders that resulted in the hiring of mental health providers to provide services to students and families in the school setting. Not only did these partnerships result in needed services, they ultimately enhanced student and family access to them by offering them on school grounds.

ACTION PRINCIPLES

Social workers can serve as key leaders in fostering and developing community partnerships to support youth success in school (Anderson-Butcher et al., 2010b). Six action principles in a community partnership capacity building model, developed by Poole (2002), are presented in Figure 118.1 to guide social workers throughout stages of the capacity building process. It is important to note that the

term “community” included within the model is inclusive of schools as part of the community. Therefore, the term “community” is used throughout the remainder of this chapter to reference a variety of community institutions including the school system.

Agenda Building

Initiate the process by getting a core group of citizens and practitioners to place the issue on the agenda of key decisionmakers. “Agenda building” refers to predecisional processes that lead decision makers to select some issues for deliberation and reject others (Cobb & Elder, 1983). The challenge is to convince leaders that an issue deserves a prominent position on the agenda. An agenda is the list of items that a local school board, youth council, city human services commission, school administrative team, or other decision-making body is willing or able to consider at a given point in time.

To illustrate, let us assume that the issue, or concern, is poor school attendance. A social worker learns that a fourth of the students at one middle school are not attending school regularly. The social worker also learns that these students’

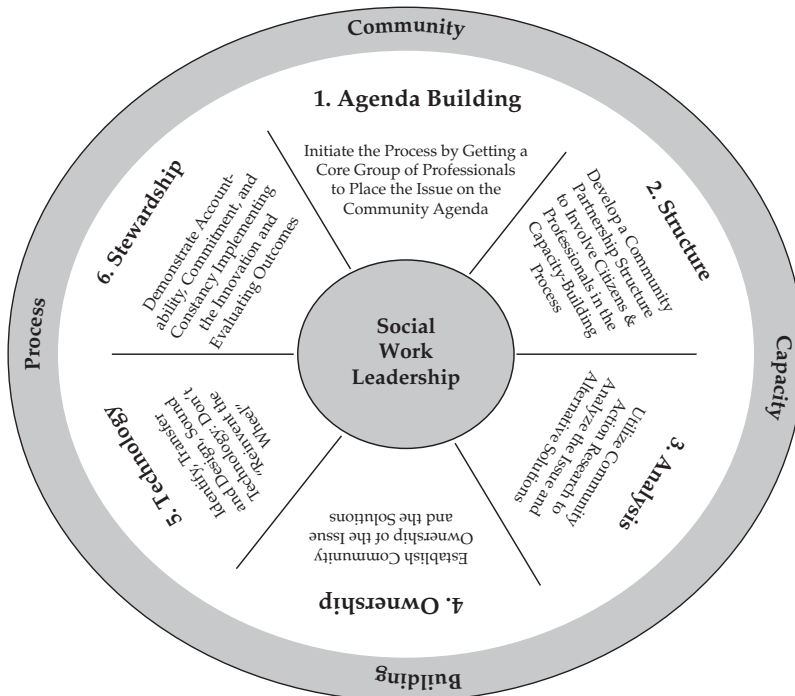

Figure 118.1 Community capacity building process.

standardized test scores and grades are low, and their disciplinary incidences are high. The social worker knows that complex social, emotional, and health forces can stand in the way of a student's ability to attend school, and that multiple community support services may be needed to address this growing concern at the middle school.

Oftentimes, the social worker's first leadership task is to raise the concern with school leaders (e.g., principals and assistant principals). Having data on key indicators to demonstrate that school attendance is a pressing problem for the school, particularly related to academic achievement, is helpful in facilitating these conversations. At this point in agenda building, school leaders may agree with the social worker that poor school attendance is a critically important threat to the educational mission of the school, and decide to make the issue a priority in the school improvement planning process (i.e., a process schools utilize to identify goals, strategies, and action steps for an academic year). The social worker also may simultaneously need to build support for an issue in the community to further demonstrate to school leadership how important a particular issue may be to the wider community. The critical role that volunteer citizens often play in agenda building should not be underestimated. They are, after all, the central actors in a democracy, as well as trustees of the public interest (Cooper, 1991), and usually have much more power than paid practitioners or staff to get an issue on the community's agenda (Cooper, 1991; Gusfield, 1981; Poole, 1997).

Accordingly, the social worker should consider involving volunteer citizens who represent various types of power to build support for the issue. For example, the social worker might enlist the support of a citizen who has *political* power. Citizens elected this person to represent their interests on the city council, local school board, county commission, or state legislature. The practitioner also might engage a citizen who has *economic* power. Citizens recognize this person as a successful business leader committed to youth services—the board president of the local United Way, for example. Moreover, the social worker might want to engage a citizen with *moral* power. Citizens respect this person as a long-standing advocate for youth, perhaps a concerned parent of a child in the target middle school of this case example. Finally, the practitioner might need to engage a citizen who has *technical* power—such as a retired teacher

or social worker with expertise on attendance issues in school.

Considering these four different types of civic power, the social worker should be purposeful and intentional in the engagement of citizens external to the school. Depending upon school administrative characteristics and preferences, the social worker might work collaboratively with administrators to set up small group meetings between concerned citizens and the school. Alternatively, one-on-one meetings with various citizens and school administrators might be the better approach. Regardless, the goal is to gain buy-in and agreement among school administrators and community stakeholders that poor school attendance is a significant issue that warrants further exploration. Ultimately the issue of poor school attendance must be “co-owned” by schools and community partners, and a partnership structure must be utilized or created to resolve it.

Structure

Develop a community partnership structure to involve citizens and practitioners in the capacity building process. Once the issue achieves agenda status, the next phase is to build a community partnership structure, or expand an already existing structure, and sustain it throughout the process. A community partnership structure provides a channel through which responsible citizens can take a leadership role with practitioners in solving pressing school and community problems. It usually operates under the auspices of a decision-making body, taking the form of a committee, task force, or advisory council. Action-oriented, a community partnership structure fosters shared responsibility for local problems, prompts behavioral change in community institutions, and initiates and sustains reform efforts over time (Poole, 1997).

Thinking about the case example, let us assume that the school decides to establish a 25-member structure called the School Attendance Community Partnership Committee, herein referred to as the “Community Partnership Committee.” One critical role for the social worker at this stage is to ensure that best practice teaming principles are attended to and monitored by the committee. Iachini, Anderson-Butcher, and Mellin (2013) identify four teaming principles to consider. They include (1) having a clear purpose for the committee, (2) having diversity

in composition and membership, (3) identifying a committee leader, and (4) establishing clear procedures for the committee and how it will operate (Iachini et al., 2013).

In reference to the Community Partnership Committee, the social worker might facilitate a discussion in early committee meetings about the importance of such teaming principles. Conversations should address the purpose of the committee and its goals, creating a clear and shared understanding among its members. Conversations also should revolve around ensuring that the “right” members are represented on the committee. For example, are leading citizens who hold critical insight and expertise on the subject of school attendance on the committee? Is there balance and diversity of membership? Are practitioners from schools and community agencies with resources to address the school attendance issue represented on the committee? In our case, school representatives might include the superintendent, middle school principal, a teacher, guidance counselor, and a social worker. Agency representatives might include administrators or staff of the public health department, mental health center, department of human services, or YMCA. Once membership is established, it is important that a key leader be selected to serve as chair of the committee, and that processes be identified on how the committee will function (e.g., meeting times, accountability mechanisms, and communication).

A social worker’s knowledge and skills in group work can be especially helpful during this stage of the process. As in treatment groups, critical leadership roles are performed in task-oriented groups. Examples of these include helping a committee identify goals and objectives, facilitating group action and interaction, maintaining group cohesiveness and member satisfaction, and providing means for group task performance (Ephross & Vassil, 2005). In the case example, the capacity building process is likely to disintegrate if the group maintenance needs of the Community Partnership Committee are not met, thwarting the opportunity to advance its efforts to resolve the school attendance problem.

Analysis

Use community action research to analyze the issue and alternative solutions. The analysis stage of the capacity building process involves community action research. Traditional research will not

satisfy the full requirements of this stage. Hiring a consultant to analyze the issue, report findings, and offer recommendations will not suffice. The main objective is for the community, rather than a consultant or a few practitioners, to become the research team (Minkler & Wallerstein, 2003).

As in traditional research, community action research seeks to improve the quality of decision making through careful collection of data and facts. Greater emphasis, however, is given to participatory strategies than to nonparticipatory strategies. Key informant interviews, public forums, and focus groups, as well as surveys on community, family, peer, and individual risk and protective factors, can be used to engage divergent community groups and organizations in data collection and analysis. Existing data also can be analyzed in conjunction with data collected through these other participatory strategies. For example, in the case of the Community Partnership Committee, secondary data already collected by schools and districts as part of accountability requirements (e.g., attendance, behavioral incidences, and grades) could be examined along with newly collected data gathered via focus groups and surveys. Together, collecting, using, and examining various types of data can foster broad-based community participation, increase public awareness of the issue, and identify community partners that must share in solving the problem.

In the case example, the key leadership role of the social worker is to ensure that each member of the Community Partnership Committee participates in data collection, shares ownership of the findings, and helps develop proposed solutions. Tasks include helping committee members reach consensus on the nature, scope, and causes of poor school attendance at the middle school; identifying alternative strategies to address the issue; and developing and submitting a written report to school or district administrators and community partners with recommendations for action. The social worker may help write the report, but his or her name is not prominently displayed. The authors are the members of the committee that gathered the information, analyzed the findings, and identified solutions included in the report.

Community Ownership

Establish community ownership of the issue and solution. “Ownership” refers to actions taken by

a decision-making body to demonstrate it owns an issue. Ownership is established when a body has the power to define the issue, determine its causes, and assign responsibility to local institutions to implement a solution. Some community institutions may not want to give up their power to define the issue because it would mean forfeiting their right to control the solution. Others may want to “disown” the issue because they might be asked to share responsibility in addressing it (Gusfield, 1981).

In the case example of school attendance, the main leadership role of the social worker is to facilitate both school and community ownership of the issue. The practitioner, however, must recognize that addressing school attendance at the middle school probably will not take place without a change in the *status quo*. This will require that all relevant organizations or groups be invested in “owning” the solution, even those that want to “disown” it. At some point in the capacity building process, a partner may attempt to renege on prior public commitments to participate in solving the problem, or attempt to control the solution. Together, members of the Community Partnership Committee must hold all relevant actors accountable for their role(s) in the solution and continue to foster broad-based ownership of the school attendance problem.

Technology

Identify, transfer, and design sound technology: do not reinvent the wheel. In the technology stage, attention shifts to the identification, transfer, and design of a sound technology to implement the strategy adopted by the community partnership structure. Frequently, too little attention is devoted to this important phase of the capacity building process. Organizations that do not have adequate and appropriate staff resources, facilities, funding, or intervention techniques usually have great difficulty implementing a new product or service innovation (Anderson-Butcher et al., 2010a, b; Poole, Ferguson, & Schwab, 2005).

Considering the case example, the social worker must recognize that attendance issues are common in schools. Other schools and communities have faced the same issue and most likely have devised good technical solutions. The social worker should help the Committee Partnership Structure find these solutions, assess their outcomes, determine transferability, and modify

proposed solutions to fit the particular needs and specifications of his or her community. Library research, surfing the Internet for evidence-based practices and strategies, phone calls, and site visits help the social worker meet this challenge. Fortunately, ample literature exists on the causes of poor school attendance, and an array of solutions involving diverse practitioners have been tested in school settings. Roles for social workers in these solutions are rich and varied (Openshaw, 2008).

The social worker also should help the committee ensure that all relevant community institutions contribute resources—cash or in kind—to implement the plan. Most service innovations in schools require a diversified funding base, reflecting the complexity of interventions needed to improve school attendance. Though a diversified funding base is usually needed to sustain a service innovation over time, small contributions from the Junior League, the United Way, or private donors can be used as seed money. Funding also may need to be redirected from an existing source to support this new effort. The value of such contributions should not be underestimated. Together they can foster greater community- and school-wide ownership of the solution, provide an opportunity to test the viability of the selected technology on a small scale, and give the committee more time to secure larger, stable sources of funding to implement the intervention if necessary.

Professional development and other support needs also are important to consider during this stage (Anderson-Butcher et al., 2010a, 2010b; Iachini et al., 2008). New infrastructure, resources, and strategies identified by the Community Partnership Committee in this case may need to be shared with a variety of stakeholders involved with implementation and management. Workshops and trainings may be needed to familiarize middle school teachers and staff, for example, with new intervention strategies being utilized to improve school attendance. In addition, school staff roles or community partner roles may need to be redefined or reorganized to align with this new school priority. The social worker might help to organize or identify what is needed to assist teachers, staff, and practitioners to make the transition successfully.

During the technology stage of the capacity building process, plans also should be developed to monitor implementation and progress toward outcomes. How will the Community Partnership Committee know when outcomes are being

achieved without indicators of progress along the way? How will barriers and challenges to implementation of the intervention strategies be identified? The social worker can guide the committee in a discussion to identify key outcomes as well as select indicators to track and monitor progress during implementation of the new intervention strategies.

Stewardship

Demonstrate accountability, commitment, and constancy implementing the innovation and evaluating outcomes. Once the community partnership structure endorses the technical plan, and resources to implement the plan are secured, its work shifts to the stewardship phase of the capacity-building process. *Stewardship* means to hold something in trust for another, beginning with the willingness to be accountable for outcomes to some body larger than ourselves—namely, the community (Block, 1993).

Stewardship is the most difficult phase in the capacity building process. Many service innovations almost never work exactly as planned. Community partners become disgruntled, paperwork gets burdensome, resources grow thin, and early outcomes inevitably fall short of expectations (Payne, Gottfredson, & Gottfredson, 2006; Poole, 1997). During the stewardship phase, it is easy for community partners to lose sight of the fact they must fulfill the public trust—that is, deliver the community good they promised, and be accountable for the results. Self-interest, burnout, and feelings of defeat usually take a toll on partners in this stage of the process.

Here, the continual use of data to guide decision-making and mid-course corrections is essential. The social worker may need to pull together data to share at each committee meeting, facilitate discussions among partners about progress made toward goals, identify challenges currently being experienced, and devise solutions to overcome them. It also is important for committee members to reflect on their collaborative efforts (Bronstein, 2003). For example, is time an issue that is impeding partners' abilities to work together successfully? Has a partner with a crucial role in the committee stopped attending meetings? Mendenhall, Iachini, and Anderson-Butcher (in press) found that inadequate time, lack of perceived buy-in, resource

challenges, and transitional issues were barriers to implementing a partnership-centered model in a school setting. Thus, a social worker could guide committee members in a conversation about what is working well, and what needs to be changed relationally and operationally. The social worker also might help them revisit procedures and processes identified during the structure phase of the capacity building process and make changes to improve the committee's ability to function collaboratively.

It is important to emphasize that this stage of the process is not easy or for the light-hearted (Poole, 2002). Victory stands faintly at the end of a long, dark tunnel. Reaching it brings great joy, however, and restores public confidence in schools and community agencies. Fortunately, a community partnership structure has many partners. Each partner can buttress and support an innovation when one partner is weak or behaves irresponsibly. The structure also can make flight from social responsibility difficult because it will hold each of the partners accountable for the public trust bestowed on them. Good stewards find ways to implement an innovation as planned, refine the technology as needed, and produce outcomes that make a difference—in this example, promoting the success of young people in school.

CONCLUSION

Promoting the healthy development and educational success of youth require schools and community agencies to partner and collaborate in order to provide coordinated and seamless services to students and families. These community partnership structures are needed to disrupt arrangements that serve youth and families in an uncoordinated, piecemeal fashion. Social workers can play critical leadership roles in developing and sustaining community partnerships to support youth success in school by adhering to the six action principles of the community partnership model presented in this chapter.

Building Community Capacity in the U.S. Air Force

Promoting a Community Practice Strategy

Gary L. Bowen & James A. Martin

INTRODUCTION

United States military installations vary on a number of dimensions, including their operational mission, their corresponding demographic composition, and the characteristics of their surrounding civilian communities. Installations also differ in their ability to achieve positive community results—“aggregate, broad-based outcomes that reflect the collective efforts of individuals and families who live within a specified area” (Bowen, Martin, Mancini, & Nelson, 2000, p. 9). Resiliency is one such community result that reflects the aggregate success of community members and families to manage their personal and family lives in the context of adversity and positive challenge (Bowen & Martin, 2011).

The U.S. Air Force (AF) has long provided broad-based programs and services to support the adaptation, readiness, and retention of its service members (and immediate family members). Over the past decade AF leaders have adopted a community practice (CP) strategy that has paralleled the continued and profound changes in the size, composition, and stationing of military forces (Bowen, Martin, & Mancini, 2013; Hoshmand & Hoshmand, 2007). This AF practice strategy focuses on promoting interagency collaboration and strengthening the interface between formal and informal networks of social care as a means to promote member and family resiliency. This strategy was field tested by the Family Advocacy

Division (Bowen, Martin, & Nelson, 2002), and by Airman & Family Readiness Centers (formerly Family Support Centers) beginning in the late 1990s (Bowen, Orthner, Martin, & Mancini, 2001; Bowen, Martin, Liston, & Nelson, 2009). Community capacity building efforts in these two AF organizations, including unit outreach, continue today.

In 2010, the USAF established a Resilience Division within the Headquarters of the Air Force that has furthered these community capacity building efforts. The Division embraced the community practice strategy in an effort to promote resiliency training across the AF and to coordinate AF-wide community-based initiatives for both airmen and their families. Civilian Community Support Coordinators (CSCs) have been hired at all AF bases to promote unit-based resilience training and to serve as the Installation Resilience Program Specialist. Working as a member of the Wing Commander’s staff, a principal role of the CSC is to serve as the Executive Director of the Installation Community Action and Information Board (CAIB) and as the Chair of the Integrated Delivery System (IDS). In these related roles, the CSC provides guidance to the installation commander and installation human services delivery staff on a wide range of resilience and quality-of-life issues, including efforts to promote cross-organizational collaboration in addressing individual, family, and community concerns. The IDS represents the action arm of

the CAIB, and the IDS has cross-organizational installation membership and responsibility for developing and implementing a biannual Community Action Plan (CAP) for informing installation level community outreach efforts. The collection and use of assessment data for identifying and monitoring individual, family, and community-level concerns is a fundamental component of the CAP.

This chapter describes the model of community capacity, which is the cornerstone of this AF practice strategy. This model, which is referenced in the literature as the Social Organization Theory of Community Action and Change (Bowen, Martin, & Mancini, 2013; Mancini & Bowen, 2013), embraces members and families within their social context and focuses on the nexus between formal and informal networks of social care as the target of intervention and prevention efforts. We first highlight the practice strategy as it is being implemented in the AF Resilience Division, including an online assessment tool, the Support & Resiliency Inventory (SRI), which is used in the context of this strategy. We conclude by discussing empirical support for the community capacity model, the need for continued research and evaluation of community practice initiatives that are framed and informed by this model, and a new initiative to train family service practitioners in both military and civilian communities in community capacity building.

THE COMMUNITY PRACTICE STRATEGY

The CP strategy promotes interagency collaboration, encourages proactive unit leadership in support of members and families, and builds informal community connections for purposes of fostering a sense of community, promoting individual and family resilience, and ensuring personnel preparedness to successfully perform military duties. This service delivery strategy is strengths-based and results-focused. It contrasts greatly with the more stove-piped, remedial, menu-driven services model that has historically informed the delivery of member and family services in the AF.

A key component of the strategy is unit outreach. CSCs assist unit commanders in meeting their leadership responsibilities for the health, welfare, and readiness of unit members and their families. CSCs are trained to help unit commanders locate and obtain necessary resources for

addressing unit-level issues and priorities. CSCs capitalize on the availability of formal and informal community resources in planning and implementing responses to priority issues—networking and collaboration are the cornerstones of this community-based approach to practice.

Training is underway to provide CSCs with the knowledge and skills to collect and use assessment data (specifically the SRI, which is described below) to inform their work at both the unit level and the larger installation level. This training is framed and informed by a results-focused planning (RFP) approach to the design and delivery of services (Orthner & Bowen, 2004). RFP focuses intervention and prevention efforts on clearly defined and anticipated results. A key aspect of this approach is to identify community partners on the installation and in the local civilian community who will help achieve the desired results, which reflects the central practice mantra of this planning process: “Never go it alone.”

THE SUPPORT & RESILIENCY INVENTORY

The Support & Resiliency Inventory (SRI) was designed to inform, monitor, and evaluate the RFP efforts at the both unit and installation levels.¹ The SRI is a brief, self-administered, web-based assessment tool that examines an individual’s perceptions about sources of informal and formal support in their lives, their individual fitness (mental, physical, social, and spiritual), their positive behaviors toward self and others, and their success in adapting to life challenges and meeting military life and duty responsibilities (resiliency). Completion of the SRI is intended to be voluntary, and the information provided is anonymous. The SRI can be completed online in 12 to 15 minutes using a computer or tablet device. All of the SRI items are worded in a positive and proactive direction—an intended focus on positive knowledge, attitudes, and behaviors rather than the negative.

The administration of the SRI can also be viewed as an intervention itself, and each respondent has access to a printable summary of his or her own responses, as well as information on how and where to seek additional assistance. CSCs are able to view and download a summary group profile that aggregates the responses. An advanced selection tool also allows CSCs to generate profiles for specific units and respondent

subgroups. Further details about the SRI, including a hard copy and reports on its psychometrics, can be obtained from the authors.

THE COMMUNITY CAPACITY MODEL

The community practice strategy aligns with a larger community capacity model that was developed and tested by a team of researchers from the AF and civilian communities (Bowen et al., 2000; Mancini, Bowen, & Martin, 2005). The model, the Social Organization Theory of Community Action and Change, continues to be elaborated and refined (Bowen & Martin, 2011; Mancini & Bowen, 2013), as well as applied to a range of social problems and community support program initiatives (Bowen, Martin, & Mancini, 2013; Farrell, Bowen, & Goodrich, in press; Huebner, Mancini, Bowen, & Orthner, 2009). A review of this model demonstrates the heuristic and stimulus value of explanatory models to the development of specific practice strategies.

The community capacity model includes three major components: (1) formal networks, (2) informal networks, and (3) community capacity. From the perspective of the model, variation in the aggregate success of members and families to manage their personal and family lives in the context of adversity and positive challenge is explained by how successfully formal and informal networks of social care operate and interact with one another in the generation of community capacity. Community capacity, which reflects the level of social organization in the community, is hypothesized as the link between community networks and community results. Social care is defined as tangible, informational, and social-emotional support available for military members and their families. The level of social care provided to members and families through the combined forces of these networks can range from high to low. Each component of the model is elaborated in the following discussion, including a discussion of the hypothesized linkages between these components and between community capacity and individual and family resiliency.

Formal and Informal Networks of Social Care

Three networks of formal and informal social care are identified in the community capacity model: (1) community agencies, (2) unit leaders,

and (3) informal community connections. Formal networks, which include community agencies and unit leaders, reflect the military policies and systems of social care that operate as instruments of socialization, support, and social control. Community agencies promote social care by demonstrating a customer- and strengths-based orientation in their coordination and delivery of intervention and prevention services to members and families. Unit leaders provide social care by promoting connections between members and families, helping members and families balance work and family demands, and when needed, helping members and families access and secure support services. The effectiveness of formal networks of social care depends in part on securing necessary input and participation from community members.

Informal networks, which include informal community connections, are voluntary and less organized. They include personal and collective relationships and group associations, such as unit-based support groups and relationships with extended family members, work associates, neighbors, and families. Mutual exchanges and reciprocal responsibilities constitute the cornerstones of informal network construction. Informal network members promote social care by reaching out to make connections with one another, exchanging information and resources, and when needed, helping one another secure support from community programs and support services—all examples of social capital (Bowen et al., 2000).

Bowen and Martin (1998) describe these informal networks metaphorically as power substations of social care in the community, which have turbines in the form of trust, commitments and obligations, information exchanges, positive regard and mutual respect, and norms of shared responsibility and social control. As compared to formal networks, informal networks play a more active and often a more important role in the day-to-day life of members and families. They typically operate as the first level of social care when members and families need support and assistance.

From the perspective of intervention and prevention planning, an important function of formal networks is to strengthen informal community connections. Formal networks may grow at the expense of informal networks (McKnight, 1997). For example, community agencies may plan and sponsor events for community members that members are capable of planning and sponsoring for themselves. When unit leaders and installation agencies perform functions the

informal community is capable of providing for itself (i.e., overfunctioning), informal community networks may be diminished. When the system of formal and informal networks is fully operative and complementary in an installation, a protective and resilient web of support surrounds and sustains members and families (Bowen, Orthner, Martin, & Mancini, 2001).

Unit leaders play a particularly important role in the community network—they stand between informal networks on one side and installation agencies on the other. In many respects, the unit is synonymous with community in the AF, and the identity of members and families typically derives more from their unit association than from their installation or local civilian community residency (Bowen & McClure, 1999).

Community Capacity

From the perspective of the model highlighted here, community capacity is the concept that links the operation of formal and informal networks of social care to produce community results. It involves two components assumed to mutually reinforce each other over time. First, community capacity reflects the extent to which installation agencies, unit leaders, and community members demonstrate a sense of *shared responsibility* for the general welfare of the community and its members (Bowen et al., 2000). When network members share responsibility for the general welfare, they invest time and energy in making the community a better place to live, work, and play, and they work together to promote the common good.

In addition to feelings of shared responsibility, installation agencies, unit leaders, and community members demonstrate *collective competence* in taking advantage of opportunities for addressing community needs and confronting situations threatening the safety and well-being of community members (Bowen et al., 2000). They pull together in the context of opportunity or adversity to identify community needs and assets, define common goals and objectives, set priorities, develop strategies for collective action, implement actions consistent with agreed-upon strategies, and monitor results.

As defined, community capacity represents behaviors and action, rather than the potential for action. When community capacity is high, members and families have access to resources and opportunities to complete duty requirements and mission requirements; develop community

identity and pride; meet individual and family needs and goals; participate meaningfully in community life; solve problems and manage conflicts; and affirm and maintain stability and order in personal, family, and work relationships.

Networks and Community Capacity

Community capacity springs from the actions and interactions *within* and *between* installation agencies, installation and unit leaders, and community members—a social energy that flows from the union between formal and informal community networks. As such, community capacity is distinct from the processes from which it emerges, and the fund of capacity is more than the sum total of actions in formal and informal networks. The *bonding* (within) and *bridging* (between) activities by these formal and informal networks of social care provide the cornerstones for achieving community results associated with member and family resiliency.

Bonding, which Putnam (2000) describes as “sociological superglue” (p. 23), captures the cohesion, trust, and positive regard within groups, such as within informal networks of social care. Putnam describes *bridging* as the “sociological WD-40” (p. 23), or the strength of ties among individuals across groups, such as the working relationships between unit leaders and representatives of community agencies. The ongoing processes of bonding and bridging among and between members from various segments of the community form a complex union that powers community capacity and provides a means to achieve community results.

Community Capacity and Community Results

Community capacity may have upper and lower threshold effects in its relationship to community results. Above a certain level of community capacity, further increases in capacity may not be associated with the further promotion of community results. On the other hand, once community capacity declines below a certain level, community results may decrease precipitously. This is consistent with Crane’s (1991) epidemic model of community effects, in which problems spread like a contagion once a certain level of community vulnerability is reached.

The influence of community capacity may vary over the work and family life course (Bowen,

Richman, & Bowen, 2000). AF members and families may need community capacity to be high in times of peak operational demands, such as during a deployment. The nature and impact of community capacity must be considered in the context of individual time (where individuals are in their own stage of development, including the military/work career), family time (where individuals are in the family life cycle), and historical time (the current context, including the economy and current military conflicts) (Bowen & Martin, 2011). These three aspects of time can intersect and merge in interesting and challenging ways as members and families move through the life course.

EVIDENCE BASE

Although the research literature supports unit leaders as the key leverage points in promoting member and family resiliency (Bowen, 1998; Pittman, Kerpelman, & McFadyen, 2004), the community capacity model includes two additional strategy platforms for launching community building efforts: interagency collaboration and informal network development. At present, the model promotes influencing these community-building components largely through unit-based efforts, including the use of community agencies as partners in planning and implementation of service action plans, as well as supporting unit commanders in their efforts to mobilize members and families in support of one another.

Although the practice strategy awaits formal evaluation, a body of basic research supports this application of the community capacity model. In an investigation with a probability sample of 20,569 married AF members, unit leader support exerted a positive and significant indirect effect on family adaptation through its direct effect on sense of community and informal community support (Bowen, Mancini, Martin, Ware, & Nelson, 2003). In a more recent investigation with 10,102 married active-duty AF members, positive perceptions of community capacity had a strong and direct effect on self-reported symptoms of depression; these perceptions were also a significant mediator of the effects of formal and informal support networks on depression, including agency support, unit leader support, and neighbor support (Bowen, Martin, Mancini, & Swick, in press).

In addition to this program of basic research, research in other areas has provided support for AF interventions that incorporate community-based components. For instance, the AF's suicide

prevention program, which incorporates interagency planning and coordination, commander awareness education and training, and peer monitoring, has been associated with a reduced rate of suicide and reductions in other adverse outcomes in an evaluation using a quasiexperimental design (Knox, Litts, Talcott, Feig, & Caine, 2003). Additional research is needed to test linkages between concepts in the community capacity model, as well as evaluate community initiatives consistent with its central linkages, to provide an evidence base for this community practice strategy in the AF.

NEXT STEPS IN IMPLEMENTATION

Through its partnership with the United States Department of Agriculture, the Office of the Secretary of Defense for Military Community and Family Policy is sponsoring the development of an online training and curriculum that aligns with the community capacity model. The University of Georgia (Dr. Jay A. Mancini, PI) and The University of North Carolina at Chapel Hill (Dr. Gary L. Bowen, PI) are developing this online training system, which is focused on instructing family service providers in both military and civilian communities in ways to build more collaborative and integrative systems of social care, including mobilization of informal networks (e.g., extended family, friends, neighbors, work associates, and so forth) in support of service members and families. Training modules include information on forming a community planning team; assessing a community and its needs; using results-focused planning to develop community action plans; working with formal and informal networks; monitoring progress; and, making efforts more sustainable. This training effort is intended to promote the ability of military and civilian leaders and human service providers to generate community capacity to support military families within their community.

120 Neoliberalism, Globalization, and Social Welfare

Michael J. Holosko

PREFACE

In the very stressful and demanding day-to-day work of social work practice, which takes place in a variety of health and human service organizations (HSOs), social workers sometimes lose sight of the broader context of the environments in which they ply their important craft. Indeed, the pervasive mission driven needs of our vulnerable clients provide the “raison d’être” [or reason for being] for our altruistic work. But such practice does not occur in a vacuum, devoid of external influences that shape what we do, how we do it, and why we do it. The two main overarching trends that directly impact these important questions or concerns are neoliberalism and globalization.

NEOLIBERALISM AND GLOBALIZATION DEFINED

Prior to defining neo-liberalism, it is important to first note that the term liberalism is a *political* doctrine, and neoliberalism is an *economic* doctrine. Further, these very different concepts are often blurred because they both possess the word “liberal” within them. Another point of conceptual fuzziness here, is when liberalism gets applied to the field of economics, it refers to policies meant to encourage entrepreneurship by removing government controls and interference, which moves the term toward more of a right wing conservative position than its truer liberal left-of-center political meaning.

Returning to liberalism’s definitional roots as a political idea, this rather revolutionary

notion became noted in 1776, when the Scottish economist Adam Smith published his landmark text *The Wealth of Nations*. Here, he proposed: (a) minimum government regulations; (b) fewer interventions from government, in order to encourage entrepreneurship; (c) no tariffs; (d) no barriers or controls; and (e) free trade as the best ways for countries to develop and grow economically (Olivia, 2011).

This concept of liberalism clearly embodies a political philosophy favoring individual freedom and liberty, equality, and capitalism (Hartz, 1955 as cited in Nilep, 2012), which has a long history and deep effect in America. For instance, the assertion in the United States Declaration of Independence that all men (sic) are created equal, and endowed with life and liberty by their creator, echoes the earlier work by John Locke’s (1690) suggestion, that no person in a state of nature “ought to harm another in his life, health, liberty, or possessions; for men being all the workmanship of one omnipotent, an infinitely wise maker” (Locke, 2005, p. 4 as cited in Nilep, 2012).

Turning to the concept of neoliberalism, neo means “new,” so this “new liberalism” was an economic shift from the previously described political concept above. The “founding fathers” primarily identified with neoliberalism were F. A. Hayek, an Austrian Nobel Laureate economist, and the American economist Milton Friedman, also a Nobel Laureate, who for much of his career was the economic advisor to President Ronald Reagan. Friedman’s monetary theories significantly influenced the U.S. Federal Reserve’s response to the global financial crises of 2007–2008. Both Hayek and Friedman were opponents of John Maynard Keynes, whose

theories [from their perspectives] were unable to economically explain the true realities of free market economies effectively. In simpler terms, neoliberalism contends that it is about the freer movement of goods, resources, and enterprises in an effort to find cheaper labor and resources, and therefore, ultimately maximize profits and efficiencies.

The key assumptions or guiding principles of neoliberalism as described by Robbins (1999) are: (i) sustained economic growth promotes human progress, (ii) free markets without government “interference” would be the most efficient and socially optimal allocation of resources, (iii) economic globalization would be beneficial for everyone, (iv) privatization removes the inefficiencies of the public sector, and (v) governments should function to provide the infrastructure to advance the rule of law, with respect to its property rights and contracts (p. 100). Martinez and Garcia (1997) from the *Corporate Watch* listed neoliberalism’s main elements as:

1. *The rule of the market*—Implies freedom for capital, goods, and services, where the market is “self-regulating.” It also includes the deunionizing of labor forces, removal of financial regulations, and more freedom from state or government.
2. *Cutting public expenditures for social services*—Means reducing the so-called social safety net for the poor, including health, human services, and education.
3. *Deregulation*—Involves the reduction of government regulation of anything that could diminish profits, including the protection of the environment and safety on the job.
4. *Privatization*—Includes selling state-owned enterprises, goods, and services to private investors including banks, key industries, railroads, toll highways, electricity, schools, and hospitals.
5. *Eliminating the concept of “public good” or “community”*—In short, these should be replaced with “individual responsibility,” at any cost.

Ronald Reagan and Margaret Thatcher were the leading conservative political forces who pushed the 35-year policies of neoliberalism strongly, both in their own countries and around the globe. As the concept relates to our post welfare states of its current citizen regimes,

neoliberalism can also be used as a term to describe social welfare, welfare policy, ideology, or governmentality (Holosko & Barner, 2013; SUNY Levin Institute, 2013).

GLOBALIZATION

Globalization has existed ever since people from one country traded or sold goods with people from another country. Marco Polo and the famed Silk Road, which linked China to Europe, and drew in India, Southeast Asia, and Africa, eventually reaching Rome, caused international global trade to blossom almost overnight. For centuries, businessmen, merchants, and bankers have invested in enterprises abroad that spurred international relations, economic exchanges, cross border trade, and migration—so rapidly and on such a scale that many observers perceive that the world has entered a new phase of global economic development with “no end in sight.” Rather contradictorily, international globalization now shapes domestic international policy in many developed and undeveloped nations of the world.

A consensual definition of globalization is offered here. *Globalization* is a process of interaction and integration among the people, companies, and governments of various nations, a process driven by international trade and investment, and aided by information technology. This process has profound effects on the environment, culture, economic development, prosperity, and on human physical well-being in societies around the world (SUNY Levin Institute, 2013). Although neoliberalism and globalization were presented separately above, given their similar economic growth and trade imperative, in the past 15–20 years these concepts have been inextricably interwoven (Holosko & Barner, 2013). In short, globalization is the reigning socio-historical reconfiguration of social space, and neoliberalism is the policy approach to it. The term now used to promote their interrelationship is neoliberal globalization.

When examining the extant literature about the so-called pluses or minuses of neoliberal globalization over time, as these policies have evolved—the minuses far outweigh the pluses of this movement. This is particularly true in the area of social welfare policy, as in the past 25 years we have seen more poverty worldwide than ever before, greater discrepancies between economic and social groups, more income

inequality between the rich and the poor, less human security and human rights, less social justice, poorer environmental health, poorer safety, and inadequate employment policies (SUNY Levin Institute, 2013).

However, during this same time, there have been some noteworthy gains made in commerce, trade, finance, investment, technology, international law, military alliances, transportation, banking, and energy (Holosko & Barner, 2013). A closer look, however, at *who* has made these gains clearly reveals that it is almost always the wealthier and dominant countries and corporations of the world, from which observers have now coined the phrase, “economic colonialism.” Unfortunately, such economic concerns, although important, are not the “life blood” of social work practice, and/or social welfare policies.

NEOLIBERAL GLOBALIZATION IMPACTING DAY-TO-DAY SOCIAL WORK PRACTICE

Often times, many entry level, and/or newly minted Bachelor of Social Work (BSW) or Master of Social Work (MSW) practitioners are rather naïve about how external trends in the world, far removed from their agency walls, such as neoliberal globalization, affect their day-to-day practice. Holosko and Barner (2013) used a hierarchal client, organizational, national, and international matrix to examine how neoliberal globalization adversely impacted these various levels of social work policy and practice. In short, they concluded that social work has not fared well at all under the umbrella of neoliberal globalization. Using another framework, this chapter focuses more on how various trends perpetuated by neoliberal globalization “trickle down” to practitioners who engage in daily in face-to-face interactions with their clients.

As indicated above, vulnerable individuals living on the margins of society, who represent the majority of persons on the caseloads of social workers, have been deeply impacted by neoliberal globalization. This is due to a few reasons. First, in almost every industrialized country in the world, there is less annual spending per capita on social welfare than during the preceding year (Holosko & Barner, 2013). Second, two additional fundamental paradigm shifts have directly descended from neoliberal globalization, both of which social workers have had to

reconcile in their daily practice. One is that their “client-centered” social work practice has now been supplanted by “problem-centered” practice. Here, the emphasis has now clearly shifted from “an individual with problems,” to “the identified problems of persons,” who are eligible to receive services. Social work’s long standing and overarching person-in-environment practice framework is being nudged aside in this shift to a “problem-solution” client focus, one more akin to the so-called medical model. This explains, in part, how case management has become so prominent in the past decade in many countries (Case Management Society of America [CMSA], 2010; CMSA 2103; Conrad N. Hilton, 2011; Work and Income, 2013).

Related to this, has been the transformation of the term “client” to “customer,” or “consumer.” This transformation literally extracts the sacred term “client” from the bowels of our professional code of ethics (NASW, 2009). Thus, it moves our once clear and solid practice footing of serving client needs, to now procuring, and/or providing customers with the things they need, require, demand, and/or are eligible to receive. This truly shakes our practice foundation a bit, as now our once core social work practice values, such as individuation, self-determinism, empowerment, autonomy, strengths perspective, and diversity are reframed differentially when applied to different customers—all of whom may have different needs, different resources to access services, and/or different methods for paying for different services as they so desire. As such, once social work “clients” become “customers,” they are not securely buttressed by the profession’s code of ethics.

NEOLIBERALISM TRENDS SHAPING SOCIAL WORK PRACTICE

Table 120.1 further distills these neoliberal globalization paradigm shifts at the local levels of social work practice and not only presents them as selected trends, but candidly offers the “stories behind the trends.”

Community Devolution: Federal → State → Local

Holosko (2009) documented the omnipresent globalization of the devolution-revolution phenomena in Canada, United States, Great Britain,

TABLE 120.1 Five Selected Neoliberal Globalization Trends Influencing Social Work Practice

Selected Trends	The “Stories Behind the Trends”
1. Community devolution: Federal → state → local	1. More local accountability 2. “Crazy Glue Syndrome”- YTI-YOI
2. Community “problem reconfiguration”	1. Communities lag behind the concept 2. Matching mandates to problems
3. Community “capacity-building”	1. No definition of capacity 2. No resource to build
4. Integrative approaches to service delivery	1. Define partners and stakeholders 2. Develop more collaborations
5. “Era of legitimacy”	1. Evaluation of program and services 2. Interventions → outcomes

and Sweden. He demonstrated how: (a) the devolution-revolution is relatively immune to the political ideology of the country; (b) it always shifts both funding and authority for social welfare service provision downward from federal → state → local levels; and, (c) often times, local infrastructures or their resource allocating systems are inadequately prepared to assume such responsibilities, which are now plunked squarely at the feet of the local community agencies (Holosko, 2009). In turn, the resultant effects of more locally administered but under-resourced care significantly impacts our definitions of what “community care” really means.

The story behind this trend includes, first, that more local accountability is accrued to the community’s actual system of care—which if reframed from a strengths-based perspective may not be such a bad or negative thing. Holosko concluded: “the ‘devolution-revolution’ to local levels therefore, provides social work with a unique opportunity to build on its history and legacy of providing ethical and humane services to the vulnerable populations in the very communities in which they reside” (p. 128).

The second story (in Table 120.1, Trend 1) has to do with the so-called “Crazy Glue Syndrome” or YTI → YOI ! The latter refers to the colloquial North American phrase—“You Touch It → You Own It!” Here, as the responsibility for providing services gets passed along locally, community agencies are now “on the hook,” to provide these essential services. And, when such agencies ask for state, and/or federal help to assist with this mandate, they are frequently reminded that—“there is no money,” “we don’t fund these programs any more,” or “it is not our responsibility to do so” (Holosko, 2000). Finally, here it becomes very apparent that local leaders need to take more proactive roles in redefining their own communities of care, as well as their problems, challenges, or concerns in providing competent services to clients (Holosko & Barner, 2013). Over two decades ago, Osborne and Gaebler (1992) called on lead governmental officials to learn to reinvent how they govern, namely, by acting as facilitators for their governments to function and serve the communities in ways that strengthen their local economies. They stated:

... city government will have to make some adjustments and in some ways re-define its traditional role... The city will more often find itself in the role of defining problems and then assembling resources for others to use in addressing those problems... City government will have to become even more willing to inter-weave scarce public and private resources in order to achieve our community’s goals. (p. 27)

The extent to which local governments have evolved in re-shaping and offering leadership in their respective communities is not well known or documented.

Community “Problem” Reconfiguration

There has been a decided shift in the quiet devolution-revolution to developing social welfare programs, interventions and services in communities, not from a population or demographic imperative—but from a “problem reconfiguration” one. Here, the community’s problems are prioritized, based on the so-called “problems of individuals in the community.” So, depending on “the problems the community has,” and the existing infrastructures—if one is fortunate enough to end up with a problem that this community “has identified”—care can be accessed.

Conversely, if one's problems do not match up with "the community problems", clients must travel [if they can], to what is usually an adjacent community to receive care (Feit & Holosko, 2013). For example, in Canada's universal health care system, smaller towns and cities cannot afford highly specialized health care for all citizens. As a result, many Canadians are accustomed to driving to, or being airlifted to, adjacent communities that have the specialized care they require and have come to expect (Holosko, 1997).

The stories behind this reality are noted in Table 120.1, Trend 2. Communities clearly lag behind this concept, and they have difficulties matching their infrastructures and mandates to the ever-changing "problems of the community." To exemplify the stories behind this trend, Brown and Stevens (2006) studied seven U.S. communities that aimed to expand health coverage to the uninsured and improve their care [the main current political agenda of President Obama]. Funded by the Robert Wood Johnson Foundation's *Communities in Charge* (CIC) program, when these communities [with identified community problems] were evaluated they concluded that: "despite solid leadership and carefully crafted plans, political, economic, and organizational obstacles precluded much expansion of coverage and constrained reforms ... CIC's record offers little evidence that communities are better equipped than are other sectors of U.S. society to solve the problems of un-insurance" (Brown & Stevens, 2006, p. W150).

Many social workers become acutely aware of the limited resources available for clients in their own communities. This forces them, by default, to expand on their definition of just what "local community care" is—to a more expansive one involving a greater geographic area beyond the local community. This, in turn, presents a new set of resource challenges for social workers, such as: networking with these new service providers; new wait list protocols; service availability; access to services; cost; formal and informal supports for clients in these new geographic areas; referrals; and transportation for services.

Community Capacity-building

Although it is a rather noble idea, the concept of community capacity-building has seen renewed interest in the health and human service field. Similarly, some researchers asserted that that "community has gained increasing prominence

as the central locus for" the search for collaborative approaches to policy development, service delivery, and research (Masuda, Creighton, Nixon, & Frankish, 2010, p. 280).

Community capacity-building refers to the ability and will of the people residing in a community to participate in actions based on community interests, both as individuals, and group organizations and networks (Williams, 2004, p. 730). The definition itself is not problematic, but its underpinning is fraught with two rather questionable assumptions. The first is that *community based groups are synonymous with capacity-building*. Indeed, this is the dominant and traditional way that capacity-building is described in the literature (Abdul et al., 2012; Suwanbamrung, 2010). However, Williams (2004) demonstrated how informal one-to-one groups and engagement are a more popular form of community involvement. They are also more characteristic of the participatory culture of less affluent populations—such as the vulnerable clients whom we routinely see on our social work caseloads. Similarly, Shirlow and Murtagh (2004) concluded their analyses of communities in Ireland, stating that if capacity-building is ever to take hold, it will have to change the assumption of affiliation of community members with community groups and reach deeper, into the concerns of local citizenry, rather than the priorities of statutory funders, as a basis for meaningful service provision and local planning.

The second rather spurious assumption about this trend is that *residing in a community implies a sense of community belonging*. Studies have shown that if one has a "sense of community," one has a greater likelihood of viewing the community positively, and will be more likely to participate in community capacity development, through bonds of unity and support and satisfaction (Bowen, Mancini, Martin, Ware, & Nelson, 2003; Bowen, Martin, Mancini, & Nelson, 2000; McMillan & Chavis, 1986). More to the truth, to many individuals, residing in any community means nothing more than a place to close their door to the external world, or a place to sleep at night. To infer that residence itself brings a greater sense of inclusive belonging, or a willingness to feel connected to one's community, or to feel attachment and some sort of well-being, is remiss from a social and/or psychological perspective (Brown, Altman, & Werner, 2012; Buchecker, 2009). It is no wonder then, that capacity-building indicators are

delimited by the variables of: person and family, neighborhood, one's health status, one's values, the community, demographics, income, county, state, resources, the economy of the community, its civic leadership, and by the will of individuals not to feel connected at all to their respective communities (Robert Wood Johnson Foundation, 2007, www.rwf.org/reports/grr/044682.htm). Such assumptions need to be more seriously addressed by community planners, if the issue of capacity-building is ever to take hold in North America in any meaningful way.

If there is really no consensus definition of capacity, so how do we envision building one? The lack of clarity around this definition and its potential negative impact for capacity-building was tabled by Levitas (2000) who stated:

my first worry about 'capacity-building' as about 'community development', is that it often seems to be a way of expecting groups of people who are poorly resourced to pull themselves up by their collective boot straps. So-called social capital is expected to take the place of economic capital. (p. 196)

This is just one of many deleterious effects of not being able to clearly define capacity-building.

From a social work perspective and using a strengths-based orientation, it appears that one's individual capacity is limitless. However, if community capacity-building is to be effective, it must have clear benchmarks delineated for success. Further, specific interventions should be marketed and targeted for specific groups, and communities should be allowed to define their community within the nature of the intervention/initiative being implemented in their respective community (Feit & Holosko, 2013; Holosko & Feit, 2006). In addition, both an understanding of the community environment itself linked with *source appropriate* information, meaning obtaining the right information from the right people, is paramount, if capacity-building is to ever have any success (www.rwf.org/reports/grr/044682.htm).

Finally here, the issue of "resources to build" a community's capacity is almost never considered, but in studies of actual capacity-building efforts, this issue is not trite (Blank, Jacobson, Melaville, 2012; Bowen et al., 2003; Shirlow & Murtagh, 2004). Capacity-building is a transformative process, and one that is time consuming and vulnerable to the local economy and political reality of any community. Given that capacity building

is also linked directly to community resources, social workers more so than other professionals, quickly come to understand the actual reality of their community's resource capacities to provide interventions to their clients.

Integrative Approaches to Service Delivery

Due to the previously noted trends of devolution and fiscal cutbacks for North American HSOs, services and providers have become collaboratively bundled together with multiple agencies offering a defined system of care in their respective communities (Cook, Michener, Lyn, Lobach, & Johnson, 2010). These are often referred to as cross-sectional collaborations—networks, alliances, or partnerships among public, secular, and faith-based nonprofits, and for-profit organizations. They may be so-called self-organizing networks, consisting of distinct organizations that develop relationships among one another in order to meet client needs. Or, they may be community organizations subcontracted with a lead organization, which is expected to create a mandated community-based network of service providers (Alexander, 1995; Provan & Milward, 2001; Whelan, 2011). The latter (the lead organization model) is the more preferred approach between the two because, to be frank, it is cheaper. Ideally, however, both arrangements are expected to yield the benefits of increased efficiency, innovation, local adaptation, increased flexibility, and enhanced community ties (Graddy & Chen, 2006, p. 534).

This idea is certainly tenable and required for an HSO's survival in today's reality, but again (as with Trend 3 above), the concept is ahead of the community's ability to implement it. The previously noted proverbial "clouds of uncertainty" about integrative service approaches loom large over issues of cost; organizational, programmatic, and community influence; democratic and consensual accountability; efficiency and effectiveness; integrative models that are viable and ones that are not; organizational and community care constraints and contingencies; community capacities; access; outcomes; policy considerations; and network size and scope (Bryson, Crosby, & Stone, 2006; Dunlop & Holosko, 2004; Graddy & Chen, 2006; Knitzer & Cooper, 2006). Despite such uncertainty, HSOs continue to move forward with this seemingly altruistic community-spirited ideal.

The neoliberal deficit reduction strategies of federal, state, and local governments has led to a resurgence of interest in community collaboration (Foreman Kready, 2011). Increasingly, mandates for collaboration are linked to conditions of funding. As governments mandate collaborative networks as an implementation mechanism for integrating social welfare services, empirical studies about how interorganizational collaboration is implemented among community partners is an emerging research, policy, and practice problem (Babiak, 2009; Bryson, Crosby, & Stone, 2006; Dunlop & Holosko, 2004; Sytch, Tatarynowicz, & Gulati, (n.d.)).

Frontline social workers, their supervisors, and HSO administrators need to be mindful of some important issues or the real “stories behind the story of collaboration” (Holosko, 2009). Here are just a few:

1. *Funding Issues Require Collaboration*—Regardless of the “will” to collaborate, such partnerships will be tied to funding. Those HSOs who do so will thrive and those who do not will wither away. Developing relationships with partners in the community, however strained, is integral to organizational survival.
2. *Voluntary versus Mandatory Collaboration*—Although some joint agreements are voluntary and others mandatory, the nature of the collaborative relationship transcends this distinction (Dunlop & Holosko, 2004). This means that agencies collaborate to ensure funding and typically will do anything they can to make the collaborative relationship work (Holosko & Dunlop, 1992).
3. *All Communities are Not Created Equal*—Communities vary in their demographics, organizational relationships, service networks, preexisting partnerships, resources, and infrastructures. Collaborations magnify such inequalities. Thus, some communities are able to develop more effective collaboration networks than others.
4. *Evaluation Complexities*—Evaluating collaborative initiatives has been challenging to say the least (Holosko & Dunlop, 1992). These initiatives are typically multisite and multilevel, with different programs/goals/objectives/costs/outcomes/services/stakeholders, etc., (Buckingham & Coffman, 1999; Dunlop & Holosko, 2004). The

assumption put forward in this global devolution-revolution movement is that complex community-based collaborations are more efficient than singular service delivery models. This has never been empirically determined or validated (Kee, 1999).

5. *Collaborations are More Likely to Succeed When They Have Legitimacy*—Human & Provan (2000) cited three necessary conditions for collaborative networks: (1) legitimacy of the *network as a form* that can attract internal and external supports, (2) legitimacy of the *network as an entity* responsible to both insiders and outsiders, and (3) legitimacy of the *network as an interaction* that builds trust among members to freely communicate with one another (Feit & Holosko, 2013, p. 26).

Era of Legitimacy

Never before in our North American social welfare history has evaluation and its focus on outcomes been “part and parcel” of the mandated delivery of HSO programs and services. Indeed, we are no longer on the frontier of program and practice evaluation activity, but are in the midst of a groundswell of such activities becoming mainstream in federal and state social welfare initiatives, programs, and services (Holosko, 2009). Thus, public scrutiny of the financing and efficiency of HSOs is more apparent than it ever was before. We have evolved from offering social welfare programs directed by the rather noble motives of altruism and case wisdom, or “a need for such services”—to much more legitimizing ways of providing educational, health, and social services. These include the empirical testing of interventions; developing more empirically defined protocols for our interventions; developing pilot projects to justify larger initiatives; ensuring interventions are tied to frameworks (i.e., logic models) and outcomes; developing organizational and community capacities to ensure success of interventions; funding initiatives with the assurance of self-sustainability over a shorter time period; ensuring that funded social welfare initiatives include timely best, and/or promising practices; and ensuring that funded programs/services are both effective and efficient.

Generally, program, practice, and intervention evaluations serve as both the validation and legitimacy for many social welfare programs, and

it is almost unconscionable in today's climate to allocate funds to such programs without building in money for evaluation costs. Outside of the aegis of government, numerous private and charitable foundations have stepped "up to the plate" here, and pushed the national agenda for evaluations of federal and state welfare programs forward. They have also had much success in advancing our evaluative knowledge in the areas of methodology; theoretical applications; using models to evaluate performance contracting; providing more timely programs and service; and linking interventions to outcomes, pilot tests, and evidence-based practices.

Finally here, all interventions require not just a traditional focus on inputs and outputs, but also (now) on outcomes and sustainable impacts (W. K. Kellogg Foundation website reference for program logic model: <http://www.wkkf.org/knowledge-center/resources/2006/02/wk-kellogg-foundation-logic-model-development-guide.aspx>). And these must be assessed empirically with a view to what it costs to provide such interventions. Clements, Chianca, and Sasaki (2008) said it succinctly when they stated: "... evaluations should estimate the total impacts that can be attributed to an intervention and also estimate the intervention's cost effectiveness... Also, evaluations of this nature are likely to be more helpful for program managers" (p. 196). Given that the current social work model is now driven by costs, it appears that soon the cost benefit or cost effectiveness of all social work interventions will need to be tabled as a bona fide agenda for all HSOs.

CONCLUDING REMARKS

With "Obama Care" on the horizon in the American political landscape, requiring a re-thinking and retooling about how social welfare, health care, and social services will be provided, financed, and configured for all Americans, the issues presented herein about external trends emanating from neoliberal globalization become important for all service providers in general, and social workers in particular. This chapter sought to illuminate such trends as they are now squarely placed at the feet of frontline practitioners working in and out of communities of care. The very real challenges of providing effective and efficient care for our clients will require the profession to

think more deeply about not only how to provide such care, but how to educate our BSW and MSW students appropriately to do so.

121 Community-led Structural Interventions as Community Practice

A Review of Initiatives in Haiti and India

Toorjo Ghose

INTRODUCTION

Structural factors such as societal stigma, lack of shelter, inadequate access to care and draconian laws undermine the physical and mental health of marginalized communities. The Centers for Disease Control and the World Health Organization have called for interventions to focus on these structural factors influencing health behaviors (Centers for Disease Control and Prevention [CDC], 2010). Scholars have recognized the benefits of community engagement in addressing these structural challenges, noting that such participation helps to identify problems accurately, sustain interventions, and use resources efficiently (Blankenship, Bray, &

Merson, 2000; Meheux, Dominey-Howes, & Lloyd, 2010). Blankenship and colleagues (2010) define community-based initiatives that target community-specific contextual factors as community-led structural interventions (CLSI) that seek to influence health conditions by improving the awareness and acceptability of interventions, and increasing community access to them. This chapter draws on two CLSIs, one in a postearthquake encampment community in Haiti, and another in a sex work community in India, to describe a protocol for community practice. Research on these two CLSIs have identified three main stages that describe the community practice protocol in both contexts: (1) establishing coalitions and goals, (2) identifying needs and

developing resources, and (3) sustaining efforts through the expansion of resources and the engagement of civil society institutions.

STAGE 1: DEVELOPING COALITIONS AND GOALS

Establishing Partners and Aligning Agendas: Scholars have highlighted the difficulty of gaining access to a community and establishing trust (Israel, Schulz, Parker, & Becker, 1998). Developing links with organizations operating in the community is one way to negotiate these challenges. In Haiti, the CLSI sought to establish HIV services in encampments that sprung up after the devastating earthquake of 2010 (Ghose, Boucicaut, King, & Shubert, 2013a; Ghose, Boucicaut, King, Doyle, & Shubert, 2013b). The initiative was implemented by a coalition comprised of community advocates living in the encampments, a Haitian network of 14 community-based HIV service providers, a U.S. community-based agency that is a major HIV service provider in the United States, and a research team from a U.S. university. The coalition was formed before the earthquake, on the basis of shared agendas and advocacy platforms. The Haitian service providers came together as a network in response to the manner in which larger institutional service providers failed to address the needs of marginalized groups and yet received most of the foreign and governmental aid flowing into the country. This critique of institutional gaps in services resonated with the U.S. agency, a vocal advocate for marginalized People Living With HIV/AIDS (PLWHA) in that country. The agency, which employed a number of Haitian counselors in New York, sought relationships with HIV service provision agencies in Haiti even before the earthquake. It forged ties with the Haitian service providers' network, with the latter inviting the U.S. agency to partner in a technical advisory role to build service capacity in Haiti. Immediately after the earthquake, the U.S. agency was one of the first to enter Haiti to provide aid, and linked up with the Haitian network of HIV providers to address the HIV needs of newly displaced encampment residents.

In India, the CLSI known as the Sonagachi HIV Intervention Project (SHIP) was initiated when Dr. Smarajit Jana of the governmental agency, the All India Institute of Physical Hygiene (AIIPH), collaborated with sex worker networks in the

community to recruit and train sex workers to go door-to-door discussing sexual health with brothel residents (Basu et al., 2004; Cornish, & Ghosh, 2007; Ghose, Swendeman, George, & Chowdhury, 2008). Building on its initial success in recruiting peers and reducing risk behaviors (Basu et al., 2004; Swendeman, Basu, Das, Jana, & Rotheram-Borus, 2009) the program grew and became a collective of sex workers known as Durbar Mahila Samanwaya Committee (DMSC). As in the case in Haiti, the CLSI was launched when various stakeholders succeeded in aligning with one another's agendas. Rather than taking on the traditional role of an expert interventionist, Dr. Jana chose to collaborate with sex workers in educating the community. Most importantly, the CLSI resisted the move to rescue women from engaging in sex work, a routine intervention strategy for the sex work community at the time. Instead, the push to make working conditions safe for sex workers was a platform that sex workers and government educators could all sign on to, given that it reduced the HIV risk environment for sex workers, without preventing them from plying their trade. Thus the Haitian and Indian CLSIs indicate that the initial community partnerships were established by (1) activating established links between agencies and partners and (2) stake holders aligning their agendas and approaches.

It is important to note that the resultant coalitions looked markedly different from traditional nongovernmental organizations (NGOs) or agencies operating in the community. Scholars have noted that these traditional service NGOs in Haiti and India are usually operated by people outside the community who are educated and well-off, resulting in class divides between NGO workers and their clients, and creating institutional barriers against local participation (Chatterjee, 2008; James, 2010; Louis-Juste, 2007; Schuller, 2007). The coalitions in Haiti and India are populated predominantly by community members and resist the manner in which traditional NGOs operate in the community. In Haiti, the coalition came together precisely because aid was being funneled to traditional institutional NGOs and service providers that tended to ignore marginalized communities in encampments. In India, the coalition departed from the traditional strategy employed by most NGOs, namely, rescuing sex workers from their lot. Taken together, the elements of this first stage of CLSIs indicate that community practice needs to

be initiated through coalitions that include community members and prioritize strategies that emerge from the community.

Developing Goals and Objectives: While the linking of agendas ensured that all the partners in the collaborations had a similar orientation, both initiatives engaged in a process of developing goals and objectives in order to make outcomes and pathways to them more concrete.

In Haiti, because the coalition was concerned with the dearth of HIV services in the encampment community, developing service capacity was the goal of the initiative. Linked to that goal was the need to base services and advocacy on empirical evidence. The three partners identified four objectives for the initiative: conduct collaborative research on the needs of PLWHA in the encampments, develop the local capacity to gather that evidence, develop services based on the research results, and develop ways to sustain efforts to expand HIV service capacity in the encampments.

In India, faced with an increasingly violent and repressive environment to conduct sex work, the collaborators decided to identify the factors contributing to the risk environment in the community, to establish governance structures that could implement changes in the community, and to engage resources outside the sex work community in order to sustain the implemented interventions. The goals and objectives identified in this step helped to guide the action research projects and the development of resources in the next phase.

STAGE 2: IDENTIFYING NEEDS AND DEVELOPING RESOURCES

An examination of the two CLSIs indicates that community resources were developed in Stage Two through action research and the development of capacity.

Identifying Needs and Strategies Through Action Research: Research was a critical component of both initiatives, given the lack of knowledge about the respective communities, and the need to capture the attention of policy makers and aid agencies by advocating for evidence-based practices. Guided by action research principles (Israel et al., 1998), the research linked academic scholars and the community, included community members as equal

research partners, assessed community needs, evaluated community-based intervention strategies, and developed research capacity in the community in order to sustain research efforts in the future.

In Haiti, the coalition decided to recruit community members and train them in qualitative research methods. In order to develop research capacity in the community, the workshops sought to train the team members to become trainers themselves. The community members' knowledge about the community, access to hidden populations within it such as gay, lesbian, bisexual, and transgendered people living with HIV, and familiarity with the encampment conditions helped to frame the research questions and recruit research participants. The research highlighted the need for basic nutrition, clean water, places to store HIV medication and HIV support services, especially for vulnerable groups such as women, children, and gay, lesbian, bisexual, and transgendered residents.

In India, several action research initiatives brought together academic partners with the sex work community in order to examine the structural conditions that molded the risk environment for sex workers. In one such project funded by a grant from the National Institutes of Health, a team of scholars from several universities in the United States trained sex workers in qualitative methods in order to examine the manner in which the laws pertaining to sex work were influencing risk behaviors in the community. In another, academic partners trained community members in survey research methods to assess the manner in which collectivization as sex workers influenced mental health outcomes and related risk behaviors among sex workers (Ghose, Chowdhuri, Ali, & Solomon, In Press). These action research initiatives helped to document community needs, excavate community-based strategies to address them, and develop research capacity in the community.

Developing Resources Through Community-based Organizations: Responding to the needs identified through the action research projects, both initiatives worked toward establishing community-based institutions to address them. In Haiti, the collaborative began a community clinic that addressed the HIV needs of tent residents. HIV service providers in the U.S.-based AIDS service organization, along with nursing faculty from a U.S. nursing

school, trained clinic medical staff in conducting HIV assessments, in HIV medication and its side effects, and in case management around the psychosocial needs of PLWHA and HIV-related risk behaviors. The clinic became a site where the collaboration's team members met and bolstered their ability to provide HIV services to the community. While formal training ensured the transfer of skills from one set of stake-holders to another within the team, informal conversations between team members helped to change attitudes. Ghose et al. (2013a) note that these conversations sensitized service providers who had never before worked with gay, lesbian, bisexual, and transgendered clients, to this population's needs and the barriers that they faced in accessing services.

In India, the action research results led to the formation of a self-regulatory board (SRB) in the sex work community that brought together various community stake-holders in order to address the legal environment surrounding sex work (Ghose, 2011). The initial collaboration invited sex workers, madams (female brothel managers), personnel from the police, university researchers, government officials, and members of non-governmental organizations operating in the red light area to join the board. The presence of noted politicians and scholars helped allay the fears of the police and madams, and of natural antagonists in the community. Guided by results of the action research, The SRB identified draconian laws and police practices as a significant risk factor for sex workers, leaving them vulnerable to getting arrested and forcing them underground, leading to risky sex practices. Moreover, the police personnel on the committee were able to impress on the madams the importance of ensuring that sex work did not disrupt the activities of the neighborhood.

The SRB organized workshops with the police and sex workers to highlight these risks, significantly reducing predatory policing practices in the neighborhood. Madams ensured that sex workers living in their brothels would be respectful of neighborhood residents and adhere to higher standards of safety and hygiene. The SRB has now become a community resource for sex workers who are being targeted by the police. Neighborhood police also recognize it as the body to approach if they have concerns about the sex work community, instead of implementing the raids on the community that were the norm in the past.

STAGE 3: SUSTAINING EFFORTS

At both sites, efforts by the collaborations were sustained through the expansion of resources and the negotiation of political opportunities.

Expanding Resources: Resources needed to be immediately expanded to target marginalized communities who were in dire need of services. The action research initiative highlighted the vulnerability of encampment residents like sex workers; gay, lesbian, bisexual, and transgendered people living with HIV; and children known as *Resteveks*, who were orphans staying with relatives or other adults and often working for them as indentured servants. In order to address these expanded goals, the coalition sought funding from various sources. The Elton John Foundation has funded an initiative to assess seroprevalence among men who have sex with men and implement interventions with them. Grants have been submitted to implement interventions with these communities to the National Institutes of Health and the MAC AIDS foundation. Moreover, given the challenges of procuring their medication in hospitals and large institutional HIV service providers in Haiti, the community clinic is securing a license to prescribe medication on-site.

In India, the research and the work of the SRB highlighted the manner in which the HIV-risk environment was linked to issues of economic sustenance and opportunity for sex workers' children. As a result, the sex workers' collective has developed a microbanking and microfinance initiative, and a school for sex workers' children. The collaboration has successfully utilized its varied membership to cast a wide net for grants and funding for these initiatives.

Engaging Political and Civil Society Institutions: Responding to structural and political forces shaping the risk environment at both sites, the initiatives in Haiti and India have actively targeted political and civil society institutions.

In Haiti, the collaboration targeted major conferences, policy makers, and aid personnel to secure resources for the encampments. The coalition partners attended the International AIDS Conference in Vienna in 2011, organizing panels, marches, and protests to highlight the dire situation of people living with HIV in the camps. In 2011 and 2012, the coalition attended the North American Housing and HIV/AIDS Research Summits and presented the action research assessment results to influential policy makers in the

U.S. government and the United Nations. The special representative of the Secretary General of the United Nations in Haiti expressed his agreement with the assessment findings and initiated discussions to involve the coalition in policy decisions about HIV service provision in the camps.

In India, the establishment of the SRB, which included various stake holders in the community, helped to engage various civic institutions outside the sex work community. The members of the government who attended the SRB helped to incorporate DMSC into health policy initiatives, resulting in the State's first public advertising campaign promoting condom use through peers talking about safe sex—a strategy implemented successfully in the sex work community. Given its links to both stakeholders, the SRB has also become an important mediator between the police and the sex work community. The success of the SRB was documented by the scholars in the initiative, leading to the World Health Organization hailing DMSC as a model structural-intervention (Gupta, Parkhurst, Ogden, Aggleton, & Mahal, 2008). Taking note of the growing importance of the SRB and its activities, State and national HIV agencies have invited DMSC to partner with them in HIV policy formulation and implementation (Ghose, 2011). In 2012, the Supreme Court of India appointed DMSC to a committee overseeing the rights of sex workers nationally, overruling the objections of the national government to its membership on the committee, given DMSC's support of decriminalizing sex work.

DISCUSSION

The protocol described above was facilitated by the activation of existing partnerships, the development of research and service resources in the community, and the use of feedback loops, as well as the engagement of civil society processes that allowed the initiatives to expand the scope of efforts on the ground (Figure 121.1). The elements and stages described in Figure 121.1 allow social workers a variety of opportunities to engage in community practice.

Utilizing Existing Partnerships: The activation of established relationships among scholars, community agencies, and community members was crucial to the success of both initiatives. Social workers seeking to engage the community need to draw on existing relationships with

networks and partners who are able to make useful contributions and are legitimate community advocates. Specifically, the results of this review indicate that social workers seeking to initiate engagement in the community need to (1) become members of teams of professionals whose knowledge and expertise is needed in the community, (2) work with established community-based organizations, and (3) identify goals and objectives in a collaborative manner with stakeholders.

Helping to Build Resources: Social workers are integral to the enterprise of building community resources, as described in Stage Two of the protocol. Research was a crucial component of both initiatives, given the lack of knowledge about the conditions of the community, and the necessity to inform policy makers and aid agencies about the needs of residents. Guided by action research principles (Israel et al., 1998), social workers at both sites were instrumental in engaging in research that included community members as equal research partners. Moreover, social workers helped to train community-based researchers and service providers at both sites. Social workers seeking to build community capacity in this stage of the protocol need to engage various community stakeholders in a collaborative research process and facilitate the transfer of skills through training and workshops.

Expanding the Scope of Efforts: The protocol of engagement initially addressed short-term goals. The fulfillment of these led to identifying further needs and issues, which, in turn, informed the broadening of goals and strategies. Feedback loops ensured that each stage in Figure 120.1 was not only being informed by processes and decisions in the previous stage, but also by developments in subsequent stages. For instance in Haiti, assessment results in Stage Two highlighted the plight of hidden encampment populations, triggering an expansion of Stage One goals to address the needs of these marginalized groups. This, in turn, triggered a reformulation of strategies in Stage Three, whereby efforts to sustain the initiative included targeting resources for these communities. Similarly, in India, the identification of economic vulnerability as a key contributor to the sexual risk environment of the community enabled the expansion of Stage One goals to include economic initiatives such as microfinancing. Our review indicates that a flexible protocol that incorporates

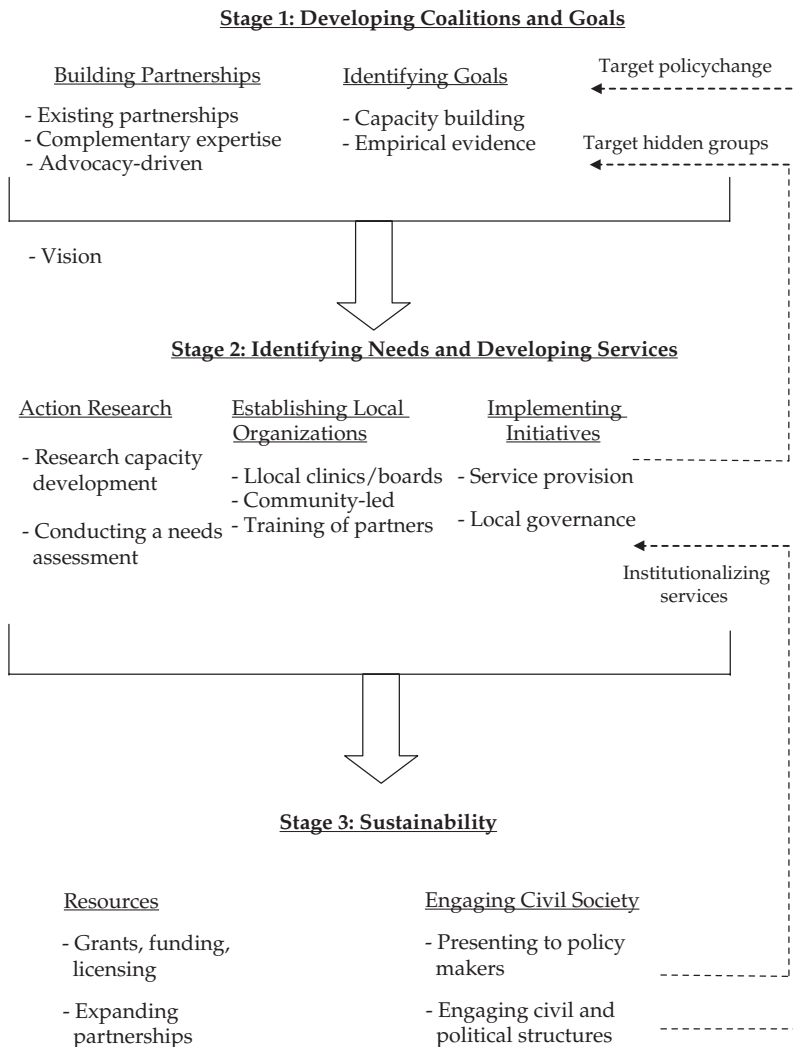

Figure 121.1 Community practice protocol (based on Ghose et al., 2013a).

these feedback loops is necessary to address the complex needs of a community incrementally. Social workers played a key role in establishing these feedback loops in both communities, constantly making sure that assessment and evaluation results informed the reformulation of goals in Stage One, and of strategies in Stage Three. They sustained this process by ensuring that the initial coalitions established in Stage One were kept updated on implementation initiatives and assessments at all times.

Finally, social workers ensured that the initiatives were sustained in Stage Three through the engagement of civil society institutions and processes. Community mobilization tactics ensured the successful staging of rallies and political

events in both communities, while presentations made in policy arenas helped to build visibility for both communities.

The protocol described in this chapter relies on the engagement of social work skills such as working with a diverse set of stakeholders in groups, collaborative goal-setting, engaging in community-based participatory research, transferring skills to community members, and negotiating in the civil and political sphere. Although the manner in which each element is executed, and the particular skills required to implement it successfully, can vary across communities, the protocol seeks to provide a useful blueprint for social workers and communities to engage in community practice.

PART XII

*Working with Vulnerable
Populations and Persons at Risk*

122 Overview of Working with Vulnerable Populations and Persons at Risk

Rowena Fong

Although all people are vulnerable, circumstances and situations make some people more vulnerable than others (Dettlaff & Fong, 2012; Fong, 2004; Fong, McRoy, & Hendricks, 2006). Persons of color, whether born in the United States or abroad, immigrants, refugees, and undocumented persons, and men and women who are gay, lesbian, bisexual, and transgendered (GLBT) experience conflicts to which others in the larger society may not be subjected. These experiences may involve racism, ageism, heterosexism, discrimination, oppression, harassment, hate crimes, rejection, homophobia, ridicule, or unjust misrepresentations.

In this section on vulnerable populations, authors Joshua Miller and Ann Marie Garran (Chapter 123) emphasize that “racism is a process that uses the differences of appearance or culture as a basis for making generalizations about intelligence and trustworthiness to justify systematic acts of subjugation and mistreatment of targeted persons.” Social workers working with these vulnerable populations need to be aware of the problems and risk factors imposed on these people and find culturally appropriate interventions and solutions that, as Miller and Garran (2008) advocate, will build a “web of resistance” to dismantle racism and other oppressive attitudes and actions.

Antioppressive practices are “an evolving and contentious variety of different practice approaches and theories oriented towards a social justice perspective” write authors Ishizuka and Husain in their chapter on antioppressive practices (Chapter 124). Social justice is a priority for

the oppressed and vulnerable populations who include many people of color for whom social workers solve problems or find resources.

The profession of social work acknowledges the vulnerability of these populations and has taken measures to enforce standards and policies to allow for culturally sensitive considerations. For example, the National Association of Social Work (NASW) *Standards for Cultural Competence in Social Work Practice* (2001) specifically mandates in Standard 3 on cross-cultural knowledge that social workers “shall have and continue to develop specialized knowledge and understanding about the history, traditions, values, family systems, and artistic expressions of major client groups they serve” (p. 1). This requires that social workers take the time to learn about the history and historical trauma, traditions and cultural values, and family systems of African Americans, Latinos and Mexican Americans, Asian and Pacific Islander Americans, and Native Americans as the chapters in this section describe.

In 2006, NASW published *Social Work Speaks: Policy Statements 2006–2009*, which enunciates a commitment to improving policies and practices related to racism; immigrants and refugees; lesbian, gay, and bisexual issues; long-term care; and end-of-life care. The policy statements apply to the vulnerable populations of GLBT persons, as well as documented and undocumented immigrant and refugee individuals and families. The populations of GLBT persons, people of color, both native and foreign-born, exemplifies NASW’s and the Council for Social Work

Education (CSWE)'s concerns for diversity issues related to race, gender, age, abilities, and sexual orientation.

People who are targeted because they are different, whether it is because of race, age, gender, sexual orientation, political persuasion, abilities, or socioeconomic class, become vulnerable, feel at risk, and often need support when they experience antioppressive practices. The NASW *Code of Ethics* (1999) mandates that all social workers "help meet the basic needs of all people who are vulnerable, oppressed, and living in poverty" (p. 1). Dignity and worth are basic needs of all people. These basic needs can be facilitated by increased culturally competent knowledge and practices, which this section on vulnerable populations will provide.

DIVERSITY AND ETHNIC POPULATIONS

Several authors in this section draw attention to the broad diversity within and between ethnic groups. Sadye Logan, in Chapter 129, makes the consequences of such intragroup variation for her subject population quite plain: "Given the diversity which exists in terms of values, education, income, lifestyles, and perceptions in the African American community, it is extremely challenging, if not impossible, to write a definitive article that captures clinical social work practice with this ethnic group." In Chapter 126 Teresa Evans-Campbell and Gordon Limb mention that in the United States "there are 566 federally recognized tribes, including 229 village groups in Alaska and close to 200 unrecognized tribes." Halaevalu Vakalahi and Rowena Fong, Chapter 127, note that Asians and Pacific Islanders include distinctly different groups from East Asia, South Asia, and Southeast Asia, as well as Pacific Islanders from Polynesia, Micronesia, and Melanesia.

Diversity within ethnic group populations applies to both American-born and foreign-born populations. Miriam Potocky, in Chapter 125, emphasizes the differences among legal statuses in the immigrant and refugee populations. Elaine Congress, in Chapter 130, reports that an estimated "one out of three immigrants are undocumented, while more than half of the immigrants who entered the country [United States] since 2000 are undocumented." Describing the Latino population in Chapter 128, Ilze Earner and Alan Dettlaff report that "Latinos are the largest

ethnic minority group in the United States and the fastest-growing segment of the U.S. population." In summary, this section on vulnerable populations highlights the diversity within the native and foreign-born populations of persons of color.

VULNERABILITY AND RISK FACTORS

Persons of color are joined by GLBT individuals as members of vulnerable populations. In Chapter 132, Mary Boes and Katherine van Wormer describe the risk factors for members of the GLBT population: "Few groups are maligned in our society, as are persons who are identified as, or are suspected of, gender nonconformity, or having a same-sex sexual orientation. The most extreme forms of discrimination, including ridicule and violence, are reserved for transgendered persons or those who have the psychological sense of being female when they are physiologically male or vice versa."

Depression and poor mental health are risk factors for older adults, GLBT clients, persons of color, and other vulnerable populations such as immigrants and refugees. Some authors describe how assessment practices can point toward these risk factors. Elaine Congress describes one tool, the Culturagram, in Chapter 130. The Afro-centered genogram referred to by Logan in Chapter 129 is another tool. Earner and Dettlaff's Chapter 128 on Latinos also recommends the stages of migration framework (Drachman, 1992) for assessment purposes. Historical and cultural experiences with colonization and immigration are important factors to consider in conducting assessments with Asian Americans and Pacific Islanders, state Vakalahi and Fong in Chapter 127.

Vulnerability and risk factors can be mediated by approaching the populations from an empowerment and strengths perspective and framework, often used in working with the ethnic minority, GLBT, and immigrant and refugee populations. In working with African Americans, Latinos, Native Americans, and Asian and Pacific Islander Americans, the chapter authors emphasize the need to use the strengths perspective approach to empower these vulnerable populations. In Chapter 127, Vakalahi and Fong discuss cultural values as strengths and the role of these values in Asian and Pacific Islander cultures. Fong and Furuto (2001) describe the importance

of culturally competent social work practice and the role of cultural values as protective factors among ethnic populations likely to uphold traditional values in their families and communities.

CULTURALLY COMPETENT EVIDENCE-BASED PRACTICE

Evidence-based practice is important in determining the effectiveness of an intervention on a problem area, and some authors mention specific therapies that work well with their vulnerable populations. In Chapter 129 Logan emphasizes the need to use an Afrocentric and strengths-based orientation, and mentions that there are “emergent and traditional practice approaches” that support such an orientation. They include solution-focused brief therapy, solution-oriented therapy, gender-sensitive therapy, cognitive-behavioral therapy, psycho-educational family therapy, task-centered treatment, structural family therapy, narrative therapy, and crisis treatment.

In Chapter 128, the use of a stages of migration framework (Drachman, 1992) is recommended when working with Latino families. Chapter 127 mentions the use of family group conferencing, an emergent evidence-based practice intervention in child protective services, used with the Pacific Islander case example. There is the tendency in working with ethnic American-born and foreign-born populations to determine which evidence-based intervention may apply to the ethnic group, and practitioners need to be cautious to not exclude indigenous interventions that work with ethnic populations and support the strengths perspective of supporting cultural values. Evans-Campbell and Limb, in Chapter 126, state:

Increasingly, the field of social work is moving toward the use of evidence-based practice interventions and strategies with diverse populations. Unfortunately, the use of evidence-based interventions with AIAN [American Indian/Alaska Native] people is complicated by the lack of intervention research that includes Native clients or examines Native-specific practice models.... When working with Native people, social workers might also consider practices that are considered promising in that there is emerging empirical evidence of their success. There are a growing number of Native-designed programs designated as promising practice models by agencies

such as Indian Health Service and SAMHSA [Substance Abuse and Mental Health Services Administration].

In conclusion, this section on vulnerable populations includes chapters on social work practice with native-born and foreign-born populations of African Americans, Latinos, Asian and Pacific Islander Americans; Native Americans; GLBT clients; and refugees and immigrants. Chapters in the section also cover the use of antioppressive practices and culturagrams with culturally diverse immigrant families, all in the context of understanding and being aware of the legacy of racism. The chapters point out the diversity among ethnic populations, the vulnerability and risk factors, and both evidence-based and culturally competent social work practices.

123 The Legacy of Racism for Social Work Practice Today and What to do About It

Ann Marie Garran & Joshua Miller

The United States has been a nation for over 235 years and is renowned for its democratic tradition. It is also a country that was founded with a “racial contract” (Mills, 1997) that has shaped its culture, laws, institutions, practices, and the relationships between various ethnic and racial groups. Racism is as much a part of the American tradition as democracy is, and it is very much a social factor today. Yet many White citizens, who are consciously against racism, view racism as something that happened in the past with little relevance today. For social workers to practice in accordance with the National Association of Social Workers (NASW) Code of Ethics (2008), we need to understand how racism shapes lives, constrains opportunity for some, and confers privileges to others based on a social construction of race. Most importantly, we need to understand how to confront the racism that exists in society and that lurks inside the psyches of practitioners. The spectrum of racism today ranges from institutional barriers and neglect of those who are the targets of racism, cultural biases, intergroup conflict, and segregation, to interpersonal transactions and internalized prejudices and stereotypes (Miller & Garran, 2008). It is manifested in communities, agencies, organizations, social policies, and the relationships and interactions that people have—or because of racism, rarely have.

Racism is based on the erroneous notion of race: that there are distinct racial groups and generalizations can be made about these groups based on alleged genetic or cultural differences or deficiencies. The American Anthropological Association (AAA) (1998) has stated that based on available scientific evidence of genetic similarities and differences between so-called racial

groups, there are no significant distinctions and there is one race, the human race. Of course, there are differences in height, skin color, facial features, and other physical characteristics, but these are not the differences that justified enslavement of African Americans, genocide of Native Americans, prohibitions against immigration for Chinese Americans, or disenfranchisement of Mexican Americans living in the Southwest, all of which are a part of this nation’s heritage. Race has limited value as a biological or genetic construct, but has been a useful underpinning for ideologies justifying the domination of one “racial” group by another. Racism is a process that uses the differences of appearance or culture as a basis for making generalizations about intelligence and trustworthiness to justify systematic acts of subjugation and mistreatment of targeted peoples. Racism shapes the notion of race rather than racial differences leading to racism. In the end, race is a social construction that determines who wields power and who has social passports of privilege at both the individual and systemic levels.

In this chapter we discuss why social workers should be concerned about racism and what racism in the United States looks like today. We also discuss institutional racism; more subtle, unconscious forms of racism, such as aversive racism (Dovidio, Gaertner, Kawakami, & Hodson, 2002) and racial microaggressions (Pierce, Carew, Pierce-Gonzalez, & Wills, 1978; Solorzano, Ceja, & Yosso, 2000; Sue, 2010); internalized stereotypes and racial prejudices; and how this is encapsulated in social identities (Miller & Garran, 2008). We conclude with some ideas about how to talk about race and racism, work with racism in direct

practice, including in supervision, confront racism in the community, and how social service organizations can become antiracism organizations. Our purpose is to take an unvarnished look at racism in the United States and the implications of it for social workers. Due to the brevity of this chapter, we particularly emphasize the role of White people and those with white skin privilege in maintaining racism. Although some of what we say might seem a bit jarring and provoke strong emotions, our goal is not to make people angry or feel badly about themselves: we want social workers to eradicate racism, not point fingers at one another or feel immobilized by feelings of guilt or shame. We recognize that the commitment to antiracism work is a lifelong process, and with this realization, readers will find ways to move from feeling overwhelmed or immobilized to a more action-oriented stance.

We need to briefly situate ourselves and define some terms that we will be using. One author (Garran) is a Puerto Rican and African American female, and the other author (Miller) is a White, Jewish American male. We are both social workers and have taught antiracism courses together for 12 years. We have coauthored a textbook for human service professionals about antiracism

(Miller & Garran, 2008). We use the terms “people of color” and “White” because they are the most common social constructions currently in use that convey who is and who is not targeted by racism. Due to the complexity of racism, we have been reluctant to define it in a way that reduces or overly simplifies its meaning. We agree with Memmi (2000) that racism involves the domination of people who are defined as being members of a racial or ethnic group by another group of people based on alleged differences of genetics, culture, values, and behavior. Racism in our view manifests along a spectrum, where there are core practices that are common to all forms of it (Miller & Garran, 2008). Figure 123.1 diagrams the range of ways that racism is expressed, all of which have occurred in the United States, many of which are still operating.

WHY IT IS IMPORTANT FOR SOCIAL WORKERS TO CARE ABOUT RACISM

All citizens should care about racism because it undermines a just society and ultimately compromises everyone, including those with race privilege who often live needlessly in fear or are

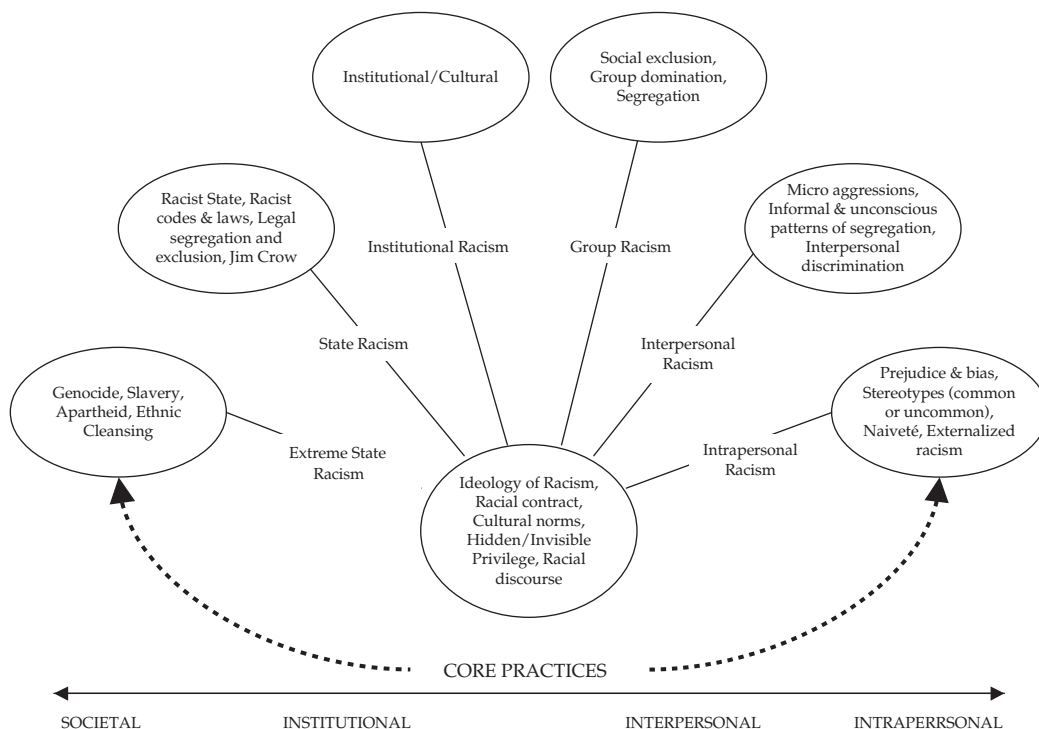

Figure 123.1 The spectrum of racism.

not in touch with their own biases, prejudices, and stereotypes, which alienates them from others. It is particularly important for social workers to understand how racism works and how to confront it because our very mission is to connect with and empower people, and work with them to improve their psychosocial functioning, as well as to advocate for social policies that uphold human rights and dignity and that further human well-being. Racism divides and alienates people, creates barriers to social participation, limits potential, and inhibits psychosocial growth. Racism engenders feelings of anger, rage, guilt, and shame that can be overwhelming and can lead to severe health, psychological, social, and behavioral problems.

Social workers are bound by a code of ethics (NASW, 2008) that commits us to work for social justice and to respect and value every individual and her cultural context. To paraphrase the NASW Code of Ethics, as social workers we are committed to enhancing human well-being and meeting everyone's basic needs, paying particular attention to those who are vulnerable, oppressed, and living in poverty (Miller & Garran, 2008). Racism is a system of inequality that is the ultimate in social injustice. It clearly values some people and cultures while both covertly and overtly allowing for the denigration of others. When not confronted, racism is a force that prevents social workers from adequately and ethically being able to carry out their jobs in a more effective manner.

A BRIEF HISTORY OF RACISM IN THE UNITED STATES

Almost immediately after the arrival of Europeans in the New World, Europeans from a number of nations—Spain, England, France, and Holland—attempted to subjugate, kill, and dislocate the Native American population that was already living here. The more than 600 autonomous societies already living in the Americas were met with disease, slaughter, and attempts at enslavement by European explorers and settlers (Wilson, 1998). Some estimate a 95% death rate among Native Americans within a few generations after European settlement (Stannard, 1992). In the first 90 years of the American republic, every treaty with Native Americans was broken by the United States government (Wilson, 1998). Native Americans were not granted citizenship until 1924.

From the beginning of settlement by Europeans, there was slavery, which evolved into chattel slavery, lifelong and intergenerational, which ultimately became limited to African Americans. Many of the founding fathers of the United States were slave owners—George Washington, Thomas Jefferson, James Madison, James Monroe, and Andrew Jackson, who was also known for his brutal treatment of Native Americans. After slavery was abolished following the Civil War, black codes, Jim Crow, violence (including lynching), and other forms of legal and de facto state terror and segregation managed to severely limit political, social, and economic opportunities for African Americans (Miller & Garran, 2008). While European immigrants were being recruited to work in Northern factories after the Industrial Revolution, African Americans were unable to compete for these jobs due to structural impediments, such as Jim Crow in the South and racial discrimination in the North (which was not limited to employers and included trade unions). Thus, it is important to acknowledge and note that many White people who descend from those immigrants were able to benefit from upward social mobility that depended on their assumption of White privilege at the expense of people of color (Goodman, 2011; Steinberg, 2001).

In the Southwest, Mexicans living in what is now Texas, New Mexico, California, Colorado, and Nevada (which had been part of Mexico prior to the Mexican–American War), lost their land, citizenship, and ability to compete for and hold jobs. In 1882, the Chinese Exclusion Act prohibited immigration to the United States by people from China (at exactly the same time that Europeans were immigrating to the United States), and the Gentleman's Agreement of 1907 prohibited Japanese immigration. Though it was difficult for groups like the Irish, Jews, and Italians when they first arrived in the United States, due in large measure to much discrimination and racial and ethnic stereotyping, they still had advantages unavailable to people of color and as such, within a few generations became "White" (Guglielmo & Salerno, 2003; Ignatiev, 1995; Sacks, 1996; Steinberg, 2001).

It is not possible for social workers to grasp the severe racial inequality that exists today without acknowledging the historical privileges afforded White immigrants and the consistent oppression and exclusion that has faced people of color since the incorporation of this nation.

RACISM IN THE UNITED STATES TODAY

Although it is no longer legal to deprive people of their rights, enslave them, or murder them due to their race, racism in the United States is an ongoing project that has evolved and shifted over the course of time, and one that continues to require confrontation and eradication. The fact that the most extreme forms of racism are illegal and considered socially abhorrent does not mean that there may not be regression or that racism is not still a major force in U.S. society today. Since September 11, 2001, the so-called war against terrorism has had echoes of America's racist past—tightening the borders, demonizing certain ethnic groups, suspending legal rights and civil liberties—to name a few worrying trends. The forms of racism of the past are no longer legally or socially acceptable, though one only needs to turn to the media to learn that there are still many racist incidents that occur, such as the recent murder of unarmed teenager Trayvon Martin in Florida, whose crime was walking through the “wrong” neighborhood while Black.

What is still contested are myriad forms of racism that continue to impede the civil rights and socioeconomic progress of people of color. As Figure 123.1 illustrates, one major form of racism is institutional racism, where many people of color—particularly poor African Americans, Latinos, and Native Americans—face a web of institutional barriers, where they are unable to live in certain neighborhoods, have less access to quality education and health care, face greater exposure to unsafe and unhealthy environments, are more likely to be targeted by law enforcement, are less likely to go to college, are under-represented politically and over-represented in prisons, and who consistently have less ability to accumulate wealth and achieve upward mobility (Alexander, 2010; Miller & Garran, 2007, 2008). Although the United States has elected its first African American president, there are very few senators of color and there is no guarantee that the occupant of the White House will not be White for generations to come. And in 2013, the Supreme Court invalidated the Voting Rights Act; within hours after the decision, the Texas Attorney General announced the implementation of a radical voter identification law, which is likely to suppress the votes of people of color. Another aspect of institutional racism is a public discourse, amplified by the media, which legitimates it. This

discourse normalizes White leadership, privilege, and power and promulgates stereotypes about African Americans, Asian Americans, Latino Americans, and other people of color. It is evident in television shows, news broadcasts, magazine advertisements, and the decisions made by the editors of newspapers and other media about what is news and how it will be portrayed (Miller & Garran, 2008). This discourse shaped public opinion about welfare reform, consistently portraying welfare mothers as African Americans, despite the fact that the majority of women on welfare were White (Gillens, 1999). Media coverage and the ensuing biased public discourse and government response in the initial aftermath of Hurricane Katrina mark another way that events are racialized and, if not confronted, can serve to disparage large groups of people (Adams, O'Brien, & Nelson, 2006).

Figure 123.1 also illustrates intergroup racism, where one racial group has privileges and powers and others are marginalized, “otherized,” or considered “minorities.” For instance, look at the racial/ethnic staffing patterns of your social service agency. Who are the receptionists and administrative assistants? Who are the senior managers? Who are the clients, and who are the workers? Who is on the board of directors? What are the norms and culture of the office? What theories of human behavior in the social environment are being used and what cultural biases are embedded in them? How often are there conversations about these things between all levels of the agency? These are but a few questions that begin to highlight how “normal” and ubiquitous White privilege often is in most social service organizations. As Tim Wise (2003) has put it, Whites swim in a sea of racial privilege, which is mostly invisible. Until we are willing to acknowledge and admit the ways that our organizations perpetuate these inequalities, we will not be positioned to make important changes that will improve service delivery at every level.

INTERNALIZED AND INTERPERSONAL RACISM

The ubiquitous nature of racism, internalized oppression, and White privilege shape how people see the world and how they feel about themselves and others. One way to think about this is that people have multiple social identities. Social identity is how we view ourselves in relation to other

people. It encompasses the groups that we see ourselves as being members of and excluded from, as well as the thoughts, feelings, and perceptions that accompany these identifications. Ultimately, social identity is our sense of our self in a social world. There are many dimensions of social identity—such as gender, ethnicity, social and economic class, race, and sexual orientation—and some of these dimensions shift over time while others remain constant. Different aspects of social identity come to light depending on the social context. For example, in a class where the professor is White and most of the students are White, the one or two students of color may be very conscious of their race. Conversely, many White class members do not think about their race at all and are more aware of their class, gender, sexual orientation, or ethnicity (Miller & Garran, 2008). The same dynamic is often reflected in the staffing of many social service agencies, where the professional staff is largely White and clients who come for services are primarily people of color.

When social identity is mirrored, reflected, and advantaged by society (e.g., being White, male, heterosexual, middle-class, physically able) the privileges that accompany the identity are often difficult to discern by the person who benefits from this special status (McIntosh, 1989, 1992; Miller & Garran, 2008; Wise, 2003). Discourses accompany these privileges that whitewash them away, so that effort, hard work, good character, and the right values are explanations for the success of one group (White people) rather than acknowledgment of exploitation, segregation, resource hoarding, and unequal opportunity (Sensoy & DiAngelo, 2011). Thus, stereotypes emerge that provide inner templates to match outer social realities and offer cognitive justifications for a socially unequal and unfair world. A White person with values and ideals that are altruistic and egalitarian may harbor stereotypes about people of color that are beneath the radar of consciousness but still manage to shape beliefs and behaviors (Dovidio et al., 2002; Miller & Garran, 2008).

Unexamined stereotypes can lead to “aversive racism” (Dovidio et al., 2002), where a well-intentioned White person is unaware of his or her prejudices and yet acts on these biases. Examples include hiring decisions in agencies or segregated housing patterns in neighborhoods, where a White person did not overtly “choose” to live in a nearly all-White neighborhood yet felt compelled to do so. Aversive racism can contribute to subtle interactions—making or not making eye

contact, a forced smile, stumbling over the words “race” or “racism”—that “create a force field of discomfort” (Kaufman, 2001, p. 33). Another way to conceptualize these interactions is to see them as “microaggressions”—subtle but repeated verbal and nonverbal insults, put-downs, and social incursions that are injurious to people of color but often occur without the conscious awareness of the White person (Miller & Garran, 2007; Pierce et al., 1978; Solorzano et al., 2000; Sue, 2010). The consequences of microaggressions are a relentless assault on one’s social identity, which, aside from being painful and exhausting, can lead people of color to withdraw from interactions with White people. Because microaggressions are so often unconscious acts, a commitment to self-reflection and self-awareness are critical if we are to interrupt their perpetuation.

ORGANIZATIONAL RACISM

Social service organizations are the nexus between institutional racism and internalized/interpersonal racism. It is nearly impossible for a mainstream social service organization not to have to deal with racism, given that the organization is part of a society permeated with racism and staffed by many people with internalized racism—it mirrors the complexity of racism in society at large. Thus, racism affects hiring and retention, staffing patterns, policies toward clients, supervision, theoretical biases and pathologizing of clients, and interpersonal relationships between staff, as well as organizational power, influence, and decision making (Miller & Garran, 2008). Many social work practices—individual treatment, appointments for 50 minute hours, the notion of boundaries—were shaped and informed by Eurocentric, Western traditions and yet are presented as universal truths (Miller, 2012). Only through sustained and intentional efforts to become an antiracism organization can social service organizations go beyond token or symbolic measures to challenge racism (Donner & Miller, 2005; Miller & Garran, 2008).

DISMANTLING RACISM AND CREATING A WEB OF RESISTANCE

There are no simple measures to eradicate racism, nor will it be eliminated over a short period of time. The history, ubiquity, and complexity of

racism make dismantling it a daunting prospect. Yet, we must not let the weight of racism, or the weight of our history around it, overwhelm us; without hope there is no prospect of changing things. So what can social workers do?

- *Learn about it.* There is no shortcut to learning about racism in all of its forms, including how it is inside of and in-between people. Racism evokes strong feelings—pain, anger, sorrow, guilt, shame—and these emotional reactions can lead people either to want to challenge it without adequately understanding it, or to withdraw from having to deal with it. Learning about racism and deciphering its many manifestations is an ongoing endeavor. Learning must take place on two levels: cognitively through education, and emotionally and psychologically through introspection and self-awareness.
- *Working with others.* Racism alienates and isolates people from one another. Social workers are committed as a profession to ending social injustice and are accustomed to working together. One of the most effective ways to undermine racism is to create multiracial coalitions that pool resources and offer mutual aid and support. Coalitions help to sustain motivation and attention to this issue.
- *Creating antiracism organizations.* Most social workers practice in agencies, and social service organizations serve clients who have been targeted by racism. Organizations can include antiracism commitments in their mission statements; hire, retain, and empower more staff of color and those with multilingual skills; review practices toward clients as well as the theories that guide such practices; make sure that the racial and ethnic identities of clients and clinicians alike is a salient factor that is discussed in clinical supervision; examine organizational structures to identify policies and practices that perpetuate systemic oppression; offer ongoing antiracism trainings; facilitate intergroup dialogues; and work to become truly multicultural. These efforts must take place consistently and must pull from multiple levels of staffing at the agency to ensure that multiple voices are being represented. If there is no one on staff to provide direction and training to enhance these efforts, then administrators must look for qualified professionals to provide this guidance.
- *Creating inclusive communities.* All social workers and clients live somewhere, although often not in the same place. In general, communities offer safety, security, and opportunities for social mobility and increasing economic and social capital; they are also sites of much institutional racism and can be places that are dangerous and glaringly devoid of the resources and amenities necessary to survive and eventually advance. Social workers can work to create communities where they live **and** work that are inclusive and where everyone is treated fairly and respectfully, and has access to decent education, jobs, health care, and other resources.
- *Being heard.* Social workers must engage in discourses and conversations not only among themselves but also with the greater public. The stereotypes and biases embedded in the mass media and culture can be identified, deconstructed, and challenged by social workers who set an example by their professional ethics and offer an alternative vision of a just and nonracist society. This idea is a critical part of social work education and should extend beyond the halls of the academy.
- *Challenging and changing laws, institutions, and practices.* This is a huge task, but it is not insurmountable. We have seen many laws and practices—for example, slavery, Jim Crow, legal segregation, forced internment—changed over time. There is much more work to do but it can be done if social workers articulate a vision, break things down into manageable pieces, and work in concert with others concerned about racism to dismantle racist policies and promulgate the means to achieve social justice.

Ultimately, all of these actions form a “web of resistance” to racism (Miller & Garran, 2008; Werkmeister Rozas & Miller, 2009). Our core values are central to all of the activities we have described—seeing clearly, listening and hearing, connecting with others, compassion, sustained engagement, and advocating for the rights and dignities of our clients, and in turn, for ourselves. Racism has been around for a long time and will not be eliminated easily, but the core values of the web of resistance correspond directly to those

articulated by the social work profession. If we can aspire to live up to the vision of our profession, we can all be antiracism activists and allies.

124 Anti-oppressive Practices

Katherine Ishizuka & Altaf Husain

INTRODUCTION

Oppression creates conditions that directly or indirectly cause some people to seek assistance from social services (Chapman, 2011). As a result, social workers engage with some of the most vulnerable and oppressed individuals, groups and communities, in pursuit of the profession's mission of enhancing well-being and meeting the basic human needs of all people (National Association of Social Workers, 2013). Although other helping professions may strive toward a similar end, a defining feature of social work is its focus on addressing the causes and consequences of social injustice and oppression (Strier, 2006). Social workers have a professional mandate to identify and challenge the ways in which oppression is upheld, both within and outside the field, across individual, organizational, and systemic domains (Maidment & Cooper, 2002). The focus on (1) mitigating the ways in which social, economic, and political systems, and the profession itself, perpetuate oppression and (2) applying models of empowerment and liberation to institutions, relationships, and values (Brown & Mistry, 2005) is known as antioppressive social work.

Antioppressive practice (AOP) in social work is not an established, monolithic framework, but rather, an evolving and contentious variety of different practice approaches and theories oriented toward a social justice perspective. Although AOP is not new within the field of social work, this is the first time that a chapter has been dedicated to the topic within the *Social Workers' Desk Reference*. This chapter will provide a snapshot of AOP, along with practical tools, guidance, and considerations for its use across a diverse range of practice settings. The

chapter is informed by a review of the literature, the authors' experiences across the spectrum of direct social work practice, macro social work practice and social work academia, and our insights as members of oppressed groups.

The chapter comprises seven sections. The first section provides a brief history of antioppressive practice in social work to situate its current approaches within the field. Sections Two and Three identify goals for antioppressive practice and describe the types and forms of oppression social workers may encounter in their work, respectively. An overview of current frameworks and approaches to AOP is presented in Section Four. Toward the operationalization of theory and analysis, AOP practice principles are described in Section Five. Section Six presents possible barriers toward actualizing antioppressive work in practice and Section Seven concludes with considerations for advancing antioppressive practice within the profession.

A BRIEF HISTORY OF ANTI-OPPRESSIVE PRACTICE IN SOCIAL WORK

Since its origins in the late 19th century, social work has wrestled with its contradictory roles in maintaining the status quo as a function of the state and challenging oppression (Abramovitz, 1999). Both internal and external political struggles have shaped the profession's relationship to social change (Abramovitz, 1999). Although the profession has been concerned with oppression since its inception, its contemporary role in social reform was ignited in the mid-1960s by the civil rights movement (Council on Social Work Education [CSWE], 2001). Prior to the mid-1960s, social work practice and education was

characterized by ethnocentrism and acculturation, in which the norms and values of dominant culture were applied universally to all client groups (Schiele, 2007). Behaviors falling outside of dominant cultural norms were seen as “problems.” For example, in 1952, homosexuality was listed in the *Diagnostic and Statistical Manual of Mental Disorders (DSM-1)* as a sociopathic personality disturbance; a mental illness to be “treated” (Group for the Advancement of Psychiatry, 2012).

Between the mid-1960s and mid-1970s, social workers of color and White allies challenged the Eurocentric bias in social work teaching and practice and the deficit-oriented view of people of color (Abrams & Moio, 2009). Activism related to racial issues prompted the Council on Social Work Education (CSWE) to mandate content on race, racism, and people of color in social work education (CSWE, 2001), and to establish five ethnic minority task forces (Schiele, 2007).
