Care has been taken to confirm the accuracy of the information presented and to describe generally accepted practices. However, the author, editors, and publisher are not responsible for errors or omissions or for any consequences from application of the information in this book and make no warranty, expressed or implied, with respect to the currency, completeness, or accuracy of the contents of the publication. Application of this information in a particular situation remains the professional responsibility of the practitioner; the clinical treatments described and recommended may not be considered absolute and universal recommendations.

The author, editors, and publisher have exerted every effort to ensure that drug selection and dosage set forth in this text are in accordance with the current recommendations and practice at the time of publication. However, in view of ongoing research, changes in government regulations, and the constant flow of information relating to drug therapy and drug reactions, the reader is urged to check the package insert for each drug for any change in indications and dosage and for added warnings and precautions. This is particularly important when the recommended agent is a new or infrequently employed drug.

Some drugs and medical devices presented in this publication have Food and Drug Administration (FDA) clearance for limited use in restricted research settings. It is the responsibility of the health care provider to ascertain the FDA status of each drug or device planned for use in his or her clinical practice.

Dedicated to the many wonderful men and women who are entering the nursing profession today, to the hard-working faculty who are teaching them the art and science of nursing, and to my family and colleagues, who have offered so much support, humor, and sunshine.

Preface

Pharmacology is a difficult course to teach in a standard nursing curriculum, whether it be a diploma, associate, baccalaureate, or graduate program. Teachers are difficult to find, and time and money often dictate that the invaluable content of such a course be incorporated into other courses. As a result, the content is often lost. At the same time, changes in medical care delivery—more outpatient and home care, shorter hospital stays, and more self-care—have resulted in additional legal and professional responsibilities for nurses, making them more responsible for the safe and effective delivery of drug therapy.

Pharmacology should not be such a formidable obstacle in the nursing curriculum. The study of drug therapy incorporates physiology, pathophysiology, chemistry, and nursing fundamentals—subjects that are already taught in most schools. A textbook that approaches pharmacology as an understandable, teachable, and learnable subject would greatly facilitate the incorporation of this subject into nursing curricula. Yet many nursing pharmacology texts are large and burdensome, mainly because they need to cover not only the basic pharmacology, but also the particulars included in each area considered.

The fifth edition of *Focus on Nursing Pharmacology* is based on the premise that students first need to have a solid and clearly focused concept of the principles of drug therapy before they can easily grasp the myriad details associated with individual drugs.

Armed with a fundamental knowledge of pharmacology, the student can appreciate and use the specific details that are so readily available in the many annually updated and published nursing drug guides, such as *Lippincott's Nursing Drug Guide*.

With this goal in mind, *Focus on Nursing Pharmacology* provides a concise, user-friendly, and uncluttered text for the modern student. This difficult subject is presented in a streamlined, understandable, teachable, and learnable manner. Because this book is designed to be used in conjunction with a handbook of current drug information, it remains streamlined. This fifth edition of *Focus on Nursing Pharmacology* continues to emphasize “need-to-know” concepts.

The text reviews and integrates previously learned knowledge of physiology, chemistry, and nursing fundamentals into chapters focused on helping students conceptualize what is important to know about each group of drugs. Illustrations, sidebars, and tables sum up concepts to enhance learning. Special features further focus student learning on clinical application, critical thinking, patient safety, lifespan issues related to drug therapy, evidence-based practice, patient teaching, and

case-study-based critical thinking exercises that incorporate nursing process principles. The text incorporates study materials that conclude each chapter. Check Your Understanding sections provide both new- and old-format National Council Licensure Examination (NCLEX)-style review questions, as well as study guide review questions to help the student master the material and prepare for the national licensing exam.

Focus on Teaching/Learning Activities

ThePoint (available at <http://thepoint.lww.com/>), a trademark of Wolters Kluwer Health, is a Web-based course and content management system that provides every resource instructors and students need in one easy-to-use site. ThePoint . . . where teaching, learning, and technology click!

Student Resources

Students can visit thePoint to access supplemental multimedia resources to enhance their learning experience, download content, upload assignments, and join an online study group. ThePoint offers a variety of free student resources, including NCLEX-Style Student Review Questions (over 1,200 NEW to this edition!), Watch and Learn video clips, Practice and Learn activities, an Alternate-Format NCLEX Tutorial, and a Spanish-English Audioglossary. It also has free journal articles related to topics discussed in the Focus on Safe Medication Administration boxes from the book. Also included are videos on preventing medication errors and three-dimensional animated depictions of pharmacology concepts. In addition, an online course is available that includes interactive activities.

Instructor Resources

Advanced technology and superior content combine at thePoint to allow instructors to design and deliver online and offline courses, maintain grades and class rosters, and communicate with students. In addition to housing the material from the Instructor's Resource DVD-ROM, thePoint also provides additional resources, including Pre-lecture Quizzes, PowerPoints with Guided Lecture Notes, Discussion Topics, Assignments, and over 1700 Test Generator questions—almost 1200 of which are brand new to this edition!

Organization

Focus on Nursing Pharmacology is organized following a “simple-to-complex” approach, much like the syllabus for a

basic nursing pharmacology course. Because students learn best “from the bottom up,” the text is divided into distinct parts.

Part I begins with an overview of basic nursing pharmacology, including such new challenges as bioterrorism, street drugs, herbal therapies, and the information overload; each of the other parts begins with a review of the physiology of the system affected by the specific drugs being discussed. This review refreshes the information for the student and provides a quick and easy reference when he or she is reading about drug actions.

Part II of the text introduces the drug classes, starting with the chemotherapeutic agents—both antimicrobial and antineoplastic drugs. Because the effectiveness of these drugs depends on their interference with the most basic element of body physiology—the cell—students can easily understand the pharmacology of this class. Mastering the pharmacotherapeutic effects of this drug class helps the student to establish a firm grasp of the basic principles taught in Part I. Once the easiest pharmacological concepts are understood, the student is prepared to move on to the more challenging physiological and pharmacological concepts.

Part III focuses on drugs affecting the immune system because recent knowledge about the immune system has made it the cornerstone of modern therapy. All of the immune system drugs act in ways in which the immune system would act if it were able. Recent immunological research has contributed to a much greater understanding of this system, making it important to position information about drugs affecting this system close to the beginning of the text instead of at the end as has been the custom.

Parts IV and **V** of the text address drugs that affect the nervous system, the basic functioning system of the body. Following the discussion of the nervous system, and closely linked with it in **Part VI**, is the endocrine system. The sequence of these parts introduces students to the concept of control, teaches them about the interrelatedness of these two systems, and prepares them for understanding many aspects of shared physiological function and the inevitable linking of the two systems into one: the neuroendocrine system.

Parts VII, VIII, and **IX** discuss drugs affecting the reproductive, cardiovascular, and renal systems, respectively. The sequencing of cardiovascular and renal drugs is logical because most of the augmenting cardiovascular drugs (such as diuretics) affect the renal system.

Part X covers drugs that act on the respiratory system, which provides the link between the left and right ventricles of the heart.

Part XI addresses drugs acting on the gastrointestinal system. The gastrointestinal system stands on its own; it does not share any actions with any other system.

Text Features

The features in this text are skillfully designed to support the text discussion, encouraging the student to look at the whole patient and to focus on the essential information that is

important to learn about each drug class. Important features in the fifth edition focus on incorporating basic nursing skills, patient safety, critical thinking, and application of the material learned to the clinical scenario, helping the student to understand the pharmacology material.

Special Elements and Learning Aids

Each chapter opens with a list of learning objectives for that chapter, helping the student to understand what the key learning points will be. A list of featured drugs and a glossary of key terms are also found on the opening chapter page. Key points appear periodically throughout each chapter to summarize important concepts. The text of each chapter ends with a summary of important concepts. This is followed by a series of review exercises, Check Your Understanding, which includes NCLEX-style questions in the new format to focus student learning on the seminal information presented in the chapter.

- In the *Nursing Considerations* section of each chapter, *italics* highlight the *rationale* for each nursing intervention, helping the student to apply the information in a clinical situation. Elsewhere in the text, the rationale is consistently provided for therapeutic drug actions, contraindications, and adverse effects.
- In the *Drug List* at the beginning of each chapter, a special icon  appears next to the drug that is considered the prototype drug of each class. In each chapter, *prototype summary* boxes spotlight need to know information for each prototype drug.
- *Drugs in Focus* tables clearly summarize and identify the drugs within a class, highlighting them by generic and trade names, usual dosage, and indications. The  icon appears in these tables next to each drug that is considered to be the prototype for its specific class.
- *Web Links* alert the student to electronic sources of drug information and sources of drug therapy information for specific diseases.
- *Focus on Safe Medication Administration* boxes present important safety information to help keep the patient safe, prevent medication errors, and increase the therapeutic effectiveness of the drugs.
- *Focus on the Evidence* boxes compile information based on research to identify the best nursing practices associated with specific drug therapy.
- *Focus on Herbal and Alternative Therapies* displays highlight known interactions with specific herbs or alternative therapies that could affect the actions of the drugs being discussed.
- *Focus on Calculations* reviews are designed to help the student hone calculation and measurement skills while learning about the drugs for which doses might need to be calculated.
- *Focus on Drug Therapy Across the Lifespan* boxes concisely summarize points to consider when using the drugs of each class with children, adults, and the elderly.

- *Focus on Gender Considerations* and *Focus on Cultural Considerations* discussions encourage the student to think about cultural awareness and to consider the patient as a unique individual with a special set of characteristics that not only influences variations in drug effectiveness, but also could influence a patient's perspective on drug therapy.
- *Critical Thinking Scenarios* tie each chapter's content together by presenting clinical scenarios about a patient using a particular drug from the class being discussed. Included in the case study are hints to guide critical thinking about the case and a discussion of *drug- and nondrug-related nursing considerations* for that particular patient and situation. Most important, the case study provides a *plan of nursing care* specifically developed for that patient and specifically based on the nursing process. The care plan is followed by a checklist of *patient teaching points* designed for the patient presented in the case study. This approach helps the student to see how assessment and the collected data are applied in the clinical situation.
- *Check Your Understanding* sections present NCLEX-style questions, including alternate format questions, to help the

student prepare for that exam. Other questions and activities in this section are designed to help students test their knowledge of the information that has been learned in the chapter.

To the Student Using This Text

As you begin your study of pharmacology, don't be overwhelmed or confused by all of the details. The study of drugs fits perfectly into your study of the human body—*anatomy, physiology, chemistry, nutrition, psychology, and sociology*. Approach the study of pharmacology from the perspective of putting all of the pieces together; this can be not only fun, but also challenging! Work to understand the concepts, and all of the details will fall into place and be easy to remember and apply to the clinical situation. This understanding will help you in creating the picture of the whole patient as you are learning to provide comprehensive nursing care. This text is designed to help you accomplish all of this in a simple and concise manner. Good luck!

Amy M. Karch, RN, MS

Acknowledgments

I would like to thank the various people who have worked so hard to make this book a reality, especially the many students and colleagues who have for so long pushed for a pharmacology book that was straightforward and user-friendly and who have taken the time to make suggestions to improve each edition. Thanks also to my summer team—Patrick Hopkins, Rebecca Tucker, Melanie Bobry, and Kathy Rideout—who brought a fresh approach to pharmacology and teaching with the humor that is so necessary to keep teaching a joy; to Ginny Hanchett for the wonderful opportunity to take on new challenges; to Hilarie Surrena, my acquisitions editor at Lippincott Williams & Wilkins; to

Helene Caprari, my amazing development editor, who had the vision and helped to make it reality; to Amy Giuffi, who got the word out; to Victoria White, Joan Wendt, and Karin Duffield, who saw it all come together; to Indu Jawwad, who worked with us to produce the finished product; to Tim, Jyoti, Mark, Tracey, Cortney, Bryan, and Kathryn, who continue to thrive and grow and have become the wonderful, supportive people in my life; to the new generation—Vikas, Nisha, Logan, and Jack—who have returned the sunshine and joy of learning to our lives; and lastly to Hayley and Brodie, whose happily wagging tails never fail to bring smiles and help to keep everything in perspective.

Introduction to Drugs

1

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Define the word pharmacology.
2. Outline the steps involved in developing and approving a new drug in the United States.
3. Describe the federal controls on drugs that have abuse potential.
4. Differentiate between generic and brand-name drugs, over-the-counter and prescription drugs.
5. Explain the benefits and risks associated with the use of over-the-counter drugs.

Glossary of Key Terms

adverse effects: drug effects that are not the desired therapeutic effects; may be unpleasant or even dangerous

brand name: name given to a drug by the pharmaceutical company that developed it; also called a trade name

chemical name: name that reflects the chemical structure of a drug

drugs: chemicals that are introduced into the body to bring about some sort of change

Food and Drug Administration (FDA): federal agency responsible for the regulation and enforcement of drug evaluation and distribution policies

generic drugs: drugs sold by their chemical name; not brand (or trade) name products

generic name: the original designation that a drug is given when the drug company that developed it applies for the approval process

genetic engineering: process of altering DNA, usually of bacteria, to produce a chemical to be used as a drug

orphan drugs: drugs that have been discovered but would not be profitable for a drug company to develop; usually drugs that would treat only a small number of people; these orphans can be adopted by drug companies to develop

over-the-counter (OTC) drugs: drugs that are available without a prescription for self-treatment of a variety of complaints; deemed to be safe when used as directed

pharmacology: the study of the biological effects of chemicals
pharmacotherapeutics: clinical pharmacology—the branch of pharmacology that deals with drugs; chemicals that are used in medicine for the treatment, prevention, and diagnosis of disease in humans

phase I study: a pilot study of a potential drug done with a small number of selected, healthy human volunteers

phase II study: a clinical study of a proposed drug by selected physicians using actual patients who have the disorder the drug is designed to treat; patients must provide informed consent

phase III study: use of a proposed drug on a wide scale in the clinical setting with patients who have the disease the drug is thought to treat

phase IV study: continual evaluation of a drug after it has been released for marketing

preclinical trials: initial trial of a chemical thought to have therapeutic potential; uses laboratory animals, not human subjects

teratogenic: having adverse effects on the fetus

The human body works through a complicated series of chemical reactions and processes. **Pharmacology** is the study of the biological effects of chemicals. **Drugs** are chemicals that are introduced into the body to cause some sort of change. When drugs are administered, the body begins a sequence of processes designed to handle the new chemicals.

These processes, which involve breaking down and eliminating the drugs, in turn affect the body's complex series of chemical reactions. In clinical practice, health care providers focus on how chemicals act on living organisms.

Nurses deal with **pharmacotherapeutics**, or clinical pharmacology, the branch of pharmacology that uses drugs to

treat, prevent, and diagnose disease. Clinical pharmacology addresses two key concerns: the drug's effects on the body, and the body's response to the drug.

For many reasons, understanding how drugs act on the body to cause changes and applying that knowledge in the clinical setting are important aspects of nursing practice. For instance, patients today often follow complicated drug regimens and receive potentially toxic drugs. Many also manage their care at home. A drug can have many effects, and the nurse must know which ones may occur when a particular drug is administered. Some drug effects are therapeutic, or helpful, but others are undesirable or potentially dangerous. These negative effects are called **adverse effects**. (See Chapter 3 for a detailed discussion of adverse effects.)

The nurse is in a unique position regarding drug therapy because nursing responsibilities include the following:

- Administering drugs
- Assessing drug effects
- Intervening to make the drug regimen more tolerable
- Providing patient teaching about drugs and the drug regimen
- Monitoring the overall patient care plan to prevent medication errors

Knowing how drugs work makes these tasks easier to handle, thus enhancing the effectiveness of drug therapy.

This text is designed to provide the pharmacological basis for understanding drug therapy. The physiology of a body system and the related actions of many drugs on that system are presented in a way that allows clear understanding of how drugs work and what to anticipate when giving a particular type of drug.

Thousands of drugs are available for use, and it is impossible to memorize all of the individual differences among drugs in a class. This text addresses *general* drug information. The nurse can refer to *Lippincott's Nursing Drug Guide (LNDG)* or to another drug guide to obtain the *specific* details required for safe and effective drug administration. Drug details are changing constantly. The practicing nurse must be knowledgeable about these changes and rely on an up-to-date and comprehensive drug guide in the clinical setting.

A section related to nursing considerations for patients receiving particular drugs will be found in each chapter of this book. This includes assessment points, nursing diagnoses to consider, and implementation or particular interventions that should be considered, and evaluation points will provide a guide for using the nursing process to effectively incorporate drug therapy into patient care. This information can be used to develop an individual nursing care plan for your patient. The monographs in *LNDG* (Table 1.1) can be used to provide the specific information that you need to plan care for each particular drug you might be giving. The various sections of each drug monograph (Figure 1.1) can provide information to help in the development of patient teaching guides

and drug cards for reference in the clinical setting. The Patient Drug Sheet: Oral Linezolid (Figure 1.2) is an example of how this information can be used to develop a patient teaching guide.

The CD-ROM in the front of this book contains patient teaching guides for all of the drugs found in *LNDG*. The nurse can use this text as a resource for basic concepts of pharmacology and a nursing drug guide as an easy-to-use reference in the clinical setting.

SOURCES OF DRUGS

Drugs are available from varied sources, both natural and synthetic. Natural sources include plants, animals, and inorganic compounds.

Natural Sources

Chemicals that might prove useful as drugs can come from many natural sources, such as plants, animals, or inorganic compounds. To become a drug, a chemical must have a demonstrated therapeutic value or efficacy without severe toxicity or damaging properties.

Plants

Plants and plant parts have been used as medicines since prehistoric times. Even today, plants are an important source of chemicals that are developed into drugs. For example, digitalis products used to treat cardiac disorders and various opiates used for sedation are still derived from plants. Table 1.2 provides examples of drugs derived from plant sources.

Drugs also may be processed using a synthetic version of the active chemical found in a plant. An example of this type of drug is dronabinol (*Marinol*), which contains the active ingredient delta-9-tetrahydrocannabinol found in marijuana. This drug helps to prevent nausea and vomiting in cancer patients but does not have all of the adverse effects that occur when the marijuana leaf is smoked. Marijuana leaf is a controlled substance with high abuse potential and has no legal or accepted medical use. The synthetic version of the active ingredient allows for an accepted form to achieve the desired therapeutic effect in cancer patients.

Ingestion of a plant-derived food can sometimes lead to a drug effect. For instance, the body converts natural licorice to a false aldosterone—a hormone found in the body—resulting in fluid retention and hypokalemia or low serum potassium levels if large amounts of licorice are eaten. However, people seldom think of licorice as a drug.

Finally, plants have become the main component of the growing alternative therapy movement. Chapter 6 discusses the alternative therapy movement and its impact on today's drug regimens.

Animal Products

Animal products are used to replace human chemicals that fail to be produced because of disease or genetic problems. Until recently, insulin for treating diabetes was obtained exclusively from the pancreas of cows and pigs. Now **genetic engineering**—the process of altering DNA—permits scientists to produce human insulin by altering *Escherichia coli* bacteria, making insulin a better product without some of the impurities that come with animal products.

Thyroid drugs and growth hormone preparations also may be obtained from animal thyroid and hypothalamic tissues. Many of these preparations are now created synthetically, however, and the synthetic preparations are considered to be purer and safer than preparations derived from animals.

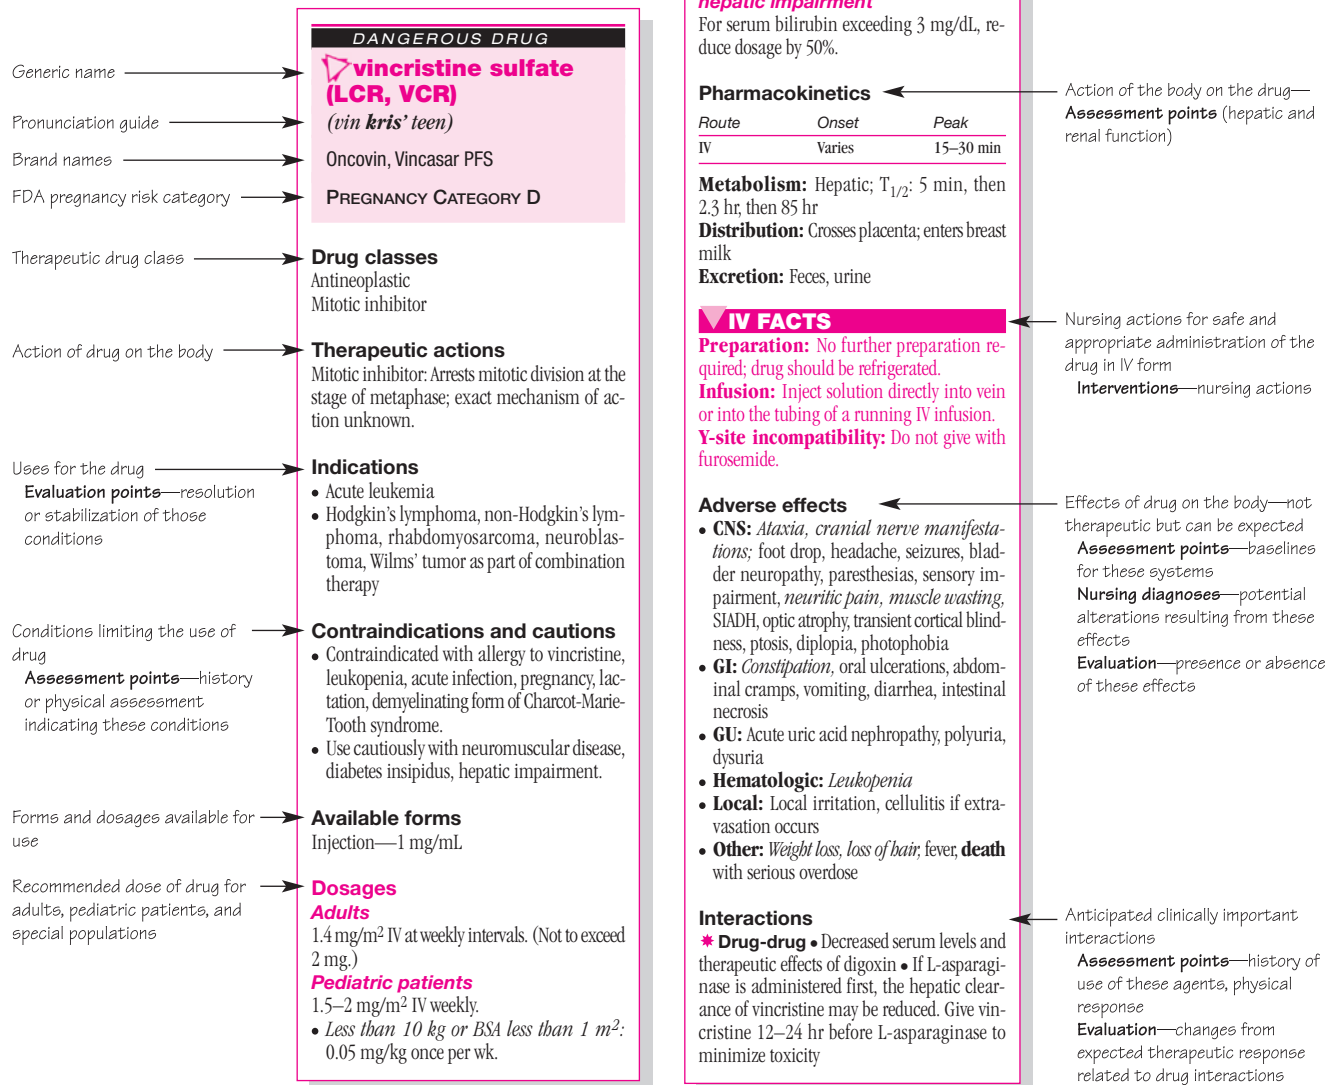

Inorganic Compounds

Salts of various chemical elements can have therapeutic effects in the human body. Aluminum, fluoride, iron, and

even gold are used to treat various conditions. The effects of these elements usually were discovered accidentally when a cause–effect relationship was observed. Table 1.3 shows examples of some elements used for their therapeutic benefit.

Synthetic Sources

Today, many drugs are developed synthetically after chemicals in plants, animals, or the environment have been tested and found to have therapeutic activity. Scientists use genetic engineering to alter bacteria to produce chemicals that are therapeutic and effective. Other technical advances allow scientists to alter a chemical with proven therapeutic effectiveness to make it better. Sometimes, a small change in a chemical's structure can make that chemical more useful as a drug—more potent, more stable, less toxic. These technological advances have led to the development of

● FIGURE 1.1 Example of a drug monograph from *Lippincott's Nursing Drug Guide*.

groups of similar drugs, all of which are derived from an original prototype, but each of which has slightly different properties, making a particular drug more desirable in a specific situation. Throughout this book, the icon  will be used to designate those drugs of a class that are considered the prototype of the class, the original drug in the class, or the drug that has emerged as the most effective. For example, the cephalosporins are a large group of antibiotics derived from the same chemical structure. Alterations in the chemical rings or attachments to that structure make it possible for some of these drugs to be absorbed orally, whereas others must be given parenterally. Some of these drugs cause severe toxic effects (e.g., renal toxicity), but others do not.

KEY POINTS

- ▶ Clinical pharmacology is the study of drugs used to treat, diagnose, or prevent a disease.
- ▶ Drugs are chemicals that are introduced into the body and affect the body's chemical processes.
- ▶ Drugs can come from plants, foods, animals, salts of inorganic compounds, or synthetic sources.

DRUG EVALUATION

After a chemical that might have therapeutic value is identified, it must undergo a series of scientific tests to evaluate its actual therapeutic and toxic effects. This process is tightly

*** Drug-food •** Decreased metabolism and risk of toxic effects if combined with grapefruit juice; avoid this combination

■ Nursing considerations

CLINICAL ALERT!
Confusion has occurred between vincristine and vinblastine; use extreme caution if giving either drug.

Assessment

- **History:** Allergy to vincristine, leukopenia, acute infection, neuromuscular disease, diabetes insipidus, hepatic impairment, pregnancy, lactation
- **Physical:** Weight; hair; T; reflexes, gait, sensation, cranial nerve evaluation, ophthalmic examination; mucous membranes, abdominal examination; CBC, serum sodium, LFTs, urinalysis

Interventions

- Ensure that patient is not pregnant before administering; using barrier contraceptives is advised.
- Tell patient to avoid grapefruit juice while being treated with this drug.

Black box warning Do not administer IM or subcutaneously due to severe local reaction and tissue necrosis. Do not give intrathecally; drug is fatal if given intrathecally. Use extreme caution.

Black box warning Watch for irritation and infiltration; extravasation causes tissue damage and necrosis. If extravasation occurs, discontinue injection immediately and give remainder of dose in another vein. Consult with physician to arrange for hyaluronidase injection into local area, and apply heat to disperse the drug and to minimize pain.

- Arrange for wig or suitable head covering if hair loss occurs; ensure that patient's head is covered in extremes of temperature.
- Monitor urine output and serum sodium; if SIADH occurs, consult with physician, and arrange for fluid restriction and perhaps a potent diuretic.

Teaching points

- Prepare a calendar of dates to return for treatment and additional therapy.
- Avoid grapefruit juice while you are using this drug.
- This drug cannot be taken during pregnancy; use birth control. If you become pregnant, consult your health care provider.
- Have regular blood tests to monitor the drug's effects.
- You may experience these side effects: Loss of appetite, nausea, vomiting, mouth sores (frequent mouth care, frequent small meals may help; maintain nutrition; request an antiemetic); constipation (bowel program may be ordered); sensitivity to light (wear sunglasses; avoid bright lights); numbness, tingling, change in style of walking (reversible; may persist for up to 6 weeks); hair loss (transient; obtain a wig or other suitable head covering; keep the head covered at extremes of temperature).
- Report change in frequency of voiding; swelling of ankles, fingers, and so forth; changes in vision; severe constipation, abdominal pain.

controlled by the U.S. **Food and Drug Administration (FDA)**, an agency of the U.S. Department of Health and Human Services that regulates the development and sale of drugs. FDA-regulated tests are designed to ensure the safety and reliability of any drug approved in this country. For every 100,000 chemicals that are identified as being potential drugs, only about 5 end up being marketed. Before receiving final FDA approval to be marketed to the public, drugs must pass through several stages of development. These include preclinical trials and phase I, II, and III studies. The drugs listed in this book have been through rigorous testing and are

approved for sale to the public, either with or without a prescription from a health care provider.

Preclinical Trials

In **preclinical trials**, chemicals that may have therapeutic value are tested on laboratory animals for two main purposes: (1) to determine whether they have the presumed effects in living tissue, and (2) to evaluate any adverse effects. Animal testing is important because unique biological differences can cause very different reactions to the chemical. These differences

Patient Drug Sheet: Oral Linezolid

Patient's Name: Mr. Kors
Prescriber's Name: J. Smith, ANP
Phone Number: 555-555-5555

Instructions:

1. The name of your drug is *linezolid*; the brand name is *Zyvox*. This drug is an antibiotic that is being used to treat your *pneumonia*. This drug is very specific in its action and is only indicated for your particular infection. Take the full course of your drug. Do not share this drug with other people or save tablets for future use.
2. The dose of the drug that has been prescribed for you is: *600 mg (1 tablet)*.
3. The drug should be taken *once every 12 hours*. The best time for you to take this drug will be *8:00 in the morning and 8:00 in the evening*. Do not skip any doses. Do not take two doses at once if you forget a dose. If you miss a dose, take the dose as soon as you remember and then again in 12 hours.
4. The drug can be taken with food if GI upset is a problem. Avoid foods that are rich in tyramine (list is below) while you are taking this drug.
5. The following side effects may occur:
 Nausea, vomiting, abdominal pain (taking the drug with food and eating frequent small meals may help).
 Diarrhea (ensure ready access to bathroom facilities). Notify your health care provider if this becomes severe.
6. Do not take this drug with over-the-counter drugs or herbal remedies without first checking with your health care provider. Many of these agents can cause problems with your drug.
7. Tell any nurse, physician, or dentist who is taking care of you that you are on this drug.
8. Keep this and all medications out of the reach of children.

Notify your health care provider if any of the following occur:

Rash, severe GI problems, bloody or excessive diarrhea, weakness, tremors, increased bleeding or bruising, anxiety.

Foods high in tyramine to avoid: Aged cheeses, avocados, bananas, beer, bologna, caffeinated beverages, chocolate, liver, over-ripe fruit, pepperoni, pickled fish, red wine, salami, smoked fish, yeast, yogurt.

● **FIGURE 1.2** Example of a patient teaching sheet from *Lippincott's Nursing Drug Guide*.

can be found only in living organisms, so computer-generated models alone are often inadequate.

At the end of the preclinical trials, some chemicals are discarded for the following reasons:

- The chemical lacks therapeutic activity when used with living animals.

● **TABLE 1.2** Drugs Derived From Plants

PLANT	PRODUCT
<i>Ricinus communis</i>	Seed Oil Castor oil (<i>Neolid</i>)
<i>Digitalis purpurea</i> (foxglove plant)	Leaves Dried leaves Digitalis leaf
<i>Papaver somniferum</i> (poppy plant)	Unripe capsule Juice Opium (paregoric) Morphine (<i>Roxanol</i>) Codeine Papaverine (<i>Pavabid</i>)

● **TABLE 1.3** Elements Used for Their Therapeutic Effects

ELEMENT	THERAPEUTIC USE
Aluminum	Antacid to decrease gastric acidity Management of hyperphosphatemia Prevention of the formation of phosphate urinary stones
Fluorine (as fluoride)	Prevention of dental cavities Prevention of osteoporosis
Gold	Treatment of rheumatoid arthritis
Iron	Treatment of iron deficiency anemia

- The chemical is too toxic to living animals to be worth the risk of developing into a drug.
- The chemical is highly **teratogenic** (causing adverse effects to the fetus).
- The safety margins are so small that the chemical would not be useful in the clinical setting.

Some chemicals, however, are found to have therapeutic effects and reasonable safety margins. This means that the chemicals are therapeutic at doses that are reasonably different from doses that cause toxic effects. Such chemicals will pass the preclinical trials and advance to phase I studies.

Phase I Studies

A **phase I study** uses human volunteers to test the drugs. These studies are more tightly controlled than preclinical trials and are performed by specially trained clinical investigators. The volunteers are fully informed of possible risks and may be paid for their participation. Usually, the volunteers are healthy, young men. Women are not good candidates for phase I studies because the chemicals may exert unknown and harmful effects on a woman's ova, and too much risk is involved in taking a drug that might destroy or alter the ova. Women do not make new ova after birth. Men produce sperm daily, so there is less potential for complete destruction or alteration of the sperm.

Some chemicals are therapeutic in other animals but have no effects in humans. Investigators in phase I studies scrutinize the drugs being tested for effects in humans. They also look for adverse effects and toxicity. At the end of phase I studies, many chemicals are dropped from the process for the following reasons:

- They lack therapeutic effect in humans.
- They cause unacceptable adverse effects.
- They are highly teratogenic.
- They are too toxic.

Some chemicals move to the next stage of testing despite undesirable effects. For example, the antihypertensive drug minoxidil (*Loniten*) was found to effectively treat malignant hypertension, but it caused unusual hair growth on the palms and other body areas. However, because it was so much more

effective for treating malignant hypertension at the time of its development than any other antihypertensive drug, it proceeded to phase II studies. (Now, its hair-growing effect has been channeled for therapeutic use into various hair-growth preparations such as *Rogaine*.)

Phase II Studies

A **phase II study** allows clinical investigators to try out the drug in patients who have the disease that the drug is designed to treat. Patients are told about the possible benefits of the drug and are invited to participate in the study. Those who consent to participate are fully informed about possible risks and are monitored very closely, often at no charge to them, to evaluate the drug's effects. Usually, phase II studies are performed at various sites across the country—in hospitals, clinics, and doctors' offices—and are monitored by representatives of the pharmaceutical company studying the drug. At the end of phase II studies, a drug may be removed from further investigation for the following reasons:

- It is less effective than anticipated.
- It is too toxic when used with patients.
- It produces unacceptable adverse effects.
- It has a low benefit-to-risk ratio, meaning that the therapeutic benefit it provides does not outweigh the risk of potential adverse effects that it causes.
- It is no more effective than other drugs already on the market, making the cost of continued research and production less attractive to the drug company.

A drug that continues to show promise as a therapeutic agent receives additional scrutiny in phase III studies.

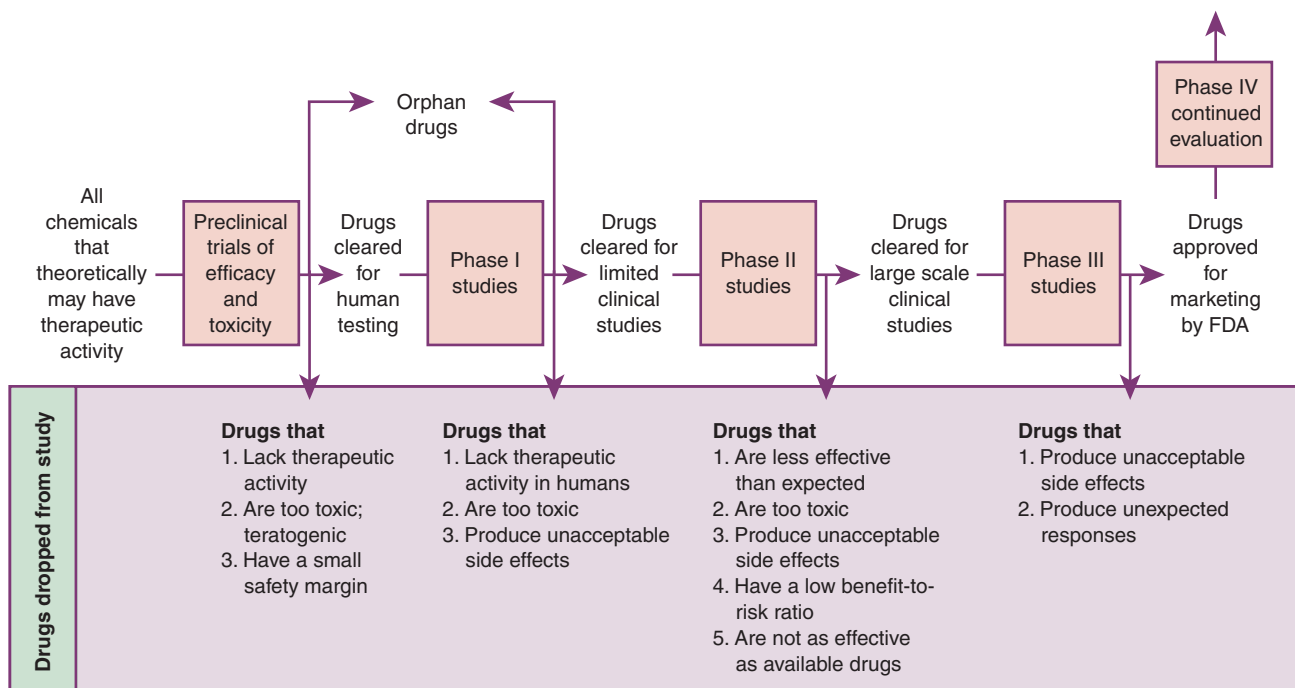

Phase III Studies

A **phase III study** involves use of the drug in a vast clinical market. Prescribers are informed of all the known reactions to the drug and precautions required for its safe use. Prescribers observe patients very closely, monitoring them for any adverse effects. Sometimes, prescribers ask patients to keep journals and record any symptoms they experience. Prescribers then evaluate the reported effects to determine whether they are caused by the disease or by the drug. This information is collected by the drug company that is developing the drug and is shared with the FDA. When a drug is used widely, totally unexpected responses may occur. A drug that produces unacceptable adverse effects or unforeseen reactions is usually removed from further study by the drug company. In some cases, the FDA may have to request that a drug be removed from the market.

Food and Drug Administration Approval

Drugs that finish phase III studies are evaluated by the FDA, which relies on committees of experts familiar with the specialty area in which the drugs will be used. Only those drugs that receive FDA committee approval may be marketed. Figure 1.3 recaps the various phases of drug development discussed.

An approved drug is given a **brand name** (trade name) by the pharmaceutical company that developed it. The **generic name** of a drug is the original designation that the drug was given when the drug company applied for the approval process. **Chemical names** are names that reflect the chemical structure of a drug. Some drugs are known by all three names. It can be confusing to study drugs when so many different

● FIGURE 1.3 Phases of drug development.

TABLE 1.4 Comparison of Generic, Chemical, and Brand Names of Drugs

levothyroxine sodium	←	generic name	→	colfosceril palmitate
L-thyroxine, T ₄	←	chemical name	→	dipalmitoylphosphatidylcholine
<i>Eltroxin, Levothroid, Synthroid</i>	←	brand names	→	<i>Exosurf Neonatal</i>

names are used for the same compound. In this text, the generic and chemical names always appear in straight print, and the brand name is always italicized (e.g., minoxidil [*Rogaine*]). Table 1.4 compares examples of drug names.

The entire drug development and approval process can take 5 to 6 years, resulting in a so-called drug lag in the United States. In some instances, a drug that is available in another country may not become available here for years. The FDA regards public safety as primary in drug approval, so the process remains strict; however, it can be accelerated in certain instances involving the treatment of deadly diseases. For example, some drugs (e.g., delavirdine [*Rescriptor*] and efavirenz [*Sustiva*]) that were thought to offer a benefit to patients with acquired immune deficiency syndrome (AIDS), a potentially fatal immune disorder, were pushed through because of the progressive nature of AIDS and the lack of a cure. All literature associated with these drugs indicates that long-term effects and other information about the drug may not yet be known.

In addition to the drug lag issue, there also are concerns about the high cost of drug approval. In 2004, *Fortune* magazine did a study that found that the estimated cost of taking a chemical from discovery to marketing as a drug was about \$802 million. Because of this kind of financial investment, pharmaceutical companies are unwilling to risk approval of a drug that might cause serious problems and prompt lawsuits.

Phase IV Studies

After a drug is approved for marketing, it enters a phase of continual evaluation, or **phase IV study**. Prescribers are obligated to report to the FDA any untoward or unexpected adverse effects associated with drugs they are using, and the FDA continually evaluates this information. Some drugs cause unexpected effects that are not seen until wide distribution occurs. Sometimes, those effects are therapeutic. For example, patients taking the antiparkinsonism drug amantadine (*Symmetrel*) were found to have fewer cases of influenza than other patients, leading to the discovery that amantadine is an effective antiviral agent.

In other instances, the unexpected effects are dangerous. In 1997, the diet drug dexfenfluramine (*Redux*) was removed from the market only months after its release because patients taking it developed serious heart problems. In 2004, the drug company Merck withdrew its cyclooxygenase-2 (Cox-2) specific nonsteroidal anti-inflammatory drug rofecoxib (*Vioxx*) from the market when postmarketing studies seemed to show a significant increase in cardiovascular mortality in patients

who were taking the drug. These problems were not seen in any of the premarketing studies of the drug. The effects were only seen with a much wider use of the drug after it had been marketed.

KEY POINTS

- ▶ The FDA carefully regulates the testing and approval of all drugs in this country.
- ▶ To be approved for marketing, a drug must pass through animal testing, testing on healthy humans, selected testing on people with the disease being treated, and then broad testing on people with the disease being treated.

LEGAL REGULATION OF DRUGS

The FDA regulates the development and sale of drugs. Local laws further regulate the distribution and administration of drugs. In most cases, the strictest law is the one that prevails. Nurses should become familiar with the rules and regulations in the area in which they practice. These regulations can vary from state to state, and even within a state.

Over the years, the FDA has become more powerful, usually in response to a drug disaster affecting many people. In the 1930s, the drug “elixir of sulfanilamide” was distributed in a vehicle of ethylene glycol that had never been tested in humans. It turned out that ethylene glycol is toxic to humans, and hundreds of people died and many others became very ill. This led to the Federal Food, Drug and Cosmetic Act of 1938, which gave the FDA power to enforce standards for testing drug toxicity and monitoring labeling.

In the 1960s, the drug thalidomide (*Thalomid*) was used as a sleeping aid by pregnant women, resulting in the birth of many babies with limb deformities. The public outcry resulted in the Kefauver-Harris Act of 1962, which gave the FDA regulatory control over the testing and evaluating of drugs and set standards for efficacy and safety.

Other laws have given the FDA control over monitoring of potentially addictive drugs and responsibility for monitoring, to some extent, the sale of drugs that are available without prescription. Table 1.5 provides a summary of these laws.

Safety During Pregnancy

As part of the standards for testing and safety, the FDA requires that each new drug be assigned to a pregnancy category (Box 1.1). The categories indicate a drug’s potential or actual teratogenic effects, thus offering guidelines for use of

TABLE 1.5 Federal Legislation Affecting the Clinical Use of Drugs

YEAR ENACTED	LAW	IMPACT
1906	Pure Food and Drug Act	Prevented the marketing of adulterated drugs; required labeling to eliminate false or misleading claims
1938	Federal Food, Drug and Cosmetic Act	Mandated tests for drug toxicity and provided means for recall of drugs; established procedures for introducing new drugs; gave FDA the power of enforcement
1951	Durham-Humphrey Amendment	Tightened control of certain drugs; specified drugs to be labeled "may not be distributed without a prescription"
1962	Kefauver-Harris Act	Tightened control over the quality of drugs; gave FDA regulatory power over the procedure of drug investigations; stated that efficacy as well as safety of drugs had to be established
1970	Controlled Substances Act	Defined drug abuse and classified drugs as to their potential for abuse; provided strict controls over the distribution, storage, and use of these drugs
1983	Orphan Drug Act	Provided incentives for the development of orphan drugs for treatment of rare diseases

that particular drug in pregnancy. Research into the development of the human fetus, especially the nervous system, has led many health care providers to recommend that no drug should be used during pregnancy because of potential effects on the developing fetus. In cases in which a drug is needed, it is recommended that the drug of choice be one for which the benefit outweighs the potential risk.

Controlled Substances

The Controlled Substances Act of 1970 established categories for ranking of the abuse potential of various drugs. This same act gave control over the coding of drugs and the enforcement of these codes to the FDA and the Drug Enforcement Agency (DEA), a part of the U.S. Department of Justice. The FDA studies the drugs and determines their abuse potential; the DEA enforces their control. Drugs with abuse potential are called *controlled substances*. Box 1.2 contains descriptions of each category, or schedule.

The prescription, distribution, storage, and use of these drugs are closely monitored by the DEA in an attempt to decrease substance abuse of prescribed medications. Each

BOX 1.1 FDA Pregnancy Categories

The Food and Drug Administration (FDA) has established five categories to indicate the potential for a systemically absorbed drug to cause birth defects. The key differentiation among the categories rests on the degree (reliability) of documentation and the risk–benefit ratio.

Category A: Adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.

Category B: Animal studies have not demonstrated a risk to the fetus but there are no adequate studies in pregnant women, *or* animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus during the first trimester of pregnancy, and there is no evidence of risk in later trimesters.

Category C: Animal studies have shown an adverse effect on the fetus but there are no adequate studies in humans; the benefits from the use of the drug in pregnant women may be acceptable despite its potential risks, *or* there are no animal reproduction studies and no adequate studies in humans.

Category D: There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.

Category X: Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in a pregnant woman clearly outweighs any possible benefit.

Regardless of the designated Pregnancy Category or presumed safety, no drug should be administered during pregnancy unless it is clearly needed.

prescriber has a DEA number, which allows the DEA to monitor prescription patterns and possible abuse. A nurse should be familiar with not only the DEA guidelines for controlled substances, but also the local policies and procedures, which might be even more rigorous.

Generic Drugs

When a drug receives approval for marketing from the FDA, the drug formula is given a time-limited patent, in much the same way as an invention is patented. The length of time for which the patent is good depends on the type of chemical involved. When the patent runs out on a brand-name drug, the drug can be produced by other manufacturers. **Generic drugs** are chemicals that are produced by companies involved solely in the manufacturing of drugs. Because they do not have the research, the advertising, or, sometimes, the quality control departments that pharmaceutical companies have, they can produce the generic drugs more cheaply. In the past, some quality-control problems were found with generic products. For example, the binders used in a generic drug might not be the same as those used in the brand-name product. As a result, the way the body breaks down and uses the generic drug may differ from that of the brand-name product. In that case, the bioavailability of the drug is different from that of the brand-name product.

BOX 1.2 DEA Schedules of Controlled Substances

The Controlled Substances Act of 1970 regulates the manufacturing, distribution, and dispensing of drugs that are known to have abuse potential. The Drug Enforcement Agency (DEA) is responsible for the enforcement of these regulations. The controlled drugs are divided into five DEA schedules based on their potential for abuse and physical and psychological dependence.

Schedule I (C-I): High abuse potential and no accepted medical use (heroin, marijuana, LSD)

Schedule II (C-II): High abuse potential with severe dependence liability (narcotics, amphetamines, and barbiturates)

Schedule III (C-III): Less abuse potential than schedule II drugs and moderate dependence liability (nonbarbiturate sedatives, nonamphetamine stimulants, limited amounts of certain narcotics)

Schedule IV (C-IV): Less abuse potential than schedule III and limited dependence liability (some sedatives, antianxiety agents, and non-narcotic analgesics)

Schedule V (C-V): Limited abuse potential. Primarily small amounts of narcotics (codeine) used as antitussives or antidiarrheals. Under federal law, limited quantities of certain schedule V drugs may be purchased without a prescription directly from a pharmacist. The purchaser must be at least 18 years of age and must furnish suitable identification. All such transactions must be recorded by the dispensing pharmacist.

Prescribing physicians and dispensing pharmacists must be registered with the DEA, which also provides forms for the transfer of Schedule I and II substances and establishes criteria for the inventory and prescribing of controlled substances. State and local laws are often more stringent than federal law. In any given situation, the more stringent law applies.

Many states require that a drug be dispensed in the generic form if one is available. This requirement helps to keep down the cost of drugs and health care. Some prescribers, however, specify that a drug prescription be “dispensed as written” (DAW), that is, that the brand-name product be used. By doing so, the prescriber ensures the quality control and the action and effect expected with that drug. These elements may be most important in drugs that have narrow safety margins, such as digoxin (*Lanoxin*), a heart drug, and warfarin (*Coumadin*), an anticoagulant. The initial cost may be higher, but some prescribers believe that, in the long run, the cost to the patient will be less.

Orphan Drugs

Orphan drugs are drugs that have been discovered but are not financially viable and therefore have not been “adopted” by any drug company. Orphan drugs may be useful in treating a rare disease, or they may have potentially dangerous adverse effects. Orphan drugs are often abandoned after preclinical trials or phase I studies. The Orphan Drug Act of 1983 provided tremendous financial incentives to drug companies to adopt these drugs and develop them. These incentives help the drug company put the drug through the rest of the testing

process, even though the market for the drug in the long run may be very small (as in the case of a drug to treat a rare neurological disease that affects only a small number of people). Some drugs in this book have orphan drug uses listed.

Over-the-Counter Drugs

Over-the-counter (OTC) drugs are products that are available without prescription for self-treatment of a variety of complaints. Some of these agents were approved as prescription drugs but later were found to be very safe and useful for patients without the need of a prescription. Some were not rigorously screened and tested by the current drug evaluation protocols because they were developed and marketed before the current laws were put into effect. Many of these drugs were “grandfathered” into use because they had been used for so long. The FDA is currently testing the effectiveness of many of these products and, in time, will evaluate all of them. Although OTC drugs have been found to be safe when taken as directed, nurses should consider several problems related to OTC drug use:

- Taking these drugs could mask the signs and symptoms of underlying disease, making diagnosis difficult.
- Taking these drugs with prescription medications could result in drug interactions and interfere with drug therapy.
- Not taking these drugs as directed could result in serious overdoses.

Many patients do not consider OTC drugs to be medications and therefore do not report their use. Nurses must always include specific questions about OTC drug use when taking a drug history and should provide information in all drug-teaching protocols about avoiding OTC use while taking prescription drugs.

KEY POINTS

- ♦ Generic drugs are drugs no longer protected by patent and can be produced by companies other than the one that developed it.
- ♦ Over-the-counter (OTC) drugs are available without a prescription and are deemed safe when used as directed.
- ♦ Orphan drugs are drugs that have been discovered but that are not financially viable because they have a limited market or a narrow margin of safety. These drugs may have then been adopted for development by a drug company in exchange for tax incentives.

SOURCES OF DRUG INFORMATION

The fields of pharmacology and drug therapy change so quickly that it is important to have access to sources of information about drug doses, therapeutic and adverse effects, and nursing-related implications. Textbooks provide valuable background and basic information to help in the understanding of pharmacology, but in clinical practice it is important to have access

to up-to-the-minute information. Several sources of drug information are readily available. Nurses often need to consult more than one source.

Drug Labels

Drug labels have specific information that identifies a specific drug. For example, a drug label identifies the brand and generic names for the drug, the drug dosage, the expiration date, and special drug warnings. Some labels also indicate the route and dose for administration. Figure 1.4 illustrates an example of a drug label.

Understanding how to read a drug label is essential. Nurses need to become familiar with each aspect of the label.

Package Inserts

All drugs come with a package insert prepared by the manufacturer according to strict FDA regulations. The package insert contains all of the chemical and study information that led to the drug’s approval. Package inserts sometimes are difficult to understand and are almost always in very small print, making them difficult to read. The FDA Web site, www.fda.gov,

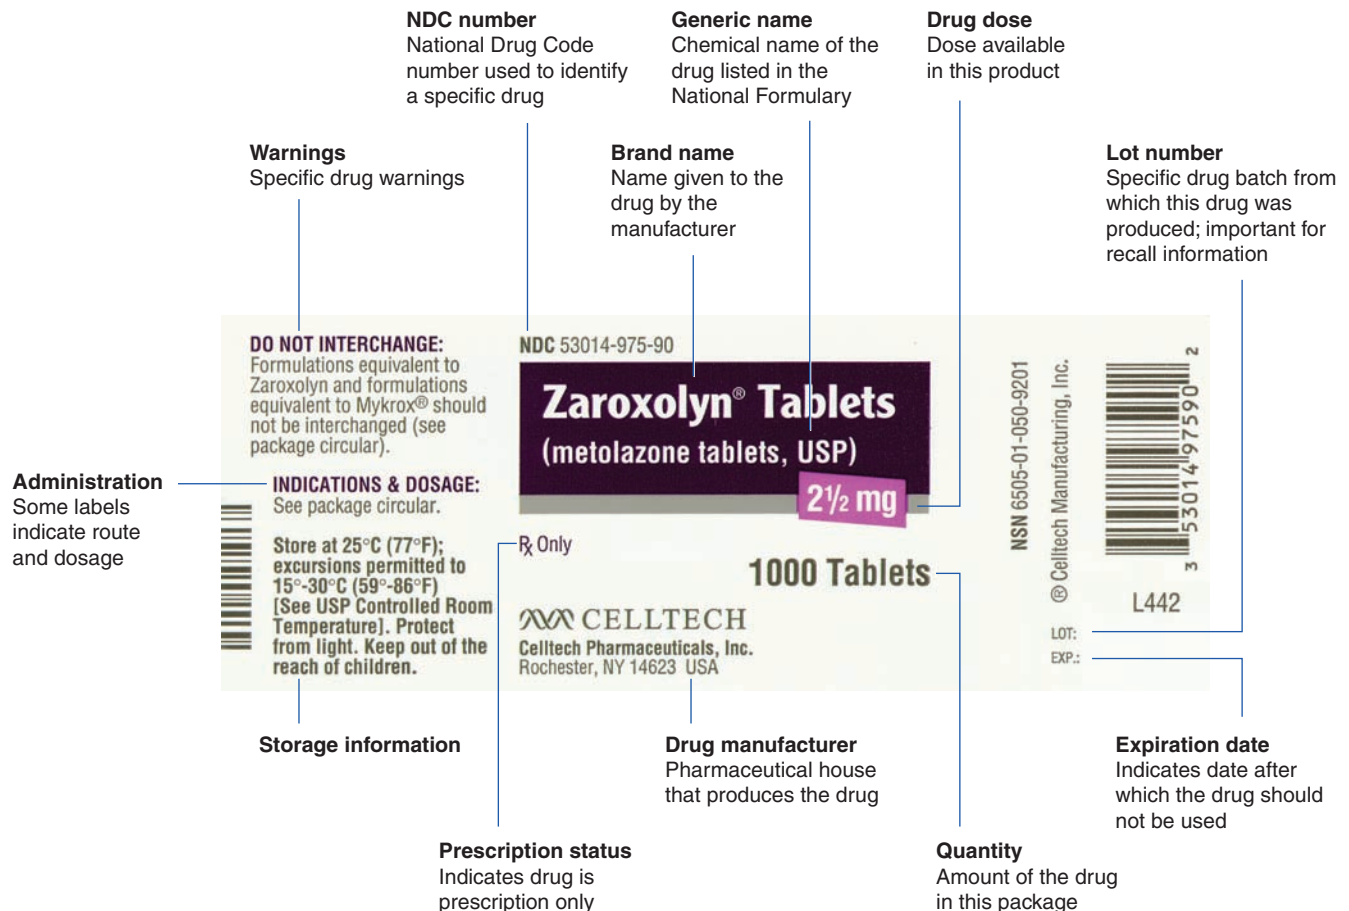

is a good resource for finding the prescribing information or package insert for most drugs.

Reference Books

A wide variety of reference books are available for drug information. The *Physician’s Drug Reference (PDR)* is a compilation of the package insert information from drugs used in this country, along with some drug advertising. Because this information comes directly from the manufacturers and is not refereed in any way, it may not be the best source for obtaining accurate information about a drug. This information is heavily cross-referenced. The book may be difficult to use.

Drug Facts and Comparisons provides a wide range of drug information, including comparisons of drug costs, patient information sections, and preparation and administration guidelines. This book is organized by drug class and can be more user-friendly than the *PDR*. However, it is cumbersome and very expensive.

AMA Drug Evaluations contains detailed monographs in an unbiased format and includes many new drugs and drugs still in the research stage.

Lippincott's Nursing Drug Guide (LNDG) has drug monographs organized alphabetically and includes nursing implications and patient teaching points.

Numerous other drug handbooks are also on the market and readily available for nurses to use.

Journals

Various journals can be used to obtain drug information. For example, the *Medical Letter* is a monthly review of new drugs, drug classes, and specific treatment protocols. The *American Journal of Nursing* offers information on new drugs, drug errors, and nursing implications.

Internet Information

Many patients now use the Internet as a source of medical information and advice. Box 1.3 lists some informative Internet

sites for obtaining drug information, patient information, or therapeutic information related to specific disease states. Nurses need to become familiar with what is available on the Internet and what patients may be referencing.

CHAPTER SUMMARY

- Drugs are chemicals that are introduced into the body to bring about some sort of change.
- Drugs can come from many sources: plants, animals, inorganic elements, and synthetic preparations.
- The FDA regulates the development and marketing of drugs to ensure safety and efficacy.
- Preclinical trials involve testing of potential drugs on laboratory animals to determine their therapeutic and adverse effects.

- Phase I studies test potential drugs on healthy human subjects.
- Phase II studies test potential drugs on patients who have the disease the drugs are designed to treat.
- Phase III studies test drugs in the clinical setting to determine any unanticipated effects or lack of effectiveness.
- FDA pregnancy categories indicate the potential or actual teratogenic effects of a drug.
- DEA controlled-substance categories indicate the abuse potential and associated regulation of a drug.
- Generic drugs are sold under their chemical names, not brand names; they may be cheaper but are not necessarily as safe as brand-name drugs.
- Orphan drugs are chemicals that have been discovered to have some therapeutic effect but that are not financially advantageous to develop into drugs.
- OTC drugs are available without prescription for the self-treatment of various complaints.

- Information about drugs can be obtained from a variety of sources, including the drug label, reference books, journals, and Internet sites.

WEB LINKS

Health care providers and students may want to consult the following Internet sources:

<http://www.fda.gov/cder/learn/CDERLearn/prescription/Labeling/default.htm>.

For review of the components of the prescribing information requirements.

http://www.fda.gov/cder/dsn/2008_winter/toc.htm.

For up-to-the minute reports of drug safety, development, and education.

<http://www.fda.gov/cder/handbook/develop.htm>.

For an interactive review of the drug approval process.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-Rom in the front of this book.

MULTIPLE CHOICE

Select the best answer to the following:

- Clinical pharmacology is the study of
 - the biological effects of chemicals.
 - drugs used to treat, prevent, or diagnose disease.
 - plant components that can be used as medicines.
 - binders and other vehicles for delivering medication.
- Phase I drug studies involve
 - the use of laboratory animals to test chemicals.
 - patients with the disease the drug is designed to treat.
 - mass marketing surveys of drug effects in large numbers of people.
 - healthy human volunteers who are often paid for their participation.
- The generic name of a drug is
 - the name assigned to the drug by the pharmaceutical company developing it.
 - the chemical name of the drug based on its chemical structure.
 - the original name assigned to the drug at the beginning of the evaluation process.
 - the name that is often used in advertising campaigns.
- An orphan drug is a drug that
 - has failed to go through the approval process.
 - is available in a foreign country but not in this country.
 - has been tested but is not considered to be financially viable.
 - is available without a prescription.
- The FDA pregnancy categories
 - indicate a drug's potential or actual teratogenic effects.
 - are used for research purposes only.
 - list drugs that are more likely to have addicting properties.
 - are tightly regulated by the DEA.
- The storing, prescribing, and distributing of controlled substances—drugs that are more apt to be addictive—are monitored by
 - the FDA.
 - the Department of Commerce.
 - the FBI.
 - the DEA.
- Healthy young women are not usually involved in phase I studies of drugs because
 - male bodies are more predictable and responsive to chemicals.
 - females are more apt to suffer problems with ova, which are formed only before birth.
 - males can tolerate the unknown adverse effects of many drugs better than females.
 - there are no standards to use to evaluate the female response.

8. A patient has been taking fluoxetine (*Prozac*) for several years, but when picking up the prescription this month, found that the tablets looked different and became concerned. The nurse, checking with the pharmacist, found that fluoxetine had just become available in the generic form and the prescription had been filled with the generic product. The nurse should tell the patient
- that the new tablet may not work at all and the patient should carefully monitor response.
 - that generic drugs are available without a prescription and they are just as safe as the brand-name medication.
 - that the law requires that prescriptions be filled with the generic form if available to cut down the cost of medications.
 - that the pharmacist filled the prescription with the wrong drug and it should be returned to the pharmacy for a refund.
- d. Reading the label of these drugs is very important; the active ingredient is very prominent; you should always check the ingredient name.
- e. It is important to read the label and to see what the recommended dose of the drug is; some of these drugs can cause serious problems if too much of the drug is taken
- f. It is important to report the use of any OTC drug to your health care provider because many of them can interact with drugs that might be prescribed for you.
2. A patient asks what generic drugs are and if he should be using them to treat his infection. Which of the following statements should be included in the nurse's explanation?
- A generic drug is a drug that is sold by the name of the ingredient, not the brand name.
 - Generic drugs are always the best drugs to use because they are never any different from the familiar brand names.
 - Generic drugs are not available until the patent expires on a specific drug.
 - Generic drugs are usually cheaper than the well-known brand names, and some insurance companies require that you receive the generic drug if one is available.
 - Generic drugs are forms of a drug that are available over the counter and do not require a prescription.
 - Your physician may want you to have the brand name of a drug, not the generic form, and DAW, or "dispense as written," will be on your prescription form.
 - Generic drugs are less likely to cause adverse effects than brand-name drugs.

MULTIPLE RESPONSE

Select all that apply:

1. When teaching a patient about over-the-counter (OTC) drugs, which points should the nurse include?
- These drugs are very safe and can be used freely to relieve your complaints.
 - These compounds are called drugs, but they aren't really drugs.
 - Some of these drugs were once prescription drugs, but are now thought to be safe when used as directed.

Drugs and the Body

2

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Describe how body cells respond to the presence of drugs that are capable of altering their function.
2. Outline the process of dynamic equilibrium that determines the actual concentration of a drug in the body.
3. Explain the meaning of half-life of a drug and calculate the half-life of given drugs.
4. List at least six factors that can influence the actual effectiveness of drugs in the body.
5. Define drug–drug, drug–alternative therapy, drug–food, and drug–laboratory test interactions.

Glossary of Key Terms

absorption: what happens to a drug from the time it enters the body until it enters the circulating fluid; intravenous administration causes the drug to directly enter the circulating blood, bypassing the many complications of absorption from other routes

active transport: the movement of substances across a cell membrane against the concentration gradient; this process requires the use of energy

chemotherapeutic agents: synthetic chemicals used to interfere with the functioning of foreign cell populations; this term is frequently used to refer to the drug therapy of neoplasms, but it also refers to drug therapy affecting any foreign cell

critical concentration: the concentration a drug must reach in the tissues that respond to the particular drug to cause the desired effect

distribution: movement of a drug to body tissues; the places where a drug may be distributed depend on the drug's solubility, perfusion of the area, cardiac output, and binding of the drug to plasma proteins

enzyme induction: process by which the presence of a chemical that is biotransformed by a particular enzyme system in the liver causes increased activity of that enzyme system

excretion: removal of a drug from the body; primarily occurs in the kidneys, but can also occur through the skin, lungs, bile, or feces

first-pass effect: a phenomenon in which drugs given orally are carried directly to the liver after absorption, where they may be largely inactivated by liver enzymes before they can enter the general circulation; oral drugs frequently are given in higher doses than drugs given by other routes because of this early breakdown

glomerular filtration: the passage of water and water-soluble components from the plasma into the renal tubule.

half-life: the time it takes for the amount of drug in the body to decrease to one half of the peak level it previously achieved

hepatic microsomal system: liver enzymes tightly packed together in the hepatic intracellular structure, responsible for the biotransformation of chemicals, including drugs

loading dose: use of a higher dose than that which is usually used for treatment to allow the drug to reach the critical concentration sooner

passive diffusion: movement of substances across a semi-permeable membrane with the concentration gradient; this process does not require energy

pharmacodynamics: the science that deals with the interactions between the chemical components of living systems and the foreign chemicals, including drugs, that enter living organisms; the way a drug affects a body

pharmacogenomics: the study of genetically determined variations in the response to drugs

pharmacokinetics: the way the body deals with a drug, including absorption, distribution, biotransformation, and excretion

placebo effect: documented effect of the mind on drug therapy; if a person perceives that a drug will be effective, the drug is much more likely to actually be effective

receptor sites: specific areas on cell membranes that react with certain chemicals to cause an effect within the cell

selective toxicity: property of a chemotherapeutic agent that affects only systems found in foreign cells without affecting healthy human cells (e.g., specific antibiotics can affect certain proteins or enzyme systems used by bacteria but not by human cells)

To understand what happens when a drug is administered, the nurse must understand **pharmacodynamics**—how the drug affects the body—and **pharmacokinetics**—how the body acts on the drug. These processes form the basis for the guidelines that have been established regarding drug administration—for example, why certain agents are given intramuscularly (IM) and not intravenously (IV), why some drugs are taken with food and others are not, and the standard dose that should be used to achieve the desired effect. Knowing the basic principles of pharmacodynamics and pharmacokinetics helps the nurse to anticipate therapeutic and adverse drug effects and to intervene in ways that ensure the most effective drug regimen for the patient.

PHARMACODYNAMICS

Pharmacodynamics is the science dealing with interactions between the chemical components of living systems and the foreign chemicals, including drugs, that enter those systems. All living organisms function by a series of complicated, continual chemical reactions. When a new chemical enters the system, multiple changes in and interferences with cell functioning may occur. To avoid such problems, drug development works to provide the most effective and least toxic chemicals for therapeutic use.

Drugs usually work in one of four ways:

1. To replace or act as substitutes for missing chemicals.
2. To increase or stimulate certain cellular activities.
3. To depress or slow cellular activities.
4. To interfere with the functioning of foreign cells, such as invading microorganisms or neoplasms. (Drugs that act in this way are called **chemotherapeutic agents**.)

Drugs can act in several different ways to achieve these results.

Receptor Sites

Many drugs are thought to act at specific areas on cell membranes called **receptor sites**. The receptor sites react with certain chemicals to cause an effect within the cell. In many situations, nearby enzymes break down the reacting chemicals and open the receptor site for further stimulation.

To better understand this process, think of how a key works in a lock. The specific chemical (the key) approaches a cell membrane and finds a perfect fit (the lock) at a receptor site (Figure 2.1). The interaction between the chemical and the receptor site affects enzyme systems within the cell. The activated enzyme systems then produce certain effects, such as increased or decreased cellular activity, changes in cell membrane permeability, or alterations in cellular metabolism.

Some drugs interact directly with receptor sites to cause the same activity that natural chemicals would cause at that site. These drugs are called *agonists* (Figure 2.1A). For example, insulin reacts with specific insulin-receptor sites to change cell membrane permeability, thus promoting the movement of glucose into the cell.

Other drugs act to prevent the breakdown of natural chemicals that are stimulating the receptor site. For example, monoamine oxidase (MAO) inhibitors block the breakdown of norepinephrine by the enzyme MAO. (Normally, MAO breaks down norepinephrine, removes it from the receptor site, and recycles the components to form new norepinephrine.) The blocking action of MAO inhibitors allows norepinephrine to stay on the receptor site, stimulating the cell longer and leading to prolonged norepinephrine effects. Those effects can be therapeutic (e.g., relieving depression) or adverse (e.g., increasing heart rate and blood pressure). Selective serotonin reuptake inhibitors (SSRIs) work similarly to MAO inhibitors in that they also exert a blocking action. Specifically, they block removal of serotonin from receptor sites. This action leads to prolonged stimulation of certain brain cells, which is thought to provide relief from depression.

Some drugs react with receptor sites to block normal stimulation, producing no effect. For example, curare (a drug used on the tips of spears by inhabitants of the Amazon basin to paralyze prey and cause death) occupies receptor sites for acetylcholine, which is necessary for muscle contraction and movement. Curare prevents muscle stimulation, causing paralysis. Curare is said to be a *competitive antagonist* of acetylcholine (Figure 2.1B).

Still other drugs react with specific receptor sites on a cell and, by reacting there, prevent the reaction of another chemical with a different receptor site on that cell. Such drugs are called *noncompetitive antagonists* (Figure 2.1C). For some drugs, the actual mechanisms of action are unknown. Speculation exists, however, that many drugs use receptor-site mechanisms to bring about their effects.

Drug–Enzyme Interactions

Drugs also can cause their effects by interfering with the enzyme systems that act as catalysts for various chemical reactions. Enzyme systems work in a cascade fashion, with one enzyme activating another, and then that enzyme activating another, until a cellular reaction eventually occurs. If a single step in one of the many enzyme systems is blocked, normal cell function is disrupted. Acetazolamide (*Diamox*) is a diuretic that blocks the enzyme carbonic anhydrase, which subsequently causes alterations in the hydrogen ion and water exchange system in the kidney, as well as in the eye.

Selective Toxicity

Ideally, all chemotherapeutic agents would act only on enzyme systems that are essential for the life of a pathogen or neoplastic cell and would not affect healthy cells. The ability of a drug to attack only those systems found in foreign cells is known as **selective toxicity**. Penicillin, an antibiotic used to treat bacterial infections, has selective toxicity. It affects an enzyme system unique to bacteria, causing bacterial cell death without disrupting normal human cell functioning.

Unfortunately, most other chemotherapeutic agents also destroy normal human cells, causing many of the adverse effects associated with antipathogen and antineoplastic chemotherapy.

● **FIGURE 2.1** Receptor theory of drug action. **A.** Agonist interaction with receptor site on cell. Molecules of drug A react with specific receptor sites on cells of effector organs and change the cells' activity. **B.** Competitive antagonism. Drug A and drug C have an affinity for the same receptor sites and compete for these sites; drug C has a greater affinity, occupies more of the sites, and antagonizes drug A. **C.** Noncompetitive antagonism. Drug D reacts with a receptor site that is different from the receptor site for drug A but still somehow prevents drug A from binding with its receptor sites. Drugs that act by inhibiting enzymes can be pictured as acting similarly to the receptor site antagonists illustrated in panels B and C. Enzyme inhibitors block the binding of molecules of normal substrate to active sites on the enzyme.

Cells that reproduce or are replaced rapidly (e.g., bone marrow cells, gastrointestinal [GI] cells, hair follicles) are more easily affected by these agents. Consequently, the goal of many chemotherapeutic regimens is to deliver a dose that will be toxic to the invading cells yet cause the least amount of toxicity to the host.

KEY POINTS

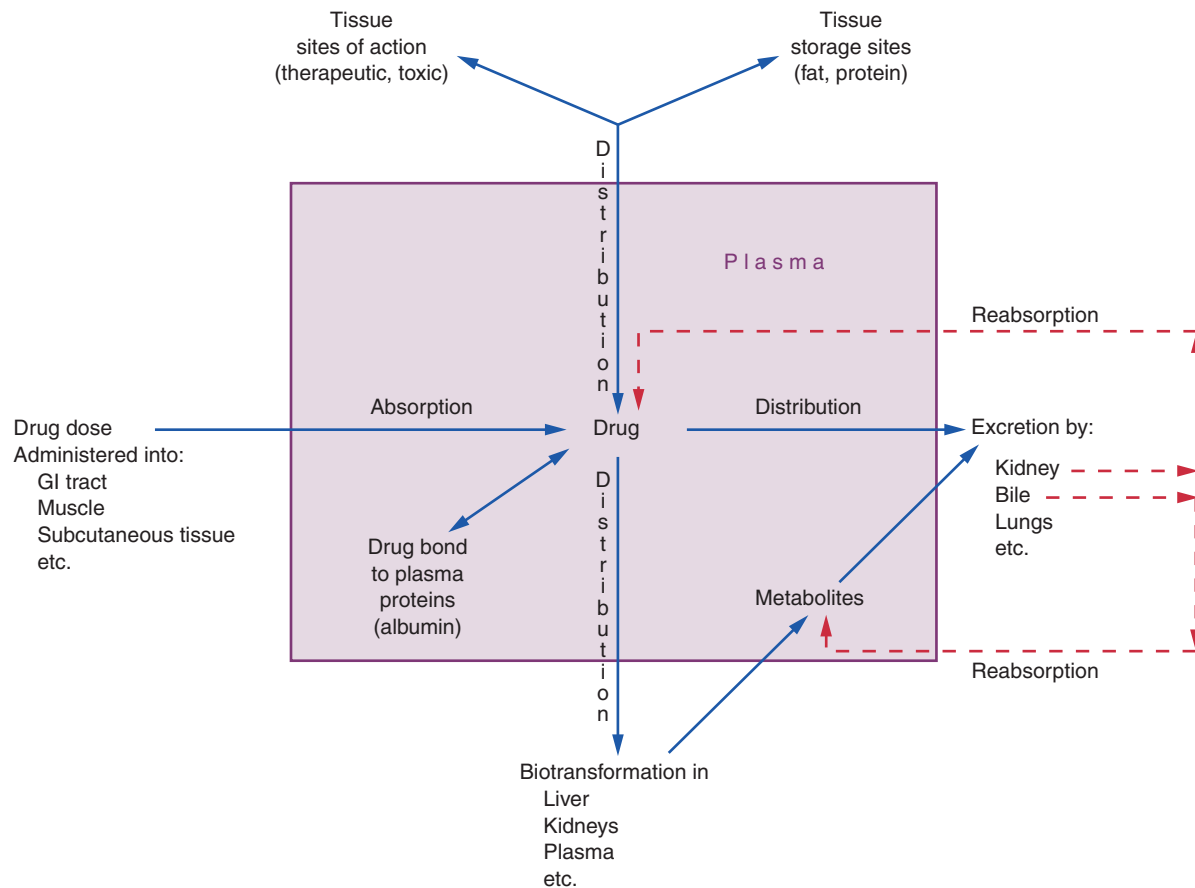

- ▶ Pharmacodynamics is the process by which a drug works or affects the body.
- ▶ Drugs may work by replacing a missing body chemical, by stimulating or depressing cellular activity, or by interfering with the functioning of foreign cells.
- ▶ Drugs are thought to work by reacting with specific receptor sites or by interfering with enzyme systems in the body.

PHARMACOKINETICS

Pharmacokinetics involves the study of absorption, distribution, metabolism (biotransformation), and excretion of drugs. In clinical practice, pharmacokinetic considerations include the onset of drug action, drug half-life, timing of the peak effect, duration of drug effects, metabolism or biotransformation of the drug, and the site of excretion. Figure 2.2 outlines these processes, which are described in the following sections.

Critical Concentration

After a drug is administered, its molecules first must be absorbed into the body; then they make their way to the reactive tissues. If a drug is going to work properly on these reactive tissues, and thereby have a therapeutic effect, it must attain a

● **FIGURE 2.2** The processes by which a drug is handled by the body. Dashed lines indicate that some portion of a drug and its metabolites may be reabsorbed from the excretory organs. The dynamic equilibrium of pharmacokinetics is shown.

sufficiently high concentration in the body. The amount of a drug that is needed to cause a therapeutic effect is called the **critical concentration**.

Drug evaluation studies determine the critical concentration required to cause a desired therapeutic effect. The recommended dose of a drug is based on the amount that must be given to eventually reach the critical concentration. Too much of a drug will produce toxic (poisonous) effects, and too little will not produce the desired therapeutic effects.

Loading Dose

Some drugs may take a prolonged period to reach a critical concentration. If their effects are needed quickly, a loading dose is recommended. Digoxin (*Lanoxin*)—a drug used to increase the strength of heart contractions—and many of the xanthine bronchodilators (e.g., aminophylline, theophylline) used to treat asthma attacks are often started with a **loading dose** (a higher dose than that usually used for treatment) to reach the critical concentration. The critical concentration then is maintained by using the recommended dosing schedule.

Dynamic Equilibrium

The actual concentration that a drug reaches in the body results from a dynamic equilibrium involving several processes:

- Absorption from the site of entry
- Distribution to the active site
- Biotransformation (metabolism) in the liver
- Excretion from the body

These processes are key elements in determining the amount of drug (dose) and the frequency of dose repetition (scheduling) required to achieve the critical concentration for the desired length of time. When administering a drug, the nurse needs to consider the phases of pharmacokinetics so that the drug regimen can be made as effective as possible.

Absorption

To reach reactive tissues, a drug must first make its way into the circulating fluids of the body. **Absorption** refers to what happens to a drug from the time it is introduced to the body until it reaches the circulating fluids and tissues. Drugs can be absorbed from many different areas in the body: through the GI tract either orally or rectally, through mucous membranes,

through the skin, through the lung, or through muscle or subcutaneous tissues (Figure 2.2).

Routes of Administration

Drug absorption is influenced by the route of administration. Generally, drugs given by the oral route are absorbed more slowly than those given parenterally. Of the parenteral route, intravenously administered drugs are absorbed the fastest.

The oral route is the most frequently used drug administration route in clinical practice. Oral administration is not invasive, and, as a rule, oral administration is less expensive than drug administration by other routes. It is also the safest way to deliver drugs. Patients can easily continue their drug regimen at home when they are taking oral medications.

Oral administration subjects the drug to a number of barriers aimed at destroying ingested foreign chemicals. The acidic environment of the stomach is one of the first barriers to foreign chemicals. The acid breaks down many compounds and inactivates others. This fact is taken into account by pharmaceutical companies when preparing drugs in capsule or tablet form. The binders that are used often are designed to break down in a certain acidity and release the active drug to be absorbed.

When food is present, stomach acidity is higher and the stomach empties more slowly, thus exposing the drug to the acidic environment for a longer period. Certain foods that increase stomach acidity, such as milk products, alcohol, and protein, also speed the breakdown of many drugs. Other foods may chemically bind drugs or block their absorption. To decrease the effects of this acid barrier and the direct effects of certain foods, oral drugs ideally are to be given 1 hour before or 2 hours after a meal.

Some drugs that cannot survive in sufficient quantity when given orally are administered via injection directly into the body. Drugs that are injected intravenously (IV) reach their full strength at the time of injection, avoiding initial breakdown. Basically, these drugs have an immediate onset and are fully absorbed at administration because they directly enter the blood stream. These drugs are more likely to cause toxic effects because the margin for error in dose is much smaller.

Drugs that are injected intramuscularly (IM) are absorbed directly into the capillaries in the muscle and sent into circulation. This takes time because the drug must be picked up by the capillary and taken into the veins. Men have more vascular muscles than women do. As a result, drugs administered to men via the IM route reach a peak level faster than they do in women. Subcutaneous injections deposit the drug just under the skin, where it is slowly absorbed into circulation. Timing of absorption varies with subcutaneous injection, depending on the fat content of the injection site and the state of local circulation. Table 2.1 outlines the various factors that affect drug absorption for different routes of administration.

Absorption Processes

Drugs can be absorbed into cells through various processes, which include passive diffusion, active transport, and filtration. **Passive diffusion** is the major process through which

TABLE 2.1 Factors That Affect Absorption of Drugs

ROUTE	FACTORS AFFECTING ABSORPTION
IV (intravenous)	None: direct entry into the venous system
IM (intramuscular)	Perfusion or blood flow to the muscle Fat content of the muscle Temperature of the muscle: cold causes vasoconstriction and decreases absorption; heat causes vasodilation and increases absorption
Subcutaneous	Perfusion or blood flow to the tissue Fat content of the tissue Temperature of the tissue: cold causes vasoconstriction and decreases absorption; heat causes vasodilation and increases absorption
PO (oral)	Acidity of stomach Length of time in stomach Blood flow to gastrointestinal tract Presence of interacting foods or drugs
PR (rectal)	Perfusion or blood flow to the rectum Lesions in the rectum Length of time retained for absorption
Mucous membranes (sublingual, buccal)	Perfusion or blood flow to the area Integrity of the mucous membranes Presence of food or smoking
Topical (skin)	Length of time retained in area Perfusion or blood flow to the area Integrity of skin
Inhalation	Perfusion or blood flow to the area Integrity of lung lining Ability to administer drug properly

drugs are absorbed into the body. Passive diffusion occurs across a concentration gradient. When there is a greater concentration of drug on one side of a cell membrane, the drug will move through the membrane to the area of lower concentration. This process does not require any cellular energy. It occurs more quickly if the drug molecule is small, is soluble in water and in lipids (cell membranes are made of lipids and proteins—see Chapter 7), and has no electrical charge that could repel it from the cell membrane.

Unlike passive diffusion, **active transport** is a process that uses energy to actively move a molecule across a cell membrane. The molecule may be large, or it may be moving against a concentration gradient. This process is not very

important in the absorption of most drugs, but it is often a very important process in drug excretion in the kidney.

Filtration involves movement through pores in the cell membrane, either down a concentration gradient or as a result of the pull of plasma proteins (when pushed by hydrostatic, blood, or osmotic pressure). Filtration is another process the body commonly uses in drug excretion.

Distribution

Distribution involves the movement of a drug to the body's tissues (Figure 2.2). As with absorption, factors that can affect distribution include the drug's lipid solubility and ionization and the perfusion of the reactive tissue.

For example, tissue perfusion is a factor in treating a patient with diabetes who has a lower-leg infection and needs antibiotics to destroy the bacteria in the area. In this case, systemic drugs may not be effective because part of the disease process involves changes in the vasculature and decreased blood flow to some areas, particularly the lower limbs. If there is not adequate blood flow to the area, little antibiotic can be delivered to the tissues, and little antibiotic effect will be seen.

In the same way, patients in a cold environment may have constricted blood vessels (vasoconstriction) in the extremities, which would prevent blood flow to those areas. The circulating blood would be unable to deliver drugs to those areas, and the patient would receive little therapeutic effect from drugs intended to react with those tissues.

Many drugs are bound to proteins and are not lipid soluble. These drugs cannot be distributed to the central nervous system (CNS) because of the effective blood–brain barrier (see later discussion), which is highly selective in allowing lipid-soluble substances to pass into the CNS.

Protein Binding

Most drugs are bound to some extent to proteins in the blood to be carried into circulation. The protein–drug complex is relatively large and cannot enter into capillaries and then into tissues to react. The drug must be freed from the protein's binding site at the tissues.

Some drugs are tightly bound and are released very slowly. These drugs have a very long duration of action because they are not free to be broken down or excreted. Therefore, they are released very slowly into the reactive tissue. Some drugs are loosely bound; they tend to act quickly and to be excreted quickly. Some drugs compete with each other for protein binding sites, altering effectiveness or causing toxicity when the two drugs are given together.

Blood–Brain Barrier

The blood–brain barrier is a protective system of cellular activity that keeps many things (e.g., foreign invaders, poisons) away from the CNS. Drugs that are highly lipid soluble are more likely to pass through the blood–brain barrier and reach the CNS. Drugs that are not lipid soluble are not able to pass the blood–brain barrier. This is clinically significant in treating a brain infection with antibiotics. Almost all antibiotics are not lipid soluble and cannot cross the blood–brain

barrier. Effective antibiotic treatment can occur only when the infection is severe enough to alter the blood–brain barrier and allow antibiotics to cross.

Although many drugs can cause adverse CNS effects, these are often the result of indirect drug effects and not the actual reaction of the drug with CNS tissue. For example, alterations in glucose levels and electrolyte changes can interfere with nerve functioning and produce CNS effects such as dizziness, confusion, or changes in thinking ability.

Placenta and Breast Milk

Many drugs readily pass through the placenta and affect the developing fetus in pregnant women. As stated earlier, it is best not to administer any drugs to pregnant women because of the possible risk to the fetus. Drugs should be given only when the benefit clearly outweighs any risk. Many other drugs are secreted into breast milk and therefore have the potential to affect the neonate. Because of this possibility, the nurse must always check the ability of a drug to pass into breast milk when giving a drug to a breast-feeding mother.

Biotransformation (Metabolism)

The body is well prepared to deal with a myriad of foreign chemicals. Enzymes in the liver, in many cells, in the lining of the GI tract, and even circulating in the body detoxify foreign chemicals to protect the fragile homeostasis that keeps the body functioning (Figure 2.2). Almost all of the chemical reactions that the body uses to convert drugs and other chemicals into nontoxic substances are based on a few processes that work to make the chemical less active and more easily excreted from the body.

The liver is the most important site of drug metabolism, or **biotransformation**, the process by which drugs are changed into new, less active chemicals. Think of the liver as a sewage treatment plant. Everything that is absorbed from the GI tract first enters the liver to be “treated.” The liver detoxifies many chemicals and uses others to produce needed enzymes and structures.

First-Pass Effect

Drugs that are taken orally are usually absorbed from the small intestine directly into the portal venous system (the blood vessels that flow through the liver on their way back to the heart). Aspirin and alcohol are two drugs that are known to be absorbed from the lower end of the stomach. The portal veins deliver these absorbed molecules into the liver, which immediately transforms most of the chemicals delivered to it by a series of liver enzymes. These enzymes break the drug into metabolites, some of which are active and cause effects in the body, and some of which are deactivated and can be readily excreted from the body. As a result, a large percentage of the oral dose is destroyed at this point and never reaches the tissues. This phenomenon is known as the **first-pass effect**. The portion of the drug that gets through the first-pass effect is delivered to the circulatory system for transport throughout the body.

Injected drugs and drugs absorbed from sites other than the GI tract undergo a similar biotransformation when they pass through the liver. Because some of the active drug already has had a chance to reach the reactive tissues before reaching the liver, the injected drug is often more effective at a lower dose than the oral equivalent. Thus, the recommended dose for oral drugs can be considerably higher than the recommended dose for parenteral drugs, taking the first-pass effect into account.

Hepatic Enzyme System

The intracellular structures of the hepatic cells are lined with enzymes packed together in what is called the **hepatic microsomal system**. Because orally administered drugs enter the liver first, the enzyme systems immediately work on the absorbed drug to biotransform it. As explained earlier, this first-pass effect is responsible for neutralizing most of the drugs that are taken. Phase I biotransformation involves oxidation, reduction, or hydrolysis of the drug via the cytochrome P450 system of enzymes. These enzymes are found in most cells but are especially abundant in the liver. Table 2.2 gives some examples of drugs that induce or inhibit the cytochrome P450 system. Phase II biotransformation usually involves a conjugation reaction that makes the drug more polar and more readily excreted by the kidneys.

The presence of a chemical that is metabolized by a particular enzyme system often increases the activity of that enzyme system. This process is referred to as **enzyme induction**. Only a few basic enzyme systems are responsible for metabolizing most of the chemicals that pass through the liver. Increased activity in an enzyme system speeds the metabolism of the drug that caused the enzyme induction, as well as any other drug that is metabolized via that same enzyme system. This explains why some drugs cannot be taken together effectively: The presence of one drug speeds the metabolism of others, preventing them from reaching their therapeutic levels. Some drugs inhibit an enzyme system, making it less effective. As a consequence, any drug that is metabolized by that system will not be broken down for excretion, and the blood levels of that drug will increase, often to toxic levels. These actions also explain why liver disease is often a contraindication or a reason to use caution when administering certain drugs. If the liver is not functioning effectively, the drug will not be metabolized as it should be, and toxic levels could develop rather quickly.

TABLE 2.2 Examples of Drugs That Alter the Effects of the Cytochrome P450 Hepatic Enzyme System

DRUGS THAT INDUCE OR INCREASE ACTIVITY	DRUGS THAT INHIBIT OR DECREASE ACTIVITY
Nicotine (cigarette smoking) Alcohol (drinking) Glucocorticoids (<i>Cortone</i> , others)	Ketoconazole (<i>Nizoral</i>) Mexiletine (<i>Mexitil</i>) Quinidine (generic)

Excretion

Excretion is the removal of a drug from the body. The skin, saliva, lungs, bile, and feces are some of the routes used to excrete drugs. The kidneys, however, play the most important role in drug excretion (Figure 2.2).

Drugs that have been made water soluble in the liver are often readily excreted from the kidney by **glomerular filtration**—the passage of water and water-soluble components from the plasma into the renal tubule. Other drugs are secreted or reabsorbed through the renal tubule by active transport systems. The active transport systems that move the drug into the tubule often do so by exchanging it for acid or bicarbonate molecules. Therefore the acidity of urine can play an important role in drug excretion. This concept is important to remember when trying to clear a drug rapidly from the system or trying to understand why a drug is being given at the usual dose but is reaching toxic levels in the system. One should always consider the patient’s kidney function and urine acidity before administering a drug. Kidney dysfunction can lead to toxic levels of a drug in the body because the drug cannot be excreted. Figure 2.3 outlines the pharmacokinetic processes that occur when a drug is administered orally.

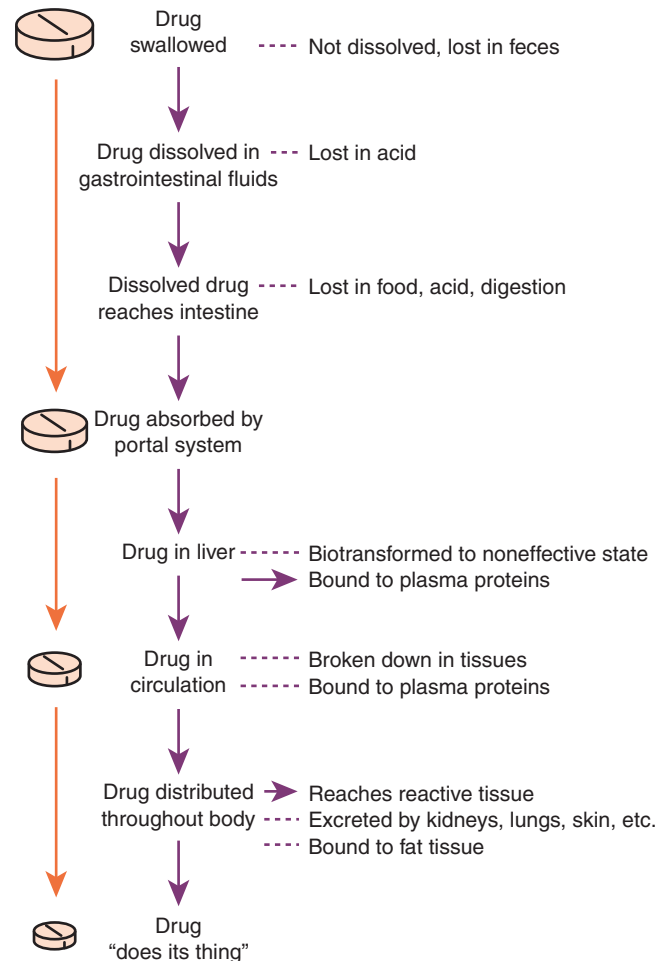

FIGURE 2.3 Pharmacokinetics affects the amount of a drug that reaches reactive tissues. Very little of an oral dose of a drug actually reaches reactive sites.

Safe Medication Administration

The liver is very important in metabolizing drugs in the body, and the kidneys are responsible for a large part of the excretion of drugs from the body. One should get into the habit of always checking a patient's liver and renal function before a patient starts a drug regimen. If the liver is not functioning properly, the drug may not be metabolized correctly and may reach toxic levels in the body. If the kidneys are not functioning properly, the drug may not be excreted properly and could accumulate in the body. Dose adjustment needs to be considered if a patient has problems with either the liver or the kidneys.

Half-Life

The **half-life** of a drug is the time it takes for the amount of drug in the body to decrease to one half of the peak level it previously achieved. For instance, if a patient takes 20 mg of a drug with a half-life of 2 hours, 10 mg of the drug will remain 2 hours after administration. Two hours later, 5 mg will be left (one half of the previous level); in 2 more hours, only 2.5 mg will remain. This information is important in determining the appropriate timing for a drug dose or determining the duration of a drug's effect on the body. (See Focus on Calculations Box 2.1.)

The absorption rate, the distribution to the tissues, the speed of biotransformation, and how fast a drug is excreted are all taken into consideration when determining the half-

life of the drug. The half-life that is indicated in any drug monograph is the half-life for a healthy person. Using this information, one can estimate the half-life of a drug for a patient with kidney or liver dysfunction (which could prolong the biotransformation and the time required for excretion of a drug), allowing the prescriber to make changes in the dosing schedule.

The timing of drug administration is important to achieve the most effective drug therapy. Nurses can use their knowledge of drug half-life to explain the importance of following a schedule of drug administration in the hospital or at home. Figure 2.4 shows the effects of drug administration on the critical concentration of a drug.

KEY POINTS

- ▶ Pharmacokinetics is the study of how the body deals with a drug.
- ▶ The concentration of a drug in the body is determined by the balance of absorption, distribution, metabolism, and excretion of the drug.
- ▶ In determining the amount, route, and appropriate timing of a drug dose, the pharmacokinetics of that drug has to be considered.

FACTORS INFLUENCING DRUG EFFECTS

When administering a drug to a patient, the nurse must be aware that the human factor has a tremendous influence on what actually happens to a drug when it enters the body. No two people react in exactly the same way to any given drug. Even though textbooks and drug guides explain the pharmacodynamics and pharmacokinetics of a drug, it must be remembered that such information usually is based on studies of healthy adult males. Things may be very different in the clinical setting. Consequently, before administering any drug, the nurse must consider a number of factors. These are discussed in detail in the following sections and summarized in Box 2.2.

Weight

The recommended dose of a drug is based on drug evaluation studies and is targeted at a 150-pound person. People who are much heavier may require larger doses to get a therapeutic effect from a drug because they have increased tissues to perfuse and increased receptor sites in some reactive tissue. People who weigh less than the norm may require smaller doses of a drug. Toxic effects may occur at the recommended dose if the person is very small.

Age

Age is a factor primarily in children and older adults. Children metabolize many drugs differently than adults do, and they have immature systems for handling drugs. Many drugs come

BOX 2.1

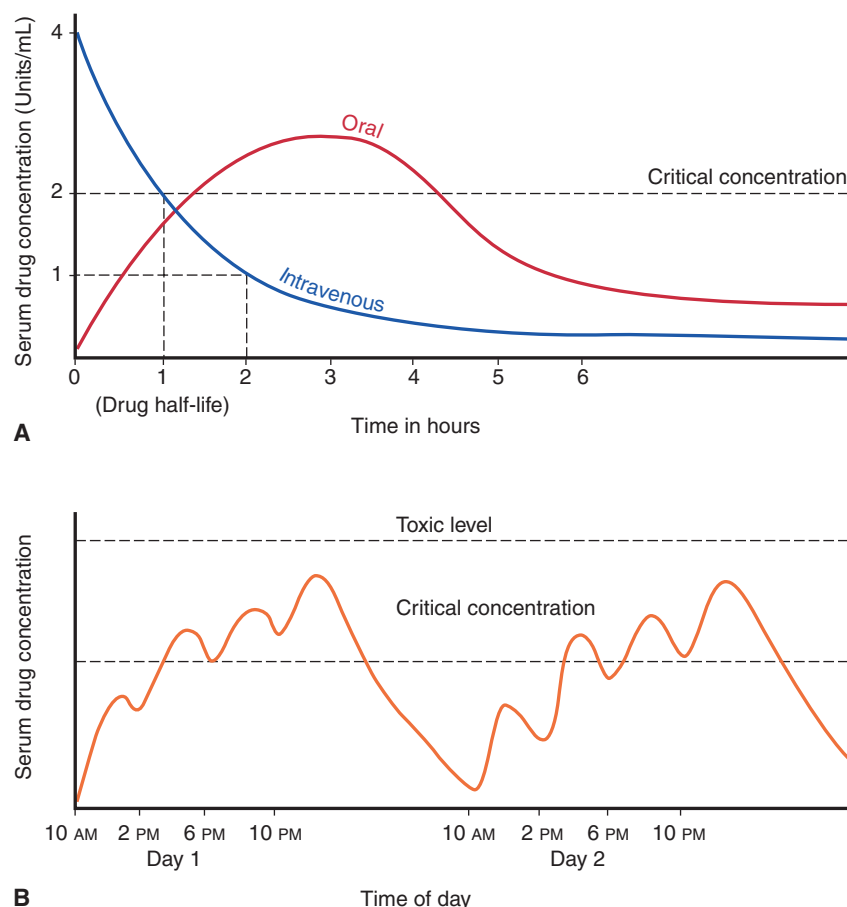

Calculations

Determining the Impact of Half-Life on Drug Levels

A patient is taking a drug that has a half-life of 12 hours. You are trying to determine when a 50-mg dose of the drug will be gone from the body:

- In 12 hours, half of the 50 mg (25 mg) would be in the body.
- In another 12 hours (24 hours), half of 25 mg (12.5 mg) would remain in the body.
- After 36 hours, half of 12.5 mg (6.25 mg) would remain.
- After 48 hours, half of 6.25 mg (3.125 mg) would remain.
- After 60 hours, half of 3.125 (1.56 mg) would remain.
- After 72 hours, half of 1.56 (0.78 mg) would remain.
- After 84 hours, half of 0.78 (0.39 mg) would remain.
- Twelve more hours (for a total of 96 hours) would reduce the drug amount to 0.195 mg.
- Finally, 12 more hours (108 hours) would reduce the amount of the drug in the body to 0.097 mg, which would be quite negligible.
- Therefore, it would take 4½ to 5 days to clear the drug from the body.

● **FIGURE 2.4** Influence of biological half-life, route of administration, and dosing regimen on serum drug levels. **A.** Influence of route of administration on the time course of drug levels after administration of a single dose of a drug. The dashed lines indicate how the biological half-life of the drug may be determined from the curve of drug concentration after an intravenous dose. At time 0, immediately after the injection, there were 4 units of the drug in each milliliter of serum. The drug concentration fell to half of this amount, 2 units/mL, after 1 hour, the drug's biological half-life. **B.** Influence of dosing regimen on serum drug levels (drug given four times daily, at 10 AM and at 2, 6, and 10 PM). The drug accumulates as successive doses are given throughout each day; the drug is being given at a rate greater than the patient's body can eliminate it. This dosing regimen has been chosen so that the patient will have a therapeutic level of the drug for a significant portion of the day yet never have a toxic level of the drug.

with recommended pediatric doses, and others can be converted to pediatric doses using one of several conversion formulas (Focus on Calculations Box 2.3).

Older adults undergo many physical changes that are a part of the aging process. Their bodies may respond very differently in all aspects of pharmacokinetics—less effective absorption, less efficient distribution because of fewer plasma proteins

and less efficient perfusion, altered biotransformation or metabolism of drugs because of age-related liver changes, and less effective excretion owing to less efficient kidneys. Many drugs now come with recommended doses for patients who are older. The doses of other drugs also may need to be decreased for the older adult.

When administering drugs to a patient at either end of the age spectrum, one should monitor the patient closely for the desired effects. If the effects are not what would normally be expected, one should consider the need for a dose adjustment.

BOX 2.2 Factors Affecting the Body's Response to a Drug

- Weight
- Age
- Gender
- Physiological factors—diurnal rhythm, electrolyte balance, acid–base balance, hydration
- Pathological factors—disease, hepatic dysfunction, renal dysfunction, gastrointestinal dysfunction, vascular disorders, low blood pressure
- Genetic factors
- Immunological factors—allergy
- Psychological factors—placebo effect, health beliefs, compliance
- Environmental factors—temperature, light, noise
- Drug tolerance
- Cumulation effects
- Interactions

Gender

Physiological differences between men and women can influence a drug's effect. When giving IM injections, for example, it is important to remember that men have more vascular muscles, so the effects of the drug will be seen sooner in men than in women.

Women have more fat cells than men do, so drugs that deposit in fat may be slowly released and cause effects for a prolonged period. For example, gas anesthetics have an affinity for depositing in fat and can cause drowsiness and sedation sometimes weeks after surgery. Women who are given any drug should always be questioned about the possibility of pregnancy because, as stated previously, the use of drugs in pregnant women is not recommended unless the benefit clearly outweighs the potential risk to the fetus.

Pediatric Doses

Children often require different doses of drugs than adults because children's bodies often handle drugs very differently from adults' bodies. The "standard" drug doses listed in package inserts and references such as the PDR refer to the adult dose. In some cases, a pediatric dose is suggested, but in many cases it will need to be calculated based on the child's age, weight, or body surface. The following are some standard formulae for calculating the pediatric dose.

Fried's Rule

$$\text{infant's dose (<1 year)} = \frac{\text{infant's age (in months)}}{150 \text{ months}} \times \text{average adult dose}$$

Young's Rule

$$\text{child's dose (1-12 years)} = \frac{\text{child's age (in years)}}{\text{child's age (in years)} + 12} \times \text{average adult dose}$$

The surface area of a child is determined using a nomogram that determines surface area based on height and weight measurements.

Pediatric dose calculations should be checked by two persons. Many institutions have procedures for double checking the dose calculation of those drugs (e.g., digoxin) used most frequently in the pediatric area.

Clark's Rule

$$\text{child's dose} = \frac{\text{weight of child (in pounds)}}{150} \times \text{average adult dose}$$

Surface Area Rule

$$\text{child's dose} = \frac{\text{surface area of child (in square meters)}}{1.73} \times \text{average adult dose}$$

Nomogram for estimating surface area of infants and young children. To determine the surface area of the patient, draw a straight line between the point representing the height on the left vertical scale and the point representing the weight on the right vertical scale. The point at which this line intersects the middle vertical scale represents the patient's surface area in square meters.

Physiological Factors

Physiological differences such as diurnal rhythm of the nervous and endocrine systems, acid–base balance, hydration, and electrolyte balance can affect the way that a drug works on the body and the way that the body handles the drug. If a drug does not produce the desired effect, one should review the patient’s acid–base and electrolyte profiles and the timing of the drug.

Pathological Factors

Drugs are usually used to treat disease or pathology. However, the disease that the drug is intended to treat can change the functioning of the chemical reactions within the body and thus change the response to the drug.

Other pathological conditions can change the basic pharmacokinetics of a drug. For example, GI disorders can affect the absorption of many oral drugs. Vascular diseases and low blood pressure alter the distribution of a drug, preventing it from being delivered to the reactive tissue, thus rendering the drug nontherapeutic. Liver or kidney diseases affect the way that a drug is biotransformed and excreted and can lead to toxic reactions when the usual dose is given.

Genetic Factors

Genetic differences can sometimes explain patients’ varied responses to a given drug. Some people lack certain enzyme systems necessary for metabolizing a drug, whereas others have overactive enzyme systems that cause drugs to be broken down more quickly. Still others have differing metabolisms or slightly different enzymatic makeups that alter their chemical reactions and the effects of a given drug.

Predictable differences in the pharmacokinetics and pharmacodynamic effects of drugs can be anticipated with people of particular cultural backgrounds because of their genetic makeup. **Pharmacogenomics** is a new area of study that explores the unique differences in response to drugs that each individual possesses based on genetic makeup. The mapping of the human genome has accelerated research in this area. It is thought that in the future, medical care and drug regimens could be individually designed based on each person’s unique genetic makeup. Trastuzumab (*Herceptin*) (see Chapter 17) is a drug that was developed to treat breast cancer when the tumor expresses human epidermal growth factor receptor 2—a genetic defect seen in some tumors. The drug has no effect on tumors that do not express that genetic defect. This drug was developed as a personalized or targeted medicine based on genetic factors. Such differences are highlighted throughout this book. In late 2007, the U.S. Food and Drug Administration (FDA) approved a blood test to check for specific genetic markers that would indicate that a patient would metabolize warfarin (*Coumadin*), an oral anticoagulant, differently than the standard patient. The test will give the prescriber information that would change the dosing schedule for the drug

and could save the patient many adverse effects while achieving the therapeutic dose for that patient.

Immunological Factors

People can develop an allergy to a drug. After exposure to its proteins, a person can develop antibodies to a drug. With future exposure to the same drug, that person may experience a full-blown allergic reaction. Sensitivity to a drug can range from mild (e.g., dermatological reactions such as a rash) to more severe (e.g., anaphylaxis, shock, and death). (Drug allergies are discussed in detail in Chapter 3.)

Psychological Factors

The patient’s attitude about a drug has been shown to have an effect on how that drug works. A drug is more likely to be effective if the patient thinks it will work than if the patient believes it will not work. This is called the **placebo effect**.

The patient’s personality also influences compliance with the drug regimen. Some people who believe that they can influence their health actively seek health care and willingly follow a prescribed regimen. These people usually trust the medical system and believe that their efforts will be positive. Other people do not trust the medical system. They may believe that they have no control over their health and may be unwilling to comply with any prescribed therapy. Knowing a patient’s health-seeking history and feelings about health care is important in planning an educational program that will work for that patient. It is also important to know this information when arranging for necessary follow-up procedures and evaluations.

As the caregiver most often involved in drug administration, the nurse is in a position to influence the patient’s attitude about drug effectiveness. Frequently, the nurse’s positive attitude, combined with additional comfort measures, can improve the patient’s response to a medication.

Environmental Factors

The environment can affect the success of drug therapy. Some drug effects are enhanced by a quiet, cool, nonstimulating environment. For example, sedating drugs are given to help a patient relax or to decrease tension. Reducing external stimuli to decrease tension and stimulation help the drug be more effective. Other drug effects may be influenced by temperature. For example, antihypertensives that work well during cold, winter months may become too effective in warmer environments, when natural vasodilation may lead to a release of heat that tends to lower the blood pressure. If a patient’s response to a medication is not as expected, look for possible changes in environmental conditions.

Tolerance

The body may develop a tolerance to some drugs over time. Tolerance may arise because of increased biotransformation of the drug, increased resistance to its effects, or other

pharmacokinetic factors. When tolerance occurs, the drug no longer causes the same reaction. Therefore, increasingly larger doses are needed to achieve a therapeutic effect. An example is morphine, an opiate used for pain relief. The longer morphine is taken, the more tolerant the body becomes to the drug, so that larger and larger doses are needed to relieve pain. Clinically, this situation can be avoided by giving the drug in smaller doses or in combination with other drugs that may also relieve pain. Cross-tolerance—or resistance to drugs within the same class—may also occur in some situations.

Cumulation

If a drug is taken in successive doses at intervals that are shorter than recommended, or if the body is unable to eliminate a drug properly, the drug can accumulate in the body, leading to toxic levels and adverse effects. This can be avoided by following the drug regimen precisely. In reality, with many people managing their therapy at home, strict compliance with a drug regimen seldom occurs. Some people take all of their medications first thing in the morning, so that they won't forget to take the pills later in the day. Others realize that they forgot a dose and then take two to make up for it. Many interruptions of everyday life can interfere with strict adherence to a drug regimen. If a drug is causing serious adverse effects, review the drug regimen with the patient to find out how the drug is being taken, and then educate the patient appropriately.

Interactions

When two or more drugs or substances are taken together, there is a possibility that an interaction can occur, causing unanticipated effects in the body. Alternative therapies, such as herbal products, act as drugs in the body and can cause these same interactions. Certain foods can interact with drugs in much the same way. Usually this is an increase or decrease in the desired therapeutic effect of one or all of the drugs or an increase in adverse effects.

Drug–Drug or Drug–Alternative Therapy Interactions

Clinically significant drug–drug interactions occur with drugs that have small margins of safety. If there is very little difference between a therapeutic dose and a toxic dose of the drug, interference with the drug's pharmacokinetics or pharmacodynamics can produce serious problems. For example, drug–drug interactions can occur in the following situations:

- *At the site of absorption:* One drug prevents or accelerates absorption of the other drug. For example, the antibiotic tetracycline is not absorbed from the GI tract if calcium or calcium products (milk) are present in the stomach.
- *During distribution:* One drug competes for the protein-binding site of another drug, so the second drug cannot be transported to the reactive tissue. For example, aspirin

competes with the drug methotrexate (*Rheumatrex*) for protein-binding sites. Because aspirin is more competitive for the sites, the methotrexate is bumped off, resulting in increased release of methotrexate and increased toxicity to the tissues.

- *During biotransformation:* One drug stimulates or blocks the metabolism of the other drug. For example, warfarin (*Coumadin*), an oral anticoagulant, is biotransformed more quickly if it is taken at the same time as barbiturates, rifampin, or many other drugs. Because the warfarin is biotransformed to an inactive state more quickly, higher doses will be needed to achieve the desired effect. Patients who use St. John's wort may experience altered effectiveness of several drugs that are affected by that herb's effects on the liver. Digoxin, theophylline, oral contraceptives, anticancer drugs, drugs used to treat HIV, and antidepressants are all reported to have serious interactions with St. John's wort.
- *During excretion:* One drug competes for excretion with the other drug, leading to accumulation and toxic effects of one of the drugs. For example, digoxin (*Lanoxin*) and quinidine are both excreted from the same sites in the kidney. If they are given together, the quinidine is more competitive for these sites and is excreted, resulting in increased serum levels of digoxin, which cannot be excreted.
- *At the site of action:* One drug may be an antagonist of the other drug or may cause effects that oppose those of the other drug, leading to no therapeutic effect. This is seen, for example, when an antihypertensive drug is taken with an antiallergy drug that also increases blood pressure. The effects on blood pressure are negated, and there is a loss of the antihypertensive effectiveness of the drug. If a patient is taking antidiabetic medication and also takes the herb ginseng, which lowers blood glucose levels, he or she may experience episodes of hypoglycemia and loss of blood glucose control.

Whenever two or more drugs are being given together, first consult a drug guide for a listing of clinically significant drug–drug interactions. Sometimes problems can be avoided by staggering the administration of the drugs or adjusting their doses.

Safe Medication Administration

Always check the monograph of any drug that is being given to monitor for clinically important drug–drug, drug–alternative therapy, or drug–food interactions.

Drug–Food Interactions

For the most part, a drug–food interaction occurs when the drug and the food are in direct contact in the stomach. Some foods increase acid production, speeding the breakdown of the drug molecule and preventing absorption and distribution

of the drug. Some foods chemically react with certain drugs and prevent their absorption into the body. The antibiotic tetracycline cannot be taken with iron products for this reason. Tetracycline also binds with calcium to some extent and should not be taken with foods or other drugs containing calcium. Grapefruit juice has been found to affect liver enzyme systems for up to 48 hours after it has been ingested. This can result in increased or decreased serum levels of certain drugs. Many drugs come with the warning that they should not be combined with grapefruit juice. This drug–food interaction does not take place in the stomach, so the grapefruit juice needs to be avoided the entire time the drug is being used, not just while the drug is in the stomach.

In most cases, oral drugs are best taken on an empty stomach. If the patient cannot tolerate the drug on an empty stomach, the food selected for ingestion with the drug should be something that is known not to interact with it. Drug monographs usually list important drug–food interactions and give guidelines for avoiding problems and optimizing the drug’s therapeutic effects.

Drug–Laboratory Test Interactions

As explained previously, the body works through a series of chemical reactions. Because of this, administration of a particular drug may alter results of tests that are done on various chemical levels or reactions as part of a diagnostic study. This drug–laboratory test interaction is caused by the drug being given and not necessarily by a change in the body’s responses or actions. Keep these interactions in mind when evaluating a patient’s diagnostic tests. If one test result is altered and does not fit in with the clinical picture or other test results, consider the possibility of a drug–laboratory test interference. For example, dalteparin (*Fragmin*), a low-molecular-weight heparin used to prevent deep vein thrombosis after abdominal surgery, may cause increased levels of the liver enzymes aspartate aminotransferase (AST) and alanine aminotransferase (ALT) with no injury to liver cells or hepatitis.

OPTIMAL THERAPEUTIC EFFECT

As overwhelming as all of this information may seem, most patients can follow a drug regimen to achieve optimal therapeutic effects without serious adverse effects. Avoiding problems is the best way to treat adverse or ineffective drug effects. One should incorporate basic history and physical assessment factors into any plan of care so that obvious problems can be spotted and handled promptly. If a drug just does not do what it is expected to do, further examine the factors that are known to influence drug effects (Box 2.2). Frequently, the drug regimen can be modified to deal with that influence. Rarely is it necessary to completely stop a needed drug regimen because of adverse or intolerable effects. In many cases, the nurse is the caregiver in the best position to assess problems early.

CHAPTER SUMMARY

- Pharmacodynamics is the study of the way that drugs affect the body.
- Most drugs work by replacing natural chemicals, by stimulating normal cell activity, or by depressing normal cell activity.
- Chemotherapeutic agents work by interfering with normal cell functioning, causing cell death. The most desirable chemotherapeutic agents are those with selective toxicity to foreign cells and foreign cell activities.
- Drugs frequently act at specific receptor sites on cell membranes to stimulate enzyme systems within the cell and to alter the cell’s activities.
- Pharmacokinetics—the study of the way the body deals with drugs—includes absorption, distribution, biotransformation, and excretion of drugs.
- The goal of established dosing schedules is to achieve a critical concentration of the drug in the body. This critical concentration is the amount of the drug necessary to achieve the drug’s therapeutic effects.
- Arriving at a critical concentration involves a dynamic equilibrium among the processes of drug absorption, distribution, metabolism or biotransformation, and excretion.
- Absorption involves moving a drug into the body for circulation. Oral drugs are absorbed from the small intestine, undergo many changes, and are affected by many things in the process. IV drugs are injected directly into the circulation and do not need additional absorption.
- Drugs are distributed to various tissues throughout the body depending on their solubility and ionization. Most drugs are bound to plasma proteins for transport to reactive tissues.
- Drugs are metabolized or biotransformed into less toxic chemicals by various enzyme systems in the body. The liver is the primary site of drug metabolism or biotransformation. The liver uses the cytochrome P450 enzyme system to alter the drug and start its biotransformation.
- The first-pass effect is the breakdown of oral drugs in the liver immediately after absorption. Drugs given by other routes often reach reactive tissues before passing through the liver for biotransformation.
- Drug excretion is removal of the drug from the body. This occurs mainly through the kidneys.
- The half-life of a drug is the period of time it takes for an amount of drug in the body to decrease to one half of the peak level it previously achieved. The half-life is affected by all aspects of pharmacokinetics. Knowing the half-life of a drug helps in predicting dosing schedules and duration of effects.
- The actual effects of a drug are determined by its pharmacokinetics, its pharmacodynamics, and many human factors that can change the drug’s effectiveness.
- To provide the safest and most effective drug therapy, the nurse must consider all of the possible factors that influence drug concentration and effectiveness.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-ROM in the front of the book.

MULTIPLE CHOICE

Select the best answer to the following.

- Chemotherapeutic agents are drugs that
 - are used only to treat cancers.
 - replace normal body chemicals that are missing because of disease.
 - interfere with foreign cell functioning, such as invading microorganisms or neoplasms.
 - stimulate the normal functioning of a cell.
- Receptor sites
 - are a normal part of enzyme substrates.
 - are protein areas on cell membranes that react with specific chemicals.
 - can usually be stimulated by many different chemicals.
 - are responsible for all drug effects in the body.
- Selective toxicity is
 - the ability of a drug to seek out a specific bacterial species or microorganism.
 - the ability of a drug to cause only specific adverse effects.
 - the ability of a drug to cause fetal damage.
 - the ability of a drug to attack only those systems found in foreign or abnormal cells.
- When trying to determine why the desired therapeutic effect is not being seen with an oral drug, the nurse should consider:
 - the blood flow to muscle beds.
 - food altering the makeup of gastric juices.
 - the weight of the patient.
 - the temperature of the peripheral environment.
- Much of the biotransformation that occurs when a drug is taken occurs as part of
 - the protein-binding effect of the drug.
 - the functioning of the renal system.
 - the first-pass effect through the liver.
 - the distribution of the drug to the reactive tissues.
- The half-life of a drug
 - is determined by a balance of all pharmacokinetic processes.
 - is a constant factor for all drugs taken by a patient.
 - is influenced by the fat distribution of the patient.
 - can be calculated with the use of a body surface nomogram.
- Jack B. has Parkinson's disease that has been controlled for several years with levodopa. After he begins a health food regimen with lots of vitamin B₆, his tremors return, and he develops a rapid heart rate, hypertension, and anxiety. The nurse investigating the problem discovers that vitamin B₆ can speed the conversion of levodopa to dopamine in the periphery, leading to these problems. The nurse would consider this problem:
 - a drug-laboratory test interaction.
 - a drug-drug interaction.
 - a cumulation effect.
 - a sensitivity reaction.

MULTIPLE RESPONSE

Select all that apply.

- When reviewing a drug to be given, the nurse notes that the drug is excreted in the urine. What points should be included in the nurse's assessment of the patient?
 - The patient's liver function tests
 - The patient's bladder tone
 - The patient's renal function tests
 - The patient's fluid intake
 - Other drugs being taken that could affect the kidney
 - The patient's intake and output for the day
- When considering the pharmacokinetics of a drug, what points would the nurse need to consider?
 - How the drug will be absorbed
 - The way the drug affects the body
 - Receptor-site activation and suppression

- d. How the drug will be excreted
- e. How the drug will be metabolized
- f. The half-life of the drug

3. Drug–drug interactions are important considerations in clinical practice. When evaluating a patient for potential drug–drug interactions, what would the nurse expect to address?
- a. Bizarre drug effects on the body
 - b. The need to adjust drug dose or timing of administration

- c. The need for more drugs to balance the effects of the drugs being given
- d. A new therapeutic effect not encountered with either drug alone
- e. Increased adverse effects
- f. The use of herbal or alternative therapies

Toxic Effects of Drugs

3

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Define the term adverse drug reaction and explain the clinical significance of this reaction.
2. List four types of allergic responses to drug therapy.
3. Discuss five common examples of drug-induced tissue damage.
4. Define the term poison.
5. Outline the important factors to consider when applying the nursing process to selected situations of drug poisoning.

Glossary of Key Terms

blood dyscrasia: bone marrow depression caused by drug effects on the rapidly multiplying cells of the bone marrow; lower-than-normal levels of blood components can be seen

dermatological reactions: skin reactions commonly seen as adverse effects of drugs; can range from simple rash to potentially fatal exfoliative dermatitis

drug allergy: formation of antibodies to a drug or drug protein; causes an immune response when the person is next exposed to that drug

hypersensitivity: excessive responsiveness to either the primary or the secondary effects of a drug; may be caused

by a pathological condition or, in the absence of one, by a particular patient's individual response

poisoning: overdose of a drug that causes damage to multiple body systems and has the potential for fatal reactions

stomatitis: inflammation of the mucous membranes related to drug effects; can lead to alterations in nutrition and dental problems

superinfections: infections caused by the destruction of bacteria of the normal flora by certain drugs, which allow other bacteria to enter the body and cause infection; may occur during the course of antibiotic therapy

All drugs are potentially dangerous. Even though chemicals are carefully screened and tested in animals and in people before they are released as drugs, drug products often cause unexpected or unacceptable reactions when they are administered. Drugs are chemicals, and the human body operates by a vast series of chemical reactions. Consequently, many effects can be seen when just one chemical factor is altered. Today's potent and amazing drugs can cause a great variety of reactions, many of which are more severe than those seen before.

ADVERSE EFFECTS

Adverse effects are undesired effects that may be unpleasant or even dangerous. They can occur for many reasons, including the following:

- The drug may have other effects on the body besides the therapeutic effect.
- The patient may be sensitive to the drug being given.
- The drug's action on the body may cause other responses that are undesirable or unpleasant.
- The patient may be taking too much or too little of the drug, leading to adverse effects.

The nurse, as the caregiver who most frequently administers medications, must be constantly alert for signs of drug reactions of various types. Patients and their families need to be taught what to look for when patients are taking drugs at home. Some adverse effects can be countered with specific comfort measures or precautions. Knowing that these effects may occur and what actions can be taken to prevent or cope with them may be the most critical factor in helping the patient to comply with drug therapy. Adverse drug effects can

be one of several types: primary actions, secondary actions, and hypersensitivity reactions.

Safe Medication Administration

Before administering any drug to a patient, it is important to review the contraindications and cautions associated with that drug, as well as the anticipated adverse effects of the drug. This information will direct your assessment of the patient, helping you to focus on particular signs and symptoms that would alert you to contraindications or to proceed cautiously, and helping you to establish a baseline for that patient so that you will be able to identify adverse effects that occur. When teaching the patient about a drug, you should list the adverse effects that should be anticipated, along with the appropriate actions that the patient can take to alleviate any discomfort associated with these effects. Being alert to adverse effects—what to assess and how to intervene appropriately—can increase the effectiveness of a drug regimen, provide for patient safety, and improve patient compliance.

Primary Actions

One of the most common occurrences in drug therapy is the development of adverse effects from simple overdose. In such cases, the patient suffers from effects that are merely an extension of the desired effect. For example, an anticoagulant may act so effectively that the patient experiences excessive and spontaneous bleeding. This type of adverse effect can be avoided by monitoring the patient carefully and adjusting the prescribed dose to fit that particular patient's needs.

In the same way, a patient taking an antihypertensive drug may become dizzy, weak, or faint when taking the "recommended dose" but will be able to adjust to the drug therapy with a reduced dose. These effects can be caused by individual response to the drug, high or low body weight, age, or underlying pathology that alters the effects of the drug.

Secondary Actions

Drugs can produce a wide variety of effects in addition to the desired pharmacological effect. Sometimes the drug dose can be adjusted so that the desired effect is achieved without producing undesired secondary reactions. Sometimes this is not possible, however, and the adverse effects are almost inevitable. In such cases, the patient needs to be informed that these effects may occur and counseled about ways to cope with the undesired effects. For example, many antihistamines are very effective in drying up secretions and helping breathing, but they also cause drowsiness. The patient who is taking antihistamines needs to know that driving a car or operating power tools or machinery should be avoided because the drowsiness could pose a serious problem. A patient taking an oral antibiotic needs to know that frequently the effects of the antibiotic on the gastrointestinal tract result in diarrhea, nausea, and

sometimes vomiting. The patient should be advised to eat small, frequent meals to help alleviate this problem.

Hypersensitivity

Some patients are excessively responsive to either the primary or the secondary effects of a drug. This is known as **hypersensitivity**, and it may result from a pathological or underlying condition. For example, many drugs are excreted through the kidneys; a patient who has kidney problems may not be able to excrete the drug and may accumulate the drug in the body, causing toxic effects. The patient will exhibit exaggerated adverse effects from a standard dose of the medication because of the accumulation of the drug. In some cases, individuals exhibit increased therapeutic and adverse effects with no definite pathological condition. Each person has slightly different receptors and cellular responses. Frequently older people will react to narcotics with increased stimulation and hyperactivity, not with the sedation that is expected. It is thought that this response is related to a change in receptors with age leading to an increased sensitivity to a drug's effects.

Hypersensitivity also can occur if a patient has an underlying condition that makes the drug's effects especially unpleasant or dangerous. For example, a patient with an enlarged prostate who takes an anticholinergic drug may develop urinary retention or even bladder paralysis when the drug's effects block the urinary sphincters. This patient needs to be taught to empty the bladder before taking the drug. A reduced dose also may be required to avoid potentially serious effects on the urinary system.

DRUG ALLERGY

A **drug allergy** occurs when the body forms antibodies to a particular drug, causing an immune response when the person is re-exposed to the drug. A patient cannot be allergic to a drug that has never been taken, although patients can have cross-allergies to drugs within the same drug class as one formerly taken. Many people state that they have a drug allergy because of the effects of a drug. For example, one patient stated that she was allergic to the diuretic furosemide (*Lasix*). On further questioning, the nurse discovered that the patient was "allergic" to the drug because it made her urinate frequently—the desired drug effect, but one that the patient thought was a reaction to the drug. Ask additional questions of patients who state that they have a drug "allergy" to ascertain the exact nature of the response and whether or not it is a true drug allergy. Many patients do not receive needed treatment because the response to the drug is not understood.

Drug allergies fall into four main classifications: anaphylactic reactions, cytotoxic reactions, serum sickness, and delayed reactions (Table 3.1). The nurse, as the primary caregiver involved in administering drugs, must constantly assess

TABLE 3.1 Interventions for Types of Drug Allergies

ALLERGY TYPE	ASSESSMENT	INTERVENTIONS
<p>Anaphylactic Reaction</p> <p>This allergy involves an antibody that reacts with specific sites in the body to cause the release of chemicals, including histamine, that produce immediate reactions (mucous membrane swelling and constricting bronchi) that can lead to respiratory distress and even respiratory arrest.</p>	<p>Hives, rash, difficulty breathing, increased BP, dilated pupils, diaphoresis, “panic” feeling, increased heart rate, respiratory arrest</p>	<p>Administer epinephrine, 0.3 mL of a 1:1,000 solution, SubQ for adults or 0.01 mg/kg of 1:1,000 SubQ for pediatric patients. Massage the site to speed absorption rate. Repeat the dose every 15–20 minutes, as appropriate. Notify the prescriber and/or primary caregiver and discontinue the drug. Be aware that prevention is the best treatment. Counsel patients with known allergies to wear MedicAlert identification and, if appropriate, to carry an emergency epinephrine kit.</p>
<p>Cytotoxic Reaction</p> <p>This allergy involves antibodies that circulate in the blood and attack antigens (the drug) on cell sites, causing death of that cell. This reaction is not immediate but may be seen over a few days.</p>	<p>Complete blood count showing damage to blood-forming cells (decreased hematocrit, white blood cell count, and platelets); liver function tests show elevated liver enzymes; renal function test shows decreased renal function</p>	<p>Notify the prescriber and/or primary caregiver and discontinue the drug. Support the patient to prevent infection and conserve energy until the allergic response is over.</p>
<p>Serum Sickness Reaction</p> <p>This allergy involves antibodies that circulate in the blood and cause damage to various tissues by depositing in blood vessels. This reaction may occur up to 1 week or more after exposure to the drug.</p>	<p>Itchy rash, high fever, swollen lymph nodes, swollen and painful joints, edema of the face and limbs</p>	<p>Notify the prescriber and/or primary caregiver and discontinue the drug. Provide comfort measures to help the patient cope with the signs and symptoms (cool environment, skin care, positioning, ice to joints, administer antipyretics or anti-inflammatory agents, as appropriate).</p>
<p>Delayed Allergic Reaction</p> <p>This reaction occurs several hours after exposure and involves antibodies that are bound to specific white blood cells.</p>	<p>Rash, hives, swollen joints (similar to the reaction to poison ivy)</p>	<p>Notify the prescriber and/or primary caregiver and discontinue drug. Provide skin care and comfort measures that may include antihistamines or topical corticosteroids.</p>

for potential drug allergies and must be prepared to intervene appropriately.

KEY POINTS

- ▶ All drugs have effects other than the desired therapeutic effect.
- ▶ Primary actions of the drug can be extensions of the desired effect.
- ▶ Secondary actions of the drug are effects that the drug causes in the body that are not related to the therapeutic effect.
- ▶ Hypersensitivity reactions to a drug are individual reactions that may be caused by increased sensitivity to the drug’s therapeutic or adverse effects.
- ▶ Drug allergies occur when a patient develops antibodies to a drug after exposure to the drug.

DRUG-INDUCED TISSUE AND ORGAN DAMAGE

Drugs can act directly or indirectly to cause many types of adverse effects in various tissues, structures, and organs (Figure 3.1). These drug effects account for many of the cautions that are noted before drug administration begins. The possibility that these effects can occur also accounts for the contraindications for the use of some drugs in patients with a particular history or underlying pathology. The specific contraindications and cautions for the administration of a given drug are noted with each drug type discussed in this book and in the individual monographs found in various drug guides. These effects occur frequently enough that the nurse should be knowledgeable about the presentation of the drug-induced damage and about appropriate interventions to be used should they occur.

● **FIGURE 3.1** Variety of adverse effects and toxicities associated with drug use.

Dermatological Reactions

Dermatological reactions are adverse reactions involving the skin. These can range from a simple rash to potentially fatal exfoliative dermatitis. Many adverse reactions involve the skin because many drugs can deposit there or cause direct irritation to the tissue.

Rashes, Hives

Many drugs are known to cause skin reactions. Procainamide (*Pronestyl*) is a drug used to treat cardiac arrhythmias. It causes a characteristic skin rash in many patients that appears like a bright red blood vessel pattern under the skin. Meprobamate (*Miltown*), a drug used to treat anxiety, is associated with an itchy, red rash and in some patients has caused the serious to potentially fatal Stevens–Johnson syndrome. Although many patients will report that they are allergic to a drug because they develop a skin rash when taking the drug, it is important to determine whether a rash is a commonly associated adverse effect of the drug.

Assessment

Hives, rashes, and other dermatological lesions may be seen. Severe reactions may include exfoliative dermatitis, which is

characterized by rash and scaling, fever, enlarged lymph nodes, enlarged liver, and the potentially fatal erythema multiforme exudativum (Stevens–Johnson syndrome), which is characterized by dark red papules appearing on the extremities with no pain or itching, often in rings or disk-shaped patches.

Interventions

In mild cases, or when the benefit of the drug outweighs the discomfort of the skin lesion, provide frequent skin care; instruct the patient to avoid rubbing, wearing tight or rough clothing, and using harsh soaps or perfumed lotions; and administer antihistamines, as appropriate. In severe cases, discontinue the drug and notify the prescriber and/or primary caregiver. Be aware that, in addition to these interventions, topical corticosteroids, antihistamines, and emollients are frequently used.

Stomatitis

Stomatitis, or inflammation of the mucous membranes, can occur because of a direct toxic reaction to the drug or because the drug deposits in the end capillaries in the mucous membranes, leading to inflammation. Many drugs are known to cause stomatitis. The antineoplastic drugs commonly cause these problems because they are toxic to rapidly turning-over cells, like those found in the gastrointestinal (GI) tract. Patients receiving antineoplastic drugs are usually given instructions for proper mouth care when the drugs are started.

Assessment

Symptoms can include swollen gums, inflamed gums (gingivitis), and swollen and red tongue (glossitis). Other symptoms include difficulty swallowing, bad breath, and pain in the mouth and throat.

Interventions

Provide frequent mouth care with a nonirritating solution. Offer nutrition evaluation and development of a tolerated diet, which usually involves frequent, small meals. If necessary, arrange for a dental consultation. Note that antifungal agents and/or local anesthetics are sometimes used.

Superinfections

One of the body's protective mechanisms is provided by the wide variety of bacteria that live within or on the surface of the body. This bacterial growth is called the *normal flora*. The normal flora protect the body from invasion by other bacteria, viruses, fungi, and so on. Several kinds of drugs (especially antibiotics) destroy the normal flora, leading to the development of **superinfections**, or infections caused by organisms that are usually controlled by the normal flora.

Assessment

Symptoms can include fever, diarrhea, black or hairy tongue, inflamed and swollen tongue (glossitis), mucous membrane lesions, and vaginal discharge with or without itching.

Interventions

Provide supportive measures (frequent mouth care, skin care, access to bathroom facilities, small and frequent meals).

Administer antifungal therapy as appropriate. In severe cases, discontinue the drug responsible for the superinfection.

Blood Dyscrasia

Blood dyscrasia is bone marrow suppression caused by drug effects. This occurs when drugs that can cause cell death (e.g., antineoplastics, antibiotics) are used. Bone marrow cells multiply rapidly; they are said to be rapidly turning over. Because they go through cell division and multiply so often, they are highly susceptible to any agent that disrupts cell function.

Assessment

Symptoms include fever, chills, sore throat, weakness, back pain, dark urine, decreased hematocrit (anemia), low platelet count (thrombocytopenia), low white blood cell count (leukopenia), and a reduction of all cellular elements of the complete blood count (pancytopenia).

Interventions

Monitor blood counts. Provide supportive measures (rest, protection from exposure to infections, protection from injury, avoidance of activities that might result in injury or bleeding). In severe cases, discontinue the drug or stop administration until the bone marrow recovers to a safe level.

KEY POINTS

- ▶ Adverse drug effects can include skin irritation ranging from rashes and hives to potentially fatal Stevens–Johnson syndrome.
- ▶ Superinfections, or infections caused by destruction of protective normal flora bacteria; blood dyscrasias caused by bone marrow suppression of the blood-forming cells; and stomatitis or mucous membrane eruptions are common adverse drug effects.

Toxicity

Introducing chemicals into the body can sometimes affect the body in a very noxious or toxic way. These effects are not acceptable adverse effects but are potentially serious reactions to a drug. When a drug is known to have toxic effects, the benefit of the drug to the patient must be weighed against the possibility of toxic effects causing the patient harm.

Liver Injury

Oral drugs are absorbed and passed directly into the liver in the first-pass effect. This exposes the liver cells to the full impact of the drug before it is broken down for circulation throughout the body. Most drugs are metabolized in the liver, so any metabolites that are irritating or toxic will also affect liver integrity.

Assessment

Symptoms may include fever, malaise, nausea, vomiting, jaundice, change in color of urine or stools, abdominal pain or colic, elevated liver enzymes (e.g., aspartate aminotransferase [AST], alanine aminotransferase [ALT]), alterations in

bilirubin levels, and changes in clotting factors (e.g., partial thromboplastin time).

Interventions

Discontinue the drug and notify the prescriber and/or primary caregiver. Offer supportive measures such as small, frequent meals, skin care, a cool environment, and rest periods.

Renal Injury

The glomerulus in the kidney has a very small capillary network that filters the blood into the renal tubule. Some drug molecules are just the right size to get plugged into the capillary network, causing acute inflammation and severe renal problems. Some drugs are excreted from the kidney unchanged; they have the potential to directly irritate the renal tubule and alter normal absorption and secretion processes. Gentamicin (*Garamycin*), a potent antibiotic, is frequently associated with renal toxicity.

Assessment

Elevated blood urea nitrogen (BUN), elevated creatinine concentration, decreased hematocrit, electrolyte imbalances, fatigue, malaise, edema, irritability, and skin rash may be seen.

Interventions

Notify the prescriber and/or primary caregiver and discontinue the drug as needed. Offer supportive measures—for example, positioning, diet and fluid restrictions, skin care, electrolyte therapy, rest periods, a controlled environment. In severe cases, be aware that dialysis may be required for survival.

Poisoning

Poisoning occurs when an overdose of a drug damages multiple body systems, leading to the potential for fatal reactions. Assessment parameters vary with the particular drug. Treatment of drug poisoning also varies, depending on the drug. Throughout this book, specific antidotes or treatments for poisoning are identified, if known. Emergency and life support measures often are needed in severe cases.

Alterations in Glucose Metabolism

All cells need glucose for energy; the cells of the central nervous system are especially dependent on constant glucose levels to function properly. The control of glucose in the body is an integrated process that involves a series of hormones and enzymes that use the liver as the place for glucose storage or release. Many drugs have an impact on glucose levels because of their effects on the liver or the endocrine system.

Hypoglycemia

Some drugs affect metabolism and the use of glucose, causing a low serum blood glucose concentration, or hypoglycemia. Glipizide (*Glucotrol*) and glyburide (*DiaBeta*) are antidiabetic agents that have the desired action of lowering the blood glucose level but can lower blood glucose too far, causing hypoglycemia.

Assessment

Symptoms may include fatigue; drowsiness; hunger; anxiety; headache; cold, clammy skin; shaking and lack of coordination (tremulousness); increased heart rate; increased blood pressure; numbness and tingling of the mouth, tongue, and/or lips; confusion; and rapid and shallow respirations. In severe cases, seizures and/or coma may occur.

Interventions

Restore glucose—orally, if possible, or intravenously (IV). Provide supportive measures (e.g., skin care, environmental control of light and temperature, rest). Institute safety measures to prevent injury or falls. Monitor blood glucose levels to help stabilize the situation. Offer reassurance to help the patient cope with the experience.

Hyperglycemia

Some drugs stimulate the breakdown of glycogen or alter metabolism in such a way as to cause high serum glucose levels, or hyperglycemia. Ephedrine (generic), a drug used as a bronchodilator and antiasthma drug and to relieve nasal congestion, can break down stored glycogen and cause an elevation of blood glucose by its effects on the sympathetic nervous system. Diazoxide (*Hyperstat*) a drug used for treatment malignant hypertension, causes a decrease in insulin release, leading to an increase in blood glucose levels.

Assessment

Fatigue, increased urination (polyuria), increased thirst (polydipsia), deep respirations (Kussmaul respirations), restlessness, increased hunger (polyphagia), nausea, hot or flushed skin, and fruity odor to breath may be observed.

Interventions

Administer insulin therapy to decrease blood glucose as appropriate, while carefully monitoring glucose levels. Provide support to help the patient deal with signs and symptoms (e.g., provide access to bathroom facilities, control the temperature of the room, decrease stimulation while the patient is in crisis, offer reassurance, provide mouth care—the patient will experience dry mouth and bad breath with the ensuing acidosis, and mouth care will help to make this more tolerable).

Electrolyte Imbalances

Because they are chemicals acting in a body that works by chemical reactions, drugs can have an affect on various electrolyte levels in the body. The electrolyte that can cause the most serious effects when it is altered, even a little, is potassium.

Hypokalemia

Some drugs affecting the kidney can cause low serum potassium levels (hypokalemia) by altering the renal exchange system. For example, loop diuretics function by causing the loss of potassium, as well as of sodium and water. Potassium is essential for the normal functioning of nerves and muscles.

Assessment

Symptoms include a serum potassium concentration ($[K^+]$) lower than 3.5 mEq/L, weakness, numbness and tingling in the extremities, muscle cramps, nausea, vomiting, diarrhea, decreased bowel sounds, irregular pulse, weak pulse, orthostatic hypotension, and disorientation. In severe cases, paralytic ileus (absent bowel sounds, abdominal distention, and acute abdomen) may occur.

Interventions

Replace serum potassium and carefully monitor serum levels and patient response; achieving the desired level can take time, and the patient may experience high potassium levels in the process. Provide supportive therapy (e.g., safety precautions to prevent injury or falls, reorientation of the patient, comfort measures for pain and discomfort). Cardiac monitoring may be needed to evaluate the effect of the fluctuating potassium levels on heart rhythm.

Hyperkalemia

Some drugs that affect the kidney, such as the potassium-sparing diuretics, can lead to potassium retention and a resultant increase in serum potassium levels (hyperkalemia). Other drugs that cause cell death or injury, such as many antineoplastic agents, also can cause the cells to release potassium, leading to hyperkalemia.

Assessment

Symptoms include a serum potassium level higher than 5.0 mEq/L, weakness, muscle cramps, diarrhea, numbness and tingling, slow heart rate, low blood pressure, decreased urine output, and difficulty breathing.

Interventions

Institute measures to decrease the serum potassium concentration, including use of sodium polystyrene sulfonate. When trying to stabilize the potassium level, it is possible that the patient may experience low potassium levels. Careful monitoring is important until the patient's potassium levels are stable. Offer supportive measures to cope with discomfort. Institute safety measures to prevent injury or falls. Monitor for cardiac irregularities because potassium is an important electrolyte in the action potential, which is needed for cell membrane stability. When potassium levels are too high, the cells of the heart become very irritable and rhythm disturbances can occur. Be prepared for a possible cardiac emergency. In severe cases, be aware that dialysis may be needed.

Sensory Effects

Drugs can affect the special senses, including the eyes and ears. Alterations in seeing and hearing can pose safety problems for patients.

Ocular Damage

The blood vessels in the retina are very tiny and are called “end arteries,” that is, they stop and do not interconnect with other arteries feeding the same cells. Some drugs are deposited

into these tiny arteries, causing inflammation and tissue damage. Chloroquine (*Aralen*), a drug used to treat some rheumatoid diseases, can cause retinal damage and even blindness.

Assessment

Blurring of vision, color vision changes, corneal damage, and blindness may be noted.

Interventions

Monitor the patient's vision carefully when the patient is receiving known oculotoxic drugs. Consult with the prescriber and/or primary caregiver and discontinue the drug as appropriate. Provide supportive measures, especially if vision loss is not reversible. Monitor lighting and exposure to sunlight.

Auditory Damage

Tiny vessels and nerves in the eighth cranial nerve are easily irritated and damaged by certain drugs. The macrolide antibiotics can cause severe auditory nerve damage. Aspirin, one of the most commonly used drugs, is often linked to auditory ringing and eighth cranial nerve effects.

Assessment

Dizziness, ringing in the ears (tinnitus), loss of balance, and loss of hearing may be assessed.

Interventions

Monitor the patient's perceptual losses or changes. Provide protective measures to prevent falling or injury. Consult with the prescriber to decrease dose or discontinue the drug. Provide supportive measures to cope with drug effects.

Neurological Effects

Many drugs can affect the functioning of the nerves in the periphery and the central nervous system. Nerves function by using a constant source of energy to maintain the resting membrane potential and allow excitation. This requires glucose, oxygen, and a balance of electrolytes.

General Central Nervous System Effects

Although the brain is fairly well protected from many drug effects by the blood-brain barrier, some drugs do affect neurological functioning, either directly or by altering electrolyte or glucose levels. Beta-blockers, which are used to treat hypertension, angina, and many other conditions, can cause feelings of anxiety, insomnia, and nightmares.

Assessment

Symptoms may include confusion, delirium, insomnia, drowsiness, hyperreflexia or hyporeflexia, bizarre dreams, hallucinations, numbness, tingling, and paresthesias.

Interventions

Provide safety measures to prevent injury. Caution the patient to avoid dangerous situations such as driving a car or operating dangerous machinery. Orient the patient and provide support. Consult with the prescriber to decrease drug dose or discontinue the drug.

Atropine-Like (Anticholinergic) Effects

Some drugs block the effects of the parasympathetic nervous system by directly or indirectly blocking cholinergic receptors. Atropine, a drug used preoperatively to dry up secretions and any other indications, is the prototype anticholinergic drug. Many cold remedies and antihistamines also cause anticholinergic effects.

Assessment

Dry mouth, altered taste perception, dysphagia, heartburn, constipation, bloating, paralytic ileus, urinary hesitancy and retention, impotence, blurred vision, cycloplegia, photophobia, headache, mental confusion, nasal congestion, palpitations, decreased sweating, and dry skin may be noted.

Interventions

Provide sugarless lozenges and mouth care to help mouth dryness. Arrange for bowel program as appropriate. Have the patient void before taking the drug, to aid voiding. Provide safety measures if vision changes occur. Arrange for medication for headache and nasal congestion as appropriate. Advise the patient to avoid hot environments and to take protective measures to prevent falling and to prevent dehydration, which may be caused by exposure to heat owing to decreased sweating.

Parkinson-Like Syndrome

Drugs that directly or indirectly affect dopamine levels in the brain can cause a syndrome that resembles Parkinson's disease. Many of the antipsychotic and neuroleptic drugs can cause this effect. In most cases, the effects go away when the drug is withdrawn.

Assessment

Lack of activity, akinesia, muscular tremors, drooling, changes in gait, rigidity, extreme restlessness or "jitters" (akathisia), or spasms (dyskinesia) may be observed.

Interventions

Discontinue the drug, if necessary. Know that treatment with anticholinergics or antiparkinson drugs may be recommended if the benefit of the drug outweighs the discomfort of its adverse effects. Provide small, frequent meals if swallowing becomes difficult. Provide safety measures if ambulation becomes a problem.

Neuroleptic Malignant Syndrome

General anesthetics and other drugs that have direct central nervous system effects can cause neuroleptic malignant syndrome, a generalized syndrome that includes high fever.

Assessment

Extrapyramidal symptoms, including slowed reflexes, rigidity, involuntary movements; hyperthermia; and autonomic disturbances, such as hypertension, fast heart rate, and fever, may be noted.

Interventions

Discontinue the drug, if necessary. Know that treatment with anticholinergics or antiparkinson drugs may be required.

BOX 3.1 Summary of Adverse Drug Effects

- | | |
|----------------------------------|--------------------------------------|
| • Extension of primary action | • Alterations in glucose metabolism |
| • Occurrence of secondary action | Hypoglycemia |
| • Allergic reactions | Hyperglycemia |
| Anaphylactic reactions | • Electrolyte imbalances |
| Cytotoxic reactions | Hypokalemia |
| Serum sickness reactions | Hyperkalemia |
| Delayed allergic reactions | • Sensory effects |
| • Tissue and organ damage | Ocular toxicity |
| Dermatological reactions | Auditory damage |
| Stomatitis | • Neurological effects |
| Superinfections | General CNS effects |
| Blood dyscrasia | Atropine-like (cholinergic) effects |
| • Toxicity | Parkinson-like syndrome |
| Liver injury | Neuroleptic malignant syndrome (NMS) |
| Renal injury | • Teratogenicity |
| Poisoning | |

Provide supportive care to lower the body temperature. Institute safety precautions as needed.

Teratogenicity

Many drugs that reach the developing fetus or embryo can cause death or congenital defects, which can include skeletal and limb abnormalities, central nervous system alterations, heart defects, and the like. The exact effects of a drug on the fetus may not be known. In some cases, a predictable syndrome occurs when a drug is given to a pregnant woman. In any situation, inform any pregnant woman who requires drug therapy about the possible effects on the baby. Before a drug is administered to a pregnant patient, the actual benefits

should be weighed against the potential risks. All pregnant women should be advised not to self-medicate during the pregnancy. Emotional and physical support is needed to assist the woman in dealing with the possibility of fetal death or birth defects.

Box 3.1 summarizes all of the adverse effects that have been described throughout this chapter.

CHAPTER SUMMARY

- No drug does only what is desired of it. All drugs have adverse effects associated with them.
- Adverse drug effects can range from allergic reactions to tissue and cellular damage. The nurse, as the health care provider most associated with drug administration, needs to assess each situation for potential adverse effects and intervene appropriately to minimize those effects.
- Adverse effects can be extensions of the primary action of a drug or secondary effects that are not necessarily desirable but are unavoidable.
- Allergic reactions can occur when a person's body makes antibodies to a drug or drug protein. If the person is exposed to that drug at another time, an immune response may occur. Allergic reactions can be of various types. The exact response should be noted to avoid future confusion in patient care.
- Tissue damage can include skin problems, mucous membrane inflammation, blood dyscrasia, superinfections, liver or renal toxicity, poisoning, hypoglycemia or hyperglycemia, electrolyte disturbances, various central nervous system problems (ocular damage, auditory damage, atropine-like effects, Parkinson-like syndrome, neuroleptic malignant syndrome), and teratogenicity.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-Rom in the front of this book.

MULTIPLE CHOICE

Select the best answer to the following.

1. An example of a drug allergy is
 - a. dry mouth occurring with use of an antihistamine.
 - b. increased urination occurring with use of a thiazide diuretic.
 - c. breathing difficulty after an injection of penicillin.
 - d. skin rash associated with procainamide use.
2. A patient taking glyburide (an antidiabetic drug) has his morning dose and then does not have a chance to eat for several hours. An adverse effect that might be expected from this would be
 - a. a teratogenic effect.
 - b. a skin rash.
 - c. an anticholinergic effect.
 - d. hypoglycemia.
3. A patient with a severe infection is given gentamicin, the only antibiotic shown to be effective in culture and sensitivity tests. A few hours after the drug is started intravenously, the patient becomes very restless and

develops edema. Blood tests reveal abnormal electrolytes and elevated BUN. This reaction was most likely caused by

- a. an anaphylactic reaction.
 - b. renal toxicity associated with gentamicin.
 - c. superinfection related to the antibiotic.
 - d. hypoglycemia.
4. Patients receiving antineoplastic drugs that disrupt cell function often have adverse effects involving cells that turn over rapidly in the body. These cells include
 - a. ovarian cells.
 - b. liver cells.
 - c. cardiac cells.
 - d. bone marrow cells.
 5. A woman has had repeated bouts of bronchitis throughout the fall and has been taking antibiotics. She calls the clinic with complaints of vaginal pain and itching. When she is seen, it is discovered that she has developed a yeast infection. You would explain to her that
 - a. her bronchitis has moved to the vaginal area.
 - b. she has developed a superinfection because the antibiotics kill bacteria that normally provide protection.
 - c. she probably has developed a sexually transmitted disease related to her lifestyle.
 - d. she will need to take even more antibiotics to treat this new infection.
 6. Knowing that a patient is taking a loop diuretic and is at risk for developing hypokalemia, the nurse would assess the patient for
 - a. hypertension, headache, and cold and clammy skin.
 - b. decreased urinary output and yellowing of the sclera.
 - c. weak pulse, low blood pressure, and muscle cramping.
 - d. diarrhea and flatulence.

MULTIPLE RESPONSE

Select all that apply.

1. A patient is taking a drug that is known to be toxic to the liver. The patient is being discharged to home. What teaching points related to liver toxicity and the drug should the nurse teach the patient to report to the physician?
 - a. Fever; changes in the color of urine
 - b. Changes in the color of stool; malaise
 - c. Rapid, deep respirations; increased sweating
 - d. Dizziness; drowsiness; dry mouth
 - e. Rash, black or hairy tongue; white spots in the mouth or throat
 - f. Yellowing of the skin or the whites of the eyes
2. Pregnant women should be advised of the potential risk to the fetus any time they take a drug during pregnancy. What fetal problems can be related to drug exposure in utero?
 - a. Fetal death
 - b. Nervous system disruption
 - c. Skeletal and limb abnormalities
 - d. Cardiac defects
 - e. Low-set ears
 - f. Deafness
3. A client is experiencing a reaction to the penicillin injection that the nurse administered approximately 1/2 hour ago. The nurse is concerned that it might be an anaphylactic reaction. What signs and symptoms would validate her suspicion?
 - a. Rapid heart rate
 - b. Diaphoresis
 - c. Constricted pupils
 - d. Hypotension
 - e. Rash
 - f. Client report of a panic feeling
4. A client is experiencing a serum sickness reaction to a recent rubella vaccination. Which of the following interventions would be appropriate when caring for this client?
 - a. Administration of epinephrine
 - b. Cool environment
 - c. Positioning to provide comfort
 - d. Ice to joints as needed
 - e. Administration of anti-inflammatory agents
 - f. Administration of topical corticosteroids

The Nursing Process in Drug Therapy and Patient Safety

4

Learning Objectives

Upon completion of this chapter, you will be able to:

1. List the responsibilities of the nurse in drug therapy.
2. Explain what is involved in each step of the nursing process as it relates to drug therapy.
3. Describe key points that must be incorporated into the assessment of a patient receiving drug therapy.
4. Describe the essential elements of a medication order.
5. Outline the important points that must be assessed and considered before administering a drug, combining knowledge about the drug with knowledge of the patient and the environment.
6. Describe the role of the nurse and the patient in preventing medication errors.

Glossary of Key Terms

assessment: information gathering regarding the current status of a particular patient, including evaluation of past history and physical examination; provides a baseline of information and clues to effectiveness of therapy

evaluation: part of the nursing process; determining the effects of the interventions that were instituted for the patient and leading to further assessment and intervention

implementation: actions undertaken to meet a patient's needs, such as administration of drugs, comfort measures, or patient teaching

nursing: the art of nurturing and administering to the sick, combined with the scientific application of chemistry,

anatomy, physiology, biology, nutrition, psychology, and pharmacology to the particular clinical situation

nursing diagnosis: statement of an actual or potential problem, based on the assessment of a particular clinical situation, which directs needed nursing interventions

nursing process: the problem-solving process used to provide efficient nursing care; it involves gathering information, formulating a nursing diagnosis statement, carrying out interventions, and evaluating the process

The delivery of medical care today is in a constant state of change, at times reaching crisis levels. The population is aging, resulting in an increased incidence and prevalence of chronic disease and more complex care issues. The population also is more transient, with individuals and families more mobile, often resulting in unstable support systems and fewer at-home care providers and helpers. At the same time, health care is undergoing a technological boom, including greater use of more sophisticated diagnostic methods and treatments, new, specialized drugs, including experimental drugs, and so on. Moreover, patients are being discharged earlier from acute care facilities or are not being

admitted at all for procedures that used to be treated in-hospital with follow-up support and monitoring. Patients also are becoming more responsible for their care and for adhering to complicated medical regimens at home. The wide use of the Internet and an emphasis in the media on the need to question all aspects of health care has led to more-knowledgeable and challenging patients. Patients may no longer accept a drug regimen or therapy without question and often feel confident in adjusting it on their own because of information that they have found on the Internet—information that might not be very accurate or even relevant to their particular situation.

NURSING: ART AND SCIENCE

Nursing is a unique and complex science, as well as a nurturing and caring art. In the traditional sense, nursing has been viewed as ministering to and soothing the sick. In the current state of medical changes, nursing also has become increasingly technical and scientific. Nurses are assuming increasing responsibilities that involve not only nurturing and caring, but also assessing, diagnosing, and intervening with patients to treat, to prevent, and to educate as they assist patients in coping with various health states.

The nurse deals with the whole person, including physical, emotional, intellectual, social, and spiritual aspects. Nurses must consider how a person responds to disease and its treatment, including the changes in lifestyle that may be required. Therefore, a nurse is a key health care provider who is in a position to assess the whole patient, to administer therapy as well as medications, to teach the patient how best to cope with the therapy so as to ensure the most favorable outcome, and to evaluate the effectiveness of the therapy. Nurses accomplish these tasks by integrating knowledge of the basic sciences (anatomy, physiology, nutrition, chemistry, pharmacology), the social sciences (sociology, psychology), education, and many other disciplines and applying the nursing process.

THE NURSING PROCESS

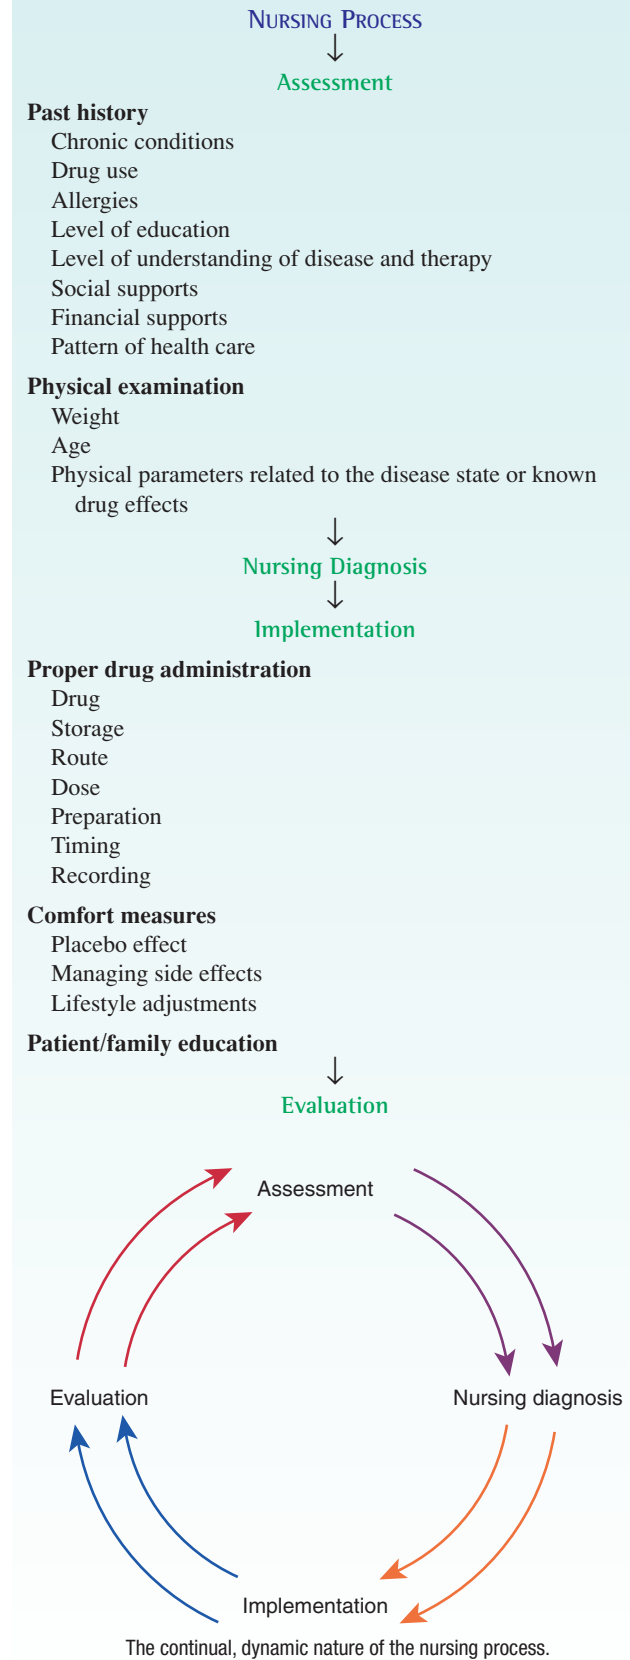

Nurses use the **nursing process**—a decision-making, problem-solving process—to provide efficient and effective care. Although not all nursing theorists completely agree on this process that defines the practice of nursing, most do include certain key elements: assessment, nursing diagnosis, implementation, and evaluation. Application of the nursing process with drug therapy ensures that the patient receives the best, safest, most efficient, scientifically based, holistic care. Box 4.1 outlines the steps of the nursing process, which are discussed in detail in the following paragraphs.

Assessment

Assessment (gathering information) is the first step of the nursing process. This involves systematic, organized collection of data about the patient. Because the nurse is responsible for holistic care, data must include information about physical, intellectual, emotional, social, and environmental factors. When viewed together, this information provides the nurse with the facts needed to plan educational and discharge programs, arrange for appropriate consultations, and monitor the physical response to treatment or to disease.

Each nurse develops a unique approach to the organization of the assessment, an approach that is functional and useful in the clinical setting and that makes sense to that nurse and in the particular clinical situation. Regardless of the approach, the process of assessment never ends because the patient is in

BOX 4.1 The Steps of the Nursing Process

a dynamic state, continuously adjusting to physical, emotional, and environmental influences.

Drug therapy is a complex and important part of health care, and the principles of drug therapy must be incorporated into every patient assessment plan. The particular information that is needed varies with each drug, but the concepts involved are similar. Two major aspects associated with assessment are the patient's history (past illnesses and the current problem) and examination of his or her physical status.

History

The patient's history is an important element of assessment related to drug therapy because his or her past experiences and illnesses can influence a drug's effect. Knowledge of this important information before beginning drug therapy will help to promote safe and effective use of the drug and prevent adverse effects, clinically important drug–drug, drug–food, or drug–alternative therapy interactions, and medication errors. Relevant aspects of the patient's history specifically related to drug therapy are discussed next.

Chronic Conditions

Chronic conditions can affect the pharmacokinetics and pharmacodynamics of a drug. For example, certain conditions (e.g., renal disease, heart disease, diabetes, chronic lung disease) may be contraindications to the use of a drug. In addition, these conditions may require cautious use or dose adjustment when administering a certain drug. For example, a patient with renal disease may require a decreased dose of a drug due to the way the drug is eliminated. If renal disease is mentioned in the patient history, the nurse should consider this factor to evaluate the dose of the drug that is prescribed.

Drug Use

Prescription drugs, over-the-counter (OTC) drugs, street drugs, alcohol, nicotine, alternative therapies, and caffeine may have an impact on a drug's effect. Patients often neglect to mention OTC drugs or alternative therapies because they do not consider them to be actual drugs or they may be unwilling to admit their use to the health care provider. Ask patients specifically about OTC drug or alternative therapy use. Patients also might forget to mention prescription drugs that they routinely take all the time, for instance, oral contraceptives. Always ask specifically about all types of medications that the patient might use.

Allergies

A patient's history of allergies can affect drug therapy. Past exposure to a drug or other allergens can provoke a future reaction or necessitate the need for cautious use of the drug, food, or animal product. Obtain specific information about the patient's allergic reaction to determine whether the patient has experienced a true drug allergy or was experiencing an actual effect or adverse effect of the drug.

Level of Education and Understanding

Information about the patient's education level provides a baseline from which the nurse can determine the appropriate

types of teaching information to use with the patient. A patient with a fifth grade education may require materials at a different level than a patient with a graduate degree. Gathering information about the patient's level of understanding about his or her condition, illness, or drug therapy helps the nurse to determine where the patient is in terms of his or her status and the level of explanation that will be required. It also provides additional baseline information for developing a patient education program. It is important not to assume anything about the patient's ability to understand based on his or her reported education level. Stress, disease, and environmental factors can all affect a patient's learning readiness and ability. Direct assessment of actual learning abilities is critical for good patient education.

Social Supports

Patients are being discharged from health care facilities earlier than ever before, often with continuing care needs. In addition, earlier discharges leave minimal time for teaching. Often patients need help at home with care and drug therapy. A key aspect of discharge planning involves determining what support, if any, is available to the patient at home. In many situations, it also involves referral to appropriate community resources.

Financial Supports

The high cost of health care in general, and of medications in particular, must be considered when initiating drug therapy and promoting patient compliance. Financial constraints may cause a patient not to follow through with a prescribed drug regimen. For example, the drug may be too expensive or the patient may lack the means to get to a pharmacy to obtain the drug. In some situations, a less expensive drug might be appropriate in place of a very expensive drug. In addition, the nurse may need to refer the patient to appropriate resources that might offer financial assistance.

Pattern of Health Care

Knowing how a patient seeks health care provides the nurse with valuable information to include when preparing the patient's teaching plan. Does this patient routinely seek follow-up care, or does he or she wait for emergency situations? Does the patient tend to self-treat many complaints, or is every problem brought to a health care provider? Information about patterns of health care also provides insight into conditions that the patient may have but has not reported or medication use that has not been stated.

Physical Examination

It is important to assess the patient's physical status before beginning drug therapy to determine if any conditions exist that would be contraindications or cautions for using the drug and to develop a baseline for evaluating the effectiveness of the drug and the occurrence of any adverse effects. Relevant aspects of the patient's physical examination specifically related to drug therapy are discussed in the following text.

Weight

A patient's weight helps to determine whether the recommended drug dose is appropriate. Because the recommended dose typically is based on a 150-pound adult man, patients who are much lighter or much heavier often need a dose adjustment.

Age

Patients at the extremes of the age spectrum—children and older adults—often require dose adjustments based on the functional level of the liver and kidneys and the responsiveness of other organs. The child's age and developmental level will also alert the nurse to possible problems with drug delivery, such as the ability to swallow pills or follow directions related to other delivery methods. The child's developmental age will also influence pharmacokinetics and pharmacodynamics; the immature liver may not metabolize drugs in the same way as in the adult, or the kidneys may not be as efficient as these of an adult. As patients age, the body undergoes many normal changes that can affect drug therapy, such as a decreased blood volume, decreased gastrointestinal (GI) absorption, reduced blood flow to muscles or skin, and changes in receptor-site responsiveness. Older adults may often have a variety of chronic medical conditions and could be receiving a number of medications that need to be evaluated for possible interactions. Older adults with various central nervous system disorders, like Alzheimer's disease or Parkinson's disease, may develop difficulty swallowing and might require liquid forms of medication. Throughout this book, Drug Therapy Across the Life Span features will present information related to the drug class being discussed as it pertains specifically to children, adults, and the older population. These boxes highlight points that the nurse should consider to assure safe and effective therapy in each age group.

Physical Parameters Related to Disease or Drug Effects

The specific parameters that need to be assessed depend on the disease process being treated and on the expected therapeutic and adverse effects of the drug therapy. Assessing these factors before drug therapy begins provides a baseline level to which future assessments can be compared to determine the effects of drug therapy. For example, if a patient is being treated for chronic pulmonary disease, his or her respiratory status and reserve need to be assessed, especially if a drug is being given that is known to affect the respiratory tract. In contrast, a thorough respiratory evaluation would not be warranted in a patient with no known pulmonary disease who is taking a drug with little or no known effects on the respiratory system. Because the nurse has the greatest direct and continued contact with the patient, the nurse is in the best position to detect minute changes that ultimately determine the course of drug therapy—therapeutic success or discontinuation because of adverse or unacceptable responses.

Safe Medication Administration

Review the monographs in a drug guide or handbook for specific parameters to be assessed in relation to the particular drug being discussed. This assessment provides not only the baseline information needed before giving that drug, but also the data required to evaluate the effects of that drug on the patient. This information should supplement the overall nursing assessment of the patient, which includes social, intellectual, financial, environmental, and other factors.

Nursing Diagnosis

A **nursing diagnosis** is simply a statement of the patient's status from a nursing perspective. The nurse analyzes the information gathered during assessment to arrive at some conclusions that lead to a particular goal and set of interventions. A nursing diagnosis shows actual or potential alterations in patient function based on the assessment of the clinical situation. Because drug therapy is only a small part of the overall patient situation, nursing diagnoses that are related to drug therapy must be incorporated into a total picture of the patient.

In the nursing considerations sections of this book, the nursing diagnoses listed are those that reflect potential alteration of function based only on the particular drug's actions (i.e., therapeutic and adverse effects). No consideration is given to environmental or disease-related problems. These diagnoses, culled from the North American Nursing Diagnosis Association (NANDA) list of accepted nursing diagnoses, are only a part of the overall nursing diagnoses related to the patient's situation. See Box 4.2 for a list of the accepted NANDA nursing diagnoses.

Implementation

Implementation involves taking the information gathered and synthesized into nursing diagnoses to plan the patient care. This process includes setting goals and desired patient outcomes to assure safe and effective drug therapy. These outcomes usually involve ensuring effective response to drug therapy, minimizing adverse effects, and understanding the drug regimen. Three types of nursing interventions are frequently involved in drug therapy: drug administration, provision of comfort measures, and patient/family education.

Proper Drug Administration

The nurse must consider seven points, or "rights," to ensure safe and effective drug administration. These are correct drug and patient, correct storage of drug, correct and most effective route, correct dose, correct preparation, correct timing, and correct recording of administration. See the later section on the prevention of medication errors for a detailed explanation of the nurse's role in implementing these rights. Remembering to review each point before administering a drug will help to prevent medication errors and improve patient outcomes.

BOX 4.2 NANDA-Approved Nursing Diagnoses

The North American Nursing Diagnosis Association (NANDA) endorsed its first nursing diagnosis taxonomic structure, NANDA Taxonomy I, in 1986. This taxonomy has been revised and updated several times. The new Taxonomy II has a code structure that is compliant with recommendations from the National Library of Medicine concerning health care terminology codes. The taxonomy that appears here represents the currently accepted classification system for nursing diagnosis (2011).

Activity Intolerance	Dignity, Risk for Compromised Human
Activity Intolerance, Risk for	Distress, Moral
Ineffective Activity Planning	Disuse Syndrome, Risk for
Airway Clearance, Ineffective	Diversional Activity, Deficient
Allergy Response, Latex	Risk for Disturbed Maternal/Fetal Dyad
Allergy Response, Risk for Latex	Risk for Electrolyte Imbalance
Anxiety	Energy Field, Disturbed
Anxiety, Death	Environmental Interpretation Syndrome, Impaired
Aspiration, Risk for	Failure to Thrive, Adult
Attachment, Risk for Impaired Parent/Child	Falls, Risk for
Autonomic Dysreflexia	Family Processes, Dysfunctional: Alcoholism
Autonomic Dysreflexia, Risk for	Family Processes, Interrupted
Behavior, Risk-Prone Health	Family Processes, Readiness for Enhanced
Risk for Bleeding	Fatigue
Body Image, Disturbed	Fear
Body Temperature, Risk for Imbalanced	Fluid Balance, Readiness for Enhanced
Bowel Incontinence	Fluid Volume, Deficient
Breastfeeding, Effective	Fluid Volume, Excess
Breastfeeding, Ineffective	Fluid Volume, Risk for Deficient
Breastfeeding, Interrupted	Fluid Volume, Risk for Imbalanced
Breathing Pattern, Ineffective	Gas Exchange, Impaired
Cardiac Output, Decreased	Dysfunctional Gastrointestinal Motility
Caregiver Role Strain	Risk for Dysfunctional Gastrointestinal Motility
Caregiver Role Strain, Risk for	Glucose, Risk for Unstable Blood
Readiness for Enhanced Childbearing Process	Grieving, Anticipatory
Comfort, Readiness for Enhanced	Grieving, Complicated
Impaired Comfort	Grieving, Risk for Complicated
Communication, Impaired Verbal	Growth and Development, Delayed
Communication, Readiness for Enhanced	Growth, Risk for Disproportionate
Conflict, Decisional	Health Maintenance, Ineffective
Conflict, Parental Role	Ineffective Self Health Maintenance
Confusion, Acute	Health-Seeking Behaviors (Specify)
Confusion, Chronic	Home Maintenance, Impaired
Confusion, Risk for Acute	Hope, Readiness for Enhanced
Constipation	Hopelessness
Constipation, Perceived	Hyperthermia
Constipation, Risk for	Hypothermia
Contamination	Identity, Disturbed Personal
Contamination, Risk for	Immunization Status, Readiness for Enhanced
Coping, Compromised Family	Incontinence, Functional Urinary
Coping, Defensive	Incontinence, Overflow Urinary
Coping, Disabled Family	Incontinence, Reflex Urinary
Coping, Ineffective	Incontinence, Stress Urinary
Coping, Ineffective Community	Incontinence, Urge Urinary
Coping, Readiness for Enhanced	Incontinence, Risk for Urge Urinary
Coping, Readiness for Enhanced Community	Infant Behavior, Disorganized
Coping, Readiness for Enhanced Family	Infant Behavior, Risk for Disorganized
Death Syndrome, Risk for Sudden Infant	Infant Behavior, Readiness for Enhanced Organized
Decision Making, Readiness for Enhanced	Infant Feeding Pattern, Ineffective
Denial, Ineffective	Infection, Risk for
Dentition, Impaired	Injury, Risk for
Development, Risk for Delayed	Injury, Risk for Perioperative-Positioning
Diarrhea	Insomnia

BOX 4.2 NANDA-Approved Nursing Diagnoses (continued)

Intracranial Adaptive Capacity, Decreased	Self-Esteem, Situational Low
Knowledge, Deficient (Specify)	Self-Esteem, Risk for Situational Low
Knowledge, Readiness for Enhanced	Readiness for Enhanced Self Health Management
Lifestyle, Sedentary	Self-Mutilation
Liver Function, Risk for Impaired	Self-Mutilation, Risk for
Loneliness, Risk for	Self Neglect
Memory, Impaired	Sensory Perception, Disturbed
Mobility, Impaired Bed	(Specify: Visual, Auditory, Kinesthetic,
Mobility, Impaired Physical	Gustatory, Tactile, Olfactory)
Mobility, Impaired Wheelchair	Sexual Dysfunction
Nausea	Sexuality Pattern, Ineffective
Neglect, Unilateral	Risk for Shock
Neonatal Jaundice	Skin Integrity, Impaired
Noncompliance	Skin Integrity, Risk for Impaired
Nutrition, Imbalanced: Less Than Body Requirements	Sleep Deprivation
Nutrition, Imbalanced: More Than Body Requirements	Sleep Pattern, Disturbed
Nutrition, Readiness for Enhanced	Sleep, Readiness for Enhanced
Nutrition, Risk for Imbalanced: More Than Body Requirements	Social Interaction, Impaired
Oral Mucous Membrane, Impaired	Social Isolation
Pain, Acute	Sorrow, Chronic
Pain, Chronic	Spiritual Distress
Parenting, Readiness for Enhanced	Spiritual Distress, Risk for
Parenting, Impaired	Spiritual Well-Being, Readiness for Enhanced
Parenting, Risk for Impaired	Stress Overload
Peripheral Neurovascular Dysfunction, Risk for	Suffocation, Risk for
Poisoning, Risk for	Suicide, Risk for
Post-Trauma Syndrome	Surgical Recovery, Delayed
Post-Trauma Syndrome, Risk for	Swallowing, Impaired
Power, Readiness for Enhanced	Therapeutic Regimen Management, Ineffective
Powerlessness	Therapeutic Regimen Management, Ineffective Family
Powerlessness, Risk for	Therapeutic Regimen Management, Readiness for Enhanced
Protection, Ineffective	Thermoregulation, Ineffective
Rape-Trauma Syndrome	Tissue Integrity, Impaired
Readiness for Enhanced Relationship	Tissue Perfusion, Ineffective Peripheral
Religiosity, Impaired	(Specify Type: Renal, Cerebral, Cardiopulmonary,
Religiosity, Readiness for Enhanced	Gastrointestinal, Peripheral)
Religiosity, Risk for Impaired	Tissue Perfusion, Ineffective Cardiac
Relocation Stress Syndrome	Transfer Ability, Impaired
Relocation Stress Syndrome, Risk for	Trauma, Risk for
Risk for Compromised Resilience	Risk for Vascular Trauma
Readiness for Enhanced Resilience	Urinary Elimination, Impaired
Impaired Individual Resilience	Urinary Elimination, Readiness for Enhanced
Role Performance, Ineffective	Urinary Retention
Self-Care, Readiness for Enhanced	Ventilation, Impaired Spontaneous
Self-Care Deficit, Bathing/Hygiene	Ventilatory Weaning Response, Dysfunctional
Self-Care Deficit, Dressing/Grooming	Violence, Risk for Other-Directed
Self-Care Deficit, Feeding	Violence, Risk for Self-Directed
Self-Care Deficit, Toileting	Walking, Impaired
Self-Concept, Readiness for Enhanced	Wandering
Self-Esteem, Chronic Low	

Comfort Measures

Nurses are in a unique position to help the patient cope with the effects of drug therapy. A patient is more likely to be compliant with a drug regimen if the effects of the regimen are not too uncomfortable or overwhelming.

Placebo Effect

The anticipation that a drug will be helpful (placebo effect) has proved to have tremendous impact on the actual success of drug therapy. Therefore, the nurse's attitude and support can be a critical part of drug therapy. For example, a back rub,

a kind word, and a positive approach may be as beneficial as the drug itself.

Managing Adverse Effects

Interventions can be directed at promoting patient safety and decreasing the impact of the anticipated adverse effects of a drug. Such interventions include environmental control (e.g., temperature, light), safety measures (e.g., avoiding driving, avoiding the sun, using side rails), and physical comfort measures (e.g., skin care, laxatives, frequent meals).

Lifestyle Adjustment

Some medications and their effects require that a patient make changes in his or her lifestyle. For example, patients taking diuretics may have to rearrange their day so as to be near toilet facilities when the drug action peaks. Patients taking bisphosphonates will need to plan their morning so they can take the drug on an empty stomach, stay upright for at least one-half hour, and plan their first food of the day at least one-half hour after taking the drug. Many drugs come with similar guidelines for assuring effectiveness and decreasing adverse effects. Patients taking monoamine oxidase inhibitors (MAOIs) must adjust their diet to prevent serious adverse effects due to potential drug–food interactions. In some cases the change in lifestyle that is needed can have a tremendous impact on the patient and can affect his or her ability to cope and comply with any medical regimen.

Safe Medication Administration

Special points regarding drug administration and related comfort measures are noted with each drug class discussed in this book. Refer to the individual drug monographs in a drug guide or handbook for more detailed interventions regarding a specific drug.

Patient and Family Education

With patients becoming increasingly responsible for their own care, it is essential that they have all of the information necessary to ensure safe and effective drug therapy at home. In fact, many states now require that patients be given written information. Box 4.3 includes key elements for any drug education program. Also see the later section on prevention of medication errors for patient-teaching tips related to the patient's role in preventing medication errors.

Evaluation

Evaluation is part of the continuing process of patient care that leads to changes in assessment, diagnosis, and intervention. The patient is continually evaluated for therapeutic response, the occurrence of adverse drug effects, and the occurrence of drug–drug, drug–food, drug–alternative therapy, or drug–laboratory test interactions. Some drug therapy requires evaluation of specific therapeutic drug levels. In addition, the efficacy of the nursing interventions and the education program also are evaluated. In some situations, the nurse

evaluates the patient simply by reapplying the beginning steps of the nursing process and then analyzing for changes, either positive or negative. The process of evaluation may lead to changes in the nursing interventions being used to provide better and safer patient care.

KEY POINTS

- ▶ Nurses use the nursing process to provide a framework for organizing the information that is needed to provide safe and effective patient care.
- ▶ The steps of the nursing process (assessment, nursing diagnosis, implementation, and evaluation) are constantly being repeated to meet the ever-changing needs of the patient.
- ▶ The nursing process provides an effective method for handling all of the scientific and technical information, as well as the unique emotional, social, and physical factors that each patient brings to a given situation.

PREVENTION OF MEDICATION ERRORS

With the increase in the older adult patient population, the increase in the number of available drugs and OTC and alternative therapy preparations, and the reduced length of hospital stays for patients, the risk for medication errors is ever-increasing. In 2000, the Institute of Medicine published a large-scale study of medication errors in the United States, entitled *To Err Is Human: Building a Safer Health System*. It reported that 44,000 reported deaths in hospitals each year occurred from medication errors, and that the number could probably be closer to 98,000. The study brought to light the many places in the system where a medication error could occur and suggested methods for improving the problem.

The drug regimen process, which includes prescribing, dispensing, and administering a drug to a patient, has a series of checks along the way to help to catch errors before they occur. These include the physician or nurse practitioner who prescribes a drug, the pharmacist who dispenses the drug, and the nurse who administers the drug. Each serves as a check within the system to catch errors—the wrong drug, the wrong patient, the wrong dose, the wrong route, or the wrong time. Often the nurse is the final check in the process because the nurse is the one who administers the drug and is the one responsible for patient education before the patient is discharged to home.

Nurse's Role

The monumental task of ensuring medication safety with all of the potential problems that could confront the patient can best be managed by consistently using the seven “rights” of medication administration. These rights are as follows:

Safe Medication Administration

1. **Right drug.** To prevent medication errors, always check to make sure the drug you are going to administer is the one that was prescribed. Many drugs may look alike and/or have sound-alike names. Ask for the generic as well as the brand name if you are unsure. Never assume the computer is correct; always double-check. Avoid abbreviations, and if you are not sure about abbreviations that were used, ask. Make sure the drug makes sense for the patient for whom it is ordered.
2. **Right storage.** Be aware that some drugs require specific storage environments (e.g., refrigeration, protection from light). Check to make sure that general guidelines have been followed.
3. **Right route.** Determine the best route of administration; this is frequently established by the formulation of the drug. Nurses can often have an impact in modifying the route to arrive at the most efficient, comfortable method for the patient based on the patient's specific situation. For example, perhaps a patient is having trouble swallowing, and a large capsule would be very difficult for the patient to handle. The nurse could check and see if the drug is available in a liquid form and bring this information to the attention of the person prescribing the drug. When establishing the prescribed route, check the proper method of administering a drug by that route. Review drug administration methods periodically to make sure you have not forgotten important techniques. If you have instructed a patient in the proper administration of a drug, be sure to have the patient explain it back to you and demonstrate the proper technique. This should be done not only when the patient first learns this technique, but also periodically to make sure he or she has not forgotten any important points. Throughout this book, Focus on Safe Medication Administration boxes will provide review of proper medication administration technique.
4. **Right dose.** Always double-check calculations, and always do the calculations if the drug is not available in the dose ordered. Calculate the drug dose appropriately, based on the available drug form, the patient's body weight or surface area, or the patient's kidney function. Do not assume that the computer or the pharmacy is always right; you are one more check in the system. Do not cut tablets to get to a correct dose without checking to make sure the tablet can be cut, crushed, or chewed. Many of the new tablets cannot. Be very cautious if you see an order that starts with a decimal point; these orders are often the cause of medication errors. You should never see .5 mg as an order because it could be interpreted as 5 mg, 10 times the ordered dose. The proper dose would be 0.5 mg. If you see an order for 5.0 mg, be cautious; it could be interpreted as 50 mg. If a dose seems too big, question it. Throughout this book, Focus on Calculations boxes will provide review for calculating dose properly.
5. **Right preparation.** Know the specific preparation required before administering any drug. For example, oral drugs may need to be crushed or shaken; parenteral drugs may need to be reconstituted or diluted with specific solutions; and topical drugs may require specific handling, such as the use of gloves during administration or shaving of a body area before application. Many current oral drugs cannot be cut, crushed, or chewed. Checking that information can help to prevent serious adverse effects. If a drug needs to be diluted or reconstituted, check the manufacturer's instructions to make sure that this is done correctly.
6. **Right time.** When drugs are studied and evaluated, a suggested timing of administration is established. This timing takes into account all aspects of pharmacokinetics to determine a dosing schedule that will provide the needed therapeutic dose of the drug. Recognize that the administration of one drug may require coordination with the administration of other drugs, foods, or physical parameters. In a busy hospital setting, getting the drug to the patient at the prescribed time can be a real challenge. As the caregiver most frequently involved in administering drugs, the nurse must be aware of and manipulate all of these factors, as well as educate the patient to do this on his or her own. Organizing the day and the drug regimen to make it the least intrusive on a patient's lifestyle can help to prevent errors and improve compliance.
7. **Right recording.** Always document drug administration. If it isn't written, it didn't happen. Document the information in accordance with the local requirements for recording medication administration after assessing the patient, making the appropriate nursing diagnoses, and delivering the correct drug, by the correct route, in the correct dose, and at the correct time. Accurately record the drug given and the time given only once you have given the drug to avoid inadvertent overdoses or missing doses, which would lead to a lack of therapeutic effect. Encourage patients to keep track of their drugs at home, what they take, and when they take it, especially if they could be confused.

The Patient's Role

With so many patients managing their drug regimens at home, one other very important check in the system also exists: the patient. Only the patient really knows what is being taken and when, and only the patient can report the actual as opposed to the prescribed drug regimen being followed. Patient and family education plays a vital role in the prevention of medication errors. Encourage patients to be their own advocates and to speak up and ask questions. Doing so

helps to prevent medication errors. The following teaching points help to reduce the risk of medication errors in the home setting:

- *Keep a written list of all medications you are taking, including prescription, over-the-counter, and herbal medications.* Keep this list with you at all times in case you are in an emergency situation and to keep your health care providers up to date. This list can be essential if you are traveling and need to refill a prescription while away from home.

 FOCUS ON

BOX 4.3 Patient and Family Teaching

Include the following key elements in any drug education program.

1. *Name, dose, and action of drug:* Ensure that patients know this information. Many patients see more than one health care provider; this knowledge is crucial to ensuring safe and effective drug therapy and avoiding drug–drug interactions. Urge patients to keep a written list of the drugs that they are taking to show to any health care provider taking care of them, and in case of an emergency when they are not able to report their drug history.
2. *Timing of administration:* Teach patients when to take the drug with respect to frequency, other drugs, and meals.
3. *Special storage and preparation instructions:* Inform patients about any special handling or storing required. Some drugs may require refrigeration; others may need to be mixed with a specific liquid such as water or fruit juice. Be sure that patients know how to carry out these requirements.
4. *Specific OTC drugs or alternative therapies to avoid:* Prevent possible interactions between prescribed drugs and other drugs or remedies the patient may be using or taking. Many patients do not consider OTC drugs or herbal or alternative therapies to be actual drugs and may inadvertently take them along with their prescribed medications, causing unwanted or even dangerous drug–drug interactions. Prevent these situations by explaining which drugs or therapies should be avoided. Encourage patients to always report all of the drugs or therapies that they are using to health care providers
5. *Special comfort measures:* Teach patients how to cope with anticipated adverse effects to ease anxiety and avoid noncompliance with drug therapy. If a patient knows that a diuretic is going to lead to increased urination, the day can be scheduled so that bathrooms are nearby when they might be needed. Also educate patients about the importance of follow-up tests or evaluation.
6. *Safety measures:* Instruct all patients to keep drugs out of the reach of children. Remind all patients to inform any health care provider they see about the drugs they are taking; this can prevent drug–drug interactions and misdiagnoses based on drug effects. Also alert patients to possible safety issues that could arise as result of drug therapy. For example, teach patients to avoid driving or performing hazardous tasks if they are taking drugs that can make them dizzy or alter their thinking or response time.
7. *Specific points about drug toxicity:* Give patients a list of warning signs of drug toxicity. Advise patients to notify their health care provider if any of these effects occur.
8. *Specific warnings about drug discontinuation:* Remember that some drugs with a small margin of safety and drugs with particular systemic effects cannot be stopped abruptly without dangerous effects. Alert patients who are taking these types of drugs to this problem and encourage them to call their health care provider immediately if they cannot take their medication for any reason (e.g., illness, financial constraints).

NOTE: Refer to the CD-ROM accompanying this book for teaching guides that can be used for patients in the actual clinical setting.

- *Know what each of your drugs is being used to treat.* If you know why you are taking each drug, you will have a better understanding of what to report, what to watch for, and when to report to your health care provider if the drug is not working.
- *Read the labels, and follow the directions.* It is easy to make up your own schedule or to just take everything all at once in the morning. Always check the labels to see if there are specific times you should be taking your drugs. Make a calendar if you take drugs on alternating days. Using a weekly pillbox may also help to keep things straight.
- *Store drugs in a dry place, away from children and pets.* Humid and hot storage areas (like the bathroom) tend to cause drugs to break down faster. Storing drugs away from children and pets can prevent possible toxic effects if these drugs are inadvertently ingested by children or your family pet.
- *Speak up.* You are the most important member of the health care team, and you have information to share that no one else knows.

Children present unique challenges related to medication errors. Children often cannot speak for themselves and rely on a caregiver or caregivers to manage their drug regimen.

Because their bodies are still developing and respond differently than those of adults to many drugs, the risk of serious adverse reactions is greater with children. The margin of safety with many drugs is very small when dealing with a child. When teaching parents about their children's drug regimens, be sure to include the following instructions:

- *Keep a list of all medications you are giving your child, including prescription, over-the-counter, and herbal medications.* Share this list with any health care provider who cares for your child. Never assume that a health care provider already knows what your child is taking.
- *Never use adult medications to treat a child.* The body organs and systems of children, primarily their livers and kidneys, are very different from those of an adult. As a result, children respond differently to drugs.
- *Read all labels before giving your child a drug.* Many over-the-counter drugs contain the same ingredients, and you could accidentally overdose your child if you are not careful. In addition, some over-the-counter drugs are not to be used with children younger than a certain age. Doses also may differ for children.
- *Measure liquid medications using appropriate measuring devices.* Never use your flatware teaspoon or tablespoon to

BOX 4.4 Reporting Medication Errors

National center for reporting actual or potential medication errors (U.S. Pharmacopeia/Institute for Safe Medication Practices Medication Errors Reporting Program [MERP]):
Call 1-800-23-ERROR.
Go online to <http://www.usp.org>.

measure your child's drugs. Always use a measured dosing device or the spoon from a measuring set.

- *Call your health care provider immediately if your child seems to get worse or seems to be having trouble with a drug. Do not hesitate; many drugs can cause serious or life-threatening problems with children, and you should act immediately.*
- *When in doubt, do not hesitate to ask questions. You are your child's best advocate.*

Reporting of Medication Errors

Medication errors must be reported on a national level as well as on an institutional level. National reporting programs are coordinated by the U.S. Pharmacopeia (USP), and they help to gather information about errors to prevent their recurrence at other health care sites and by other health care providers. These reports might prompt the issuing of health care provider warnings, which point out potential or actual medication errors and suggest ways to avoid these errors in the future. For example, in 2007, the name of the drug *Omacor* (omega-3 fatty acid) was changed to *Lovaza* after many reports of confusion between *Omacor* and *Amicar* (aminocaproic acid). Other reports have led to public warnings about look-alike or sound-alike drug names and common dosing errors and transcribing issues.

Institutions also have their own policies for reporting medication errors that protect patients and staff and identify particular areas in which education or system changes may be needed. Always be aware of the policies of your employing institution or agency. If you see or participate in a medication error, report it to your institution, and then to report it to the national reporting program. Box 4.4 provides information about reporting medication errors. Your report will be shared with all of the appropriate agencies—the U.S. Food and Drug Administration (FDA), the drug manufacturer, and the Institute for Safe Medication Practices. Health care providers working together and sharing information can make a big impact in decreasing the occurrence of medication errors.

CHAPTER SUMMARY

- Nursing is a complex art and science that provides for nurturing and care of the sick, as well as prevention and education services.

- Components of the nursing assessment (history of past illnesses and the current complaint, as well as a physical examination) provide a database of baseline information to ensure safe administration of a drug and to evaluate the drug's effectiveness and adverse effects.
- Nursing assessment must include information on the history of past illnesses and the current complaint, as well as a physical examination; this provides a database of baseline information to ensure safe administration of a drug and to evaluate the drug's effectiveness and adverse effects.
- Nursing diagnoses are developed from the information gathered during the assessment phase of the nursing process. A nursing diagnosis states the actual or potential response of a patient to a clinical situation.
- Implementation involves taking the information gathered and synthesized into nursing diagnoses to plan the patient care. This process includes determining the desired patient outcomes, setting goals for safe and effective drug administration, providing comfort measures to help the patient cope with the therapeutic or adverse effects of a drug, and providing patient and family education to ensure safe and effective drug therapy.
- Evaluation is part of the continuing process of patient care that leads to changes in assessment, diagnosis, and intervention. The patient is continually evaluated for therapeutic response, the occurrence of adverse drug effects, and the occurrence of drug–drug, drug–food, drug–alternative therapy, or drug–laboratory test interactions.
- A nursing care guide and patient education materials can be prepared for each drug being given, using information about a drug's therapeutic effects, adverse effects, and special considerations.
- Prevention of medication errors is a complicated task that involves the prescriber, the pharmacist, the nurse administering the drugs, and the patient. The nurse needs to be vigilant in administering drugs to check the seven “rights” of drug administration. The patient needs to be educated to be his or her own advocate and to take steps to avoid medication errors.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-Rom in the front of this book.

MULTIPLE CHOICE

Select the best answer to the following.

1. A patient reports that she has a drug allergy. In exploring the allergic reaction with the patient, which of the following might indicate an allergic response?
 - a. Increased urination.
 - b. Dry mouth.
 - c. Rash.
 - d. Drowsiness.
2. The nurse obtains a medical history from a patient before beginning drug therapy based on an understanding of which of the following?
 - a. Medical conditions can alter a drug's pharmacokinetics and pharmacodynamics.
 - b. A medical history is a key component of any nursing protocol.
 - c. A baseline of information is necessary to evaluate a drug's effects.
 - d. The medical history is the first step in the nursing process.
3. The nurse writes a nursing diagnosis for which reason?
 - a. Direct medical care.
 - b. Help to increase patient compliance.
 - c. Identify actual or potential alteration in patient function.
 - d. Determine insurance reimbursement in most cases.
4. A patient receiving an antihistamine complains of dry mouth and nose. An appropriate comfort measure for this patient would be to:
 - a. suggest that the patient use a humidifier.
 - b. encourage voiding before taking the drug.
 - c. have the patient avoid sun exposure.
 - d. give the patient a back rub.
5. When establishing the nursing interventions appropriate for a given patient
 - a. the patient should not be actively involved.
 - b. the patient support systems should be included only at discharge.
 - c. teaching should be done when the patient states he or she is ready to learn.
 - d. an evaluation of all of the data accumulated should be incorporated to achieve an effective care plan.
6. The evaluation step of the nursing process
 - a. is often used as a last resort.
 - b. is important primarily in the acute setting.
 - c. is a continuous process.
 - d. includes making nursing diagnoses.
7. After teaching a patient about digoxin (generic)—a drug used to increase the effectiveness of the heart's contractions—which statement would indicate that the teaching was effective?
 - a. "I need to take my pulse every morning before I take my pill."
 - b. "If I forget my pills, I usually make up the missed dose once I remember."
 - c. "This pill might help my hay fever when it becomes a problem."
 - d. "I don't remember the name of it, but it is the white one."

MULTIPLE RESPONSE

Select all that apply.

1. A client is being started on a laxative regimen. Before beginning the regimen, the nurse would perform which of the following assessments?
 - a. Liver function test.
 - b. Abdominal examination
 - c. Skin color and lesion evaluation
 - d. Lung auscultation
 - e. 24-hour urine analysis
 - f. Cardiac assessment
2. The nursing care of a patient receiving drug therapy should include measures to decrease the anticipated adverse effects of the drug. Which of the following measures would a nurse consider?
 - a. A positive approach
 - b. Environmental temperature control
 - c. Safety measures
 - d. Skin care
 - e. Refrigeration of the drug
 - f. Involvement of the family
3. A nurse is preparing to administer a drug to a client for the first time. What questions should the nurse consider before actually administering the drug?
 - a. Is this the right patient?
 - b. Is this the right drug?
 - c. Is there a generic drug available?
 - d. Is this the right route for this patient?
 - e. Is this the right dose, as ordered?
 - f. Did I record this properly?

Dosage Calculations

5

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Describe four measuring systems that can be used in drug therapy.
2. Convert between different measuring systems when given drug orders and available forms of the drugs.
3. Calculate the correct dose of a drug when given examples of drug orders and available forms of the drugs ordered.
4. Discuss why children require different dosages of drugs than adults.
5. Explain the calculations used to determine a safe pediatric dose of a drug.

Glossary of Key Terms

apothecary system: a very old system of measure that was specifically developed for use by apothecaries or pharmacists; it uses the minim as the basic unit of liquid measure and the grain as the basic unit of solid measure.

Clark's rule: a method of determining the correct drug dose for a child based on the known adult dose (assumes that the adult dose is based on a 150-lb person); it states

$$\text{child's dose} = \frac{\text{weight of child (lb)}}{150 \text{ lb}} \times \text{average adult dose}$$

conversion: finding the equivalent values between two systems of measure

Fried's rule: a method of determining a pediatric drug dose for a child younger than 1 year of age, based on the child's age and the usual adult dose (assumes that an adult dose would be appropriate for a 12.5-year-old child); it states

$$\text{child's dose (age} < 1 \text{ yr)} = \frac{\text{child's age (mo)}}{150 \text{ mo}} \times \text{average adult dose}$$

metric system: the most widely used system of measure, based on the decimal system; all units in the system are determined as multiples of 10

ratio and proportion: an equation in which a ratio containing two known equivalent amounts is on one side and a ratio containing the amount desired to convert and its unknown equivalent is on the other side

Young's rule: a method for determining pediatric drug dose based on the child's age and the usual adult dose; it states

$$\text{child's dose (age 1–12 yr)} = \frac{\text{child's age (yr)}}{\text{child's age (yr)} + 12} \times \text{average adult dose}$$

To determine the correct dose of a particular drug for a patient, we consider the patient's sex, weight, age, and physical condition, as well as the other drugs that the patient is taking. Frequently, the dose that is needed for a patient is not the dose that is available, and it is necessary to convert the dose form available into the prescribed dose. Doing the necessary mathematical calculations to determine what should

be given is the responsibility of the prescriber who orders the drug, the pharmacist who dispenses the drug, and the nurse who administers the drug. This allows the necessary checks on the dose being given before the patient actually receives the drug. Another check to help prevent medication errors is that in many institutions, drugs arrive at the patient care area in unit-dose form, prepackaged for each individual

TABLE 5.1 Comparing Basic Units of Measure by Measuring Systems

SYSTEM	SOLID MEASURE	LIQUID MEASURE
Metric	gram (g) 1 milligram (mg) = 0.001 g 1 microgram (mcg) = 0.000001 g 1 kilogram (kg) = 1000 g	liter (L) 1 milliliter (mL) = 0.001 L 1 mL = 1 cubic centimeter = 1 cc
Apothecary	grain (gr) 60 gr = 1 dram (dr) 8 dr = 1 ounce (oz)	minim (min) 60 min = 1 fluidram (f dr) 8 f dr = 1 fluidounce (f oz)
Household	pound (lb) 1 lb = 16 ounces (oz)	pint (pt) 2 pt = 1 quart (qt) 4 qt = 1 gallon (gal) 16 oz = 1 pt = 2 cups (c) 32 tablespoons (tbsp) = 1 pt 3 teaspoons (tsp) = 1 tbsp 60 drops (gtt) = 1 tsp

patient. The nurse who will administer the drug may come to rely on this prepackaged system, forgoing any recalculation or rechecking of the dose to match the written order. Unfortunately, mistakes still happen, and the nurse, as the person who is administering the drug, is legally and professionally responsible for any error that might occur. Practicing nurses must know how to convert drug dosing orders into appropriate doses of available forms of a drug to ensure that the right patient is getting the right dose of a drug.

MEASURING SYSTEMS

At least four different systems are currently used in drug preparation and delivery: the metric system, the apothecary system, the household system, and the avoirdupois system. Table 5.1 compares the basic units of measure of three of the measuring systems. With the growing number of drugs available and increasing awareness of medication errors that occur in daily practice, efforts have been made to decrease the dependence on so many different systems. In 1995, the U.S. Pharmacopeia Convention established standards requiring that all prescriptions, regardless of the system that was used in the drug dosing, include the metric measure for the quantity and strength of drug. It was also established that drugs may be dispensed only in the metric form. Prescribers are not totally converted to this new standard, however, so the nurse must be able to convert the dose ordered into the available dose form to ensure patient safety. It is important to be able to perform **conversions**—finding the equivalent values between two types of measure, within each system of measure, and between systems of measure.

Metric System

The **metric system** is the most widely used system of measure. It is based on the decimal system, so all units are determined as multiples of 10. This system is used worldwide and makes the sharing of knowledge and research information

easier. The metric system uses the gram as the basic unit of solid measure and the liter as the basic unit of liquid measure (see Table 5.1).

Apothecary System

The **apothecary system** is a very old system of measurement that was specifically developed for use by apothecaries or pharmacists. The apothecary system uses the minim as the basic unit of liquid measure and the grain as the basic unit of solid measure (see Table 5.1). This system is much harder to use than the metric system and is rarely seen in most clinical settings. Occasionally a prescriber will write an order in this system, and the dose will have to be converted to an available form. An interesting feature of this system is that it uses Roman numerals placed after the unit of measure to denote amount. For example, 15 grains would be written “gr xv.”

Household System

The household system is the measuring system that is found in recipe books. This system uses the teaspoon as the basic unit of fluid measure and the pound as the basic unit of solid measure (see Table 5.1). Although efforts have been made in recent years to standardize these measuring devices, wide variations have been noted in the capacity of some of them. Patients need to be advised that flatware teaspoons and drinking cups vary tremendously in the volume that they contain. A flatware teaspoon could hold up to two measuring teaspoons of quantity. When a patient is using a liquid medication at home, it is important to clarify that the measures indicated in the instructions refer to a standardized measuring device.

Avoirdupois System

The avoirdupois system is another older system that was very popular when pharmacists routinely had to compound medications. This system uses ounces and grains, but they

measure differently than those of the apothecary and household systems. The avoirdupois system is seldom used by prescribers but may be used for bulk medications that come directly from the manufacturer.

Other Systems

Some drugs are measured in units other than those already discussed. These measures may reflect chemical activity or biological equivalence. One of these measures is the unit. A unit usually reflects the biological activity of the drug in 1 mL of solution. The unit is unique for the drug it measures; a unit of heparin is not comparable to a unit of insulin. Milliequivalents (mEq) are used to measure electrolytes (e.g., potassium, sodium, calcium, fluoride). The milliequivalent refers to the ionic activity of the drug in question; the order is usually written for a number of milliequivalents instead of a volume of drug. International units (IU) are sometimes used to measure certain vitamins or enzymes. These are also unique to each drug and cannot be converted to another measuring form.

KEY POINTS

- At least four different systems are currently used in drug preparation and delivery. These are the metric system, the apothecary system, the household system, and the avoirdupois system.
- The metric system is the most widely used system of measure. The U.S. Pharmacopeia Convention established standards requiring that all prescriptions, regardless of the system that was used in the drug dosing, include the metric measure for the quantity and strength of drug. All drugs are dispensed in the metric system.

CONVERSION BETWEEN SYSTEMS

The simplest way to convert measurements from one system to another is to set up a **ratio and proportion** equation. The ratio containing two known equivalent amounts is placed on one side of an equation, and the ratio containing the amount you wish to convert and its unknown equivalent is placed on the other side. To do this, it is necessary to first check a table of conversions to determine the equivalent measure in the two systems you are using. Table 5.2 presents some accepted conversions equivalents between systems of measurement. It is a good idea to post a conversion guide in the medication room or on the medication cart for easy access. When conversions are used frequently, it is easy to remember them. When conversions are not used frequently, it is best to look them up.

Try the following conversion using Table 5.2. Convert 6 f oz (apothecary system) to the metric system of measure. According to Table 5.2, 1 f oz is equivalent to 30 mL. Use this information to set up a ratio:

$$\frac{1 \text{ f oz}}{30 \text{ mL}} = \frac{6 \text{ f oz}}{X}$$

TABLE 5.2 Commonly Accepted Conversions Between Systems of Measurement

METRIC SYSTEM	APOTHECARY SYSTEM	HOUSEHOLD SYSTEM
Solid Measure		
1 kg		2.2 lb
454 g		1.0 lb
1 g = 1000 mg	15 gr (gr xv)	
60 mg	1 gr (gr i)	
30 mg	½ gr (gr ss)	
Liquid Measure		
1 L = 1000 mL		about 1 qt
240 mL	8 f oz (f oz viii)	1 c
30 mL	1 f oz (f oz i)	2 tbsp
15–16 mL	4 f dr (f dr iv)	1 tbsp = 3 tsp
8 mL	2 f dr (f dr ii)	2 tsp
4–5 mL	1 f dr (f dr i)	1 tsp = 60 gtt
1 mL	15–16 min (min xv) or min xvi)	
0.06 mL	1 min (min i)	

The known ratio—1 f oz (apothecary system) is equivalent to 30 mL (metric system)—is on one side of the equation. The other side of the equation contains 6 f oz, the amount (apothecary system) that you want to convert, and its unknown (metric system) equivalent, X . Because the fluid ounce measurement is in the numerator (top number) on the left side of the equation, it must also be in the numerator on the right side of the equation. This equation would read as follows: One fluid ounce is to thirty milliliters as six fluid ounces is to how many milliliters?

The first step in the conversion is to cross-multiply (multiply the numerator from one side of the equation by the denominator from the other side, and vice versa):

$$\frac{1 \text{ f oz}}{30 \text{ mL}} = \frac{6 \text{ f oz}}{X}$$

$$1 \text{ f oz} \times X = 6 \text{ f oz} \times 30 \text{ mL}$$

This could also be written

$$(1 \text{ f oz})(X) = (6 \text{ f oz})(30 \text{ mL})$$

After multiplying the numbers, you have

$$1 \text{ (f oz)}X = 180 \text{ (f oz)(mL)}$$

Next, rearrange the terms to let the unknown quantity stand alone on one side of the equation:

$$X = \frac{180 \text{ (mL)(f oz)}}{1 \text{ f oz}}$$

Whenever possible, cancel out numbers, as well as units of measure. In this example, canceling out leaves $X = 180 \text{ mL}$.

By canceling out, you are left with the appropriate amount and unit of measure. The answer to the problem is that 6 f oz is equivalent to 180 mL.

Try another conversion. Convert 32 gr (apothecary system) to its equivalent in the metric system, expressing the answer in milligrams. First, find the conversion on Table 5.2: 1 gr is equal to 60 mg. Set up the ratio

$$\frac{1 \text{ gr}}{60 \text{ mg}} = \frac{32 \text{ gr}}{X}$$

Cross-multiply:

$$(1 \text{ gr})(X) = (32 \text{ gr})(60 \text{ mg})$$

$$1 (\text{gr}) X = 1920 (\text{gr})(\text{mg})$$

Rearrange:

$$X = \frac{1920 (\text{gr})(\text{mg})}{1 \text{ gr}}$$

Finally, cancel out like units and numbers:

$$X = 1920 \text{ mg}$$

Therefore, 32 gr is equivalent to 1920 mg.

CALCULATING DOSE

As mentioned earlier, because there are several systems of measurement available that might be used when a drug is ordered and because drugs are made available only in certain forms or doses, it may be necessary to calculate what the patient should be receiving.

Oral Drugs

Frequently, tablets or capsules for oral administration are not available in the exact dose that has been ordered. In these situations, the nurse who is administering the drug must calculate the number of tablets or capsules to give for the ordered dose. The easiest way to determine this is to set up a ratio and proportion equation. The ratio containing the two known equivalent amounts is put on one side of the equation, and the ratio containing the unknown value is put on the other side. The known equivalent is the amount of drug available in one tablet or capsule; the unknown is the number of tablets or capsules that are needed for the prescribed dose:

$$\frac{\text{amount of drug available}}{\text{one tablet or capsule}} = \frac{\text{amount of drug prescribed}}{\text{number of tablets or capsules to give}}$$

The phrase “amount of drug” serves as the unit, so this information must be in the numerator of each ratio.

Try this example: An order is written for 10 grains of aspirin (gr x, aspirin). The tablets that are available each contain 5 grains. How many tablets should the nurse give? First, set up the equation:

$$\frac{5 \text{ gr}}{\text{one tablet}} = \frac{10 \text{ gr}}{X}$$

Cross-multiply the ratio:

$$5 (\text{gr}) X = 10 (\text{gr})(\text{tablet})$$

Rearrange and cancel like units and numbers:

$$X = \frac{10 (\text{gr})(\text{tablets})}{5 (\text{gr})}$$

$$X = 2 \text{ tablets}$$

Therefore, the nurse would administer two tablets.

Try another example: An order is written for 0.05 g *Aldactone* (spironolactone) to be given orally (PO). The *Aldactone* is available in 25-mg tablets. How many tablets would you have to give? First, you will need to convert the grams to milligrams:

$$\frac{1 \text{ g}}{100 \text{ mg}} = \frac{0.05 \text{ g}}{X}$$

Cross-multiply:

$$1 (\text{g}) X = (0.05 \times 1000)(\text{g})(\text{mg})$$

Simplify:

$$X = \frac{50 (\text{g})(\text{mg})}{1 (\text{g})}$$

$$X = 50 \text{ mg}$$

So 0.05 g of Aldactone is equal to 50 mg of Aldactone.

The order has been converted to the same measurement as the available tablets. Now solve for the number of tablets that you will need, letting X be the desired dose:

$$\frac{25 \text{ mg}}{1 \text{ tablet}} = \frac{50 \text{ mg}}{X}$$

$$25 (\text{mg}) X = (50 \times 1) (\text{mg})(\text{tablet})$$

$$X = 2 \text{ tablets}$$

Sometimes the desired dose will be a fraction of a tablet or capsule, 1/2 or 1/4. Some tablets come with scored markings that allow them to be cut. Pill cutters are readily available in most pharmacies to help patients cut tablets appropriately. However, one must use caution when advising a patient to cut a tablet. Many tablets come in a matrix system that allows for slow and steady release of the active drug. These drugs cannot be cut, crushed, or chewed. Always consult a drug reference before cutting a tablet. However, as a quick reference, any tablet that is designated as having delayed or sustained release may very well be one that cannot be cut. Capsules can be very difficult to divide precisely, and some of them also come with warnings that they cannot be cut, crushed, or chewed. If the only way to deliver the correct dose to a patient is by cutting one of these preparations, a different formulation of the drug, a different drug, or a different approach to treating the patient should be tried.

Other oral drugs come in liquid preparations. Many of the drugs used in pediatrics and for adults who might have difficulty swallowing a pill or tablet are prepared in a liquid form.

Some drugs that do not come in a standard liquid form can be prepared as a liquid by the pharmacist. If the patient is not able to swallow a tablet or capsule, check for other available forms and consult with the pharmacist about the possibility of preparing the drug in a liquid as a suspension or a solution. The same principle used to determine the number of tablets needed to arrive at a prescribed dose can be used to determine the volume of liquid that will be required to administer the prescribed dose. The ratio on the left of the equation shows the known equivalents, and the ratio on the right side contains the unknown. The phrase “amount of drug” must appear in the numerator of both ratios, and the volume to administer is the unknown (X).

Try this example: An order has been written for 250 mg of sulfisoxazole. The bottle states that the solution contains 125 mg/5 mL. How much of the liquid should you give?

Cross-multiply:

$$125 \text{ (mg)} X = (250 \times 5) \text{ (mg)(mL)}$$

Simplify:

$$X = \frac{1250 \text{ (mg)(mL)}}{125 \text{ (mg)}}$$

So the desired dose is $X = 10 \text{ mL}$.

Even if you are working in an institution that provides unit-dose medications, practice your calculation skills occasionally to keep them sharp. Power can be lost, computers can go down, and the ability to determine conversions is a skill that anyone who administers drugs should have in reserve. Periodically throughout this text you will find a Focus on Calculations box to help you refresh your dose calculation skills as they apply to the drugs being discussed.

Parenteral Drugs

All drugs administered parenterally must be administered in liquid form. The person administering the drug needs to calculate the volume of the liquid that must be given to administer the prescribed dose. The same formula can be used for this determination that was used for determining the dose of an oral liquid drug:

$$\frac{\text{amount of drug available}}{\text{volume available}} = \frac{\text{amount of drug prescribed}}{\text{volume to administer}}$$

Try this example: An order has been written for 75 mg of meperidine to be given intramuscularly (IM). The vial states that it contains meperidine, 1.0 mL = 50.0 mg. Set up the equation just as before:

$$\frac{50 \text{ mg}}{1 \text{ mL}} = \frac{75 \text{ mg}}{X}$$

$$50 \text{ (mg)} X = (75 \times 1) \text{ (mg)(mL)}$$

$$X = \frac{75 \text{ (mg)(mL)}}{50 \text{ (mg)}}$$

Thus, $X = 1.5 \text{ mL}$

Intravenous Solutions

Intravenous (IV) solutions are used to deliver a prescribed amount of fluid, electrolytes, vitamins, nutrients, or drugs directly into the bloodstream. Although most institutions now use electronically monitored delivery systems, it is still important to be able to determine the amount of an IV solution that should be given, using standard calculations. Most IV delivery systems come with a standard control called a microdrip, by which each milliliter delivered contains 60 drops. Macrodrop systems, which usually deliver 15 drops/mL, are also available; they are usually used when a large volume must be delivered quickly. Always check the packaging of the IV tubing to see how many drops/mL are delivered by that particular device if you have any doubts or are unfamiliar with the system.

Use the following ratio to determine how many drops of fluid to administer per minute:

$$\frac{\text{drops}}{\text{minute}} = \frac{\text{(mL of solution prescribed per hour)}}{\text{(drops delivered per mL)}} \times \frac{60 \text{ min}}{1 \text{ h}}$$

That is, the number of drops per minute, or the rate that you will set by adjusting the valve on the IV tubing, is equal to the amount of solution that has been prescribed per hour times the number of drops delivered per milliliter (mL), divided by 60 minutes in an hour.

Try this example: An order has been written for a patient to receive 400 mL of 5% dextrose in water (D5W) over a period of 4 hours in a standard microdrip system (i.e., 60 drops/mL). Calculate the correct setting (drops per minute):

$$X = \frac{(400 \text{ mL}/4 \text{ h})(60 \text{ drops/min})}{(60 \text{ min})/(1 \text{ h})}$$

Simplify:

$$X = \frac{(100 \text{ mL/h})(60 \text{ drops/min})}{(60 \text{ min})/(1 \text{ h})}$$

$$X = \frac{6000 \text{ drops/h}}{(60 \text{ min})/(1 \text{ h})}$$

Therefore, $X = 100 \text{ drops/min}$.

Now calculate the same order for an IV set that delivers 15 drops/mL:

$$X = \frac{(400 \text{ mL}/4 \text{ h})(15 \text{ drops/min})}{(60 \text{ min})/(1 \text{ h})}$$

$$X = \frac{(100 \text{ mL/h})(15 \text{ drops/min})}{(60 \text{ min})/(1 \text{ h})}$$

$$X = \frac{1500 \text{ drops/h}}{(60 \text{ min})/(1 \text{ h})}$$

Therefore $X = 25 \text{ drops/min}$.

If a patient has an order for an IV drug, the same principle can be used to calculate the speed of the delivery. For

example, an order is written for a patient to receive 50 mL of an antibiotic over 30 minutes. The IV set used dispenses 60 drops/mL, which allows greater control. Calculate how fast the delivery should be:

$$X = \frac{(50 \text{ mL}/0.5 \text{ h})(60 \text{ drops/min})}{(60 \text{ min})/(1 \text{ h})}$$

$$X = \frac{(100 \text{ mL/h})(60 \text{ drops/min})}{(60 \text{ min})/(1 \text{ h})}$$

$$X = \frac{6000 \text{ drops/h}}{(60 \text{ min})/(1 \text{ h})}$$

Therefore $X = 100$ drops/min.

Pediatric Considerations

For most drugs, children require doses different from those given to adults. The “standard” drug dose that is listed on package inserts and in many references refers to the dose that has been found to be most effective in the adult male. An adult’s body handles drugs differently and may respond to drugs differently than a child’s. For example, a child’s body may handle a drug differently in all areas of pharmacokinetics—absorption, distribution, metabolism, and excretion. In addition, the responses of the child’s organs to the effects of the drug also may vary because of the immaturity of the organs. Most of the time a child requires a smaller dose of a drug to achieve the comparable critical concentration as that for an adult. On rare occasions, a child may require a higher dose of a drug. For ethical reasons, drug research per se is not done on children. Over time, however, enough information can be accumulated from experience with the drug to have a recommended pediatric dose. The drug guide that you have selected to use in the clinical setting will have the pediatric dose listed if this information is available. Unfortunately, there may be times when no recommended dose for a child is available but that particular drug is needed. In these situations, established formulas can be used to estimate the appropriate dose. These methods of determining a pediatric dose take into consideration the child’s age, weight, or body surface. Box 5.1 highlights Fried’s rule, which considers age for a child under the age of 1 year; Young’s rule, which calculates doses for children 1 to 12 years of age; and Clark’s rule, which accounts for weight in the dose formula. These rules are not usually used today; the nomogram that uses body surface area is more accurate for determining doses (see Figure 5.1). If such a nomogram is not available, however, it is good to know that other methods can be used.

Regardless of the calculation method used for children, even a tiny dose error can be critical. When working in pediatrics, one needs to be familiar with at least one of these methods of determining the drug dose. Many institutions require that two nurses check critical pediatric doses. This is a good practice when working with small children.

BOX 5.1 Calculations

Formulas for Calculating Pediatric Doses

Fried’s rule is a calculation method that applies to a child younger than 1 year of age. The rule assumes that an adult dose would be appropriate for a child who is 12.5 years (150 months) old. Fried’s rule states

$$\text{child's dose (age} < 1 \text{ yr)} = \frac{\text{child's age (mo)}}{150 \text{ mo}} \times \text{average adult dose}$$

Young’s rule is a calculation method that applies to children 1 to 12 years of age. It states

$$\text{child's dose (age 1–12 yr)} = \frac{\text{child's age (yr)}}{\text{child's age (yr)} + 12} \times \text{average adult dose}$$

Clark’s rule uses the child’s weight to calculate the appropriate dose and assumes that the adult dose is based on a 150-lb person. It states

$$\text{child's dose} = \frac{\text{weight of child (lb)}}{150 \text{ lb}} \times \text{average adult dose}$$

For example, a 3-year-old child weighing 30 lb is to receive a therapeutic dose of aspirin. The average adult dose is 5 gr, and the dose to be given is the unknown (X). The calculation may be made from the child’s age by Young’s rule:

$$X = \frac{3 \text{ yr}}{3 + 12 \text{ yr}} \times 5 \text{ gr}$$

$$X = \frac{15 \text{ (yr)(gr)}}{15 \text{ yr}}$$

Therefore, $X = 1$ gr.

Alternatively, the calculation could be based on the child’s weight, using Clark’s rule:

$$X = \frac{30 \text{ lb}}{150 \text{ lb}} \times 5 \text{ gr}$$

$$X = \frac{150 \text{ (lb)(gr)}}{150 \text{ lb}}$$

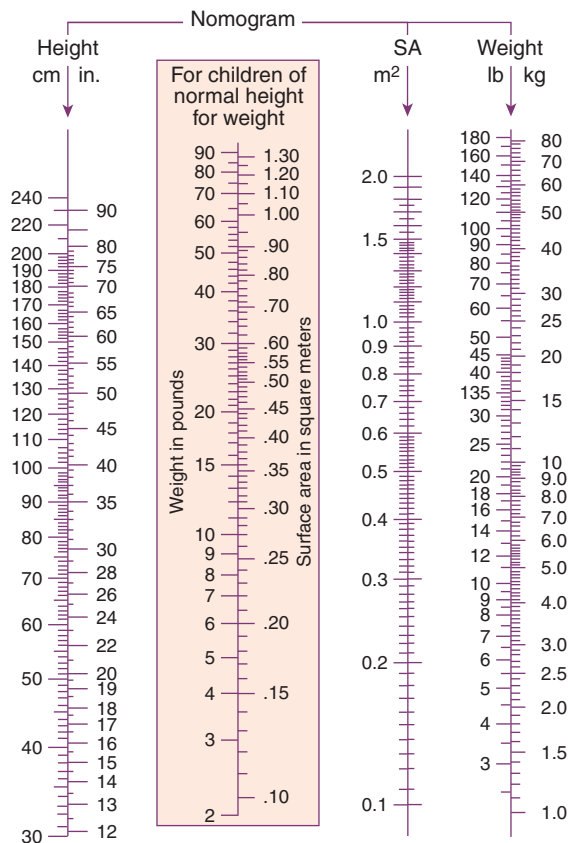

This again yields $X = 1$ gr.

Body Surface Area

The surface area of a child’s body may also be used to determine the approximate dose that should be used. To do this, the child’s surface area is determined with the use of a nomogram (Figure 5.1). The height and weight of the child are taken into consideration in this chart. The following formula is then used:

$$\text{child's dose} = \frac{\text{surface area (m}^2\text{)}}{1.73} \times \text{average adult dose}$$

This method is more precise than the formula methods, but you have to have a nomogram available to determine the surface area.

● **FIGURE 5.1** The West nomogram for calculating body surface area (BSA). Draw a straight line connecting the child's height (left scale) to the child's weight (right scale). The BSA value, which is calculated in square meters, is found at the point where the line intersects the SA column. The formula for estimating a child's dose is as follows: child's BSA (in m^2) \times adult dose \div 1.73. Normal values are shown in the box.

Milligrams/Kilograms of Body Weight

When a safe and effective pediatric dose has been established, the orders for the drug dose are often written in milligrams/kilograms. This method of prescribing takes into consideration the varying weights of children and the need for a higher dose of the drug when the weight increases. For example, if a child with postoperative nausea is to be treated

with *Vistaril* (hydroxyzine) the recommended dose is 1.1 mg/kg by intramuscular injection. If the child weighs 22 kg, the dose for this child would be 1.1 mg/kg times 22 kg, or 24.2 mg, rounded down to 24 mg. If a child weighed only 6 kg, the recommended dose would be 1.1 mg/kg times 6 kg, or 6.6 mg. The established guidelines allow the drug to be used safely within a large range of children. Some adult doses will also be written in this way. This is usually found in drugs with a small margin of safety or high potential for toxic effects, such as anti-neoplastic drugs.

CHAPTER SUMMARY

- At least four different systems are currently used in drug preparation and delivery. These are the metric system, the apothecary system, the household system, and the avoirdupois system.
- The metric system is the most widely used system of measure. The U.S. Pharmacopeia Convention established standards requiring that all prescriptions, regardless of the system that was used in the drug dosing, include the metric measure for the quantity and strength of drug. All drugs are dispensed in the metric system.
- It is important to know how to convert doses from one system to another. The method of ratio and proportion, which uses basic principles of algebra to find an unknown, is the easiest method of converting doses within and between systems.
- Children require doses of most drugs different from those of adults due to the way their bodies handle drugs and the way that drugs affect their tissues and organs.
- Standard formulas, such as Fried's rule (for age less than 1 year), Clark's rule (which considers the child's weight), and Young's rule (which considers weight and age greater than 1 year) can be used to determine the approximate dose that should be given to a child when the average adult dose is known. However, these rules are used less frequently today. Instead, most pediatric doses are based on body surface area, which requires the use of a nomogram, and milligrams per kilogram of body weight.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-Rom in the front of this book.

MULTIPLE CHOICE

Select the best answer to the following.

1. Digoxin 0.125 mg is ordered for a patient who is having trouble swallowing. The bottle of digoxin elixir reads 0.5 mg/2 mL. How much would you give?
 - a. 5 mL
 - b. 0.5 mL
 - c. 1.5 mL
 - d. 1 mL
2. The usual adult dose of diphenhydramine (*Benadryl*) is 50 mg. What would be the safe dose for a child weighing 27 lb?
 - a. 0.9 mg
 - b. 1.8 mg
 - c. 9.0 mg
 - d. 18 mg

3. An order is written for 700 mg of ampicillin PO. The drug is supplied in liquid form as 1 g/3.5 mL. How much of the liquid should be given?
 - a. 5 mL
 - b. 2.5 mL
 - c. 6.2 mL
 - d. 2.45 mL
4. An order is written for 1000 mL of normal saline to be administered IV over 10 hours. The drop factor on the IV tubing states 15 drops/mL. What is the IV flow rate?
 - a. 50 mL/h at 50 drops/min
 - b. 100 mL/h at 25 drops/min
 - c. 100 mL/h at 100 drops/min
 - d. 100 mL/h at 15 drops/min
5. The average adult dose of meperidine is 75 mg. What dose would be appropriate for a 10-month-old infant?
 - a. 50 mg
 - b. 5 mg
 - c. 25 mg
 - d. 0.5 mg
6. A patient needs to take 0.75 g of tetracycline PO. The drug comes in 250-mg tablets. How many tablets should the patient take?
 - a. 2 tablets
 - b. 3 tablets
 - c. 4 tablets
 - d. 30 tablets
7. Aminophylline is supplied in a 500 mg/2.5 mL solution. How much would be given if an order were written for 100 mg of aminophylline IV?
 - a. 5 mL
 - b. 1.5 mL
 - c. 2.5 mL
 - d. 0.5 mL
8. Heparin 800 units is ordered for a patient. The heparin is supplied in a multidose vial that is labeled 10,000 units/mL. How many milliliters of heparin would be needed to treat this patient?
 - a. 0.8 mL
 - b. 0.08 mL
 - c. 8.0 mL
 - d. 0.4 mL

COMPLETE THE FOLLOWING PROBLEMS

1. Change to equivalents within the system:
 - a. 100 mg = _____ g
 - b. 1500 g = _____ kg
 - c. 0.1 L = _____ mL
 - d. 500 mL = _____ L
2. Convert to units in the metric system:
 - a. 150 gr = _____ g
 - b. gr = _____ mg
 - c. 45 min = _____ MI
 - d. 2 qt = _____ L
3. Convert to units in the household system:
 - a. 5 mL = _____ tsp
 - b. 30 mL = _____ tbs
4. Convert the weights in the following problems:
 - a. A patient weighs 170 lb. What is the patient's weight in kilograms?
170 lb = _____ kg
 - b. A patient weighs 3200 g. What is the patient's weight in pounds?
3200 g = _____ lb
5. Robitussin cough syrup 225 mg PO is ordered. The bottle reads: 600 mg in 1 oz. How much cough syrup should be given? _____ mL.
6. A postoperative order is written for 15 gr of codeine every 4 hours as needed (PRN) for pain. Each dose given will contain how many milligrams of codeine? _____ mg.
7. Ordered: 6.5 mg. Available: 10 mg/mL. Proper dose: _____ mL.
8. Ordered: 0.35 mg. Available: 1.2 mg/2 mL. Proper dose: _____ mL.
9. Ordered: 80 mg. Available: 50 mg/mL. Proper dose: _____ mL.
10. Ordered: 150,000 units. Available: 400,000 units/5 mL. Proper dose: _____ mL.

Challenges to Effective Drug Therapy

6

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Discuss the impact of the media, the Internet, and direct-to-consumer advertising on drug sales and prescriptions.
2. Explain the growing use of over-the-counter drugs and the impact it has on safe medical care.
3. Discuss the lack of controls on herbal or alternative therapies and the impact this has on safe drug therapy.
4. Define the off-label use of a drug.
5. Describe measures being taken to protect the public in cases of bioterrorism.

Glossary of Key Terms

alternative therapy: includes herbs and other “natural” products as often found in ancient records; these products are not controlled or tested by the U.S. Food and Drug Administration; however, they are often the basis for discovery of an active ingredient that is later developed into a regulated medication

biological weapons: so-called germ warfare; the use of bacteria, viruses, and parasites on a large scale to incapacitate or destroy a population

cost comparison: a comparison of the relative cost of the same drug provided by different manufacturers to determine the costs to the consumer

Internet: the worldwide digital information system accessed through computer systems

off-label uses: uses of a drug that are not part of the stated therapeutic indications for which the drug was approved by the FDA; off-label uses may lead to new indications for a drug

self-care: tendency for patients to self-diagnose and determine their own treatment needs

street drugs: nonprescription drugs with no known therapeutic use; used to enhance mood or increase pleasure

The dawn of the 21st century arrived with myriad new considerations and pressures in the health care industry. For the first time, consumers have access to medical and pharmacological information from many sources. Consumers are taking steps to demand specific treatments and considerations. Alternative therapies are being offered and advertised at a record pace, and this is causing people to rethink their approach to medical care and the medical system. At the same time, financial pressures have led to early discharge of patients from health care facilities and to provision of outpatient care for patients who, in the past, would have been hospitalized and monitored closely. Health care providers are being pushed to make decisions about patient care and prescriptions based on finances in addition to

medical judgment. The events of 9/11 and the increased threat of terrorism have led to serious concerns about dealing with exposure to biological or chemical weapons. Illicit drug use is at an all-time high, bringing increased health risks and safety concerns. There are increasing concerns about the environment and the need to protect it from contamination. The nurse is caught in the middle of all of this change. Patients are demanding information but may not understand it when they get it. Patient teaching and home care provisions are vital to the success of any health regimen. The nurse is frequently in the best position to listen, teach, and explain some of this confusing information to the patient and to facilitate the care of the patient in the health system.

CONSUMER AWARENESS

Access to information has become so broad over the last decade that consumers are often overwhelmed with details, facts, and choices that affect their health care. Gone is the era when the health care provider was seen as omniscient and always right. The patient now comes into the health care system burdened with the influence of advertising, the Internet, and a growing alternative therapy industry. Many patients no longer calmly accept whatever medication is selected for them. They often come with requests and demands, and they partake of a complex array of over-the-counter (OTC) and alternative medicines that further complicate the safety and efficacy of standard drug therapy.

Media Influence

The last 20 years have seen an explosion of drug advertising in the mass media. It became legal to advertise prescription drugs directly to the public in the 1990s, and it is now impossible to watch television, listen to the radio, or flip through a magazine without encountering numerous drug advertisements.

Federal guidelines determine what can be said in an advertisement, but in some cases this further confuses the issue for many consumers. If a drug advertisement states what the drug is used for, it must also state contraindications, adverse effects, and precautions. Because in many cases listing the possible adverse effects is not a good selling point, many advertisements are pure business ploys intended to interest consumers in the drug and to have them request it from their health care providers (even if it is unclear what the drug is used for). It is not unusual to see an ad featuring a smiling, healthy-looking person romping through a field of beautiful flowers on a sunny day with a cute baby or puppy in tow. The ad might simply state how wonderful it is to be outside on a day like today—contact your health care provider if you, too, would like to take drug X. Although most people now know what the erectile dysfunction drug *Viagra* is used for, some of the ads for this drug simply show a happy older couple smiling and dancing the night away and then encourage viewers to ask their health care providers about *Viagra*. What older person wouldn't want a drug that makes him or her feel young, happy, and energetic?

Parenting magazines, which are often found in pediatricians' offices, are full of advertisements for antibiotics and asthma medications. These ads picture smiling, cute children and encourage readers to check with their pediatricians about the use of these drugs. If the drug's indication is mentioned, the second page of the ad may well have the U.S. Food and Drug Administration (FDA)—approved drug insert printed out in extremely tiny print and in full medical lingo. Most readers have trouble reading the words on these required pages. Even if the words are legible, they frequently don't have any meaning for the reader. The pediatrician or nurse may spend a great deal of time explaining why a particular drug is not indicated for a particular child and may

actually experience resistance on the part of the parent who wants the drug for his or her child. As the marketing power for prescription drugs continues to grow, the health care provider must be constantly aware of what patients are seeing, what the ads are promising, and the real data behind the indications and contraindications for these “hot” drugs. It is a continuing challenge to stay up to date and knowledgeable about drug therapy.

The media also look for headlines in current medical research or reports. It is not unusual for the media to take a headline or research title and make it into news. Sometimes the interpretation of the medical report is not accurate, and this can influence a patient's response to suggested therapy or provide a whole new set of demands or requests for the health care provider. Many of the usual television talk shows include a medical segment that presents just a tiny bit of information, frequently out of context, which opens a whole new area of interest for the viewer. Some health care providers have learned to deal with the “disease of the week” as seen on these shows; others can be unprepared to deal with what was presented and may lose credibility with the patient.

The Internet

The **Internet**, the worldwide digital information system accessed through computer systems, and World Wide Web are now readily accessible to most consumers. People who do not have Internet access at home can find it readily available at the local library, at work, or even in computer centers that allow community access. The information available over the Internet is completely overwhelming to most people. A person can spend hours looking up information on a drug—including pharmaceutical company information sites, chat rooms with other people who are taking the drug, online pharmacies, lists of government regulations, and research reports about the drug and its effectiveness. Many people do not know how to evaluate the information that they can access. Is it accurate or anecdotal? Patients often come into the health care system with pages of information downloaded from the Internet that they think pertains to their particular situation. The nurse or physician can spend a tremendous amount of time deciphering and interpreting the information and explaining it to the patient. Some tips that might be helpful in determining the usefulness or accuracy of information found on the Internet are given in Box 6.1.

KEY POINTS

- ◆ An overwhelming amount of readily accessible information is available to consumers. This information has changed the way people approach the health care system.
- ◆ Consumer advertising of prescription drugs, mass media health reports and suggestions, and the Internet influence some patients to request specific treatments, to question therapy, and to challenge the health care provider.

BOX 6.1 Evaluating Internet Sites**ADDRESS IDENTIFICATION**

- *.com*: commercial, advertising, selling, business site
- *.edu*: education site—school system, university, college
- *.gov*: government site
- *.net*: part of a linked network system, may include any of the above
- *.org*: sponsored by an organization, including professional, charitable, and educational groups

SITE EVALUATION

- Navigation—Is the site easy to access and navigate or confusing?
- Contributors—Who prepared the site? Is it reviewed? Is it purely commercial? What are the qualifications of the person(s) maintaining the site? Is there a mechanism for feedback or interaction with the site?
- Dates—Is the site updated frequently? When was the site last updated?
- Accuracy/reliability—Is the information supported by other sites? Is the information accurate and in agreement with other sources you have reviewed? Does the site list other links that are reasonable and reliable?

OVER-THE-COUNTER DRUGS

OTC medications allow people to take care of simple medical problems without seeking advice from their health care providers. Although OTC drugs have been deemed to be safe when used as directed, many of these medications were “grandfathered in” as drugs when stringent testing and evaluation systems became law and have not been tested or evaluated to the extent that new drugs are today. Aspirin, one of the non-prescription standbys for many years, falls into this category. Slowly, the FDA is looking at all of these drugs to determine their effectiveness and safety. Ipecac, a former standard OTC drug, was used for many years by parents to induce vomiting in children in cases of suspected poisoning or suspected drug

overdose. The drug was finally tested, and in 2003, the FDA announced that it was not found to be effective for its intended use. New guidelines have since been established for parents regarding possible poisoning, and parents were advised to dispose of any ipecac that they had at home. Some well-known approved OTC drugs are cimetidine (*Tagamet*) for decreasing gastric upset and heartburn; various vaginal antifungal medications for treating yeast infections; and omeprazole and famotidine, two other drugs for dealing with heartburn.

Each year several prescription drugs are reviewed for possible OTC status. One factor involved in the review process is the ability of the patient for **self-care**, which is the act of self-diagnosing and determining one’s treatment needs. In 2006 and again in 2007, lovastatin, an antihyperlipidemic drug, was considered for OTC status. The FDA eventually decided that the public would have a hard time self-prescribing this drug because high lipid levels can be determined only with a blood test and present no signs and symptoms, so the drug’s OTC status was not approved. OTC drugs can also mask the signs and symptoms of an underlying problem, making it difficult to arrive at an accurate diagnosis if the condition persists. These drugs are safe when used as directed, but many times the directions are not followed or even read. The idea that “If one makes me feel better, two will make me feel really good” is not always safe in the use of these drugs. Many people are not aware of which drugs are contained in these preparations and can inadvertently overdose when taking one preparation for each symptom they have. Table 6.1 gives an example of the ingredients that are found in some common cold and allergy preparations. Patients who take doses of different preparations to cover their various symptoms could easily wind up with an unintended overdose or toxic reaction.

Because many OTC drugs interact with prescription drugs, with possibly serious adverse or toxic effects for the patient, it is important that the health care provider specifically ask the patient when taking a drug history whether he or she is taking any OTC drugs or other medications. Many patients do not consider OTC drugs to be “real” drugs and

TABLE 6.1 Ingredients Found in Some Common Cold and Flu OTC Preparations*

DRUG NAME	INGREDIENTS	USE
<i>Vicks Formula 44 Cough & Decongestant</i>	pseudoephedrine, dextromethorphan	Cough, stuffy nose
<i>Vicks 44D Cough & Head Congestion</i>	pseudoephedrine, dextromethorphan	Cough, sinus pressure
<i>Vicks 44M Cold, Flu & Cough</i>	pseudoephedrine, chlorpheniramine, dextromethorphan	Cough, aches, stuffy head, flu
<i>Vicks NyQuil LiquiCaps</i>	pseudoephedrine, doxylamine, dextromethorphan	Cough, aches, need to sleep, stuffy head
<i>Thera-Flu Non-Drowsy Formula</i>	pseudoephedrine, dextromethorphan	Stuffy head, need to stay awake, cough, aches

*Safety Precautions: A patient could take one preparation for cough, a second to cover sinus pressure, a third to cover the aches and pains, and a fourth to stay awake or fall asleep—when the total amounts of the drugs contained in these products are calculated, a serious overdose of pseudoephedrine or dextromethorphan could easily occur.

do not mention their use when reporting a drug history to the health care provider. Every patient drug-teaching session should include information on which particular OTC drugs must be avoided or advice to check with the health care provider before taking any other medications or OTC products.

ALTERNATIVE THERAPIES AND HERBAL MEDICINE

Another aspect of the increasing self-care movement is the rapidly growing market of alternative therapies and herbal medicines. Herbal medicines and **alternative therapies** are found in ancient records and have often been the basis for the discovery of an active ingredient that is later developed into a regulated medication. Today, alternative therapies can also include nondrug measures, such as imaging and relaxation. There is an element of the placebo effect in using some of these therapies. The power of believing that something will work and that there is some control over the problem is often very beneficial in achieving relief from pain and suffering. The challenge for the health care provider is to balance the therapies that the patient wishes to use with the medical regimen that is prescribed. This may involve altering doses or timing of various drugs. See Appendix E for an extensive listing of alternative and complementary therapies.

Currently, these products are not controlled or tested by the FDA; they are considered to be dietary supplements, and therefore the advertising surrounding these products is not as restricted or as accurate as with classic drugs. Consumers are urged to use the “natural” approach to medical care and to self-treat with a wide variety of products. Numerous Internet sites point out natural treatments that can be used to cure various disorders. Television ads and magazine spreads push the use of these products in place of prescribed medications. Many people who want to gain control of their medical care or who do not want to take “drugs” for their diabetes, depression, or fatigue are drawn to these products. The Dietary Supplement Health and Education Act of 1994, updated in 2000, classifies herbal products, vitamins and minerals, and amino acids as “dietary supplements” that are not required to go through premarketing testing. The advertising that is permitted for these products does not allow direct claims to cure, treat, diagnose, or prevent a specific disease but does allow for nondisease claims such as “for muscle enhancement,” “for hot flashes,” or “for memory loss.” Appendix E lists common alternative therapies and their suggested uses.

Several issues are of concern to the health care provider when a patient elects to self-treat with alternative therapies. The active ingredients in these products have not been tested by the FDA; when test results are available, often the tests were for only a very small number of people with no repro-

ducible results. When a patient decides to take bilberry to control diabetes, for example, the reaction that will occur is not really known. In some patients, the blood glucose level might decrease; in others, it might increase. The incidental ingredients in many of these products are unknown. Many ingredients come directly from plants or from the conditions under which they grow, such as the fertilizer used for the plant, or depend on the time of the year when the plant was harvested. The other ingredients that are compounded with the product have a direct effect on its efficacy. Saw palmetto, an herb that has been used successfully to alleviate the symptoms of benign prostatic hypertrophy, is available in a wide variety of preparations from different manufacturers. A random sampling of these products performed in 2000 revealed that the contents of the identified active ingredient varied from 20% to 400% of the recommended dose. It is difficult to guide patients to the correct product with such a wide range of variability.

Patients often do not mention the use of alternative therapies to the health care provider. Some patients believe that the health care provider will disapprove of the use of these products and do not want to discuss it; others believe that these are just natural products and do not need to be mentioned. With the increasing use of these products, however, several drug interactions that can cause serious complications for patients taking prescription medication have been reported to the FDA. Diabetic patients who decide to use juniper berries, ginseng, garlic, fenugreek, coriander, dandelion root, or celery to “maintain their blood glucose level” may run into serious problems with hypoglycemia when they also use their prescription antidiabetic drugs. If the patient does not report the use of these alternative therapies to the health care provider, extensive medical tests and dose adjustments might be done to no avail.

St. John’s wort, a highly advertised and popular alternative therapy, has been found to interact with oral contraceptives, digoxin (a heart medication), the selective serotonin reuptake inhibitors (used for depression), theophylline (a drug used to treat lung disease), various antineoplastic drugs used to treat cancer, and the antivirals used to treat acquired immune deficiency syndrome (AIDS). Patients using St. John’s wort for the symptoms of depression who are also taking *Prozac* (fluoxetine) for depression may experience serious side effects and toxic reactions. If the health care provider is not told about the use of St. John’s wort, treatment of the toxicity can become very complicated.

Asking patients specifically about the use of any herbal or alternative therapies should become a routine part of any health history. If a patient presents with an unexpected reaction to a medication, ask the patient about any herbal or natural remedies he or she may be using. If a patient reports the use of an unusual or difficult-to-find remedy, try looking it up on the Internet at <http://nccam.nih.gov>, a site with general information about complementary and alternative medicines.

KEY POINTS

- ▶ OTC drugs have been deemed safe when used as directed and do not require a prescription or advice from a health care provider.
- ▶ OTC drugs can mask the signs and symptoms of disease, can interact with prescription drugs, and can be taken in greater than the recommended dose, leading to toxicity.
- ▶ Herbal or alternative therapies are considered to be dietary supplements and are not tightly regulated by the FDA.
- ▶ Herbal therapies can produce unexpected effects and toxic reactions, can interact with prescription drugs, and can contain various unknown ingredients that alter their effectiveness and toxicity.

OFF-LABEL USES

When a drug is approved by the FDA, the therapeutic indications for which the drug is approved are stated. **Off-label use** refers to uses of a drug that are not part of the stated therapeutic indications for which the drug was approved by the FDA. Once a drug becomes available for use, it may be found to be effective in a situation not on the approved list. Using it for this indication may eventually lead to a new approval of the drug for that new indication. Off-label use is commonly done for groups of patients for which there is little premarketing testing, particularly pediatric and geriatric groups. With the ethical issues involved in testing drugs on children, the use of particular drugs in children often occurs by trial and error when the drug is released with adult indications. Dosing calculations and nomograms become very important in determining the approximate dose that should be used for a child. Drugs often used for off-label indications include the drugs used to treat various psychiatric problems. The fact that little is really known about the way the brain works and what happens when chemicals in the brain are altered has led to a polypharmacy approach in psychiatry—mixing and juggling drugs until the wanted effect is achieved. That same combination might not work in another patient with the same diagnosis because of brain and chemical differences in that patient.

Off-label use of drugs is widespread and often leads to discovery of a new use for a drug. The nurse needs to be cognizant of off-label uses, and know when to question the use of a drug before administering it. Liability issues surrounding many of these uses are very fuzzy, and the nurse should be clear about the intended use, why the drug is being tried, and its potential for problems.

COSTS OF HEALTH CARE AND THE IMPORTANCE OF PATIENT TEACHING

The health care crisis in this country has caused the cost of medical care and drugs to skyrocket in the last few years.

This is partly due to the demand to have the best possible, most up-to-date, and safest care and drug therapies. The research and equipment requirements to meet these demands are huge. At the same time, the rising cost of health insurance to pay for all of this is a major complaint for employers and consumers. As a result, health maintenance organizations (HMOs) have surged in popularity. These groups treat the medical care system like a business, with financial aspects becoming the overriding concern. Decisions are often made by nonmedical personnel with a keen eye on the bottom line. To save costs, patients are being discharged from hospitals far earlier than ever before, and many are not even admitted to hospitals for surgical or invasive procedures that used to require several days of hospitalization and monitoring. As a result, there is less monitoring of the patient, and more responsibility for care falls on the patient or the patient's significant others. Teaching the patient about self-care, drug therapies, and what to expect is even more crucial now. The nurse is the one who most often is responsible for this teaching.

Health Maintenance Organizations and Regulations

HMOs maintain a centralized control system to provide patient medical care within a budget. In many communities, the HMO provides a centralized building with participating physicians and services housed in one area. Consumers are often provided with all of their health care at this facility and find the HMO insurance is less expensive than traditional medical insurance. The tradeoff is often a loss of choice. The health care providers in the organization are the only ones who can be consulted. The HMO may regulate access to emergency facilities, types and timing of tests allowed, and procedures covered. Accessibility to prescription drugs is also controlled. The formulary for each HMO differs. Sometimes only generic products are covered, and newer drugs must be paid for by the patient; in other instances, a tier system exists, and the patient may urge the provider to choose a drug from a lower tier, at a lower cost. Many health care providers believe that their ability to make decisions is limited by such regulations and that decisions are often made by nonmedical personnel at the other end of a telephone, who have no contact with the patient. The regulatory power of HMOs is being challenged in various court cases and through legislation and may change dramatically in the coming years.

Home Care

The home care industry is one of the most rapidly growing responses to the changes in costs and medical care delivery. Patients go home directly from surgery with the responsibility for changing dressings, assessing wounds, and monitoring their recovery. Patients are being discharged from hospitals because the hospital days allowed for a particular diagnosis

have run out. These patients may be responsible for their monitoring, rehabilitation, and drug regimens. At the same time, the population is aging and may be less accepting of all of this responsibility. Home health aides, visiting nurses, and home care programs are taking over some of the responsibilities that used to be handled in the hospital.

The responsibility of meeting the tremendous increase in teaching needs of patients frequently resides with the nurse. Patients need to know exactly what medications they are taking (generic and brand names), the dose of each medication, and what each is supposed to do. Patients also need to know what they can do to alleviate some of the adverse effects that are expected with each drug (e.g., small meals if gastrointestinal upset is common, use of a humidifier if secretions will be dried and make breathing difficult); which OTC drugs or alternative therapies they need to avoid while taking their prescribed drugs; and what to watch for that would indicate a need to call the health care provider. With patients who are taking many drugs at the same time, this information should be provided in writing, in language that is clear and understandable. Many pharmacies provide written information with each drug that is dispensed, but trying to organize these sheets of information into a usable and understandable form is difficult for many patients. The nurse is often the one who needs to sort through the provided information to organize, simplify, and make sense of it for the patient. The cost of dealing with toxic or adverse effects is often much higher, in the long run, than the cost of the time spent teaching and explaining things to the patient.

The projections for trends in health care indicate even greater expansion of the home health care system, with hospitals being used for only the most critically ill patients. The role of the nurse in this home health system is crucial—as teacher, assessor, diagnostician, and patient advocate.

Cost Considerations

Despite the insurance coverage a patient may have for prescription medications, it is often necessary for the health care provider to choose a drug therapy based on the costs of the drugs available. With more and more of the population reaching retirement age and depending on a fixed income, costs are a real issue. Sometimes this may mean not selecting a first-choice drug but settling for a drug that should be effective. Patients who take antibiotics must be reminded to take the full course and not to stop the drug when they feel better. Patients may be tempted to stop taking the antibiotic in order to save the remaining pills for the next time they feel sick and to save the costs of another health care visit and a new prescription. This practice has contributed to the problem of resistant bacteria, which is becoming more dangerous all the time.

Patients also need to be advised not to split tablets in half unless specifically advised to do so. Some drugs can be split, and it is cheaper to order the larger size and have the patient

cut the tablet. Some patients think that by cutting the drug in half they will have coverage for twice the time allowed by the prescription and will not be as dependent on the drug. With the new matrix delivery systems used for many medications, however, splitting the drug can cause it to become toxic or ineffective. Patients should be specifically alerted to avoid cutting drugs when it could be dangerous, especially if they are being advised to cut other tablets to be economical. The cost of treating the toxic reactions may far exceed the cost of the original drug.

Generic drug availability in many cases reduces the cost of a drug. Generic drugs are preparations that are off patent and therefore can be sold by their generic name, without the cost associated with brand-name products. Generic drugs are tested for bioequivalence with the brand-name product, and resulting information is available to prescribers. When a drug has a small margin of safety (a small difference between the therapeutic and the toxic dose), a prescriber may feel more comfortable ordering the drug by brand name to ensure that the dose and binders are what the prescriber expects. When “DAW” (dispense as written) is on a prescription, the prescription is filled with the brand-name drug—such as *Lanoxin* instead of digoxin, or *Coumadin* instead of warfarin. In some situations the generic drug is not less expensive than the brand-name drug, so using only generic drugs does not guarantee that the patient is getting the least expensive preparation. Many pharmacies post the costs of commonly used drugs, and patients may do **cost comparisons** to compare the relative cost of the same drug among various pharmacies or the cost differences among manufacturers of drugs and request that a different drug be prescribed. The nurse is often the person who is in the middle of this issue and must be able to explain the reason for the drug choice or request that the prescriber consider an alternative treatment.

Table 6.2 presents an example of a cost comparison of some beta-blockers commonly used to treat hypertension. When deciding which drug to use, the patient or nurse may need to consider the range of costs. *Drug Facts and Comparisons* provides a cost comparison of drugs in each class, and *The Medical Letter on Drugs and Therapeutics* provides cost comparisons of drugs that are reviewed in each issue.

In the last few years, with the cost of drugs becoming a political as well as a social issue, many people have begun ordering drugs on the Internet, often from other countries. These drugs may be cheaper, do not require the patient to see a health care provider (many of these sites simply have customers fill out a questionnaire that is reviewed by a doctor), and are delivered right to the patient’s door. The FDA has begun checking these drugs as they arrive in this country and have found many discrepancies between what was ordered and what is in the product, as well as problems in the storage of these products. Some foreign brand names are the same as brand names in this country but are associated with different generic drugs. The FDA has issued many warnings to

TABLE 6.2 Generic or Trade-Name Drugs? What Do They Cost?

DRUG NAME	DOSE (mg)	COST OF A 30-DAY SUPPLY
acebutolol (generic) <i>Sectral</i>	200–1200	\$21.30 \$37.50
atenolol (generic) <i>Tenormin</i>	25–100	\$8.70 \$32.40
betaxolol (generic) <i>Kerlone</i>	5–40	\$24.60 \$28.80
bisoprolol (generic) <i>Zebeta</i>	5–20	\$36.30 \$37.80
carvedilol <i>Coreg</i>	12.5–50	\$92.40
metoprolol (generic) <i>Lopressor</i>	50–200	\$7.80 \$21.90
nadolol (generic) <i>Corgard</i>	20–240	\$18.30 \$41.40
propranolol (generic) <i>Inderal</i>	40–240	\$8.40 \$21.60
timolol (generic) <i>Blocadren</i>	10–40	\$16.20 \$31.80

This table shows general prescription drug prices in the earliest years of the 21st century for beta-blockers used to treat hypertension. It is presented to illustrate the wide price range between generic and trade-name drugs.

consumers about the risk of taking some of these drugs without medical supervision, reminding consumers that they are not protected by U.S. laws or regulations when they purchase drugs from other countries. The FDA Web site, <http://www.fda.gov>, provides important information and guidelines for people who elect to use the Internet to get cheaper drugs.

EMERGENCY PREPAREDNESS

The events of 9/11 brought a change in the sense of security and safety that generally prevailed in this country. Now there are terrorist alerts, long lines for security at airports, and increased inspection of bags and carryalls at sporting events and theme parks. One of the potential threats that is being addressed by the Centers for Disease Control and Prevention (CDC) and the Office of Homeland Security is the risk of exposure to biological and chemical weapons. Chemical weapons have been encountered in the wars in the Middle East, as well as in terrorist attacks in Japan, and guidelines have been established for dealing with this exposure (see Table 6.3). The threat of exposure to **biological weapons**, so-called germ warfare, is somewhat theoretical but very real, as seen in the anthrax mail scares in Washington, D.C., Pennsylvania, and New York. The CDC has worked diligently to establish guidelines for treating possible exposure to biological weapons (see Table 6.3). Education of health care providers and the public is one of the central points in coping effectively with any biological assault. The CDC posts regularly updated information on

signs and symptoms of infection by various biological agents; guidelines for management of patients who are exposed and those who are actually infected; and ongoing research into detection, diagnosis, prevention, and management of diseases associated with biological agents. The nurse is often called upon to answer questions, reassure the public, offer educational programs, and serve on emergency preparedness committees. Go to <http://www.cdc.gov> and click on Emergency Preparedness to keep up to date and informed about these issues.

DRUG ABUSE

Illicit drug use in this country is a growing problem. Professional athletes are cited regularly for abusing anabolic steroids. Hollywood stars are often part of the drug scene, using **street drugs**—nonprescription drugs with no known therapeutic use—to enhance their moods and increase pleasure. Alcohol and nicotine are two commonly abused drugs that cause serious problems for the abuser or can interact with various drugs and alter a patient’s response to a prescribed drug but that are often not seen as drug addiction issues. Parents are often very concerned that their children will use street drugs. The “everyone is doing it” argument is hard to counter when today’s heroes are thought to be heavily involved. Some people abuse and become addicted to prescription drugs following an injury, when confronted with chronic pain, when their occupation puts them in contact with readily available drugs, or when someone else in the home is using a prescription drug. Many of the drugs used illicitly are addictive and can change a person’s entire life, with drug-seeking behavior becoming a major factor. Researchers have identified actual changes in the brain and neurotransmitter patterns of people who abuse and become addicted to such drugs. Trying to reverse these changes and return the person to a nonaddicted state is a physiological, as well as a psychological, challenge. The use of these drugs can have severe consequences on health, can mask underlying signs and symptoms of medical problems, and can interact with other medications that the user may need (Table 6.4).

Being informed about drugs available in the community, current trends among teenagers or young adults, and community resources available to help patients can guide parents and health care professionals while dealing with this drug culture problem. Education provides a crucial defense against drug abuse and helps the public and health care professionals recognize the problem and deal with it when it occurs. The National Institutes of Health has a division called the National Institute on Drug Abuse. Go to <http://www.nida.nih.gov> to find educational programs for teens, parents, and health care professionals; the latest information on the hottest fads in illicit drugs; research on dealing with drug abuse problems; and links to sites for identifying unknown drugs, community resources, and laws.

TABLE 6.3 Recommended Treatments for Biological/Chemical Weapons Exposure

BIOLOGICAL/CHEMICAL AGENT	SUGGESTED TREATMENT
Anthrax (<i>Bacillus anthracis</i>) Cutaneous anthrax	Adult: 500 mg ciprofloxacin PO b.i.d. for 60 d or 100 mg doxycycline PO b.i.d. for 60 d Pediatric: 10–15 mg/kg ciprofloxacin PO q12h for 60 d or >8 yr and >45 kg: 100 mg doxycycline PO q12h >8 yr and ≤45 kg: 2.2 mg/kg doxycycline PO q12h ≤8 yr: 2.2 mg/kg doxycycline PO q12h for 60 d
Inhalational anthrax	Adult: 400 mg ciprofloxacin IV q12h, then 500 mg ciprofloxacin PO b.i.d. for a total of 60 d or 100 mg doxycycline IV q12h, then 100 mg doxycycline PO b.i.d. for a total of 60 d Pediatric: 10–15 mg/kg ciprofloxacin IV q12h, then 10–15 mg/kg PO q12h for a total of 60 d or >8 yr and >45 kg: 100 mg doxycycline IV, then PO q12h >8 yr and ≤45 kg: 2.2 mg/kg doxycycline IV, then PO q12h ≤8 yr: 2.2 mg/kg doxycycline PO q12h for a total of 60 d Switch from IV to PO form is based on patient response. If patient is not responding to ciprofloxacin or doxycycline, one or two additional antimicrobials can be added to the drug regimen, including rifampin, vancomycin, penicillin, ampicillin, chloramphenicol, imipenem, clindamycin, and clarithromycin.
Botulism (<i>Clostridium botulinum</i> toxin)	Supportive therapy, antitoxin administered early, available from the CDC
Brucellosis (<i>Brucella</i> species)	Adult: 100 mg/d doxycycline PO with 600 mg/d rifampin PO for 6 wk Pediatric: 2.2 mg/d doxycycline PO with 10 mg/kg rifampin PO for 6 wk
Cholera (<i>Vibrio cholerae</i>) <i>Escherichia coli</i>	Replacement of fluids and electrolytes, IV if necessary Recovery usually occurs in 5–10 d; replace fluids
Hemorrhagic fevers Ebola virus Marburg virus Lassa fever Arenaviruses	Supportive therapy; fresh-frozen plasma and judicious use of heparin to control DIC Ribavirin: 30 mg/kg IV followed by 15 mg/kg IV q6h for 4 d, then 7.5 mg/kg IV q8h for 6 d
Nerve gas (sarin, organophosphates)	Adult: atropine 2–4 mg IM and 2-PAM Cl 600 mg IM Severe symptoms: atropine 6 mg IM and 2-PAM Cl 1800 mg IM Pediatric: 0–2 yr: atropine 0.05 mg/kg IM and 2-PAM Cl 15 mg/kg IM Severe symptoms: atropine 0.1 mg/kg IM and 2-PAM Cl 25 mg/kg IM 2–10 yr: atropine 1 mg IM and 2-PAM Cl 15 mg/kg IM Severe symptoms: atropine 2 mg IM and 2-PAM Cl 25 mg/kg IM >10 yr: atropine 2 mg IM and 2-PAM Cl 15 mg/kg IM Severe symptoms: atropine 4 mg IM and 2-PAM Cl 25 mg/kg IM Geriatric: atropine 1 mg IM and 2-PAM Cl 10 mg/kg IM Severe symptoms: atropine 2–4 mg IM and 2-PAM Cl 25 mg/kg IM Repeat atropine (2 mg IM) at 5- to 10-min intervals until secretions have diminished and breathing is comfortable or airway resistance has returned to near normal. Assisted ventilation should be started after administration of antidotes for severe exposures.
Plague (<i>Yersinia pestis</i>)	Adults: 100 mg doxycycline PO b.i.d. or 500 mg ciprofloxacin PO b.i.d. Pediatric: >45 kg: adult dose of doxycycline <45 kg: 2.2 mg/kg doxycycline PO b.i.d. or 20 mg/kg ciprofloxacin PO b.i.d. Treatment of acute plague may include 15 mg/kg streptomycin IM b.i.d. or 2.5 mg/kg gentamicin IM or IV t.i.d.; 15 mg/kg chloramphenicol IV q.i.d. is also useful.
Q fever (<i>Coxiella burnetii</i>)	Adult: 100 mg doxycycline PO b.i.d. for 15–21 d Pediatric: >45 kg: adult dose of doxycycline <45 kg: 2.2 mg/kg doxycycline PO b.i.d. for 15–21 d
Ricin poisoning	No antidote exists; the most important factor is getting the ricin off or out of the body as quickly as possible; medical supportive therapy
Salmonellosis (<i>Salmonella</i> species)	Rehydration, support Severe cases: 500 mg ampicillin PO q6h (adults and children >20 kg), or 100 mg/kg/d ampicillin PO (if <20 kg) or ciprofloxacin 500 mg PO b.i.d. (adults), or 20 mg/kg PO b.i.d. (children)

TABLE 6.3 Recommended Treatments for Biological/Chemical Weapons Exposure (continued)

BIOLOGICAL/CHEMICAL AGENT	SUGGESTED TREATMENT
Shigellosis (<i>Shigella</i>)	Adult: 500 mg ampicillin PO q6h or 500 mg ciprofloxacin PO b.i.d. or <i>Septra/Bactrim</i> 160 mg trimethoprim/800 mg sulfamethoxazole PO q12h for 5 d Pediatric <20 kg: 100 mg/kg/d ampicillin PO or 20 mg/kg ciprofloxacin PO b.i.d. or <i>Septra/Bactrim</i> 160 mg trimethoprim/800 mg sulfamethoxazole in divided doses of 8–10 mg/kg/d PO for 5 d
Smallpox (<i>Variola major</i>)	No treatment available; active immunization possible
Tularemia (<i>Francisella tularensis</i>)	Adult: 1 g streptomycin IM b.i.d. or 5 mg/kg gentamicin IM or IV once daily If these cannot be used, one of the following: 100 mg doxycycline IV b.i.d. 15 mg/kg chloramphenicol IV q.i.d. 400 mg ciprofloxacin IV b.i.d. Pediatric: 15 mg/kg streptomycin IM b.i.d. or 2.5 mg/kg gentamicin IM or IV t.i.d. If these cannot be used, one of the following: 100 mg doxycycline IV b.i.d. (≥45 kg) 2.2 mg/kg doxycycline IV b.i.d. (<45 kg) 15 mg/kg chloramphenicol IV q.i.d. 15 mg/kg ciprofloxacin IV b.i.d.
Typhoid fever (<i>Salmonella typhi</i>)	Adult: 500 mg ampicillin PO q6h or 500 mg ciprofloxacin PO b.i.d. or <i>Septra/Bactrim</i> 160 mg trimethoprim/800 mg sulfamethoxazole PO q12h for 5 d Pediatric <20 kg: 100 mg/kg/d ampicillin PO or 20 mg/kg ciprofloxacin PO b.i.d. or <i>Septra/Bactrim</i> 160 mg trimethoprim/800 mg sulfamethoxazole in divided doses of 8–10 mg/kg/d PO for 5 d

CDC, Centers for Disease Control and Prevention; DIC, disseminated intravascular coagulation; 2-PAL c, pralidoxime chloride.

The table provides recommended treatments for exposure to biological or chemical weapons. For complete information on presenting signs and symptoms, diagnoses, and current research in this area, go to www.cdc.gov and click on Emergency Preparedness.

(Adapted from Karch, A. M. (2008). *2009 Lippincott's nursing drug guide*. Philadelphia: Lippincott Williams & Wilkins.)

PROTECTING THE ENVIRONMENT

In March 2008, many news services across the country reported studies showing that many prescription drugs had been found in the drinking water of various large cities. These studies showed ground and watershed contamination with many pharmaceutical products. The levels of these drugs were small, but the question was raised about what this would mean for the future and for the people, animals, and crops that were being affected by the presence of these drugs. The problem is quite real. Patients get a prescription and then get switched to a different drug. Some patients end up with extra pills at the end of a prescription because they did not follow the dosing guidelines exactly. Many people store these extra pills and end up with a medicine cabinet full of prescription drugs. In the past, people would often just flush these extras down the toilet, where they would enter the water system. Some people just threw them out, where they would eventually enter the ground of various landfills or would be diverted for illicit use by drug seekers going through garbage sites. With these things in mind and the push to protect the environment, the Office of National Drug Control Policy has released specific guidelines for the proper disposal of prescription drugs. See Box 6.2 for the guidelines for drug disposal. It is important to teach patients how to dispose of drugs

properly. Encourage patients to clean out their medicine cabinet at least yearly and to properly dispose of the drugs that they are no longer using.

BOX 6.2

Patient and Family Teaching

Proper Disposal of Unused, Unneeded, or Expired Medications

- Take unused, unneeded, or expired prescription drugs out of their original containers.
- Mix the prescription drugs with an undesirable substance, such as used coffee grounds or kitty litter, and put them in impermeable, nondescript containers, such as empty cans or sealable bags, further ensuring that the drugs are not diverted or accidentally ingested by children or pets.
- Throw these closed containers in the trash.
- Flush prescription drugs down the toilet **only** if the accompanying patient information **specifically instructs** that this is safe to do.
- Return unused, unneeded, or expired prescription drugs to pharmaceutical take-back locations that allow the public to bring unused drugs to a central location for safe disposal. Many hospitals have these locations. Check with your local hospital or Health Department.

TABLE 6.4 Frequently Abused Street Drugs and Their Potential Health Consequences

DRUG	STREET NAMES	CLASS	HEALTH CONSEQUENCES
Amphetamines	Uppers, whites, dexies	Stimulant	Hypertension, tachycardia, insomnia, restlessness
Amyl nitrate	Boppers, pearls	Stimulant	Tachycardia, restlessness, hypotension, vertigo
Anabolic steroids	Roids, muscle	Steroid	Hypertension, hyperlipidemia, acne, cancer, cardiomyopathy
Barbiturates	Downers, reds	Depressant	Bradycardia, hypotension, laryngospasm, ataxia, impaired thinking
Benzodiazepines	M&Ms, Uncle Miltie	Depressant	Confusion, fatigue, impaired memory, impaired coordination
Cannabis	Pot, grass, weed,	Mixed CNS	Drowsiness, elation, dizziness, memory lapse, hallucinations
With formaldehyde	THC; fry sticks;		
With cocaine	primo		
Cocaine	Snow, blow, crack	Stimulant	Tachycardia, hypertension, hallucinations, confused thinking
Fentanyl	Jackpot, China white	Opioid	Sedation, arrhythmias, shock, cardiac arrest, decreased respirations, constipation
Gamma-hydroxybutyrate	GHB, fantasy, liquid X, liquid E, "date rape" drug	Depressant	Memory loss, hypotension, somnolence
Heroin	Brown sugar, joy, crank, fairy dust	Opioid	Sedation, arrhythmias, shock, cardiac arrest, decreased respirations, constipation
Ketamine	Super acid, special K	Depressant	Paralysis, loss of sensation, disorientation, psychic changes
LSD	Acid, sunshine, blotter acid	Hallucinogen	Hallucinations, hypotension, changes in thinking, loss of social control
MDMA	Ecstasy, b-bombs, go, Scooby snacks	Hallucinogen	Hallucinations, psychic change, loss of memory, hypotension, cardiac arrest
Methamphetamine	Crystal, glass, speed, crystal meth, working mother's cocaine	Stimulant	Hypertension, tachycardia, restlessness, changes in thinking
Methylphenidate	Ritalin	Stimulant	Agitation, tachycardia, hypertension, hyperreflexia, fever
Morphine	Mort, Miss Emma	Opioid	Sedation, arrhythmias, shock, cardiac arrest, decreased respirations, constipation
OxyContin	Oxy, Oxycontin, Oxy 80s, hillbilly heroin, poor man's heroin, cotton	Opioid	Sedation, arrhythmias, shock, cardiac arrest, decreased respirations, constipation
PCP with steroids	Angel dust, zombie; juices	Hallucinogen	Acute psychosis, HF, death, seizures, memory loss
Peyote	Button, mesc	Hallucinogen	Acute psychosis, tremor, altered perception, death
Rohypnol	Rophies	Amnesiac	Date rape drug, loss of memory, immobility
Viagra/MDMA	Sextasy	Hallucinogen, ED drug	Severe hypotension, hallucinations, increased sexual function

CNS, central nervous system; ED, erectile dysfunction; HF, heart failure; LSD, lysergic acid diethylamide; MDMA, methylenedioxymethamphetamine; PCP, phencyclidine; THC, tetrahydrocannabinol.

CHAPTER SUMMARY

- In the 21st century, drugs pose new challenges for patients and health care providers, including information overload, demands for specific treatments, increased access to self-care systems, and financial pressures to provide cost-effective care.
- The mass media bombard consumers with medical reviews, research updates, and advertising for prescription drugs. If the use of a drug is stated, the adverse effects and cautions also must be stated. If the use is not stated, the drug adver-

tisement is free to use any images and suggestions to sell the drug.

- Increasing access to the Internet and World Wide Web has increased consumer access to drug information, advertising, and even purchasing without a mediator of this information. Determining the reliability of an Internet site is a challenge for the consumer and the health care provider.
- OTC drugs and herbal and alternative therapies allow patients to make medical decisions and self-treat many common signs and symptoms. Problems arise when they are used inappropriately, when they interact with prescription

drugs, or when they mask signs and symptoms, making diagnosis difficult.

- Off-label uses of drugs occur when a drug has been released and is available for use. The use of a drug for an indication that is not approved by the FDA occurs commonly in pediatric and in psychiatric medicine, in which testing is limited or made ineffective by individual differences.
- Increasing costs of drugs and health care has led to the emergence of HMOs and tight regulations on medical therapy and drug therapy alternatives. The choice of a drug to be used may be determined by the HMO formulary or by cost comparison with other drugs in the same or a similar class. Cost comparison is a major consideration in the use of many drugs.
- Home care is one of the most rapidly growing areas of medical care. Patients are increasingly more responsible for managing their medical regimens from home with dependence on home health providers and teaching and support from knowledgeable nurses.
- Emergency preparedness in the post-9/11 era includes awareness of risks associated with biological or chemical weapon exposure and medical management for the victims.
- Illicit drug use can lead to dependence on the drug and physiological changes, causing health problems and changing the body's response to traditional drugs.
- Proper disposal of unused or expired medications can help to protect the environment and may decrease drug-searching behaviors in some situations.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-Rom in the front of this book.

MULTIPLE CHOICE

Select the best answer to the following.

1. Drugs can be advertised in the mass media only if
 - a. the FDA indication is clearly stated.
 - b. the actual use is never stated.
 - c. adverse effects and precautions are stated if the use is stated.
 - d. all adverse effects are clearly stated.
2. Herbal treatments and alternative therapies
 - a. are considered drugs and regulated by the FDA.
 - b. are considered dietary supplements and are not regulated by the FDA.
 - c. have no restrictions on claims and advertising.
 - d. contain no drugs, only natural substances.
3. OTC drugs are drugs that are
 - a. deemed to be safe when used as directed.
 - b. harmless to the public.
 - c. too old to be tested.
 - d. cheaper to use than prescription drugs.
4. The home health care industry is booming because
 - a. there is a shortage of hospital beds.
 - b. patients feel safer at home and prefer to be cared for at home.
 - c. patients are going home sooner and becoming responsible for their own care sooner than in the past.
 - d. the nursing shortage makes it difficult to care for patients in hospitals.
5. The cost of drug therapy is a major consideration in most areas because
 - a. generic drugs are always cheaper.
 - b. the high cost of drugs combined with more fixed-income consumers puts constraints on drug use.
 - c. pharmacies usually carry only one drug from each class.
 - d. patients like to shop around and get the best drug for their money.
6. An off-label use of a drug means that the drug
 - a. was found without a label and its actual contents are not known.
 - b. has been found to be safe when used as directed and no restrictions are needed.
 - c. is being used for an indication not listed in the approved indications noted by the FDA.
 - d. has expired but is still found to be useful when used as directed.

MULTIPLE RESPONSE

Select all that apply.

1. When taking a health history, the nurse should include specific questions about the use of OTC drugs and alternative therapies. This is an important aspect of the health history because
 - a. many insurance policies cover these drugs.
 - b. patients should be reprimanded about the use of these products.
 - c. patients often do not consider them to be drugs and do not report their use.
 - d. patients should never use these products when taking prescription drugs.

- e. these products can mask or alter presenting signs and symptoms.
- f. many of these products interact with traditional prescription drugs.

2. A nurse is caring for a patient who has been diagnosed with type 2 diabetes. The patient has reported that he frequently uses herbal remedies. Before administering any antidiabetic medications, the nurse should caution

the patient about the use of which of the following herbal therapies?

- a. Glucosamine
- b. Ginseng
- c. St. John's wort
- d. Juniper berries
- e. Garlic
- f. Kava

Introduction to Cell Physiology

7

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Identify the parts of the human cell.
2. Describe the role of each organelle found within the cell cytoplasm.
3. Explain the unique properties of the cell membrane.
4. Describe three processes used by the cell to move things across the cell membrane.
5. Outline the cell cycle, including the activities going on within the cell in each phase.

Glossary of Key Terms

cell cycle: life cycle of a cell, which includes the phases G_0 , G_1 , S, G_2 , and M; during the M phase, the cell divides into two identical daughter cells

cell membrane: lipoprotein structure that separates the interior of a cell from the external environment; regulates what can enter and leave a cell

cytoplasm: lies within the cell membrane; contains organelles for producing proteins, energy, and so on

diffusion: movement of solutes from an area of high concentration to an area of low concentration across a concentration gradient

endocytosis: the process of engulfing substances and moving them into a cell by extending the cell membrane around the substance; pinocytosis and phagocytosis are two kinds of endocytosis

endoplasmic reticulum: fine network of interconnected channels known as cisternae found in the cytoplasm; site of chemical reactions within the cell

exocytosis: removal of substances from a cell by pushing them through the cell membrane

genes: sequences of DNA that control basic cell functions and allow for cell division

Golgi apparatus: a series of flattened sacs in the cytoplasm that prepare hormones or other substances for secretion and may produce lysosomes and store other synthesized proteins

histocompatibility antigens: proteins found on the surface of the cell membrane; they are determined by the genetic code and provide cellular identity as a self-cell (i.e., a cell belonging to that individual)

lipoprotein: structure composed of proteins and lipids; the bipolar arrangement of the lipids monitors substances passing in and out of the cell

lysosomes: encapsulated digestive enzymes found within a cell; they digest old or damaged areas of the cell and are responsible for destroying the cell when the membrane ruptures and the cell dies

mitochondria: rod-shaped organelles that produce energy within the cell in the form of adenosine triphosphate (ATP)

nucleus: the part of a cell that contains the DNA and genetic material; regulates cellular protein production and cellular properties

organelles: distinct structures found within the cell cytoplasm

osmosis: movement of water from an area of low solute concentration to an area of high solute concentration in an attempt to equalize the concentrations

ribosomes: membranous structures that are the sites of protein production within a cell

Chemotherapeutic drugs are used to destroy both organisms that invade the body (e.g., bacteria, viruses, parasites, protozoa, fungi) and abnormal cells within the body (e.g., neoplasms, cancers). These drugs affect cells by altering cellular function or disrupting cellular integrity, causing cell death, or by preventing cellular reproduction, eventually leading to cell death. Because most chemotherapeutic agents do not possess complete selective toxicity, they also, to some extent, affect the normal cells of patients. To understand the actions and adverse effects caused by chemotherapeutic agents and to determine interventions that increase therapeutic effectiveness, it is important to understand the various properties and the basic structure and function of the cell.

THE CELL

The cell is the basic structural unit of the body. The cells that make up living organisms, which are arranged into tissues and organs, all have the same basic structure. Each cell has a nucleus, a cell membrane, and cytoplasm, which contains a variety of organelles (Figure 7.1).

Cell Nucleus

Each cell is “programmed” by the **genes**, or sequences of DNA, that allow for cell division, produce specific proteins that allow the cell to carry out its functions, and maintain cell

homeostasis or stability. The **nucleus** is the part of a cell that contains all genetic material necessary for cell reproduction and for the regulation of cellular production of proteins. The nucleus is encapsulated in its own membrane and remains distinct from the rest of the cytoplasm. A small spherical mass, called the nucleolus, is located within the nucleus. Within this mass are dense fibers and proteins that will eventually become **ribosomes**, the sites of protein synthesis within the cell. Genes are responsible for the formation of messenger RNA and transcription RNA, which are involved in production of the proteins unique to the cell. The DNA necessary for cell division is found on long strands called chromatin. These structures line up and enlarge during the process of cell division.

Cell Membrane

The cell is surrounded by a thin barrier called the **cell membrane**, which separates intracellular fluid from extracellular fluid. The membrane is essential for cellular integrity and is equipped with many mechanisms for maintaining cell homeostasis.

Lipoproteins

The cell membrane is a **lipoprotein** structure, meaning that it is mainly composed of proteins and lipids—phospholipids, glycolipids, and cholesterol; the bipolar arrangement of the lipids monitors substances passing in and out of the cell. The phospholipids, which are bipolar in nature, line up with their

● **FIGURE 7.1** General structure of a cell and the location of its organelles.

● **FIGURE 7.2** Structure of the lipid bilayer of the cell membrane.

polar regions pointing toward the interior or exterior of the cell and their nonpolar region lying within the cell membrane. The polar regions mix well with water, and the nonpolar region repels water. These properties allow the membrane to act as a barrier to regulate what can enter the cell (Figure 7.2). The freely moving nature of the membrane allows it to adjust to the changing shape of the cell so that areas of the membrane can move together to repair itself if it should become torn or injured. Some of the outward-facing phospholipids have a sugar group attached to them; these are called glycolipids. Cholesterol is found in large quantities in the membrane, and it works to keep the phospholipids in place and the cell membrane stable.

Receptor Sites

Embedded in the cell membrane are a series of peripheral proteins with several functions. As discussed in Chapter 2, one type of protein located on the cell membrane is known as a receptor site. This protein reacts with specific chemicals outside the cell to stimulate a reaction within the cell. For example, the receptor site for insulin reacts with the hormone insulin to cause activation of adenosine triphosphate (ATP) within the cell. This reaction alters the cell's permeability to glucose. Receptor sites are very important in the functioning of neurons, muscle cells, endocrine glands, and other cell types, and they play a very important role in clinical pharmacology.

Identifying Markers

Other surface proteins are surface antigens, or genetically determined identifying markers. These proteins are called **histocompatibility antigens** or human leukocyte antigens (HLAs), which the body uses to identify a cell as a self-cell

(i.e., a cell belonging to that individual). The body's immune system recognizes these proteins and acts to protect self-cells and to destroy non-self-cells. When an organ is transplanted from one person to another, a great effort is made to match as many histocompatibility antigens as possible to reduce the chance that the "new" body will reject the transplanted organ.

Histocompatibility antigens can be changed in several ways: by cell injury, with viral invasion of a cell, with age, and so on. If the markers are altered, the body's immune system reacts to the change and can ignore it, allowing neoplasms to grow and develop. The immune system may also attack the cell, leading to many of the problems associated with autoimmune disorders and chronic inflammatory conditions.

Channels

Channels or pores within the cell membrane are made by proteins in the cell wall that allow the passage of small substances in or out of the cell. Specific channels have been identified for sodium, potassium, calcium, chloride, bicarbonate, and water; other channels may also exist. Some drugs are designed to affect certain channels specifically. For example, calcium-channel blockers prevent the movement of calcium into a cell through calcium channels.

KEY POINTS

- ▶ The cell is the basic structure of all living organisms.
- ▶ The cell membrane features specific receptor sites that allow interaction with various chemicals, histocompatibility proteins that allow for self-identification, and channels or pores that allow for the passage of substances into and out of the cell.

Cytoplasm

The cell **cytoplasm** lies within the cell membrane and outside the nucleus and is the site of activities of cellular metabolism and special cellular functions. The cytoplasm contains many **organelles**, which are structures with specific functions such as producing proteins and energy. The organelles within the cytoplasm include the mitochondria, the endoplasmic reticulum, free ribosomes, the Golgi apparatus, and the lysosomes.

Mitochondria

Mitochondria are rod-shaped “power plants” within each cell that produce energy in the form of ATP, which allows the cell to function. Mitochondria are plentiful in very active cells such as muscle cells and are relatively scarce in inactive cells such as bone cells. Mitochondria, which can reproduce when a cell is very active, are always very abundant in cells that consume energy. For example, cardiac muscle cells, which must work continually to keep the heart contracting, contain a great number of mitochondria. Milk-producing cells in breast tissue, which are normally quite dormant, contain very few mitochondria. If a woman is lactating, however, the mitochondria become more abundant to meet the demands of the milk-producing cells. The mitochondria can take carbohydrates, fats, and proteins from the cytoplasm and make ATP via the Krebs cycle, which depends on oxygen. Cells use the ATP to maintain homeostasis, produce proteins, and carry out specific functions. If oxygen is not available, lactic acid builds up as a byproduct of cellular respiration. Lactic acid leaves the cell and is transported to the liver for conversion to glycogen and carbon dioxide.

Endoplasmic Reticulum

Much of the cytoplasm of a cell is made up of a fine network of interconnected channels known as cisternae, which form the **endoplasmic reticulum**. The undulating surface of the endoplasmic reticulum provides a large surface for chemical reactions within the cell. Many granules that contain enzymes and ribosomes, which produce protein, are scattered over the surface of the rough endoplasmic reticulum. Production of proteins, phospholipids, and cholesterol takes place in the rough endoplasmic reticulum. The smooth endoplasmic reticulum is the site of further lipid and cholesterol production and the production of cell products, such as hormones. The breakdown of many toxic substances may also occur here in particular cells.

Free Ribosomes

Other ribosomes that are not bound to the surface of the endoplasmic reticulum exist throughout the cytoplasm. These free-floating ribosomes produce proteins that are important to the structure of the cell and some of the enzymes that are necessary for cellular activity.

Golgi Apparatus

The **Golgi apparatus** is a series of flattened sacs that may be part of the endoplasmic reticulum. These structures prepare hormones or other substances for secretion by processing

them and packaging them in vesicles to be moved to the cell membrane for excretion from the cell. In addition, the Golgi apparatus may produce lysosomes and store other synthesized proteins and enzymes until they are needed.

Lysosomes

Lysosomes are membrane-covered organelles that contain specific digestive enzymes that can break down proteins, nucleic acids, carbohydrates, and lipids and are responsible for digesting worn or damaged sections of a cell when the membrane ruptures and the cell dies. Lysosomes form a membrane around any substance that needs to be digested and secrete the digestive enzymes directly into the isolated area, protecting the rest of the cytoplasm from injury. This phenomenon can be seen with old lettuce in the refrigerator. The side of the lettuce head that has been “lying down” for a prolonged period becomes brown and wet as the lettuce cells die and self-digest when their lysosomes are released. If the lettuce is not used, the released lysosomes begin to digest any healthy lettuce that remains, with eventual destruction of the entire head. Lysosomes are important in ecology. Dead trees, animals, and other organisms self-digest.

KEY POINTS

- ▶ The cytoplasm of the cell contains various organelles that are important for cellular function.
- ▶ The mitochondria produce energy for the cell; the endoplasmic reticulum contains ribosomes that produce proteins; the Golgi apparatus packages proteins; and lysosomes contain protein-dissolving enzymes that are important for digestion and the recycling of organisms in nature.

CELL PROPERTIES

Cells have certain properties that allow them to survive. **Endocytosis** involves incorporation of material into the cell by extending the cell membrane around the substance. Pinocytosis, a form of endocytosis, refers to the engulfing of specific substances that have reacted with a receptor site on the cell membrane. This process allows cells to absorb nutrients, enzymes, and other materials. Phagocytosis is a similar process; it allows the cell, usually a neutrophil or macrophage, to engulf a bacterium or a foreign protein and destroy it within the cell by secreting digestive enzymes into the area. **Exocytosis** is the opposite of endocytosis and involves removing substances from a cell by pushing them through the cell membrane. Hormones, neurotransmitters, enzymes, and other substances produced within a cell are excreted into the body by this process (Figure 7.3).

Homeostasis

The main goal of a cell is to maintain homeostasis, which means keeping the cytoplasm stable within the cell membrane. Each cell uses a series of active and passive transport systems to achieve homeostasis; the exact system used depends on the

● **FIGURE 7.3** Schematic representation of endocytosis and exocytosis. **A.** Exocytosis is the movement of substances (waste products, hormones, neurotransmitters) out of the cell. **B.** Endocytosis involves the destruction of engulfed proteins or bacteria.

type of cell and its reactions with the immediate environment. For a cell to produce the energy needed to carry out cellular metabolism and other processes, the cell must have a means to obtain necessary elements from the outside environment. In addition, it must have a way to dispose of waste products that could be toxic to its cytoplasm. To accomplish this, the cell moves substances across the cell membrane, either by passive transport or by active (energy-requiring) transport (Figure 7.4).

Passive Transport

Passive transport happens without the expenditure of energy and can occur across any semipermeable membrane. There are essentially three types of passive transport: diffusion, osmosis, and facilitated diffusion.

Diffusion

Diffusion is the movement of a substance from a region of higher concentration to a region of lower concentration. The

difference between the concentrations of the substance in the two regions is called the *concentration gradient* of the substance; usually, the greater the concentration gradient, the faster does the substance move. Movement into and out of a cell is regulated by the cell membrane. Some substances move through channels or pores in the cell membrane. Small substances and materials with no ionic charge move most freely through the channels. Substances with a negative charge move more freely than substances with a positive charge. Substances that move into and out of a cell by diffusion include sodium, potassium, calcium, carbonate, oxygen, bicarbonate, and water.

When a cell is very active and is using energy and oxygen, the concentration of oxygen within the cell decreases. The concentration of oxygen outside the cell remains relatively high, so oxygen moves across the cell membrane (down the concentration gradient) to supply needed oxygen to the inside of the cell. Cells use this process to maintain homeostasis during many activities that occur during their life.

● **FIGURE 7.4** Schematic representation of transport across a cell membrane (**A**), which includes *diffusion* through the cell membrane (**B**) and *pore diffusion* through a protein channel (**C**).

Osmosis

Osmosis, a special form of diffusion, is the movement of water across a semipermeable membrane from an area that is low in dissolved solutes to one that is high in dissolved solutes. The water is attempting to equalize the dilution of the solutes. This diffusion of water across a cell membrane from an area of high concentration (of water) to an area of low concentration creates pressure on the cell membrane called *osmotic pressure*. The greater the concentration of solutes in the solution to which the water is flowing, the higher is the osmotic pressure.

A fluid that contains the same concentration of solutes as human plasma is called an *isotonic* solution. A fluid that contains a higher concentration of solutes than human plasma is a *hypertonic* solution, and it draws water from cells. A fluid that contains a lower concentration of solutes than human plasma is *hypotonic*; it loses water to cells. If a human red blood cell, which has a cytoplasm that is isotonic with human plasma, is placed into a hypertonic solution, it shrinks and shrivels because the water inside the cell diffuses out of the cell into the solution. If the same cell is placed into a hypotonic solution, the cell swells and bursts because water moves from the solution into the cell (Figure 7.5).

Facilitated Diffusion

Sometimes a substance cannot move freely on its own in or out of a cell. Such a substance may attach to another molecule, called a carrier, to be diffused. This form of diffusion, known as *facilitated diffusion*, does not require energy, just the presence of the carrier. Carriers may be hormones, enzymes, or proteins. Because the carrier required for facilitated diffusion is usually present in a finite amount, this type of diffusion is limited.

Active Transport

Sometimes a cell requires a substance in greater concentration than is found in the environment around it or needs to maintain its cytoplasm in a situation that would normally allow chemicals to leave the cell. When this happens, the cell must move substances against the concentration gradient using active transport, which requires energy. When a cell is deprived of oxygen because of a blood supply problem or insufficient oxygenation of the blood, systems of active transport begin to malfunction, placing the cell's integrity in jeopardy.

One of the best-known systems of active transport is the sodium–potassium pump. Cells use active transport to maintain a cytoplasm with a higher level of potassium and a lower level of sodium than the extracellular fluid contains. This allows the cell to maintain an electrical charge on the cell membrane, which gives many cells the electrical properties of excitation (the ability to generate a movement of electrons) and conduction (the ability to send this stimulus to

Hypertonic solution
A red blood cell placed in hypertonic solution will shrink and shrivel up as water moves out of the cell

Isotonic solution
A red blood cell placed in isotonic solution is stable and will retain its shape

Hypotonic solution
A red blood cell placed in hypotonic solution will swell and burst as water moves into the cell

● **FIGURE 7.5** Red blood cell, showing the cell's response to hypertonic, isotonic, and hypotonic solutions.

other areas of the membrane). Some drugs use energy to move into cells by active transport. Drugs are frequently bonded with a carrier when they are moved into the cell. Cells in the kidney use active transport to excrete drugs from the body, as well as to maintain electrolyte and acid–base balances.

CELL CYCLE

Most cells have the ability to reproduce themselves through the process of mitosis. The genetic makeup of a particular cell determines the rate at which that cell can multiply. Some cells reproduce very quickly (e.g., the cells lining the gastrointestinal tract have a generation time of 72 hours), and some reproduce very slowly (e.g., the cells found in breast tissue have a generation time of a few months). In some cases, certain factors influence cell reproduction. Erythropoietin, a hormone produced by the kidney, can stimulate the production of new red blood cells. Active leukocytes release chemicals that stimulate the production

● **FIGURE 7.6** Diagram of the cell cycle, showing G₀, G₁, S, G₂, and M phases.

of white blood cells when the body needs new ones. Regardless of the rate of reproduction, each cell has approximately the same life cycle. The life cycle of a cell, called the **cell cycle**, consists of four active phases and a resting phase (Figure 7.6).

G₀ Phase

During the G₀ phase, or resting phase, the cell is stable. It is not making any proteins associated with cell division and is basically dormant as far as reproduction goes. These cells are just functioning to do whatever they are supposed to do. Cells in the G₀ phase cause a problem in the treatment of some cancers. Cancer chemotherapy usually works on active, dividing cells, leaving resting cells fairly untouched. When the resting cells are stimulated to become active and regenerate, the cancer can return, which is why cancer chemotherapeutic regimens are complicated and extended over time, and why a 5-year cancer-free period is usually the basic guide for considering a cancer to be cured.

G₁ Phase

When a cell is stimulated to emerge from its resting phase, it enters what is called the G₁ phase, which lasts from the time of stimulation from the resting phase until the formation of DNA. During this period, the cell synthesizes substances needed for DNA formation. The cell is actively collecting materials to make these substances and producing the building blocks for DNA.

S Phase

The next phase, called the S phase, involves the actual synthesis of DNA, which is an energy-consuming activity. The cell remains in this phase until the amount of cellular DNA has doubled.

G₂ Phase

After the cellular DNA has doubled in preparation for replication, the G₂ phase begins. During this phase, the cell produces all of the substances required for the manufacture of the mitotic spindles.

M Phase

After the cell has produced all of the substances necessary for formation of a new cell, or daughter cell, it undergoes cell division. This occurs during the M phase of the cell cycle. During this phase, the cell splits to form two identical daughter cells, a process called mitosis.

KEY POINTS

- ◆ All cells progress through a cell cycle, which allows them to reproduce.
- ◆ Each cell goes through a resting phase (G₀); a gathering phase (G₁), when the components needed for cell division are collected by the cell; a synthesizing phase (S), when DNA and other components are produced; a final gathering phase (G₂), when the last substances needed for division are collected and produced; and an M phase, when actual cell division occurs, producing two identical daughter cells.

CHAPTER SUMMARY

- The cell is composed of a nucleus, which contains genetic material and controls the production of proteins by the cell; a cell membrane, which separates the inside of the cell from the outside environment; and a cytoplasm, which contains various organelles important to cell function.
- The cell membrane functions as a fluid barrier made of lipids and proteins. The arrangement of the lipoprotein membrane controls what enters and leaves the cell.
- Proteins on the cell membrane surface can act either as receptor sites for specific substances or as histocompatibility markers that identify the cell as a self-cell (i.e., a cell belonging to that individual).
- Channels or pores in the cell membrane allow for easier movement of specific substances needed by the cell for normal functioning.
- Mitochondria are rod-shaped organelles that produce energy in the form of ATP for use by cells.
- Ribosomes are sites of protein production within the cell cytoplasm. The specific proteins produced by a cell are determined by the genetic material within the cell nucleus.
- The Golgi apparatus packages particular substances for removal from the cell (e.g., neurotransmitters, hormones).
- Lysosomes are packets of digestive enzymes located in the cell cytoplasm. These enzymes are responsible for destroying injured or nonfunctioning parts of the cell and for promoting cellular disintegration when the cell dies.

- Endocytosis is the process of moving substances into a cell by extending the cell membrane around the substance and engulfing it. Pinocytosis refers to the engulfing of necessary materials, and phagocytosis refers to the engulfing and destroying of bacteria or other proteins by white blood cells.
- Exocytosis is the process of removing substances from a cell by moving them toward the cell membrane and then changing the cell membrane to allow passage of the substance out of the cell.
- Cells maintain homeostasis by regulating the movement of solutes and water into and out of the cell.
- Diffusion, which does not require energy, is the movement of solutes from a region of high concentration to a region of lower concentration across a concentration gradient.
- Osmosis, which, like diffusion, does not require energy, is the movement of water from an area low in solutes to an area high in solutes. Osmosis exerts a pressure against the cell membrane that is called osmotic pressure.
- Active transport, an energy-requiring process, is the movement of particular substances against a concentration gradient. Active transport is important in maintaining cell homeostasis.
- Cells replicate at differing rates, depending on the genetic programming of the cell. All cells go through a

life cycle consisting of the following phases: G_0 , the resting phase; G_1 , which involves the production of proteins for DNA synthesis; S, which involves the synthesis of DNA; G_2 , which involves manufacture of the materials needed for mitotic spindle production; and M, the mitotic phase, in which the cell splits to form two identical daughter cells.

- Chemotherapeutic drugs act on cells to cause cell death or alteration. All properties of the drug that affect cells should be considered when administering a chemotherapeutic agent.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-Rom in the front of this book.

MULTIPLE CHOICE

Select the best answer to the following.

1. The basic unit of human structure is
 - a. the mitochondria.
 - b. the nucleus.
 - c. the nucleolus.
 - d. the cell.
2. The cell membrane is composed of
 - a. a phospholipid structure.
 - b. channels of protein.
 - c. a cholesterol-based membrane.
 - d. Golgi apparatus.
3. The saying, "One rotten apple can spoil the whole barrel," can be used to refer to the cell-degrading properties of
 - a. calcium channels.
 - b. lysosomes.
 - c. histocompatibility receptors.
 - d. nuclear spindles.
4. The ribosomes are important sites for
 - a. digestion of nutrients.
 - b. excretion of waste products.
 - c. production of proteins.
 - d. hormone receptors.
5. A human cell placed in salty seawater will
 - a. burst from water entering the cell.
 - b. shrivel and die from water leaving the cell.
 - c. not be affected in any way.
 - d. break apart from the salt effect.
6. The sodium-potassium pump maintains a negative charge on the cell membrane by
 - a. osmosis.
 - b. diffusion.
 - c. active transport.
 - d. facilitated diffusion.
7. All cells progress through basically the same cell cycle, including
 - a. two phases.
 - b. four active phases and a resting phase.
 - c. three periods of rest and a splitting phase.
 - d. four active phases.

MULTIPLE RESPONSE

Select all that apply.

1. The amount of time that a cell takes to progress through the cell cycle is determined by which of the following?
 - a. The acidity of the environment
 - b. The genetic makeup of the cell
 - c. The location of the cell in the body
 - d. The number of ribosomes in the cell
 - e. The cell response to contact inhibition
 - f. The availability of nutrients and oxygen

2. Some substances will pass into the human cell by simple diffusion. Which of the following substances diffuse into the cell?
 - a. Calcium
 - b. Nitrogen
 - c. Sodium
 - d. Carbon dioxide
 - e. Oxygen
 - f. Potassium

3. Some substances require a channel or pore to enter a cell membrane. Which of the following substances use a channel to enter the cell?
 - a. Calcium
 - b. Urea
 - c. Fat-soluble vitamins
 - d. Sodium
 - e. Oxygen
 - f. Potassium

Anti-Infective Agents

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Explain what is meant by selective toxicity and discuss its importance in anti-infective therapies.
2. Differentiate between broad-spectrum and narrow-spectrum drugs.
3. Define bacterial resistance to antibiotics and discuss the emergence of resistant strains.
4. Explain three ways to minimize bacterial resistance.
5. Describe three common adverse reactions associated with the use of antibiotics.

Glossary of Key Terms

bactericidal: substance that causes the death of bacteria, usually by interfering with cell membrane stability or with proteins or enzymes necessary to maintain the cellular integrity of the bacteria

bacteriostatic: substance that prevents the replication of bacteria, usually by interfering with proteins or enzyme systems necessary for reproduction of the bacteria

culture: sample of the bacteria (e.g., from sputum, cell scrapings, urine) to be grown in a laboratory to determine the species of bacteria that is causing an infection

prophylaxis: treatment to prevent an infection before it occurs, as in the use of antibiotics to prevent bacterial endocarditis or antiprotozoals to prevent malaria

resistance: ability of bacteria over time to adapt to an antibiotic and produce cells that are no longer affected by a particular drug

selective toxicity: the ability to affect certain proteins or enzyme systems that are used by the infecting organism but not by human cells.

sensitivity testing: evaluation of bacteria obtained in a culture to determine the antibiotics to which the organisms are sensitive and which agent would be appropriate for treatment of a particular infection

spectrum: range of bacteria against which an antibiotic is effective (e.g., broad-spectrum antibiotics are effective against a wide range of bacteria)

superinfection: infections that occur when opportunistic pathogens that were kept in check by the “normal” bacteria have the opportunity to invade tissues and cause infections because the normal flora bacteria have been destroyed by antibiotic therapy

DRUG LIST

bacitracin
chloramphenicol

meropenem
polymyxin B

spectinomycin
vancomycin

Anti-infective agents are drugs designed to target foreign organisms that have invaded and infected the body of a human host. For centuries, people have used various naturally occurring chemicals in an effort to treat disease. Often this was a random act that proved useful. For instance, the ancient Chinese found that applying moldy soybean curds to boils and infected wounds helped prevent infection or hastened cure. Their finding was, perhaps, a forerunner to the penicillins used today.

The use of drugs to treat systemic infections is a relatively new concept, beginning with Paul Ehrlich in the 1920s. Ehrlich's research to develop a synthetic chemical that would be effective only against infection-causing cells, not human cells, led the way for the scientific investigation of anti-infective agents. In the late 1920s, scientists discovered penicillin in a mold sample; in 1935, the sulfonamides were introduced. Since then, the number of anti-infectives available for use has grown tremendously. However, many of the organisms these drugs were designed to treat are rapidly adapting to repel the effects of anti-infectives, and, therefore, much work remains to deal with these emergent strains.

ANTI-INFECTIVE AGENTS

Although anti-infective agents target foreign organisms infecting the body of a human host, they do not possess **selective toxicity**, which is the ability to affect certain proteins or enzyme systems used by the infecting organism but not by human cells. Because all living cells are somewhat similar, however, no anti-infective drug has yet been developed that does not affect the host.

This chapter focuses on the principles involved in the use of anti-infective therapy, and presents some anti-infectives as examples of these principles. The following chapters discuss specific agents used to treat particular infections: antibiotics for bacterial infections; antivirals; antifungals; antiprotozoals for infections caused by specific protozoa, including malaria; and anthelmintics for infections caused by worms. The final chapter in this section discusses antineoplastics—drugs used for treating diseases caused by abnormal cells such as cancers. Antineoplastics specifically affect human cells to cause cell death or prevent cell growth and reproduction. The effects of anti-infectives on various age groups are discussed in Box 8.1.

Therapeutic Actions

Anti-infective agents may act on the cells of invading organisms in several different ways. The goal is interference with the normal function of the invading organism to prevent it from reproducing and to cause cell death without affecting host cells. Various mechanisms of action are briefly described here and shown in Figure 8.1. The specific mechanism of action for each drug class is discussed in the chapters that follow.

- Some anti-infectives interfere with biosynthesis of the bacterial cell wall. Because bacterial cells have a slightly different composition than human cells, this is an effective way to destroy the bacteria without interfering with the host (Box 8.2). The penicillins work in this way.
- Some anti-infectives prevent the cells of the invading organism from using substances essential to their growth and development, leading to an inability to divide and eventually to cell death. The sulfonamides, the antimycobacterial drugs, and trimethoprim-sulfamethoxazole (a combination

BOX 8.1

Drug Therapy Across the Lifespan

This box presents general principles of use of anti-infectives across the lifespan. Specifics for each type of anti-infective agent are discussed in their respective chapters within this unit.

Anti-Infective Agents

CHILDREN

Use anti-infectives with caution; early exposure can lead to early sensitivity.

Controversy is widespread regarding the use of antibiotics to treat ear infections, a common pediatric problem. Some believe that the habitual use of antibiotics for what might well be a viral infection has contributed greatly to the development of resistant strains.

Because children can have increased susceptibility to the gastrointestinal and nervous system effects of anti-infectives, monitor hydration and nutritional status carefully.

ADULTS

Adults often demand anti-infectives for a "quick cure" of various signs and symptoms. Drug allergies and the emer-

gence of resistant strains can be a big problem with this group.

Pregnant and nursing women must exercise extreme caution in the use of anti-infectives. Many of them can affect the fetus and also cross into breast milk, leading to toxic effects in the neonate.

OLDER ADULTS

Older patients often do not present with the same signs and symptoms of infection that are seen in younger people.

Culture and sensitivity tests are important to determine the type and extent of many infections.

The older patient is susceptible to severe adverse gastrointestinal, renal, and neurological effects and must be monitored for nutritional status and hydration during drug therapy.

Anti-infectives that adversely affect the liver and kidneys must be used with caution in older patients, who may have decreased organ function.

● **FIGURE 8.1** Anti-infectives can affect cells by disrupting the cell membrane, interfering with DNA synthesis, altering RNA, or blocking the use of essential nutrients.

drug frequently used to treat urinary tract infections) work in this way.

- Many anti-infectives interfere with the steps involved in protein synthesis, a function necessary to maintain the cell and allow for cell division. The aminoglycosides, the macrolides, and chloramphenicol (see the section on adverse effects for a box on chloramphenicol) work in this way.

BOX 8.2 Anti-Infective Mechanism: Interference With Cell Wall Synthesis

Bacitracin (*Baci-IM*, *AK-Tracin*, *Baciguent*) is an antibiotic that interferes with the cell wall synthesis of susceptible staphylococcal bacteria. Adverse effects include nephrotoxicity and superinfection. Because of the development of resistant strains and more potent antibiotics, bacitracin is now indicated only for the treatment of respiratory infections in infants caused by susceptible staphylococci, treatment of eye infections, prevention of infections in minor skin wounds, and treatment of minor skin infections caused by susceptible strains of staphylococci. Bacitracin is available in intramuscular, ophthalmic, and topical preparations.

USUAL DOSAGE

Infants less than 2.5 kg: 900 units/kg/d IM in three divided doses; greater than 2.5 kg: 1,000 units/kg/d IM in two to three divided doses.

Ophthalmic use: ½-in. ribbon to affected eye, b.i.d. to q3–4h.
Topical use: apply to affected area one to five times per day.

- Some anti-infectives interfere with DNA synthesis in the cell, leading to inability to divide and cell death. The fluoroquinolones work in this way.
- Other anti-infectives alter the permeability of the cell membrane to allow essential cellular components to leak out, causing cell death. Some antibiotics, antifungals, and antiprotozoal drugs work in this manner.

Anti-Infective Activity

The anti-infectives used today vary in their **spectrum** of activity; that is, they vary in their effectiveness against invading organisms. Some anti-infectives are so selective in their action that they are effective against only a few microorganisms with a very specific metabolic pathway or enzyme. These drugs are said to have a narrow spectrum of activity (Box 8.3). Other drugs interfere with biochemical reactions in many different kinds of microorganisms, making them

BOX 8.3 Narrow-Spectrum Antibiotic

Spectinomycin (*Trobicin*) is an example of an antibiotic with very specific effects. This drug interferes with protein synthesis, leading to cell death, only in susceptible strains of *Neisseria gonorrhoeae*. Spectinomycin is not known to be effective against any other bacterial species, and its use is limited to the treatment of specific gonococcal infections. The drug is given as one 2-g IM injection, which may be increased to a 4-g IM injection in areas where bacterial resistance is prevalent.

useful in the treatment of a wide variety of infections. Such drugs are said to have a broad spectrum of activity.

Some anti-infectives are so active against the infective microorganisms that they actually cause the death of the cells they affect. These drugs are said to be **bactericidal**. Some anti-infectives are not as aggressive against invading organisms; they interfere with the ability of the cells to reproduce or divide. These drugs are said to be **bacteriostatic**. Several drugs are both bactericidal and bacteriostatic, often depending on the concentration of the drug that is present. Many of the adverse effects noted with the use of anti-infectives are associated with the aggressive properties of the drugs and their effect on the cells of the host in addition to those of the pathogen.

Human Immune Response

The goal of anti-infective therapy is reduction of the population of the invading organism to a point at which the human immune response can take care of the infection. If a drug were aggressive enough to eliminate all traces of any invading pathogen, it also might be toxic to the host. The immune response (see Chapter 15) involves a complex interaction among chemical mediators, leukocytes, lymphocytes, antibodies, and locally released enzymes and chemicals. When this response is completely functional and all of the necessary proteins, cells, and chemicals are being produced by the body, it can isolate and eliminate foreign proteins, including bacteria, fungi, and viruses. However, if a person is immunocompromised for any reason (e.g., malnutrition, age, acquired immune deficiency syndrome [AIDS], use of immunosuppressant drugs), the immune system may be incapable of dealing effectively with the invading organisms. It is difficult to treat any infections in such patients for two reasons: (1) Anti-infective drugs cannot totally eliminate the pathogen without causing severe toxicity in the host, and (2) these patients do not have the immune response in place to deal with even a few invading organisms. Immunocompromised patients present a significant challenge to health care providers. In helping these people cope with infections, prevention of infection and proper nutrition are often as important as drug therapy.

Resistance

Resistance can be natural or acquired, and refers to the ability over time to adapt to an antibiotic and produce cells that are no longer affected by a particular drug. Because anti-infectives act on specific enzyme systems or biological processes, many microorganisms that do not use that system or process are not affected by a particular anti-infective drug and are said to have a natural or intrinsic resistance. When prescribing a drug for treatment of an infection, this innate resistance should be anticipated. The selected drug should be one that is known to affect the specific microorganism causing the infection.

Since the advent of anti-infective drugs, microorganisms that were once very sensitive to the effects of particular drugs have begun to develop acquired resistance to the agents (Box 8.4). This can result in a serious clinical problem. The emergence of resistant strains of bacteria and other organisms

BOX 8.4 Bacterial Resistance to an Anti-Infective Drug

Vancomycin (*Vancocin*, *Vancoled*) is an antibiotic that interferes with cell wall synthesis in susceptible bacteria. It was developed as a result of a need for a drug that could be used both in patients who are intolerant to or allergic to penicillin and/or cephalosporins and in the treatment of patients with staphylococcal infections that no longer respond to penicillin or cephalosporins. This anti-infective drug can be used orally or intravenously to treat life-threatening infections when less toxic drugs cannot be used. It is used orally as prophylaxis against bacterial endocarditis in patients who cannot take penicillins or cephalosporins and to treat staphylococcal infections in people who cannot take these groups of drugs.

Because vancomycin may be highly toxic, its use is reserved for very special situations. It can cause renal failure, ototoxicity, superinfections, and a condition known as “red man syndrome,” which is characterized by sudden and severe hypotension, fever, chills, paresthesias, and erythema or redness of the neck and back. When it is the only antibiotic that is effective against a specific bacterium, however, the benefits outweigh the risks.

USUAL DOSAGE

Adult: 500 mg to 1 g PO or IV q6h for 7–10 d.

Pediatric: 40 mg/kg/d PO or IV in four divided doses; do not exceed 2 g/d.

poses a threat: Anti-infective drugs may no longer control potentially life-threatening diseases, and uncontrollable epidemics may occur.

Acquiring Resistance

Microorganisms develop resistance in a number of ways, including the following:

- Producing an enzyme that deactivates the antimicrobial drug. For example, some strains of bacteria that were once controlled by penicillin now produce an enzyme called penicillinase, which inactivates penicillin before it can affect the bacteria. This occurrence led to the development of new drugs that are resistant to penicillinase.
- Changing cellular permeability to prevent the drug from entering the cell or altering transport systems to exclude the drug from active transport into the cell.
- Altering binding sites on the membranes or ribosomes, which then no longer accept the drug.
- Producing a chemical that acts as an antagonist to the drug.

Most commonly, the development of resistance depends on the degree to which the drug acts to eliminate the invading microorganisms that are most sensitive to its effects. The cells that remain may be somewhat resistant to the effects of the drug, and, with time, these cells form the majority in the population. These cells differ from the general population of the species because of slight variations in their biochemical processes or biochemicals. The drug does not cause a mutation of these cells; it simply allows the somewhat different cells to become the majority or dominant group after elimination of the sensitive cells. Other microbes may develop

resistance through actual genetic mutation. A mutant cell survives the effects of an antibiotic and divides, forming a new colony of resistant microbes with a genetic composition that provides resistance to the anti-infective agent.

Preventing Resistance

Because the emergence of resistant strains of microbes is a serious public health problem that continues to grow, health care providers must work together to prevent the emergence of resistant pathogens. Exposure to an antimicrobial agent leads to the development of resistance, so it is important to limit the use of antimicrobial agents to the treatment of specific pathogens known to be sensitive to the drug being used.

Drug dosing is important in preventing the development of resistance. Doses should be high enough and the duration of drug therapy should be long enough to eradicate even slightly resistant microorganisms. The recommended dosage for a specific anti-infective agent takes this issue into account. Around-the-clock dosing eliminates the peaks and valleys in drug concentration and helps to maintain a constant therapeutic level to prevent the emergence of resistant microbes during times of low concentration. The duration of drug use is critical to ensure that the microbes are completely, not partially, eliminated and are not given the chance to grow and develop resistant strains. It has proved to be difficult to convince people who are taking anti-infective drugs that the timing of doses and the length of time they continue to take the drug are important. Many people stop taking a drug once they start to feel better and then keep the remaining pills to treat themselves at some time in the future when they do not feel well. This practice favors the emergence of resistant strains. Box 8.5 gives tips on patient teaching.

Health care providers should also be cautious about the indiscriminate use of anti-infectives. Antibiotics are not effective in the treatment of viral infections or illnesses such as the common cold. However, many patients demand prescriptions for these drugs when they visit practitioners because they are convinced that they need to take something to feel better. Health care providers who prescribe anti-infectives without knowing the causative organism and which drugs might be

appropriate are promoting the emergence of resistant strains of microbes. With many serious illnesses, including pneumonias for which the causative organism is suspected, antibiotic therapy may be started as soon as a sample of the bacteria, or **culture**, is taken and before the results are known. Health care providers also tend to try newly introduced, more powerful drugs when a more established drug may be just as effective. Use of a powerful drug in this way leads to the rapid emergence of resistant strains to that drug, perhaps limiting its potential usefulness when it might be truly necessary.

KEY POINTS

- ▶ The goal of anti-infective therapy is the reduction of the invading organisms to a point at which the human immune response can take care of the infection.
- ▶ Anti-infectives can act to destroy an infective pathogen (bactericidal) or to prevent the pathogen from reproducing (bacteriostatic).
- ▶ Anti-infectives can have a small group of pathogens against which they are effective (narrow spectrum), or they can be effective against many pathogens (broad spectrum).

Using Anti-Infective Agents

Anti-infective agents are used to treat systemic infections and sometimes as a means of prophylaxis (to prevent infections before they occur).

Treatment of Systemic Infections

Many infections that once led to lengthy, organ-damaging, or even fatal illnesses are now managed quickly and efficiently with the use of systemic anti-infective agents. Before the introduction of penicillin to treat streptococcal infections, many people developed rheumatic fever with serious cardiac complications. Today, rheumatic fever and the resultant cardiac valve defects are seldom seen. Several factors should be considered before beginning one of these chemotherapeutic regimens to ensure that the patient obtains the greatest benefit possible with the fewest adverse effects. These factors include identification of the correct pathogen and selection of a drug that is most likely to (1) cause the least complications for that patient and (2) be most effective against the pathogen involved.

Identification of the Pathogen

Identification of the infecting pathogen is done by culturing a tissue sample from the infected area. Bacterial cultures are performed in a laboratory, in which a swab of infected tissue is allowed to grow on an agar plate. Staining techniques and microscopic examination are used to identify the offending bacterium. When investigators search for parasitic sources of infection, they may examine stool for ova and parasites. Microscopic examination of other samples is also used to detect fungal and protozoal infections. The correct identification of the organism causing the infection is an important first step in determining which anti-infective drug should be used.

BOX 8.5

Patient and Family Teaching

Using Anti-Infective Agents

When teaching patients who are prescribed an anti-infective agent, it is important to always include some general points:

- This drug is prescribed for treating the particular infection that you have now. Do not use this drug to treat other infections.
- This drug needs to be taken as prescribed—for the correct number of times each day and for the full number of days. Do not stop taking the drug if you start feeling better. You need to take the drug for the full number of treatment days to ensure that the infection has been destroyed.

Sensitivity of the Pathogen

In many situations, health care providers use a broad-spectrum anti-infective agent that has been shown likely to be most effective in treating an infection with certain presenting signs and symptoms. In other cases of severe infection, a broad-spectrum antibiotic is started after a culture is taken but before the exact causative organism has been identified. Again, experience influences selection of the drug, based on the presenting signs and symptoms. In many cases, it is necessary to perform **sensitivity testing** on the cultured microbes to evaluate bacteria and determine which drugs are capable of controlling the particular microorganism. This testing is especially important with microorganisms that have known resistant strains. In these cases, culture and sensitivity testing identify the causal pathogen and the most appropriate drug for treating the infection.

Combination Therapy

In some situations, a combination of two or more types of drugs effectively treats the infection. When the offending pathogen is known, combination drugs may be effective in interfering with its cellular structure in different areas or developmental phases.

Combination therapy may be used for several reasons:

- The health care provider may be encouraged to use a smaller dose of each drug, leading to fewer adverse effects but still having a therapeutic impact on the pathogen.
- Some drugs are synergistic, which means that they are more powerful when given in combination.
- Many microbial infections are caused by more than one organism, and each pathogen may react to a different anti-infective agent.
- Sometimes, the combined effects of the different drugs delay the emergence of resistant strains. This is important in the treatment of tuberculosis (a mycobacterial infection), malaria (a protozoal infection), HIV infection (a viral infection) and some bacterial infections. Resistant strains may be more likely to emerge when fixed combinations are used over time; however, this may be prevented by individualizing the combination.

Prophylaxis

Sometimes it is clinically useful to use anti-infectives as a means of **prophylaxis** to prevent infections before they occur. For example, when patients anticipate traveling to an area where malaria is endemic, they may begin taking antimalarial drugs before the journey and periodically during the trip. Patients who are undergoing gastrointestinal (GI) or genitourinary surgery, which might introduce bacteria from those areas into the system, often have antibiotics ordered immediately after the surgery and periodically thereafter, as appropriate, to prevent infection. Patients with known cardiac valve disease, valve replacements, and other conditions are especially prone to the development of subacute bacterial endocarditis because of the vulnerability of their heart valves. These patients use

prophylactic antibiotic therapy as a precaution when undergoing invasive procedures, including dental work. Refer to the American Heart Association's recommended schedule for this prophylaxis.

KEY POINTS

- ◆ Resistance of a pathogen to an anti-infective agent can be natural (the pathogen does not use the process on which the anti-infective works) or acquired (the pathogen develops a process to oppose the anti-infective agent).
- ◆ The emergence of resistant strains is a serious public health problem. Health care providers need to be alert to preventing the emergence of resistant strains by not using antibiotics inappropriately, assuring that the anti-infective is taken at a high enough dose for a long enough period of time, and avoiding the use of newer, powerful anti-infectives if other drugs would be just as effective.

Adverse Reactions to Anti-Infective Therapy

Because anti-infective agents affect cells, it is always possible that the host cells will also be damaged (Box 8.6). No anti-infective agent has been developed that is completely free of adverse effects. The most commonly encountered adverse effects associated with the use of anti-infective agents are direct toxic effects on the kidney, GI tract, and nervous system. Hypersensitivity reactions and superinfections also can occur.

Kidney Damage

Kidney damage occurs most frequently with drugs that are metabolized by the kidney and then eliminated in the urine. Such drugs, which have a direct toxic effect on the fragile cells in the kidney, can cause conditions ranging from renal

BOX 8.6 Serious Adverse Effects of Antibiotic Treatment

Chloramphenicol (*Chloromycetin*), an older antibiotic, prevents bacterial cell division in susceptible bacteria. Because of the potential toxic effects of this drug, its use is limited to serious infections for which no other antibiotic is effective. Chloramphenicol produces a “gray syndrome” in neonates and premature babies, which is characterized by abdominal distention, pallid cyanosis, vasomotor collapse, irregular respirations, and even death. In addition, the drug may cause bone marrow depression, including aplastic anemia that can result in death. These effects are seen even with the use of the ophthalmic and otic forms of the drug. Although the use of chloramphenicol is severely limited, it has stayed on the market because it is used to treat serious infections caused by bacteria that are not sensitive to any other antibiotic. It is available in oral, IV, ophthalmic, and otic forms.

USUAL DOSAGE

Adult or pediatric: 50 mg/kg/d PO or IV in divided doses.
 Ophthalmic: instill ointment or solution as prescribed.
 Otic: 2–3 drops (gtt) into affected ear t.i.d.

dysfunction to full-blown renal failure. When patients are taking these drugs (e.g., aminoglycosides), they should be monitored closely for any sign of renal dysfunction. To prevent any accumulation of the drug in the kidney, patients should be well hydrated throughout the course of the drug therapy.

Gastrointestinal Toxicity

GI toxicity is very common with many of the anti-infectives. Many of these agents have direct toxic effects on the cells lining the GI tract, causing nausea, vomiting, stomach upset, or diarrhea, and such effects are sometimes severe (Box 8.7). There is also some evidence that the death of the microorganisms releases chemicals and toxins into the body, which can stimulate the chemoreceptor trigger zone (CTZ) in the medulla and induce nausea and vomiting.

In addition, some anti-infectives are toxic to the liver. These drugs can cause hepatitis and even liver failure. When patients are taking drugs known to be toxic to the liver (e.g., many of the cephalosporins), they should be monitored closely, and the drug should be stopped at any sign of liver dysfunction.

Neurotoxicity

Some anti-infectives can damage or interfere with the function of nerve tissue, usually in areas where drugs tend to accumulate in high concentrations (Box 8.8). For example, the aminoglycoside antibiotics collect in the eighth cranial nerve and can cause dizziness, vertigo, and loss of hearing. Chloroquine, which is used to treat malaria and some other rheumatoid disorders, can accumulate in the retina and optic nerve and cause blindness. Other anti-infectives can cause dizziness, drowsiness, lethargy, changes in reflexes, and even hallucinations when they irritate specific nerve tissues.

Hypersensitivity Reactions

Allergic or hypersensitivity reactions reportedly occur with many antimicrobial agents. Most of these agents, which are

BOX 8.7 Severe Gastrointestinal Toxicity Resulting From Anti-Infective Treatment

Meropenem (*Merrem IV*), an IV antibiotic, inhibits the synthesis of bacterial cell walls in susceptible bacteria. It is used to treat intra-abdominal infections and some cases of meningitis caused by susceptible bacteria. Meropenem almost always causes very uncomfortable gastrointestinal effects; in fact, use of this drug has been associated with potentially fatal pseudomembranous colitis. It also results in headache, dizziness, rash, and superinfections. Because of its toxic effects on gastrointestinal cells, it is used only in those infections with proven sensitivity to meropenem and reduced sensitivity to less toxic antibiotics.

USUAL DOSAGE

Adult: 1 g IV q8h.

Pediatric: younger than 3 mo: not recommended; older than 3 mo: 20–40 mg/kg IV q8h; if greater than 50 kg, 1–2 g IV q8h.

Geriatric: lower dose in accordance with creatinine clearance levels.

BOX 8.8 Nerve Damage Caused by an Anti-Infective Agent

Polymyxin B (generic), an older antibiotic, uses a surfactant-like reaction to enter the bacterial cell membrane and disrupt it, leading to cell death in susceptible gram-negative bacteria. This drug is available for IM, IV, or intrathecal use, as well as an ophthalmic agent for the treatment of infections caused by susceptible bacteria. Because of the actions of polymyxin B on cell membranes, however, it can be toxic to the human host, leading to nephrotoxicity, neurotoxicity (facial flushing, dizziness, ataxia, paresthesias, and drowsiness), and drug fever and rashes. Therefore, it is reserved for use in acute situations when the invading bacterium has been proven to be sensitive to polymyxin B and less sensitive to other, less toxic antibiotics.

USUAL DOSAGE

Adult and pediatric: 15,000–25,000 units/kg/d IV may be divided into two doses *or*

25,000–30,000 units/kg/d IM divided into four to six doses *or* 50,000 units intrathecal daily for 3–4 d, then every other day for at least 2 wk *or*

1–2 drops (gtt) ophthalmic preparation in affected eye b.i.d. q4h.

protein bound for transfer through the cardiovascular system, are able to induce antibody formation in susceptible people. With the next exposure to the drug, immediate or delayed allergic responses may occur. In severe cases, anaphylaxis can occur, which can be life-threatening. Some of these drugs have demonstrated cross-sensitivity (e.g., penicillins, cephalosporins), and care must be taken to obtain a complete patient history before administering one of these drugs. It is important to determine what the allergic reaction was and when the patient experienced it (e.g., after first use of the drug, or after years of use). Some patients report having a drug allergy, but closer investigation indicates that their reaction actually constituted an anticipated effect or a known adverse effect of the drug. Proper interpretation of this information is important to allow treatment of a patient with a drug to which the patient reported a supposed allergic reaction but that would be very effective against a known pathogen.

Superinfections

One offshoot of the use of anti-infectives, especially broad-spectrum anti-infectives, is destruction of the normal flora. **Superinfections** are infections that occur when opportunistic pathogens that were kept in check by the “normal” bacteria have the opportunity to invade tissues. Common superinfections include vaginal or GI yeast infections, which are associated with antibiotic therapy, and infections caused by *Proteus* and *Pseudomonas* throughout the body, which are a result of broad-spectrum antibiotic use. If patients receive drugs that are known to induce superinfections, they should be monitored closely for any signs of a new infection—sore patches in the mouth, vaginal itching, diarrhea—and the appropriate treatment for any superinfection should be started as soon as possible.

CHAPTER SUMMARY

- Anti-infectives are drugs designed to act on foreign organisms that have invaded and infected the human host with selective toxicity, which means that they affect biological systems or structures found in the invading organisms but not in the host.
- Anti-infectives include antibiotics, antivirals, antifungals, antiprotozoals, and anthelmintic agents.
- The goal of anti-infective therapy is interference with the normal function of invading organisms to prevent them from reproducing and promotion of cell death without negative effects on the host cells. The infection should be eradicated with the least toxicity to the host and the least likelihood for development of resistance.
- Anti-infectives can work by altering the cell membrane of the pathogen, by interfering with protein synthesis, or by interfering with the ability of the pathogen to obtain needed nutrients.
- Anti-infectives also work to kill invading organisms or to prevent them from reproducing, thus depleting the size of the invasion to one that can be dealt with by the human immune system.
- Pathogens can develop resistance to the effects of anti-infectives over time when (1) mutant organisms that do not respond to the anti-infective become the majority of the pathogen population or (2) the pathogen develops enzymes to block the anti-infectives or alternative routes to obtain nutrients or maintain the cell membrane.
- An important aspect of clinical care involving anti-infective agents is preventing or delaying the development of resistance. This can be done by ensuring that the particular anti-infective agent is the drug of choice for the specific pathogen involved and that it is given in high enough doses for sufficiently long periods to rid the body of the pathogen.
- Culture and sensitivity testing of a suspected infection ensures that the correct drug is being used to treat the infection effectively. Culture and sensitivity testing should be performed before an anti-infective agent is prescribed.
- Anti-infectives can have several adverse effects on the human host, including renal toxicity, multiple GI effects, neurotoxicity, hypersensitivity reactions, and superinfections.
- Some anti-infectives are used as a means of prophylaxis when patients expect to be in situations that will expose them to a known pathogen, such as travel to an area where malaria is endemic, or oral or invasive GI surgery in a person who is susceptible to subacute bacterial endocarditis.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-Rom in the front of this book.

Select the best answer to the following.

1. The spectrum of activity of an anti-infective indicates
 - a. the acidity of the environment in which they are most effective.
 - b. the cell membrane type that the anti-infective affects.
 - c. the anti-infective's effectiveness against different invading organisms.
 - d. the resistance factor that bacteria have developed to this anti-infective.
2. The emergence of resistant strains of microbes is a serious public health problem. Health care providers can work to prevent the emergence of resistant strains by
 - a. encouraging the patient to stop the antibiotic as soon as the symptoms are resolved to prevent overexposure to the drug.
 - b. encouraging the use of antibiotics when patients feel they will help.
 - c. limiting the use of antimicrobial agents to the treatment of specific pathogens known to be sensitive to the drug being used.
 - d. using the most recent powerful drug available to treat an infection to ensure eradication of the microbe.
3. Sensitivity testing of a culture shows
 - a. drugs that are capable of controlling that particular microorganism.
 - b. the patient's potential for allergic reactions to a drug.
 - c. the offending microorganism.
 - d. an immune reaction to the infecting organism.
4. Combination therapy is often used in treating infections. An important consideration for using combination therapy would be that
 - a. it is cheaper to use two drugs in one tablet than one drug alone.
 - b. most infections are caused by multiple organisms.
 - c. the combination of drugs can delay the emergence of resistant strains.
 - d. combining anti-infectives will prevent adverse effects from occurring.

5. Superinfections can occur when anti-infective agents destroy the normal flora of the body. *Candida* infections are commonly associated with antibiotic use. A patient with this type of superinfection would exhibit
- difficulty breathing.
 - vaginal discharge or white patches in the mouth.
 - elevated blood urea nitrogen.
 - dark lesions on the skin.
6. An example of an anti-infective used as a means of prophylaxis would be
- amoxicillin used for tonsillitis.
 - penicillin used to treat an abscess.
 - an antibiotic used before dental surgery.
 - norfloxacin used for a bladder infection.
7. A broad-spectrum antibiotic would be the drug of choice when
- the patient has many known allergies.
 - one is waiting for culture and sensitivity results.
 - the infection is caused by one specific bacterium.
 - treatment is being given for an upper respiratory infection of unknown cause.

MULTIPLE RESPONSE

Select all that apply.

- Bacterial resistance to an anti-infective could be the result of which of the following?
 - Natural or intrinsic properties of the bacteria
 - Changes in cellular permeability or cellular transport systems
 - The production of chemicals that antagonize the drug
 - Initial exposure to the anti-infective
 - Combination of too many antibiotics for one infection
 - Narrow spectrum of activity
- Anti-infective drugs destroy cells that have invaded the body. They do not specifically destroy only the cell of the invader, and because of this, many adverse effects can be anticipated when an anti-infective is used. Which of the following adverse effects are often associated with anti-infective use?
 - Superinfections
 - Hypotension
 - Renal toxicity
 - Diarrhea
 - Loss of hearing
 - Constipation

Antibiotics

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Explain how an antibiotic is selected for use in a particular clinical situation.
2. Describe therapeutic actions, indications, pharmacokinetics, contraindications, most common adverse reactions, and important drug–drug interactions associated with each of the classes of antibiotics.
3. Discuss use of antibiotics as they are used across the lifespan.
4. Compare and contrast prototype drugs for each class of antibiotics with other drugs in that class.
5. Outline nursing considerations for patients receiving each class of antibiotic.

Glossary of Key Terms

aerobic: bacteria that depend on oxygen for survival

anaerobic: bacteria that survive without oxygen, which are often seen when blood flow is cut off to an area of the body

antibiotic: chemical that is able to inhibit the growth of specific bacteria or cause the death of susceptible bacteria

gram-negative: bacteria that accept a negative stain and are frequently associated with infections of the genitourinary or GI tract

gram-positive: bacteria that take a positive stain and are frequently associated with infections of the respiratory tract and soft tissues

synergistic: drugs that work together to increase drug effectiveness

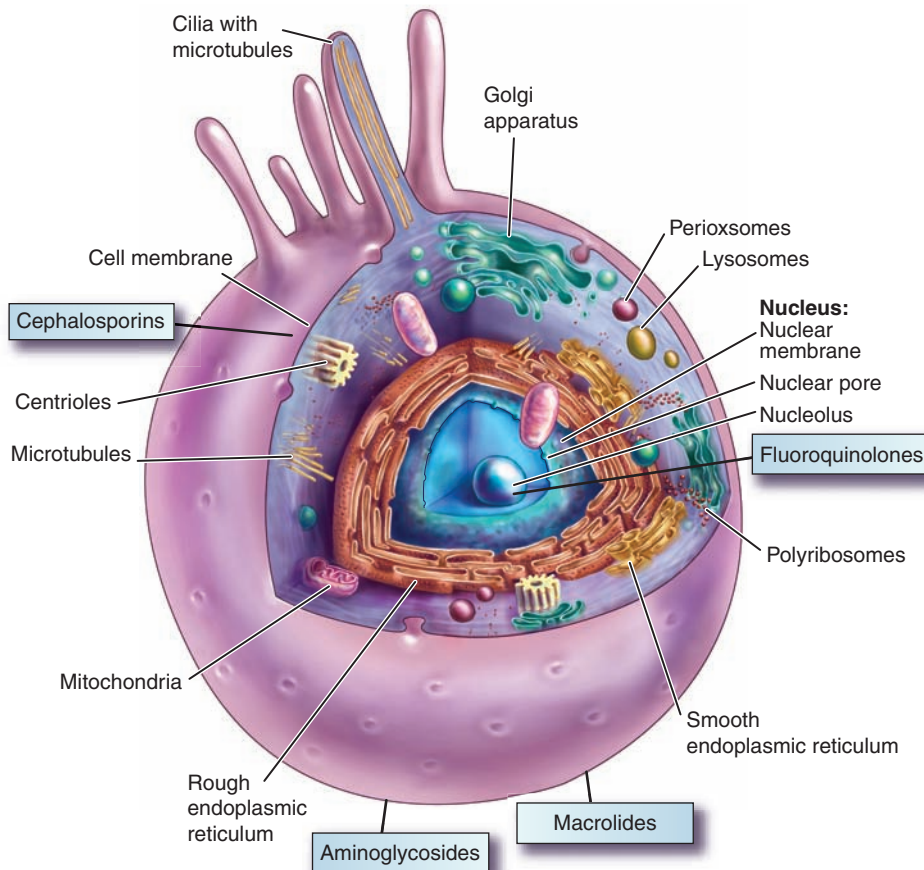

Many new bacteria appear each year, and researchers are challenged to develop new **antibiotics**—chemicals that inhibit specific bacteria—to deal with each new threat. Antibiotics are made in three ways: by living microorganisms, by synthetic manufacture, and, in some cases, through genetic engineering. Antibiotics may either be bacteriostatic (preventing the growth of bacteria) or bactericidal (killing bacteria directly), although several antibiotics are both bactericidal and bacteriostatic, depending on the concentration of the particular drug. This chapter discusses the major classes of antibiotics: aminoglycosides, carbapenems, cephalosporins, fluoroquinolones, penicillins and penicillinase-resistant drugs, sulfonamides, tetracyclines, and the disease-specific antimy-

cobacterials, including the antitubercular and leprostatic drugs. Antibiotics that do not fit into the large antibiotic classes include ketolides, lincosamides, macrolides, and monobactams. Figures 9.1 and 9.2 show sites of cellular action of these classes of antibiotics.

Safe Medication Administration

Many antibiotics used to treat childhood infections, such as otitis media and other upper respiratory infections (URIs), come in an oral suspension, suitable for children. The order for these solutions is usually written in teaspoons for the convenience of

● **FIGURE 9.1** Sites of cellular action of aminoglycosides, cephalosporins, fluoroquinolones, and macrolides. Aminoglycosides disrupt the cell membrane. Cephalosporins cause bacteria to build weak cell walls when dividing. Fluoroquinolones interfere with the DNA enzymes needed for growth and reproduction. Macrolides change protein function by binding to the cell membrane to cause cell death or prevent cell division.

● **FIGURE 9.2** Sites of cellular action of carbapenems, ketolides, lincosamides, aztreonam, penicillins, sulfonamides, tetracyclines, and antimycobacterials. Carbapenems, ketolides, and lincosamides change protein function and prevent cell division or cause cell death. Aztreonam alters cell membranes to allow leakage of intracellular substances and causes cell death. Penicillins prevent bacteria from building their cells during division. Sulfonamides inhibit folic acid synthesis for RNA and DNA production. Tetracyclines inhibit protein synthesis, thereby preventing reproduction. Antimycobacterial drugs affect mycobacteria in three ways: They (1) affect the mycotic coat of the bacteria, (2) alter DNA and RNA, and (3) prevent cell division.

the parent who will be dispensing the medication. It is very important to make sure that the parent understands that the teaspoon in the prescription refers to a measuring teaspoon (5 mL). Inadvertent overdoses have been reported when parents used a flatware teaspoon to measure out the child's dose. Flatware teaspoons vary greatly in volume. If a parent calls to report that the medicine is all gone on day 4 and it was supposed to be given for 7 days, check to see how the medicine is being measured. Teaching the parent when the drug is first ordered can prevent problems during the course of treatment.

BACTERIA AND ANTIBIOTICS

Bacteria can invade the human body through many routes: for example, respiratory, gastrointestinal (GI), and skin. Once the bacteria invade the body, the human immune response is activated, and signs and symptoms of an infection occur as the body tries to rid itself of the foreign cells. Fever, lethargy, slow-wave sleep induction, and the classic signs of inflammation (e.g., redness, swelling, heat, and pain) all indicate that the body is responding to an invader. The body becomes the host for the bacteria and supplies proteins and enzymes the bacteria need for reproduction. Unchallenged, the invading

bacteria can multiply and send out other bacteria to further invade tissue.

The goal of antibiotic therapy is to decrease the population of invading bacteria to a point at which the human immune system can effectively deal with the invader. To determine which antibiotic will effectively interfere with the specific proteins or enzyme systems for treatment of a specific infection, the causative organism must be identified through a culture. Sensitivity testing is also done to determine the antibiotic to which that particular organism is most sensitive (e.g., which antibiotic best kills or controls the bacteria).

Gram-positive bacteria are those whose cell wall retains a stain known as Gram's stain or resists decolorization with alcohol during culture and sensitivity testing. Gram-positive bacteria are commonly associated with infections of the respiratory tract and soft tissues. An example of a gram-positive bacterium is *Streptococcus pneumoniae*, a common cause of pneumonia. In contrast, **gram-negative** bacteria are those whose cell walls lose a stain or are decolorized by alcohol. These bacteria are frequently associated with infections of the genitourinary (GU) or GI tract. An example of a gram-negative bacterium is *Escherichia coli*, a common cause of cystitis. **Aerobic** bacteria depend on oxygen for survival, whereas **anaerobic** bacteria (e.g., those bacteria associated with gangrene) do not use oxygen.

If culture and sensitivity testing is not possible, either because the source of the infection is not identifiable or because the patient is too sick to wait for test results to determine the best treatment, clinicians attempt to administer a drug with a broad spectrum of activity against gram-positive or gram-negative bacteria or against anaerobic bacteria. Antibiotics that interfere with a biochemical reaction common to many organisms are known as broad-spectrum antibiotics. These drugs are often given at the beginning of treatment until the exact organism and sensitivity can be established. Because these antibiotics have such a wide range of effects, they are frequently associated with adverse effects. Human cells have many of the same properties as bacterial cells and can be affected in much the same way, so damage may occur to the human cells, as well as to the bacterial cells.

Because there is no perfect antibiotic that is without effect on the human host, clinicians try to select an antibiotic with selective toxicity, or the ability to strike foreign cells with

little or no effect on human cells. Certain antibiotics may be contraindicated in some patients because of known adverse effects; this includes those patients who are immunocompromised, who have severe GI disease, or who are debilitated. (See Box 9.1 for effects of antibiotics across the lifespan.) The antibiotic of choice is one that affects the causative organism and leads to the fewest adverse effects for the patient involved.

In some cases, antibiotics are given in combination because they are **synergistic**, meaning their combined effect is greater than their effect if they are given individually (Box 9.2). Use of synergistic antibiotics also allows the patient to take a lower dose of each antibiotic to achieve the desired effect, which helps to reduce the adverse effects that a particular drug may have.

In some situations, antibiotics are used as a means of prophylaxis, or prevention of potential infection. Patients who will soon be in a situation that commonly results in a specific

BOX 9.1**Drug Therapy Across the Lifespan****Antibiotics****CHILDREN**

Children are very sensitive to the gastrointestinal and central nervous system (CNS) effects of most antibiotics, and more severe reactions can be expected when these drugs are used in children. It is important to monitor the hydration and nutritional status of children who are adversely affected by drug-induced diarrhea, anorexia, nausea, and vomiting. Superinfections can be a problem for small children as well. For example, thrush (oral candidiasis) is a common superinfection that makes eating and drinking difficult.

Many antibiotics do not have proven safety and efficacy in pediatric use, and extreme caution should be used when giving them to children. The fluoroquinolones, for instance, are associated with damage to developing cartilage and are not recommended for growing children.

Pediatric dosages of antibiotics should be double-checked to make sure that the child is receiving the correct dose, thereby improving the chance of eradicating the infection and decreasing the risk of adverse effects.

Antibiotic treatment of ear infections, a common pediatric problem, is controversial. Ongoing research suggests that judicious use of decongestants and anti-inflammatories may be just as successful as the use of antibiotics without the risk of development of resistant bacterial strains.

Parents, not wanting to see their child sick, may demand antibiotics as a cure-all whenever their child is fussy or feverish. Parent education is very important in helping to cut down the unnecessary use of antibiotics in children.

ADULTS

Many adults believe that antibiotics are a cure-all for any discomfort and fever. It is very important to explain that antibiotics are useful against only specific bacteria and actually

can cause problems when used unnecessarily for viral infections, such as the common cold.

Adults need to be cautioned to take the entire course of the medication as prescribed and not to store unused pills for future infections or share antibiotics with symptomatic friends.

Pregnant and breast-feeding women should not take antibiotics unless the benefit clearly outweighs the potential risk to the fetus or neonate. Tetracyclines, for example, are associated with pitting of enamel in developing teeth and with calcium deposits in growing bones. These drugs can cause serious problems for neonates. Women of childbearing age should be advised to use barrier contraceptives if any of these drugs are used.

Many antibiotics interfere with the effectiveness of oral contraceptives, and unplanned pregnancies can occur.

OLDER ADULTS

In many instances, older adults do not present with the same signs and symptoms of infections as other patients. Therefore, assessing the problem and obtaining appropriate specimens for culture is especially important with this population.

Older patients may be more susceptible to the adverse effects associated with antibiotic therapy. Their hydration and nutritional status should be monitored closely, as should the need for safety precautions if CNS effects occur. If hepatic or renal dysfunction is expected (particularly in very old patients, those who may depend on alcohol, and those who are taking other hepatotoxic or nephrotoxic drugs), the dose may need to be lowered and the patient should be monitored more frequently.

Elderly patients also need to be cautioned to complete the full course of drug therapy, even when they feel better, and not to save pills for self-medication at a future time.

BOX 9.2 Using Combination Drugs to Fight Resistant Bacteria

Clavulanic acid protects certain beta-lactam antibiotics from breakdown in the presence of penicillinase enzymes.

A combination of amoxicillin and clavulanic acid (*Augmentin*) is commonly used to allow the amoxicillin to remain effective against certain strains of resistant bacteria (usual dosage, 250–500 mg PO q8h for adults or 20–40 mg/kg/d PO in divided doses for children). The theory behind the combination of ticarcillin and clavulanic acid (*Timentin*) is similar (usual dosage 3.1 g IM q4–6h for adults; safety not established for children).

Sulbactam is another drug that increases the effectiveness of antibiotics against certain resistant bacteria. When combined with ampicillin in the drug *Unasyn*, sulbactam inhibits many bacterial penicillinase enzymes, broadening the spectrum of the ampicillin. In this combination, sulbactam is also slightly antibacterial (usual adult dosage, 0.5–1 g sulbactam, with 1–2 g ampicillin IM or IV q6–8h).

infection (e.g., patients undergoing GI surgical procedures, which may introduce GI bacteria into the bloodstream or peritoneum) may be given antibiotics before they are exposed to the bacteria. Usually a large, one-time dose of an antibiotic is given to destroy any bacteria that enter the host immediately and thereby prevent a serious infection.

BACTERIA AND RESISTANCE TO ANTIBIOTICS

Bacteria have survived for hundreds of years because they can adapt to their environment. They do this by altering their cell wall or enzyme systems to become resistant to (e.g., protect themselves from) unfavorable conditions or situations. Many species of bacteria have developed resistance to certain antibiotics. For example, bacteria that were once very sensitive to penicillin have developed an enzyme called penicillinase, which effectively inactivates many of the penicillin-type drugs. New drugs had to be developed to effectively treat infections involving these once-controlled bacteria. It is very important to use these drugs only when the identity and sensitivity of the offending bacterium have been established. Indiscriminate use of these new drugs can lead to the development of more resistant strains for which there is no effective antibiotic (see later discussion of new antibiotics for additional information on *Synercid* and linezolid).

The longer an antibiotic has been in use, the greater is the chance that the bacteria will develop into a resistant strain. Efforts to control the emergence of resistant strains involve intensive educational programs that advocate the use of antibiotics only when necessary and effective and not for the treatment of viral infections such as the common cold (Box 9.3).

BOX 9.3

The Evidence

Using Antibiotics Properly

In 2003, the Food and Drug Administration (FDA) and Centers for Disease Control and Prevention (CDC) joined efforts to educate the public and health care providers about the dangers of inappropriate use of antibiotics. The evidence-based practice guidelines combine data from many studies to outline the most efficacious use of antibiotics. To review some of the studies, review the references listed in the Bibliography and References section. Nurses should include some of the following points about the risks and dangers of antibiotic abuse in the patient education plan:

- Explain clearly that a particular antibiotic is effective against only certain bacteria and that a culture needs to be taken to identify the bacteria.
- Explain that bacteria can develop resistant strains that will not be affected by antibiotics in the future, so use of antibiotics now may make them less effective in situations in which they are really necessary.
- Ensure that patients understand the importance of taking the full course of medication as prescribed, even if they feel better. Stopping an antibiotic midway through a regimen often leads to the development of resistant bacteria. Using all of the medication will also prevent patients'

saving unused medication to self-treat future infections or to share with other family members.

- Tell patients that allergies may develop with repeated exposures to certain antibiotics. In addition, explain to patients that saving antibiotics to take later, when they think they need them again, may lead to earlier development of an allergy, which will negate important tests that could identify the bacteria making them sick.
- Offer other medications, such as antihistamines, decongestants, or even chicken soup, to patients who request antibiotics; this may satisfy their need for something to take. Explaining that viral infections do not respond to antibiotics usually offers little consolation to patients who are suffering from a cold or the flu.

The publicity that many emergent, resistant strains of bacteria have received in recent years may help to get the message across to patients about the need to take the full course of an antibiotic and to use antibiotics only when they are appropriate. To view the educational program developed by the FDA and the CDC for use with patients and the data behind these efforts, go to <http://www.cdc.gov/drugresistance/community/>.

In addition, the use of antibiotics may result in the development of superinfections or overgrowth of resistant pathogens, such as bacteria, fungi, or yeasts, because antibiotics (particularly broad-spectrum agents) destroy bacteria in the flora that normally work to keep these opportunistic invaders in check. When “normal” bacteria are destroyed or greatly reduced in number, there is nothing to prevent the invaders from occupying the host. In most cases the superinfection is an irritating adverse effect (e.g., vaginal yeast infection, candidiasis, diarrhea), but in some cases, the superinfection can be more severe than the infection that was originally being treated. Treatment of the superinfection leads to new adverse effects and the potential for different superinfections. A vicious cycle of treatment and resistance is the result.

KEY POINTS

- ▶ The goal of antibiotic therapy is to reduce the population of invading bacteria to a size that the human immune response can deal with.
- ▶ Bacteria can be classified as gram-positive (frequently found in respiratory infections) or gram-negative (frequently found in GI and GU infections). They can also be classified as anaerobic (not needing oxygen) or aerobic (dependent on oxygen).
- ▶ Culture and sensitivity testing ensures that the correct antibiotic is chosen for each infection, a practice that may help to decrease the number of emerging resistant-strain bacteria.

AMINOGLYCOSIDES

The aminoglycosides (Table 9.1) are a group of powerful antibiotics used to treat serious infections caused by gram-negative aerobic bacilli. Because most of these drugs have potentially serious adverse effects, newer, less toxic drugs have replaced aminoglycosides in the treatment of less serious infections. Aminoglycosides include amikacin (*Amikin*), gentamicin (*Garamycin*), kanamycin (*Kantrex*), neomycin (*Mycifradin*), streptomycin (generic), and tobramycin (*TOBI*, *Tobrex*).

Therapeutic Actions and Indications

The aminoglycosides are bactericidal. They inhibit protein synthesis in susceptible strains of gram-negative bacteria. They irreversibly bind to a unit of the bacteria ribosomes, leading to misreading of the genetic code and cell death (Figure 9.1). These drugs are used to treat serious infections caused by susceptible strains of gram-negative bacteria, including *Pseudomonas aeruginosa*, *E. coli*, *Proteus* species, the *Klebsiella–Enterobacter–Serratia* group, *Citrobacter* species, and *Staphylococcus* species such as *S. aureus*. Aminoglycosides are indicated for the treatment of serious infections that are susceptible to penicillin when penicillin is contraindicated, and they can be used in severe infections before culture and sensitivity tests have been completed. See Table 9.1 for usual indications for each of these drugs.

TABLE 9.1 DRUGS IN FOCUS Aminoglycosides

Drug Name	Dosage/Route	Usual Indications
amikacin (<i>Amikin</i>)	15 mg/kg/d IM or IV divided into two or three equal doses; reduce dose in renal failure	Treatment of serious gram-negative infections
 gentamicin (<i>Garamycin</i>)	Adult: 3 mg/kg/d IM or IV in three equal doses q8h; reduce dose in renal failure Pediatric: 2–2.5 mg/kg/d q8h IV or IM	Treatment of <i>Pseudomonas</i> infections and a wide variety of gram-negative infections
kanamycin (<i>Kantrex</i>)	7.5 mg/kg q12h IM or 15 mg/kg/d IV divided into two to three equal doses given slowly; orally 1 g/h for 4 h followed by 1 g q6h for 36–72 h (bacterial suppression), 8–12 g/h in divided doses (hepatic coma)	Treatment of hepatic coma and to decrease GI normal flora
neomycin (<i>Mycifradin</i>)	Adult: 4–12 g/d in divided doses PO for 5–6 d Pediatric: 50–100 mg/kg/d in divided doses PO for hepatic coma	Suppression of GI normal flora preoperatively; treatment of hepatic coma; topical treatment of skin wounds
streptomycin (generic)	Adult: 1–2 g/d IM in divided doses q6–12h Pediatric: 20–40 mg/kg/d IM in divided doses q6–12h	Fourth drug in combination therapy regimen for treatment of tuberculosis; treatment of severe infections if the organism has been shown to be sensitive to streptomycin and no less-toxic drugs can be used
tobramycin (<i>Nebcin</i> , <i>Tobrex</i>)	Adult: 3 mg/kg/d in three equal doses IM or IV q8h; reduce dose in renal failure; 300 mg b.i.d. by nebulizer Pediatric: 300 mg b.i.d. by nebulizer	Short-term IV or IM treatment of serious infections; ocular infections caused by susceptible bacteria; nebulizer management of cystic fibrosis and <i>Pseudomonas aeruginosa</i> infections

Pharmacokinetics

The aminoglycosides are poorly absorbed from the GI tract but rapidly absorbed after intramuscular (IM) injection, reaching peak levels within 1 hour. These drugs have an average half-life of 2 to 3 hours. They are widely distributed throughout the body, cross the placenta and enter breast milk, and are excreted unchanged in the urine (see contraindications and cautions).

Amikacin is available for short-term IM or intravenous (IV) use.

Gentamicin is available in many forms: ophthalmic, topical, IV, intrathecal, impregnated beads on surgical wire, and liposomal injection.

Kanamycin is available in parenteral and oral forms.

Neomycin is available in topical and oral forms.

Streptomycin is only available for IM use.

Tobramycin is used for short-term IM or IV treatment and is also available in an ophthalmic form and as a nebulizer solution.

Contraindications and Cautions

Aminoglycosides are contraindicated in the following conditions: known allergy to any of the aminoglycosides; renal or hepatic disease *that could be exacerbated by toxic aminoglycoside effects and that could interfere with drug metabolism and excretion, leading to higher toxicity*; preexisting hearing loss, *which could be intensified by toxic drug effects on the auditory nerve*; active infection with herpes or mycobacterial infections *that could be worsened by the effects of an aminoglycoside on normal defense mechanisms*; myasthenia gravis or parkinsonism, *which often are exacerbated by the effects of a particular aminoglycoside on the nervous system*; and lactation, *because aminoglycosides are excreted in breast milk and potentially could cause serious effects in the infant*.

Caution is necessary when these agents are administered during pregnancy *because aminoglycosides are used to treat only severe infections, and the benefits of the drug must be carefully weighed against potential adverse effects on the fetus*. It is necessary to test urine function frequently when these drugs are used *because they depend on the kidney for excretion and are toxic to the kidney*.

The potential for nephrotoxicity and ototoxicity with amikacin is very high, so the drug is used only as long as absolutely necessary. Do not use kanamycin for longer than 7 to 10 days, because of its potential toxic effects, which include renal damage, bone marrow depression, and GI complications. Streptomycin, once a commonly used drug, is reserved for use in special situations *because is very toxic to the eighth cranial nerve and kidney*. It can be used in severe infections if the organism has been shown to be sensitive to streptomycin and no less-toxic drugs can be used.

Adverse Effects

The many serious adverse effects associated with aminoglycosides limit their usefulness. The drugs come with a black

box warning alerting health care professionals to the serious risk of ototoxicity and nephrotoxicity. Central nervous system (CNS) effects include ototoxicity, possibly leading to irreversible deafness; vestibular paralysis resulting from drug effects on the auditory nerve; confusion; depression; disorientation; and numbness, tingling, and weakness related to drug effects on other nerves.

Renal toxicity, which may progress to renal failure, is caused by direct drug toxicity in the glomerulus, meaning that the drug molecules cause damage (e.g., obstruction) directly to the kidney. Bone marrow depression may result from direct drug effects on the rapidly dividing cells in the bone marrow, leading, for example, to immune suppression and resultant superinfections.

GI effects include nausea, vomiting, diarrhea, weight loss, stomatitis, and hepatic toxicity. These effects are a result of direct GI irritation, loss of bacteria of the normal flora with resultant superinfections, and toxic effects in the mucous membranes and liver as the drug is metabolized.

Cardiac effects can include palpitations, hypotension, and hypertension. Hypersensitivity reactions include purpura, rash, urticaria, and exfoliative dermatitis.

Clinically Important Drug–Drug Interactions

Most aminoglycosides have a synergistic bactericidal effect when given with penicillins, cephalosporins, carbenicillin, or ticarcillin. In certain conditions, this synergism is used therapeutically to increase the effectiveness of treatment. Avoid combining aminoglycosides with potent diuretics; this increases the incidence of ototoxicity, nephrotoxicity, and neurotoxicity. If these antibiotics are given with anesthetics, nondepolarizing neuromuscular blockers, succinylcholine, or citrate anticoagulated blood, increased neuromuscular blockade with paralysis is possible. If a patient who has been receiving an aminoglycoside requires surgery, indicate prominently on the patient's chart the fact that the aminoglycoside has been given. Provide extended monitoring and support after surgery.

Prototype Summary: *Gentamicin*

Indications: Treatment of serious infections caused by susceptible bacteria.

Actions: Inhibits protein synthesis in susceptible strains of gram-negative bacteria, disrupting functional integrity of the cell membrane and causing cell death.

Pharmacokinetics:

Route	Onset	Peak
IM, IV	Rapid	30–90 min

$T_{1/2}$: 2 to 3 hours; metabolized in the liver and excreted in the urine.

Adverse effects: Sinusitis, dizziness, rash, fever, risk of nephrotoxicity.

Nursing Considerations for Patients Receiving Aminoglycosides

Assessment: History and Examination

- Assess for *possible contraindications or cautions*: known allergy to any aminoglycoside (obtain specific information about the nature and occurrence of allergic reactions); history of renal or hepatic disease; preexisting hearing loss; active infection with herpes, vaccinia, varicella, or fungal or mycobacterial organisms; myasthenia gravis; parkinsonism; infant botulism; and current pregnancy or lactation status.
- Perform a physical assessment *to establish baseline data for assessing the effectiveness of the drug and the occurrence of any adverse effects associated with drug therapy*.
- Perform culture and sensitivity tests at the site of infection.
- Conduct orientation and reflex assessment, as well as auditory testing, *to evaluate any CNS effects of the drug*.
- Assess vital signs: respiratory rate and adventitious sounds *to monitor for signs of infection or hypersensitivity reactions*; temperature *to assess for signs and symptoms of infection*; blood pressure *to monitor for cardiovascular effects of the drug*.
- Perform renal and hepatic function tests *to determine baseline function of these organs and, possibly, the need to adjust dose*.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to GI or CNS effects of drug
- Disturbed Sensory Perception (Auditory) related to CNS effects of drug
- Risk for Infection related to bone marrow suppression
- Excess Fluid Volume related to nephrotoxicity
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Check culture and sensitivity reports *to ensure that this is the drug of choice for this patient*.
- Ensure that the patient receives a full course of aminoglycoside as prescribed, divided around the clock, *to increase effectiveness and decrease the risk for development of resistant strains of bacteria*.
- Monitor the infection site and presenting signs and symptoms (e.g., fever, lethargy) throughout the course of drug therapy. *Failure of these signs and symptoms to resolve may indicate the need to reculture the site*. Arrange to continue drug therapy for at least 2 days after all signs and symptoms resolve *to decrease the development of resistant strains of bacteria*.
- Monitor patient regularly for signs of nephrotoxicity, neurotoxicity, and bone marrow suppression *to effectively arrange for discontinuation of drug or decreased dose, as appropriate, if any of these toxicities occurs*.

- Provide safety measures *to protect the patient if CNS effects, such as confusion, disorientation, or numbness and tingling, occur*.
- Provide small, frequent meals as tolerated; frequent mouth care; and ice chips or sugarless candy to suck if stomatitis and sore mouth are problems *to relieve discomfort*.
- Provide *adequate fluids to replace fluid lost with diarrhea*.
- Ensure that patient is hydrated at all times during drug therapy *to minimize renal toxicity from drug exposure*.
- Instruct the patient about the appropriate dosage regimen and possible adverse effects *to enhance patient knowledge about drug therapy and to promote compliance*.
- Provide the following patient teaching:
 - Take safety precautions, such as changing position slowly and avoiding driving and hazardous tasks, if CNS effects occur.
 - Try to drink a lot of fluids and to maintain nutrition (very important) even though nausea, vomiting, and diarrhea may occur.
 - Avoid exposure to other infections (e.g., crowded areas, people with known infectious diseases).
 - Report difficulty breathing, severe headache, loss of hearing or ringing in the ears, or changes in urine output.

Evaluation

- Monitor patient response to the drug (resolution of bacterial infection).
- Monitor for adverse effects (orientation and affect, hearing changes, bone marrow suppression, renal toxicity, hepatic dysfunction, GI effects).
- Evaluate effectiveness of the teaching plan (patient can name drug, dosage, possible adverse effects to watch for, and specific measures to help avoid adverse effects).
- Monitor effectiveness of comfort and safety measures and compliance with the therapeutic regimen.

KEY POINTS

- ◆ Aminoglycosides inhibit protein synthesis in susceptible strains of gram-negative bacteria.
- ◆ These drugs are reserved for use in serious infections because of potentially serious adverse effects. Monitor for ototoxicity, renal toxicity, GI disturbances, bone marrow depression, and superinfections.

CARBAPENEMS

The carbapenems (Table 9.2) are a relatively new class of broad-spectrum antibiotics effective against gram-positive and gram-negative bacteria. Meropenem, the first drug of the class, was discussed in Chapter 8 and has limited use because of the severe risk for potentially fatal GI toxicities. Newer

TABLE 9.2 DRUGS IN FOCUS Carbapenems

Drug Name	Dosage/Route	Usual Indications
doripenem (<i>Doribax</i>)	500 mg IV, over 1 h every 8 h for 5–14 d	Treatment of complicated intraabdominal infections or complicated UTIs, including pyelonephritis, caused by susceptible bacteria
 ertapenem (<i>Invanz</i>)	1 g/d IV or IM for 5–14 d	Treatment of community acquired pneumonia, complicated GU infections, acute pelvic infections, complicated intraabdominal infections, skin and skin structure infections
imipenem-cilastin (<i>Primaxin</i>)	250–500 mg IV q6–8h or 500–750 mg IM q12h Pediatric: <1 wk: 25 mg/kg q12h IV 1–4 wk: 25 mg/kg q8h IV 4 wk–3 mo: 25 mg/kg q6h IV ≥3 mo: 15–25 mg/kg q6h IV	Treatment of serious respiratory, intraabdominal, urinary tract, gynecological, bone and joint, skin and skin structure infections; septicemia, endocarditis, bone and joint infections, and polymicrobial infections

carbapenems are not as toxic. Carbapenems discussed here include doripenem (*Doribax*), ertapenem (*Invanz*), and imipenem-cilastin (*Primaxin*).

Therapeutic Actions and Indications

The carbapenems are bactericidal. They inhibit cell membrane synthesis in susceptible bacteria, leading to cell death (Figure 9.2). These drugs are used to treat serious infections caused by susceptible strains of *Streptococcus pneumoniae*, *Haemophilus influenzae*, *Moraxella catarrhalis*, *Staphylococcus aureus*, *Streptococcus pyogenes*, *Escherichia coli*, *Peptostreptococcus*, *Klebsiella pneumoniae*, *Clostridium clostridiiforme*, *Eubacterium lentum*, *Bacteroides fragilis*, *Bacteroides distasonis*, *Bacteroides ovatus*, *Bacteroides thetaiotaomicron*, *Bacteroides uniformis*, *Proteus mirabilis*, *Pseudomonas aeruginosa*, *Acinetobacter baumannii*, *Streptococcus agalactiae*, *Porphyromonas asaccharolytica*, *Prevotella bivia*, and other susceptible bacteria. They are indicated for treating serious intraabdominal, urinary tract, skin and skin structure, bone and joint, and gynecological infections. See Table 9.2 for usual indications for each of these drugs.

Pharmacokinetics

These drugs are rapidly absorbed if given IM and reach peak levels at the end of the infusion if given IV. They are widely distributed throughout the body, although it is not known whether they cross the placenta or enter breast milk (see contraindications and cautions). Carbapenems are excreted unchanged in the urine and have an average half-life of 1 to 4 hours.

Doripenem is the newest drug of the class. It is given IV every 8 hours by a 1-hour IV infusion for 5 to 14 days.

Ertapenem can be given IV or IM. It is given once a day for 5 to 14 days, depending on the infection.

Imipenem-cilastin is a combination of imipenem, which interferes with cell wall synthesis and causes bacterial cell

death, and cilastin, which inactivates the imipenem and leads to increased urinary excretion of the drug and decreased renal toxicity. It can be given IM or IV and is approved for use in children.

Contraindications and Cautions

Carbapenems are contraindicated in the following conditions: known allergy to any of the carbapenems or beta-lactams; seizure disorders, *which could be exacerbated by the drug*; meningitis, *because safety in patients with meningitis has not been established*; lactation, *because it is not known whether these drugs enter breast milk, but potentially they could cause serious effects in the infant*.

Use caution during pregnancy *because carbapenems are used to treat only severe infections, and the benefits of the drug must be carefully weighed against potential adverse effects on the fetus*. Test urine function regularly when these drugs are used *because they depend on the kidney for excretion and are toxic to the kidney*.

Ertapenem is not recommended for use in patients younger than 18 years of age.

Safe Medication Administration

Name confusion has occurred between *Invanz* (ertapenem) and *Avinza* (extended-release morphine). Use extreme caution if your patient is prescribed either of these drugs to avoid possible confusion.

Adverse Effects

Toxic effects on the GI tract can limit the use of carbapenems in some patients. Pseudomembranous colitis, *Clostridium difficile* diarrhea, and nausea and vomiting can lead to serious dehydration and electrolyte imbalances, as well as to new serious infections.

Superinfections can occur with any of the carbapenems. Closely monitor patients to deal with the new infection before it becomes overwhelming.

CNS effects can include headache, dizziness, and altered mental state. Seizures have been reported when carbapenems are combined with other drugs. Monitor patients to provide safety measures if any of these occur.

Clinically Important Drug–Drug Interactions

Consider an alternative antibiotic treatment if a patient is on valproic acid. Combination of these drugs can cause serum valproic acid levels to fall and increase the risk of seizures. Avoid concurrent use of imipenem with ganciclovir because this combination may also cause seizures.

Prototype Summary: Ertapenem

Indications: Treatment of community-acquired pneumonia, complicated GU infections, complicated intraabdominal infections, skin and skin structure infections, and acute pelvic infections caused by susceptible bacteria.

Actions: Inhibits protein synthesis in susceptible strains of gram-negative bacteria, disrupting functional integrity of the cell membrane and causing cell death.

Pharmacokinetics:

Route	Onset	Peak
IM, IV	Rapid	30–120 min

$T_{1/2}$: 4 hours; excreted unchanged in the urine.

Adverse effects: Headache, dizziness, nausea, vomiting, pseudomembranous colitis, rash, pain at injection site.

Nursing Considerations for Patients Receiving Carbapenems

Assessment: History and Examination

- Assess for *possible contraindications or cautions*: known allergy to any carbapenem or beta-lactam (obtain specific information about the nature and occurrence of allergic reactions); history of renal disease; history of seizures and current pregnancy or lactation status.
- Perform physical assessment *to establish baseline data for assessing the effectiveness of the drug and the occurrence of any adverse effects associated with drug therapy*.
- Perform culture and sensitivity tests at the site of infection.
- Conduct orientation and reflex assessment *to evaluate any CNS effects of the drug*.
- Assess vital signs: respiratory rate and adventitious sounds *to monitor for signs of infection or hypersensitivity reactions*; temperature *to assess for signs and symptoms of infection*.
- Perform renal function tests *to determine baseline function of the kidneys and, possibly, the need to adjust dose*.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to GI or CNS effects of the drug
- Risk for Infection related to loss of normal flora
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Check culture and sensitivity reports *to ensure that this is the drug of choice for this patient*.
- Ensure that the patient receives the full course of the carbapenem as prescribed *to increase effectiveness and decrease the risk for the development of resistant strains of bacteria*.
- Monitor the site of infection and presenting signs and symptoms (e.g., fever, lethargy) throughout the course of drug therapy. *Failure of these signs and symptoms to resolve may indicate the need to reculture the site*. Arrange to continue drug therapy for at least 2 days after all signs and symptoms resolve *to decrease the development of resistant strains of bacteria*.
- Monitor the patient regularly for signs of pseudomembranous colitis, severe diarrhea, or superinfections *to effectively arrange for discontinuation of drug or decreased dose, as appropriate, if any of these toxicities occurs*.
- Provide safety measures *to protect the patient if CNS effects, such as confusion, dizziness, or seizures, occur*.
- Provide small, frequent meals as tolerated *to relieve GI discomfort*. Also provide adequate fluids *to replace fluid lost with diarrhea, if appropriate*.
- Ensure that patient is hydrated at all times during drug therapy *to minimize renal toxicity from drug exposure*.
- Instruct the patient about the appropriate dosage regimen and possible adverse effects *to enhance patient knowledge about drug therapy and to promote compliance*.
- Provide the following patient teaching:
 - Take safety precautions, such as changing position slowly and avoiding driving and hazardous tasks, if CNS effects occur.
 - Try to drink a lot of fluids and to maintain nutrition (very important) even though nausea, vomiting, and diarrhea may occur.
 - Report difficulty breathing, severe headache, severe diarrhea, fever, and signs of infection.

Evaluation

- Monitor patient response to the drug (resolution of bacterial infection).
- Monitor for adverse effects (orientation and affect, superinfections, GI toxicity, severe diarrhea effects).
- Evaluate effectiveness of the teaching plan (patient can name drug, dosage, possible adverse effects to watch for, and specific measures to help avoid adverse effects).
- Monitor effectiveness of comfort and safety measures and compliance with the therapeutic regimen.

KEY POINTS

- ▶ Carbapenems are used to treat serious infections caused by a wide range of bacteria.
- ▶ Monitor for GI effects, serious diarrhea, dizziness, and superinfections.

CEPHALOSPORINS

The cephalosporins (Table 9.3) were first introduced in the 1960s. These drugs are similar to the penicillins in structure and in activity. Over time, four generations of cephalosporins have been introduced, each group with its own spectrum of activity.

First-generation cephalosporins are largely effective against the same gram-positive bacteria that are affected by penicillin G, as well as the gram-negative bacteria *Proteus mirabilis*, *E. coli*, and *Klebsiella pneumoniae* (use the letters *PEcK* as a mnemonic device to remember which bacteria are susceptible to the first-generation cephalosporins). First-generation drugs include cefadroxil (*Duricef*), cefazolin (*Ancef*, *Zolicef*), and cephalexin (*Keflex*, *Biocef*).

Second-generation cephalosporins are effective against the previously mentioned strains, as well as *Haemophilus influenzae*, *Enterobacter aerogenes*, and *Neisseria* species (remember *HENPeCK*). Second-generation drugs are less effective against gram-positive bacteria. These include cefaclor (*Ceclor*), cefoxitin (*Mefoxin*), cefprozil (*Cefzil*), and cefuroxime (*Ceftin*, *Zinacef*).

Third-generation cephalosporins, which are effective against all of the previously mentioned strains, are relatively weak against gram-positive bacteria but are more potent against the gram-negative bacilli, as well as against *Serratia marcescens* (remember *HENPeCKS*). Third-generation drugs include cefdinir (*Omnicef*), cefoperazone (*Cefobid*), cefotaxime (*Claforan*), cefpodoxime (*Vantin*), ceftazidime (*Ceptaz*, *Tazicef*), ceftibuten (*Cedax*), ceftizoxime (*Ceftizox*), and ceftriaxone (*Rocephin*).

Fourth-generation cephalosporins are in development. The first drug of this group, cefepime (*Maxipime*), is active against gram-negative and gram-positive organisms, including cephalosporin-resistant staphylococci and *P. aeruginosa*. Fourth-generation drugs also include ceftidoren (*Spectracef*).

Therapeutic Actions and Indications

The cephalosporins are both bactericidal and bacteriostatic, depending on the dose used and the specific drug involved. In susceptible species, these agents basically interfere with the cell wall–building ability of bacteria when they divide; that is, they prevent the bacteria from biosynthesizing the framework of their cell walls. The bacteria with weakened cell walls swell and burst as a result of the osmotic pressure within the cell (see Figure 9.1).

Cephalosporins are indicated for the treatment of infections caused by susceptible bacteria. See Table 9.3 for usual indications for each of these agents. Selection of an antibiotic from

this class depends on the sensitivity of the involved organism, the route of choice, and sometimes the cost involved. It is important to reserve cephalosporins for appropriate situations because cephalosporin-resistant bacteria are appearing in increasing numbers. Before therapy begins, perform a culture and sensitivity test to evaluate the causative organism and appropriate sensitivity to the antibiotic being used.

Pharmacokinetics

The following cephalosporins are well absorbed from the GI tract: the first-generation drugs cefadroxil and cephalexin; the second-generation drugs cefaclor, cefprozil, and cefuroxime; the third-generation drugs cefdinir, cefpodoxime, and ceftibuten; and the fourth-generation drugs ceftidoren and cefepime. The others are absorbed well after IM injection or IV administration. (Box 9.4 provides calculation practice using cefdinir.)

The cephalosporins are primarily metabolized in the liver and excreted in the urine. These drugs cross the placenta and enter breast milk (see contraindications and cautions).

Contraindications and Cautions

Avoid the use of cephalosporins in patients with known allergies to cephalosporins or penicillins *because cross-sensitivity is common*. Use with caution in patients with hepatic or renal impairment *because these drugs are toxic to the kidneys and could interfere with the metabolism and excretion of the drug*. In addition, use with caution in pregnant or lactating patients *because potential effects on the fetus and infant are not known; use only if the benefits clearly outweigh the potential risk of toxicity to the fetus or infant*.

BOX 9.4

Calculations

Your patient is a 20-kg child with a severe case of tonsillitis. An order is written for cefdinir (*Omnicef*) 14 mg/kg/day PO for 10 days. The drug comes in an oral suspension 125 mg/mL. What should you administer at each dose?

The order is for 14 mg/kg, so $14 \text{ mg/kg} \times 20 \text{ kg} = 280 \text{ mg}$. The available form is 125 mg/mL. Use the formula

$$\frac{\text{amount of drug available}}{\text{volume available}} = \frac{\text{amount of drug prescribed}}{\text{volume to administer}}$$

$$\frac{125 \text{ mg}}{1 \text{ mL}} = \frac{280 \text{ mg}}{X}$$

$$125 \text{ mg}/(X) = 280 \text{ mg/mL}$$

$$X = \frac{280 \text{ mg/mL}}{125 \text{ mg}}$$

$$X = 2.24 \text{ mL}$$

TABLE 9.3 DRUGS IN FOCUS Cephalosporins

Drug Name	Dosage/Route	Usual Indications
First-generation Cephalosporins		
cefadroxil (<i>Duricef</i>)	Adult: 1–2 g PO in a single or two divided doses; reduce dose in renal impairment Pediatric: 30 mg/kg/d PO in divided doses q12h	Treatment of UTIs, pharyngitis, and tonsillitis caused by group A beta-hemolytic streptococci, as well as skin infections
cefazolin (<i>Ancef</i> , <i>Zolicef</i>)	Adult: 250–500 mg IM or IV q4–8h; reduce dose in renal impairment Pediatric: 25–50 mg/kg/d IM or IV in three or four divided doses	Treatment of respiratory tract, skin, GU, biliary tract, bone, joint, and myocardial infections, as well as sepsis
cephalexin (<i>Keflex</i> , <i>Biocef</i>)	Adult: 250 mg PO q6h Pediatric: 25–50 mg/kg/d PO in divided doses	Treatment of respiratory, skin, bone, and GU infections; used for otitis media in children
Second-generation Cephalosporins		
 cefaclor (<i>Ceclor</i>)	Adult: 250 mg PO q8h—do not exceed 4 g/d; must be taken every 8–12 h around the clock Pediatric: 20 mg/kg/d PO in divided doses q8h; do not exceed 1 g/d	Treatment of respiratory tract infections, skin infections, UTIs, otitis media, typhoid fever, anthrax exposure
cefoxitin (<i>Mefoxin</i>)	Adult: 1–2 g IM or IV q6–8h; reduce dose with renal impairment Pediatric: 80–160 mg/kg/d IM or IV in divided doses q4–6h	Treatment of severe infections; preoperative prophylaxis for cesarean section and abdominal, vaginal, biliary or colorectal surgery; more effective in gynecological and intraabdominal infections than some other agents
cefprozil (<i>Cefzil</i>)	Adult: 250–500 mg PO q12h for 10 d; reduce dose with renal impairment Pediatric: 7.5–20 mg/kg PO q12h for 10 d; for child 6 mo–2 yr of age, 7.5–15 mg/kg PO q12h for 10 d	Treatment of pharyngitis, tonsillitis, otitis media, sinusitis, secondary bronchial infections, and skin infections
cefuroxime (<i>Ceftin</i> , <i>Zinacef</i>)	Adult: 250 mg PO b.i.d.; 750 mg to 1.5 g IM q8h; reduce dose with renal impairment Pediatric: 125–250 mg PO b.i.d.; 50–100 mg/kg/d IM or IV in divided doses q6–8h	Treatment of a wide range of infections, as listed for other second-generation drugs; Lyme disease; preferred treatment in situations involving an anticipated switch from parenteral to oral drug use
Third-generation Cephalosporins		
cefdinir (<i>Omnicef</i> ; a suspension form is available for children)	Adult: 300 mg PO q12h for 10 d; reduce dose with renal impairment Pediatric: 7 mg/kg PO q12h	Treatment of respiratory infections, otitis media, sinusitis, laryngitis, bronchitis, skin infections
cefoperazone (<i>Cefobid</i>)	Adult: 2–4 g/d IM or IV in divided doses q12h; reduce dose with hepatic impairment Pediatric: safety not established	Treatment of moderate to severe skin, urinary tract, and respiratory tract infections; pelvic inflammatory disease; intraabdominal infections; peritonitis; septicemia
cefotaxime (<i>Claforan</i>)	Adult: 2–8 g/d IM or IV in divided doses q6–8h; reduce dose with renal impairment Pediatric: 50–180 mg/kg/d IM or IV in divided doses q4–6h	Treatment of moderate to severe skin, urinary tract, and respiratory tract infections; pelvic inflammatory disease; intraabdominal infections; peritonitis; septicemia; bone infections; CNS infections; preoperative prophylaxis
cefepodoxime (<i>Vantin</i>)	Adult: 100–400 mg PO q12h; reduce dose with renal impairment Pediatric: 5–10 mg/kg PO q12h for 7–14 d	Treatment of respiratory infections, UTIs, gonorrhea, skin infections, and otitis media

Drug Name	Dosage/Route	Usual Indications
Third-generation Cephalosporins		
ceftazidime (<i>Ceptaz</i> , <i>Tazicef</i>)	Adult: 1 g q8–12h IM or IV; reduce dose with renal impairment Pediatric: 30–50 mg/kg q8–12h IM or IV	Treatment of moderate to severe skin, urinary tract, and respiratory tract infections; intraabdominal infections; septicemia; bone infections; CNS infections
ceftibuten (<i>Cedax</i> ; available in a suspension form for children)	Adult: 400 mg PO every day for 10 d; reduce dose with renal impairment Pediatric: 9 mg/kg/d PO for 10 d <i>Note:</i> Once-a-day dosing increases compliance	Treatment of pharyngitis, tonsillitis, exacerbations of bronchitis, otitis media
ceftizoxime (<i>Cefizox</i>)	Adult: 500 mg to 2 g IM or IV q8–12h; reduce dose with renal impairment Pediatric: 50 mg/kg IM or IV q6–8h	Treatment of respiratory, gynecological, pelvic inflammatory, intraabdominal, skin, and bone and joint infections; also used for sepsis and meningitis
ceftriaxone (<i>Rocephin</i>)	Adult: 1–2 g/d IM or IV in divided doses b.i.d.–q.i.d. Pediatric: 50–75 mg/kg/d IV or IM in divided doses q12h	Treatment of moderate to severe skin, urinary tract, and respiratory tract infections; pelvic inflammatory disease; intraabdominal infections; peritonitis; septicemia; bone infections; CNS infections; preoperative prophylaxis; off-label use for treatment of Lyme disease
Fourth-generation Cephalosporins		
cefditoren (<i>Spectracef</i>)	Adult and pediatric (> 12 yr): 200–400 mg PO b.i.d.; reduce dose with renal impairment	Treatment of acute exacerbations of chronic bronchitis; pharyngitis and tonsillitis; skin and skin structure infections
cefepime (<i>Maxipime</i>)	Adult: 0.5–2 g IM or IV q12h; must be injected for greatest effectiveness q12h for 7–10 d; reduce dose with renal impairment Pediatric: 50 mg/kg per dose q12h IV or IM for 7–10 d	Treatment of moderate to severe skin, urinary tract, and respiratory tract infections

Reserve cephalosporins for appropriate situations because cephalosporin-resistant bacteria are appearing in increasing numbers. Before therapy begins, perform a culture and sensitivity test to evaluate the causative organism and appropriate sensitivity to the antibiotic being used.

Adverse Effects

The most common adverse effects of the cephalosporins involve the GI tract and include nausea, vomiting, diarrhea, anorexia, abdominal pain, and flatulence. Pseudomembranous colitis—a potentially dangerous disorder—has also been reported with some cephalosporins. A particular drug should be discontinued immediately at any sign of violent, bloody diarrhea or abdominal pain.

CNS symptoms include headache, dizziness, lethargy, and paresthesias. Nephrotoxicity is also associated with the use of cephalosporins, most particularly in patients who have a predisposing renal insufficiency. Other adverse effects include superinfections, which occur frequently because of the death of protective bacteria of the normal flora. Monitor patients receiving parenteral cephalosporins for the possibility of

phlebitis with IV administration or local abscess at the site of an IM injection.

Clinically Important Drug–Drug Interactions

Concurrent administration of cephalosporins with aminoglycosides increases the risk for nephrotoxicity. Frequently monitor patients receiving this combination, and evaluate serum blood urea nitrogen (BUN) and creatinine levels.

Patients who receive oral anticoagulants in addition to cephalosporins may experience increased bleeding. Teach these patients how to monitor for blood loss (e.g., bleeding gums, easy bruising) and to be aware that the dose of the oral anticoagulant may need to be reduced.

Instruct the patient receiving cephalosporins to avoid alcohol for up to 72 hours after discontinuation of the drug to prevent a disulfiram-like reaction, which results in unpleasant symptoms such as flushing, throbbing headache, nausea and vomiting, chest pain, palpitations, dyspnea, syncope, vertigo, blurred vision, and, in extreme reactions, cardiovascular collapse, convulsions, or even death.

P Prototype Summary: *Cefaclor*

Indications: Treatment of respiratory, dermatological, urinary tract, and middle ear infections caused by susceptible strains of bacteria.

Actions: Inhibits the synthesis of bacterial cell walls, causing cell death in susceptible bacteria.

Pharmacokinetics:

Route	Peak	Duration
Oral	30–60 min	8–10 h

$T_{1/2}$: 30 to 60 minutes; excreted unchanged in the urine.

Adverse effects: Nausea, vomiting, diarrhea, rash, superinfection, bone marrow depression, risk for pseudomembranous colitis.

Nursing Considerations for Patients Receiving Cephalosporins

Assessment: History and Examination

- Assess for *possible contraindications or cautions*: known allergy to any cephalosporin, penicillin, or any other allergens *because cross-sensitivity often occurs* (obtain specific information about the nature and occurrence of the allergic reactions); history of renal disease, *which could exacerbate nephrotoxicity related to the cephalosporin*; and current pregnancy or lactation status.
- Perform physical assessment *to establish baseline data for assessing the effectiveness of the drug and the occurrence of any adverse effects associated with drug therapy*.
- Examine the skin for any rash or lesions, examine injection sites for abscess formation, and note respiratory status—including rate, depth, and adventitious sounds—*to provide a baseline for determining adverse reactions*.
- Perform culture and sensitivity tests at the site of infection.
- Check renal function test results, including BUN and creatinine clearance, *to assess the status of renal functioning and to detect the possible need to alter dose*.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to GI or CNS effects of drug
- Risk for Infection related to repeated injections
- Deficient Fluid Volume and Imbalanced Nutrition: Less Than Body Requirements, related to diarrhea
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Check culture and sensitivity reports *to ensure that this is the drug of choice for this patient*.

- Monitor renal function test values before and periodically during therapy *to arrange for appropriate dose reduction as needed*.
- Ensure that patient receives the full course of the cephalosporin as prescribed, divided around the clock *to increase effectiveness and to decrease the risk of development of resistant strains*.
- Monitor the infection site and presenting signs and symptoms (e.g., fever, lethargy) throughout the course of drug therapy. *Failure of these signs and symptoms to resolve may indicate the need to reculture the site*. Arrange to continue drug therapy for at least 2 days after the resolution of all signs and symptoms *to help prevent the development of resistant strains of bacteria*.
- Provide small, frequent meals as tolerated, frequent mouth care, and ice chips or sugarless candy to suck if stomatitis and sore mouth are problems *to relieve discomfort and provide nutrition*.
- Provide *adequate fluids to replace fluid lost with diarrhea*.
- Monitor the patient for any signs of superinfection *to arrange for treatment if superinfection occurs*.
- Monitor injection sites regularly *to provide warm compresses and gentle massage to injection sites if they are painful or swollen*. If signs of phlebitis occur, remove the IV line and reinsert in a different vein.
- Initiate safety measures, including adequate lighting, side rails on the bed, and assistance with ambulation *to protect the patient from injury if CNS effects occur*.
- Instruct the patient about the appropriate dosage schedule and about possible side effects *to enhance patient knowledge about drug therapy and to promote compliance*.
- Provide the following patient teaching:
 - Take safety precautions, including changing position slowly and avoiding driving and hazardous tasks, if CNS effects occur.
 - Try to drink a lot of fluids and to maintain nutrition (very important) even though nausea, vomiting, and diarrhea may occur.
 - Report difficulty breathing, severe headache, severe diarrhea, dizziness, or weakness.
 - Avoid consuming alcoholic beverages while receiving cephalosporins and for at least 72 hours after completing the drug course because serious side effects could occur.

Evaluation

- Monitor patient response to the drug (resolution of bacterial infection).
- Monitor for adverse effects (orientation and affect; renal toxicity; hepatic dysfunction; GI effects; and local irritation, including phlebitis at injection and IV sites).
- Evaluate effectiveness of the teaching plan (patient can name drug, dosage, possible adverse effects to expect, and specific measures to help avoid adverse effects).
- Monitor effectiveness of comfort and safety measures and the patient's compliance with the regimen.

KEY POINTS

- ▶ Cephalosporins are a large group of antibiotics, similar to penicillin, that are effective against a wide range of bacteria.
- ▶ Monitor for GI upsets and diarrhea, pseudomembranous colitis, headache, dizziness, and superinfections.

FLUOROQUINOLONES

The fluoroquinolones (Table 9.4) are a relatively new synthetic class of antibiotics with a broad spectrum of activity. Fluoroquinolones include ciprofloxacin (*Cipro*), which is the most widely used fluoroquinolone; gemifloxacin (*Factive*), levofloxacin (*Levaquin*), lomefloxacin (*Maxaquin*), moxifloxacin (*Avelox*), norfloxacin (*Noroxin*), and ofloxacin (*Floxin*, *Ocuflox*).

Therapeutic Actions and Indications

The fluoroquinolones enter the bacterial cell by passive diffusion through channels in the cell membrane. Once inside, they interfere with the action of DNA enzymes necessary for the growth and reproduction of the bacteria (see Figure 9.1). This leads to cell death because the bacterial DNA is damaged and the cell cannot be maintained. The fluoroquinolones have the advantage of a unique way of disrupting bacterial activity. There is little cross-resistance with other forms of antibiotics. However, misuse of these drugs in the short time the class has been available has led to the existence of resistant strains of bacteria (see cautions and contraindications).

The fluoroquinolones are indicated for treating infections caused by susceptible strains of gram-negative bacteria, including *E. coli*, *P. mirabilis*, *K. pneumoniae*, *Enterobacter cloacae*, *Proteus vulgaris*, *Proteus rettgeri*, *Morganella morganii*, *Moraxella catarrhalis*, *H. influenzae*, *H. parainfluenzae*, *P. aeruginosa*, *Citrobacter freundii*, *S. aureus*, *Staphylococcus epidermidis*, some *Neisseria gonorrhoeae*, and group D streptococci. These infections frequently include urinary tract, respiratory tract, and skin infections. Ciprofloxacin is effective against a wide spectrum of gram-negative bacteria. In 2001, it was approved for prevention of anthrax infection in areas that might be exposed to germ warfare. It is also effective against typhoid fever. See Table 9.4 for usual indications for each of these agents.

Pharmacokinetics

The fluoroquinolones are absorbed from the GI tract, metabolized in the liver, and excreted in the urine and feces. These drugs are widely distributed in the body and cross the placenta and enter breast milk (see contraindications and cautions).

Ciprofloxacin is available in injectable, oral, and topical forms. Gemifloxacin, lomefloxacin, and moxifloxacin are oral agents. Levofloxacin is available in oral and IV forms. Because of its parenteral availability, it may be preferred for severe infections or for use when the patient cannot take oral drugs. Norfloxacin is only available in an oral form. Ofloxacin can be given IV or orally and is also available as an ophthalmic agent for the treatment of ocular infections caused by susceptible bacteria.

TABLE 9.4 DRUGS IN FOCUS Fluoroquinolones

Drug Name	Dosage/Route	Usual Indications
 ciprofloxacin (<i>Cipro</i>)	Adult: 100–500 mg b.i.d. PO for up to 6 wk; reduce dose in renal failure Pediatric: not recommended because of potential effects on developing cartilage	Treatment of infections caused by a wide spectrum of gram-negative bacteria
gemifloxacin (<i>Factive</i>)	Adult: 320 mg/d PO for 5–7 d	Treatment of acute exacerbations of chronic bronchitis, community-acquired pneumonia
levofloxacin (<i>Levaquin</i>)	Adult: 250–750 mg/d PO or IV; reduce dose in renal impairment After exposure to anthrax: 500 mg/d PO or IV for 60 d	Treatment of respiratory, urinary tract, skin, and sinus infections caused by susceptible gram-negative bacteria in adults; treatment after exposure to anthrax
lomefloxacin (<i>Maxaquin</i>)	Adult: 400 mg/d PO for 10–14 d; reduce dose with renal impairment	Treatment of lower respiratory tract and urinary tract infections in adults; preoperative and postoperative prophylaxis for transurethral prostate biopsies
moxifloxacin (<i>Avelox</i>)	Adult: 400 mg/d PO or IV for 5–10 d; reduce dose in renal impairment	Treatment of adults with sinusitis, bronchitis, or community-acquired pneumonia
norfloxacin (<i>Noroxin</i>)	Adult: 400 mg PO q12h for up to 28 d; reduce dose in renal impairment	Treatment of various urinary tract infections
ofloxacin (<i>Floxin</i> , <i>Ocuflox</i>)	Adult: 200–400 mg q12h PO for up to 10 d; reduce dose in renal impairment	Treatment of respiratory, skin, and urinary tract infections; pelvic inflammatory disease; ocular infections; otic form available for otitis media

Contraindications and Cautions

Fluoroquinolones are contraindicated in patients with known allergy to any fluoroquinolone and in pregnant or lactating patients *because potential effects on the fetus and infant are not known*. Use with caution in the presence of renal dysfunction, *which could interfere with the metabolism and excretion of the drug*, and seizures, *which could be exacerbated by the drugs' effects on cell membrane channels*.

Because so many resistant strains are emerging, always perform culture and sensitivity tests of infected tissue *to determine the exact bacterial cause and sensitivity*. These drugs have been associated with lesions in developing cartilage and therefore are not recommended for use in children younger than 18 years of age.

Adverse Effects

These drugs are associated with relatively mild adverse reactions. The most common are headache, dizziness, insomnia, and depression related to possible effects on the CNS membranes. GI effects include nausea, vomiting, diarrhea, and dry mouth, related to direct drug effect on the GI tract and possibly to stimulation of the chemoreceptor trigger zone (CTZ) in the CNS.

Immunological effects include bone marrow depression, which may be related to drug effects on the cells of the bone marrow that rapidly turn over. Other adverse effects include fever, rash, and photosensitivity, a potentially serious adverse effect that can cause severe skin reactions. Advise patients to avoid sun and ultraviolet light exposure and to use protective clothing and sunscreens.

Clinically Important Drug–Drug Interactions

When fluoroquinolones are taken concurrently with iron salts, sucralfate, mineral supplements, or antacids, the therapeutic effect of the fluoroquinolone is decreased. If this drug combination is necessary, administration of the two agents should be separated by at least 4 hours.

If fluoroquinolones are taken with drugs that increase the QT_c interval or cause torsades de pointes (quinidine, procainamide, amiodarone, sotalol, erythromycin, terfenadine, pentamidine, tricyclics, phenothiazines), severe-to-fatal cardiac reactions are possible. These combinations should be avoided, but if they must be used, patients should be hospitalized with continual cardiac monitoring.

Combining fluoroquinolones with theophylline leads to increased theophylline levels because the two drugs use similar metabolic pathways. The theophylline dose should be decreased by one-half, and serum theophylline levels monitored carefully. In addition, when fluoroquinolones are combined with nonsteroidal anti-inflammatory drugs (NSAIDs), an increased risk of CNS stimulation is possible. If this combination is used, closely monitor patients, especially those who have a history of seizures or CNS problems.

Prototype Summary: Ciprofloxacin

Indications: Treatment of respiratory, dermatological, urinary tract, ear, eye, bone, and joint infections; treatment after anthrax exposure, typhoid fever.

Actions: Interferes with DNA replication in susceptible gram-negative bacteria, preventing cell reproduction.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	Varies	60–90 min	4–5 h
IV	10 min	30 min	4–5 h

$T_{1/2}$: 3.5 to 4 hours; metabolized in the liver, excreted in bile and urine.

Adverse effects: Headache, dizziness, hypotension, nausea, vomiting, diarrhea, fever, rash.

Nursing Considerations for Patients Receiving Fluoroquinolones

Assessment: History and Examination

- Assess for *possible contraindications or cautions*: known allergy to any fluoroquinolone (obtain specific information about the nature and occurrence of allergic reactions); history of renal disease, *which could interfere with excretion of the drug*; and current pregnancy or lactation status *because of potential adverse effects on the fetus or infant*.
- Perform physical assessment *to establish baseline data for assessing the effectiveness of the drug and the occurrence of any adverse effects associated with drug therapy*.
- Examine the skin for any rash or lesions *to provide a baseline for possible adverse effects*.
- Perform culture and sensitivity tests at the site of infection.
- Conduct assessment of orientation, affect, and reflexes *to establish a baseline for any CNS effects of the drug*.
- Perform renal function tests, including BUN and creatinine clearance, *to evaluate the status of renal functioning and to assess necessary changes in dose*.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to GI, CNS, or skin effects of the drug
- Deficient Fluid Volume and Imbalanced Nutrition: Less Than Body Requirements, related to GI effects of the drug
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Check culture and sensitivity reports *to ensure that this is the drug of choice for this patient*.
- Monitor renal function tests before initiating therapy *to appropriately arrange for dose reduction if necessary*.

- Ensure that the patient receives the full course of the fluoroquinolone as prescribed *to eradicate the infection and to help prevent the emergence of resistant strains.*
- Monitor the site of infection and presenting signs and symptoms (e.g., fever, lethargy, urinary tract signs and symptoms) throughout the course of drug therapy. *Failure of these signs and symptoms to resolve may indicate the need to reculture the site.* Arrange to continue drug therapy for at least 2 days after resolution of all signs and symptoms *to help decrease the development of resistant strains.*
- Provide small, frequent meals as tolerated, frequent mouth care, and ice chips or sugarless candy to suck if dry mouth is a problem *to relieve discomfort and provide nutrition,* and provide *adequate fluids to replace those lost with diarrhea.*
- Implement safety measures, including adequate lighting, use of side rails, and assistance with ambulation *to protect the patient from injury if CNS effects occur.*
- Instruct the patient about the appropriate dosage schedule and possible adverse effects *to enhance patient knowledge about drug therapy and to promote compliance.*
- Provide the following patient teaching:
 - Take safety precautions, including changing position slowly and avoiding driving and hazardous tasks, if CNS effects occur.
 - Try to drink a lot of fluids and to maintain nutrition (very important), although nausea, vomiting, and diarrhea may occur.
 - Avoid ultraviolet light and sun exposure, using protective clothing and sunscreens.
 - Report difficulty breathing, severe headache, severe diarrhea, severe skin rash, fainting spells, and heart palpitations.

Evaluation

- Monitor patient response to the drug (resolution of bacterial infection).
- Monitor for adverse effects (orientation and affect, GI effects, photosensitivity).
- Evaluate effectiveness of the teaching plan (patient can name drug, dosage, possible adverse effects to expect, and specific measures to help avoid adverse effects).
- Monitor effectiveness of comfort and safety measures and compliance with the therapeutic regimen.

KEY POINTS

- ▶ Fluoroquinolones inhibit the action of DNA enzymes in susceptible gram-negative bacteria. They are used to treat a wide range of infections.
- ▶ Monitor the patient for headache, dizziness, GI upsets, and bone marrow depression, and caution the patient about the risk of photosensitivity reactions.

PENICILLINS AND PENICILLINASE-RESISTANT ANTIBIOTICS

Penicillin (Table 9.5) was the first antibiotic introduced for clinical use. Sir Alexander Fleming used *Penicillium* molds to produce the original penicillin in the 1920s. Subsequent versions of penicillin were developed to decrease the adverse effects of the drug and to modify it to act on resistant bacteria. Penicillins include penicillin G benzathine (*Bicillin, Permapen*), penicillin G potassium (*Pfizerpen*), penicillin G procaine (*Crysticillin-AS*), penicillin V (*Veetids*), amoxicillin (*Amoxil, Trimox*), ampicillin (*Principen*), and ticarcillin (*Ticar*).

With the prolonged use of penicillin, more and more bacterial species have synthesized the enzyme penicillinase to counteract the effects of penicillin. Researchers have developed a group of drugs with a resistance to penicillinase, which allows them to remain effective against bacteria that are now resistant to the penicillins. Penicillin-resistant antibiotics include nafcillin and oxacillin. The actual drug chosen depends on the sensitivity of the bacteria causing the infection, the desired and available routes, and the personal experience of the clinician with the particular agent.

Therapeutic Actions and Indications

The penicillins and penicillinase-resistant antibiotics produce bactericidal effects by interfering with the ability of susceptible bacteria to build their cell walls when they are dividing (see Figure 9.2). These drugs prevent the bacteria from biosynthesizing the framework of the cell wall, and the bacteria with weakened cell walls swell and then burst from osmotic pressure within the cell. Because human cells do not use the biochemical process that the bacteria use to form the cell wall, this effect is a selective toxicity.

The penicillins are indicated for the treatment of streptococcal infections, including pharyngitis, tonsillitis, scarlet fever, and endocarditis; pneumococcal infections; staphylococcal infections; fusospirochetal infections; rat-bite fever; diphtheria; anthrax; syphilis; and uncomplicated gonococcal infections. At high doses, these drugs are also used to treat meningococcal meningitis. See Table 9.5 for usual indications for each agent.

Pharmacokinetics

Most of the penicillins are rapidly absorbed from the GI tract, reaching peak levels in 1 hour. They are sensitive to the gastric acid levels in the stomach and should be taken on an empty stomach to ensure adequate absorption. Penicillins are excreted unchanged in the urine, making renal function an important factor in safe use of the drug. Penicillins enter breast milk and can cause adverse reactions (see contraindications and cautions).

Contraindications and Cautions

These drugs are contraindicated in patients with allergies to penicillin or cephalosporins or other allergens. Penicillin

TABLE 9.5 DRUGS IN FOCUS Penicillins and Penicillinase-Resistant Antibiotics

Drug Name	Dosage/Route	Usual Indications
Penicillins		
penicillin G benzathine (<i>Bicillin, Permapen</i>)	Adult: 1.2–2.4 million units IM Pediatric: 900,000 to 1.2 million units IM as a single injection	Severe infections caused by sensitive organisms; treatment of syphilis and erysipeloid infections
penicillin G potassium (<i>Pfizerpen</i>)	Adult: 1–20 million units/d IM or IV, depending on condition Pediatric: 100,000 to 1 million units/d IM or IV	Treatment of severe infections; used for several days in some cases
penicillin G procaine (<i>Crysticillin-AS</i>)	Adult: 600,000 to 1.2 million units/d IM Pediatric: 50,000 units/kg/d IM	Treatment of moderately severe infections daily for 8–12 d
penicillin V (<i>Veetids</i>)	Adult: 250–500 mg q6–8h PO Pediatric: 15–62.5 mg/kg/d PO in divided doses q6–8h	Used for prophylaxis for bacterial endocarditis; Lyme disease, urinary tract infections
Extended-spectrum Penicillins		
 amoxicillin (<i>Amoxil, Trimox</i>)	Adult: 250–500 mg PO q8h Pediatric: 20 mg/kg/d PO in divided doses q8h	Broad spectrum of uses for adults and children
ampicillin (<i>Principen</i>)	Adult: 250–500 mg IM or IV q6h, then 500 mg PO q6h when oral use is feasible Pediatric: 60 mg/kg/d IM or IV in four to six divided doses, then 250 mg PO q6h	Broad spectrum of activity; useful form if switch from parenteral to oral is anticipated; monitor for nephritis
ticarcillin (<i>Ticar</i>)	Adult: 1 g IM or direct IV q6h; reduce dose with renal impairment Pediatric: 50–100 mg/kg/d IM or direct IV q6–8h	Severe infections caused by susceptible bacteria
Penicillin-resistant Antibiotics		
naftacillin	Adult: 500–1000 mg IV q4h, 500 mg IM q6h, or 250–500 mg PO q4–6h Pediatric: 25 mg/kg IM b.i.d. or 25–50 mg/kg/day PO in four divided doses	Infections by penicillinase-producing staphylococci as well as group A hemolytic streptococci, plus <i>Streptococcus viridans</i> ; drug of choice if switch to oral form is anticipated
oxacillin	Adult: 500 mg PO q4–6h or 250–500 mg IM or IV q4–6h Pediatric: 50 mg/kg/d IM, IV, or PO in equally divided doses q4–6h	Infections by penicillinase-producing staphylococci; streptococci; drug of choice if switch to oral form is anticipated

sensitivity tests are available if the patient's history of allergy is unclear and a penicillin is the drug of choice. Use with caution in patients with renal disease (lowered doses are necessary *because excretion is reduced*). Although there are no adequate studies of use during pregnancy, use in patients who are pregnant and in lactating patients should be limited to situations in which the mother clearly would benefit from the drug, *because diarrhea and superinfections may occur in the infant*.

Perform culture and sensitivity tests *to ensure that the causative organism is sensitive to the penicillin selected for use*. With the emergence of many resistant strains of bacteria, this has become increasingly important.

Adverse Effects

The major adverse effects of penicillin therapy involve the GI tract. Common adverse effects include nausea, vomiting,

diarrhea, abdominal pain, glossitis, stomatitis, gastritis, sore mouth, and furry tongue. These effects are primarily related to the loss of bacteria from the normal flora and the subsequent opportunistic infections that occur. Superinfections, including yeast infections, are also very common and are again associated with the loss of bacteria from the normal flora. Pain and inflammation at the injection site can occur with injectable forms of the drugs. Hypersensitivity reactions may include rash, fever, wheezing, and, with repeated exposure, anaphylaxis that can progress to anaphylactic shock and death.

Clinically Important Drug–Drug Interactions

If penicillins and penicillinase-resistant antibiotics are taken concurrently with tetracyclines, a decrease in the effectiveness of the penicillins results. This combination should be avoided if at all possible, or the penicillin doses should

be raised, which could increase the occurrence of adverse effects.

In addition, when the parenteral forms of penicillins and penicillinase-resistant drugs are administered in combination with any of the parenteral aminoglycosides, inactivation of the aminoglycosides occurs. These combinations should also be avoided.

Prototype Summary: Amoxicillin

Indications: Treatment of infections caused by susceptible strains of bacteria, postexposure prophylaxis for anthrax, treatment of *Helicobacter* infections as part of combination therapy.

Actions: Inhibits synthesis of the cell wall in susceptible bacteria, causing cell death.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	Varies	1 h	6–8 h

$T_{1/2}$: 1 to 1.4 hours; excreted unchanged in the urine.

Adverse effects: Nausea, vomiting, diarrhea, glossitis, stomatitis, bone marrow suppression, rash, fever, superinfections, lethargy.

Nursing Considerations for Patients Receiving Penicillins and Penicillinase-Resistant Antibiotics

Assessment: History and Examination

- Assess for *possible contraindications or cautions*: known allergy to any cephalosporins, penicillins, or other allergens *because cross-sensitivity often occurs* (obtain specific information about the nature and occurrence of allergic reactions); history of renal disease *that could interfere with excretion of the drug*; and current pregnancy or lactation status.
- Perform a physical assessment *to establish baseline data for evaluating the effectiveness of the drug and the occurrence of any adverse effects associated with drug therapy*.
- Examine skin and mucous membranes for any rashes or lesions and injection sites for abscess formation *to provide a baseline for possible adverse effects*.
- Perform culture and sensitivity tests at the site of infection *to ensure that this is the drug of choice for this patient*.
- Note respiratory status *to provide a baseline for the occurrence of hypersensitivity reactions*.
- Examine the abdomen *to monitor for adverse effects*. Evaluate renal function test findings, including BUN and creatinine clearance, *to assess the status of renal functioning and to determine any needed alteration in dose*.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to GI effects of drug

- Imbalanced Nutrition: Less Than Body Requirements related to multiple GI effects of the drug or to superinfections
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Check culture and sensitivity reports *to ensure that this is the drug of choice for this patient*.
- Monitor renal function tests before and periodically during therapy *to arrange for dose reduction as needed*.
- Ensure that the patient receives the full course of the penicillin as prescribed, in doses around the clock, *to increase effectiveness*.
- Explain storage requirements for suspensions and the importance of completing the prescribed therapeutic course even if signs and symptoms have disappeared, *to increase the effectiveness of the drug and decrease the risk of developing resistant strains*.
- Monitor the site of infection and presenting signs and symptoms (e.g., fever, lethargy) throughout the course of drug therapy. *Failure of these signs and symptoms to resolve may indicate the need to reculture the site*. Arrange to continue drug therapy for at least 2 days after the resolution of all signs and symptoms *to reduce the risk of development of resistant strains*.
- Provide small, frequent meals as tolerated, ensure frequent mouth care, and offer ice chips or sugarless candy to suck if stomatitis and sore mouth are problems *to relieve discomfort and ensure nutrition*.
- Provide adequate fluids *to replace fluid lost with diarrhea*.
- Monitor the patient for any signs of superinfection *to arrange for treatment if superinfections occur*.
- Monitor injection sites regularly, and *provide warm compresses and gentle massage to injection sites if they are painful or swollen*. If signs of phlebitis occur, remove the IV line and reinsert it in a different vein to continue the drug regimen.
- Instruct the patient regarding the appropriate dosage regimen and possible adverse effects *to enhance the patient's knowledge about drug therapy and promote compliance*.
- Provide the following patient teaching:
 - Try to drink a lot of fluids and to maintain nutrition (very important) even though nausea, vomiting, and diarrhea may occur.
 - Report difficulty breathing, severe headache, severe diarrhea, dizziness, weakness, mouth sores, and vaginal itching or sores to a health care provider. Box 9.5 contains a teaching checklist for penicillins.

Evaluation

- Monitor patient response to the drug (resolution of bacterial infection).
- Monitor for adverse effects (GI effects; local irritation, phlebitis at injection and IV sites; superinfections).
- Evaluate the effectiveness of the teaching plan (patient can name the drug, dosage, possible adverse effects to expect, and specific measures to help avoid adverse effects).
- Monitor the effectiveness of comfort and safety measures and compliance with the regimen

FOCUS ON
BOX 9.5

Patient and Family Teaching

Penicillins

- The penicillins are used to help destroy specific bacteria that are causing infections in the body. They are effective against only certain bacteria; they are not effective against viruses (such as cold germs) or other bacteria. To clear up a bacterial infection, the penicillins must act on the bacteria over a period of time, so it is very important to complete the full course of this penicillin to avoid recurrence of the infection.
- The drug should be taken on an empty stomach with a full 8-oz glass of water—1 hour before meals or 2 to 3 hours after meals is best. Do not use fruit juice, soft drinks, or milk to take your drug, because these foods may interfere with its effectiveness. (This does not apply to bacampicillin, amoxicillin, or penicillin V.)
- Common effects of these drugs include stomach upset, diarrhea, changes in taste, and change in the color of the tongue. Small, frequent meals may help. It is important to try to maintain good nutrition. These effects should go away when the drug is stopped.
- Report any of the following to your health care provider: hives, rash, fever, difficulty breathing, severe diarrhea.
- Tell any doctor, nurse, or other health care provider that you are taking this drug.
- Keep this drug and all medications out of the reach of children and pets.
- Do not share this drug with other people, and do not use this medication to self-treat other infections.
- It is very important that you complete the full course of your prescription, even if you feel better before you finish it.

KEY POINTS

- ▶ The penicillins are one of the oldest classes of antibiotics, and many resistant strains have developed. The penicillinase-resistant antibiotics were created to combat bacteria that produce an enzyme to destroy the penicillin. Penicillins are used to treat a broad spectrum of infections, including respiratory tract infections and UTIs.
- ▶ Monitor the patient on penicillin for nausea, vomiting, diarrhea, superinfections, and the possibility of hypersensitivity reactions.

SULFONAMIDES

The sulfonamides, or sulfa drugs (Table 9.6), are drugs that inhibit folic acid synthesis. Sulfonamides include sulfadiazine (generic), sulfisoxazole (*Gantrisin*), sulfasalazine (*Azulfidine*), and cotrimoxazole (*Septra*, *Bactrim*).

Therapeutic Actions and Indications

Folic acid is necessary for the synthesis of purines and pyrimidines, which are precursors of RNA and DNA. For cells to grow and reproduce, they require folic acid. Humans cannot synthesize folic acid and depend on the folate in their diet to obtain this essential substance. Bacteria are impermeable to folic acid and must synthesize it inside the cell. The sulfonamides competitively block *para*-aminobenzoic acid (PABA) to prevent the synthesis of folic acid in susceptible bacteria that synthesize their own folates for the production of RNA and DNA (see Figure 9.2). This includes gram-negative and gram-positive bacteria such as *Chlamydia trachomatis* and *Nocardia* and some strains of *H. influenzae*, *E. coli*, and *P. mirabilis*.

TABLE 9.6 DRUGS IN FOCUS Sulfonamides

Drug Name	Dosage/Route	Usual Indications
sulfadiazine (generic)	Adult: 2–4 g PO loading dose, then 2–4 g/d PO in four to six divided doses Pediatric: 75 mg/kg PO, then 120–150 mg/kg/d PO in four to six divided doses	Treatment of a broad spectrum of infections
sulfisoxazole (<i>Gantrisin</i>)	Adult: 2–4 g PO loading dose, then 4–8 g/d PO in four to six divided doses Pediatric: 75 mg/kg PO, then 120–150 mg/kg/d PO in four to six divided doses	Treatment of a wide range of infections, including various sexually transmitted diseases
sulfasalazine (<i>Azulfidine</i>)	Adult: 3–4 g/d PO in evenly divided doses, then 500 mg PO q.i.d.; 500 mg PO q.i.d. (arthritis) Pediatric: 40–60 mg/kg/d PO in divided doses, then 20–30 mg/kg/d PO in four equally divided doses	Treatment of ulcerative colitis and Crohn disease; rheumatoid arthritis
 cotrimoxazole (<i>Septra</i> , <i>Bactrim</i>)	Adult: 2 tablets PO q12h; reduce dose with renal impairment Pediatric: 8 mg/kg/d trimethoprim plus 40 mg sulfamethoxazole PO q12h	Treatment of otitis media, bronchitis, urinary tract infections, and pneumonitis caused by <i>Pneumocystis carinii</i>

Because of the emergence of resistant bacterial strains and the development of newer antibiotics, the sulfa drugs are no longer used much. However, they remain an inexpensive and effective treatment for UTIs and trachoma, especially in developing countries and when cost is an issue. These drugs are used to treat trachoma (a leading cause of blindness), nocardiosis (which causes pneumonias, as well as brain abscesses and inflammation), UTIs, and sexually transmitted diseases. Sulfisoxazole has an off-label use of prophylaxis for recurrent otitis media. See Table 9.6 for usual indications for each of these agents.

Pharmacokinetics

The sulfonamides are teratogenic; they are distributed into breast milk (see contraindications and cautions). These drugs, given orally, are absorbed from the GI tract, metabolized in the liver, and excreted in the urine. The time to peak level and the half-life of the individual drug vary.

Sulfadiazine is an oral agent slowly absorbed from the GI tract, reaching peak levels in 3 to 6 hours.

Sulfisoxazole is rapidly absorbed from the GI tract, reaching peak levels in 2 hours. After being metabolized in the liver, it is excreted in the urine with a half-life of 4.5 to 7.8 hours.

Sulfasalazine is a sulfapyridine that is carried by aminosalicic acids (aspirin), which release the aminosalicic acid in the colon. In a delayed-release form, this sulfa drug is also used to treat rheumatoid arthritis that does not respond to other treatments. It is rapidly absorbed from the GI tract, reaching peak levels in 2 to 6 hours. After being metabolized in the liver, it is excreted in the urine with a half-life of 5 to 10 hours.

Cotrimoxazole is a combination drug that contains sulfamethoxazole and trimethoprim, another antibacterial drug. It is rapidly absorbed from the GI tract, reaching peak levels in 2 hours. After being metabolized in the liver, it is excreted in the urine with a half-life of 7 to 12 hours.

Contraindications and Cautions

The sulfonamides are contraindicated with any known allergy to any sulfonamide, to sulfonyleureas, or to thiazide diuretics *because cross-sensitivities occur*; during pregnancy *because the drugs can cause birth defects, as well as kernicterus*; and during lactation *because of a risk of kernicterus, diarrhea, and rash in the infant*. They should be used with caution in patients with renal disease or a history of kidney stones *because of the possibility of increased toxic effects of the drugs*.

Adverse Effects

Adverse effects associated with sulfonamides include GI effects such as nausea, vomiting, diarrhea, abdominal pain, anorexia, stomatitis, and hepatic injury, which are all related to direct irritation of the GI tract and the death of

normal bacteria. Renal effects are related to the filtration of the drug in the glomerulus and include crystalluria, hematuria, and proteinuria, which can progress to a nephrotic syndrome and possible toxic nephrosis. CNS effects include headache, dizziness, vertigo, ataxia, convulsions, and depression (possibly related to drug effects on the nerves). Bone marrow depression may occur and is related to drug effects on the cells that turn over rapidly in the bone marrow.

Dermatological effects include photosensitivity and rash related to direct effects on the dermal cells. A wide range of hypersensitivity reactions may also occur.

Clinically Important Drug–Drug Interactions

If sulfonamides are taken with tolbutamide, tolazamide, glyburide, glipizide, acetohexamide, or chlorpropamide, the risk of hypoglycemia increases. If this combination is needed, the patient should be monitored and a dose adjustment of the antidiabetic agent should be made. An increase in dose will then be needed when sulfonamide therapy stops.

When sulfonamides are taken with cyclosporine, the risk of nephrotoxicity rises. If this combination is essential, the patient should be monitored closely and the sulfonamide stopped at any sign of renal dysfunction.

Prototype Summary: *Cotrimoxazole*

Indications: Treatment of urinary tract infection, acute otitis media in children, exacerbations of chronic bronchitis in adults, traveler's diarrhea in adults, and *Pneumocystis carinii* pneumonia when caused by susceptible strains of bacteria.

Actions: Blocks two consecutive steps in protein and nucleic acid production, leading to inability for cells to multiply.

Pharmacokinetics:

Route	Onset	Peak
Oral	rapid	1–4 hours

$T_{1/2}$: 8 to 10 hours; excreted in the urine.

Adverse effects: Nausea, vomiting, diarrhea, hepatocellular necrosis, hematuria, bone marrow suppression, Stevens–Johnson syndrome, rash, urticaria, photophobia, fever, chills.

Nursing Considerations for Patients Receiving Sulfonamides

Assessment: History and Examination

- Assess for *possible contraindications or cautions*: known allergy to any sulfonamide, sulfonyleureas, or thiazide diuretic *because cross-sensitivity often results* (obtain specific information about the nature and occurrence of allergic reactions); history of renal disease *that could interfere with excretion of the drug and lead to increased toxicity*; and current pregnancy or lactation status.

- Perform a physical assessment *to establish baseline data for assessing the effectiveness of the drug and the occurrence of any adverse effects associated with drug therapy.*
- Examine skin and mucous membranes for any rash or lesions *to provide a baseline for possible adverse effects.*
- Obtain specimens for culture and sensitivity tests at the site of infection *to ensure that this is the appropriate drug for this patient.*
- Note respiratory status *to provide a baseline for the occurrence of hypersensitivity reactions.*
- Conduct assessment of orientation, affect, and reflexes *to monitor for adverse drug effects* and examination of the abdomen *to monitor for adverse effects.*
- Monitor renal function test findings, including BUN and creatinine clearance, *to evaluate the status of renal functioning and to determine any needed alteration in dosage.* Also perform a complete blood count (CBC) *to establish a baseline to monitor for adverse effects.*

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to GI, CNS, or skin effects of the drug
- Disturbed Sensory Perception related to CNS effects
- Imbalanced Nutrition: Less Than Body Requirements related to multiple GI effects of the drug
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Check culture and sensitivity reports *to ensure that this is the drug of choice for this patient and repeat cultures if response is not as anticipated.*
- Monitor renal function tests before and periodically during therapy *to arrange for a dose reduction as necessary.*
- Ensure that the patient receives the full course of the sulfonamide as prescribed *to increase therapeutic effects and decrease the risk for development of resistant strains.*
- Administer oral drug on an empty stomach 1 hour before or 2 hours after meals with a full glass of water *to promote adequate absorption of the drug.*
- Discontinue immediately if hypersensitivity reactions occur *to prevent potentially fatal reactions.*
- Provide small, frequent meals and adequate fluids as tolerated, encourage frequent mouth care, and offer ice chips or sugarless candy to suck if stomatitis and sore mouth are problems *to relieve discomfort, ensure nutrition, and replace fluid lost with diarrhea.*
- Monitor CBC and urinalysis test results before and periodically during therapy *to check for adverse effects.*
- Instruct the patient about the appropriate dosage regimen, the proper way to take the drug (on an empty stomach with a full glass of water), and possible adverse effects, *to enhance patient knowledge about drug therapy and to promote compliance.*

- Provide the following patient teaching:
 - Avoid driving or operating dangerous machinery because dizziness, lethargy, and ataxia may occur.
 - Try to drink a lot of fluids and maintain nutrition (very important), even though nausea, vomiting, and diarrhea may occur.
 - Report difficulty in breathing, rash, ringing in the ears, fever, sore throat, or blood in the urine.

Evaluation

- Monitor patient response to the drug (resolution of bacterial infection).
- Monitor for adverse effects (GI effects, CNS effects, rash, and crystalluria).
- Evaluate the effectiveness of the teaching plan (patient can name the drug, dosage, possible adverse effects to expect, and specific measures to help avoid adverse effects).
- Monitor the effectiveness of comfort and safety measures and compliance with the regimen.

KEY POINTS

- ♦ Sulfonamides are older drugs; many strains have developed resistance to the sulfonamides, so they are no longer widely used.
- ♦ Monitor the patient for CNS toxicity, nausea, vomiting, diarrhea, liver injury, renal toxicity, and bone marrow depression.

TETRACYCLINES

The tetracyclines (Table 9.7) were developed as semisynthetic antibiotics based on the structure of a common soil mold. They are composed of four rings, which is how they got their name. Researchers have developed newer tetracyclines to increase absorption and tissue penetration. Widespread resistance to the tetracyclines has limited their use in recent years. Tetracyclines include tetracycline (*Sumycin, Panmycin*), demeclocycline (*Declomycin*), doxycycline (*Doryx, Periostat*) and minocycline (*Minocin*).

Therapeutic Actions and Indications

The tetracyclines work by inhibiting protein synthesis in a wide range of bacteria, leading to the inability of the bacteria to multiply (see Figure 9.2). Because the affected protein is similar to a protein found in human cells, these drugs can be toxic to humans at high concentrations.

Tetracyclines are indicated for treatment of infections caused by *Rickettsiae*, *M. pneumoniae*, *Borrelia recurrentis*, *H. influenzae*, *Haemophilus ducreyi*, *Pasteurella pestis*, *Pasteurella tularensis*, *Bartonella bacilliformis*, *Bacteroides* species, *Vibrio comma*, *Vibrio fetus*, *Brucella* species, *E. coli*, *E. aerogenes*, *Shigella* species, *Acinetobacter calcoaceticus*, *Klebsiella* species, *Diplococcus pneumoniae*, and *S. aureus*; against agents that cause psittacosis, ornithosis, lymphogran-

TABLE 9.7 DRUGS IN FOCUS Tetracyclines

Drug Name	Dosage/Route	Usual Indications
demeclocycline (<i>Declomycin</i>)	Adult: 150 mg PO q.i.d. or 300 mg PO b.i.d. Pediatric (>8 yr): 6–12 mg/kg /d PO in two to four divided doses	Treatment of a wide variety of infections when penicillin cannot be used
doxycycline (<i>Doryx</i> , <i>Periostat</i>)	Adult: 200 mg/d IV in two infusions of 1–4 h each or 100–300 mg/d PO Pediatric (>8 yr): 4.4 mg/kg/d PO	Treatment of a wide variety of infections, including traveler's diarrhea and sexually transmitted diseases; periodontal disease
minocycline (<i>Minocin</i>)	Adult: 200 mg IV, followed by 100 mg IV q12h, or 200 mg PO, then 100 mg PO q12h Pediatric (>8 yr): 4 mg/kg IV followed by 2 mg/kg IV or PO q12h	Treatment of meningococcal carriers and of various uncomplicated genitourinary and gynecological infections
 tetracycline (<i>Sumycin</i> , <i>Panmycin</i>)	Adult: 1–2 g/d PO in divided doses; topical applied generously to affected area Pediatric (>8 yr): 25–50 mg/kg/d PO in four divided doses	Treatment of a wide variety of infections when penicillin is contraindicated, including acne vulgaris and minor skin infections caused by susceptible organisms; as an ophthalmic agent to treat superficial ocular lesions caused by susceptible microorganisms; as a prophylactic agent for ophthalmia neonatorum caused by <i>Neisseria gonorrhoeae</i> and <i>Chlamydia trachomatis</i>

uloma venereum, and granuloma inguinale; when penicillin is contraindicated in susceptible infections; and for treatment of acne and uncomplicated GU infections caused by *C. trachomatis*. Some of the tetracyclines are also used as adjuncts in the treatment of certain protozoal infections. See Table 9.7 for usual indications for each agent.

Pharmacokinetics

Tetracyclines are absorbed adequately, but not completely, from the GI tract. Their absorption is affected by food, iron, calcium, and other drugs in the stomach. Tetracyclines are concentrated in the liver and excreted unchanged in the urine, with half-lives ranging from 12 to 25 hours. These drugs cross the placenta and pass into breast milk (see contraindications and cautions).

Tetracycline is available in oral and topical forms, in addition to being available as an ophthalmic agent. Demeclocycline is available in oral form. Doxycycline and minocycline are available in IV and oral forms.

Contraindications and Cautions

Tetracyclines are contraindicated in patients with known allergy to tetracyclines or to tartrazine (e.g., in specific oral preparations that contain tartrazine) and during pregnancy and lactation *because of effects on developing bones and teeth*. The ophthalmic preparation is contraindicated in patients who have fungal, mycobacterial, or viral ocular infections *because the drug kills not only the undesired bacteria, but also bacteria of the normal flora, which increases the risk for exacerbation of the ocular infection that is being treated*.

Tetracyclines should be used with caution in children younger than 8 years of age *because they can potentially*

damage developing bones and teeth; and in patients with hepatic or renal dysfunction *because they are concentrated in the bile and excreted in the urine*.

Adverse Effects

The major adverse effects of tetracycline therapy involve direct irritation of the GI tract and include nausea, vomiting, diarrhea, abdominal pain, glossitis, and dysphagia. Fatal hepatotoxicity related to the drug's irritating effect on the liver has also been reported. Skeletal effects involve damage to the teeth and bones. Because tetracyclines have an affinity for teeth and bones, they accumulate there, weakening the structure and causing staining and pitting of teeth and bones. Dermatological effects include photosensitivity and rash. Superinfections, including yeast infections, occur when bacteria of the normal flora are destroyed. Local effects, such as pain and stinging with topical or ocular application, are fairly common. Hematological effects are less frequent, such as hemolytic anemia and bone marrow depression secondary to the effects on bone marrow cells that turn over rapidly. Hypersensitivity reactions reportedly range from urticaria to anaphylaxis and also include intracranial hypertension.

Clinically Important Drug–Drug Interactions

When penicillin G and tetracyclines are taken concurrently, the effectiveness of penicillin G decreases. If this combination is used, the dose of the penicillin should be increased.

When oral contraceptives are taken with tetracyclines, the effectiveness of the contraceptives decreases, and patients who take oral contraceptives should be advised to use an additional form of birth control while receiving the tetracycline. (See Critical Thinking Scenario.)

CRITICAL THINKING SCENARIO

Antibiotics and Oral Contraceptives

THE SITUATION

G.S., a 27-year-old married female graduate student, is seen in the student health clinic a few weeks into the fall semester. She has developed a severe sinusitis and complains of head pressure, difficulty sleeping, fever, and muscle aches and pains. A culture is done, and the next day the culture and sensitivity report identifies the infecting organism as a strain of *Klebsiella* that is sensitive to tetracycline. G.S. returns to the clinic to get the prescription for tetracycline.

In talking with you, G.S. tells you that she began graduate school with plans to start a family in 2 years, after completing her program. She is a very organized person and has carefully planned her rigorous course work and her nonacademic activities so that almost every hour is scheduled. She states that she has successfully used low-dose oral contraceptives for 4 years and plans to continue this method of birth control.

CRITICAL THINKING

How do tetracyclines and some other antibiotics and oral contraceptives interact? What are the possible ramifications of continuing to take oral contraceptives during a pregnancy?

What nursing interventions are appropriate for G.S.?

What teaching points should be stressed with G.S.?

Think about the nature of her personality and the problems that an unplanned pregnancy might cause. How can you help G.S. to cope with her infection, her drug regimen, and her rigorous schedule?

DISCUSSION

Several antibiotics, including tetracycline, are known to lead to the failure of oral contraceptives as evidenced by breakthrough bleeding and unplanned pregnancy. Although the exact way in which these drugs interact is incompletely understood, it is thought that the antibiotics destroy certain bacteria in the normal flora of the gastrointestinal (GI) tract. These bacteria are necessary for the breakdown and eventual absorption of the female hormones contained in the contraceptives. The 5 days of antibiotic treatment together with the time necessary for rebuilding the normal flora can be long enough for the hypothalamus to lose the negative feedback signal provided by the contraceptives that prevents ovulation and preparation of the uterus. Sensing the low hormone levels, the hypothalamus releases gonadotropin-releasing hormone, which leads to the release of follicle-stimulating hormone and luteinizing hormone, with subsequent ovulation.

G.S. will need a clear explanation and follow-up in written form about the risks of oral contraceptive failure while she is receiving tetracycline therapy. She should be encouraged to use an additional form of birth control during the course of her antibiotic use and to read all of the literature that comes with oral contraceptives, as well as patient teaching information that should be provided with the antibiotic.

G.S. also may need a great deal of support and encouragement at this time. The sinus infection may increase her stress by interfering with her ability to stick to her rigid schedule. Discussing the possibility of an unplanned pregnancy may cause even more stress. The health clinic visit could be used as opportunity to allow G.S. to talk, to vent any frustrations and stress, and then to encourage her to make time for herself. The nurse should stress the importance of a good diet, which will ensure that her body has the components she will need to fight this infection and to heal and to ward off other infections, as well as the importance of adequate rest and exercise. The nurse should also make sure that G.S. is receiving annual gynecological exams and has been advised not to smoke.

All health care professionals who are involved with G.S. should consider the impact that an unplanned pregnancy could have on this very organized woman and use this as an example of the importance of clear, concise patient teaching in the administration of drug therapy.

NURSING CARE GUIDE FOR G.S.: TETRACYCLINE

Assessment: History and Examination

Allergy to any tetracycline

Hepatic or renal dysfunction

Pregnancy or lactation

Concurrent use of oral contraceptives, antacids, iron products, digoxin, or penicillins

General: site of infection, culture and sensitivity

Skin: color, lesions

Respiratory: respiration, adventitious sounds

GI: liver evaluation, bowel sounds, usual output

Laboratory data: liver and renal function tests, urinalysis

Nursing Diagnoses

Acute Pain related to GI effects, superinfections

Imbalanced Nutrition: Less Than Body Requirements related to GI effects

Potential for Injury related to central nervous system (CNS) effects

Deficient Knowledge regarding drug therapy

Antibiotics and Oral Contraceptives (continued)**Implementation**

- Perform culture and sensitivity tests before beginning therapy.
- Administer drug on an empty stomach, 1 hour before or 2 to 3 hours after meals. Do not give with antacids, milk, or iron products.
- Do not use outdated drug because of the risk of nephrotoxicity. Monitor for and provide hygiene measures and treatment if superinfections occur.
- Monitor nutritional status and fluid intake.
- Provide ready access to bathroom facilities if diarrhea is a problem.
- Provide support and reassurance for dealing with the drug effects and infection.
- Provide patient teaching regarding drug name, dosage, adverse effects, precautions, warnings to report, and drugs that might cause a drug–drug interaction, including the need to use a second form of contraception if using oral contraceptives.

Evaluation

- Evaluate drug effects: resolution of bacterial infections.
- Monitor for adverse effects: GI effects, superinfections, CNS effects.
- Monitor for drug–drug interactions: lack of effectiveness of oral contraceptives, lack of antibacterial effect with antacids or iron.
- Evaluate effectiveness of patient teaching program.
- Evaluate effectiveness of comfort and safety measures.

Patient Teaching for G.S.

- Tetracycline is an antibiotic that is specific for your infection. You should take it throughout the day for best results.
- Take this drug on an empty stomach, 1 hour before or 2 to 3 hours after meals, with a full glass of water.
- Do not take this drug with food, dairy products, iron preparations, or antacids.
- Take the full course of this antibiotic. Do not stop taking it if you feel better.
- Do not save tetracycline; outdated products can be very toxic to your kidneys.
- Oral contraceptives may become ineffective while you are taking this drug. If you rely on oral contraceptives for birth control, use a second form of contraceptive while on this drug.
- You may experience stomach upset or diarrhea.
- You may develop other infections in your mouth or vagina. (If this occurs, consult with your health care provider for appropriate treatment.)
- Tell any health care provider who is caring for you that you are taking this drug.
- Keep this, and all medications, out of the reach of children and pets.
- Report any of the following to your health care provider: changes in color of urine or stool, severe cramps, difficulty breathing, rash or itching, yellowing of the skin or eyes.

When methoxyflurane is combined with tetracycline, the risk of nephrotoxicity increases. If at all possible, this combination should be avoided. In addition, digoxin toxicity rises when tetracyclines are taken concurrently. Digoxin levels should be monitored and dose adjusted appropriately during treatment and after tetracycline therapy is discontinued. Finally, decreased absorption of tetracyclines results from oral combinations with calcium salts, magnesium salts, zinc salts, aluminum salts, bismuth salts, iron, urinary alkalizers, and charcoal.

Clinically Important Drug–Food Interactions

Because oral tetracyclines are not absorbed effectively if taken with food or dairy products, they should be administered on an empty stomach 1 hour before or 2 to 3 hours after any meal or other medication.

Prototype Summary: Tetracycline

Indications: Treatment of various infections caused by susceptible strains of bacteria; acne; when penicillin is contraindicated for eradication of susceptible organisms.

Actions: Inhibits protein synthesis in susceptible bacteria, preventing cell replication.

Pharmacokinetics:

Route	Onset	Peak
Oral	Varies	2–4 h
Topical	Minimal absorption occurs	

$T_{1/2}$: 6 to 12 hours; excreted unchanged in the urine.

Adverse effects: Nausea, vomiting, diarrhea, glossitis, discoloring and inadequate calcification of primary teeth of fetus when used in pregnant women or of secondary teeth when used in children, bone marrow suppression, photosensitivity, superinfections, rash, local irritation with topical forms.

Nursing Considerations for Patients Receiving Tetracyclines

Assessment: History and Examination

- Assess for *possible contraindications or cautions*: known allergy to any tetracycline or to tartrazine in certain oral preparations *because cross-sensitivity often occurs* (obtain specific information about the nature and occurrence of allergic reactions); any history of renal or hepatic disease *that could interfere with metabolism and excretion of the drug and lead to increased toxicity*; current pregnancy or lactation status *because of the potential for adverse effects to the fetus or infant*; and age *because of the risk of damage to bones and teeth*.
- Perform a physical examination *to establish baseline data for assessing the effectiveness of the drug and the occurrence of any adverse effects associated with drug therapy*.
- Examine the skin for any rash or lesions *to provide a baseline for possible adverse effects*.
- Perform culture and sensitivity tests at the site of infection *to ensure that this is the appropriate drug for this patient*.
- Note respiratory status *to provide a baseline for the occurrence of hypersensitivity reactions*.
- Evaluate renal and liver function test reports, including BUN and creatinine clearance, *to assess the status of renal and liver functioning, which helps to determine any needed changes in dose*.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Diarrhea related to drug effects
- Imbalanced Nutrition: Less Than Body Requirements related to GI effects, alteration in taste, and superinfections
- Impaired Skin Integrity related to rash and photosensitivity
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Check culture and sensitivity reports *to ensure that this is the drug of choice for this patient*. Arrange for repeated cultures if response is not as anticipated.
- Monitor renal and liver function test results before and periodically during therapy *to arrange for a dose reduction as needed*.
- Ensure that the patient receives the full course of the tetracycline as prescribed. The oral drug should be taken on an empty stomach 1 hour before or 2 hours after meals with a full 8-oz glass of water. Concomitant use of antacids or salts should be avoided because they interfere

with drug absorption. *These precautions will increase drug effectiveness and decrease the development of resistant strains of bacteria.*

- Discontinue the drug immediately if hypersensitivity reactions occur *to avoid the possibility of severe reactions*.
- Provide small, frequent meals as tolerated, frequent mouth care, and ice chips or sugarless candy to suck if stomatitis and sore mouth are problems *to relieve discomfort and ensure nutrition*. Also provide adequate fluids *to replace fluid lost with diarrhea*.
- Monitor for signs of superinfections *to arrange for treatment as appropriate*.
- Encourage the patient to apply sunscreen and wear clothing *to protect exposed skin from skin rashes and sunburn associated with photosensitivity reactions*.
- Instruct the patient about the appropriate dosage regimen, how to take the oral drug, and possible side effects *to enhance patient knowledge about drug therapy and to promote compliance*.
- Provide the following patient teaching:
 - Try to drink a lot of fluids and maintain nutrition (very important) even though nausea, vomiting, and diarrhea may occur.
 - Use a barrier contraceptive method because oral contraceptives may not be effective while a tetracycline is being used.
 - Know that superinfections may occur. Appropriate treatment can be arranged through the health care provider.
 - Use sunscreens and protective clothing if sensitivity to the sun occurs.
 - Know when to report dangerous adverse effects, such as difficulty breathing, rash, itching, watery diarrhea, cramps, or changes in color of urine or stool.

Evaluation

- Monitor the patient's response to the drug (resolution of bacterial infection).
- Monitor for adverse effects (GI effects, rash, and superinfections).
- Evaluate the effectiveness of the teaching plan (patient can name the drug, dosage, possible adverse effects to expect, and specific measures to help avoid adverse effects).
- Monitor the effectiveness of comfort and safety measures and compliance with the regimen.

KEY POINTS

- ▶ Tetracyclines inhibit protein synthesis and prevent bacteria from multiplying.
- ▶ Tetracyclines can cause damage to developing teeth and bones and should not be used with pregnant women or children.

- ◆ Monitor the patient for GI effects, bone marrow depression, rash, and superinfections. Caution women that tetracyclines may make oral contraceptives ineffective.

ANTIMYCOBACTERIALS

Mycobacteria—the group of bacteria that contain the pathogens that cause tuberculosis and leprosy—are classified on the basis of their ability to hold a stain even in the presence of a “destaining” agent such as acid. Because of this property, they are called “acid-fast” bacteria. The mycobacteria have an outer coat of mycolic acid that protects them from many disinfectants and allows them to survive for long periods in the environment. It may be necessary to treat these slow-growing bacteria for several years before they can be eradicated.

Mycobacteria cause serious infectious diseases. The bacterium *Mycobacterium tuberculosis* causes tuberculosis, the leading cause of death from infectious disease in the world. For several years the disease was thought to be under control, but with the increasing number of people with compromised immune systems and the emergence of resistant bacterial strains, tuberculosis is once again on the rise.

Mycobacterium leprae causes leprosy, also known as Hansen disease, which is characterized by disfiguring skin lesions and destructive effects on the respiratory tract. Leprosy is also a worldwide health problem; it is infectious when the mycobacteria invade the skin or respiratory tract of susceptible individuals. *Mycobacterium avium-intracellulare*, which causes mycobacterium avium complex (MAC), is seen in patients with AIDS or in other patients who are severely immunocompromised. Rifabutin (*Mycobutin*), which was developed as an antituberculosis drug, is most effective against *M. avium-intracellulare*.

Antituberculosis Drugs

Tuberculosis can lead to serious damage in the lungs, the GU tract, bones, and the meninges. Because *M. tuberculosis* is so slowly growing, the treatment must be continued for 6 months to 2 years. Using the drugs in combination helps to decrease the emergence of resistant strains and to affect the bacteria at various phases during their long and slow life cycle (Table 9.8).

First-line drugs for treating tuberculosis are used in combinations of two or more agents until bacterial conversion occurs or maximum improvement is seen. The first-line drugs for treating tuberculosis are isoniazid (*Nydrasid*), rifampin (*Rifadin*), pyrazinamide (generic), ethambutol (*Myambutol*), streptomycin (generic), and rifapentine (*Priftin*).

If the patient cannot take one or more of the first-line drugs, or if the disease continues to progress because of the emergence of a resistant strain, second-line drugs can be used. The second-line drugs include ethionamide (*Trecator-SC*), capreomycin (*Capastat*), cycloserine (*Seromycin*), and rifabutin (*Mycobutin*).

In addition, drugs from other antibiotic classes have been found to be effective in second-line treatment, such as kanamycin (*Kantrex*), which is an aminoglycoside, and ciprofloxacin (*Cipro*), ofloxacin (*Floxin*), and levofloxacin (*Levaquin*), which are fluoroquinolones.

Leprostatic Drugs

The antibiotic used to treat leprosy is dapsone (generic), which has been the mainstay of leprosy treatment for many years, although resistant strains are emerging (Table 9.8). Similar to the sulfonamides, dapsone inhibits folate synthesis in susceptible bacteria. In addition to its use in leprosy, dapsone is used to treat *Pneumocystis carinii* pneumonia in AIDS patients and for a variety of infections caused by susceptible bacteria, as well as for brown recluse spider bites.

Recently, the hypnotic drug thalidomide (*Thalomid*) was approved for use in a condition that occurs after treatment for leprosy (Box 9.6).

Therapeutic Actions and Indications

Most of the antimycobacterial agents act on the DNA and/or RNA of the bacteria, leading to a lack of growth and eventually to bacterial death (see Figure 9.2). Isoniazid (INH) specifically affects the mycolic acid coat around the bacterium. Although many of the antimycobacterial agents are effective against other species of susceptible bacteria, their primary indications are in the treatment of tuberculosis or

BOX 9.6 New Indication for Thalidomide

In the 1950s, the drug thalidomide became internationally known because it caused serious abnormalities (e.g., lack of limbs, defective limbs) in the fetuses of many women who received the drug during pregnancy to help them sleep and to decrease stress. This tragedy led to the recall of thalidomide in the United States and the establishment of more stringent standards for drug testing and labeling. In 1998, the Food and Drug Administration (FDA) approved the use of this controversial drug for the treatment of erythema nodosum leprosum, which is a painful inflammatory condition related to an immune reaction to dead bacteria that occurs after treatment for leprosy. It is also approved for use in the treatment of multiple myeloma, brain tumors, Crohn disease, human immunodeficiency virus–wasting syndrome, and graft–host reaction in bone marrow transplant.

To take thalidomide, a woman must have a negative pregnancy test, receive instruction in using birth control, and sign a release stating that she understands the risks associated with the drug. These limits on the use of a drug were the first such restrictions ever ordered by the FDA.

Thalidomide (*Thalomid*) is given in doses of 100 to 300 mg/d PO at bedtime for at least 2 weeks, followed by tapered dose in 50-mg increments over the next 2 to 4 weeks.

TABLE 9.8 DRUGS IN FOCUS Antimycobacterials

Drug Name	Dosage/Route	Usual Indications
Antituberculosis Drugs		
First-line drugs		
ethambutol (Myambutol)	Adult: 15 mg/kg/d PO as a single dose Pediatric: not recommended for children <13 yr	Treatment of <i>Mycobacterium tuberculosis</i>
 isoniazid (INH) (Nydrazid)	Adult: 5 mg/kg/d PO Pediatric: 10–12 mg/kg/d PO	Treatment of <i>M. tuberculosis</i>
pyrazinamide (generic)	Adult and pediatric: 15–30 mg/kg/d PO	Treatment of <i>M. tuberculosis</i>
rifampin (<i>Rifadin</i> , <i>Rimactane</i>)	Adult: 600 mg PO or IV as a single daily dose Pediatric: 10–20 mg/kg/d PO or IV	Treatment of <i>M. tuberculosis</i>
rifapentine (<i>Priftin</i>)	Adult: 600 mg PO 2 times per week for 2 mo Pediatric: safety not established	Treatment of <i>M. tuberculosis</i>
streptomycin	15 mg/kg/d IM or 25/30 mg/kg IM given 2–3 times a week Pediatric: 20–40 mg/kg/d IM or 25–30 mg/kg IM given 2–3 times a week	Treatment of <i>M. tuberculosis</i> , tularemia, plague, subacute bacterial endocarditis
Second-line drugs		
capreomycin (<i>Capastat</i>)	Adult: 1 g/d IM for 60–120 d, followed by 1 g IM 2–3 times per week for 18–24 mo; reduce dose with renal impairment Pediatric: 15 mg/kg/d IM	Second-line drug for treatment of <i>M. tuberculosis</i>
cycloserine (<i>Seromycin</i>)	Adult: 250 mg PO b.i.d. for 2 wk, then 500 mg to 1 g/d PO in divided doses Pediatric: safety not established	Second-line treatment of <i>M. tuberculosis</i>
ethionamide (<i>Trecator SC</i>)	Adult: 15–20 mg/kg/d PO in divided doses with pyridoxine Pediatric: 10–20 mg/kg/d PO in divided doses with pyridoxine	Second-line treatment of <i>M. tuberculosis</i>
rifabutin (<i>Mycobutin</i>)	Adult: 300 mg PO daily Pediatric: 10–20 mg/kg/d PO or IV	Second-line treatment of <i>M. tuberculosis</i>
Leprostatic Drug		
 dapsone (generic)	Adult: 50–100 mg/d PO Pediatric: 1 × 2 mg/kg/d PO for 3 yr; do not exceed 100 mg/d	Treatment of leprosy, <i>Pneumocystis carinii</i> pneumonia in AIDS patients, and a variety of infections caused by susceptible bacteria and brown recluse spider bites

leprosy (as previously indicated). The antituberculosis drugs are always used in combination to affect the bacteria at various stages and to help to decrease the emergence of resistant strains. See Table 9.8.

Pharmacokinetics

The antimycobacterial agents are generally well absorbed from the GI tract. These drugs, given orally, are metabolized

in the liver and excreted in the urine; they cross the placenta and enter breast milk, placing the fetus or child at risk for adverse reactions (see contraindications and cautions).

Contraindications and Cautions

Antimycobacterials are contraindicated for patients with any known allergy to these agents; in those with severe renal or hepatic failure, *which could interfere with the metabolism or*

excretion of the drug; in those with severe CNS dysfunction, *which could be exacerbated by the actions of the drug*; and in pregnancy *because of possible adverse effects on the fetus*. If an antituberculosis regimen is necessary during pregnancy, the combination of isoniazid, ethambutol, and rifampin is considered the safest.

Adverse Effects

CNS effects, such as neuritis, dizziness, headache, malaise, drowsiness, and hallucinations, are often reported and are related to direct effects of the drugs on neurons. These drugs also are irritating to the GI tract, causing nausea, vomiting, anorexia, stomach upset, and abdominal pain. Rifampin, rifabutin, and rifapentine cause discoloration of body fluids from urine to sweat and tears. Alert patients that in many instances orange-tinged urine, sweat, and tears may stain clothing and permanently stain contact lenses. This can be frightening if the patient is not alerted to the possibility that it will happen. As with other antibiotics, there is always a possibility of hypersensitivity reactions. Monitor the patient on a regular basis.

Clinically Important Drug–Drug Interactions

When rifampin and INH are used in combination, the possibility of toxic liver reactions increases. Patients should be monitored closely.

Increased metabolism and decreased drug effectiveness occur as a result of administration of quinidine, metoprolol, propranolol, corticosteroids, oral contraceptives, oral anticoagulants, oral antidiabetic agents, digoxin, theophylline, methadone, phenytoin, verapamil, cyclosporine, or ketoconazole in combination with rifampin or rifabutin. Patients who are taking these drug combinations should be monitored closely and dose adjustments made as needed.

Prototype Summary: Isoniazid

Indications: Treatment of tuberculosis as part of combination therapy; prophylactic treatment of household members of recently diagnosed tuberculars.

Actions: Interferes with lipid and nucleic acid synthesis in actively growing tubercle bacilli.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	Varies	1–2 h	24 h

$T_{1/2}$: 1 to 4 hours; metabolized in the liver, excreted in the urine.

Adverse effects: Peripheral neuropathies, nausea, vomiting, hepatitis, bone marrow suppression, fever, local irritation at injection sites, gynecomastia, lupus syndrome.

● Nursing Considerations for Patients Receiving Antimycobacterials

Assessment: History and Examination

- Assess for *possible contraindications or cautions*: known allergy to any antimycobacterial drug (obtain specific information about the nature and occurrence of allergic reactions); history of renal or hepatic disease, *which could interfere with metabolism and excretion of the drug and lead to toxicity*; history of CNS dysfunction, including seizure disorders and neuritis, *which could be exacerbated by adverse drug effects*; and current pregnancy status *to ensure appropriate drug selection to prevent adverse effects on the fetus*.
- Perform a physical examination *to establish baseline data for assessing the effectiveness of the drug and the occurrence of any adverse effects associated with drug therapy*.
- Examine the skin for any rash or lesions *to provide a baseline for possible adverse effects*.
- Obtain specimens for culture and sensitivity testing *to establish the sensitivity of the organism being treated*.
- Evaluate CNS for orientation, affect, and reflexes *to establish a baseline and to monitor for adverse effects*.
- Note respiratory status *to provide a baseline for the occurrence of hypersensitivity reactions*.
- Evaluate renal and liver function tests, including BUN and creatinine clearance, *to assess the status of renal and liver functioning so as to determine any needed alteration in dose*.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Imbalanced Nutrition: Less Than Body Requirements related to GI effects
- Disturbed Sensory Perception (Kinesthetic) related to CNS effects of the drug
- Acute Pain related to GI effects of the drug
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Check culture and sensitivity reports *to ensure that this is the drug of choice for this patient, and arrange repeated cultures if response is not as anticipated*.
- Monitor renal and liver function test results before and periodically during therapy *to arrange for dose reduction as needed*.
- Ensure that the patient receives the full course of the drugs *to improve effectiveness and decrease the risk of development of resistant bacterial strains*. These drugs are taken for years and often in combination. Periodic medical evaluation and retraining are often essential to ensure compliance.
- Discontinue drug immediately if hypersensitivity reactions occur *to avert potentially serious reactions*.
- Encourage the patient to eat small, frequent meals as tolerated, perform frequent mouth care, and drink adequate

fluids to ensure adequate nutrition and hydration. Monitor nutrition if GI effects become a problem.

- Instruct the patient about the appropriate dosage regimen, use of drug combinations, and possible adverse effects to enhance patient knowledge about drug therapy and to promote compliance.
- Provide the following patient teaching:
 - Try to drink a lot of fluids to maintain nutrition (very important) even though nausea, vomiting, and diarrhea may occur.
 - Use barrier contraceptives and understand that oral contraceptives may not be effective if antimycobacterials are being used.
 - Understand that normally some of these drugs impart an orange stain to body fluids. If this occurs, the fluids may stain clothing and tears may stain contact lenses.
 - Report difficulty breathing, hallucinations, numbness and tingling, worsening of condition, fever and chills, or changes in color of urine or stool.

Evaluation

- Monitor patient response to the drug (resolution of mycobacterial infection).
- Monitor for adverse effects (GI effects, CNS changes, and hypersensitivity reactions).
- Evaluate the effectiveness of the teaching plan (patient can name the drug, dosage, possible adverse effects to expect, and specific measures to help avoid adverse effects).
- Monitor the effectiveness of comfort and safety measures and compliance with the regimen.

KEY POINTS

- ▶ The mycobacteria have an outer coat of mycolic acid that protects them from many disinfectants and allows them to survive for long periods in the environment. These slow-growing bacteria may need to be treated for several years before they can be eradicated. They cause tuberculosis and leprosy.
- ▶ Antituberculosis drugs are used in combination to increase effectiveness and decrease the emergence of resistant strains. These drugs are divided into first-line and second-line drugs. Adverse effects include rashes, an orange tint to body fluids, and GI reactions.
- ▶ Dapsone is the only antibiotic now used to treat leprosy. Thalidomide recently was reintroduced to treat an unusual reaction many patients develop after being on dapsone.

OTHER ANTIBIOTICS

There are other antibiotics that do not fit into the large antibiotic classes. These drugs—the ketolides, lincosamides, macrolides, and monobactams—work in unique ways and are effective against specific bacteria (Table 9.9).

Ketolides

The ketolide class of antibiotics was first introduced in 2004. At this time, telithromycin (*Ketek*) is the only approved drug in the class.

Therapeutic Actions and Indications

The ketolides block protein synthesis within susceptible bacteria, leading to cell death, which makes them structurally related to the macrolide antibiotics (see later discussion of macrolides). Telithromycin binds to specific ribosome subunits, leading to cell death in susceptible bacteria, which includes several strains resistant to other antibiotics. Telithromycin is effective against *S. pneumoniae*, including certain multidrug-resistant strains, *H. influenzae*, *M. catarrhalis*, *Chlamydia pneumoniae*, and *Mycoplasma pneumoniae*. It is only approved for use in treating mild to moderate community-acquired pneumonia (see Table 9.9).

Pharmacokinetics

Telithromycin is available as an oral drug only. It is rapidly absorbed through the GI tract, reaching peak levels in 1 hour. The drug is widely distributed, may cross the placenta, and does pass into breast milk. It is metabolized in the liver with a half-life of 10 hours. It is excreted in the urine and feces.

Contraindications and Cautions

Telithromycin is contraindicated with known allergy to any component of the drug or to macrolide antibiotics to avoid hypersensitivity reactions; with known congenital prolonged QT interval, bradycardia, or any proarrhythmic condition such as hypokalemia to avoid potentially serious cardiac effects; with concurrent use of pimozide, cardiac antiarrhythmics, simvastatin, atorvastatin, or lovastatin because of the risk of serious adverse effects if these are combined; and with myasthenia gravis, which is a black box warning with this drug because of the risk of potentially fatal respiratory failure.

Use with caution in cases of renal or hepatic impairment because this could alter the metabolism and excretion of the drug, leading to serious adverse effects. Use with caution with pregnant and lactating patients because of the potential for toxic effects on the fetus or infant.

Perform culture and sensitivity testing to ensure that the drug is used appropriately.

Adverse Effects

The adverse effects associated with telithromycin are largely secondary to toxic effects on the GI tract: nausea, vomiting, taste alterations, and the potential for pseudomembranous colitis. Superinfections are common, related to the loss of normal flora bacteria. Serious hypersensitivity reactions, including anaphylaxis, have occurred.

TABLE 9.9 DRUGS IN FOCUS Other Antibiotics

Drug Name	Dosage/Route	Usual Indications
Ketolide		
 telithromycin (<i>Ketek</i>)	800 mg/d PO for 7–10 d; reduce dose with renal impairment	Treatment of mild to moderate community-acquired pneumonia caused by susceptible bacteria
Lincosamides		
 clindamycin (<i>Cleocin</i>)	Adult: 150–300 mg PO q6h or 600–2700 mg/d in two to four equal doses; reduce dose with renal impairment Pediatric: 8–25 mg/kg/d PO or 15–40 mg/kg /d IM or IV in three to four divided doses	Treatment of severe infections when penicillin or other, less toxic antibiotics cannot be used
lincomycin (<i>Lincocin</i>)	Adult: 500 mg PO q6–8h, 600 mg IM q12–24h, or 600 mg to 1 g q8–12h; reduce dose with renal impairment Pediatric: 30–60 mg/kg/d PO in three to four divided doses, 10 mg/kg IM q12–24h, or 10–20 mg/kg/d IV in divided doses	Treatment of severe infections when penicillin or other less toxic antibiotics cannot be used
Macrolides		
azithromycin (<i>Zithromax</i>)	Adult: 500 mg PO as a single dose on day 1, then 250 mg/d PO to a total dose of 1.5 g or 1–2 g as a single dose Pediatric: 10 mg/kg PO as a single dose on day 1, then 5 mg/kg PO on d 2–5 or 30 mg/k PO as a single dose	Treatment of mild to moderate respiratory infections and urethritis in adults and otitis media and pharyngitis/tonsillitis in children
clarithromycin (<i>Biaxin</i>)	Adult: 250–500 mg q12h PO for 7–14 d; reduce dose with renal impairment Pediatric: 15 mg/kg/d PO given q12h for 10 d	Treatment of various respiratory, skin, sinus, and maxillary infections; effective against mycobacteria
dirithromycin (<i>Dynabac</i>)	Adults and pediatric (>12 yr): 500 mg/d PO for 5–14 d Pediatric (<12 yr): safety not established	Treatment of respiratory tract and skin infections
 erythromycin (<i>Ery-Tab, Eryc</i>)	Adult: 15–20 mg/kg/d IV or PO Pediatric: 30–50 mg/kg/d PO in divided doses	Treatment of infections in patients allergic to penicillin; drug of choice for treatment of Legionnaire's disease, infections caused by <i>Corynebacterium diphtheriae</i> , <i>Ureaplasma</i> species, syphilis, mycoplasma pneumonia, and chlamydial infections
Monobactam		
 aztreonam (<i>Azactam</i>)	Adult: 500 mg to 1 g q8–12h IM or IV; reduce dose in renal and hepatic impairment Pediatric: 30 mg/kg IM or IV q6–8h	Treatment of gram-negative enterobacterial infections; safe alternative for treating infections caused by susceptible bacteria in patients who may be allergic to penicillins or cephalosporins

Clinically Important Drug–Drug Interactions

There is a risk of increased serum levels of telithromycin and potentially serious adverse effects if it is combined with pimozone, simvastatin, lovastatin, or atorvastatin. These combinations should be avoided. There is risk of increased serum levels of digoxin and metoprolol if they are combined with

telithromycin; if this combination is used, the patient should be monitored closely and dose adjustments made.

There is a risk of decreased serum levels of telithromycin and loss of therapeutic effects if it is taken with rifampin, phenytoin, carbamazepine, or phenobarbital; if these drugs are needed, a different antibiotic should be used. Increased GI toxicity associated with theophylline can occur if the two

drugs are used together. Separate the doses by at least 1 hour if both drugs are needed.

Prototype Summary: *Telithromycin*

Indications: Treatment of community-acquired pneumonia caused by susceptible bacteria.

Actions: Binds to bacterial ribosomes, altering protein function and leading to bacterial cell death.

Pharmacokinetics:

Route	Onset	Peak
Oral	Rapid	0.5–4 h

$T_{1/2}$: 10 hours; metabolized in the liver and excreted in the feces and urine.

Adverse effects: Headache, dizziness, nausea, vomiting, pseudomembranous colitis, superinfections.

Lincosamides

The lincosamides (Table 9.9) are similar to the macrolides but are more toxic. These drugs include clindamycin (*Cleocin*) and lincomycin (*Lincocin*).

Therapeutic Actions and Indications

The lincosamides react at almost the same site in bacterial protein synthesis and are effective against the same strains of bacteria (Figure 9.2). These drugs are used in the treatment of severe infections when a less toxic antibiotic cannot be used.

Pharmacokinetics

The lincosamides are rapidly absorbed from the GI tract or from IM injections and are metabolized in the liver and excreted in the urine and feces. These drugs cross the placenta and enter breast milk (see contraindications and cautions).

Clindamycin has a half-life of 2 to 3 hours. It is available in parenteral and oral forms, as well as in topical and vaginal forms for the treatment of local infections.

Lincomycin has a half-life of 5 hours. It can be given orally, IM, or IV.

Contraindications and Cautions

Use lincosamides with caution in patients with hepatic or renal impairment, which could interfere with the metabolism and excretion of the drug. Use during pregnancy and lactation only if the benefit clearly outweighs the risk to the fetus or neonate.

Adverse Effects

Severe GI reactions, including fatal pseudomembranous colitis, have occurred, limiting the usefulness of lincosamides. However, for a serious infection caused by a susceptible

bacterium, a lincosamide may be the drug of choice. Some other toxic effects that limit usefulness are pain, skin infections, and bone marrow depression.

Prototype Summary: *Clindamycin*

Indications: Treatment of serious infections caused by susceptible strains of bacteria, including some anaerobes; useful in septicemia and chronic bone and joint infections.

Actions: Inhibits protein synthesis in susceptible bacteria, causing cell death.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	Varies	1–2 h	8–12 h
IM	20–30 min	1–3 h	8–12 h
IV	Immediate	Minutes	8–12 h
Topical	Minimal absorption		

$T_{1/2}$: 2 to 3 hours; metabolized in the liver, excreted in the urine and feces.

Adverse effects: Nausea, vomiting, diarrhea, pseudomembranous colitis, bone marrow suppression, hypotension, cardiac arrest with rapid IV infusion, rash, pain on injection, abscess at injection site.

Macrolides

The macrolides (Table 9.9) are antibiotics that interfere with protein synthesis in susceptible bacteria. Macrolides include erythromycin (*Ery-Tab*, *Eryc*, and others), azithromycin (*Zithromax*), clarithromycin (*Biaxin*), and dirithromycin (*Dynabac*).

Therapeutic Actions and Indications

The macrolides, which may be bactericidal or bacteriostatic, exert their effect by binding to the bacterial cell membrane and changing protein function (see Figure 9.1). This action can prevent the cell from dividing or cause cell death, depending on the sensitivity of the bacteria and the concentration of the drug.

Macrolides are indicated for treatment of the following conditions: acute infections caused by susceptible strains of *S. pneumoniae*, *M. pneumoniae*, *Listeria monocytogenes*, and *Legionella pneumophila*; infections caused by group A beta-hemolytic streptococci; pelvic inflammatory disease caused by *N. gonorrhoeae*; upper respiratory tract infections caused by *H. influenzae* (with sulfonamides); infections caused by *Corynebacterium diphtheriae* and *Corynebacterium minutissimum* (with antitoxin); intestinal amebiasis; and infections caused by *C. trachomatis*. See Table 9.9 for usual indications for each of these agents.

In addition, macrolides may be used as prophylaxis for endocarditis before dental procedures in patients with valvular heart disease who are allergic to penicillin. Topical macrolides are indicated for the treatment of ocular infections caused by

susceptible organisms and for acne vulgaris, and they may also be used prophylactically against infection in minor skin abrasions and for the treatment of skin infections caused by sensitive organisms.

Pharmacokinetics

The macrolides are widely distributed throughout the body; they cross the placenta and enter the breast milk (see contraindications and cautions). These drugs are absorbed in the GI tract.

Erythromycin is metabolized in the liver, with excretion mainly in the bile to feces. The half-life of erythromycin is 1.6 hours.

Azithromycin and clarithromycin are mainly excreted unchanged in the urine, making it necessary to monitor renal function when patients are taking these drugs. The half-life of azithromycin is 68 hours, making it useful for patients who have trouble remembering to take pills because it can be given once a day. The half-life of clarithromycin is 3 to 7 hours.

Dirithromycin is converted from the prodrug dirithromycin to erythromycylamine in the intestinal wall. Most of the drug is excreted through the feces. It has a half-life of 2 to 36 hours. It also has the advantage of once-a-day dosing, which increases compliance in many cases.

Contraindications and Cautions

Macrolides are contraindicated in patients with a known allergy to any macrolide *because cross-sensitivity occurs*. Ocular preparations are contraindicated for viral, fungal, or mycobacterial infections of the eye, *which could be exacerbated by loss of bacteria of the normal flora*. Use with caution in patients with hepatic dysfunction, *which could alter the metabolism of the drug*, and in those with renal disease, *which could interfere with the excretion of some of the drug*. Also use with caution in lactating women *because macrolides secreted in breast milk can cause diarrhea and superinfections in the infant* and in pregnant women *because of potential adverse effects on the developing fetus*; use only if the benefit clearly outweighs the risk to the fetus or the infant.

Adverse Effects

Relatively few adverse effects are associated with the macrolides. The most frequent ones, which involve the direct effects of the drug on the GI tract, are often uncomfortable enough to limit the use of the drug. These include abdominal cramping, anorexia, diarrhea, vomiting, and pseudomembranous colitis. Other effects include neurological symptoms such as confusion, abnormal thinking, and uncontrollable emotions, which could be related to drug effects on the CNS membranes; hypersensitivity reactions ranging from rash to anaphylaxis; and superinfections related to the loss of normal flora.

Clinically Important Drug–Drug Interactions

Increased serum levels of digoxin occur when digoxin is taken concurrently with macrolides. Patients who receive both drugs should have their digoxin levels monitored and dose adjusted during and after treatment with the macrolide.

In addition, when oral anticoagulants, theophyllines, carbamazepine, or corticosteroids are administered concurrently with macrolides, the effects of these drugs reportedly increase as a result of metabolic changes in the liver. Patients who take any of these combinations may require reduced dose of the particular drug and careful monitoring.

When cycloserine is taken with macrolides, increased serum levels of cycloserine have occurred, with a resultant risk of renal toxicity. This combination should be avoided if at all possible.

Clinically Important Drug–Food Interactions

Food in the stomach decreases absorption of oral macrolides. Therefore, the antibiotic should be taken on an empty stomach with a full, 8-oz glass of water 1 hour before or at least 2 to 3 hours after meals.

Prototype Summary: Erythromycin

Indications: Treatment of respiratory, dermatological, urinary tract, and GI infections caused by susceptible strains of bacteria.

Actions: Binds to cell membranes, causing a change in protein function and cell death; can be bacteriostatic or bactericidal.

Pharmacokinetics:

Route	Onset	Peak
Oral	1–2 h	1–4 h
IV	Rapid	1 h

$T_{1/2}$: 3 to 5 hours; metabolized in the liver, excreted in bile and urine.

Adverse effects: Abdominal cramping, vomiting, diarrhea, rash, superinfection, liver toxicity, risk for pseudomembranous colitis, potential for hearing loss.

Monobactam Antibiotic

The only monobactam antibiotic currently available for use is aztreonam (*Azactam*) (Table 9.9).

Therapeutic Actions and Indications

Among the antibiotics, aztreonam's structure is unique, and little cross-resistance occurs. It is effective against gram-negative enterobacteria and has no effect on gram-positive or anaerobic bacteria. Aztreonam disrupts bacterial cell wall synthesis, which promotes leakage of cellular contents and cell death in susceptible bacteria (see Figure 9.2). The drug is indicated for the treatment of urinary tract, skin, intraabdominal,

and gynecological infections, as well as septicemia caused by susceptible bacteria, including *E. coli*, *Enterobacter*, *Serratia*, *Proteus*, *Salmonella*, *Providencia*, *Pseudomonas*, *Citrobacter*, *Haemophilus*, *Neisseria*, and *Klebsiella*.

Pharmacokinetics

Aztreonam is available for IV and IM use only and reaches peak effect levels in 1 to 1.5 hours. Its half-life is 1.5 to 2 hours. The drug is excreted unchanged in the urine. It crosses the placenta and enters breast milk (see contraindications and cautions).

Contraindications and Cautions

Aztreonam is contraindicated with any known allergy to aztreonam. Use with caution in patients with a history of acute allergic reaction to penicillins or cephalosporins *because of the possibility of cross-reactivity*; in those with renal or hepatic dysfunction *that could interfere with the clearance and excretion of the drug*; and in pregnant and lactating women *because of potential adverse effects on the fetus or neonate*.

Adverse Effects

The adverse effects associated with the use of aztreonam are relatively mild. Local GI effects include nausea, GI upset, vomiting, and diarrhea. Hepatic enzyme elevations related to direct drug effects on the liver may also occur. Other effects include inflammation, phlebitis, and discomfort at injection sites, as well as the potential for allergic response, including anaphylaxis.

Clinically Important Drug–Drug Interactions

Aztreonam is incompatible in solution with nafcillin, cephadrine, and metronidazole.

Prototype Summary: Aztreonam

Indications: Treatment of lower respiratory, dermatological, urinary tract, intra-abdominal, and gynecological infections caused by susceptible strains of gram-negative bacteria.

Actions: Interferes with bacterial cell wall synthesis, causing cell death in susceptible gram-negative bacteria; is not effective against gram-positive or anaerobic bacteria.

Pharmacokinetics:

Route	Onset	Peak	Duration
IM	Varies	60–90 min	6–8 h
IV	Immediate	30 min	6–8 h

$T_{1/2}$: 1.5 to 2 hours; excreted unchanged in the urine.

Adverse effects: Nausea, vomiting, diarrhea, rash, superinfection, anaphylaxis, local discomfort at injection sites.

Nursing Considerations for Patients Receiving Other Antibiotics

Assessment: History and Examination

- Assess for *possible contraindications or precautions*: known allergy to ketolides, lincosamides, macrolides and monobactams (obtain specific information about the nature and occurrence of allergic reactions); history of liver disease *that could interfere with metabolism of the drug*; and current pregnancy or lactation status *because of potential adverse effects on the fetus or infant*.
- Perform a physical assessment *to establish baseline data for assessing the effectiveness of the drug and the occurrence of any adverse effects associated with drug therapy*.
- Examine the skin for any rash or lesions *to provide a baseline for possible adverse effects*.
- Obtain specimens for culture and sensitivity testing from the site of infection.
- Monitor temperature *to detect infection*.
- Conduct assessment of orientation, affect, and reflexes *to establish a baseline for any CNS effects of the drug*.
- Assess liver and renal function test values *to determine the status of renal and liver functioning and to determine any needed alteration in dosage*.
- Obtain baseline electrocardiogram *to rule out conditions that could put the patient at risk for serious arrhythmias*.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to GI or CNS effects of the drug
- Risk for Infection related to potential for superinfections
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Check culture and sensitivity reports *to ensure that this is the drug of choice for this patient*.
- Monitor hepatic and renal function test values before therapy begins *to arrange to reduce dose as needed*.
- Ensure that the patient receives the full course of the medication as prescribed *to eradicate the infection and to help prevent the emergence of resistant strains*.
- Ensure that the patient swallows the tablet whole; it should not be cut, crushed or chewed, *to ensure therapeutic dose of the drug*.
- Monitor the site of infection and presenting signs and symptoms (e.g., fever, lethargy, urinary tract signs and symptoms) throughout the course of drug therapy. *Failure of these signs and symptoms to resolve may indicate the need to reculture the site*. Arrange to continue drug therapy for at least 2 days after all signs and symptoms resolve, *to help prevent the development of resistant strains*.
- Provide small, frequent meals as tolerated *to ensure adequate nutrition with GI upset*; frequent mouth care and ice

chips or sugarless candy to suck to provide relief of discomfort if dry mouth is a problem; and adequate fluids to replace fluid lost with diarrhea.

- Ensure ready access to bathroom facilities to assist patients with problems associated with diarrhea.
- Institute safety measures to protect patient from injury if CNS effects occur.
- Arrange for appropriate treatment of superinfections as needed to decrease the severity of infection and complications.
- Instruct the patient about the appropriate dosage regimen and possible adverse effects to enhance patient knowledge about drug therapy and to promote compliance. For the monobactam agent aztreonam: This drug can be given only IV or IM, so the patient will not be responsible for administering the drug.
- For lincosamides, take additional precautions that include careful monitoring of GI activity and fluid balance and stopping the drug at the first sign of severe or bloody diarrhea.
- Provide the following patient teaching:
 - Take safety precautions, including changing position slowly and avoiding driving and hazardous tasks, if CNS effects occur.
 - Try to drink a lot of fluids and to maintain nutrition (very important) even though nausea, vomiting, and diarrhea may occur.
 - Report difficulty breathing, severe headache, severe diarrhea, severe skin rash, and mouth or vaginal sores.

Evaluation

- Monitor patient response to the drug (resolution of bacterial infection).
- Monitor for adverse effects (orientation and affect, GI effects, superinfections).
- Evaluate the effectiveness of the teaching plan (patient can name the drug, dosage, possible adverse effects to expect, and specific measures to help avoid adverse effects).
- Monitor the effectiveness of comfort and safety measures and compliance with the regimen.

KEY POINTS

- ▶ Ketolides block protein synthesis in susceptible bacteria, leading to cell death. Telithromycin is the only ketolide currently available. It is used to treat community-acquired pneumonia. Monitor the patient for nausea, vomiting, diarrhea, and CNS effects, including dizziness and headache.
- ▶ Lincosamides are similar to macrolides but are more toxic. They are used to treat severe infections. Monitor the patient for pseudomembranous colitis, bone marrow depression, pain, and CNS effects.

- ▶ Macrolides are in a class of older antibiotics that can be bactericidal or bacteriostatic. They are used to treat URIs and UTIs, and are often used when patients are allergic to penicillin. Monitor the patient for nausea, vomiting, diarrhea, dizziness, and other CNS effects.
- ▶ The monobactam antibiotic aztreonam is effective against only gram-negative enterobacteria; it is safely used when patients are allergic to penicillin or cephalosporins. Monitor the patient taking aztreonam for GI problems, liver toxicity, and pain at the injection site.

NEW CLASSES OF ANTIBIOTICS AND ADJUNCTS

Research is constantly being done to develop new antibiotics to affect the emerging resistant strains of bacteria. New classes of antibiotics are daptomycin (*Cubicin*), linezolid (*Zyvox*), tigecycline (*Tygacil*), and quinupristin and dalfopristin (available only in a combination form called *Synercid*). See the following for additional information about each of these agents.

Adjuncts to antibiotic therapy include clavulanic acid and sulbactam (see Box 9.2) and thalidomide (see Box 9.6).

- Daptomycin was introduced in the fall of 2003 as a cyclic lipopeptide antibiotic. This class of drugs binds to bacterial cell membranes, causing a rapid depolarization of membrane potential. The loss of membrane potential leads to the inhibition of protein and DNA and RNA synthesis, which results in bacterial cell death. Daptomycin is approved for treating complicated skin and skin structure infections caused by susceptible gram-positive bacteria, including methicillin-resistant strains of *S. aureus*. It must be given IV over 30 minutes, once each day for 7 to 14 days, which makes its use inconvenient. Patients should be monitored for pseudomembranous colitis and myopathies.
- Linezolid (*Zyvox*) was introduced in 2000. This drug is indicated specifically for treatment of infections caused by vancomycin-resistant and methicillin-resistant strains of bacteria. It is available in intravenous and oral forms. The usual adult dosage is 600 mg PO, or it may be administered IV q12h for 10 to 14 days. This drug must also be used cautiously and only when a sensitive bacterial species has been clearly identified. It is the first oral drug approved for the treatment of diabetic foot ulcers. These drugs are part of a wide variety of compounds that are being investigated to deal with the increasing problem of resistant bacteria.
- Tigecycline, approved by the Food and Drug Administration in 2005, was the first drug of a new class of antibiotics called glycylcyclines. This antibiotic inhibits protein translation on ribosomes of certain bacteria, leading to their inability to maintain their integrity and culminating in the death of the bacterium. It is approved for use in the treatment of complicated skin and skin structure

infections and intraabdominal infections caused by susceptible bacteria. Caution should be used with a known allergy to tetracycline antibiotics because a cross-sensitivity may occur. Women should be advised to use a barrier form of contraceptive when on this drug. Patients should be monitored for pseudomembranous colitis, rash, and superinfections. *Tygacil* is given as 100 mg IV followed by 50 mg IV every 12 hours, infused over 30 to 60 minutes for 5 to 14 days.

- Streptogramins became available in 1999 and include quinupristin and dalfopristin, which are available only in a combination form called *Synercid*. Together, they work synergistically and have been effective in treating vancomycin-resistant enterococci (VRE), resistant *S. aureus*, and resistant *Staphylococcus epidermidis*. The drug is approved for VRE and methicillin-sensitive *S. aureus* (MSSA) infections. The drug also seems to be active against penicillin-resistant pneumococcus. The usual dosage of this drug for patients 16 years old and older is 7.5 mg/kg IV every 12 hours for 7 days. The drug should not be used unless the bacterium is clearly identified as being resistant to other antibiotics and sensitive to this one. Indiscriminate use of this new drug can lead to the development of even more invasive and resistant bacteria.

CHAPTER SUMMARY

- Antibiotics work by disrupting protein or enzyme systems within a bacterium, causing cell death (bactericidal) or preventing multiplication (bacteriostatic).
- The proteins or enzyme systems affected by antibiotics are more likely to be found or used in bacteria than in human cells.
- The primary therapeutic use of each antibiotic is determined by the bacterial species that are sensitive to that drug, the clinical condition of the patient receiving the drug, and the benefit-to-risk ratio for the patient.

- The longer an antibiotic has been available, the more likely it is that mutant bacterial strains resistant to the mechanisms of antibiotic activity will have developed.
- The most common adverse effects of antibiotic therapy involve the GI tract (nausea, vomiting, diarrhea, anorexia, abdominal pain) and superinfections (invasion of the body by normally occurring microorganisms that are usually kept in check by the normal flora).
- To prevent or contain the growing threat of drug-resistant strains of bacteria, it is very important to use antibiotics cautiously, to complete the full course of an antibiotic prescription, and to avoid saving antibiotics for self-medication in the future. A patient and family teaching program should address these issues, as well as the proper dosing procedure for the drug (even if the patient feels better) and the importance of keeping a record of any reactions to antibiotics.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-Rom in the front of this book.

MULTIPLE CHOICE

Select the best answer to the following.

1. A bacteriostatic substance is one that
 - a. directly kills any bacteria it comes in contact with.
 - b. directly kills any bacteria that are sensitive to the substance.
 - c. prevents the growth of any bacteria.
 - d. prevents the growth of specific bacteria that are sensitive to the substance.
2. Gram-negative bacteria
 - a. are mostly found in the respiratory tract.
 - b. are mostly associated with soft tissue infections.
 - c. are mostly found in the GI and GU tracts.
 - d. accept a positive stain when tested.

3. Antibiotics that are used together to increase their effectiveness and limit the associated adverse effects are said to be
 - a. broad spectrum.
 - b. synergistic.
 - c. bactericidal.
 - d. anaerobic.
4. An aminoglycoside antibiotic might be the drug of choice in treating
 - a. serious infections caused by susceptible strains of gram-negative bacteria.
 - b. otitis media in an infant.
 - c. cystitis in a woman who is 4 months pregnant.
 - d. suspected pneumonia before the culture results are available.
5. Which of the following is not a caution for the use of cephalosporins?
 - a. Allergy to penicillin
 - b. Renal failure
 - c. Allergy to aspirin
 - d. Concurrent treatment with aminoglycosides
6. The fluoroquinolones
 - a. are found freely in nature.
 - b. are associated with severe adverse reactions.
 - c. are widely used to treat gram-positive infections.
 - d. are broad-spectrum antibiotics with few associated adverse effects.
7. Cipro, a widely used antibiotic, is an example of
 - a. a penicillin.
 - b. a fluoroquinolone.
 - c. an aminoglycoside.
 - d. a macrolide antibiotic.
8. A patient receiving a fluoroquinolone should be cautioned to anticipate
 - a. increased salivation.
 - b. constipation.
 - c. photosensitivity.
 - d. cough.
9. The goal of antibiotic therapy is
 - a. to eradicate all bacteria from the system.
 - b. to suppress resistant strains of bacteria.
 - c. to reduce the number of invading bacteria so that the immune system can deal with the infection.
 - d. to stop the drug as soon as the patient feels better.
10. The penicillins
 - a. are bacteriostatic.
 - b. are bactericidal, interfering with bacteria cell walls.
 - c. are effective only if given intravenously.
 - d. do not produce cross-sensitivity within their class.

MULTIPLE RESPONSE

Select all that apply.

1. A young woman is found to have a soft tissue infection that is most responsive to tetracycline. Your teaching plan for this woman should include which of the following points?
 - a. Tetracycline can cause gray baby syndrome.
 - b. Do not use this drug if you are pregnant because it can cause tooth and bone defects in the fetus.
 - c. Tetracycline can cause severe acne.
 - d. You should use a second form of contraception if you are using oral contraceptives because tetracycline can make them ineffective.
 - e. This drug should be taken in the middle of a meal to decrease GI upset.
 - f. You may experience a vaginal yeast infection as a result of this drug therapy.
2. In general, all patients receiving antibiotics should receive teaching that includes which of the following points?
 - a. The need to complete the full course of drug therapy
 - b. The possibility of oral contraceptive failure
 - c. When to take the drug related to food and other drugs
 - d. The need for assessment of blood tests
 - e. Advisability of saving any leftover medication for future use
 - f. How to detect superinfections and what to do if they occur

Antiviral Agents

10

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Discuss problems with treating viral infections in humans and the use of antivirals across the lifespan.
2. Describe characteristics of common viruses and the resultant clinical presentations of common viral infections.
3. Describe the therapeutic actions, indications, pharmacokinetics, contraindications, most common adverse reactions, and important drug–drug interactions associated with each of the types of antivirals discussed in the chapter.
4. Compare and contrast the prototype drugs for each type of antiviral with the other drugs within that group.
5. Outline the nursing considerations for patients receiving each class of antiviral agent.

Glossary of Key Terms

acquired immunodeficiency syndrome (AIDS): collection of opportunistic infections and cancers that occurs when the immune system is severely depressed by a decrease in the number of functioning helper T cells; caused by infection with human immunodeficiency virus (HIV)

AIDS-related complex (ARC): collection of less serious opportunistic infections with HIV infection; the decrease in

the number of helper T cells is less severe than in fully developed AIDS

CCR5 coreceptor antagonist: a drug that blocks the receptor site the HIV virus needs to interact with in order to enter the cell.

Glossary of Key Terms (continued)

cytomegalovirus (CMV): DNA virus that accounts for many respiratory, ophthalmic, and liver infections

fusion inhibitor: a drug that prevents the fusion of the HIV-1 virus with the human cellular membrane, preventing it from entering the cell

helper T cell: human lymphocyte that helps to initiate immune reactions in response to tissue invasion

hepatitis B: a serious to potentially fatal viral infection of the liver, transmitted by body fluids

herpes: DNA virus that accounts for many diseases, including shingles, cold sores, genital herpes, and encephalitis

human immunodeficiency virus (HIV): retrovirus that attacks helper T cells, leading to a decrease in immune function and AIDS or ARC

influenza A: RNA virus that invades tissues of the respiratory tract, causing the signs and symptoms of the common cold or “flu”

integrase inhibitor: a drug that inhibits the activity of the virus-specific enzyme integrase, an encoded enzyme

needed for viral replication, blocking this enzyme prevents the formation of the HIV-1 provirus

interferon: tissue hormone that is released in response to viral invasion; blocks viral replication

nonnucleoside reverse transcriptase inhibitors: drugs that bind to sites on the reverse transcriptase, preventing RNA- and DNA-dependent DNA polymerase activities needed to carry out the viral DNA synthesis; prevents the transfer of information that allows the virus to replicate and survive

nucleoside reverse transcriptase inhibitors: drugs that prevent the growth of the viral DNA chain, preventing it from inserting into the host DNA, so viral replication cannot occur

protease inhibitors: drugs that block the activity of the enzyme protease in HIV; protease is essential for the maturation of infectious virus, and its absence leads to the formation of an immature and noninfective HIV particle

virus: particle of DNA or RNA surrounded by a protein coat that survives by invading a cell to alter its functioning

Viruses cause a variety of conditions, ranging from warts, to the common cold and “flu,” to diseases such as chickenpox and measles. A single virus particle is composed of a piece of DNA or RNA inside a protein coat. To carry on any metabolic processes, including replication, a virus must enter a cell. Once a virus has fused with a cell wall and injected its DNA or RNA into the host cell, that cell

is altered—that is, it is “programmed” to control the metabolic processes that the virus needs to survive. The virus, including the protein coat, replicates in the host cell (Figure 10.1). When the host cell can no longer carry out its own metabolic functions because of the viral invader, the host cell dies and releases the new viruses into the body to invade other cells.

● **FIGURE 10.1** The stages in the replication cycle of a virus.

Because viruses are contained inside human cells while they are in the body, researchers have difficulty developing effective drugs that destroy a virus without harming the human host. **Interferons** (see Chapter 15) are released by the host in response to viral invasion of a cell and act to prevent the replication of that particular virus. Some interferons that affect particular viruses can now be genetically engineered to treat particular viral infections. Other drugs that are used in treating viral infections are not natural substances and have been effective against only a limited number of viruses.

Viruses that respond to some antiviral therapy include influenza A and some respiratory viruses, herpes viruses, cytomegalovirus (CMV), the human immunodeficiency virus (HIV) that causes acquired immune deficiency syndrome (AIDS), hepatitis B, and some viruses that cause warts and certain eye infections. Patients need to be cautioned against using certain alternative therapies while on antiviral medication (Box 10.1). Box 10.2 discusses the use of antivirals across the lifespan. Figures 10.2 and 10.3 show sites of action for these agents.

BOX 10.1

**Herbal and Alternative Therapies****Alternative Therapies and Antiviral Drugs**

An increasing number of people are using alternative therapies as part of their daily regimen. St. John's wort is one of the more popular alternative therapies sold today. This herb has been used as an anti-inflammatory agent, as an antidepressant, as a diuretic, and as a treatment for gastritis and insomnia. Multimedia advertisements urge the use of St. John's wort to increase one's sense of well-being and to decrease depression "without the use of drugs." Many people with viral infections just do not feel well. They are tired, have muscle aches and pains, and feel feverish and low on energy. This herbal remedy seems to be aimed at these people. Unfortunately, St. John's wort has been shown to interact with many prescription drugs. When taken with St. John's wort, the protease inhibitors used in treating HIV were found to have decreased serum levels, leading to possible treatment failure. Because St. John's wort may induce the cytochrome P450 system in the liver, there is a possibility that it could increase the metabolism of many other antiviral drugs that are metabolized by that system and cause treatment failures with those drugs.

Patients may be reluctant to discuss their use of alternative therapies with the health care provider because they want to maintain control over that aspect of their medical regimen or because they believe that the health care provider would not approve of the use of these therapies. It is important, when a patient is prescribed an antiviral agent, to ask specifically about the use of herbal or alternative medicines. Explain to the patient that antiviral drugs may interact with some herbal medicines and that it is important to try to avoid any adverse effects or drug failures.

AGENTS FOR INFLUENZA A AND RESPIRATORY VIRUSES

Influenza A and other respiratory viruses, including influenza B and respiratory syncytial virus (RSV), invade the respiratory tract and cause the signs and symptoms of respiratory "flu." Vaccines have been developed (see Chapter 18) to stimulate immunity against influenza A and RSV. Preventing the viral infection is the best option, but if patients do develop a viral infection, some drug therapies are available. Agents for Influenza A and respiratory viruses include amantadine (*Symmetrel*), oseltamivir (*Tamiflu*), ribavirin (*Virazole*), rimantadine (*Flumadine*), and zanamivir (*Relenza*). These drugs are described in detail in Table 10.1.

Therapeutic Actions and Indications

The exact mechanism of action of drugs that combat Influenza A and respiratory viruses is not known. The belief is that these agents prevent shedding of the viral protein coat and entry of the virus into the cell (Figure 10.2). This action prevents viral replication, causing viral death. These agents for influenza A and respiratory viruses are especially important for health care workers and other high-risk individuals and for reducing the severity of infection if it occurs. See Table 10.1 for usual indications specific to each antiviral drug. Oseltamivir is the only antiviral agent that has been shown to be effective in treating avian flu.

Pharmacokinetics

Amantadine is slowly absorbed from the gastrointestinal (GI) tract, reaching peak levels in 4 hours. Excretion occurs unchanged through the urine, with a half-life of 15 hours. Oseltamivir is readily absorbed from the GI tract, extensively metabolized in the urine, and excreted in the urine with a half-life of 6 to 10 hours.

Ribavirin, an inhaled drug, is slowly absorbed through the respiratory tract. It is metabolized at the cellular level and is excreted in the feces and urine with a half-life of 9.5 hours. It is teratogenic and is rated pregnancy category X.

Rimantadine is absorbed from the GI tract with peak levels achieved in 6 hours. This drug is extensively metabolized in the liver and excreted in the urine.

Zanamivir must be delivered by a Diskhaler device, which comes with every prescription of zanamivir. It is absorbed through the respiratory tract and excreted unchanged in the urine with a half-life of 2.5 to 5.1 hours.

Contraindications and Cautions

Because of its renal clearance, amantadine must be used at reduced doses and with caution in patients who have any renal impairment *to avoid altered metabolism and excretion of the drug*. Amantadine is embryotoxic in animals and crosses

BOX 10.2 *Drug Therapy Across the Lifespan*

Antivirals

CHILDREN

Children are very sensitive to the effects of most antiviral drugs, and more severe reactions can be expected when these drugs are used in children.

Many of these drugs do not have proven safety and efficacy in children, and extreme caution should be used.

Most of the drugs for prevention and treatment of influenza virus infections can be used, in smaller doses, for children.

Acyclovir is the drug of choice for children with herpes virus or cytomegalovirus infections.

The drugs used in the treatment of AIDS are frequently used in children, even when no scientific data are available, because of the seriousness of the disease. Dose should be lowered according to body weight, and children must be monitored very closely for adverse effects on kidneys, bone marrow, and liver.

ADULTS

Adults need to know that these drugs are specific for the treatment of viral infections. The use of antibiotics to treat such infections can lead to the development of resistant strains and superinfections that can cause more problems.

Patients with HIV infection who are taking antiviral medications need to be taught that these drugs do not cure the

disease, that opportunistic infections can still occur, and that precautions to prevent transmission of the disease need to be taken.

Pregnant women, for the most part, should not use these drugs unless the benefit clearly outweighs the potential risk to the fetus or neonate. Women of childbearing age should be advised to use barrier contraceptives if they take any of these drugs. Zidovudine has been safely used in pregnant women.

The Centers for Disease Control and Prevention advises that women with HIV infection should not breast-feed, to protect the neonate from the virus.

OLDER ADULTS

Older patients may be more susceptible to the adverse effects associated with these drugs; they should be monitored closely.

Patients with hepatic dysfunction are at increased risk for worsening hepatic problems and toxic effects of those drugs that are metabolized in the liver. Drugs that are excreted unchanged in the urine can be especially toxic to patients who have renal dysfunction. If hepatic or renal dysfunction is expected (extreme age, alcohol abuse, use of other hepatotoxic or nephrotoxic drugs), the dose may need to be lowered and the patient should be monitored more frequently.

● **FIGURE 10.2** Agents for treating influenza A and respiratory viruses prevent shedding of the protein coat and entry of virus into the cell. Herpes virus agents alter viral DNA production. Anti-hepatitis B agents block DNA formation, preventing the formation of new viruses.

● **FIGURE 10.3** Agents that attempt to control HIV and AIDS work in the following ways: interference with HIV replication by blocking synthesis of viral DNA (nonnucleoside and nucleoside reverse transcriptase inhibitors); blockage of protease within the virus, leading to immature, noninfective virus particles (protease inhibitors); prevention of virus from fusing with the cellular membrane, thereby preventing the HIV-1 virus from entering the cell (fusion inhibitors); blockage of HIV virus reaction with the receptor site that would allow it to enter the cell (CCR5 coreceptor antagonists); and prevention of necessary encoded enzyme action for viral reproduction (integrase inhibitors).

into breast milk. Therefore, it should be used during pregnancy and lactation only if the benefits clearly outweigh the risks to the fetus or neonate.

Patients with renal dysfunction who are taking oseltamivir require reduced doses and close monitoring *to avoid altered metabolism and excretion of the drug*. There are no adequate studies in pregnancy and lactation, so oseltamivir should be used during pregnancy and lactation only if the benefits clearly outweigh the risks to the fetus or neonate.

Women of childbearing age should be advised to use barrier contraceptives if they are taking ribavirin. The drug has been associated with serious fetal effects.

Rimantadine is embryotoxic in animals and should be used during pregnancy only if the benefits clearly outweigh the risks. The drug should not be used by nursing mothers because

it crosses into breast milk and can cause toxic reactions in the neonate. Use in children should be limited to prevention of influenza A infections.

Because of the renal excretion, zanamivir must be used cautiously in patients with any renal impairment. It should be used during pregnancy and lactation only if the benefits clearly outweigh the risks to the fetus or neonate.

Adverse Effects

Use of these antiviral agents is frequently associated with various adverse effects that may be related to possible effects on dopamine levels in the brain. These adverse effects include light-headedness, dizziness, and insomnia; nausea; orthostatic hypotension; and urinary retention.

TABLE 10.1 DRUGS IN FOCUS Agents for Influenza A and Respiratory Viruses

Drug Name	Dosage/Route	Usual Indications
amantadine (<i>Symmetrel</i>)	Adult: 200 mg/d PO Pediatric (9–12 yr): 100 mg PO b.i.d. Pediatric (1–9 yr): 2–4 mg/lb PO daily	Treatment of Parkinson disease; treatment and prevention of respiratory virus infections
oseltamivir (<i>Tamiflu</i>)	Adult: 75 mg PO b.i.d. for 5 d (treatment); 75 mg/d PO for 7 d (prevention) Pediatric (1–12 yr): 30–75 mg b.i.d. PO for 5 d (treatment); 30–75 mg/d for 7 d (prevention)	Treatment and prevention of uncomplicated influenza for patient who is symptomatic for <2 d; only antiviral agent effective in treatment of avian flu
ribavirin (<i>Rebetron</i> , <i>Virazole</i>)	Adult: 400 mg/d PO in AM with 600 mg/d PO in PM with 3 million International Units of interferon alpha-2b SC 3 times per week Pediatric: 20 mg/mL in the reservoir for aerosol treatment over 12–18 h each day for 3–7 d	Used in combination with interferon alfa-2b as an oral drug for the treatment of chronic hepatitis C in children and adults who relapse after interferon-alpha therapy Treatment of influenza A, respiratory syncytial virus (RSV), and herpes virus infections; treatment of children with RSV; has undergone testing for use in several other viral conditions
 rimantadine (<i>Flumadine</i>) zanamivir (<i>Relenza</i>)	Adult: 100 mg PO b.i.d. Pediatric (≥10 yr): 5 mg/kg PO daily Adult and children ≥7 yr: Two inhalations b.i.d. (12 h apart) for 5 d; prevention of influenza in patients >5 yr; two inhalations per day for 10 d (household) to 28 d (community)	Treatment and prevention of influenza A infections Approved in 1999 for treatment and prevention of uncomplicated influenza infections in adults and in children >7 years of age who have had symptoms for <2 d

Clinically Important Drug–Drug Interactions

Patients who receive amantadine or rimantadine may experience increased atropine-like effects if either of these drugs is given with an anticholinergic drug. Patients taking rimantadine may also experience a loss of effectiveness of aspirin and acetaminophen if these are also being used. Ribavirin levels may be reduced if it is given with antacids. The use of ribavirin should be avoided if the patient is also receiving a nucleoside reverse transcriptase inhibitor. Rifampin is known to decrease the effectiveness of many drugs, including antiarrhythmics, digoxin, hormonal contraceptives, corticosteroids, antifungals, and central nervous system (CNS) depressants. Patients should be monitored closely for loss of effectiveness of these drugs if this combination is used. There is an increased incidence of rifampin-related hepatitis if it is used concurrently with isoniazid. This combination should be avoided.

Prototype Summary: Rimantadine

Indications: Prophylaxis and treatment of illness caused by influenza A virus in adults; prophylaxis against influenza A virus in children.

Actions: Inhibits viral replication, possibly by preventing the uncoating of the virus.

Pharmacokinetics:

Route	Onset	Peak
Oral	Slow	6 h

$T_{1/2}$: 25.4 hours; excreted unchanged in the urine.

Adverse effects: Light-headedness, dizziness, insomnia, nausea, dyspnea, orthostatic hypotension, depression.

Nursing Considerations for Patients Receiving Agents for Influenza A and Respiratory Viruses

Assessment: History and Examination

- Assess for *contraindications or cautions*: known history of allergy to antivirals *to avoid hypersensitivity reactions*; history of liver or renal dysfunction *that might interfere with drug metabolism and excretion*; and current status related to pregnancy or lactation.
- Perform a physical assessment to *establish baseline data for evaluating the effectiveness of the drug and the occurrence of any adverse effects associated with drug therapy*.
- Assess for orientation and reflexes *to evaluate any CNS effects of the drug*; vital signs (temperature, respiratory rate, breath sounds for adventitious sounds) *to assess for signs and symptoms of the viral infection*; blood pressure to

monitor for orthostatic hypotension; urinary output to monitor genitourinary (GU) effects of the drug; and renal and hepatic function tests to determine baseline function of these organs.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to GI, CNS, or GU effects of the drug
- Disturbed Sensory Perception (Kinesthetic) related to CNS effects of the drug
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Start the drug regimen as soon after exposure to the virus as possible to enhance effectiveness and decrease the risk of complications due to viral infection.
- Administer influenza A vaccine before the flu season begins, if at all possible, to decrease the risk of contracting the flu and decrease the risk of complications.
- Administer the full course of the drug to obtain the full beneficial effects.
- Provide safety provisions if CNS effects occur to protect the patient from injury.
- Instruct the patient about the appropriate dosage scheduling regimen; safety precautions, including changing position slowly and avoiding driving and hazardous tasks, that should be taken if CNS effects occur; and the need to report any adverse effects such as difficulty walking or talking to enhance patient knowledge about drug therapy and to promote compliance.

Evaluation

- Monitor patient response to the drug (prevention of respiratory flu-like symptoms; alleviation of flu-like symptoms).
- Monitor for adverse effects (changes in orientation and affect, blood pressure, urinary output).
- Determine the effectiveness of the teaching plan (patient can name the drug, dosage, possible adverse effects to watch for, and specific measures to help to avoid or minimize adverse effects).
- Monitor the effectiveness of comfort and safety measures and compliance with the regimen.

KEY POINTS

- ▶ Viruses are segments of RNA or DNA enclosed in a protein coat.
- ▶ A virus must enter a human cell to survive, making it difficult to treat without serious toxic effects for the host.
- ▶ Antiviral drugs that prevent the viral replication of respiratory viruses can be used to prevent or treat influenza A or other respiratory viruses.

AGENTS FOR HERPES AND CYTOMEGALOVIRUS

Herpes viruses account for a broad range of conditions, including cold sores, encephalitis, shingles, and genital infections. **Cytomegalovirus (CMV)**, although slightly different from the herpes virus, can affect the eye, respiratory tract, and liver and reacts to many of the same drugs. Antiviral drugs used to combat these infections include acyclovir (*Zovirax*), cidofovir (*Vistide*), famciclovir (*Famvir*), foscarnet (*Foscavir*), ganciclovir (*Cytovene*), valacyclovir (*Valtrex*), and valganciclovir (*Valcyte*). See Table 10.2.

Therapeutic Actions and Indications

Drugs that combat herpes and CMV inhibit viral DNA replication by competing with viral substrates to form shorter, non-effective DNA chains (see Figure 10.2). This action prevents replication of the virus, but it has little effect on the host cells of humans because human cell DNA uses different substrates. These antiviral agents are indicated for treatment of the DNA viruses herpes simplex, herpes zoster, and CMV. Research has shown that they are very effective in immunocompromised individuals, such as patients with AIDS, those taking immunosuppressants, and those with multiple infections. See Table 10.2 for usual indications for each of these agents.

Pharmacokinetics

Most of the agents for herpes and cytomegalovirus are readily absorbed and excreted through the kidney. Although cidofovir has been proven to be embryotoxic in animals, no adequate studies have been completed for the other agents.

Acyclovir, which can be given orally and parenterally or applied topically, reaches peak levels within 1 hour and has a half-life of 2.5 to 5 hours. It is excreted unchanged in the urine. It crosses into breast milk, which exposes the neonate to high levels of the drug.

Cidofovir, which is given by intravenous (IV) infusion, reaches peak levels at the end of the infusion and in studies was cleared from the system within 15 minutes after the infusion. It is excreted unchanged in the urine and must be given with probenecid to increase renal clearance of the drug. The dose must be decreased according to renal function and creatinine clearance; renal function tests must be done before each dose and the dose planned accordingly.

Famciclovir, an oral drug, is well absorbed from the GI tract, reaching peak levels in 2 to 3 hours. Famciclovir is metabolized in the liver and excreted in the urine and feces. It has a half-life of 2 hours and is known to cross the placenta.

Foscarnet is available in IV form only. It reaches peak levels at the end of the infusion and has a half-life of 4 hours. About 90% of foscarnet is excreted unchanged in the urine, making it highly toxic to the kidneys. Use caution and at reduced dose in patients with renal impairment.

Ganciclovir is available in IV and oral forms. It has a slow onset and reaches peak levels at 1 hour if given IV and 2 to

TABLE 10.2 DRUGS IN FOCUS Agents for Herpes Virus and Cytomegalovirus (CMV)

Drug Name	Dosage/Route	Usual Indications
 acyclovir (<i>Zovirax</i>)	Adult: 5–10 mg/kg q8h IV, IM, or SC, or 200 mg q4h per day for 10 d and then 400 mg PO b.i.d. for 12 mo Pediatric: 250–500 mg/m ² q8h IV, IM, or SC for 7–10 d, or 20 mg/kg q.i.d. PO for 5 d	Treatment of herpes virus infections
cidofovir (<i>Vistide</i>)	5 mg/kg IV (over 1 h) once weekly for 2 wk, then every other week, with probenecid 2 g PO at 3 h before and 1 g PO at 2 and 8 h after cidofovir infusion	Treatment of CMV retinitis in AIDS patients
famciclovir (<i>Famvir</i>)	Herpes zoster: 500 mg PO q8h for 7 d Genital herpes: 125 mg b.i.d. PO for 5 d	Treatment of herpes virus infections such as herpes zoster or shingles and for recurrent episodes of genital herpes
foscarnet (<i>Foscavir</i>)	Adult: 40–60 mg/kg q8–12h IV given as a 2-h infusion Pediatric: safety and efficacy not established	Treatment of CMV and acyclovir-resistant mucocutaneous herpes simplex infections in immunocompromised patients
ganciclovir (<i>Cytovene</i>)	Adult: 5 m/kg q12h IV given over 1 h for 14–21 d, then over 1 h daily 7 d/wk or 6 mg/kg per day for 5 d/wk for prophylaxis	Long-term treatment and prevention of CMV infection
valacyclovir (<i>Valtrex</i>)	Herpes zoster: 1 g PO t.i.d. for 7 d Genital herpes: 500 mg b.i.d. PO for 5 d	Treatment of herpes zoster and recurrent genital herpes; cold sores (herpes labialis)
valganciclovir (<i>Valcyte</i>)	900 mg PO b.i.d. for 21 d, then 900 mg PO once a day for maintenance; reduce dose with renal impairment	Treatment of CMV retinitis in AIDS patients

4 hours if given orally. This drug is primarily excreted unchanged in the feces with some urinary excretion, with a half-life of 2 to 4 hours.

Valacyclovir is an oral agent and is rapidly absorbed from the GI tract and metabolized in the liver to acyclovir. Excretion occurs through the urine, so caution should be used in patients with renal impairment.

Valganciclovir is the oral prodrug, that is, it is immediately converted to ganciclovir once it is in the body. It is rapidly absorbed and reaches peak levels in 3 hours. It is primarily excreted unchanged in the feces with some urinary excretion, with a half-life of 2.5 to 3 hours.

Contraindications and Cautions

Drugs indicated for the treatment of herpes and CMV are highly toxic and should not be used during pregnancy or lactation *to prevent adverse effects on the fetus or infant*; use only if the benefits clearly outweigh the potential risks to the fetus or infant. Avoid use in patients with known allergies to antiviral agents *to prevent serious hypersensitivity reactions*; in patients with renal disease, *which could interfere with excretion of the drug*; or in patients with severe CNS disorders *because the drug can affect the CNS, causing headache, neuropathy, paresthesias, confusion, and hallucinations*

Cidofovir has been proven to be embryotoxic in animals. Use cidofovir with caution in children with AIDS because of the

potential carcinogenic effects and effects on fertility. If no other treatment option is available, monitor the child very closely.

For famciclovir, safety of use in children younger than 18 years of age has not been established.

Foscarnet has been shown to affect bone development and growth. Foscarnet, as well as ganciclovir and valganciclovir, should not be used in children unless the benefit clearly outweighs the risk and the child is monitored very closely.

Adverse Effects

The adverse effects most commonly associated with these antivirals include nausea and vomiting, headache, depression, paresthesias, neuropathy, rash, and hair loss. Rash, inflammation, and burning often occur at sites of IV injection and topical application. Renal dysfunction and renal failure also have been reported. Cidofovir is associated with severe renal toxicity and granulocytopenia. Ganciclovir and valganciclovir have been associated with bone marrow suppression. Foscarnet has been associated with seizures, especially in patients with electrolyte imbalance.

Clinically Important Drug–Drug Interactions

The risk of nephrotoxicity increases when agents indicated for the treatment of herpes and CMV are used in combination with other nephrotoxic drugs, such as the aminoglycoside antibiotics.

The risk of drowsiness also rises when these antiviral agents are taken with zidovudine, an antiretroviral agent.

Prototype Summary: *Acyclovir*

Indications: Treatment of herpes simplex virus (HSV) 1 and 2 infections; treatment of severe genital HSV infections; treatment of HSV encephalitis; acute treatment of shingles and chickenpox; ointment for the treatment of genital herpes infections; cream for the treatment of cold sores (herpes labialis).

Actions: Inhibits viral DNA replication.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	Varies	1.5–2 h	Not known
IV	Immediate	1 h	8 h
Topical	Not generally absorbed systemically		

$T_{1/2}$: 2.5–5 hours; excreted unchanged in the urine.

Adverse effects: Headache, vertigo, tremors, nausea, vomiting, rash.

● Nursing Considerations for Patients Receiving Agents for Herpes Virus and Cytomegalovirus

Assessment: History and Examination

- Assess patients receiving DNA-active antiviral agents for **contraindications or cautions:** any history of allergy to antivirals *to avoid hypersensitivity reactions*; renal dysfunction *that might interfere with the metabolism and excretion of the drug and increase the risk of renal toxicity*; severe CNS disorders *that could be aggravated*; and pregnancy or lactation.
- Perform a physical assessment *to establish baseline data for assessing the effectiveness of the DNA-active antiviral drug and the occurrence of any adverse effects associated with drug therapy.*
- Assess orientation and reflexes *to monitor CNS baseline and adverse effects of the drug.*
- Examine skin (color, temperature, and lesions) *to monitor adverse effects such as rashes.*
- Evaluate renal function tests *to determine baseline function of the kidneys and to assess adverse effects on the kidney and need to adjust the dose of the drug.*

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to GI, CNS, or local effects of the drug
- Disturbed Sensory Perception (Kinesthetic) related to CNS effects of the drug
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Administer the drug as soon as possible after the diagnosis has been made *to improve effectiveness of the antiviral activity.*
- Ensure good hydration *to decrease the toxic effects on the kidneys.*
- Ensure that the patient takes the complete course of the drug regimen *to improve effectiveness and decrease the risk of the emergence of resistant viruses.*
- Wear protective gloves when applying the drug topically *to decrease the risk of exposure to the drug and inadvertent absorption.*
- Provide safety precautions (e.g., use of side rails, appropriate lighting, orientation, assistance) if CNS effects occur *to protect the patient from injury.*
- Warn the patient that GI upset, nausea, and vomiting can occur *to prevent undue anxiety and increase awareness of the importance of nutrition.*
- Monitor renal function tests periodically during treatment *to ensure prompt detection and early intervention, should renal toxicity develop*
- Instruct the patient about the drug *to enhance patient knowledge about drug therapy and to promote compliance.*
- Provide the following patient teaching:
 - Avoid sexual intercourse if genital herpes is being treated because these drugs do not cure the disease.
 - Wear protective gloves when applying topical agents.
 - Avoid driving and hazardous tasks if dizziness or drowsiness occurs.

Evaluation

- Monitor patient response to the drug (alleviation of signs and symptoms of herpes or CMV infection).
- Monitor for adverse effects (orientation and affect, GI upset, and renal function).
- Evaluate the effectiveness of the teaching plan (patient can name the drug, dosage, possible adverse effects to watch for, and specific measures to help avoid adverse effects).
- Monitor the effectiveness of comfort and safety measures and compliance with the regimen.

KEY POINTS

- ◆ Drugs that interfere with viral DNA replication are used to treat herpes infections and CMV infections.
- ◆ Antiviral drugs are associated with GI upset and nausea, confusion, insomnia, and dizziness.

AGENTS FOR HIV AND AIDS

The **human immunodeficiency virus (HIV)** attacks the **helper T cells** (CD4 cells) within the immune system. This virus (an RNA strand) enters the helper T cell, where it uses

reverse transcriptase to copy the RNA and produce a double-stranded viral DNA. The virus uses various nucleosides found in the cell to synthesize this DNA strand. The DNA enters the host cell nucleus and slides into the chromosomal DNA to change the cell's processes to ones that produce new viruses. This changes the cell into a virus-producing cell. As a result, the cell loses its ability to perform normal immune functions. The newly produced viruses mature through the action of various proteases and then are released from the cell. Upon release, they find a new cell to invade, and the process begins again. Eventually, as more and more viruses are released and invade more CD4 cells, the immune system loses an important mechanism responsible for propelling the immune reaction into full force when the body is invaded.

Loss of T cell function causes **acquired immune deficiency syndrome (AIDS)** and **AIDS-related complex (ARC)**, diseases that are characterized by the emergence of a variety of opportunistic infections and cancers that occur when the immune system is depressed and unable to function properly. The HIV mutates over time, presenting a slightly different configuration with each new generation. Treatment of AIDS and ARC has been difficult for two reasons: (1) the length of time the virus can remain dormant within the T cells (i.e., months to years), and (2) the adverse effects of many potent drugs, which may include further depression of the immune system. A combination of several different antiviral drugs is used to attack the virus at various points in its life cycle to achieve maximum effectiveness with the least amount of toxicity. The types of antiviral agents that are used to treat HIV infections are the nonnucleoside and nucleoside reverse transcriptase inhibitors, the protease inhibitors, and three newer classes of drugs—the fusion inhibitors, CCR5 coreceptor antagonists, and integrase inhibitors (Table 10.3). Collectively, these drugs are known as antiretroviral agents. The HIV virus poses a serious health risk. The patient and the family of the patient diagnosed with HIV infection will need tremendous support and teaching to cope with the disease and its treatment. See Box 10.3 for public education information regarding AIDS.

Nonnucleoside Reverse Transcriptase Inhibitors

The nonnucleoside reverse transcriptase inhibitors have direct effects on the HIV virus activities within the cell. The nonnucleoside reverse transcriptase inhibitors available include delavirdine (*Rescriptor*), efavirenz (*Sustiva*), and nevirapine (*Viramune*).

Therapeutic Actions and Indications

The **nonnucleoside reverse transcriptase inhibitors** bind directly to HIV reverse transcriptase, blocking both RNA- and DNA-dependent DNA polymerase activities. They prevent the transfer of information that would allow the virus to carry on the formation of viral DNA. As a result, the virus is

unable to take over the cell and reproduce. These antiviral agents are indicated for the treatment of patients with documented AIDS or ARC who have decreased numbers of T cells and evidence of increased opportunistic infections in combination with other antiviral drugs (see Table 10.3).

Pharmacokinetics

Delavirdine is rapidly absorbed from the GI tract, with peak levels occurring within 1 hour. Delavirdine is extensively metabolized by the cytochrome P450 system in the liver and is excreted through the urine.

Efavirenz is absorbed rapidly from the GI tract, reaching peak levels in 3 to 5 hours. Efavirenz is metabolized in the liver by the cytochrome P450 system and is excreted in the urine and feces with a half-life of 52 to 76 hours.

Nevirapine is recommended for use in adults and children older than 2 months. After rapid GI absorption with a peak effect occurring at 4 hours, nevirapine is metabolized by the cytochrome P450 system in the liver. Excretion is through the urine with a half-life of 45 hours. Box 10.4 provides information about the emergence of resistance to certain reverse transcriptase inhibitor combinations.

Contraindications and Cautions

There are no adequate studies of nonnucleoside reverse transcriptase inhibitors in pregnancy, so use should be limited to situations in which the benefits clearly outweigh any risks. It is suggested that women not breast-feed if they are infected with HIV. Safety for the use of delavirdine in children has not been established.

Adverse Effects

The adverse effects most commonly experienced with these drugs are GI related—dry mouth, constipation or diarrhea, nausea, abdominal pain, and dyspepsia. Dizziness, blurred vision, and headache have also been reported. A flu-like syndrome of fever, muscle aches and pains, fatigue, and loss of appetite often occurs with the anti-HIV drugs, but these signs and symptoms may also be related to the underlying disease.

Clinically Important Drug–Drug Interactions

Life-threatening effects can occur if delavirdine is combined with antiarrhythmics, clarithromycin, dapsone, antituberculosis drugs, calcium-channel blockers, warfarin, quinidine, indinavir, saquinavir, or dapsone. These combinations should be avoided if at all possible. There is a risk of serious adverse effects if efavirenz is combined with midazolam, rifabutin, triazolam, or ergot derivatives; these combinations should be avoided. There may be a lack of effectiveness if nevirapine is combined with hormonal contraceptives or protease inhibitors. St. John's wort should not be used with these drugs; a decrease in antiviral effects can occur.

TABLE 10.3 DRUGS IN FOCUS Agents for HIV and AIDS

Drug Name	Dosage/Route	Usual Indications
Nonnucleoside Reverse Transcriptase Inhibitors		
delavirdine (<i>Rescriptor</i>)	Adult: 400 mg PO t.i.d.	Part of combination therapy regimens for treatment of HIV in adults
efavirenz (<i>Sustiva</i>)	Adult: 600 mg/d PO Pediatric: dose determined by age and weight	Treatment of adults and children with HIV in combination with other antiretroviral agents
 nevirapine (<i>Viramune</i>)	Adult: 200 mg/d PO for 14 d, then 200 mg PO b.i.d. Pediatric: 4 mg/kg PO for 14 d, then 4–7 mg/kg PO b.i.d.	Treatment of adults or children with HIV in combination with other antiretroviral agents
Nucleoside Reverse Transcriptase Inhibitors		
abacavir (<i>Ziagen</i>)	Adult: 300 mg PO b.i.d. Pediatric: 8 mg/kg PO b.i.d.	Combination therapy for the treatment of adults and children with HIV
didanosine (<i>Videx</i>)	Adult: 250–400 mg/d PO or 125–200 mg PO b.i.d. Pediatric: 120 mg/m ² PO b.i.d.	Treatment of advanced infections in adults and children with HIV as part of combination therapy
emtricitabine (<i>Emtriva</i>)	Adult: 200 mg/d PO or 240 mg oral solution/d Pediatric (3 mo–17 yr): 6 mg/kg per day PO to a maximum 240 mg	Part of combination therapy for treatment of HIV-1 infection
lamivudine (<i>Epivir</i>)	Adult: 150 mg PO b.i.d.; for chronic hepatitis B, 100 mg PO q.d. Pediatric (3 mo–16 yr): 4 mg/kg PO b.i.d.	With other antiretroviral agents for the treatment of adults and children with HIV; as an oral solution for the treatment of chronic hepatitis B
stavudine (<i>Zerit XR</i>)	Adult (≥60 kg): 100 mg/d PO Adult (30–60 kg): 75 mg/d PO	Treatment of adults with HIV in combination with other antiretroviral agents
tenofovir (<i>Viread</i>)	Adult: 300 mg/d PO	Treatment of adults with HIV infection in combination with other antiretroviral drugs
zalcitabine (<i>Hivid</i>)	Adult: 0.75 mg PO q8h	Treatment of advanced infections in adults with HIV as part of combination therapy
 zidovudine [AZT] (<i>Retrovir, Aztec</i>)	Adult: 100 mg PO q4h Pediatric 6 wk–12 yr): 90–180 mg/m ² PO q6h Maternal: 100 mg PO five times per day from 14-wk gestation until start of labor	Treatment of symptomatic HIV in adults and children as part of combination therapy; prevention of maternal transmission of HIV
Protease Inhibitors		
atazanavir (<i>Reyataz</i>)	Adult: 400 mg PO, q8h	Treatment of adults with HIV as part of combination therapy
 fosamprenavir (<i>Lexiva</i>)	Adult: 1,400 mg/d PO with 100 mg/d ritonavir PO or 700 mg PO b.i.d. with ritonavir 100 mg PO b.i.d.	Part of combination therapy for the treatment of HIV in adults
indinavir (<i>Crixivan</i>)	Adult: 800 mg PO q8h	Treatment of adults with HIV as part of combination therapy
lopinavir (<i>Kaletra</i>)	Adult: three capsules or 5 mL PO b.i.d. Pediatric (6 mo–12 yr): 10–12 mg/kg PO b.i.d.	Treatment of adults and children with HIV in combination with other antiretroviral agents
nelfinavir (<i>Viracept</i>)	Adult: 750 mg PO t.i.d. Pediatric (2–13 yr): 20–30 mg/kg per dose PO t.i.d.	Combination therapy for the treatment of adults and children with HIV
ritonavir (<i>Norvir</i>)	Adult and pediatric (>2 yr): 600 mg PO b.i.d.	Part of combination therapy for the treatment of adults and children with HIV

(drug table continues on page 144)

TABLE 10.3 DRUGS IN FOCUS Agents for HIV and AIDS (continued)

Drug Name	Dosage/Route	Usual Indications
Protease Inhibitors (continued)		
saquinavir (<i>Fortovase</i>) (<i>Invirase</i>)	<i>Fortovase</i> : Adult: six 200-mg tablets PO t.i.d. <i>Invirase</i> : Adult: three 200-mg tablets PO t.i.d.	Treatment of adults with HIV as part of combination therapy
tipranavir (<i>Aptivus</i>)	Adult: 300 mg/d PO with 200 mg ritonavir	Treatment of adults with HIV in combination with ritonavir
Fusion Inhibitor		
 enfuvirtide (<i>Fuzeon</i>)	Adult: 90 mg PO b.i.d. by SC injection Pediatric 6–16 yr: 2 mg/kg b.i.d. by SC injection	Part of combination therapy in treatment of HIV patients with evidence of HIV replication despite antiretroviral therapy
CCR5 Coreceptor Antagonist		
 maraviroc (<i>Selzentry</i>)	Adult: 150 mg PO b.i.d.	Part of combination therapy for treatment of HIV-1 infections
Integrase Inhibitor		
 raltegravir (<i>Isentress</i>)	Adult: 400 mg PO b.i.d.	Part of combination therapy for treatment of HIV-1 infections

BOX 10.3

**The Evidence****Public Education About AIDS**

When AIDS was first diagnosed in the early 1980s, it was found in a certain population in New York City. The people in this group tended to be homosexuals, intravenous drug users, and debilitated persons with poor hygiene and nutrition habits. Originally, a number of health care practitioners thought that the disease was a syndrome of opportunistic infections that occurred in a population with repeated exposures to infections that naturally deplete the immune system. It was not until several years later that the human immunodeficiency virus (HIV) was identified. Since then, it has been discovered that HIV infection is rampant in many African countries. The infection also has spread throughout the United States in populations that are not homosexual or intravenous drug users and who have good nutrition and hygiene habits. As health care practitioners have learned, HIV is not particular about the body it invades. Once introduced into a body, it infects T cells and causes HIV infection.

The evidence shows that when a patient is diagnosed with HIV infection, the nurse faces a tremendous challenge for patient education and support. The patient and any significant others should be counseled about the risks of trans-

mission and reassured about ways in which the virus is not transmitted. They will need to learn about drug protocols, T-cell levels, adverse drug effects, and anticipated progress of the disease. They also will need consistent support and a telephone number to call with questions at any time. Many communities have AIDS support groups and other resources that can be very helpful; the nurse can direct the patient to these resources as appropriate.

The combinations of drugs that are being used today and the constant development of more drugs make the disease less of a death sentence than it was in the past. The result, however, is that many people must take a large number of pills each day, at tremendous cost and inconvenience. Many people today do live for long periods with HIV infection. An AIDS vaccine is currently being studied and offers hope for preventing this disease in the future.

Public education is key for promoting the acceptance and support of patients with HIV infection or AIDS, who need a great deal of support and assistance. Nurses can be role models for dealing with HIV patients and can provide informal public education whenever the opportunity presents.

BOX 10.4

The Evidence

HIV Resistance

In late 2003, Gilead Sciences, Inc., notified health care professionals of a high rate of early virological failure and the emergence of nucleoside reverse transcriptase inhibitor (NRTI) resistance-associated mutations. This was observed in a clinical study of HIV-infected, treatment-naïve patients receiving a once-daily triple NRTI regimen containing didanosine enteric-coated beadlets (*Videx EC*), lamivudine (*Epivir*), and tenofovir disoproxil fumarate (*Viread*).

Based on these studies, tenofovir in combination with didanosine and lamivudine is not recommended when considering a new treatment regimen for therapy-naïve or experienced patients with HIV infection. Patients currently on this regimen should be considered for treatment modification.

In a similar study, patients receiving unboosted *Reyataz* (atazanavir sulfate) and *Viread* (tenofovir) showed less decrease in viral concentrations and loss of virological response, which could show a possible resistance to *Reyataz*. For patients taking atazanavir and tenofovir, the Food and Drug Administration advises that a boosted dose of atazanavir should be used to overcome a decrease in concentration of the drug that seems to occur when it is used with tenofovir.

Prototype Summary: Nevirapine

Indications: Treatment of HIV-1-infected patients who have experienced clinical or immunological deterioration, in combination with other antiretrovirals.

Actions: Binds to HIV-1 reverse transcriptase and blocks replication of the HIV by changing the structure of the HIV enzyme.

Pharmacokinetics:

Route	Onset	Peak
Oral	Rapid	4 h

$T_{1/2}$: 45 hours, then 25 to 30 hours; metabolized in the liver and excreted in the urine.

Adverse effects: Headache, nausea, vomiting, diarrhea, rash, liver dysfunction, chills, fever.

Nucleoside Reverse Transcriptase Inhibitors

The **nucleoside reverse transcriptase inhibitors** (Table 10.3) were the first class of drugs developed to treat HIV infections. These are drugs that compete with the naturally occurring nucleosides within a human cell that the virus would need to develop. The nucleoside reverse transcriptase inhibitors include the following agents: abacavir (*Ziagen*), didanosine (*Videx*), emtricitabine (*Emtriva*), lamivudine (*Epivir*), stavudine (*Zerit XR*), tenofovir (*Viread*), zalcitabine (*Hivid*), and zidovudine (*Retrovir*, *Aztec*).

Therapeutic Actions and Indications

Nucleoside reverse transcriptase inhibitors compete with the naturally occurring nucleosides within the cell that the virus would use to build the DNA chain. These nucleosides, however, lack a substance needed to extend the DNA chain. As a result, the DNA chain cannot lengthen and cannot insert itself into the host DNA. Thus the virus cannot reproduce. They are used as part of combination therapy for the treatment of HIV infection. See Table 10.3 for usual indications for each of these agents.

Pharmacokinetics

Abacavir is an oral drug that is rapidly absorbed from the GI tract. It is metabolized in the liver and excreted in feces and urine with a half-life of 1 to 2 hours.

Didanosine is rapidly destroyed in an acid environment and therefore must be taken in a buffered form. It reaches peak levels in 15 to 75 minutes. Didanosine undergoes intracellular metabolism with a half-life of 8 to 24 hours. It is excreted in the urine.

Emtricitabine has the advantage of being a one-capsule-a-day therapy. Emtricitabine has a rapid onset and peaks in 1 to 2 hours. It has a half-life of 10 hours, and after being metabolized in the liver is excreted in the urine and feces. Dose needs to be reduced in patients with renal impairment. It has been associated with severe and even fatal hepatomegaly with steatosis, a fatty degeneration of the liver.

Lamivudine is rapidly absorbed from the GI tract and is excreted primarily unchanged in the urine. It peaks within 4 hours and has a half-life of 5 to 7 hours. Because excretion depends on renal function, dose reduction is recommended in the presence of renal impairment. The drug is available as an oral solution, *Epivir-HBV*, it is also recommended for the treatment of chronic hepatitis B.

Stavudine is rapidly absorbed from the GI tract, reaching peak levels in 1 hour. Most of the drug is excreted unchanged in the urine, making it important to reduce dose and monitor patients carefully in the presence of renal dysfunction. It can be used for adults and children and is only available in an extended-release form, allowing for once-a-day dosing.

Tenofovir is a newer drug that affects the virus at a slightly different point in replication—a nucleotide that becomes a nucleoside. It is used only in combination with other antiretroviral agents. It is rapidly absorbed from the GI tract, reaching peak levels in 45 to 75 minutes. Its metabolism is not known, but it is excreted in the urine.

Zalcitabine is used to treat advanced cases of HIV/AIDS in adults, as a monotherapy in adults who have become intolerant to zidovudine or who have progressive disease while taking zidovudine, and as combination therapy with zidovudine for the treatment of advanced HIV infection. After absorption from the GI tract, zalcitabine is excreted unchanged in the urine with a half-life of 2 hours.

Zidovudine was one of the first drugs found to be effective in the treatment of AIDS. It is rapidly absorbed from the GI

tract, with peak levels occurring within 30 to 75 minutes. Zidovudine is metabolized in the liver and excreted in the urine, with a half-life of 1 hour.

Contraindications and Cautions

Of the nucleosides, zidovudine is the only agent that has been proven to be safe when used during pregnancy. Of the other agents, there have been no adequate studies in pregnancy, so use should be limited to situations in which the benefits clearly outweigh any risks. Women infected with HIV are urged not to breast-feed. Tenofovir, zidovudine, and emtricitabine should be used with caution in the presence of hepatic dysfunction or severe renal impairment. Zidovudine should also be used with caution with any bone marrow suppression.

Adverse Effects

Serious-to-fatal hypersensitivity reactions have occurred with abacavir, and it must be stopped immediately at any sign of a hypersensitivity reaction (fever, chills, rash, fatigue, GI upset, flu-like symptoms). Patients exhibiting any signs of hypersensitivity should be listed with the Abacavir Hypersensitivity Registry, a drug follow-up registry that is maintained by the drug company and reported to the U.S. Food and Drug Administration.

Serious pancreatitis, hepatomegaly, and neurological problems have been reported with didanosine, which is why its use is limited to the treatment of advanced infections.

Emtricitabine has been associated with severe and even fatal hepatomegaly with steatosis.

Severe hepatomegaly with steatosis has been reported with tenofovir, so it must be used with extreme caution in any patient with hepatic impairment or lactic acidosis. Patients also need to be alerted that the drug may cause changes in body fat distribution, with loss of fat from arms, legs, and face and deposition of fat on the trunk, neck, and breasts.

It is not advisable to use zalcitabine during pregnancy, and women of childbearing age should use barrier contraceptives while taking this drug. Safety for use in children younger than 13 years has not been established. Severe and even fatal adverse reactions, including neuropathies, lactic acidosis, pancreatitis, and hepatic toxicity, have occurred with this drug. Use should be limited to severe or recalcitrant cases.

Severe bone marrow suppression has occurred with zidovudine.

Clinically Significant Drug–Drug Interactions

Tenofovir can cause large increases in the serum level of didanosine. If both of these drugs are given, tenofovir should be given 2 hours before or 1 hour after didanosine. Lamivudine and zalcitabine inhibit the effects of each other and should not be used together. Severe toxicity can occur if abacavir is combined with alcohol; this combination should be avoided. Didanosine can cause decreased effects of several antibiotics

and antifungals; any antibiotic or antifungal started with didanosine should be evaluated carefully. There is an increased risk of potentially fatal pancreatitis if stavudine is combined with didanosine and increased risk of severe hepatomegaly if it is combined with other nonnucleoside antivirals; these combinations are often used, and the patient needs to be monitored very closely. There have been reports of severe drowsiness and lethargy if zidovudine is combined with cyclosporine; warn the patient to take appropriate safety precautions.

Prototype Summary: Zidovudine

Indications: Management of adults with symptomatic HIV infection in combination with other antiretrovirals; prevention of maternal–fetal HIV transmission.

Actions: A thymidine analogue that is activated to a triphosphate form, which inhibits the replication of various retroviruses, including HIV.

Pharmacokinetics:

Route	Onset	Peak
Oral	Varies	30–90 min
IV	Rapid	End of infusion

$T_{1/2}$: 30 to 60 minutes; metabolized in the liver and excreted in the urine.

Adverse effects: Headache, insomnia, dizziness, nausea, diarrhea, fever, rash, bone marrow suppression.

Protease Inhibitors

The **protease inhibitors** block protease activity within the HIV virus. The protease inhibitors that are available for use include atazanavir (*Reyataz*), fosamprenavir (*Lexiva*), indinavir (*Crixivan*), lopinavir (*Kaletra*), nelfinavir (*Viracept*), ritonavir (*Norvir*), saquinavir (*Fortovase*), and tipranavir (*Aptivus*).

Therapeutic Actions and Indications

Protease is essential for the maturation of an infectious virus; without it, an HIV particle is immature and noninfective, unable to fuse with and inject itself into a cell. All of these drugs are used as part of combination therapy for the treatment of HIV infection (see Table 10.3).

Pharmacokinetics

Atazanavir is rapidly absorbed from the GI tract and can be taken with food. After metabolism in the liver, it is excreted in the urine and feces with a half-life of 6.5 to 7.9 hours. It is not recommended for patients with severe hepatic impairment; for those with moderate hepatic impairment, the dose should be reduced.

Fosamprenavir is rapidly absorbed after oral administration, reaching peak levels in 1.5 to 4 hours. It is metabolized in the liver and excreted in urine and feces.

Indinavir is rapidly absorbed from the GI tract, reaching peak levels in 0.8 hour. Indinavir is metabolized in the liver by the cytochrome P450 system. It is excreted in the urine with a half-life of 1.8 hours. Patients with hepatic or renal impairment are at risk for increased toxic effects, necessitating a reduction in dose.

Lopinavir is used as a fixed combination drug that combines lopinavir and ritonavir. The ritonavir inhibits the metabolism of lopinavir, leading to increased lopinavir serum levels and effectiveness. (Box 10.5 reviews the dose calculation with lopinavir.). It is readily absorbed from the GI tract, reaching peak levels in 3 to 4 hours, and undergoes extensive hepatic metabolism by the cytochrome P450 system. Lopinavir is excreted in urine and feces.

Tipranavir was approved in 2005 for the treatment of HIV infection in adults in combination with 200 mg of ritonavir. It is taken orally with food, two 250-mg capsules each day with the ritonavir. It is slowly absorbed, reaching peak levels in 2.9 hours. It is metabolized in the liver with a half-life of 4.8 to 6 hours; excretion is through urine and feces.

Nelfinavir is well absorbed from the GI tract, reaching peak levels in 2 to 4 hours. Nelfinavir is metabolized in the liver using the cytochrome P450 CY3A system, and caution must be used in patients with any hepatic dysfunction. It is primarily excreted in the feces, with a half-life of 3.5 to 5 hours. Because there is little renal excretion, this is considered a good drug for patients with renal impairment.

FOCUS BOX 10.5 Calculations

The health care provider prescribes lopinavir (*Kaletra*), 10 mg/kg, PO b.i.d. for a 14-year-old child weighing 50 kg. The drug comes in 200-mg tablets. How many tablets should the child receive at each dose?

To figure out the ordered dose, perform the following calculation:

$$10 \text{ mg/kg} \times 50 \text{ kg} = 500 \text{ mg/dose}$$

Then use

$$200 \text{ mg} (X) = 500 \text{ mg (tablets)}$$

$$X = 500 \text{ mg (tablets)}$$

$$200 \text{ mg}$$

$$X = 2.5 \text{ mg (tablets)}$$

You would give 2.5 of the 200-mg tablets.

You notice that it is also available in an 80-mg/mL solution. How much solution would you give?

$$\frac{500 \text{ mg}}{\text{dose}} = \frac{80 \text{ mg}}{\text{mL}}$$

$$80 \text{ mg(dose)} = 500 \text{ mg(mL)}$$

$$\text{Dose} = \frac{500 \text{ mg/(mL)}}{80 \text{ mg}}$$

$$\text{Dose} = 6.25 \text{ mL}$$

You would give 6.25 mL of the 80-mg/mL solution.

Ritonavir is rapidly absorbed from the GI tract, reaching peak levels in 2 to 4 hours. Ritonavir undergoes extensive metabolism in the liver and is excreted in feces and urine.

Saquinavir is slowly absorbed from the GI tract and is metabolized in the liver by the cytochrome P450 mediator, so it must be used cautiously in the presence of hepatic dysfunction. It is primarily excreted in the feces with a short half-life.

Because therapy for HIV infection involves the use of several different antiviral drugs, many are now available as combination drugs, which reduces the number of tablets a patient has to take each day. Box 10.6 discusses combination drugs.

Contraindications and Cautions

Of the protease inhibitors listed, saquinavir is the only agent that has not been shown to be teratogenic; however, its use during pregnancy should be limited. Saquinavir crosses into breast milk, and women are advised not to breast-feed while taking this drug. For the other agents, there are no adequate studies in pregnancy, so use should be limited to situations in which the benefits clearly outweigh any risks. It is suggested that women not breast-feed if they are infected with HIV.

BOX 10.6 Fixed Combination Drugs for Treatment of HIV Infection

Patients who are taking combination drug therapy for HIV infection may have to take a very large number of pills each day. Keeping track of these pills and swallowing such a large number each day can be an overwhelming task. In an effort to improve patient compliance and make it easier for some of these patients, some anti-HIV agents are now available in combination products.

Combivir is a combination of 150 mg lamivudine and 300 mg zidovudine. The patient takes one tablet twice a day. Because this is a fixed combination drug, it is not the drug of choice for patients who require a dose reduction owing to renal impairment or adverse effects that limit dose tolerance.

Trizivir combines 300 mg abacavir, 150 mg lamivudine, and 300 mg zidovudine. The patient takes one tablet twice a day. Because this is a fixed combination drug, it is not the drug of choice for patients who require a dose reduction owing to renal impairment or adverse effects that limit dose tolerance. Patients taking *Trizivir* should be warned at the time the prescription is filled about the potentially serious hypersensitivity reactions associated with abacavir and should be given a written list of warning signs to watch for.

In 2004, two new combination products were approved to help make compliance with an HIV drug regimen easier.

Epzicom (600 mg abacavir with 300 mg lamivudine) is taken as one tablet once a day. *Truvada* (200 mg emtricitabine with 300 mg tenofovir) is also a once-a-day tablet. Patient should be stabilized on each antiviral individually before being switched to the combination form.

The year 2006 saw another combination product, *Atripla*—600 mg efavirenz, 200 mg emtricitabine, and 300 mg tenofovir. *Atripla* is recommended for patients 18 years old and older who have already been stabilized on each antiviral individually.

Patients with mild to moderate hepatic dysfunction should receive a lower dose of fosamprenavir, and patients with severe hepatic dysfunction should not receive this drug because of its toxic effects on the liver. Patients receiving tipranavir must have liver function monitored regularly because of the possibility of potentially fatal liver dysfunction. Saquinavir must also be used cautiously in the presence of hepatic dysfunction.

The safety of indinavir for use in children younger than 12 years has not been established.

Adverse Effects

As with the other antivirals, patients taking these drugs often experience GI effects, including nausea, vomiting, diarrhea, anorexia, and changes in liver function. Elevated cholesterol and triglyceride levels may occur. There is often a redistribution of fat to a buffalo hump with thinning of arms and legs. Rashes, pruritus, and the potentially fatal Steven–Johnson syndrome have also occurred.

Clinical Significant Drug–Drug Interactions

Fosamprenavir should not be used in patients who are receiving ritonavir if they have used protease inhibitors to treat their disease because of a risk of serious adverse effects. If nelfinavir is combined with pimozone, rifampin, triazolam, or midazolam, severe toxic effects and life-threatening arrhythmias may occur. Such combinations should be avoided.

Indinavir and nevirapine interact to cause severe toxicity. If these two drugs are given in combination, the doses should be adjusted and the patient should be monitored closely.

Tipranavir and fosamprenavir have been shown to interact with many other drugs. Before administering these drugs, it is important to check a drug guide to assess for potential interactions with other drugs being given.

Many potentially serious toxic effects can occur when ritonavir is taken with nonsedating antihistamines, sedative/hypnotics, or antiarrhythmics because of the activity of ritonavir in the liver. Patients with hepatic dysfunction are at increased risk for serious effects when taking ritonavir and require a reduced dose and close monitoring.

Prototype Summary: Fosamprenavir

Indications: Management of adults with symptomatic HIV infection in combination with other antiretrovirals.

Actions: Inhibits protease activity, leading to the formation of immature, noninfectious virus particles.

Pharmacokinetics:

Route	Onset	Peak
Oral	Varies	1.5–4 min

$T_{1/2}$: 7.7 hours; metabolized in the liver and excreted in the feces and urine.

Adverse effects: Headache, mood changes, nausea, diarrhea, fatigue, rash, Stevens–Johnson syndrome, redistribution of body fat (buffalo hump, thin arms and legs).

Fusion Inhibitor

A new class of drug called a fusion inhibitor (Table 10.3) was introduced in 2003. This agent acts at a different site than do other HIV antivirals. The fusion inhibitor prevents the fusion of the virus with the human cellular membrane, which prevents the HIV-1 virus from entering the cell. Enfuvirtide (*Fuzeon*) is used in combination with other antiretroviral agents to treat adults and children older than 6 years who have evidence of HIV-1 replication despite ongoing antiretroviral therapy.

Enfuvirtide is given by subcutaneous injection and peaks in effect in 4 to 8 hours. After metabolism in the liver, it is recycled in the tissues and not excreted. The half-life of enfuvirtide is 3.2 to 4.4 hours. Enfuvirtide is contraindicated with hypersensitivity to any component of the drug and in nursing mothers. It should be used with caution in the presence of lung disease or pregnancy. The drug has been associated with insomnia, depression, peripheral neuropathy, nausea, diarrhea, pneumonia, and injection-site reactions. There are no reported drug interactions, but caution should be used when it is combined with any other drug.

Prototype Summary: Enfuvirtide

Indications: Treatment of HIV-1–infected patients who have experienced clinical or immunological deterioration after treatment with other agents, in combination with other antiretrovirals.

Actions: Prevents the entry of the HIV-1 virus into cells by inhibiting the fusion of the virus membrane with the cellular membrane.

Pharmacokinetics:

Route	Onset	Peak
Subcutaneous	Slow	4–8 h

$T_{1/2}$: 3.2 to 4.4 hours; metabolized in the liver, tissues recycle the amino acids, not excreted.

Adverse effects: Headache, nausea, vomiting, diarrhea, rash, anorexia, pneumonia, chills, injection-site reactions.

CCR5 Coreceptor Antagonist

In 2007, another new class of drugs was introduced for the treatment of HIV. Maraviroc (*Selzentry*) is a CCR5 coreceptor antagonist. It blocks the receptor site to which the HIV virus needs to interact to enter the cell. It is indicated for the treatment of HIV in adults as part of combination therapy with other antivirals. Maraviroc is rapidly absorbed from the GI tract, metabolized in the liver, and excreted primarily through the feces. It has a half-life of 14 to 18 hours. Maraviroc should not be used with known hypersensitivity to any component of the drug or by nursing mothers. Caution should be used in the presence of liver disease or coinfection with hepatitis B because of the risk of serious hepatic toxicity.

Patients at increased risk for cardiovascular events or with hypotension should be monitored very closely if this is the drug of choice for them. As with other antivirals, it should be used in pregnancy only if the benefit outweighs the potential risk to the fetus.

Severe hepatotoxicity has been reported with this drug, often preceded by a systemic allergic reaction with eosinophilia and rash. Regular monitoring of liver function should be routine when using this drug. CNS effects including dizziness and changes in consciousness have been reported; patients experiencing these should be cautioned to take measures to assure safety. Patients may also be at increased risk of infections because of the way the drug affects the cell membrane of the CD4 cells. Appropriate precautions are necessary.

There is a risk of increased serum levels and toxicity when combined with cytochrome P450 CYP3A inhibitors (ketoconazole, lopinavir/ritonavir, ritonavir, saquinavir, atazanavir, delavirdine), and the maraviroc dose should be adjusted accordingly. Decreased serum levels and loss of effectiveness may occur if maraviroc is combined with CYP3A inducers (nevirapine, rifampin, efavirenz), and the maraviroc dose should be adjusted accordingly. Patients should not use St. John's wort while on this drug because there is a loss of antiviral effects when the two are combined.

Prototype Summary: Maraviroc

Indications: Combination antiretroviral treatment of adults infected with CCR5-tropic HIV-1 who have evidence of viral replication and HIV-1 strains resistant to multiple antiretroviral agents.

Actions: Selectively binds to the human chemokine receptor CCR5 on the cell membrane, preventing interaction of HIV-1 and CCR5, which is necessary for the HIV to enter the cell; HIV cannot enter the cell and cannot multiply.

Pharmacokinetics:

Route	Onset	Peak
Oral	Slow	0.5–4 h

T_{1/2}: 14 to 28 hours; metabolized in the liver, excreted in the feces and urine.

Adverse effects: Dizziness, paraesthesias, nausea, vomiting, diarrhea, cough, URI, fever, musculoskeletal symptoms, hepatotoxicity.

Integrase Inhibitor

In late 2007, another class of drugs—integrase inhibitors—was introduced to treat HIV infection. The drug raltegravir (*Isentress*) belongs to this class. Raltegravir inhibits the activity of the virus-specific enzyme integrase, an encoded enzyme needed for viral replication. Blocking this enzyme prevents the formation of the HIV-1 provirus and leads to a decrease in viral load and increase in active CD4 cells. It is reserved for use in patients who have been treated with other antivirals

and have evidence of a return to viral replication. Raltegravir is rapidly absorbed from the GI tract and metabolized in the liver. It has a half-life of 3 hours and is excreted primarily in the feces.

Raltegravir is contraindicated with known hypersensitivity to any component of the drug, as initial treatment in adults, for use in children, and for nursing mothers. Caution should be used if the patient is at risk for rhabdomyolysis or myopathy and during pregnancy. Patients taking this drug must be very careful to continue the drug regimen to help decrease the development of resistant strains of the virus.

Common adverse effects include headache, dizziness, and an increase risk for the development of rhabdomyolysis and myopathy. There is a risk of decreased serum levels of raltegravir if it is combined with rifampin; the monitor patient and adjust the dose if this combination must be used. Patients should avoid the use of St. Johns wort, which can interfere with the drug's effectiveness.

Prototype Summary: Raltegravir

Indications: In combination with other antiviral agents for the treatment of HIV-1 infection in treatment-experienced adult patients who have evidence of viral replication and HIV-1 strains resistant to multiple antiretroviral agents.

Actions: Inhibits the activity of the virus-specific enzyme integrase, an encoded enzyme needed for viral replication. Blocking this enzyme prevents the formation of the HIV-1 provirus and leads to a decrease in viral load and an increase in active CD4 cells.

Pharmacokinetics:

Route	Onset	Peak
Oral	Rapid	3 h

T_{1/2}: 9 hours; metabolized in the liver, excreted in the feces and urine.

Adverse effects: Headache, dizziness, nausea, vomiting, diarrhea, fever, rhabdomyolysis.

Nursing Considerations for Patients Receiving Agents for HIV and AIDS

Assessment: History and Examination

- Assess for *contraindications and cautions to the use of these drugs*: any history of allergy to antivirals to avoid hypersensitivity reactions; renal or hepatic dysfunction that might interfere with the metabolism and excretion of the drug; and pregnancy or lactation because of possible adverse effects on the fetus or infant.
- Perform a physical assessment to establish baseline data for assessing the effectiveness of the drug and the occurrence of any adverse effects associated with drug therapy.
- Assess level of orientation and reflexes to evaluate any CNS effects of the drug.

- Examine the skin (color, temperature, and lesions) *to monitor for adverse effects of the drug.*
- Check temperature *to monitor for infections.*
- Evaluate hepatic and renal function tests *to determine base-line function of the kidneys and liver.* Check results of a complete blood count (CBC) with differential *to monitor bone marrow activity and T cell number to determine the severity of the disease and indicate the effectiveness of the drugs.*

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to GI, CNS, or dermatological effects of the drugs
- Disturbed Sensory Perception (Kinesthetic) related to CNS effects of the drugs
- Imbalanced Nutrition: Less Than Body Requirements related to GI effects of the drugs
- Risk for injury related to CNS effects of the drugs.
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Monitor renal and hepatic function before and periodically during therapy *to detect changes requiring dose adjustments or additional treatment as needed.*
- Ensure that the patient takes the complete course of the drug regimen and takes all drugs included in a particular combination *to improve the effectiveness of the drug and decrease the risk of emergence of resistant viral strains.*

- Administer the drug around the clock, if indicated, *to provide the critical concentration needed for the drug to be effective.*
- Monitor nutritional status if GI effects are severe, and take appropriate action *to maintain nutrition, including small, frequent meals and balanced nutrition to provide protein and other nutrients.*
- Stop drug if severe rash occurs, especially if accompanied by blisters, fever, and other signs, *to avert potentially serious reactions.*
- Provide safety precautions (e.g., the use of side rails, appropriate lighting, orientation, assistance) if CNS effects occur, *to protect patient from injury.*
- Teach the patient about the drugs prescribed *to enhance patient knowledge about drug therapy and to promote compliance.* Include as a teaching point the fact that these drugs do not cure the disease, so appropriate precautions should still be taken *to prevent transmission.*
- Provide the following patient teaching:
 - Have regular medical care.
 - Set up a regular schedule for taking all of your drugs at the correct time during the day.
 - Have periodic blood tests, which are necessary to monitor the effectiveness and toxicity of the drug.
 - Realize that GI upset, nausea, and vomiting may occur but that efforts must be taken to maintain adequate nutrition.
 - Avoid driving and hazardous tasks if dizziness or drowsiness occurs.
 - Report extreme fatigue, severe headache, difficulty breathing, or severe rash to a health care provider.

See the Critical Thinking Scenario for a case study and focused follow-up for the antiviral agents used for HIV and AIDS.

CRITICAL THINKING SCENARIO

Antiviral Agents for HIV and AIDS

THE SITUATION

H.P. is a 34-year-old attorney who was diagnosed with AIDS, having had a positive HIV test 3 years ago. Although his T cell count had been stabilized with treatment with zidovudine and efavirenz, it recently dropped remarkably. He presents with numerous opportunistic infections and Kaposi sarcoma. H.P. admits that he has been under tremendous stress at work and at home in the last few weeks. He begins a combination regimen of lamivudine, zidovudine, ritonavir, and zalcitabine.

CRITICAL THINKING

- What are the important nursing implications in this case?
- What role would stress play in the progress of this disease?
- What specific issues should be discussed?
- What other clinical implications should be considered?

DISCUSSION

Combination therapy with antivirals has been found to be effective in decreasing some of the morbidity and mortality associated with HIV and AIDS. However, this treatment does not cure the disease. H.P. needs to understand that opportunistic infections can still occur and that regular medical help should be sought. He also needs to understand that these drugs do not decrease the risk of transmitting HIV by sexual contact or through blood contamination and he should be encouraged to take appropriate precautions.

It is important to make a dosing schedule for H.P., or even to prepare a weekly drug box, to ensure that all medications are taken as indicated. H.P. should also receive interventions to help him decrease his stress because activation of the sympathetic nervous system during periods of stress depresses the immune system. Further depression of

Antiviral Agents for HIV and AIDS (continued)

his immune system could accelerate the development of opportunistic infections and decrease the effectiveness of his antiviral drugs. Measures that could be used to decrease stress should be discussed and tried with H.P.

Discussing the adverse effects that H.P. may experience is important because GI upset and discomfort may occur while he is taking all of these anti-HIV/AIDS medications. Small, frequent meals may help alleviate the discomfort. It is important that every effort be made to maintain H.P.'s nutritional state, and a nutritional consultation may be necessary if GI effects are severe. H.P. also may experience dizziness, fatigue, and confusion, which could cause more problems for him at work and may necessitate changes in his workload. Because some of the prescribed drugs must be taken around the clock, provisions may be needed to allow H.P. to take his drugs on time throughout the day. For example, he may need to wear an alarm wristwatch, establish planned breaks in his schedule at dosing times, or devise other ways to follow his drug regimen without interfering with his work schedule. The adverse effects and inconvenience of taking this many drugs may add to his stress. It is important that a health care provider work consistently with him to help him to manage his disease and treatment as effectively as possible.

NURSING CARE GUIDE FOR H.P.: ANTIVIRAL AGENTS FOR HIV AND AIDS

Assessment: History and Examination

Allergies to any of these drugs
 Bone marrow depression
 Renal or liver dysfunction
 Skin: color, lesions, texture
 CNS: affect, reflexes, orientation
 GI: abdominal and liver evaluation
 Hematological: CBC and differential; viral load; T-cell levels;
 renal and hepatic function tests

Nursing Diagnoses

Acute Pain related to GI, skin, CNS effects
 Disturbed Sensory Perception (Kinesthetic) related to CNS effects
 Imbalanced Nutrition: Less Than Body Requirements related to GI effects
 Deficient Knowledge regarding drug therapy

Implementation

Monitor CBC and differential before and every 2 weeks during therapy.
 Provide comfort and implement safety measures: assistance, temperature control, lighting control, mouth care, back rubs.
 Provide small, frequent meals and monitor nutritional status.
 Monitor for opportunistic infections and arrange treatment as indicated.
 Provide support and reassurance for dealing with drug effects and discomfort.

Provide patient teaching regarding drug name, dosage, adverse effects, warnings, precautions, use of OTC or herbal remedies, and signs to report.

Evaluation

Evaluate drug effects: relief of signs and symptoms of AIDS and AIDS-related complex (ARC) stabilization of T-cell levels.
 Monitor for adverse effects: GI alterations, dizziness, confusion, headache, fever.
 Monitor for drug–drug interactions as indicated for each drug.
 Evaluate effectiveness of patient teaching plan.
 Evaluate effectiveness of comfort and safety measures.

PATIENT TEACHING FOR H.P.

A combination of antiviral drugs has been prescribed to treat your HIV infection. These drugs work in combination to stop the replication of HIV, to control AIDS, and to maintain the functioning of your immune system. A schedule will be plotted out to show exactly when to take each of the drugs. It is very important that you take all of the drugs and that you stick to this schedule to ensure that the drugs can be effective and won't encourage the development of resistant strains of the virus.

These drugs are not a cure for HIV, AIDS, or ARC. Opportunistic infections may occur, and regular medical follow-up should be sought to deal with the disease.

These drugs do not reduce the risk of transmission of HIV to others by sexual contact or by blood contamination; use appropriate precautions.

Common effects of these drugs include the following:

- *Dizziness, weakness, and loss of feeling:* Change positions slowly. If you feel drowsy, avoid driving and dangerous activities.
- *Headache, fever, muscle aches:* Analgesics may be ordered to alleviate this discomfort. Consult with your health care provider.
- *Nausea, loss of appetite, change in taste:* Small, frequent meals may help. It is important to try to maintain good nutrition. Consult your health care provider if this becomes a severe problem.
- Report any of the following to your health care provider: excessive fatigue, lethargy, severe headache, difficulty breathing, or skin rash.
- Avoid over-the-counter medications and herbal therapies; many of them interact with your drugs and may make them ineffective. If you feel that you need one of these, check with your health care provider first.
- Schedule regular medical evaluations, including blood tests, which are needed to monitor the effects of these drugs on your body and to adjust doses as needed.
- Tell any doctor, nurse, or other health care provider that you are taking these drugs.
- Keep these drugs and all medications out of the reach of children. Do not share these drugs with other people.

Evaluation

- Monitor patient response to the drug (alleviation or reduction of signs and symptoms of AIDS or ARC and maintenance of T cell levels).
- Monitor for adverse effects (level of orientation and affect, GI upset, renal and hepatic function, skin, levels of blood components).
- Evaluate the effectiveness of the teaching plan (patient can name the drug, dosage, possible adverse effects to watch for, and specific measures to help avoid adverse effects).
- Monitor the effectiveness of comfort and safety measures and compliance with the regimen.

KEY POINTS

- ▶ The HIV virus infects helper T cells, leading to a loss of immune function and the development of opportunistic infections.
- ▶ Drugs used to treat HIV usually are given in combination to affect the virus at various points in the body: nonnucleoside and nucleoside reverse transcriptase inhibitors block RNA and DNA activity in the cell; protease inhibitors prevent maturation of the virus; fusion inhibitors prevent the entry of the virus into the cell; CCR5 coreceptor antagonists prevent the virus from reacting with the receptor on the cell membrane, preventing its entry into the cell; and integrase inhibitors block an enzyme essential for formation of the provirus within the cell, leading to decrease in the number of viruses.
- ▶ Patients taking drugs to treat HIV need to take all of the medications continuously as prescribed and take precautions to prevent the spread of the disease to others.

ANTI-HEPATITIS B AGENTS

Hepatitis B is a serious-to-potentially fatal viral infection of the liver. The hepatitis B virus can be spread by blood or

blood products, sexual contact, or contaminated needles or instruments. Health care workers are at especially high risk for contracting hepatitis B due to needle sticks. Hepatitis B has a higher mortality than other types of hepatitis. Individuals infected may also develop a chronic condition or become a carrier. In the past, hepatitis B was treated with interferons (see Chapter 17). In 2004 and 2005, adefovir (*Hepsera*) and entecavir (*Baraclude*) were approved specifically for treating chronic hepatitis B. In 2006, another nucleoside reverse transcriptase inhibitor, telbivudine (*Tyzeka*) was found to be very effective in preventing viral replication in active hepatitis B patients (see Table 10.4).

Therapeutic Actions and Indications

All three of these antiviral drugs are indicated for the treatment of adults with chronic hepatitis B who have evidence of active viral replication and either evidence of persistent elevations in serum aminotransferases or histologically active disease. The drugs inhibit reverse transcriptase in the hepatitis B virus and cause DNA chain termination, leading to blocked viral replication and decreased viral load (see Table 10.4).

Pharmacokinetics

These drugs are rapidly absorbed from the GI tract, with peak effects occurring in 0.5 to 1.5 hours (entecavir), 0.5 to 4 hours (adefovir), and 1 to 4 hours (telbivudine). Entecavir and adefovir are metabolized in the liver and excreted in the urine. Telbivudine is excreted unchanged in the urine. Adefovir has a half-life of 7.5 hours; entecavir has a half-life of 128 to 149 hours; and telbivudine has a half-life of 40 to 49 hours. It is not known whether any of these drugs crosses the placenta or enters breast milk.

Contraindications and Cautions

These drugs are contraindicated with any known allergy to the drugs and with lactation because of potential toxicity to the infant. Use caution when administering these drugs to patients

TABLE 10.4 DRUGS IN FOCUS Anti-Hepatitis B Agents

Drug Name	Dosage/Route	Usual Indications
 adefovir (<i>Hepsera</i>)	Adult: 10 mg/d PO Renal impairment: CrCl 20–40 mL/min: 10 mg PO q48h CrCl 10–19 mL/min: 10 mg PO q72h	Treatment of hepatitis B with evidence of active viral replication and persistent elevations in liver enzymes
entecavir (<i>Baraclude</i>)	Adults and children (≥ 16 yr): 0.5 mg/d; also receiving lamivudine: 1 mg/d Reduce dose with renal impairment	Treatment of chronic hepatitis B in adults with evidence of active viral replication and persistent liver enzyme elevations
telbivudine (<i>Tyzeka</i>)	Adults and children >16 yr: 600 mg/d PO; reduce dose with renal impairment	Treatment of chronic hepatitis B in patients >16 yr with evidence of viral replication and persistent liver enzyme elevations

CrCl, creatinine clearance.

with renal impairment and severe liver disease and those who are pregnant.

Adverse Effects

The adverse effects most frequently seen with these drugs are headache, dizziness, nausea, diarrhea, and elevated liver enzymes. Severe hepatomegaly with steatosis, sometimes fatal, has been reported with adefovir and telbivudine use. Lactic acidosis and renal impairment have been reported with entecavir and adefovir. A potential risk for hepatitis B exacerbation could occur when the drugs are stopped. Therefore, teach patients the importance of not running out of their drugs and use extreme caution when discontinuing these drugs.

Clinically Important Drug-Drug Interactions

There is an increased risk of renal toxicity if these drugs are taken with other nephrotoxic drugs. If such a combination is used, monitor the patient closely. An evaluation of risks versus benefits may be necessary if renal function begins to deteriorate.

Prototype Summary: Adefovir

Indications: Treatment of chronic hepatitis B in adults with evidence of active viral replication and either evidence of persistent elevations in alanine aminotransferase (ALT) and aspartate aminotransferase (AST) or histologically active disease.

Actions: Inhibits hepatitis B virus reverse transcriptase, causes DNA chain termination, and blocks viral replication.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	Rapid	0.6–4 h	Unknown

$T_{1/2}$: 7.5 hours; excreted in the urine.

Adverse effects: Headache, asthenia, nausea, severe-to-fatal hepatomegaly with steatosis, nephrotoxicity, lactic acidosis, exacerbation of hepatitis B when discontinued.

Nursing Considerations for Patients Receiving Anti-Hepatitis B Agents

Assessment: History and Examination

- Assess for *contraindications or cautions*: any history of allergy to adefovir or entecavir *to avoid hypersensitivity reactions*; renal dysfunction, *which could be exacerbated by the nephrotoxic effects of these drugs*; severe liver impairment, *which could affect the metabolism and exacerbate the liver toxicity of these drugs*; and pregnancy and lactation *because the potential effects of these drugs on the fetus or baby are not known*.
- Perform a physical assessment *to establish baseline data for assessing the effectiveness of these drugs and the occurrence of any adverse effects associated with drug toxicity*.
- Assess body temperature *to monitor underlying disease*.
- Assess level of orientation and reflexes *to assess for CNS changes*.

- Evaluate renal and liver function tests *to monitor for developing toxicity and to determine drug effectiveness*.

Nursing Diagnoses

Nursing diagnoses related the drug therapy might include the following:

- Acute Pain related to CNS and GI effects of the drug
- Imbalanced Nutrition: Less Than Body Requirements related to the GI effects of the drug
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Monitor renal and hepatic function prior to and periodically during therapy *to detect renal or hepatic function changes and determine the need for possible dose reduction or institute treatment as needed*.
- Withdraw the drug and monitor the patient if he or she develops signs of lactic acidosis or hepatotoxicity *because these adverse effects can be life threatening*.
- Caution patient to not run out of this drug but to take it continually *because acute exacerbation of hepatitis B can occur when the drug is stopped*.
- Advise women of childbearing age to use barrier contraceptives *because the potential adverse effects of this drug on the fetus are not known*.
- Advise women who are breast-feeding to find another method of feeding the baby while using the drug *because the potential toxic effects on the baby are not known*.
- Advise patients that these drugs do not cure the disease and there is still a risk of transferring the disease, *so the patient should continue to take appropriate steps to prevent transmission of hepatitis B*.
- Instruct the patient about the drug prescribed *to enhance patient knowledge about drug therapy and to promote compliance*.
- Provide the following patient teaching:
 - Have regular blood tests and medical follow-up.
 - Take precautions to avoid running out of the drug because it must be taken continually.
 - Realize that GI upset, with nausea and diarrhea, is common with this drug.
 - Report severe weakness, muscle pain, palpitations, yellowing of the eyes or skin, and trouble breathing.

Evaluation

- Monitor patient response to the drug (decreased viral load of hepatitis B).
- Monitor for adverse effects (liver or renal dysfunction, headache, nausea, diarrhea).
- Evaluate the effectiveness of the teaching plan (patient can name the drug, dosage, possible adverse effects to watch for, and specific measures to avoid adverse effects).
- Monitor the effectiveness of comfort and safety measures and compliance with the drug regimen.

KEY POINTS

- ▶ Hepatitis B is a serious-to-potentially fatal viral infection of the liver spread by blood or blood products, sexual contact, or contaminated needles or instruments. Hepatitis B has a higher mortality than other types of hepatitis.
- ▶ Prevention of infection through use of hepatitis B vaccines and avoiding exposure is essential in stopping the spread of this disease.
- ▶ Hepatitis B used to be treated only with interferons and rest. Entecavir, adefovir, and telbivudine are antivirals now available for the treatment of hepatitis B.

LOCALLY ACTIVE ANTIVIRAL AGENTS

Some antiviral agents are given locally to treat local viral infections. These agents include docosanol (*Abreva*), ganciclovir (*Vitrasert*), imiquimod (*Aldara*), penciclovir (*Denavir*), and trifluridine (*Viroptic*).

Therapeutic Actions and Indications

These antiviral agents act on viruses by interfering with normal viral replication and metabolic processes. They are indicated for specific, local viral infections (see Table 10.5).

Contraindications and Cautions

Locally active antiviral drugs are not absorbed systemically, but caution must be used in patients with known allergic reactions to any topical drugs.

Adverse Effects

Because these drugs are not absorbed systemically, the adverse effects most commonly reported are local burning, stinging, and discomfort. These effects usually occur at the time of administration and pass with time.

Nursing Considerations for Patients Receiving Locally Active Antiviral Agents

Assessment: History and Examination

- Assess for history of allergy to antivirals *to avoid allergic response to these drugs.*
- Perform a physical assessment *to establish baseline data for evaluating the effectiveness of the drug and the occurrence of any adverse effects associated with drug therapy:*
 - Assess the infected area, including location, size, and character of lesions.
 - Evaluate for signs of inflammation at the site of infection.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to local effects of the drug
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Ensure proper administration of the drug *to improve effectiveness and decrease risk of adverse effects.*
- Stop the drug if severe local reaction occurs or if open lesions occur near the site of administration *to prevent systemic absorption and adverse effects.*
- Instruct the patient about the drug being used *to enhance patient knowledge about drug therapy and to promote compliance.* Include as a teaching point the fact that these drugs do not cure the disease but should alleviate discomfort and prevent damage to healthy tissues. Encourage the patient to report severe local reaction or discomfort.

Evaluation

- Monitor patient response to the drug (alleviation of signs and symptoms of viral infection).
- Monitor for adverse effects (local irritation and discomfort).
- Evaluate the effectiveness of the teaching plan (patient can name the drug, the dosage, proper administration)

TABLE 10.5 DRUGS IN FOCUS Locally Active Antiviral Agents

Drug Name	Usual Indications
docosanol (<i>Abreva</i>)	Local treatment of oral and facial herpes simplex cold sores and fever blisters
ganciclovir (<i>Vitrasert</i>)	Implanted for treatment of CMV in patients with AIDS
imiquimod (<i>Aldara</i>)	Local treatment of genital and perianal warts
penciclovir (<i>Denavir</i>)	Local treatment of herpes labialis (cold sores) on the face and lips
trifluridine (<i>Viroptic</i>)	Ophthalmic ointment to treat herpes simplex infections in the eye

technique, and adverse effects to watch for and report to a health care provider).

- Monitor the effectiveness of comfort and safety measures and compliance with the regimen.

KEY POINTS

- ▶ Some antivirals are available only for the local treatment of viral infections, including warts and eye infections.
- ▶ Topical antivirals should not be applied to open wounds; local reactions can occur with administration.

CHAPTER SUMMARY

- Viruses are particles of DNA or RNA surrounded by a protein coat that survive by injecting their own DNA or RNA into a healthy cell and taking over its functioning.
- Because viruses are contained within human cells, it has been difficult to develop drugs that are effective antivirals and yet do not destroy human cells. Antiviral agents are available that are effective against only a few types of viruses.
- Influenza A and respiratory viruses cause the signs and symptoms of the common cold or “flu.” The drugs that are available to prevent the replication of these viruses are used for prophylaxis against these diseases during peak seasons and to treat disease when it occurs.
- Herpes viruses and CMV are DNA viruses that cause a multitude of problems, including cold sores, encephalitis, infections of the eye and liver, and genital herpes.
- Helper T cells are essential for maintaining a vigilant, effective immune system. When these cells are decreased in number or effectiveness, opportunistic infections occur. AIDS and ARC are syndromes of opportunistic infections that occur when the immune system is depressed.

- HIV, which specifically attacks helper T cells, may remain dormant in T cells for long periods and has been known to mutate easily.
- Antiviral agents that are effective against HIV and AIDS include nonnucleoside and nucleoside reverse transcriptase inhibitors, protease inhibitors, fusion inhibitors, CCR5 coreceptor antagonists, and integrase inhibitors, all of which affect the way the virus communicates, replicates, or matures within the cell. These drugs are known as anti-retroviral agents. They are given in combination to most effectively destroy the HIV virus and prevent mutation.
- Recently three drugs have been approved to treat hepatitis B infection: adefovir, entecavir, and telbivudine.
- Some antivirals are available only for the local treatment of viral infections, including warts and eye infections. These drugs are not absorbed systemically.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-Rom in the front of this book.

MULTIPLE CHOICE

Select the best answer to the following.

1. In assessing a patient, a viral cause might be suspected if the patient was diagnosed with
 - a. tuberculosis.
 - b. leprosy.
 - c. the common cold.
 - d. gonorrhea.
2. Virus infections have proved difficult to treat because they
 - a. have a protein coat.
 - b. inject themselves into human cells to survive and to reproduce.
 - c. are bits of RNA or DNA.
 - d. easily resist drug therapy.
3. Naturally occurring substances that are released in the body in response to viral invasion are called
 - a. antibodies.
 - b. immunoglobulins.
 - c. interferons.
 - d. interleukins.

4. Herpes viruses cause a broad range of conditions but have not been identified as the causative agent in
 - a. cold sores.
 - b. shingles.
 - c. genital infections.
 - d. leprosy.
5. Which of the following would be an important teaching point for the patient receiving an agent to treat herpes virus or CMV?
 - a. Stop taking the drug as soon as the lesions have disappeared.
 - b. Sexual intercourse is fine—as long as you are taking the drug, you are not contagious.
 - c. Drink plenty of fluids to decrease the drug's toxic effects on the kidneys.
 - d. There are few if any associated GI adverse effects.
6. HIV selectively enters which of the following cells:
 - a. B clones.
 - b. helper T cells.
 - c. suppressor T cells.
 - d. cytotoxic T cells.
7. Nursing interventions for the patient receiving antiviral drugs for the treatment of HIV probably would include
 - a. monitoring renal and hepatic function periodically during therapy.
 - b. administering the drugs just once a day to increase drug effectiveness.
 - c. encouraging the patient to avoid eating if GI upset is severe.
 - d. stopping the drugs and notifying the prescriber if severe rash occurs.
8. Locally active antiviral agents can be used to treat
 - a. HIV infection.
 - b. warts.
 - c. RSV.
 - d. CMV systemic infections.

MULTIPLE RESPONSE

Select all that apply.

1. When explaining to a client the reasoning behind using combination therapy in the treatment of HIV, the nurse would include which of the following points?
 - a. The virus can remain dormant within the T cell for a very long time; they can mutate while in the T cell.
 - b. Adverse effects of many of the drugs used to treat this virus include immunosuppression, so the disease could become worse
 - c. The drugs are cheaper if used in combination.
 - d. The virus slowly mutates with each generation.
 - e. Attacking the virus at many points in its life cycle has been shown to be most effective.
 - f. Research has shown that using only one type of drug that targeted only one point in the virus life cycle led to more mutations and more difficulty in controlling the disease.
2. Appropriate nursing diagnoses related to the drug therapy for a patient receiving combination antiviral therapy for the treatment of HIV infection would include the following:
 - a. Disturbed Sensory Perception (Kinesthetic) related to the CNS effects of the drugs.
 - b. Imbalanced Nutrition: More Than Body Requirements related to appetite stimulation.
 - c. Heart Failure related to cardiac effects of the drugs.
 - d. Adrenal Insufficiency related to endocrine effects of the drugs.
 - e. Acute Pain related to GI, CNS, or dermatological effects of the drugs.
 - f. Deficient Knowledge regarding drug therapy.

Antifungal Agents

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Describe the characteristics of a fungus and a fungal infection.
2. Discuss the therapeutic actions, indications, pharmacokinetics, contraindications, proper administration, most common adverse reactions, and important drug–drug interactions associated with systemic and topical antifungals.
3. Compare and contrast the prototype drugs for systemic and topical antifungals with the other drugs in each class.
4. Discuss the impact of using antifungals across the lifespan.
5. Outline the nursing considerations for patients receiving a systemic or topical antifungal.

Glossary of Key Terms

azoles: a group of drugs used to treat fungal infections

Candida: fungus that is normally found on mucous membranes; can cause yeast infections or thrush of the GI tract and vagina in immunosuppressed patients

ergosterol: steroid-type protein found in the cell membrane of fungi; similar in configuration to adrenal hormones and testosterone

fungus: a cellular organism with a hard cell wall that contains chitin and many polysaccharides, as well as a cell membrane that contains ergosterols

mycosis: disease caused by a fungus

tinea: fungus called ringworm that causes such infections as athlete's foot, jock itch, and others

SYSTEMIC ANTIFUNGALS

Azole Antifungals

- P** fluconazole
- itraconazole
- ketoconazole
- posaconazole
- terbinafine
- voriconazole

Echinocandin Antifungals

- anidulafungin

- caspofungin
- micafungin

Other Antifungals

- amphotericin B
- flucytosine
- griseofulvin
- nystatin

TOPICAL ANTIFUNGALS

Azole Topical Antifungals

- butoconazole

- P** clotrimazole
- econazole
- ketoconazole
- miconazole
- oxiconazole
- sertaconazole
- sulconazole
- terbinafine
- terconazole
- tioconazole

Other Topical Antifungals

- butenafine
- ciclopirox
- gentian violet
- naftifine
- tolnaftate
- undecylenic acid

Fungal infections in humans range from conditions such as the annoying “athlete’s foot” to potentially fatal systemic infections. An infection caused by a **fungus** is called a **mycosis**. Fungi differ from bacteria in that the fungus has a rigid cell wall that is made up of chitin and various polysaccharides and a cell membrane that contains **ergosterol**. The composition of the protective layers of the fungal cell makes the organism resistant to antibiotics. Conversely, because of their cellular makeup, bacteria are resistant to antifungal drugs.

The incidence of fungal infections has increased with the rising number of immunocompromised individuals—patients with acquired immune deficiency syndrome (AIDS) and AIDS-related complex (ARC), those taking immunosuppressant drugs, those who have undergone transplantation surgery or cancer treatment, and members of the increasingly large elderly population, whose body is no longer able to protect itself from the many fungi that are found throughout the environment (Box 11.1). For example, *Candida*, a fungus that is normally found on mucous membranes, can cause yeast infections or “thrush” in the gastrointestinal (GI) tract and yeast infections or “vaginitis” in the vagina.

SYSTEMIC ANTIFUNGALS

The drugs used to treat systemic fungal infections (Table 11.1) can be toxic to the host and are not used indiscriminately. It is important to get a culture of the fungus causing the infection

to ensure that the right drug is being used so that the patient is not put at additional risk from the toxic adverse effects associated with these drugs.

Azole Antifungals

The **azoles** are a large group of antifungals used to treat systemic and topical fungal infections (Table 11.1). The azoles include fluconazole (*Diffucan*), itraconazole (*Sporanox*), ketoconazole (*Nizoral*), posaconazole (*Noxafil*), terbinafine (*Lamisil*), and voriconazole (*Vfend*). Although azoles are considered less toxic than some other antifungals, such as amphotericin B, they may also be less effective in very severe and progressive infections.

Therapeutic Actions and Indications

These drugs bind to sterols and can cause cell death (a fungicidal effect) or interfere with cell replication (a fungistatic effect), depending on the type of fungus being affected and the concentration of the drug. (See Figure 11.1).

Ketoconazole, fluconazole, and itraconazole work by blocking the activity of a sterol in the fungal wall. In addition, they may block the activity of human steroids, including testosterone and cortisol (see usual indications in Table 11.1).

Posaconazole is one of the newest antifungals (see Table 11.1 for uses). This drug and voriconazole inhibit the synthesis of ergosterol, which leads to the inability of the

BOX 11.1

Drug Therapy Across the Lifespan

Antifungal Agents

CHILDREN

Children are very sensitive to the effects of most antifungal drugs, and more severe reactions can be expected when these drugs are used in children.

Many of these drugs do not have proven safety and efficacy in children, and extreme caution should be exercised when using them. Fluconazole, ketoconazole, terbinafine, and griseofulvin have established pediatric doses and would be drugs of choice if appropriate for a particular infection.

Topical agents should not be used over open or draining areas that would increase the risk of systemic absorption and toxicity. Occlusive dressings, including tight diapers, should be avoided over the affected areas.

ADULTS

These drugs can be very toxic to the body, and their use should be reserved for situations in which the causative organism has been identified. Over-the-counter topical preparations are widely used, and patients should be cautioned to follow the instructions and to report continued problems to their health care provider.

Pregnant and nursing women should not use these drugs unless the benefit clearly outweighs the potential risk to the

fetus or neonate. Women of childbearing age should be advised to use barrier contraceptives if any of these drugs are used. A severe fungal infection may threaten the life of the mother and/or fetus; in these situations, the potential risk of treatment should be carefully explained.

Topical agents should not be used over open or draining areas, which would increase the risk of systemic absorption.

OLDER ADULTS

Older patients may be more susceptible to the adverse effects associated with these drugs and should be monitored closely.

Patients with hepatic dysfunction are at increased risk for worsening hepatic problems and toxic effects of many of these drugs (ketoconazole, itraconazole, griseofulvin). If hepatic dysfunction is expected (extreme age, alcohol abuse, use of other hepatotoxic drugs), the dose may need to be lowered and the patient monitored more frequently.

Other agents are associated with renal toxicity (flucytosine, fluconazole, griseofulvin) and should be used cautiously in the presence of renal impairment. Patients at risk for renal toxicity should be monitored carefully.

TABLE 11.1 DRUGS IN FOCUS Systemic Antifungals

Drug Name	Dosage/Route	Usual Indications
Azole Antifungals		
<p> fluconazole (<i>Diflucan</i>)</p>	<p>Adult: 200–400 mg PO on day 1, followed by 100 mg/d PO; IV route can be used, but do not exceed 200 mg/h Pediatric: 3–6 mg/kg PO; do not exceed 12 mg/kg</p>	<p>Treatment of candidiasis, cryptococcal meningitis, other systemic fungal infections; prophylaxis for reducing the incidence of candidiasis in bone marrow transplant recipients</p>
itraconazole (<i>Sporanox</i>)	<p>Adult: 100–400 mg/d PO Pediatric: safety and efficacy not established</p>	Treatment of blastomycosis, histoplasmosis, and aspergillosis
<p>ketoconazole (<i>Nizoral</i>, <i>Xolegel</i>)</p>	<p>Adult: 200 mg/d PO, up to 400 mg/d PO in severe cases Pediatric (≥ 2 yr): 3.3–6.6 mg/kg per day PO Pediatric (< 2 yr): safety not established Topical: as a shampoo and topical</p>	Treatment of aspergillosis, leishmaniasis, cryptococcosis, blastomycosis, moniliasis, coccidioidomycosis, histoplasmosis, and mucormycosis; topical treatment of mycoses (cream), and to reduce the scaling of dandruff (shampoo)
posaconazole (<i>Noxafil</i>)	<p>Adults and children ≥ 13 yr: 200 mg PO t.i.d. with food</p>	Prophylaxis of invasive <i>Aspergillus</i> and <i>Candida</i> infections in adults and children > 13 yr who are immunosuppressed secondary to antineoplastic, chemotherapy, graft-versus-host disease following transplants, or hematological malignancies
terbinafine (<i>Lamisil</i>)	<p>250 mg/d PO for 6 wk (fingernail) or 12 wk (toenail) Pediatric: 125–250 mg/d PO for 6 wk (sprinkle capsules)</p>	Treatment of onychomycosis of the fingernail or toenail caused by dermatophytes; the drug was approved in late 2007 for treatment of tinea capitis (ringworm of the scalp) in children ≥ 4 yr
voriconazole (<i>Vfend</i>)	<p>Adult: 6 mg/kg IV q12h for two doses, then 4 mg/kg IV q12h; switch to oral dose as soon as possible > 40 kg: 200 mg PO q12h < 40 kg: 100 mg PO q12h</p>	Treatment of invasive aspergillosis; treatment of serious fungal infections caused by <i>Scedosporium apiospermum</i> or <i>Fusarium</i> species when the patient is intolerant to or not responding to other therapy
Echinocandin Antifungals		
anidulafungin (<i>Eraxis</i>)	<p>100–200 mg IV on day 1, then 50–100 mg/d IV for 14 d; dose varies with infection being treated</p>	Treatment of candidemia (infection of the blood stream) and other forms of <i>Candida</i> infection, intraabdominal infections, and esophageal candidiasis
casprofungin acetate (<i>Cancidas</i>)	<p>Adult: 70 mg/d IV loading dose, then 50 mg/d IV infusion; dose should be reduced to 35 mg/d IV infusion with hepatic impairment</p>	Treatment of invasive aspergillosis in patients who do not respond or are intolerant to other therapies
micafungin (<i>Mycamine</i>)	<p><i>Esophageal candidiasis:</i> Adult: 150 mg/d IV over 1 h for 6–30 d Prophylaxis: 50 mg/d IV over 1 h for about 19 d</p>	Treatment of patients with esophageal candidiasis; prophylaxis of <i>Candida</i> infections in patients with hematopoietic stem cell transplant
Other Antifungals		
amphotericin B (<i>Abelcet</i> , <i>Amphotec</i> , <i>AmBisome</i> , <i>Fungizone</i>)	<p>0.25–1.5 mg/kg per day IV based on the infection being treated</p>	Treatment of aspergillosis, leishmaniasis, cryptococcosis, blastomycosis, moniliasis, coccidioidomycosis, histoplasmosis and mucormycosis; use is reserved for progressive, potential fatal infections due to many associated adverse effects
flucytosine (<i>Ancobon</i>)	<p>50–150 mg/kg per day PO in divided doses at 6-h intervals</p>	Treatment of systemic infections caused by <i>Candida</i> or <i>Cryptococcus</i>
griseofulvin (generic)	<p>Tinea corporis, tinea cruris, and tinea capitis: Adult: 500 mg (microsize) or 330–375 mg/d (ultramicrosize) PO Tinea pedis and tinea unguium: Adult: 0.75–1 g (microsize) or 660–750 mg (ultramicrosize) PO daily Pediatric (> 2 yr): 11 mg/kg per day (microsize) or 7.3 mg (ultramicrosize) PO daily (not recommended for children ≤ 2 yr)</p>	Treatment of variety of ringworm or tinea infections caused by susceptible <i>Trichophyton</i> species, including tinea corporis, tinea pedis, tinea cruris, tinea barbae, tinea capitis, and tinea unguium
nystatin (<i>Mycostatin</i> , <i>Nilstat</i> , <i>Nystex</i>)	<p>500,000–1,000,000 units t.i.d. PO; continue for 48 h after resolution to prevent relapse; also used topically</p>	Treatment of candidiasis (oral form); treatment of local candidiasis, vaginal candidiasis, and cutaneous and mucocutaneous infections caused by <i>Candida</i> species

● **FIGURE 11.1** Sites of action of antifungal agents. Both systemic and topical antifungals alter fungal cell permeability, leading to prevention of replication and cell death.

fungus to form a cell wall, which results in cell death. Terbinafine is a similar drug that blocks the formation of ergosterol. It inhibits a cytochrome P450 2D6 (CYP2D6) enzyme system, so it may be a better choice for patients who need to take drugs metabolized by the cytochrome P450 (CYP450) system. It is available in a sprinkle formulation for children.

Pharmacokinetics

Ketoconazole, itraconazole, posaconazole, and terbinafine are administered orally. Ketoconazole is also available as a shampoo and a cream, and terbinafine is also available in a sprinkle formulation for children.

Fluconazole and voriconazole are available in oral and intravenous (IV) preparations, making it possible to start the drug intravenously for a serious infection and then switch to an oral form when the patient's condition improves and he or she is able to take oral medications.

Ketoconazole is absorbed rapidly from the GI tract, with peak levels occurring within 1 to 3 hours. It is extensively metabolized in the liver and excreted through the feces. Fluconazole reaches peak levels within 1 to 2 hours after administration. Most of the drug is excreted unchanged in the urine, so extreme caution should be used in the presence of renal dysfunction. Itraconazole is slowly absorbed from the GI tract and is metabolized in the liver by the CYP450 system. It is

excreted in the urine and feces. Posaconazole is given orally, has a rapid onset of action, and peaks within 3 to 5 hours. It is metabolized in the liver and excreted in the feces. Terbinafine is rapidly absorbed from the GI tract, extensively metabolized in the liver, and excreted in the urine with a half-life of 36 hours. Voriconazole reaches peak levels in 1 to 2 hours if given orally, and at the onset of the infusion if given IV. It is metabolized in the liver with a half-life of 24 hours and is excreted in the urine.

Contraindications and Cautions

Ketoconazole has been associated with severe hepatic toxicity and should be avoided in patients with hepatic dysfunction. In addition, ketoconazole is not the drug of choice for patients with endocrine or fertility problems. Although fluconazole should be used with caution in the presence of liver or renal impairment, fluconazole is not associated with the endocrine problems seen with ketoconazole.

Itraconazole has been associated with hepatic failure, should not be used in patients with hepatic failure, and should be used with caution in those with hepatic impairment. It is not known whether posaconazole crosses the placenta or enters breast milk, so it should not be used during pregnancy or lactation unless the benefits clearly outweigh the potential risks. Caution should be used if posaconazole is used in the presence of liver impairment. Carefully monitor patients for bone marrow suppression and GI

and liver toxicity if using this drug. Terbinafine has been associated with severe liver toxicity and is contraindicated with liver failure. It may cross the placenta and may enter breast milk, and so it should not be used in pregnant or nursing women because of the potential toxic effects on the fetus or baby.

Voriconazole should not be used with any other drugs that prolong the QT_c interval and can cause ergotism if taken with ergot alkaloids.

Safe Medication Administration

Name confusion has occurred between *Lamisil* (terbinafine) and *Lamictal* (lamotrigine, an antiepileptic agent). Use extreme caution if your patient is receiving either of these drugs to make sure that the correct drug is being used.

Adverse Effects

Many of the azoles are associated with liver toxicity and can cause severe effects on a fetus or nursing baby.

Clinically Important Drug–Drug Interactions

Ketoconazole and fluconazole strongly inhibit the CYP450 enzyme system in the liver and are associated with many drug–drug interactions, such as increased serum levels of the following agents: cyclosporine, digoxin, oral hypoglycemics, warfarin, oral anticoagulants, and phenytoin. If these combinations cannot be avoided, closely monitor patients and anticipate the need for dose adjustments. A drug guide should be consulted any time one of these drugs is added to or removed from a drug regimen. Itraconazole has a black box warning regarding the potential for serious cardiovascular effects if it is given with lovastatin, simvastatin, triazolam, midazolam, pimozide, or dofetilide. These combinations should be avoided. Voriconazole and posaconazole should not be used with any other drugs that prolong the QT_c interval and can cause ergotism if taken with ergot alkaloids. Box 11.2 highlights important information about hazardous interactions between voriconazole and posaconazole and the herb ergot.

Echinocandin Antifungals

The echinocandin antifungals are another group of antifungals. Drugs in this class include anidulafungin, caspofungin, and micafungin.

BOX 11.2 Herbal and Alternative Therapies

Patients being treated with voriconazole or posaconazole should be cautioned about the risk of ergotism if they combine this drug with ergot, an herb frequently used to treat migraine headache and menstrual problems. If the patient is using voriconazole, it should be suggested that ergot not be used until the antifungal therapy is finished.

Therapeutic Actions and Indications

The echinocandins work by inhibiting glucan synthesis. Glucan is an enzyme that is present in the fungal cell wall but not in human cell walls. If this enzyme is inhibited, the fungal cell wall cannot form, leading to death of the cell wall. See Table 11.1 for usual indications for each of these agents.

Pharmacokinetics

Anidulafungin is given as a daily IV infusion for at least 14 days. It has a rapid onset of action, is metabolized by degradation, and has half-life of 40 to 50 hours. This drug is excreted in the feces.

Caspofungin is available for IV use. This drug is slowly metabolized in the liver, with half-lives of 9 to 11 hours, then 6 to 48 hours, and then 40 to 50 hours. It is bound to protein and widely distributed throughout the body. It is excreted through the urine.

Micafungin is an intravenous drug. It has a rapid onset, a half-life of 14 to 17 hours, and is excreted in the urine.

Contraindications and Cautions

Anidulafungin may cross the placenta and enter breast milk and should not be used by pregnant or lactating women. Caution must be used in the presence of hepatic impairment because it can be toxic to the liver. Caspofungin can be toxic to the liver; therefore, reduced doses must be used if a patient has known hepatic impairment. Caspofungin is embryotoxic in animal studies and is known to enter breast milk; therefore, it should be used with great caution during pregnancy and lactation. Because of the potential for adverse reactions in the fetus or the neonate, micafungin should be used during pregnancy and lactation only if the benefits clearly outweigh the risks.

Adverse Effects

Anidulafungin and caspofungin are associated with hepatic toxicity, and liver function should be monitored closely when using these drugs. Potentially serious hypersensitivity reactions have occurred with micafungin. In addition, bone marrow suppression can occur; monitor patients closely.

Clinically Important Drug–Drug Interactions

Concurrent use of cyclosporine with caspofungin is contraindicated unless the benefit clearly outweighs the risk of hepatic injury.

Other Antifungal Agents

Other antifungal drugs that are available do not fit into either of these classes. These include amphotericin B (*Abelcet*, *AmBisome*, *Amphotec*, *Fungizone*), flucytosine (*Ancobon*), griseofulvin (generic), and nystatin (*Mycostatin*, *Nilstat*).

Therapeutic Actions and Indications

Other antifungal agents work to cause fungal cell death or to prevent fungal cell reproduction. Amphotericin B is a very potent drug with many unpleasant adverse effects (see adverse effects). The drug binds to the sterols in the fungus cell wall, changing cell wall permeability. This change can lead to cell death (fungicidal effect) or prevent the fungal cells from reproducing (fungistatic effect). (See Table 11.1 for usual indications.) Because of the many adverse effects associated with this agent, its use is reserved for progressive, potentially fatal infections.

Flucytosine is a less toxic drug that alters the cell membrane of susceptible fungi, causing cell death (see Table 11.1 for usual indications).

Griseofulvin is an older antifungal that acts in much the same way, changing cell membrane permeability and causing cell death.

Nystatin binds to sterols in the cell wall, changing membrane permeability and allowing leaking of the cellular components, which will result in cell death.

Pharmacokinetics

Amphotericin B and flucytosine are available in IV form. They are excreted in the urine, with an initial half-life of 24 hours and then a 15-day half-life. Their metabolism is not fully understood. Flucytosine is well absorbed from the GI tract, with peak levels occurring in 2 hours. Most of the drug is excreted unchanged in the urine and a small amount in the feces, with a half-life of 2.4 to 4.8 hours. Griseofulvin is administered orally and reaches peak levels in around 4 hours. It is metabolized in the liver and excreted in the urine with a half-life of 24 hours. Nystatin is not absorbed from the GI tract and passes unchanged in the stool.

Contraindications and Cautions

Amphotericin B has been used successfully during pregnancy, but it should be used cautiously. It crosses into breast milk and should not be used during lactation because of the potential risk to the neonate. Because flucytosine is excreted primarily in the urine, extreme caution is needed in the presence of renal impairment because drug accumulation and toxicity can occur. Toxicity is associated with serum levels higher than 100 mcg/mL. Because of the potential for adverse reactions in the fetus or neonate, flucytosine should be used during pregnancy and lactation only if the benefits clearly outweigh the risks. It is not known whether nystatin crosses the placenta or enters breast milk, so it should not be used during pregnancy or lactation unless the benefits clearly outweigh the potential risks.

Adverse Effects

Adverse effects of these drugs are related to their toxic effects on the liver and kidneys. Patients should be monitored closely for any changes in liver or kidney functions. Bone

marrow suppression has also been reported with the use of these drugs. Rash and dermatological changes have been reported with these antifungals. Amphotericin B is associated with severe renal impairment, bone marrow suppression, GI irritation with nausea, vomiting, and potentially severe diarrhea, anorexia and weight loss, and pain at the injection site with the possibility of phlebitis or thrombophlebitis. Adverse effects of griseofulvin are relatively mild, with headache and central nervous system (CNS) changes occurring most frequently.

Clinically Important Drug–Drug Interactions

Patients who receive amphotericin B should not take other nephrotoxic drugs such as nephrotoxic antibiotics or antineoplastics, cyclosporine, or corticosteroids unless absolutely necessary *because of the increased risk of severe renal toxicity*.

Prototype Summary: Fluconazole

Indications: Treatment of oropharyngeal, esophageal, and vaginal candidiasis; cryptococcal meningitis; systemic fungal infections; prophylaxis to decrease the incidence of candidiasis in bone marrow transplants.

Actions: Binds to sterols in the fungal cell membrane, changing membrane permeability; fungicidal or fungistatic, depending on the concentration of drug and the organism.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	Slow	1–2 h	2–4 d
IV	Rapid	1 h	2–4 d

$T_{1/2}$: 30 hours; metabolized in the liver and excreted in the urine.

Adverse effects: Headache, nausea, vomiting, diarrhea, abdominal pain, rash.

Nursing Considerations for Patients Receiving Systemic Antifungals

Assessment: History and Examination

- Assess the patient for *contraindications or cautions*: history of allergy to antifungals *to prevent potential hypersensitivity reactions*; history of liver or renal dysfunction *that might interfere with metabolism and excretion of the drug*; and pregnancy or lactation *because of potential adverse effects to the fetus or infant*.
- Perform a physical assessment *to establish baseline data for assessing the effectiveness of the drug and the occurrence of any adverse effects associated with drug therapy*; test orientation and reflexes *to evaluate any CNS effects*; and examine skin for color and lesions *to monitor for any dermatological effects*.

- Obtain a culture of the infected area *to make an accurate determination of the type and responsiveness of the fungus.*
- Evaluate renal and hepatic function tests and complete blood count *to determine baseline function of these organs and to assess possible toxicity during drug therapy.*

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to GI, CNS, and local effects of the drug
- Disturbed Sensory Perception (Kinesthetic) related to CNS effects
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Arrange for appropriate culture and sensitivity tests before beginning therapy *to ensure that the appropriate drug is being used.* However, in some cases, treatment can begin before test results are known because of the seriousness of the systemic infections.
- Administer the entire course of the drug *to get the full beneficial effects;* this may take as long as 6 months for some chronic infections.
- Monitor IV sites *to ensure that phlebitis or infiltration does not occur.* Treat appropriately and restart IV at another site if phlebitis occurs.
- Monitor renal and hepatic function before and periodically during treatment to assess for possibly dysfunction *and arrange to stop the drug if signs of organ failure occur.*
- Provide comfort and safety provisions if CNS effects occur (e.g., side rails and assistance with ambulation for dizziness and weakness, analgesics for headache, antipyretics for fever and chills, temperature regulation for fever) *to protect the patient from injury.*
- Provide small, frequent, nutritious meals if GI upset is severe. Monitor nutritional status and arrange a dietary consultation as needed *to ensure nutritional status.* GI upset may be decreased by taking an oral drug with food.
- Instruct the patient *to enhance patient knowledge about drug therapy and to promote compliance.*
- Provide the following patient teaching:
 - Follow the appropriate dosage regimen.
 - Take safety precautions, including changing position slowly and avoiding driving and hazardous tasks, if CNS effects occur.
 - Take an oral drug with meals and try small, frequent meals if GI upset is a problem.
 - Report to a health care provider any of the following: sore throat, unusual bruising and bleeding, or yellowing of the eyes or skin, all of which could indicate hepatic toxicity; or severe nausea and vomiting, which could interfere with nutritional state and slow recovery.

Evaluation

- Monitor patient response to the drug (resolution of fungal infection).
- Monitor for adverse effects (orientation and affect, nutritional state, skin color and lesions, renal and hepatic function).
- Evaluate the effectiveness of the teaching plan (patient can name the drug, dosage, possible adverse effects to watch for, and specific measures to help avoid adverse effects).
- Monitor the effectiveness of comfort and safety measures and compliance with the regimen

KEY POINTS

- Fungi can cause many different infections in humans.
- Fungi differ from bacteria in that a fungus has a rigid cell wall that is made up of chitin and various polysaccharides and a cell membrane that contains ergosterol.
- Systemic antifungal drugs can be very toxic; extreme care should be taken to ensure that the right drug is used to treat an infection and that the patient is monitored closely to prevent severe toxicity.
- Systemic antifungals are associated with many drug–drug interactions because of their effects on the liver. Monitor a patient closely when adding or removing a drug from a drug regimen if the patient is receiving a systemic antifungal.

TOPICAL ANTIFUNGALS

Some antifungal drugs are available only in topical forms for treating a variety of mycoses of the skin and mucous membranes. Some of the systemic antifungals are also available in topical forms. Fungi that cause these mycoses are called *dermatophytes*. These diseases include a variety of **tinea** infections, which are often referred to as ringworm, although the causal organism is a fungus, not a worm. These mycoses include tinea infections such as athlete's foot (*tinea pedis*), jock itch (*tinea cruris*), and yeast infections of the mouth and vagina often caused by *Candida*. Because the antifungal drugs reserved for use as topical agents are often too toxic for systemic administration, care is necessary when using them near open or draining wounds that might permit systemic absorption. Topical antifungals include the azole-type antifungals—butoconazole (*Gynazole*), clotrimazole (*Lotrimin*, *Mycelex*), econazole (*Spectazole*), ketoconazole (*Extina*, *Nizoral*, *Xolegel*), miconazole (*Fungoid*, *Lotrimin AF*, *Monistat*), oxiconazole (*Oxistat*), sertaconazole nitrate (*Ertaczo*), sulconazole (*Exelderm*), terbinafine (*Lamisil*), terconazole (*Terazol*), and tioconazole (*Vagistat-1*, *Monistat-1*)—and other antifungals—butenafine (*Mentax*), ciclopirox (*Loprox*, *Penlac Nail Lacquer*), gentian violet (generic), naftifine (*Naftin*), tolnaftate (*Aftate*, *Tinactin*), and undecylenic acid (*Cruex*, *Desenex*, *Pedi-Dri*, *Fungoid AF*). (See Table 11.2.)

TABLE 11.2 DRUGS IN FOCUS Topical Antifungals

Drug Name	Application/Available Form	Usual Indications
Azole Topical Antifungals		
butoconazole (<i>Gynazole I</i>)	Vaginal cream; applied only once a day for 4 wk	Available over the counter (OTC) for treatment of vaginal <i>Candida</i> infections
 clotrimazole (<i>Lotrimin, Mycelex</i>)	Available OTC as a cream, lotion, or solution; applied as a thin layer twice a day for 2–4 wk	Available OTC for treatment of oral and vaginal <i>Candida</i> infections; tinea infections
econazole (<i>Spectazole</i>)	Available OTC as a cream; applied as a thin layer once or twice daily for 2 wk	Treatment of tinea
ketoconazole (<i>Extina, Nizoral, Xolegel</i>)	Available in cream, gel, foam, and shampoo form; applied once to twice daily for 2–4 wk	Treatment of seborrheic dermatitis, tinea corporis, tinea cruris, tinea pedis
miconazole (<i>Monistat, Fungoid, Lotrimin AF, Monistat</i>)	Available as an OTC product in several topical forms (vaginal suppository, cream, powder, solution, ointment, gel and spray); applied twice daily for 2–4 wk	Treatment of local, topical mycoses, including bladder and vaginal infections and athlete's foot
oxiconazole (<i>Oxistat</i>)	Available as a cream or lotion; applied once daily or twice daily as needed	Short-term (up to 4 wk) treatment of topical mycosis
sertaconazole nitrate (<i>Ertaczo</i>)	Available as a topical cream; applied between toes affected by tinea pedis and to the surrounding healthy tissue two times a day for 4 wk	Treatment of tinea pedis infections (up to 4 wk)
sulconazole (<i>Exelderm</i>)	Available as a cream for athlete's foot and a solution for other tinea infections; applied once or twice a day for 4–6 wk	Treatment of tinea infections
terbinafine (<i>Lamisil</i>)	Available as a cream or gel; used for 1–4 wk; applied twice daily	Short-term (1–4 wk) treatment of topical mycosis; treatment of tinea infections
terconazole (<i>Terazol</i>)	Available as a suppository or a vaginal cream; applied for 3–7 consecutive days; used for 1–4 wk; applied twice daily	Local treatment of <i>Candida</i> infections
tioconazole (<i>Monistat-1, Vagistat-1</i>)	Vaginal ointment, meant for one-dose treatment only; one applicator-full of ointment is inserted vaginally at bedtime	Treatment of recurrent vaginal <i>Candida</i> infections
Other Topical Antifungals		
butenafine (<i>Mentax</i>)	Topical cream; applied in a thin layer once to twice daily for up to 4 wk	Treatment of tinea infections
ciclopirox (<i>Loprox, Penlac Nail Lacquer</i>)	Available as a gel, cream, lotion, suspension, solution, and shampoo; applied twice daily for up to 4 wk	Treatment of topical tinea infections; solution for treatment of toenail and fingernail tinea infections caused by <i>Trichophyton rubrum</i>
gentian violet	Available as a topical solution; applied twice a day to affected area	Treatment of topical mycosis
naftifine (<i>Naftin</i>)	Available as a cream or gel; applied twice a day for up to 4 wk	Short-term treatment of severe topical mycosis (up to 4 wk)
tolnaftate (<i>Aftate, Tinactin</i>)	Available as a cream, solution, gel, powder, and spray; applied twice a day for 2–4 wk	Available OTC for treatment of athlete's foot
undecylenic acid (<i>Cruex, Desenex, Fungoid AF, Pedi-Dri</i>)	Available as a powder, cream, or ointment; used as needed	Available OTC for treatment of athlete's foot, jock itch, diaper rash, burning and chafing in the groin area

Therapeutic Actions and Indications

The topical antifungal drugs work to alter the cell permeability of the fungus, causing prevention of replication and fungal death (see Figure 11.1). They are indicated only for local treatment of mycoses, including tinea infections. See Table 11.2 for usual indications. (See Critical Thinking Scenario related to drug therapy.)

Pharmacokinetics

These drugs are not absorbed systemically and do not undergo metabolism or excretion in the body.

Contraindications and Cautions

Because these drugs are not absorbed systemically, contraindications are limited to a known allergy to any of these drugs and open lesions. Econazole can cause intense, local burning and irritation and should be discontinued if these conditions become severe. Gentian violet stains skin and clothing bright purple; in addition, it is very toxic when absorbed, so it cannot be used near active lesions. Naftifine, oxiconazole, and sertaconazole nitrate should not be used for longer than 4 weeks due to the risk of adverse effects and possible emergence of resistant strains of fungi. Sulconazole should not be used for longer than 6 weeks due to the risk of adverse effects and possible emergence of resistant strains of fungi. Terbinafine should not be used for longer than 4 weeks. This drug should be stopped when the fungal condition

appears to be improved or if local irritation and pain become too great to avoid toxic effects.

Adverse Effects

When these drugs are applied locally as a cream, lotion, or spray, local effects include irritation, burning, rash, and swelling. When they are taken as a suppository or troche, adverse effects include nausea, vomiting, and hepatic dysfunction (related to absorption of some of the drug by the GI tract) or urinary frequency, burning, and change in sexual activity (related to local absorption in the vagina).

Prototype Summary: Clotrimazole

Indications: Treatment of oropharyngeal candidiasis (troche); prevention of oropharyngeal candidiasis in patients receiving radiation or chemotherapy; local treatment of vulvovaginal candidiasis (vaginal preparations); topical treatment of tinea pedis, tinea cruris, and tinea corporis.

Actions: Binds to sterols in the fungal cell membrane, changing membrane permeability and allowing leakage of intracellular components, causing cell death.

Pharmacokinetics: Not absorbed systemically; pharmacokinetics is unknown.

Adverse effects: Troche: nausea, vomiting, abnormal liver function tests. Topical: stinging, redness, urticaria, edema. Vaginal: lower abdominal pain, urinary frequency, burning or irritation in the sexual partner.

CRITICAL THINKING SCENARIO

Poor Nutrition and Opportunistic Infections

THE SITUATION

P.P., a 19-year-old woman and aspiring model, complains of abdominal pain, difficulty swallowing, and a very sore throat. The strict diets she has followed for long periods have sometimes amounted to a starvation regimen. In the last 18 months, she has received treatment for a variety of bacterial infections (e.g., pneumonia, cystitis) with a series of antibiotics.

P.P. appears to be a very thin, extremely pale young woman who looks older than her stated age. Her mouth is moist, and small, white colonies that extend down the pharynx cover the mucosa. A vaginal examination reveals similar colonies. Cultures are performed, and it is determined that she has mucocutaneous candidiasis. Ketoconazole (*Nizoral*) is prescribed, and P.P. is asked to return in 10 days for follow-up.

CRITICAL THINKING

What are the effects of taking a variety of antibiotics on the normal flora? *Think about the possible cause of the mycosis.*

What happens to the immune system and to the skin and mucous membranes when a person's nutritional status becomes insufficient?

How is P.P.'s chosen profession affecting her health? What are the possible ramifications of suggesting that P.P. change her profession or her lifestyle?

What are the important nursing implications for P.P.?

Think about how the nurse can work with P.P. to ensure some compliance with therapy and a return to a healthy state.

(scenario continues on page 166)

Poor Nutrition and Opportunistic Infections (continued)**DISCUSSION**

Because of P.P.'s appearance, a complete physical examination should be performed before drug therapy is initiated. It is necessary to know baseline functioning to evaluate any underlying problems that may exist. Poor nutrition and total starvation result in characteristic deficiencies that predispose individuals to opportunistic infections and prevent their bodies from protecting themselves adequately through inflammatory and immune responses. In this case, the fact that liver changes often occur with poor nutrition is particularly important; such hepatic dysfunction may cause deficient drug metabolism and lead to toxicity.

An intensive program of teaching and support should be started for P.P., who should have an opportunity to vent her feelings and fears. She needs help accepting her diagnosis and adapting to the drug therapy and nutritional changes that are necessary for the effective treatment of this infection. She should understand the possible causes of her infection (poor nutrition and the loss of normal flora secondary to antibiotic therapy); the specifics of her drug therapy, including timing and administration; and adverse effects and warning signs that should be reported. P.P. should be monitored closely for adverse effects and should return for follow-up regularly while taking the ketoconazole. Nutritional counseling or referral to a dietitian for thorough nutritional teaching may prove beneficial.

The actual resolution of the fungal infection may occur only after a combination of prolonged drug and nutritional therapy. Because the required therapy will affect P.P.'s lifestyle tremendously, she will need a great deal of support and encouragement to make the necessary changes and to maintain compliance. A health care provider, such as a nurse who P.P. trusts and with whom she can regularly discuss her concerns, may be an essential element in helping to eradicate the fungal infection.

NURSING CARE GUIDE FOR P.P.: ANTIFUNGAL AGENTS**Assessment: History and Examination**

Assess history of allergy to any antifungal drug. Also check history of renal or hepatic dysfunction and pregnancy or breast-feeding status.

Focus the physical examination on the following:

Local: culture of infected site

Skin: color, lesions, texture

GU: urinary output

GI: abdominal, liver evaluation

Hematological: renal and hepatic function tests

Nursing Diagnoses

Acute Pain related to GI, local, CNS effects

Disturbed Sensory Perception (Kinesthetic) related to CNS effects

Imbalanced Nutrition: Less Than Body Requirements related to GI effects

Deficient Knowledge regarding drug therapy

Implementation

Culture infection before beginning therapy.

Provide comfort and implement safety measures (e.g., provide assistance and raise side rails).

Ensure temperature control, lighting control, mouth care, and skin care.

Provide small, frequent meals and monitor nutritional status.

Provide support and reassurance for dealing with drug effects and discomfort.

Provide patient teaching regarding drug name, dosage, adverse effects, precautions, and warning signs to report.

Evaluation

Evaluate drug effects: relief of signs and symptoms of fungal infection.

Monitor for adverse effects: GI alterations, dizziness, confusion, headache, fever, renal or hepatic dysfunction, local pain, discomfort.

Monitor for drug–drug interactions as indicated for each drug.

Evaluate effectiveness of patient teaching program and of comfort and safety measures.

PATIENT TEACHING FOR P.P.

- Ketoconazole is an antifungal drug that works to destroy the fungi that have invaded the body. Because of the way that antifungal drugs work, they may need to be taken over a long period of time.
- It is very important to take all of the prescribed medication.
- Common adverse effects of this drug include the following:
 - *Headache and weakness*—Change positions slowly. An analgesic may be ordered to help alleviate the headache. If you feel drowsy, avoid driving or dangerous activities.
 - *Stomach upset, nausea, and vomiting*—Small, frequent meals may help. Take the drug with food if appropriate because this may decrease the gastrointestinal upset associated with these drugs. (Ketoconazole must be taken on an empty stomach at least 2 hours before taking a meal, antacids, milk products, or any other drugs.) Try to maintain adequate nutrition.
- Report any of the following to your health care provider: severe vomiting, abdominal pain, fever or chills, yellowing of the skin or eyes, dark urine or pale stools, or skin rash.
- Avoid over-the-counter medications. If you feel that you need one of these, check with your health care provider first.
- Take the full course of your prescription. Never use this drug to self-treat any other infection, and never give this drug to any other person.
- Tell any doctor, nurse, or other health care provider involved in your care that you are taking this drug.
- Keep this drug and all medications out of the reach of children.

● Nursing Considerations for Patients Receiving Topical Antifungals

Assessment: History and Examination

- Assess for known allergy to any topical antifungal agent.
- Perform a physical assessment *to establish baseline data for evaluation of the effectiveness of the drug and the occurrence of any adverse effects associated with drug therapy.*
- Perform culture and sensitivity testing of the affected area *to determine the causative fungus and appropriate medication.*
- Inspect the area of application for color, temperature, and evidence of lesions to establish a baseline *to monitor the effectiveness of the drug and to monitor for local adverse effects of the drug.*

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to local effects of the drug
- Deficient Knowledge regarding drug therapy
- Risk for impaired skin integrity

Implementation With Rationale

- Culture the affected area before beginning therapy *to identify the causative fungus.*
- Ensure that the patient takes the complete course of the drug regimen *to achieve maximal results.*
- Instruct the patient in the correct method of administration, depending on the route, *to improve effectiveness and decrease the risk of adverse effects:*
 - Troches should be dissolved slowly in the mouth.
 - Vaginal suppositories, creams, and tablets should be inserted high into the vagina with the patient remaining recumbent for at least 10 to 15 minutes after insertion.
 - Topical creams and lotions should be gently rubbed into the affected area after it has been cleansed with soap and water and patted dry. Occlusive bandages should be avoided.
- Advise the patient to stop the drug if a severe rash occurs, especially if it is accompanied by blisters or if local irritation and pain are very severe. *This development may indicate a sensitivity to the drug or worsening of the condition being treated.*
- Provide patient instruction *to enhance patient knowledge about drug therapy and to promote compliance.*
- Provide the following patient teaching:
 - The correct method of drug administration; demonstrate proper application.
 - The length of time necessary to treat the infection adequately.
 - Use of clean, dry socks when treating athlete's foot, to help eradicate the infection.
 - The need to keep the infected area clean, washing with mild soap and water and patting dry; keep area dry.

- The need to avoid scratching the infected area; use of cool compresses to decrease itching can be advised.
- The need to avoid occlusive dressings because of the risk of increasing systemic absorption.
- The importance of not placing drugs near open wounds or active lesions because these agents are not intended to be absorbed systemically.
- The need to report severe local irritation, burning, or worsening of the infection to a health care provider.

Evaluation

- Monitor patient response to the drug (alleviation of signs and symptoms of the fungal infection).
- Monitor for adverse effects: rash, local irritation, and burning.
- Evaluate the effectiveness of the teaching plan (patient can name the drug, dosage, possible adverse effects to watch for, and specific measures to help avoid adverse effects).
- Monitor the effectiveness of comfort and safety measures and compliance with the regimen

KEY POINTS

- ▶ Local fungal infections include vaginal and oral yeast infections (*Candida*) and a variety of tinea infections, including athlete's foot and jock itch.
- ▶ Topical antifungals are agents that are too toxic to be used systemically but are effective in the treatment of local fungal infections.
- ▶ Proper administration of topical antifungals improves their effectiveness. They should not be used near open wounds or lesions.
- ▶ Topical antifungals can cause serious local irritation, burning, and pain. The drug should be stopped if these conditions occur.

CHAPTER SUMMARY

- A fungus is a cellular organism with a hard cell wall that contains chitin and polysaccharides and a cell membrane that contains ergosterols.
- Any infection with a fungus is called a mycosis. Systemic fungal infections, which can be life threatening, are increasing with the rise in the number of immunocompromised patients.
- Systemic antifungals alter the cell permeability, leading to leakage of cellular components. This causes prevention of cell replication and cell death.
- Because systemic antifungals can be very toxic, patients should be monitored closely while receiving them. Adverse effects may include hepatic and renal failure.

- Local fungal infections include vaginal and oral yeast infections (*Candida*) and a variety of tinea infections, including athlete's foot and jock itch.
- Topical antifungals are agents that are too toxic to be used systemically but are effective in the treatment of local fungal infections.
- Proper administration of topical antifungals improves their effectiveness. They should not be used near open wounds or lesions.
- Topical antifungals can cause serious local irritation, burning, and pain. The drug should be stopped if these conditions occur.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in the Answers to Check Your Understanding Questions on the CD-Rom in the front of this book.

MULTIPLE CHOICE

Select the best answer to the following.

1. A patient with a fungal infection asks the nurse why she cannot take antibiotics. The nurse explains that the reason for this is that a fungus is resistant to antibiotics because
 - a. a fungal cell wall has fewer but more selective protective layers.
 - b. the composition of the fungal cell wall is highly rigid and protective.
 - c. a fungus does not reproduce by the usual methods of cell division.
 - d. antibiotics are developed to affect only bacterial cell walls.
2. When administering a systemic antifungal agent, the nurse incorporates understanding that all systemic antifungal drugs function to
 - a. break apart the fungus nucleus.
 - b. interfere with fungus DNA production.
 - c. alter cell permeability of the fungus, leading to cell death.
 - d. prevent the fungus from absorbing needed nutrients.
3. After assessing a patient, the nurse would question an order for amphotericin B to prevent the possibility of serious nephrotoxicity if the patient was also receiving which of the following?
 - a. digoxin
 - b. oral anticoagulants
 - c. phenytoin
 - d. corticosteroids
4. The nurse is describing fungi that cause infections of the skin and mucous membranes, appropriately calling these which of the following?
 - a. mycoses
 - b. meningeal fungi
 - c. dermatophytes
 - d. worms
5. After teaching a group of students about topical fungal infections, the instructor determines that the students need additional instruction when they identify which of the following as an example?
 - a. athlete's foot
 - b. Rocky Mountain spotted fever
 - c. jock itch
 - d. vaginal yeast infections
6. Which of the following would the nurse recommend that a woman with repeated vaginal yeast infections keep on hand?
 - a. tolnaftate
 - b. butenafine
 - c. clotrimazole
 - d. naftifine
7. The nurse instructs the patient to use care when applying topical antifungal agents to prevent systemic absorption because
 - a. the fungus is only on the surface.
 - b. these drugs are too toxic to be given systemically.
 - c. absorption would prevent drug effectiveness.
 - d. these drugs can cause serious local burning and pain.

8. A patient with a severe case of athlete's foot is seen with lesions between the toes, which are oozing blood and serum. After teaching the patient, the nurse determines that the instruction was effective if the patient states which of the following?
- "I have to wear black socks and must be careful not to change them very often because it could pull more skin off of my feet."
 - "I need to apply a thick layer of the antifungal cream between my toes, making sure that all of the lesions are full of cream."
 - "I should wear white socks and keep my feet clean and dry. I shouldn't use the antifungal cream in areas where I have open lesions."
 - "After I apply the cream to my feet, I should cover my feet in plastic wrap for several hours to make sure the drug is absorbed."
- Ensuring that the patient stays flat for at least 1 hour if receiving a vaginal suppository.
 - Monitoring the IV site to prevent phlebitis.
 - Keeping the patient NPO (nothing by mouth) if GI upset occurs to prevent vomiting.
 - Providing antipyretics if fever occurs with IV antifungals.
2. The nurse would include which of the following in a teaching plan for a patient who is receiving an oral antifungal drug?
- It is important that you complete the full course of your drug therapy.
 - You can share this drug with other family members if they develop the same symptoms.
 - If you feel drowsy or dizzy, you should avoid driving or operating dangerous machinery.
 - If GI upset occurs, avoid eating and drinking so you don't vomit and lose the drug.
 - Use over-the-counter drugs to counteract any adverse effects like headache, fever, or rash.
 - Notify your health care provider if you experience yellowing of the skin or eyes, dark urine or light-colored stools, or fever and chills.

MULTIPLE RESPONSE

Select all that apply.

1. When administering a systemic antifungal, the nurse would include which of the following in the patient's plan of care?
- Ensuring that a culture of the affected area had been done.
 - Having the patient swallow the troche used for oral *Candida* infections.

Antiprotozoal Agents

12

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Outline the life cycle of the protozoan that causes malaria.
2. Describe the therapeutic actions, indications, pharmacokinetics, contraindications, proper administration, most common adverse reactions, and important drug–drug interactions associated with drugs used to treat malaria.
3. Describe other common protozoal infections, including cause and clinical presentation.
4. Compare and contrast the antimalarials with other drugs used to treat protozoal infections.
5. Outline the nursing considerations for patients receiving an antiprotozoal agent across the lifespan.

Glossary of Key Terms

amebiasis: amebic dysentery, which is caused by intestinal invasion of the trophozoite stage of the protozoan

Entamoeba histolytica

Anopheles mosquito: type of mosquito that is essential to the life cycle of *Plasmodium*; injects the protozoa into humans for further maturation

cinchonism: syndrome of quinine toxicity characterized by nausea, vomiting, tinnitus, and vertigo

giardiasis: protozoal intestinal infection that causes severe diarrhea and epigastric distress; may lead to serious malnutrition

leishmaniasis: skin, mucous membrane, or visceral infection caused by a protozoan passed to humans by the bites of sand flies

malaria: protozoal infection with *Plasmodium*, characterized by cyclic fever and chills as the parasite is released from ruptured red blood cells; causes serious liver, CNS, heart, and lung damage

Plasmodium: a protozoan that causes malaria in humans; its life cycle includes the *Anopheles* mosquito, which injects protozoa into humans

***Pneumocystis carinii* pneumonia (PCP):** opportunistic infection that occurs when the immune system is depressed; a frequent cause of pneumonia in patients with AIDS and in those who are receiving immunosuppressive therapy

protozoa: single-celled organisms that pass through several stages in their life cycle, including at least one phase as a human parasite; found in areas of poor sanitation and hygiene and crowded living conditions

trichomoniasis: infestation with a protozoan that causes vaginitis in women but no signs or symptoms in men

trophozoite: a developing stage of a parasite, which uses the host for essential nutrients needed for growth

trypanosomiasis: African sleeping sickness, which is caused by a protozoan that inflames the CNS and is spread to humans by the bite of the tsetse fly; also, Chagas disease, which causes a serious cardiomyopathy after the bite of the house fly

ANTIMALARIALS

 chloroquine
hydroxychloroquine

mefloquine
primaquine
pyrimethamine

OTHER ANTIPROTOZOALS

 atovaquone
metronidazole

nitazoxanide
pentamidine
tinidazole

BOX 12.1

Drug Therapy Across the Lifespan

Antiprotozoal Agents

CHILDREN

Children are very sensitive to the effects of most antiprotozoal drugs, and more severe reactions can be expected when these drugs are used in children.

Many of these drugs do not have proven safety and efficacy in children, and extreme caution should be used. The dangers of infection resulting from travel to areas endemic with many of these diseases are often much more severe than the potential risks associated with cautious use of these drugs.

If a child needs to travel to an area with endemic protozoal infections, the CDC or local health department should be consulted about the safest possible preventative measures.

ADULTS

Adults should be well advised about the need for prophylaxis against various protozoal infections and the need for immediate treatment if the disease is contracted. It is very helpful to mark calendars as reminders of the days before, during, and after exposure on which the drugs should be taken.

Pregnant and nursing women should not use these drugs unless the benefit clearly outweighs the potential risk to the fetus or neonate. Women of childbearing age should be advised to use barrier contraceptives if any of these drugs are used. A pregnant woman traveling to an area endemic with protozoal infections should be advised of the serious risks to the fetus associated with both preventive therapy and treatment of acute attacks, as well as the risks associated with contracting the disease.

OLDER ADULTS

Older patients may be more susceptible to the adverse effects associated with these drugs. They should be monitored closely.

Patients with hepatic dysfunction are at increased risk for worsening hepatic problems and toxic effects of many of these drugs. If hepatic dysfunction is expected (extreme age, alcohol abuse, use of other hepatotoxic drugs), the dose may need to be lowered and the patient monitored more frequently.

Infections caused by **protozoa**—single-celled organisms that pass through several stages in their life cycles, including at least one phase as a human parasite—are very common in several parts of the world. In tropical areas, where protozoal infections are most prevalent, many people suffer multiple infestations at the same time. These illnesses are relatively rare in the United States, but with people traveling throughout the world in increasing numbers, it is not unusual to find an individual who returns home from a trip to Africa, Asia, or South America with fully developed protozoal infections. Protozoa thrive in tropical climates, but they may also survive and reproduce in any area where people live in very crowded and unsanitary conditions. This chapter focuses on agents used for protozoal infections that are caused by insect bites (malaria, trypanosomiasis, and leishmaniasis) and those that result from ingestion or contact with the causal organism (amebiasis, giardiasis, and trichomoniasis). Box 12.1 discusses the use of antiprotozoals across the lifespan. Figure 12.1 shows sites of action for these agents.

MALARIA

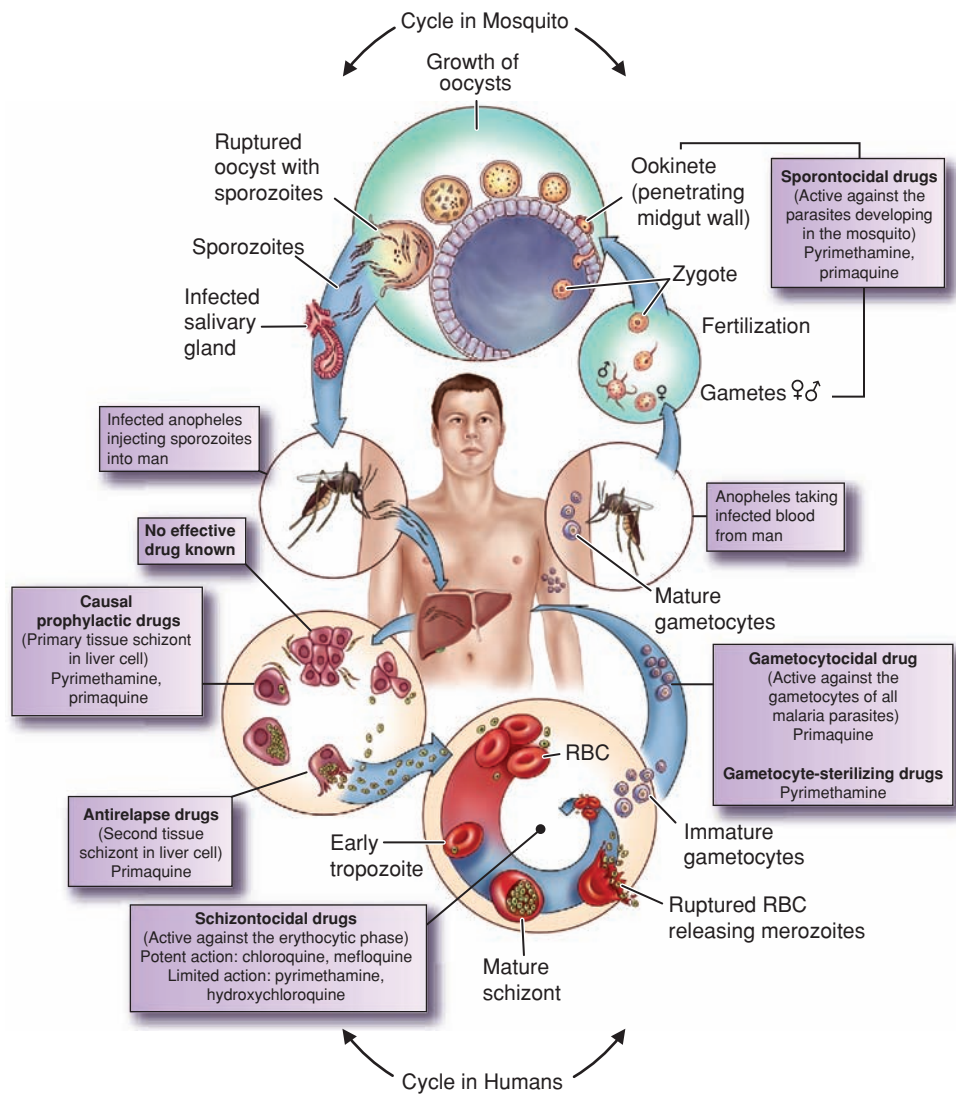

Malaria is a parasitic disease that has killed hundreds of millions of people and even changed the course of history. The progress of several African battles and the building of the Panama Canal were altered by outbreaks of malaria. Even with the introduction of drugs for the treatment of this disease, it remains endemic in many parts of the world. The only

known method of transmission of malaria is through the bite of a female **Anopheles mosquito**, an insect that harbors the protozoal parasite and carries it to humans.

Four protozoal parasites, all in the genus **Plasmodium**, have been identified as causes of malaria:

- *Plasmodium falciparum* is considered to be the most dangerous type of protozoan. Infection with this protozoan results in an acute, rapidly fulminating disease with high fever, severe hypotension, swelling and reddening of the limbs, loss of red blood cells, and even death.
- *Plasmodium vivax* causes a milder form of the disease, which seldom results in death.
- *Plasmodium malariae* is endemic in many tropical countries and causes very mild signs and symptoms in the local population. It can cause more acute disease in travelers to endemic areas.
- *Plasmodium ovale*, which is rarely seen, seems to be in the process of being eradicated.

A major problem with controlling malaria involves the mosquito that is responsible for transmitting the disease, which has developed a resistance to the insecticides designed to eradicate it. Over the years, widespread efforts at mosquito control were successful, with fewer cases of malaria being seen each year. However, the rise of insecticide-resistant mosquitoes has allowed malaria to continue to flourish, increasing the incidence of the disease. In addition, the protozoa that cause malaria have developed strains resistant to the usual antimalarial drugs. This combination of factors has led to a worldwide public health challenge.

● FIGURE 12.1 Sites of action of antimalarials and other antiprotozoals. Antimalarials block protein synthesis and cause cell death. Other antiprotozoals block DNA synthesis, prevent cell reproduction, and lead to cell death. RBC, red blood cell.

Life Cycle of *Plasmodium*

The parasites that cause human malaria spend part of their life in the *Anopheles* mosquito and part in the human host (Figure 12.2). When a mosquito bites a human who is infected with malaria, it sucks blood infested with gametocytes, which are male and female forms of the *Plasmodium*. These gametocytes mate in the stomach of the mosquito and produce a zygote that goes through several phases before forming sporozoites (spore animals) that make their way to the mosquito’s salivary glands. The next person who is bitten by that mosquito is injected with thousands of sporozoites. These organisms travel through the bloodstream, where they quickly become lodged in the human liver and other tissues and invade the cells.

Inside human cells, the organisms undergo asexual cell division and reproduction. Over the next 7 to 10 days, these primary tissue organisms called schizonts grow and multiply within their invaded cells, using the cell for needed nutrients (as **trophozoites**). Merozoites are then formed from the primary schizonts and burst from invaded cells when they

rupture because of overexpansion. These merozoites enter the circulation and invade red blood cells. Here they continue to divide until the blood cells also burst, sending more merozoites into the circulation to invade yet more red blood cells.

Eventually, there are a large number of merozoites in the body, as well as many ruptured and invaded red blood cells. At this point, the acute malarial attack occurs. The rupture of the red blood cells causes chills and fever related to the pyrogenic effects of the protozoa and the toxic effects of the red blood cell components on the system. This cycle of chills and fever usually occurs about every 72 hours.

With *P. vivax* and *P. malariae* malaria, this cycle may continue for a long period. Many of the tissue schizonts lay dormant until they eventually find their way to the liver, where they multiply and then invade more red blood cells, again causing the acute cycle. This cycle of emerging from dormancy to cause a resurgence of the acute cycle may occur for years in an untreated patient.

● **FIGURE 12.2** Types of antimalarial drugs in relation to the stages in the life cycle of *Plasmodium*.

With *P. falciparum* malaria, there are no extrahepatic sites for the schizonts. If the patient survives an acute attack, no prolonged periods of relapse occur. The first attack of this type of malaria can destroy so many red blood cells that the patient's capillaries become clogged and the circulation to vital organs is interrupted, leading to death.

ANTIMALARIALS

Antimalarial drugs (Table 12.1) are usually given in combination form to attack the *Plasmodium* at various stages of its life cycle. Using this approach, it is possible to prevent the acute malarial reaction in individuals who have been infected by the parasite. These drugs can be schizonticidal (acting against the red-blood-cell phase of the life cycle), gametocytocidal (acting against the gametocytes), sporontocidal (acting against the parasites that are developing in the mosquito), or work against tissue schizonts as prophylactic or antirelapse agents. Quinine (generic) was the first drug found to be effective in the treatment of malaria; it is no longer available. Antimalarials used today include chloroquine (*Aralen*), hydroxychloroquine (*Plaquenil*), mefloquine (*Lariam*), primaquine (generic), and pyrimethamine (*Daraprim*). Fixed-dose combination drugs for malaria prevention and treatment are discussed in Box 12.2.

Therapeutic Actions and Indications

Chloroquine is currently the mainstay of antimalarial therapy. This drug enters human red blood cells and changes the metabolic pathways necessary for the reproduction of the *Plasmodium* (Figure 12.1). In addition, this agent is directly toxic to parasites that absorb it; it is acidic, and it decreases the ability of the parasite to synthesize DNA, leading to a blockage of reproduction. Because many strains of the parasite are developing resistance to chloroquine, the Centers for Disease Control and Prevention often recommends the use of certain antibiotics as part of combination therapy for treatment of malaria caused by these resistance strains. Box 12.3 lists the antibiotics used to treat malaria. See Table 12.1 for usual indications. Mechanisms of action are as follows:

Hydroxychloroquine inhibits parasite reproduction, and by blocking the synthesis of protein production, it can cause the death of the *Plasmodium*. This drug is used in combination therapy, usually with primaquine, for greatest effectiveness.

Mefloquine increases the acidity of plasmodial food vacuoles, causing cell rupture and death. In combination therapy, mefloquine is used in malarial prevention, as well as treatment.

Primaquine, another very old drug for treating malaria, similar to quinine, disrupts the mitochondria of the *Plasmodium*. It also causes death of gametocytes and exoerythrocytic (outside

TABLE 12.1 DRUGS IN FOCUS Antimalarials

Drug Name	Dosage/Route	Usual Indications
<p> chloroquine (Aralen)</p>	<p>Suppression: Adult: 300 mg PO every week beginning 1–2 wk before exposure and continuing for 4 wk after leaving endemic area Pediatric: 5 mg/kg/wk PO, using same schedule as for an adult Acute attacks: Adult: 600 mg PO, followed by 300 mg PO in 6 h; then 300 mg PO on days 2 and 3 Pediatric: 10 mg/kg PO, followed by 5 mg/kg PO in 6 h and on days 2 and 3</p>	Prevention and treatment of <i>Plasmodium</i> malaria; treatment of extraintestinal amebiasis
hydroxychloroquine (Plaquenil)	<p>Suppression: Adult: 310 mg PO every week, beginning 1–2 wk before exposure and continuing for 4 wk after leaving endemic area Pediatric: 5 mg/kg/wk, following adult schedule Acute attack: Adult: 620 mg PO, followed by 310 mg PO in 6 h and on days 2 and 3 Pediatric: 10 mg/kg PO, followed by 5 mg/kg PO in 6 h and on days 2 and 3</p>	Treatment of <i>Plasmodium</i> malaria in combination with other drugs, particularly primaquine
mefloquine (Lariam)	<p>Treatment: Adult: 1250 mg PO as a single dose Prevention: Adult: 250 mg PO once weekly, starting 1 wk before travel and continuing for 4 wk after leaving endemic area Pediatric: 15–19 kg, 1/4 tablet; 20–30 kg, 1/2 tablet; 31–45 kg, 3/4 tablet; >45 kg, 1 tablet; once a week, starting 1 wk before travel and continuing until 4 wk after leaving area</p>	Prevention and treatment of <i>Plasmodium</i> malaria in combination with other drugs
primaquine (generic)	<p>Adult: 26.3 mg/d PO for 14 d Pediatric: 0.5 mg/kg per day PO for 14 d; begin therapy during last 2 wk of (or after) therapy with chloroquine or other drugs</p>	Prevention of relapses of <i>P. vivax</i> and <i>P. malariae</i> infections; radical cure of <i>P. vivax</i> malaria
pyrimethamine (Daraprim)	<p>Prevention: Adult: 25 mg PO every week Pediatric (>10 yr): same as adult Pediatric (4–10 yr): 12.5 mg PO every week Pediatric (<4 yr): 6.25 mg PO every week Toxoplasmosis: Adult: 50–75 mg/d PO with 1–4 g of a sulfonamide, for 4–5 wk Pediatric: 1 mg/kg/d PO, divided into two equal doses, for 2–4 d; then cut dose in half and continue for 1 mo</p>	Prevention of <i>Plasmodium</i> malaria, in combination with other agents to suppress transmission; treatment of toxoplasmosis

of the red blood cell) forms and prevents other forms from reproducing.

Pyrimethamine is used in combination with agents that act more rapidly to suppress malaria; it acts by blocking the use of folic acid in protein synthesis by the *Plasmodium*, eventually leading to inability to reproduce and cell death.

Pharmacokinetics

Chloroquine is readily absorbed from the gastrointestinal (GI) tract, with peak serum levels occurring in 1 to 6 hours. It is concentrated in the liver, spleen, kidney, and brain and is excreted very slowly in the urine, primarily as unchanged drug.

BOX 12.2 Combination Drugs Used for Malaria Prevention and Treatment

Two fixed-combination drugs are available for use in the prevention and treatment of malaria. Combining two different preparations in one drug may increase compliance by reducing the number of pills a patient has to take, and it conforms to the treatment protocol of taking drugs that effect the protozoa at different stages on their life cycle.

Fansidar is a combination of sulfadoxine and pyrimethamine. It is indicated for the treatment of *Plasmodium falciparum* malaria when chloroquine resistance is suspected. It is used for prophylaxis of malaria when travelers are going to areas in which chloroquine-resistant strains are known to be endemic. *Fansidar* is contraindicated in pregnancy, and women should be advised to use barrier contraceptives while taking it. Both of the constituent drugs cross into breast milk and can cause serious reactions in the neonate.

Usual dosage, acute attack:

Adult: 2–3 tablets PO as a single dose

Pediatric (9–14 yr): 2 tablets PO as a single dose

Pediatric (4–8 yr): 1 tablet PO as a single dose

Pediatric (<4 yr): ½ tablet PO as a single dose

Usual dosage, prevention:

Adult: 1 tablet PO every week or 2 tablets every other week

Pediatric (9–14 yr): ¾ tablet PO every week or 1½ tablets every other week

Pediatric (4–8 yr): ½ tablet PO every week or 1 tablet every other week

Pediatric (<4 yr): ¼ tablet PO every week or ½ tablet every other week

Preventive therapy should begin 1–2 days before exposure and should continue throughout and 4–6 weeks after leaving the area.

Malarone and *Malarone Pediatric* combine atovaquone and proguanil. They are indicated for the prevention of *P. falciparum* malaria when chloroquine resistance has been reported. They are used for the treatment of uncomplicated *P. falciparum* malaria when chloroquine, halofantrine, and mefloquine have not proved successful, most likely because of resistance. This combination should be used in pregnancy and lactation only if the benefit clearly outweighs the potential risk to the fetus or neonate.

Usual dosage, acute attack:

Adult: 4 tablets PO as a single daily dose for 3 consecutive days

Pediatric (11–20 kg): 1 adult tablet PO daily for 3 consecutive days

Pediatric (21–30 kg): 2 adult tablets PO daily as a single daily dose for 3 consecutive days

Pediatric (31–40 kg): 3 adult tablets PO daily as a single daily dose for 3 consecutive days

Pediatric (>40 kg): 4 adult tablets PO daily as a single daily dose for 3 consecutive days

Prevention:

Adult: 1 tablet PO daily

Pediatric (11–20 kg): 1 pediatric tablet PO daily

Pediatric (21–30 kg): 2 pediatric tablets PO daily

Pediatric (31–40 kg): 3 pediatric tablets PO daily

Pediatric (>40 kg): 1 adult tablet PO daily

Prevention should start 1–2 days before exposure and continue throughout and 7 days after leaving the area.

Hydroxychloroquine is readily absorbed from the GI tract, with peak serum levels occurring in 1 to 6 hours. It is excreted slowly in the urine, primarily as unchanged drug.

Mefloquine is a mixture of molecules that are absorbed, metabolized, and excreted at different rates. The terminal half-life is 13 to 24 days. Metabolism occurs in the liver; caution should be used in patients with hepatic dysfunction.

Primaquine is readily absorbed and metabolized in the liver. Excretion occurs primarily in the urine. Safety for use during pregnancy has not been established.

Pyrimethamine is readily absorbed from the GI tract, with peak levels occurring within 2 to 6 hours. It is metabolized in the liver and has a half-life of 4 days. It usually maintains suppressive concentrations in the body for about 2 weeks.

BOX 12.3 Antibiotics Used to Treat Malaria

With the emergence of chloroquine-resistant strains of *Plasmodium*, the Centers for Disease Control and Prevention recommends the use of quinine and one of the following antibiotics as a combination therapy for the treatment of uncomplicated or severe malaria caused by chloroquine-resistant strains or uncomplicated malaria caused by strains with unknown resistance:

doxycycline: 100 mg/d PO for 7 days for adults; 2.2 mg/kg PO q12h for 7 days for children

tetracycline: 250 mg PO for 7 days for adults; 25 mg/kg per day PO in divided doses q.i.d. for 7 days for children

clindamycin: 20 mg base/kg per day PO in divided doses t.i.d. for 7 days for adults and children

In severe cases, the antibiotics can be started IV and then switched to oral forms as soon as the patient is able to take oral drugs

See Chapter 10 for a full discussion of these drugs

Contraindications and Cautions

Antimalarials are contraindicated in the presence of known patient allergy to any of these drugs; liver disease or alcoholism, *both because of the parasitic invasion of the liver and because of the need for the hepatic metabolism to prevent toxicity*; and lactation *because the drugs can enter breast milk and could be toxic to the infant*. Another method of feeding the baby should be used if treatment is necessary. These drugs should be avoided during pregnancy *because they are associated with birth defects*. With mefloquine, which is teratogenic in preclinical studies, pregnancy should be avoided during and for 2 months after completion of therapy. Use caution in patients with retinal disease or damage *because many of these drugs can affect vision and the retina, and the likelihood of problems increases if the retina is already damaged*; with psoriasis or porphyria *because of skin damage*; or with damage to mucous membranes, *which can*

FOCUS ON BOX 12.4 Cultural Considerations

Potential for Hemolytic Crisis

Patients with glucose-6-phosphate dehydrogenase (G6PD) deficiency—which is more likely to occur in Greeks, Italians, and other people of Mediterranean descent—may experience a hemolytic crisis if they are taking the antimalarial agent chloroquine or primaquine. Patients of Greek, Italian, or other Mediterranean ancestry should be questioned about any history of potential G6PD deficiency. If no history is known, the patient should be tested before any of these drugs are prescribed. If testing is not possible and the drugs are needed, the patient should be monitored very closely and informed about the potential need for hospitalization and emergency services.

occur as a result of the effects of the drug on proteins and protein synthesis. There have been some genetic enzyme differences identified in various groups that predispose them to adverse effects associated with these drugs. See Box 12.4 for cultural consideration and the use of some antimalarials.

Adverse Effects

A number of adverse effects may be encountered with the use of these antimalarial agents. Central nervous system (CNS) effects include headache and dizziness. Immune reaction effects related to the release of merozoites include fever, shivering, chills, and malaise. Nausea, vomiting, dyspepsia, and anorexia are associated with direct effects of the drug on the GI tract and the effects on CNS control of vomiting caused by the products of cell death and protein changes. Hepatic dysfunction is associated with the toxic effects of the drug on the liver and the effects of the disease on the liver. Dermatological effects include rash, pruritus, and loss of hair associated with changes in protein synthesis of the hair follicles. Visual changes, including possible blindness related to retinal damage from the drug, and ototoxicity related to other nerve damage may occur. Cinchonism (nausea, vomiting, tinnitus, and vertigo) may occur with high levels of hydroxychloroquine or primaquine.

Clinically Important Drug–Drug Interactions

The patient who is receiving combinations of the quinine derivatives and quinine is at increased risk for cardiac toxicity and convulsions. Therefore, monitor the patient closely, checking drug levels and anticipating dose adjustments as needed.

Increased bone marrow suppression may occur if antifolate drugs (methotrexate, sulfonamides, etc.) are combined with pyrimethamine; discontinue pyrimethamine if signs of folate deficiency develop (diarrhea, fatigue, weight loss, anemia).

Prototype Summary: Chloroquine

Indications: Treatment and prophylaxis of acute attacks of malaria caused by susceptible strains of *Plasmodium*; treatment of extraintestinal amebiasis.

Actions: Inhibits protozoal reproduction and protein synthesis.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	Varies	1–2 h	1 wk

$T_{1/2}$: 70 to 120 hours; metabolized in the liver and excreted in the urine.

Adverse effects: Visual disturbances, retinal changes, hypotension, nausea, vomiting, diarrhea.

Nursing Considerations for Patients Receiving Antimalarial Agents

Assessment: History and Examination

- Assess for contraindications or cautions: history of allergy to any of the antimalarials *to prevent hypersensitivity reactions*; liver dysfunction or alcoholism *that might interfere with the metabolism and excretion of the drug*; porphyria or psoriasis, *which could be exacerbated by the drug effects*; retinal disease *that could increase the visual disturbances associated with these drugs*; and pregnancy and lactation *because these drugs could affect the fetus and could enter the breast milk and be toxic to the infant*.
- Perform a physical assessment *to establish baseline data for assessment of the effectiveness of the drug and the occurrence of any adverse effects associated with drug therapy*. Assess CNS (reflexes and muscle strength).
- Perform ophthalmic and retinal examinations and auditory screening *to determine the need for cautious administration and to evaluate changes that occur as a result of drug therapy*.
- Assess the patient's liver function, including liver function tests *to determine appropriateness of therapy and to monitor for toxicity*.
- Obtain blood culture *to identify the causative Plasmodium species*.
- Inspect the skin closely for color, temperature, texture, and evidence of lesions *to monitor for adverse effects*.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to GI, CNS, and skin effects of the drug
- Disturbed Sensory Perception (Kinesthetic, Visual) related to CNS effects
- Risk for injury related to CNS changes
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Arrange for appropriate culture and sensitivity tests before beginning therapy *to ensure proper drug for susceptible Plasmodium species*. Treatment may begin before test results are known.
- Administer the complete course of the drug *to get the full beneficial effects*. Mark a calendar for prophylactic doses. Use combination therapy as indicated.
- Monitor hepatic function and perform ophthalmological examination before and periodically during treatment *to ensure early detection and prompt intervention with cessation of drug if signs of failure or deteriorating vision occur*.
- Provide comfort and safety measures if CNS effects occur (e.g., side rails and assistance with ambulation if dizziness and weakness are present) *to prevent patient injury*. Provide oral hygiene and ready access to bathroom facilities as needed *to cope with GI effects*.
- Provide small, frequent, nutritious meals if GI upset is severe *to ensure adequate nutrition*. Monitor nutritional status and arrange a dietary consultation as needed. Taking the drug with food may also decrease GI upset.
- Instruct the patient concerning the appropriate dosage regimen and the importance of adhering to the drug schedule *to enhance patient knowledge about drug therapy and to promote compliance*.
- Provide the following patient teaching:
 - Take safety precautions, including changing position slowly and avoiding driving and hazardous tasks, if CNS effects occur.
 - Take the drug with meals and try small, frequent meals if GI upset is a problem.
 - Report blurring of vision, which could indicate retinal damage; loss of hearing or ringing in the ears, which could indicate CNS toxicity; and fever or worsening of condition, which could indicate a resistant strain or noneffective therapy.

Evaluation

- Monitor patient response to the drug (resolution of malaria or prevention of malaria).
- Monitor for adverse effects (orientation and affect, nutritional state, skin color and lesions, hepatic function, and visual and auditory changes).
- Evaluate the effectiveness of the teaching plan (patient can name the drug, dosage, possible adverse effects to watch for, and specific measures to help avoid adverse effects).
- Monitor the effectiveness of comfort and safety measures and compliance with the regimen.

KEY POINTS

- ▶ A protozoan is a parasitic cellular organism. Its life cycle includes a parasitic phase inside human tissues or cells.
- ▶ Malaria is the most common protozoal infection and is spread to humans by the bite of an *Anopheles* mosquito.

The signs and symptoms of malaria are related to the destruction of red blood cells and toxicity to the liver.

- ▶ Antimalarial agents attack the parasite at the various stages of its development inside and outside the human body.

OTHER PROTOZOAL INFECTIONS

Other protozoal infections that are encountered in clinical practice include amebiasis, leishmaniasis, trypanosomiasis, trichomoniasis, and giardiasis. These infections, which are caused by single-celled protozoa, are usually associated with unsanitary, crowded conditions and use of poor hygienic practices. Patients traveling to other countries may encounter these infections, which also appear increasingly in the United States. Box 12.5 discusses the impact of travel and tourism on the spread of pathogens.

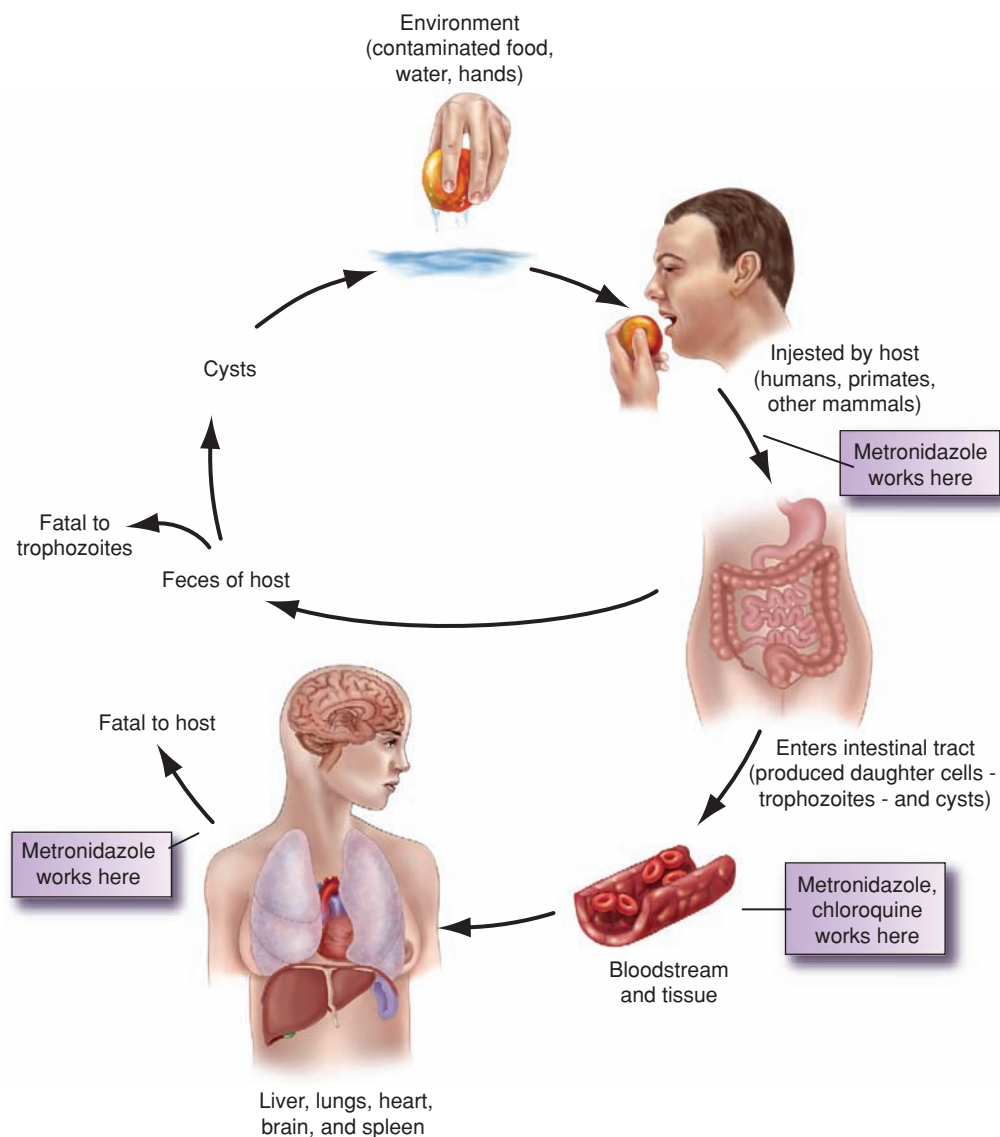

FOCUS ON BOX 12.5 The Evidence

World Travel and the Spread of Pathogens

Nowadays, people are traveling to more exotic areas of the world than ever before. Because of this, people are being exposed to more pathogens than ever before, and they also are potentially spreading pathogens to different areas of the world. Pathogens that are endemic in one area of the world and cause mild disease to the local population there can be quite devastating in a population that has not previously been exposed to that pathogen.

World health agencies and governments have established guidelines for prophylaxis and treatment of such diseases for travelers. People who are planning to travel out of the country should contact their local Health Department or the Centers for Disease Control and Prevention (CDC; website <http://www.cdc.gov/travel>) for the latest information on what prophylactic measures are required in the area they plan to visit and to learn about potential health hazards in that area. The information is updated frequently; treatment and prophylaxis suggestions are based on current clinical experience in the area and should be consulted regularly. Nurses should access this information when working with patients who are traveling to provide pertinent teaching points and to ensure that appropriate prophylactic measures are taken. Nurses caring for patients with tropical diseases should access this information regularly for best treatment practices.

Patients who have been traveling to other areas of the world and who present with any illness should be questioned about where they traveled, what precautions (including prophylactic measures) they took, and when they first experienced any signs or symptoms of illness. The CDC can be consulted about diagnosis and treatment guidelines for any tropical disease that is unfamiliar to a health care provider, as well as about what precautions should be used in caring for such patients.

● **FIGURE 12.3** Life cycle of *Entamoeba histolytica* and the sites of action of metronidazole and chloroquine, which are used to treat amebiasis. Cysts ingested by the host enter the intestinal tract and produce trophozoites. Trophozoites enter the bloodstream to reach tissue. Trophozoites enter the liver, lungs, heart, brain, and spleen, which can be fatal to the host. Trophozoites are excreted in the stool and die. Cysts excreted in the stool contaminate water and can be ingested by the host.

Amebiasis

Amebiasis, an intestinal infection caused by *Entamoeba histolytica*, is often known as amebic dysentery. *E. histolytica* has a two-stage life cycle (Figure 12.3). The organism exists in two stages: (1) a cystic, dormant stage, in which the protozoan can live for long periods outside the body or in the human intestine, and (2) a trophozoite stage in the ideal environment—the human large intestine.

The disease is transmitted while the protozoan is in the cystic stage in fecal matter, from which it can enter water and the ground. It can be passed to other humans who drink this water or eat food that has been grown in this ground. The cysts are swallowed and pass, unaffected by gastric acid, into the intestine. Some of these cysts are passed in fecal matter,

and some of them become trophozoites that grow and reproduce. The trophozoites migrate into the mucosa of the colon, where they penetrate into the intestinal wall, forming erosions. These forms of *Entamoeba* release a chemical that dissolves mucosal cells, and eventually they eat away tissue until they reach the vascular system, which carries them throughout the body. The trophozoites lodge in the liver, lungs, heart, brain, and so on.

Early signs of amebiasis include mild to fulminate diarrhea. In the worst cases, if the protozoan is able to invade extraintestinal tissue, it can dissolve the tissue and eventually cause the death of the host. Some individuals can become carriers of the disease without having any overt signs or symptoms. These people seem to be resistant to the intestinal invasion but pass the cysts on in the stool.

Leishmaniasis

Leishmaniasis is a disease caused by a protozoan that is passed from sand flies to humans. The sand fly injects an asexual form of this flagellated protozoan, called a promastigote, into the body of a human, where it is rapidly attacked and digested by human macrophages. Inside the macrophages, the promastigote divides, developing many new forms called amastigotes, which keep dividing and eventually kill the macrophage, releasing the amastigotes into the system to be devoured by more macrophages. Thus, a cyclic pattern of infection is established. These amastigotes can cause serious lesions in the skin, the viscera, or the mucous membranes of the host.

Trypanosomiasis

Trypanosomiasis is caused by infection with *Trypanosoma*. Two parasitic protozoal species cause very serious and often fatal diseases in humans:

- African sleeping sickness, which is caused by *Trypanosoma brucei gambiense*, is transmitted by the tsetse fly. After the pathogenic organism has lived and grown in human blood, it eventually invades the CNS, leading to an acute inflammation that results in lethargy, prolonged sleep, and even death.
- Chagas disease, which is caused by *Trypanosoma cruzi*, is almost endemic in many South American countries. It is passed to humans by the common housefly. This protozoan results in a severe cardiomyopathy that accounts for numerous deaths and disabilities in certain regions.

Trichomoniasis

Trichomoniasis, which is caused by another flagellated protozoan, *Trichomonas vaginalis*, is a common cause of vaginitis. This infection is usually spread during sexual intercourse by men who have no signs and symptoms of infection. In women, this protozoan causes reddened, inflamed vaginal mucosa, itching, burning, and a yellowish-green discharge.

Giardiasis

Giardiasis, which is caused by *Giardia lamblia*, is the most commonly diagnosed intestinal parasite in the United States. This protozoan forms cysts, which survive outside the body and allow transmission through contaminated water or food, and trophozoites, which break out of the cysts in the upper small intestine and eventually cause signs and symptoms of disease. Diarrhea, rotten egg–smelling stool, and pale and mucus-filled stool are commonly seen. Some patients experience epigastric distress, weight loss, and malnutrition as a result of the invasion of the mucosa.

Pneumocystis carinii Pneumonia

Pneumocystis carinii is an endemic protozoan that does not usually cause illness in humans. When an individual's immune

system becomes suppressed because of acquired immune deficiency syndrome (AIDS) or AIDS-related complex (ARC), the use of immunosuppressant drugs, or advanced age, this parasite is able to invade the lungs, leading to severe inflammation and the condition known as ***Pneumocystis carinii* pneumonia (PCP)**. This disease is the most common opportunistic infection in patients with AIDS.

OTHER ANTIPROTOZOAL AGENTS

Drugs that are available specifically for the treatment of these various protozoan infections include many of the malarial drugs; chloroquine is effective against extraintestinal amebiasis, and pyrimethamine is also effective in treating toxoplasmosis. Other drugs, including some tetracyclines and aminoglycosides, are used for treating these conditions at various stages of the disease. Other antiprotozoals include atovaquone (*Mepron*), metronidazole (*Flagyl*, *MetroGel*, *Noritrate*), nitazoxanide (*Alinia*), pentamidine (*Pentam 300*, *NebuPent*), and tinidazole (*Tindamax*). (See Table 12.2.)

Therapeutic Actions and Indications

These antiprotozoal agents act to inhibit DNA synthesis in susceptible protozoa, interfering with the cell's ability to reproduce, subsequently leading to cell death (see Figure 12.1). These drugs are indicated for the treatment of infections caused by susceptible protozoa. See Table 12.2 for usual indications for each of these agents.

Pharmacokinetics

Atovaquone is slowly absorbed and is highly protein bound in circulation. It is excreted slowly through the feces, with a half-life of 67 to 76 hours.

Metronidazole is well absorbed orally, reaching peak levels in 1 to 2 hours. It is metabolized in the liver with a half-life of 8 to 15 hours. Excretion occurs primarily through the urine.

Nitazoxanide is rapidly absorbed after oral administration, reaching peak levels in 1 to 4 hours. Nitazoxanide is metabolized in the liver and excreted in the urine and feces; it has a half-life of 8 to 12 hours.

Pentamidine is readily absorbed through the lungs. Excretion occurs in the urine, with traces found in the urine for up to 6 weeks.

Tinidazole is rapidly absorbed after oral administration, reaching peak levels within 60 to 90 minutes. It is excreted in the urine with a half-life of 12 to 14 hours.

Contraindications and Cautions

Contraindications include the presence of any known allergy or hypersensitivity to any of these drugs and pregnancy *because drug effects on developing fetal DNA and proteins can cause fetal abnormalities and even death*. Use caution

TABLE 12.2 DRUGS IN FOCUS Other Antiprotozoals

Drug Name	Dosage/Route	Usual Indications
atovaquone (<i>Mepron</i>)	Prevention: Adult and pediatric (>13 yr): 1500 mg/d PO Treatment: Adult and pediatric (>13 yr): 750 mg PO b.i.d. with meals for 12 d (treatment)	Prevention and treatment of <i>Pneumocystis carinii</i> pneumonia; used in combination with proguanil for treatment of chloroquine-resistant malaria
 metronidazole (<i>Flagyl, MetroGel, Noritate</i>)	Amebiasis: Adult: 750 mg PO t.i.d. for 5–10 d Pediatric: 35–50 mg/kg per day PO in three divided doses for 10 d Trichomoniasis: Adult: 2 g PO as one dose, or divided into two doses given on the same day or 250 mg PO t.i.d. for 7 d Pediatric: 5 mg/kg per dose PO t.i.d. for 7 d	Treatment of amebiasis, trichomoniasis, giardiasis
nitazoxanide (<i>Alinia</i>)	<i>Giardia</i> : Pediatric (12–47 mo): 100 mg PO q12h for 3 d Pediatric (4–11 yr): 200 mg PO q12h for 3 d <i>Cryptosporidium parvum</i> Pediatric (1–11 yr): same as for <i>Giardia</i> Adult and pediatric (≥ 12 yr): 500 mg PO q12h for 3 d	Treatment of diarrhea associated with <i>Cryptosporidium parvum</i> or <i>Giardia lamblia</i>
pentamidine (<i>Pentam 300, NebuPent</i>)	Inhalation: 300 mg once every 4 wk Injection: 4 mg/kg per day IM or IV for 14 d	As inhalation treatment of <i>P. carinii</i> pneumonia; as a systemic agent in the treatment of trypanosomiasis and leishmaniasis
tinidazole (<i>Tindamax</i>)	Trichomoniasis, giardiasis: Adult: 2 g PO as a single dose with food Pediatric (≥ 3 yr): 50 mg/kg PO as a single dose with food Amebiasis: Adult: 2 g/d PO with food for 3 d Pediatric (≥ 3 yr): 50 mg/kg per day PO with food, do not exceed 2 g/d	Treatment of trichomoniasis, giardiasis, amebiasis

when administering these drugs to patients with CNS disease because of possible disease exacerbation due to drug effects on the CNS; hepatic disease because of possible exacerbation when hepatic drug effects occur; candidiasis because of the risk of superinfections; and women who are lactating because these drugs may pass into breast milk and could have severe adverse effects on the infant. The safety and efficacy of pentamidine in children have not been established. Tinidazole should never be combined with alcohol and should be used with caution in patients with renal dysfunction, which could interfere with excretion of the drug.

Adverse Effects

Adverse effects that can be seen with these antiprotozoal agents include CNS effects such as headache, dizziness, ataxia, loss of coordination, and peripheral neuropathy related to drug effects on the neurons. GI effects include nausea, vomiting,

diarrhea, unpleasant taste, cramps, and changes in liver function. Superinfections also can occur when the normal flora are disrupted.

Clinically Important Drug–Drug Interactions

Tinidazole and metronidazole should not be combined with alcohol, which could cause severe adverse effects; patients are advised to avoid alcohol for at least 3 days after treatment has ended. Metronidazole and tinidazole combined with oral anticoagulants can lead to increased bleeding; patients should be monitored closely and dose adjustments made to the anticoagulant during therapy and for up to 8 days after stopping therapy. Psychotic reactions have been reported when tinidazole or metronidazole is combined with disulfiram; this combination should be avoided, and 2 weeks should elapse between tinidazole therapy and the starting of disulfiram.

Prototype Summary: *Metronidazole*

Indications: Acute intestinal amebiasis, amebic liver abscess, trichomoniasis, acute infections caused by susceptible strains of anaerobic bacteria, and preoperative and postoperative prophylaxis for patients undergoing colorectal surgery.

Actions: Inhibits DNA synthesis of specific anaerobes, causing cell death; mechanism of action as an antiprotozoal and amebicidal is not known.

Pharmacokinetics:

Route	Onset	Peak
Oral	Varies	1–2 h
IV	Rapid	1–2 h

$T_{1/2}$: 6 to 8 hours; metabolized in the liver and excreted in the urine and feces.

Adverse effects: Headache, dizziness, ataxia, nausea, vomiting, metallic taste, diarrhea, darkening of the urine.

Nursing Considerations for Patients Receiving Antiprotozoal Agents

Assessment: History and Examination

- Assess for contraindications and cautions: history of allergy to any of the antiprotozoals *to prevent hypersensitivity reactions*; liver dysfunction *that might interfere with metabolism and excretion of the drug or be exacerbated by the drug*; pregnancy, *which is a contraindication*, and lactation *because these drugs could enter the breast milk and be toxic to the infant*; CNS disease *that could be exacerbated by the drug*; and candidiasis *that could become severe as a result of the effects of these drugs on the normal flora*.
- Perform a physical assessment *to establish baseline data for determining the effectiveness of the drug and the occurrence of any adverse effects associated with drug therapy*.
- Evaluate the CNS *to check reflexes and muscle strength to identify the need for cautious drug use and to evaluate changes that occur as a result of drug therapy*.
- Examine the skin and mucous membranes to check for lesions, color, temperature, and texture *to monitor for adverse effects and superinfections*.
- Evaluate liver function, including liver function tests, *to determine the appropriateness of therapy and to monitor for toxicity*.
- Obtain cultures *to determine the exact protozoal species causing the disease*.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to GI and CNS effects of the drug
- Imbalanced Nutrition: Less Than Body Requirements related to severe GI effects of the drug

- Disturbed Sensory Perception (Kinesthetic, Visual) related to CNS effects
- Deficient Knowledge regarding drug therapy
- Diarrhea related to GI effects of the drug

Implementation With Rationale

- Arrange for appropriate culture and sensitivity tests before beginning therapy *to ensure proper drug for susceptible organisms*. Treatment may begin before test results are known.
- Administer a complete course of the drug *to get the full beneficial effects*. Use combination therapy as indicated.
- Monitor hepatic function before and periodically during treatment *to arrange to effectively stop the drug if signs of failure or worsening liver function occur*.
- Provide comfort and safety measures if CNS effects occur, such as side rails and assistance with ambulation if dizziness and weakness are present, *to prevent injury to the patient*.
- Provide oral hygiene and ready access to bathroom facilities as needed *to cope with GI effects*.
- Arrange for the treatment of superinfections as appropriate *to prevent severe infections*.
- Provide small, frequent, nutritious meals if GI upset is severe *to ensure proper nutrition*. Monitor nutritional status and arrange a dietary consultation as needed. Taking the drug with food may also decrease GI upset.
- Instruct the patient about the appropriate dosage regimen *to enhance patient knowledge about drug therapy and to promote compliance*.
- Provide the following patient teaching:
 - Take safety precautions, including changing position slowly and avoiding driving and hazardous tasks, if CNS effects occur.
 - Take the drug with meals and try small, frequent meals if GI upset is a problem.
 - Follow drug dosing guidelines carefully.
 - Report severe GI problems and interference with nutrition; fever and chills, which may indicate the presence of a superinfection; and dizziness, unusual fatigue, or weakness, which may indicate CNS effects.

Evaluation

- Monitor patient response to the drug (resolution of infection and negative cultures for parasite).
- Monitor for adverse effects (orientation and affect, nutritional state, skin color and lesions, hepatic function, and occurrence of superinfections).
- Evaluate the effectiveness of the teaching plan (patient can name the drug, dosage, possible adverse effects to watch for, and specific measures to help avoid adverse effects).
- Monitor the effectiveness of comfort and safety measures and compliance with the regimen.

See *Critical Thinking Scenario* for additional information related to coping with amebiasis and the use of metronidazole.

CRITICAL THINKING SCENARIO

Coping With Amebiasis

THE SITUATION

J.C., a 20-year-old male college student, reported to the university health center complaining of severe diarrhea, abdominal pain, and, most recently, blood in his stool. He had a mild fever and appeared to be dehydrated and very tired. The young man, who denied travel outside the country, reported eating most of his meals at the local beer joint, where he worked in the kitchen each night making pizza.

A stool sample for ova and parasites (O&P) was obtained, and a diagnosis of amebiasis was made. Metronidazole was prescribed. A public health referral was sent to find the source of the infection, which was the kitchen of the beer joint where J.C. worked. The kitchen was shut down until all the food, utensils, and environment passed state health inspection. Although a potential epidemic was averted (only three other cases of amebiasis were reported), the action of the public health officials added new stress to this student's life because he was unemployed for several months.

CRITICAL THINKING

What are the important nursing implications for J.C.? *Think about the usual nutritional state of a college student who eats most of his meals in a pizza place.*

What are the implications for recovery when a patient is malnourished and then has a disease that causes severe diarrhea, dehydration, and potential malnourishment? *Consider how difficult it will be for J.C. to be a full-time student while trying to cope with the signs and symptoms of his disease, as well as the adverse effects associated with his drug therapy and the need to maintain adequate nutrition to allow some healing and recovery.*

What potential problems could the added stress of being out of work have for J.C.? *Consider the physiological impact of stress, as well as the psychological problems of trying to cope with one more stressor.*

DISCUSSION

J.C. needed a great deal of reassurance and an explanation of his disease. He learned that oral hygiene and small, frequent meals would help alleviate some of his discomfort until the metronidazole could control the amebiasis and that good hygiene and strict hand washing when the disease is active would help to prevent transmission. He was advised to watch for the occurrence of specific adverse drug effects, such as a possible severe reaction to alcohol (he was advised to avoid alcoholic beverages while taking this drug); gastrointestinal upset and a strange metallic taste (the importance of good nutrition to promote healing of the gastrointestinal tract was stressed); dizziness or light-headedness; and superinfections.

J.C. was scheduled for a follow-up examination for stool O&P and nutritional status. Metronidazole was continued until the stool sample came back negative. He needed and received a great deal of support and encouragement because he was far from home and the disease and the drug effects were sometimes difficult to cope with. The effects of stress—decreasing blood flow to the gastrointestinal tract, for example—can make it more difficult for patients such as J.C. to recover from this disease. Support and encouragement can be major factors in their eventual recovery. J.C. was given a telephone number to call if he needed information or support and a complete set of written instructions regarding the disease and the drug therapy.

NURSING CARE GUIDE FOR J.C.: METRONIDAZOLE

Assessment: History and Examination

Allergies to metronidazole, renal or liver dysfunction
 Concurrent use of barbiturates, oral anticoagulants, alcohol
 Local: culture of stool for accurate diagnosis of infection
 CNS: orientation, affect, vision, reflexes
 Skin: color, lesions, texture
 GI: abdominal, liver evaluation
 Hematological: CBC, liver function tests

Nursing Diagnoses

Acute Pain related to GI, superinfection effects
 Disturbed Sensory Perception (Kinesthetic, Visual) related to CNS effects
 Imbalanced Nutrition: Less Than Body Requirements related to GI effects
 Deficient Knowledge regarding drug therapy

Implementation

Culture infection before beginning therapy.
 Provide comfort and safety measures: oral hygiene, safety precautions, treatment of superinfections, maintenance of nutrition.
 Provide small, frequent meals and monitor nutritional status.
 Provide support and reassurance for dealing with drug effects and discomfort.
 Provide patient teaching regarding drug name, dosage, adverse effects, precautions, and warning signs to report and hygiene measures to observe.

Evaluation

Evaluate drug effects: resolution of protozoal infection.
 Monitor for adverse effects: GI alterations, dizziness, confusion, CNS changes, vision loss, hepatic function, superinfections.
 Monitor for drug–drug interactions with oral anticoagulants, alcohol, or barbiturates.
 Evaluate effectiveness of patient teaching program.
 Evaluate effectiveness of comfort and safety measures.

Coping With Amebiasis (continued)**PATIENT TEACHING FOR J.C.**

You have been prescribed metronidazole to treat your amebic infection. This antiprotozoal drug acts to destroy certain protozoa that have invaded your body. Because it affects specific phases of the protozoal life cycle, it must be taken over a period of time to be effective. It is very important to take all the drug that has been ordered for you.

- This drug frequently causes stomach upset. If it causes you to have nausea, heartburn, or vomiting, take the drug with meals or a light snack.
- Common effects of this drug include the following:
 - *Nausea, vomiting, and loss of appetite:* Take the drug with food and have small, frequent meals.
 - *Superinfections of the mouth, skin:* These go away when the course of the drug has been completed. If they become uncomfortable, notify your health care provider for an appropriate solution.
- *Dry mouth, strange metallic taste:* Frequent mouth care and sucking sugarless lozenges may help. This effect will also go away when the course of the drug is finished.
- *Intolerance to alcohol (nausea, vomiting, flushing, headache, and stomach pain):* Avoid alcoholic beverages or products containing alcohol while taking this drug.
- Report any of the following to your health care provider: sore throat, fever, or chills; skin rash or redness; severe gastrointestinal upset; and unusual fatigue, clumsiness, or weakness.
- Take the full course of your prescription. Never use this drug to self-treat any other infection or give it to any other person.
- Tell any doctor, nurse, or other health care provider that you are taking this drug.
- Keep this drug and all medications out of the reach of children.

KEY POINTS

- ▶ Other protozoal infections include amebiasis, leishmaniasis, trypanosomiasis, trichomoniasis, giardiasis, and *Pneumocystis carinii*.
- ▶ Patients receiving antiprotozoal agents should be monitored regularly to detect any serious adverse effects, including loss of vision, liver toxicity, and so on.

CHAPTER SUMMARY

- A protozoan is a parasitic cellular organism. Its life cycle includes a parasitic phase inside human tissues or cells.
- Malaria is caused by *Plasmodium* protozoa, which must go through a cycle in the *Anopheles* mosquito before being passed to humans by the mosquito bite. Once inside a human, the protozoa invade red blood cells.
- The characteristic cyclic chills and fever of malaria occur when red blood cells burst, releasing more protozoa into the bloodstream.
- Malaria is treated with a combination of drugs that attack the protozoan at various stages in its life cycle.
- Amebiasis is caused by the protozoan *Entamoeba histolytica*, which invades human intestinal tissue after being passed to humans through unsanitary food or water. It is best treated with metronidazole or tinidazole.
- Leishmaniasis, a protozoan-caused disease, can result in serious lesions in the mucosa, viscera, and skin. It is treated with systemic pentamidine.
- Trypanosomiasis, which is caused by infection with a *Trypanosoma* parasite, may assume two forms. African sleeping sickness leads to inflammation of the CNS, and Chagas disease results in serious cardiomyopathy. These diseases can be treated with systemic pentamidine.
- Trichomoniasis is caused by *Trichomonas vaginalis*. This common cause of vaginitis results in no signs or symptoms in men but serious vaginal inflammation in women. It is treated with metronidazole and tinidazole.
- Giardiasis, which is caused by *Giardia lamblia*, is the most commonly diagnosed intestinal parasite in the United States. This disease may lead to serious malnutrition when the pathogen invades intestinal mucosa. It is treated with nitazoxanide, metronidazole, and tinidazole.
- *Pneumocystis carinii* is an endemic protozoan that does not usually cause illness in humans unless they become immunosuppressed. *P. carinii* pneumonia (PCP) is the most common opportunistic infection seen in AIDS patients. It is treated with inhaled pentamidine and oral atovaquone.
- Patients receiving antiprotozoal agents should be monitored regularly to detect any serious adverse effects, including loss of vision, liver toxicity, and so on.

Information about giardiasis—support, treatment, prevention, and teaching.

<http://www.cdc.gov/ncidod/dpd/parasites/amebiasis>.

Information about amebiasis prevention, incidence, and treatments.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in the Answers to Check Your Understanding Questions on the CD-Rom in the front of this book.

MULTIPLE CHOICE

Select the best answer to the following.

- After a group of students is taught about protozoal infections, which infection, if stated by the group as caused by an insect bite, would indicate the need for additional teaching?
 - malaria
 - trypanosomiasis
 - leishmaniasis
 - giardiasis
- When describing the development of malaria caused by the *Plasmodium* protozoan, the instructor would explain that the organism depends on
 - a snail to act as intermediary in the life cycle of the protozoan.
 - a mosquito and a red blood cell for maturation.
 - a human liver cell for cell division and reproduction.
 - stagnant water for maturation.
- A patient who is receiving a combination drug to treat malaria asks the nurse why. The nurse responds to the patient based on the understanding that combination drugs are
 - associated with a much lower degree of toxicity when used in combination.
 - absorbed more completely when administered and taken together.
 - more effective in preventing mosquitoes from biting the individual.
 - effective at various stages in the life cycle of the protozoan.
- A patient traveling to an area of the world where malaria is known to be endemic should be taught to
 - avoid drinking the water.
 - begin prophylactic antimalarial therapy before traveling and continue it through the visit and for 2 to 3 weeks after the visit.
 - take a supply of antimalarial drugs in case he or she gets a mosquito bite.
 - begin prophylactic antimalarial therapy 2 weeks before traveling and stop the drugs on arriving at the destination.
- Amebiasis or amebic dysentery
 - is seen only in Third World countries.
 - is caused by a protozoan that enters the body through an insect bite.
 - is caused by a protozoan that can enter the body in the cyst stage in water or food.
 - usually has no signs and symptoms.
- Giardiasis is the most common intestinal parasite seen in the United States, and it
 - does not respond to drug therapy.
 - can invade the liver and cause death.
 - is seen only in areas with no sanitation.
 - is associated with rotten egg-smelling stool, diarrhea, and mucus-filled stool.
- PCP (*Pneumocystis carinii* pneumonia) is
 - an endemic protozoan found in the human respiratory system.
 - responsive to inhaled pentamidine.
 - an opportunistic bacterial infection.
 - frequently associated with children in day care settings.

8. Trypanosomiasis may assume two different forms:
 - a. African sleeping sickness and Chagas disease.
 - b. elephantiasis and malaria.
 - c. dysentery and African sleeping sickness.
 - d. malaria and Chagas disease.
9. A nurse would note that a patient had a good understanding of his antimalarial drug regimen if the patient reported
 - a. "I keep these pills with me at all times while I'm away and take them only when I have been bitten by a mosquito."
 - b. "I will need to start these pills now and then continue to take them every day for the rest of my life."
 - c. "I'll start the pills before my trip, keep taking them during the trip, and for a period of time after I'm home."
 - d. "I start taking these pills as soon as I arrive at my vacation destination, but before I get off the plane."

MULTIPLE RESPONSE

Select all that apply.

1. A mother calls in concerned that her son, a college freshman, has been diagnosed with giardiasis. The nurse would respond to the mother's concerns by telling her which of the following?
 - a. You should have your son come home immediately so that he can be treated appropriately.
 - b. This is a very rare disorder; it is not usually seen in this country.
 - c. This is the most common protozoal infection seen in this country and is usually transmitted through food or water.
 - d. This infection can be treated with oral drugs, and he should be able to get the drugs where his infection was diagnosed.
 - e. This is an infection that has to be treated quickly with IV medications.
 - f. Encourage your son to get the medicine and to try very hard to eat nutritious food.

Anthelmintic Agents

13

Learning Objectives

Upon completion of this chapter, you will be able to:

1. List the common worms that cause disease in humans.
2. Describe the therapeutic actions, indications, pharmacokinetics, contraindications, most common adverse reactions, and important drug–drug interactions associated with the anthelmintics.
3. Discuss the use of anthelmintics across the lifespan.
4. Compare and contrast the prototype drug mebendazole with other anthelmintics.
5. Outline the nursing considerations, including important teaching points to stress, for patients receiving an anthelmintic.

Glossary of Key Terms

Ascaris: the most prevalent helminthic infection; fertilized roundworm eggs are ingested, which hatch in the small intestine and then make their way to the lungs, where they may cause cough, fever, and other signs of a pulmonary infiltrate

cestode: tapeworm with a head and segmented body parts that is capable of growing to several yards in the human intestine

filariasis: infection of the blood and tissues of healthy individuals by worm embryos or filariae

helminth: worm that can cause disease by invading the human body

hookworms: worms that attach themselves to the small intestine of infected individuals, where they suck blood from the walls of the intestine, damaging the intestinal wall and leading to severe anemia with lethargy, weakness, and fatigue

nematode: roundworms such as the commonly encountered pinworm, whipworm, threadworm, *Ascaris*, or hookworm that cause a common helminthic infection in humans; can cause intestinal obstruction as the adult worms clog the intestinal lumen or severe pneumonia when the larvae migrate to the lungs and form a pulmonary infiltrate

pinworm: nematode that causes a common helminthic infection in humans; lives in the intestine and causes anal and possible vaginal irritation and itching

platyhelminth: flatworms, including the cestodes or tapeworms; a worm that can live in the human intestine or can invade other human tissues (flukes)

schistosomiasis: infection with a blood fluke that is carried by a snail; it poses a common problem in tropical countries, where the snail is the intermediary in the life cycle of the worm; larvae burrow into the skin in fresh water and migrate throughout the human body, causing a rash and then symptoms of diarrhea and liver and brain inflammation

threadworm: pervasive nematode that can send larvae into the lungs, liver, and CNS; can cause severe pneumonia or liver abscess

trichinosis: disease that results from ingestion of encysted roundworm larvae in undercooked pork; larvae migrate throughout the body to invade muscles, nerves, and other tissues; can cause pneumonia, heart failure, and encephalitis

whipworm: worm that attaches itself to the intestinal mucosa and sucks blood; may cause severe anemia and disintegration of the intestinal mucosa

DRUG LIST

Anthelmintics
albendazole

ivermectin
mebendazole
praziquantel

pyrantel
thiabendazole

Helminthic infections, or infections in the gastrointestinal tract or other tissues due to worm infestation, affect about 1 billion people, making these types of infections among the most common of all diseases. These infestations are very common in tropical areas, but they are also often found in other regions, including countries such as the United States and Canada. With so many people traveling to many parts of the world, it is not uncommon for a traveler to contract a helminthic infection in one country and inadvertently bringing it home, where the worms then can infect other individuals (Box 13.1). The **helminths** that most commonly infect humans are of two types: the nematodes (or roundworms) and the platyhelminths (or flatworms) that cause intestine-invading worm infections; and tissue-invading worms.

Frequently, patients have a very difficult time dealing with a diagnosis of worm infestation. It is very important for the nurse to understand the disease process and to explain the disease and treatment carefully to help the patient to cope with both the diagnosis and the treatment.

INTESTINE-INVADING WORM INFECTIONS

Many of the worms that infect humans live only in the intestinal tract. Proper diagnosis of a helminthic infection requires a stool examination for ova (eggs) and parasites. Treatment of a helminthic infection entails the use of an anthelmintic drug. Another important part of therapy for helminthic infections

BOX 13.1

Cultural Considerations

Travelers and Helminths

People who come from or travel to areas of the world where schistosomiasis is endemic should always be assessed for the possibility of infection with such a disease when seen for health care. Areas of the world in which this disease is endemic are mainly tropical settings, such as Puerto Rico, islands of the West Indies, Africa, parts of South America, the Philippines, China, Japan, and Southeast Asia. People traveling to these areas should be warned about wading, swimming, or bathing in freshwater streams, ponds, or lakes. For example, swimming in the Nile River is a popular attraction on Egyptian vacation tours; however, this activity may result in a lasting (unhappy) memory when the traveler returns home and is diagnosed with schistosomiasis. The nurse can suggest to patients who are planning a visit to one of these areas that they contact the Centers for Disease Control and Prevention (CDC) for health and safety guidelines, as well as what signs and symptoms to watch for after returning home. The CDC can be reached on the World Wide Web at <http://www.cdc.gov/travel>.

involves the prevention of reinfection or spread of an existing infection. Measures such as thorough hand washing after use of the toilet; frequent laundering of bed linens and underwear in very hot, chlorine-treated water; disinfection of toilets and bathroom areas after each use; and good personal hygiene to wash away ova are important to prevent the spread of the disease. See Table 13.1 for a summary of worms that cause intestinal infections.

Infections by Nematodes

Nematodes, or roundworms, include the commonly encountered pinworms, whipworms, threadworms, *Ascaris*, and hookworms. These worms cause diseases that range from mild to potentially fatal.

Pinworm Infections

Pinworms are usually transmitted when the worm eggs are ingested, either by transfer by touching the eggs when they are shed to clothing, toys, or bedding; or by the inhalation of eggs that become airborne and are then swallowed. Pinworms, which remain in the intestine, cause little discomfort except for perianal itching or occasionally vaginal itching. Infection with pinworms is the most common helminthic infection among school-aged children.

Whipworm Infections

Whipworms are transmitted when eggs found in the soil are ingested. Whipworms attach to the wall of the colon. In large numbers, they cause colic and bloody diarrhea. In severe cases, whipworm infestation may result in prolapse of the intestinal wall and anemia related to blood loss.

Threadworm Infestation

Threadworms can cause more damage to humans than most of the other helminths. Threadworms are transmitted as larvae found in the soil and inadvertently ingested. The larvae mature into worms, and, after burrowing into the wall of the small intestine, female worms lay eggs. These eggs hatch into larvae that invade many body tissues, including the lungs, liver, and heart. In very severe cases, death may occur from pneumonia or from lung or liver abscesses that result from larval invasion.

Ascaris

Worldwide, *Ascaris* infection is the most prevalent helminthic infection. It may occur wherever sanitation is poor. Eggs in the soil are ingested with vegetables or other improperly washed foods. Many individuals are unaware that they have this infestation unless they see a worm in their stool. However, others become quite ill.

Initially, the individual ingests fertilized roundworm eggs, which hatch in the small intestine and then make their way to the lungs, where they may cause cough, fever, and other signs of a pulmonary infiltrate. The larvae then migrate back to the intestine, where they grow to adult size (i.e., about as long

● TABLE 13.1 Helminthic Infections

INTESTINE-INVADING WORM	MECHANISM OF DISEASE	MANIFESTATIONS
Pinworms	Remain in intestine	Perianal itching Occasionally, vaginal itching
Whipworms	Attach to wall of colon	Colic Bloody diarrhea (with large numbers of worms)
Threadworms	Burrow into intestine; can enter lungs, liver, and other tissue	Pneumonia, liver abscess
<i>Ascaris</i>	Burrow into intestine; enter the blood and infect lungs	Cough, fever, pulmonary infiltrates; abdominal distention and pain
Hookworms	Attach to the wall of the intestine	Anemia, fatigue, malabsorption
Cestodes	Live in the intestine, ingesting nutrients from the host	Weight loss, abdominal distention

and as big around as an earthworm), causing abdominal distention and pain. In the most severe cases, intestinal obstruction by masses of worms can occur.

Hookworm Infections

Hookworms eggs are found in the soil, where they hatch into a larva that molts and becomes infective to humans. The larvae penetrate the skin and then enter the blood and within about a week reach the intestine. Hookworms attach to the small intestine of infected individuals. The worms suck blood from the walls of the intestine, damaging the intestinal wall and leading to severe anemia with lethargy, weakness, and fatigue. Malabsorption problems may occur as the small intestinal mucosa is altered. Treatment for anemia and fluid and electrolyte disturbances is an important part of the therapy for this infection.

Infections Caused by Platyhelminths

The **platyhelminths** (flatworms) include the cestodes (tapeworms) that live in the human intestine and the flukes (schistosomes) that live in the intestine and that also invade other tissues as part of their life cycle. Because schistosomes invade tissues, they are discussed in the following section on tissue-invading worm infections.

Cestodes

Cestodes are segmented flatworms with a head, or scolex, and a variable number of segments that grow from the head. Cestodes enter the body as larvae that are found in undercooked meat or fish; they sometimes form worms that are several yards long, persons with a tapeworm may experience some abdominal discomfort and distention, as well as weight loss because the worm eats ingested nutrients. Many infected patients require a great deal of psychological support when they excrete parts of the tapeworm or when the worm occasionally exits through the mouth or nose.

TISSUE-INVADING WORM INFECTIONS

Some of the worms that invade the body exist outside of the intestinal tract and can seriously damage the tissues they invade. Because of their location within healthy tissue, they can also be more difficult to treat.

Trichinosis

Trichinosis is the disease caused by ingestion of the encysted larvae of the roundworm, *Trichinella spiralis*, in undercooked pork. Once ingested, the larvae are deposited in the intestinal mucosa, pass into the bloodstream, and are carried throughout the body. They can penetrate skeletal muscle and can cause an inflammatory reaction in cardiac muscle and in the brain. Fatal pneumonia, heart failure, and encephalitis may occur.

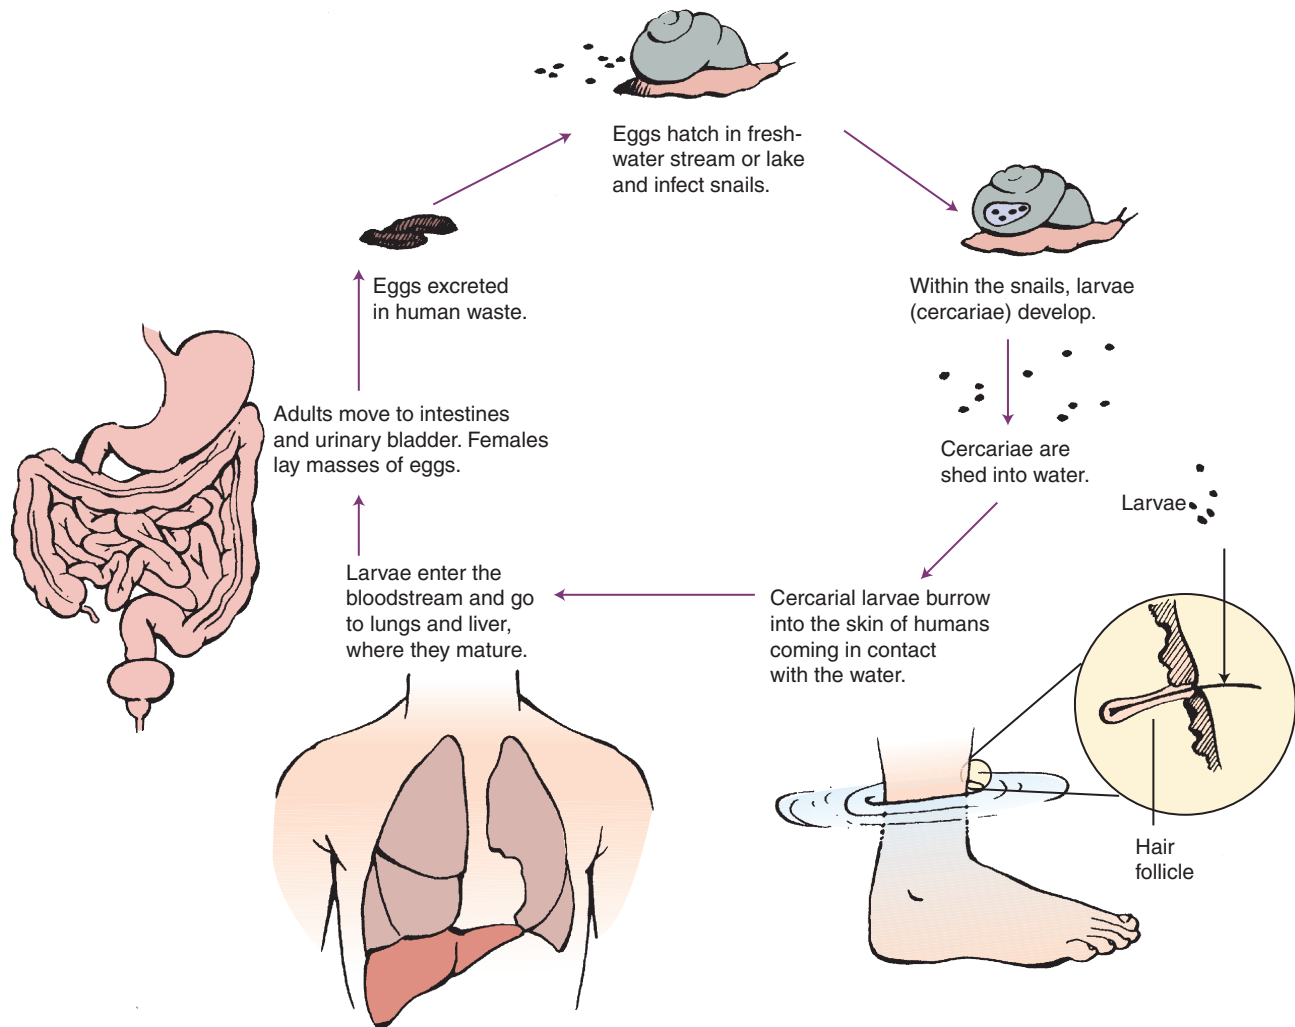

The best treatment for trichinosis is prevention. Because the larvae are ingested by humans in undercooked pork, freezing pork meat, monitoring the food eaten by pigs, and instructing individuals about properly cooking pork can be most beneficial.

Filariasis

Filariasis refers to infection of the blood and tissues of healthy individuals by worm embryos, which enter the body via insect bites. These thread-like embryos, or filariae, can overwhelm the lymphatic system and cause massive inflammatory reactions. This may lead to severe swelling of the hands, feet, legs, arms, scrotum, or breast—a condition called elephantiasis.

Schistosomiasis

Schistosomiasis (Figure 13.1) is a platyhelminthic infection by a fluke that is carried by a snail. This disease is a common problem in parts of Africa, Asia, and certain South American

● **FIGURE 13.1** Life cycle of schistosomes.

and Caribbean countries that have climates and snails conducive to the life cycle of schistosomes.

Eggs that are excreted in the urine and feces of infected individuals hatch in fresh water into a form that infects a certain snail. In the snail, larvae known as cercariae develop. The snail sheds the cercariae back into the freshwater pond or lake. People become infected when they come in contact with the infested water. The larvae attach to the skin and quickly burrow into the bloodstream and lymphatics. Then they move into the lungs, and later to the liver, where they mature into adult worms that mate and migrate to the intestines and urinary bladder. The female worms then lay large numbers of eggs, which are expelled in the feces and urine, and the cycle begins again.

Signs and symptoms may include a pruritic rash, often called swimmer's itch, where the larva attaches to the skin. About 1 or 2 months later, affected individuals may experience several weeks of fever, chills, headache, and other symptoms. Chronic or severe infestation may lead to abdominal pain and diarrhea, as well as blockage of blood flow to

areas of the liver, lungs, and central nervous system (CNS). These blockages can lead to liver and spleen enlargement, as well as signs of CNS and cardiac ischemia. (See Critical Thinking Scenario for a case study of a patient diagnosed with chronic schistosomiasis.)

KEY POINTS

- ◆ Helminths are worms that cause disease by invading the human body. Some helminths invade body tissues and can seriously damage lymphatic tissue, lungs, CNS, heart, or liver.
- ◆ Pinworms are the most frequent cause of helminth infection in the United States, and roundworms called *Ascaris* are the most frequent cause of helminth infections throughout the world.
- ◆ Patient teaching is important for decreasing the stress and anxiety that may occur when individuals are diagnosed with a worm infestation.

CRITICAL THINKING SCENARIO

Anthelmintics

THE SITUATION

V.Y., a 33-year-old man from Vietnam, underwent a complete physical examination in preparation for a training job in custodial work at a local hospital. He was a refugee who had come to the United States 6 months ago as part of a church-sponsored resettlement program. In the course of the examination, it was found that he had a history of chronic diarrhea, hepatomegaly, pulmonary rales, and splenomegaly. Further tests indicated that he had chronic schistosomiasis. Because of V.Y.'s limited use of the English language, he was hospitalized so that his disease, which was unfamiliar to most of the associated health care providers, could be monitored. He was treated with praziquantel.

CRITICAL THINKING

What are the important nursing implications for V.Y.? *Think about the serious limitations that are placed on medical care, particularly patient teaching, when the patient and the health care workers do not speak the same language.*

What innovative techniques could be used to teach this patient about the disease, the drugs, and the hygiene measures that are important for him to follow?

Are the other patients or workers in the hospital exposed to any health risks? What sort of educational program should be developed to teach them about this disease and to allay any fears or anxieties they may have?

What special interventions are needed to explain the drug therapy and any adverse effects or warning signs that V.Y. should be watching for?

DISCUSSION

A language barrier can be a real handicap in the health care system. In many cases, pictures can assist communication. For example, the need for nutritious food is conveyed by using appropriate pictures of foods that should be eaten. Frequent reinforcement is necessary because the patient has no way of letting you know that he really understands the message that you are trying to convey. The patient is prepared for discharge through careful patient teaching that may involve pictures, calendars, and clocks so that he is given every opportunity to comply with his medical regimen.

In addition, the nursing staff should contact the local health department to determine whether the local sewer system can properly handle contaminated wastes. In this case, the staff learned from the Centers for Disease Control and Prevention that the snail's intermediate host does not live in this country, so the hazards posed by this waste are small, and normal disposal of the wastes should be appropriate.

V.Y. should also be observed for signs of adverse effects, although praziquantel is a relatively mild drug. Drug fever, abdominal pain, or dizziness may occur. If dizziness occurs, safety precautions, such as assistance with ambulation, use of side rails, and adequate lighting, need to be taken without alarming the patient.

NURSING CARE GUIDE FOR V.Y.: ANTHELMINTIC AGENTS

Assessment: History and Examination

Allergies to this drug, renal or liver dysfunction

Drug history: use of albendazole

Local: culture of infection

CNS: orientation, affect

Skin: color, lesions, texture

GI: abdominal and liver evaluation, including hepatic function tests

GU: renal function tests

Nursing Diagnoses

Acute Pain related to GI or CNS effects

Disturbed Personal Identity related to diagnosis and treatment

Fear related to communication problems, health issues

Deficient Knowledge regarding drug therapy

Implementation

Culture for ova and parasites before beginning therapy.

Provide comfort and safety measures: small, frequent meals; safety precautions; hygiene measures; maintenance of nutrition.

Monitor nutritional status as needed.

Provide support and reassurance to deal with drug effects, discomfort, and diagnosis.

Provide patient teaching regarding drug name, dosage regimen, adverse effects and precautions to report, and hygiene measures to observe.

Evaluation

Evaluate drug effects: resolution of helminth infection.

Monitor for adverse effects: GI alterations, CNS changes, dizziness and confusion, renal and hepatic function.

Monitor for drug–drug interactions: concurrent use of albendazole.

Evaluate effectiveness of patient teaching program.

Evaluate effectiveness of comfort and safety measures.

PATIENT TEACHING FOR V.Y.

- This drug is called an anthelmintic. It works to destroy certain helminths, or worms, that have invaded your body.
- It is important that you take the full course of the drug—three doses the first day, then retesting to repeat this course

Anthelmintics (continued)

- if needed to ensure that all of the worms, in all phases of their life cycle, have disappeared from your body.
- You may take this drug with meals or with a light snack to help decrease any stomach upset that you may experience. Swallow the tablets whole and avoid holding them in your mouth for any length of time because a very unpleasant taste may occur.
 - Common effects of this drug include
 - Nausea, vomiting, and loss of appetite:* Take the drug with food, and eat small, frequent meals.
 - Dizziness and drowsiness:* If this occurs, avoid driving a car or operating dangerous machinery. Change positions slowly to avoid falling or injury.
 - Report any of the following conditions to your health care provider: fever, chills, rash, headache, weakness, or tremors.
 - Take all of the drug that has been prescribed. Never use this drug to self-treat any other infection or give it to any other person.
 - Tell any doctor, nurse, or other health care provider that you are taking this drug.
 - Keep this drug and all medications out of the reach of children.

ANTHELMINTICS

The anthelmintic drugs (Table 13.2) act on metabolic pathways that are present in the invading worm but are absent or significantly different in the human host. Anthelmintic drugs include albendazole (*Albenza*), ivermectin (*Stromectol*),

mebendazole (*Vermox*), praziquantel (*Biltricide*), pyrantel (*Antiminth, Pin-Rid, Pin-X, Reese's Pinworm*), and thiabendazole (*Mintezol*). Box 13.2 includes information about use of these drugs across the lifespan. See the Critical Thinking Scenario for a case study of a patient receiving anthelmintics.

TABLE 13.2 DRUGS IN FOCUS Anthelmintics

Drug Name	Dosage/Route	Usual Indications
albendazole (<i>Albenza</i>)	Hydatid disease: ≥60 kg: 400 mg b.i.d. PO <60 kg: 15 mg/kg per day PO in divided doses, b.i.d., on a 28-day cycle, followed by 14 days of rest, for a total of three cycles Neurocysticercosis: ≥60 kg: 400 mg b.i.d. PO <60 kg: 15/mg/kg per day PO in divided doses, b.i.d., for 8–30 d of treatment	Treatment of active lesions caused by pork tapeworm and cystic disease of the liver, lungs, and peritoneum caused by dog tapeworm
ivermectin (<i>Stromectol</i>)	150–200 mg/kg PO as a single dose	Treatment of threadworm disease or strongyloidiasis; onchocerciasis or river blindness, which is found in tropical areas of Africa, Mexico, and South America
 mebendazole (<i>Vermox</i>)	100 mg PO morning and evening on 3 consecutive days Enterobiasis: 100 mg PO as a single dose	Treatment of diseases caused by pinworms, roundworms, whipworms, and hookworms
praziquantel (<i>Biltricide</i>)	Three doses of 20–25 mg/kg PO as a 1-d treatment	Treatment of a wide number of schistosomes or flukes
pyrantel (<i>Antiminth, Pin-Rid, Pin-X, Reese's Pinworm</i>)	11 mg/kg PO as a single dose; maximum dose, 1 g	Treatment of diseases caused by pinworms and roundworms; because administered in single dose, may be preferred for patients who could have trouble remembering to take medication or following drug regimens
thiabendazole (<i>Mintezol</i>)	<150 lb: 10 mg/lb per dose PO, 2 doses per day ≥150 lb: 1.5 g/dose PO, 2 doses per day	Treatment of diseases caused by roundworms, hookworms, and whipworms; although not drug of choice if other anthelmintics can be used (see adverse effects), it is drug of choice for treatment of threadworm infections; can be used to alleviate the signs and symptoms of invasive trichinosis

FOCUS ON
BOX 13.2
Drug Therapy Across the Lifespan
Anthelmintic Agents
CHILDREN

Culture of the suspected worm is important before beginning any drug therapy.

The more toxic drugs—albendazole, ivermectin, and praziquantel—should be avoided in children.

The most commonly used anthelmintic, mebendazole, comes in a chewable tablet that is convenient for use in children.

Nutritional status and hydration are major concerns with children taking these drugs who develop serious gastrointestinal effects.

ADULTS

Adults may be somewhat repulsed by the idea that they have a worm infestation, and they may be reluctant to

discuss the needed lifestyle adjustments and treatment plans.

Pregnant and nursing women should not use these drugs unless the benefit clearly outweighs the potential risk to the fetus or neonate. If a severe helminth infestation threatens the mother, some of the drugs can be used as long as the mother is informed of the potential risk.

OLDER ADULTS

Older patients may be more susceptible to the central nervous system and gastrointestinal effects of some of these drugs. Dose adjustment is needed for these agents.

Monitor hydration and nutritional status carefully.

Therapeutic Actions and Indications

Anthelmintic agents are indicated for the treatment of infections by certain susceptible worms and are very specific in the worms that they affect; they are not interchangeable for treating various worm infections. See Table 13.2 for usual indications for each of these agents. Anthelmintics interfere

with metabolic processes in particular worms, as described previously. Figure 13.2 shows sites of actions for these drugs.

Pharmacokinetics

Mebendazole is available in the form of a chewable tablet, and a typical 3-day course can be repeated in 3 weeks if

● **FIGURE 13.2** General structure of a cell, showing the sites of action of the anthelmintic agents. Mebendazole interferes with the ability to use glucose, leading to an inability to reproduce and cell death. Albendazole blocks tubule formation, resulting in cell death. Ivermectin blocks calcium channels, leading to nerve and muscle paralysis and cell death. Praziquantel is a neuromuscular polarizing agent that causes paralysis and cell death. Thiabendazole both suppresses egg and larva production and blocks a helminth-specific enzyme that promotes the development of eggs and larvae. Praziquantel increases membrane permeability, leading to a loss of intracellular calcium and muscular paralysis; it may also result in disintegration of the integument

needed. Very little of the mebendazole is absorbed systemically, so adverse effects are few. The drug is not metabolized in the body, and most of it is excreted unchanged in the feces. A small amount may be excreted in the urine.

Albendazole is poorly absorbed from the gastrointestinal (GI) tract, reaching peak plasma levels in about 5 hours. It is metabolized in the liver and primarily excreted in urine.

Ivermectin is readily absorbed from the GI tract and reaches peak plasma levels in 4 hours. It is completely metabolized in the liver with a half-life of 16 hours; excretion is through the feces.

Praziquantel is taken in a series of three oral doses at 4- to 6-hour intervals. It is rapidly absorbed from the GI tract and reaches peak plasma levels within 1 to 3 hours. It is metabolized in the liver with a half-life of 0.8 to 1.5 hours. Excretion of praziquantel occurs primarily through the urine.

Pyrantel is poorly absorbed, and most of the drug is excreted unchanged in the feces, although a small amount may be found in the urine.

Thiabendazole is readily absorbed from the GI tract, reaching peak levels in 1 to 2 hours. It is completely metabolized in the liver and primarily excreted in the urine.

Contraindications and Cautions

Overall contraindications to the use of anthelmintic drugs include the presence of known allergy to any of these drugs; lactation *because the drugs can enter breast milk and could be toxic to the infant*—women are advised to refrain from breast-feeding when using these drugs; and pregnancy (in most cases) *because of reported associated fetal abnormalities or death*. Women of childbearing age should be advised to use barrier contraceptives while taking these drugs. Pyrantel has not been established as safe for use in children younger than 2 years. Albendazole should be used only after the causative worm has been identified *because it can cause adverse effects on the liver, which could be problematic if the patient has liver involvement*.

Use caution in the presence of renal or hepatic disease *that interferes with the metabolism or excretion of drugs that are absorbed systemically* and in cases of severe diarrhea and malnourishment, *which could alter the effects of the drug on the intestine and any preexisting helminths*.

Adverse Effects

Adverse effects frequently encountered with the use of these anthelmintic agents are related to their absorption or direct action in the intestine. Mebendazole and pyrantel, which are not absorbed systemically, may cause abdominal discomfort, diarrhea, or pain but have very few other effects and are well tolerated. Anthelmintics that are absorbed systemically may cause the following effects: headache and dizziness; fever, shaking, chills, and malaise associated with an immune reaction to the death of the worms; rash; pruritus; and loss of hair.

Changes in protein synthesis by the liver caused by Stevens–Johnson syndrome is associated with thiabendazole use and can be fatal. In addition, renal failure and severe bone marrow depression are associated with albendazole, which is toxic to some human tissues. Patients taking this drug require careful monitoring.

Clinically Important Drug–Drug Interactions

Combinations of theophylline and thiabendazole may lead to increased theophylline levels, and patients who take both of these drugs may require frequent monitoring and dose reduction of the theophylline. The effects of albendazole, which are already severe, may increase if the drug is combined with dexamethasone, praziquantel, or cimetidine. These combinations should be avoided if at all possible; if they are necessary, patients should be monitored closely for the occurrence of adverse effects.

Prototype Summary: Mebendazole

Indications: Treatment of whipworm, pinworm, roundworm, and hookworm infections.

Actions: Irreversibly blocks glucose uptake by susceptible helminths, depleting glycogen stores needed for survival and reproduction, causing the death of the helminth.

Pharmacokinetics:

Route	Onset	Peak
Oral	Slow	2–4 h

T_{1/2}: 2.5 to 9 hours; metabolized in the liver and excreted in the feces.

Adverse effects: Transient abdominal pain, diarrhea, fever.

Nursing Considerations for Patients Receiving Anthelmintics

Assessment: History and Examination

- Assess for possible contraindications or cautions: history of allergy to any of the anthelmintics *to avoid hypersensitivity reactions*; history of hepatic or renal dysfunction *that might interfere with drug metabolism and excretion of the drug*; and current status related to pregnancy and lactation, *which are contraindications to the use of these drugs*.
- Perform a physical assessment to *establish baseline data for determining the effectiveness of the drug and the occurrence of any adverse effects associated with drug therapy*.
- Obtain a culture of stool for ova and parasites *to determine the infecting worm and establish appropriate treatment*.
- Examine reflexes and muscle strength *to evaluate changes that occur as a result of drug therapy*.
- Evaluate liver function and renal function tests *to determine appropriateness of therapy and to monitor for toxicity*.

- Examine skin, including color, temperature, and texture, and note any lesions to assess for possible adverse effects.
- Assess the abdomen *to evaluate for any changes from baseline related to the infection, identify possible adverse effects, and monitor for improvement.*

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include:

- Acute Pain related to GI, CNS, or skin effects of drug
- Disturbed Personal Identity related to diagnosis and treatment
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Arrange for appropriate culture and sensitivity tests before beginning therapy *to ensure identification of the correct cause and use of the appropriate drug.*
- Administer the complete course of the drug *to obtain the full beneficial effects.* Ensure that chewable tablets are chewed. Give the drug with food if necessary, but avoid giving the drug with high-fat meals, which might interfere with drug effectiveness.
- Monitor hepatic and renal function before and periodically during treatment *to allow for early identification and prompt intervention if signs of failure due to albendazole administration occur.*

- Provide comfort and safety measures if CNS effects occur (e.g., side rails and assistance with ambulation in the presence of dizziness and weakness) *to protect the patient from injury.* Provide oral hygiene and ready access to bathroom facilities as needed *to cope with GI effects.*
- Provide small, frequent, nutritious meals if GI upset is severe *to ensure adequate nutrition.* Monitor nutritional status and arrange a dietary consultation as needed. Taking the drug with food may also decrease GI upset.
- Instruct the patient about the appropriate dosage regimen and other measures *to enhance patient knowledge about drug therapy and to promote compliance*
- Provide the following patient teaching:
 - Take safety precautions, including changing position slowly and avoiding driving and hazardous tasks, if CNS effects occur.
 - Take the drug with meals and try small, frequent meals if GI upset is a problem.
 - Identify the importance of strict hand washing and hygiene measures, including daily laundering of underwear and bed linens, daily disinfection of toilet facilities, and periodic disinfection of bathroom floors (Box 13.3).
 - Report fever, severe diarrhea, or aggravation of condition, which could indicate a resistant strain or noneffective therapy, to a health care provider.

BOX 13.3

Patient and Family Teaching

Managing Pinworm Infections

Infestation with worms can be a frightening and traumatic experience for most people. Seeing the worm can be an especially difficult experience. Some worm infestations are not that uncommon in the United States, especially infestation with pinworms.

Pinworms can spread very rapidly among children in schools, summer camps, and other institutions. Once the infestation starts, careful hygiene measures and drug therapy are required to eradicate the disease. After the diagnosis has been made and appropriate drug therapy started, proper hygiene measures are essential. Some suggested hygiene measures that might help to control the infection include the following:

- Keep the child's nails cut short and hands well scrubbed because reinfection results from the worm's eggs being carried back to the mouth after becoming lodged under the fingernails when the child scratches the pruritic perianal area.
- Give the child a shower in the morning to wash away any ova deposited in the anal area during the night.
- Change and launder undergarments, bed linens, and pajamas every day.
- Disinfect toilet seats daily and the floors of bathrooms and bedrooms periodically.
- Encourage the child to wash hands vigorously after using the toilet.

In some areas of the United States, parents are asked to check for worm ova by pressing sticky tape against the anal area in the morning before bathing. The sticky tape is then pressed against a slide that can be taken or sent to a clinical laboratory for evaluation. It may take 5 to 6 weeks to get a clear reading with this method of testing. Some health care providers believe that the psychological trauma involved in doing this type of follow-up, especially with a school-age child, makes this task too onerous to ask parents to do. Instead, many believe that the ease of treating this relatively harmless disease makes it more prudent to continue to treat as prescribed and to forgo the follow-up testing.

It is important to reassure patients and families that these types of infections do not necessarily reflect negatively on their hygiene or lifestyle. It takes a coordinated effort among medical personnel, families, and patients to control a pinworm infestation.

Evaluation

- Monitor patient response to the drug (resolution of helminth infestation and improvement in signs and symptoms).
- Monitor for adverse effects (changes in orientation and affect, nutritional state, skin color and evidence of lesions, hepatic and renal function, and reports of abdominal discomfort and pain).
- Evaluate the effectiveness of the teaching plan (patient can name the drug, dosage, possible adverse effects to watch for, and specific measures to help avoid adverse effects).
- Monitor the effectiveness of comfort and safety measures and compliance with the regimen.

KEY POINTS

- ▶ Anthelmintic drugs affect metabolic processes that are either different in worms than in human hosts or are not found in humans. These agents all cause death of the worm by interfering with normal functioning.
- ▶ Proper hygiene and sanitation process are an important part in preventing the spread of helminths, including good hand hygiene and preparation and storage of food.

CHAPTER SUMMARY

- Helminths are worms that cause disease by invading the human body. Helminths that affect humans include nematodes (round-shaped worms) such as pinworms, hookworms, threadworms, whipworms, and roundworms; and platyhelminths (flatworms), which include tapeworms and flukes.
- Pinworms are the most frequent cause of helminth infection in the United States, and roundworms called *Ascaris* are the most frequent cause of helminth infections throughout the world.
- Some helminths invade body tissues and can seriously damage lymphatic tissue, lungs, CNS, heart, liver, and so on. These include trichinosis-causing tapeworms, which

are found in undercooked pork; filariae, which occur when thread-like worm embryos clog up vascular spaces; and schistosomiasis-causing flukes. Schistosomiasis is a common problem in many tropical areas where the snail that is necessary in the life cycle of the fluke lives.

- Anthelmintic drugs affect metabolic processes that are either different in worms than in human hosts or are not found in humans. These agents all cause death of the worm by interfering with normal functioning.
- Prevention is a very important part of the treatment of helminths. Thorough hand washing; laundering of bed linens, pajamas, and underwear to destroy ova that are shed during the night; and disinfection of toilet facilities at least daily and of bathroom floors periodically help to stop the spread of these diseases. In addition, proper sanitation and hygiene in food preparation and storage is essential for reducing the incidence of these infestations.
- Patient teaching is important for decreasing the stress and anxiety that may occur when individuals are diagnosed with a worm infestation.

WEB LINKS

Health care providers and patients may want to consult the following Internet sources:

Information for travelers about potential helminth infestations, precautions, treatments, and warning signs.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-Rom in the front of the book.

MULTIPLE CHOICE

Select the best answer to the following.

- To ensure effective treatment of pinworm infections, which instruction would be most important to emphasize to the patient and family?
 - keeping nails long so cutting will not introduce more infection.
 - laundering undergarments, bed linens, and pajamas every day.
 - boiling all drinking water.
 - maintaining a clear liquid diet for at least 7 to 10 days.
- Which of the following would the nurse expect to assess in a patient who is suspected of having an *Ascaris* infection?
 - cough and signs of pulmonary infestation.
 - cardiac arrhythmias and low blood pressure.
 - seizures and disorientation.
 - bloody diarrhea and excessive vomiting.

3. The nurse describes schistosomiasis to a group of students as an infection caused by
 - a. a protozoan carried by a mosquito.
 - b. improperly cooked pork.
 - c. a fluke carried by a snail.
 - d. eating food contaminated by fecal material.
4. A patient has traveled to Egypt and come home with schistosomiasis. The family is very concerned about spreading the disease. Which of the following would be most helpful to teach the family?
 - a. Strict hand washing will stop the spread of the disease.
 - b. Isolating the patient will be necessary to stop the spread of the disease.
 - c. Carefully cooking all of the patient's food will help to stop the spread of the disease.
 - d. The snail needed for the life cycle of this worm does not live in this climate.
5. A patient is prescribed mebendazole. The nurse knows that this is the most commonly used anthelmintic, being the drug of choice for treating
 - a. pinworms, roundworms, whipworms, and hookworms.
 - b. trichinosis, flukes, cestodes, and hookworms.
 - c. pork tapeworm, threadworms, cestodes, and whipworms.
 - d. all stages of schistosomal infections.
6. Patient teaching regarding the use of anthelmintics should include counseling about
 - a. the use of oral contraceptives.
 - b. maintenance of nutrition during therapy.
 - c. the use of oral anticoagulants.
 - d. cardiac drug effects.
7. Patients may experience anxiety about the diagnosis and treatment of helminthic infections. Teaching may help to alleviate this anxiety and should include
 - a. what they may experience if the worms are passed from the body.
 - b. focus on the cleanliness of the home.
 - c. measures to isolate the organism in the home.
 - d. criticism of their personal hygiene practices.

MULTIPLE RESPONSE

Select all that apply.

1. An adult client is being treated with mebendazole for a pinworm infection. Appropriate nursing diagnoses that might apply to this patient would include
 - a. Disturbed Personal Identity related to treatment.
 - b. Abdominal distention related to worm infestation.
 - c. Acute Pain related to GI effects.
 - d. Risk for Social Isolation related to quarantine conditions.
 - e. Impaired Physical Mobility related to muscle infestation.
 - f. Deficient Knowledge related to drug therapy.

Antineoplastic Agents

14

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Describe the nature of cancer and the changes the body undergoes when cancer occurs.
2. Describe the therapeutic actions, indications, pharmacokinetics, contraindications, most common adverse reactions, and important drug–drug interactions associated with each class of antineoplastic agents and with adjunctive therapy use with these drugs
3. Discuss the use of antineoplastic drugs across the lifespan.
4. Compare and contrast the prototype drugs for each class of antineoplastic agents with the other drugs in that class.
5. Outline the nursing considerations and teaching needs for patients receiving each class of antineoplastic agents.

ALKYLATING AGENTS

altretamine
bendamustine
busulfan
carboplatin
carmustine
chlorambucil
cisplatin
cyclophosphamide
dacarbazine
ifosfamide
lomustine
mechlorethamine
melphalan
oxaliplatin
procarbazine
streptozocin
temozolomide
thiotepa

ANTIMETABOLITES

capecitabine
cladribine
clofarabine
cytarabine
floxuridine
fludarabine
flourouracil
gemcitabine
mercaptopurine
methotrexate

pemetrexed
pentostatin
thioguanine

ANTINEOPLASTIC ANTIBIOTICS

bleomycin
dactinomycin
daunorubicin
doxorubicin
epirubicin
idarubicin
mitomycin
mitoxantrone
valrubicin

MITOTIC INHIBITORS

docetaxel
etoposide
ixabepilone
paclitaxel
teniposide
vinblastine
vincristine
vinorelbine

HORMONES AND HORMONE MODULATORS

anastrozole
bicalutamide

degarelix
estramustine
exemestane
flutamide
fulvestrant
goserelin
histrelin
letrozole
leuprolide
megestrol
mitotane
nilutamide
tamoxifen
toremifene
triptorelin pamoate

CANCER CELL-SPECIFIC AGENTS

bortezomib
erlotinib
everolimus
gefitinib
imatinib
lapatinib
nilotinib
sorafenib
sunitinib
temsirolimus

MISCELLANEOUS ANTINEOPLASTICS

arsenic trioxide
asparaginase
azacitidine
bexarotene
decitabine
hydroxyurea
irinotecan
nelarabine
pegaspargase
porfimer
talc powder
topotecan
tretinoin
vorinostat

ANTINEOPLASTIC ADJUNCTIVE THERAPY

amifostine
dexrazoxane
leucovorin
levoleucovorin
mesna
rasburicase

Glossary of Key Terms

alopecia: hair loss; a common adverse effect of many antineoplastic drugs, which are more effective against rapidly multiplying cells such as those of hair follicles

anaplasia: loss of organization and structure; property of cancer cells

angiogenesis: the generation of new blood vessels; cancer cells release an enzyme that will cause angiogenesis or the growth of new blood vessels to feed the cancer cells

antineoplastic agent: drug used to combat cancer or the growth of neoplasms

autonomy: loss of the normal controls and reactions that inhibit growth and spreading; property of cancer cells

bone marrow suppression: inhibition of the blood-forming components of the bone marrow; a common adverse

effect of many antineoplastic drugs, which are more effective against rapidly multiplying cells, such as those in bone marrow; also seen in anemia, thrombocytopenia, and leukopenia

carcinoma: tumor that originates in epithelial cells

metastasis: ability to enter the circulatory or lymphatic system and travel to other areas of the body that are conducive to growth and survival; property of cancer cells

neoplasm: new or cancerous growth; occurs when abnormal cells have the opportunity to multiply and grow

sarcoma: tumor that originates in the mesenchyme and is made up of embryonic connective tissue cells

The use of the term chemotherapy implies cancer treatment to most people. However, only one branch of chemotherapy involves drugs developed to act on and kill or alter human cells—the **antineoplastic agents**, which are designed to fight **neoplasms**, or cancers.

Antineoplastic drugs alter human cells in a variety of ways. Their action is intended to target the abnormal cells that compose the neoplasm or cancer, having a greater impact on them than on normal cells. Unfortunately, normal cells also are affected by antineoplastic agents.

This area of pharmacology, which has grown tremendously in recent years, now includes many drugs that act on or are part of the immune system. These substances fight the cancerous cells using components of the immune system instead of destroying cells directly (see Chapter 15). This chapter discusses the classic antineoplastic agents and includes those drugs that are used in cancer chemotherapy.

CANCER

Cancer is a disease that can strike a person at any age. It remains second only to coronary disease as the leading cause of death in the United States. Treatment of cancer can be prolonged and often debilitating. The patient can experience numerous and wide-ranging complications and effects.

All cancers start with a single cell that is genetically different from the other cells in the surrounding tissue. This cell divides, passing along its abnormalities to daughter cells, eventually producing a tumor or neoplasm that has characteristics quite different from those of the original tissue (Figure 14.1). As the abnormal cells continue to divide, they lose more and more of their original cell characteristics. The cancerous cells exhibit **anaplasia**—a loss of cellular differentiation and organization, which leads to a loss of their ability to function normally. They also exhibit **autonomy**, growing without the usual homeostatic restrictions that regulate

cell growth and control. This loss of control allows the cells to form a tumor.

Over time, these neoplastic cells grow uncontrollably, invading and damaging healthy tissue in the area and even undergoing **metastasis**, or traveling from the place of origin to develop new tumors in other areas of the body where conditions are favorable for cell growth (Figure 14.2). The abnormal cells release enzymes that generate blood vessels (**angiogenesis**) in the area to supply both oxygen and nutrients to the cells, thus contributing to their growth. Overall, the cancerous cells rob the host cells of energy and nutrients and block normal lymph and vascular vessels as the result of pressure and intrusion on normal cells, leading to a loss of normal cellular function.

The body's immune system can damage or destroy some neoplastic cells. T cells, which recognize the abnormal cells

● **FIGURE 14.1** Malignant tumors develop from one cell, with somatic mutations occurring during cell division as the tumor grows.

● FIGURE 14.2 Metastasis of cancer cells.

and destroy them; antibodies, which form in response to parts of the abnormal cell protein; interferons; and tissue necrosis factor (TNF) all play a role in the body's attempt to eliminate the abnormal cells before they become uncontrollable and threaten the life of the host. Once the neoplasm has grown and enlarged, it may overwhelm the immune system, which is no longer able to manage the problem.

Causes of Cancer

What causes the cells to mutate and become genetically different is not clearly understood. In some cases, a genetic predisposition to such a mutation can be found. Breast cancer, for example, seems to have a definite genetic link. In other cases, viral infection, constant irritation and cell turnover, and even stress have been blamed for the ensuing cancer. Stress reactions suppress the activities of the immune system (see Chapter 29), so if a cell is mutating while a person is under prolonged stress, research suggests that the cell has a better chance of growing into a neoplasm than when the person's immune system is fully active. Pipe smokers are at increased risk for development of tongue and mouth cancers because the heat of the pipe and chemicals in the pipe tobaccos and smoke continuously destroy normal cells, which must be replaced rapidly, increasing the chances for development of a mutant cell. People living in areas with carcinogenic or cancer-causing chemicals in the air, water, or even the ground are at increased risk of developing mutant cells in response to exposure to these toxic chemicals. Cancer clusters are often identified in such high-risk area. Not everyone exposed to carcinogens or undergoing stress or having a genetic predisposition to develop cancer actually develops cancer. Researchers have not discovered what the actual trigger for cancer development is or what protective abilities some people have that other people lack. Most likely, a mosaic of factors coming together in one person leads to development of the neoplasm.

Types of Cancer

Cancers can be divided into two groups: (1) solid tumors and (2) hematological malignancies such as the leukemias and lymphomas, which occur in the blood-forming organs. Solid tumors may originate in any body organ and may be further divided into **carcinomas**, or tumors that originate in epithelial cells, and **sarcomas**, or tumors that originate in the mesenchyme and are made up of embryonic connective tissue cells. Examples of carcinomas include granular cell tumors of the breast, bronchogenic tumors arising in cells that line the bronchial tubes, and squamous and basal tumors of the skin. Sarcomas include osteogenic tumors, which form in the primitive cells of the bone, and rhabdomyosarcomas, which occur in striated muscles. Hematological malignancies involve the blood-forming organs of the body, the bone marrow, and the lymphatic system. These malignancies alter the body's ability to produce and regulate the cells found in the blood.

KEY POINTS

- ▶ Cancers arise from a single abnormal cell that multiplies and grows.
- ▶ Cancer cells lose their normal function (anaplasia), develop characteristics that allow them to grow in an uninhibited way (autonomy), and have the ability to travel to other sites in the body that are conducive to their growth (metastasis). They also have the ability to grow new blood vessels to feed the tumor (angiogenesis).
- ▶ The goal of cancer chemotherapy is to decrease the size of the neoplasm so that the human immune system can deal with it.

ANTINEOPLASTIC DRUGS

Antineoplastic drugs can work by affecting cell survival or by boosting the immune system in its efforts to combat the abnormal cells (Figure 14.3). Chapter 17 discusses the immune agents that are used to combat cancer. This chapter focuses on those drugs that affect cell survival. The antineoplastic drugs that are commonly used today include alkylating agents, antimetabolites, antineoplastic antibiotics, mitotic inhibitors, hormones and hormone modulators, cancer cell-specific agents, protein tyrosine kinase inhibitors (which target enzymes specific to the cancer cells), and a group of antineoplastic agents that cannot be classified elsewhere. Other drugs are used to combat the serious adverse effects that can be associated with the antineoplastic drugs. These drugs are used as adjunctive therapy. Figure 14.4 shows sites of action of these drugs. Box 14.1 discusses use of these drugs across the lifespan.

As discussed in Chapter 7, all cells progress through a cell cycle. Different types of cells progress at different rates (see Figure 7.6 in Chapter 7). Rapidly multiplying cells, or cells that replace themselves quickly, include those lining the gastrointestinal (GI) tract and those in hair follicles, skin, and

● **FIGURE 14.3** Cell kill theory. A set percentage of cells is killed after each dose of chemotherapy. The percentage killed is dependent upon the drug therapy. In this example, each course of chemotherapy kills 90% of cells in a cancerous tumor. After the fifth course of chemotherapy in this example, a 1-cell tumor remains; the patient's immune system would destroy this malignant cell.

● **FIGURE 14.4** Sites of action of non-cell cycle-specific antineoplastic agents. Alkylating agents interfere with RNA, DNA, or other cellular proteins. For example, dacarbazine blocks DNA and RNA synthesis, whereas procarbazine blocks DNA, RNA, and protein synthesis. Hormone modulators react with specific receptor sites to block cell growth and activity. Mitotic inhibitors such as docetaxel and paclitaxel inhibit microtubular reorganization. The antimetabolite cladribine and miscellaneous agent hydroxyurea block DNA synthesis. The miscellaneous agent irinotecan disrupts DNA strands. Cell-specific agents such as gefitinib, erlotinib, lapatinib, nilotinib, sorafenib, sunitinib, temsirolimus, and imatinib inhibit protein tyrosine kinases. Bortezomib is a proteasome inhibitor.

BOX 14.1
Drug Therapy Across the Lifespan
Antineoplastic Agents
CHILDREN

Antineoplastic protocols have been developed for the treatment of most pediatric cancers. Combination therapy is stressed to eliminate as many of the mutant cells as possible. Dose and timing of these combinations is crucial.

Double checking of dose, including recalculating desired dose and verifying the drug amount with another nurse, is good practice when giving these toxic drugs to children.

Children need to be monitored closely for hydration and nutritional status. The nutritional needs of a child are greater than those of an adult, and this needs to be considered when formulating a care plan.

These children need support and comfort and also need to be allowed to explore and learn like any other children. Body image problems, lack of energy, and the need to protect the child from exposure to infection can isolate a child receiving antineoplastic agents. The total care plan of the child needs to include social, emotional, and intellectual stimulation.

Monitor bone marrow activity very carefully, and adjust the dose accordingly.

ADULTS

The adult receiving antineoplastic drugs is confronted with many dilemmas that the nurse needs to address. Changes in body image are common, with loss of hair, skin changes, gastrointestinal complaints, and weight loss. Fear of the diagnosis and the treatment is also common with these patients. Networking support systems and providing teaching, reassurance, and comfort can have a tremendous impact on the success of the drug therapy.

Pregnant and nursing women should not receive these drugs, which are toxic to the developing cells of the fetus. Pregnant women who are diagnosed with cancer are in a difficult situation: The drug therapy can have serious adverse effects on the fetus, and not using the drug therapy can be detrimental to the mother. Education, support, and referrals to appropriate specialists are important. Nursing women should find another method of feeding the baby to prevent the adverse effects to the fetus that occur when these drugs cross into breast milk. Use of barrier contraceptives is urged when these drugs are being used by women of childbearing age.

OLDER ADULTS

Older adults may be more susceptible to the CNS and gastrointestinal effects of some of these drugs. Older patients should be monitored for hydration and nutritional status regularly. Safety precautions should be instituted if CNS effects occur, including increased lighting, assistance with ambulation, and use of supports.

Many older patients have decreased renal and/or hepatic function. Many of these drugs depend on the liver and kidney for metabolism and excretion. Renal and liver function tests should be done before (baseline) and periodically during the use of these drugs, and dose should be adjusted accordingly.

Protecting these patients from exposure to infection and injury is a very important aspect of their nursing care. Older patients are naturally somewhat immunosuppressed because of age, and giving drugs that further depress the immune system can lead to infections that are serious and difficult to treat. Monitor blood counts carefully, and arrange for rest or reduced dose as indicated.

bone marrow. These cells complete the cell cycle every few days. Cells that proceed very slowly through the cell cycle include those in the breasts, testicles, and ovaries. Some cells take weeks, months, or even years to complete the cycle.

Cancer cells tend to move through the cell cycle at about the same rate as their cells of origin. Malignant cells that remain in a dormant phase for long periods are difficult to destroy. These cells can emerge long after cancer treatment has finished—after weeks, months, or years—to begin their division and growth cycle all over again. For this reason, antineoplastic agents are often given in sequence over periods of time, in the hope that the drugs will affect the cancer cells as they emerge from dormancy or move into a new phase of the cell cycle. A combination of antineoplastic agents targeting different phases of the cell cycle is frequently most effective in treating many cancers.

The goal of cancer therapy, much like that of anti-infective therapy, is to limit the offending cells to the degree that the immune system can then respond without causing too much toxicity to the host. However, this is a particularly difficult task when using antineoplastic drugs because, for the

most part, these agents are not specific to mutant cells, and affect normal human cells as well. In most cases, antineoplastic drugs primarily affect human cells that are rapidly multiplying with many cells in many phases of the cell cycle (e.g., those in the hair follicles, GI tract, and bone marrow). Much research is being done to develop drugs that will affect only the abnormal cells. Imatinib, released in 2001, was the first of a growing number of drugs to target the enzymes used by very specific abnormal cells. Other agents that affect only the mechanisms of cancer cells have been marketed. It is anticipated that many more such drugs will be released in the near future.

Antineoplastic drugs are associated with many adverse effects, with specific adverse effects occurring with particular drugs. These effects are often unpleasant and debilitating. Some antineoplastic drugs exert toxic effects on ova and sperm production, affecting the person's fertility. These agents are also usually selective for rapidly growing cells, posing a danger to the developing fetus during pregnancy. Consequently, pregnancy is a contraindication to the use of antineoplastic drugs. These agents also jeopardize the

immune system by causing **bone marrow suppression**, inhibiting the blood-forming components of the bone marrow and interfering with the body's normal protective actions against abnormal cells. The patient's hematological profile must always be assessed for toxic effects. Patients also need to understand the importance of returning every few weeks to go through the chemotherapy, with its adverse effects, over and over again.

Many antineoplastic drugs often result in another adverse effect, cancer itself. Cell death due to these agents increases the need for cellular growth, placing the person at increased risk for mutant cell development.

Most cancer patients are not considered to be "cured" until they have been cancer-free for a period of 5 years due to the possibility that cancer cells will emerge from dormancy to cause new tumors or problems. No cells have yet been identified that can remain dormant for longer than 5 years, so the chance of the emergence of one after that time is very slim.

A cancerous mass may be so large that no therapy can arrest its growth without killing the host. In such cases, antineoplastic agents are used as palliative therapy to shrink the size of the tumor and alleviate some of the signs and symptoms of the cancer, decreasing pain and increasing function. Here the goal of drug therapy is not to cure the disease but to try to improve the patient's quality of life in a situation in which there is no cure. Some emerging antineoplastic agents are discussed in Box 14.2.

FOCUS BOX 14.2 The Evidence

New Drugs for the Battle Against Cancer

Arsenic trioxide (*Trisenox*), known as a poison in forensic medicine, has been approved for the induction and remission of promyelocytic leukemia (PML) in patients whose disease is refractory to conventional therapy and whose leukemia is characterized by t(15;17) translocation of PML/RAR- α gene expression. It is given intravenously at a rate of 0.15 mg/kg per day until bone marrow remission occurs and then 0.15 mg/kg per day starting 3 to 6 weeks after induction. The patient needs to be screened carefully for toxic reactions.

Other drugs are under development that target specific areas of the human genome. In the future, antineoplastic drugs may be able to target abnormal cells and not affect the healthy cells. This could relieve the suffering of many patients undergoing cancer chemotherapy.

Several familiar drugs are being studied for their ability to block angiogenesis. By blocking the development of new blood vessels to feed the tumor, the growing cells in the tumor will lack nutrition and oxygen and will not be able to survive. Celecoxib (*Celebrex*), an anti-inflammatory drug, is being studied in various cancer combination-drug trials for this effect. Some low-molecular-weight heparins, such as dalteparin (*Fragmin*), are also being studied for this effect.

ALKYLATING AGENTS

Because alkylating agents can affect cells even in the resting phase, these drugs are said to be non-cell cycle specific (Figure 14.4). They are most useful in the treatment of slow-growing cancers, which have many cells in the resting phase. Alkylating agents (Table 14.1) include the following drugs: altretamine (*Hexalen*), bendamustine (*Treanda*), busulfan (*Busulfex*, *Myleran*), carboplatin (*Paraplatin*), carmustine (*BiCNU*, *Gliadel*), chlorambucil (*Leukeran*), cisplatin (*Platinol-AQ*), cyclophosphamide (*Cytoxan*, *Neosar*), dacarbazine (*DTIC-Dome*), ifosfamide (*Ifex*), lomustine (*CeeNU*), mechlorethamine (*Mustargen*), melphalan (*Alkeran*), oxaliplatin (*Eloxatin*), procarbazine (*Matulane*), streptozocin (*Zanosar*), temozolomide (*Temodar*), and thiopeta (*Thioplex*).

Therapeutic Actions and Indications

Alkylating agents produce their cytotoxic effects by reacting chemically with portions of the RNA, DNA, or other cellular proteins, being most potent when they bind with cellular DNA. The oldest drugs in this class are the nitrogen mustards, and modifications of the structure of these drugs have led to the development of the nitrosoureas.

These drugs are most useful in the treatment of slow-growing cancers such as various lymphomas, leukemias, myelomas, some ovarian, testicular, and breast cancers, and some pancreatic cancers. See Table 14.1 for usual indications for each of the alkylating agents. These agents are not used interchangeably.

Pharmacokinetics

The alkylating agents vary in their degree of absorption, and little is known about their distribution in the tissues. They are metabolized and sometimes activated in the liver, with many of these agents using the cytochrome P450 systems. They are excreted in the urine.

Contraindications and Cautions

Alkylating agents are contraindicated during pregnancy and lactation due to their potential for severe effects on the fetus and neonate. Caution is necessary when giving alkylating agents to any individual with a known allergy to any of them; with bone marrow suppression, *which is often the index for redosing and dosing levels*; or with suppressed renal or hepatic function, *which may interfere with metabolism or excretion of these drugs and often indicates a need to change the dose*.

Adverse Effects

Adverse effects frequently encountered with the use of these alkylating agents are listed here; see Table 14.1 for a list of adverse effects specific to each agent. Amifostine (*Ethylol*) and mesna (*Mesnex*) are cytoprotective (cell-protecting) drugs that may be given to limit certain effects of cisplatin and ifosfamide, respectively (Box 14.3).

TABLE 14.1 DRUGS IN FOCUS Alkylating Agents

Drug Name	Dosage/Route	Usual Indications
altretamine (<i>Hexalen</i>)	260 mg/m ² per day PO for 14–21 consecutive days of a 28-d cycle	Treatment of myelodysplastic syndrome Special considerations: premedicate with antiemetic; monitor blood counts and CNS status regularly
bendamustine (<i>Treanda</i>)	100 mg/m ² IV over 30 min on days 1 and 2 of a 28-d cycle for up to 6 cycles	Treatment of chronic lymphocytic leukemia Special considerations: dosing may need to be adjusted based on blood counts; monitor for infection, skin reactions
buserfan (<i>Busulfex</i> , <i>Myleran</i>)	Induction: 4–8 mg/d PO Maintenance: 1–3 mg/d PO Injection: 0.8 mg/kg as a 2-h IV infusion q6h for 4 d via a central venous catheter	Treatment of chronic myelogenous leukemia; not effective in blastic phase or without the Philadelphia chromosome Special considerations: dosing monitored by effects on bone marrow; always push fluids to decrease toxic renal effects; alopecia is common
carboplatin (<i>Paraplatin</i>)	360 mg/m ² IV on day 1 every 4 wk; reduce dose as needed based on blood counts and with renal impairment	Palliative or initial treatment of returning ovarian cancer after prior chemotherapy; initial treatment of ovarian cancer with other chemotherapy; may be useful in several other cancers Special considerations: dose and timing determined by bone marrow response; alopecia is common
carmustine (<i>BiCNU</i> , <i>Gliadel</i>)	150–200 mg/m ² IV every 6 wk as a single dose or divided daily injections; wafers implanted into brain at time of surgery	Treatment of brain tumors, Hodgkin disease, and multiple myelomas; available in implantable wafer form for treatment of glioblastoma Special considerations: dose determined by bone marrow toxicity; do not repeat for 6 wk because of delayed toxicity; often used in combination therapy
 chlorambucil (<i>Leukeran</i>)	0.1–0.2 mg/kg per day PO for 3–6 wk; or 0.4 mg/kg PO every 2 wk with maintenance dose of 0.03–0.1 mg/kg per day PO	Palliative treatment of lymphomas and leukemias including Hodgkin disease; being considered for the treatment of rheumatoid arthritis and other conditions Special considerations: toxic to liver and bone marrow; dosing based on bone marrow response
cisplatin (<i>Platinol-AQ</i>)	20–50 mg/m ² per day IV, once every 3 wk used in combination with other antineoplastic agents	Combination therapy for metastatic testicular or ovarian tumors, advanced bladder cancers Special considerations: neurotoxic, nephrotoxic, and can cause serious hypersensitivity reactions
cyclophosphamide (<i>Cytoxan</i> , <i>Neosar</i>)	Induction: 40–50 mg/kg per day IV over 2–5 d, or 1–5 mg/kg per day PO Maintenance: 1–5 mg/kg per day PO, or 10–15 mg/kg IV q7–10d	Treatment of lymphoma, myelomas, leukemias, and other cancers in combination with other drugs Special considerations: hemorrhagic cystitis is a potentially fatal side effect; alopecia is common
dacarbazine (<i>DTIC-Dome</i>)	2–4.5 mg/kg per day IV for 10 d, repeat at 4-wk intervals; or 1500–250 mg/m ² per day IV for 5 d in combination with other drugs	Treatment of metastatic malignant melanoma and as second-line therapy with other drugs for the treatment of Hodgkin disease. Special considerations: bone marrow depression, GI toxicity, severe photosensitivity are common; extrava- sation can cause tissue necrosis or cellulitis—use extreme care, and monitor injection sites regularly
ifosfamide (<i>Ifex</i>)	1.2 g/m ² per day IV for 5 consecutive days; repeat every 3 wk	Combination therapy as a third-line agent in treating germ cell testicular cancers; being tested for treatment of other cancers Special considerations: alopecia is common
lomustine (<i>CeeNU</i>)	130 mg/m ² PO as a single dose every 6 wk; adjust dose based on blood counts	Palliative combination therapy for Hodgkin disease and primary and metastatic brain tumors Special considerations: immune suppression and gastrointestinal effects are common
mechlorethamine (<i>Mustargen</i>)	0.4 mg/kg IV for each course; usually repeated every 3–6 wk; intracavity 0.2–0.4 mg/kg	Nitrogen mustard; palliative treatment in Hodgkin disease, leukemia, bronchial carcinoma, other cancers; injected for treatment of effusions secondary to cancer metastases Special considerations: Gastrointestinal toxicity, bone marrow suppression, and impaired fertility are common

(drug table continues on page 204)

TABLE 14.1 DRUGS IN FOCUS Alkylating Agents (continued)

Drug Name	Dosage/Route	Usual Indications
melphalan (<i>Alkeran</i>)	Multiple myeloma: 6 mg/d PO for 2–3 wk, then a rest period, or 16 mg/m ² IV at 2-wk intervals for four doses, then at 4-wk intervals Ovarian cancer: 0.2 mg/kg per day PO for 5 d; repeat course every 4–5 wk	Nitrogen mustard; treatment for multiple myeloma, ovarian cancers Special considerations: oral route is preferred; pulmonary fibrosis, bone marrow suppression, and alopecia are common
oxaliplatin (<i>Eloxatin</i>)	85 mg/m ² IV with leucovorin, followed by fluorouracil (5-FU) at 2-wk cycles, or 1000 mg/m ² IV at weekly intervals	Treatment of metastatic carcinoma of the colon or rectum when disease progresses after standard therapy; used in combination therapy Special considerations: Premedicate with antiemetics and dexamethasone; monitor for potentially dangerous anaphylactic reactions
procarbazine (<i>Matulane</i>)	Adults; 2–6 mg/kg/d PO; base the dose on bone marrow response Pediatric: 50 mg/m ² /d; adjust the dose based on bone marrow response	Used in combination therapy for treatment of stages III and IV of Hodgkin disease Special considerations: bone marrow toxicity; GI toxicity and skin lesions also limit use in some patients; severity of adverse effects regulates the dose of the drug
streptozocin (<i>Zanosar</i>)	500 mg/m ² IV for 5 consecutive days, usually given every week, or 1000 mg/m ³ IV at weekly intervals	Treatment of metastatic islet cell carcinoma of the pancreas Special considerations: gastrointestinal and renal toxicity are common; causes infertility; wear rubber gloves to avoid drug contact with the skin—if contact occurs, wash with soap and water
temozolomide (<i>Temodar</i>)	75 mg/m ² /d PO with radiation	Treatment of refractory astrocytoma or glioblastoma in patients refractory to other treatments Special considerations: monitor bone marrow closely; especially toxic in women and the elderly
thiotepa (<i>Thioplex</i>)	0.3–0.4 mg/kg IV at 1–4-wk intervals; intracavity, 0.6–0.8 mg/kg	Treatment of adenocarcinoma of the breast and uterus and papillary carcinoma of the bladder; available intrathecally to treat effusion Special considerations: infertility, rash, gastrointestinal toxicity, dizziness, headache, and bone marrow suppression are common

BOX 14.3 Drugs That Protect Cells From Alkylating Agents

Amifostine (*Ethyol*) is a cytoprotective (cell-protecting) drug that preserves healthy cells from the toxic effects of cisplatin. It is thought to react to the specific acidity and vascularity of nontumor cells to protect them, and it may also act as a scavenger of free radicals released by cells that have been exposed to cisplatin. Amifostine is given at a dose of 910 mg/m² four times a day as a 15-minute IV infusion starting within 30 minutes after starting cisplatin therapy; timing is very important to its effectiveness. Now approved for use to prevent the renal toxicity associated with the use of cisplatin in patients with advanced ovarian cancer, amifostine is under investigation as an agent for protecting lung fibroblasts from the effects of paclitaxel. Because amifostine is associated with severe nausea and vomiting, concurrent administration of an antiemetic is recommended. It also can cause hypotension, and patients should be monitored closely for this condition.

Mesna (*Mesnex*) is a cytoprotective agent that is used to reduce the incidence of hemorrhagic cystitis caused by ifos-

famide or cyclophosphamide. Mesna, which is known to react chemically with urotoxic metabolites of ifosfamide, is given intravenously at the time of the ifosfamide injection at a dose that is 20% of the ifosfamide dose and is repeated 4 and 8 hours afterward. Because mesna has been associated with nausea and vomiting, an antiemetic may be useful.

Dexrazoxane (*Totect*) was approved in 2007 for the treatment of extravasation resulting from IV antineoplastic antibiotic chemotherapy. It is given as an IV infusion over 1 to 2 hours once daily for three days. Dosage is as follows: day 1, 1000 mg/m², maximum dose 2000 mg; day 2, 1000 mg/m², maximum dose 2000 mg; day 3, 500 mg/m², maximum dose 1000 mg. The mechanism of action that allows this drug to protect cells from damage related to extravasation is not understood but it may block certain enzymes affected by the drugs. Dose should be reduced in patients with renal failure.

BOX 14.4 Drug to Manage Rising Uric Acid Levels Associated With Tumor Lysis

Rasburicase (*Elitek*) was approved in 2004 for the management of plasma uric acid levels in pediatric patients with leukemia, lymphoma, and solid tumor malignancies who are receiving antineoplastic therapy associated with tumor lysis and subsequent elevated serum uric acid levels. It is administered as a single daily IV infusion of 0.15 to 0.2 mg/kg over 30 minutes for 5 days. Chemotherapy should be started 4 to 24 hours after the first dose of rasburicase. Uric acid levels should be monitored frequently, using prechilled, heparinized vials that are kept in an ice-water bath. This analysis should be done within 4 hours of each rasburicase dose.

Hematological effects include bone marrow suppression, with leukopenia, thrombocytopenia, anemia, and pancytopenia, secondary to the effects of the drugs on the rapidly multiplying cells of the bone marrow. GI effects include nausea, vomiting, anorexia, diarrhea, and mucous membrane deterioration, all of which are related to the drugs' effects on the rapidly multiplying cells of the GI tract. Hepatic toxicity and renal toxicity may occur, depending on the exact mechanism of action. **Alopecia**, or hair loss, related to effects on the hair follicles, may also occur. All drugs that cause cell death can cause a potentially toxic increase in uric acid levels. In 2004, a new drug, rasburicase, was introduced to manage uric acid levels in pediatric patients (Box 14.4).

Clinically Important Drug–Drug Interactions

Alkylating agents that are known to cause hepatic or renal toxicity should be used cautiously with any other drugs that have similar effects. In addition, drugs that are toxic to the liver may adversely affect drugs that are metabolized in the liver or that act in the liver (e.g., oral anticoagulants). Always check for specific drug–drug interactions for each agent in a nursing drug guide.

Prototype Summary: Chlorambucil

Indications: Palliative treatment of chronic lymphocytic leukemia, malignant lymphomas, and Hodgkin disease.

Actions: Alkylates cellular DNA, interfering with the replication of susceptible cells.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	Varies	1 h	15–20 h

T_{1/2}: 60 to 90 minutes, metabolized in the liver and excreted in the urine.

Adverse effects: Tremors, muscle twitching, confusion, nausea, hepatotoxicity, bone marrow suppression, sterility, cancer.

Nursing Considerations for Patients Receiving Alkylating Agents**Assessment: History and Examination**

- Assess for contraindications or cautions: history of allergy to any of the alkylating agents *to avoid hypersensitivity reactions*; bone marrow suppression *to prevent further suppression*; renal or hepatic dysfunction *that might interfere with drug metabolism and excretion*; and current status related to pregnancy or lactation *to prevent potentially serious adverse effects on the fetus or nursing baby*.
- Perform a physical assessment *to establish baseline data for determining the effectiveness of the drug and the occurrence of any adverse effects associated with drug therapy*.
- Assess orientation and reflexes *to evaluate any central nervous system (CNS) effects*; respiratory rate and adventitious sounds *to monitor the disease and to evaluate for respiratory or hypersensitivity effects*; pulse, rhythm, and auscultation *to monitor for systemic or cardiovascular effects*; and bowel sounds and mucous membrane status *to monitor for GI effects*.
- Monitor the results of laboratory tests such as complete blood count (CBC) with differential *to identify possible bone marrow suppression and toxic drug effects*; and renal and liver function tests *to determine need for possible dose adjustment and identify toxic drug effects*.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to GI, CNS, and skin effects of the drug
- Disturbed Body Image related to alopecia, skin effects, impaired fertility
- Imbalanced Nutrition, less than body requirements
- Risk for Infection
- Fear, Anxiety related to diagnosis and treatment
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Arrange for blood tests before, periodically during, and for at least 3 weeks after therapy *to monitor bone marrow function to aid in determining the need for a change in dose or discontinuation of the drug*.
- Administer medication according to scheduled protocol and in combination with other drugs as indicated *to improve effectiveness*.
- Ensure that the patient is well hydrated *to decrease risk of renal toxicity*.

- Protect the patient from exposure to infection; limit invasive procedures *when bone marrow suppression limits the patient's immune/inflammatory responses.*
- Provide small, frequent meals, frequent mouth care, and dietary consultation as appropriate *to maintain nutrition when GI effects are severe.* Anticipate the need for antiemetics if necessary. (See Box 14.5.)
- Arrange for proper head covering at extremes of temperature if alopecia occurs; a wig, scarf, or hat *is important for maintaining body temperature.* If alopecia is an anticipated effect of drug therapy, advise the patient to obtain a wig or head covering before the condition occurs *to promote self-esteem and a positive body image.*
- Provide patient teaching about the following:
 - Follow the appropriate dosage regimen, including dates to return for further doses.
 - Cover the head at extremes of temperature.
 - Maintain nutrition if GI effects are severe.
 - Avoid exposure to infection.

- Plan for appropriate rest periods because fatigue and weakness are common effects of the drugs.
- Consult with a health care provider, if appropriate, related to the possibility of impaired fertility.
- Use barrier contraceptives *to reduce the risk of pregnancy during therapy.*

Evaluation

- Monitor patient response to the drug (alleviation of cancer being treated, palliation of signs and symptoms of cancer).
- Monitor for adverse effects (bone marrow suppression, GI toxicity, neurotoxicity, alopecia, renal or hepatic dysfunction).
- Evaluate the effectiveness of the teaching plan (patient can name the drug, dosage, possible adverse effects to watch for, and specific measures to help avoid adverse effects).

BOX 14.5 Antiemetics and Cancer Chemotherapy

Antineoplastic drugs can directly stimulate the chemoreceptor trigger zone (CTZ) in the medulla to induce nausea and vomiting. These drugs also cause cell death, which releases many toxins into the system, which in turn stimulate the CTZ. Because patients expect nausea and vomiting with the administration of antineoplastic agents, the higher cortical centers of the brain can stimulate the CTZ to induce vomiting just at the thought of the chemotherapy.

A variety of antiemetic agents have been used in the course of antineoplastic therapy. Sometimes a combination of drugs is most helpful. It should also be remembered that an accepting environment, plenty of comfort measures (e.g., environmental control, mouth care, ice chips), and support for the patient can help to decrease the discomfort associated with the emetic effects of these drugs. Antihistamines to decrease secretions and corticosteroids to relieve inflammation are useful as adjunctive therapies.

Drugs that are known to help in treating antineoplastic chemotherapy-induced nausea and vomiting include the following:

- Dronabinol (*Marinol*) and nabilone (*Cesamet*) are synthetic derivatives of delta-9- tetrahydrocannabinol, the active ingredient in marijuana; this is not usually a first-line drug because of associated CNS effects. The usual dosage for dronabinol is 5 mg/m² PO 1 to 3 hours before chemotherapy and repeated every 2 to 4 hours after chemotherapy. Nabilone is given orally as 1 to 2 mg PO twice daily initially, then daily during the cycle and for 48 hours after the last dose of chemotherapy.
- Ondansetron (*Zofran*), granisetron (*Kytril*), and palonosetron (*Aloxi*) block serotonin receptors in the CTZ and are among the most effective antiemetics, especially if combined with a corticosteroid such as dexamethasone. The usual dosage is three 0.15-mg/kg doses IV or 8 mg PO three times a day starting 30 minutes before chemotherapy (ondansetron) or

10 mg/kg IV or 1 mg PO twice a day (granisetron), or 0.25 mg IV over 30 seconds, starting 30 minutes before chemotherapy (palonosetron).

- Aprepitant (*Emend*) blocks human substance P/neurokinin 1 receptors in the CNS, blocking the nausea and vomiting caused by severely emetogenic antineoplastic drugs without effects on dopamine, serotonin, or norepinephrine. The usual dosage is 125 mg PO 1 hour before chemotherapy (day 1) and 80 mg PO once daily in the morning on days 2 and 3; given in combination with 12 mg dexamethasone PO on day 1 and 8 mg dexamethasone PO on days 2 to 4, and 32 mg ondansetron IV on day 1 only.
- Two benzodiazepines—alprazolam (*Xanax*), 0.5 mg PO four times a day, and lorazepam (*Ativan*), 2 to 6 mg/day PO—seem to be effective in directly blocking the CTZ to relieve nausea and vomiting caused by cancer chemotherapy; they are especially effective when combined with a corticosteroid.
- Haloperidol (*Haldol*), 0.5 to 2.0 mg PO four times a day, or 2 to 25 mg intramuscularly (IM) or IV, is a dopaminergic blocker that also is believed to have direct CTZ effects.
- Metoclopramide (*Reglan*), 2 mg/kg IV over at least 30 minutes, calms the activity of the GI tract; it is especially effective if combined with a corticosteroid, an antihistamine, and a centrally acting blocker such as haloperidol or lorazepam.
- Prochlorperazine (*Compazine*), 5 to 10 mg PO three to four times a day, or 5 to 10 mg IM, is a phenothiazine that has been found to have strong antiemetic action in the CNS; it can be given by a variety of routes.

Nausea and vomiting are unavoidable aspects of many chemotherapeutic regimens. However, treating the patient as the chemotherapy begins, using combination regimens, and providing plenty of supportive and comforting nursing care can help to alleviate some of the distress associated with these adverse effects.

KEY POINTS

- Alkylating agents affect cellular RNA, DNA, or other cellular proteins, are cell cycle nonspecific, and are most effective against slow-growing tumors.
- Patients receiving alkylating agents may experience alopecia, nausea, and vomiting and need to be monitored for bone marrow suppression and CNS toxicity.

ANTIMETABOLITES

Antimetabolites (Table 14.2) are drugs that have chemical structures similar to those of various natural metabolites that are necessary for the growth and division of rapidly growing neoplastic cells and normal cells. Antimetabolites include

capecitabine (*Xeloda*), cladribine (*Leustatin*), clofarabine (*Clolar*), cytarabine (*DepoCyt*, *Tarabine PFS*), floxuridine (*FUDR*), fludarabine (*Fludara*), fluorouracil (*Adrucil*, *Carac*, *Efudex*, *Fluoroplex*), gemcitabine (*Gemzar*), mercaptopurine (*Purinethol*), methotrexate (*Rheumatrex*, *Trexall*), pemetrexed (*Alimta*), pentostatin (*Nipent*), and thioguanine (*Tabloid*).

Therapeutic Actions and Indications

Antimetabolites inhibit DNA production in cells that depend on certain natural metabolites to produce their DNA. They replace these needed metabolites and thereby prevent normal cellular function. Many of these agents inhibit thymidylate synthetase, DNA polymerase, or folic acid reductase, all of

TABLE 14.2 DRUGS IN FOCUS Antimetabolites

Drug Name	Dosage/Route	Usual Indications
capecitabine (<i>Xeloda</i>)	2,500 mg/m ² per day PO in two divided doses for 2 wk, then 1 wk of rest, for three cycles Dukes C colon cancer: 1250 mg/m ² PO b.i.d. for 2 wk, then 1 wk of rest for a total of eight 3-wk cycles	Treatment of metastatic breast cancer with resistance to paclitaxel or anthracyclines; treatment of metastatic colorectal cancer as first-line therapy treatment of breast cancer with docetaxel in patients with metastatic disease; postsurgery Dukes C colon cancer Special considerations: severe diarrhea can occur—monitor hydration and nutrition; monitor for bone marrow suppression
cladribine (<i>Leustatin</i>)	0.09 mg/kg per day IV for 7 consecutive days	Treatment of active hairy cell leukemia Special considerations: severe bone marrow depression can occur—monitor patient closely and reduce dose as needed; fever is common, especially early in treatment
clofarabine (<i>Clolar</i>)	52 mg/m ² by IV infusion over 2 h daily for 5 d; repeat every 2–6 wk, based on baseline function	Treatment of patients 1–21 yr of age with acute lymphocytic leukemia (ALL) after at least two relapses on other regimens Special considerations: GI toxicity, bone marrow suppression, and infection are common
cytarabine (<i>DepoCyt</i> , <i>Tarabine PFS</i>)	200 mg/m ² per day by continuous IV infusion for 5 d, repeat every 2 wk; intrathecal use, 30 mg/m ² every 4 d	Treatment of meningeal and myelocytic leukemias; used in combination with other agents; lymphomatous meningitis; non-Hodgkin lymphoma in children Special considerations: GI toxicity and cytarabine syndrome (fever, myalgia, bone pain, chest pain, rash, conjunctivitis, and malaise) are common—this syndrome sometimes responds to corticosteroids; alopecia may occur
floxuridine (<i>FUDR</i>)	0.1–0.6 mg/kg per day via intraarterial line	Palliative management of GI adenocarcinoma metastatic to the liver in patients who are not candidates for surgery Special considerations: administer by intraarterial line only; bone marrow suppression, GI toxicity, neurotoxicity, and alopecia are common
fludarabine (<i>Fludara</i>)	25 mg/m ² per day IV for 5 d; repeat every 28 d	Treatment of chronic lymphocytic leukemia (CLL); unresponsive B cell CLL with no progress with at least one other treatment Special considerations: CNS toxicity can be severe; GI toxicity, respiratory complications, renal failure, and a tumor lysis syndrome are common

(drug table continues on page 208)

TABLE 14.2 DRUGS IN FOCUS Antimetabolites (continued)

Drug Name	Dosage/Route	Usual Indications
fluorouracil (<i>Adrucil, Carac, Efudex, Fluoroplex</i>)	12 mg/kg per day IV on days 1–4, then 6 mg/kg IV on days 6, 8, 10, and 12	Palliative treatment of various GI cancers; topical treatment of basal cell carcinoma and actinic and solar keratoses Special considerations: GI toxicity, bone marrow suppression, alopecia, and skin rash are common; avoid occlusive dressings with topical forms; wash hands thoroughly after coming in contact with drug
gemcitabine (<i>Gemzar</i>)	1000–1250 mg/m ² IV over 30 min once a week; timing based on other therapies and patient response	Treatment of locally advanced or metastatic adenocarcinoma of the pancreas; given with cisplatin for the treatment of inoperable non–small cell lung cancer; metastatic breast cancer, ovarian cancer after failure of a platinum-based therapy Special considerations: can cause severe bone marrow depression, GI toxicity, pain, alopecia, interstitial pneumonitis
mercaptopurine (<i>Purinethol</i>)	2.5 mg/kg per day PO for 4 wk; then reevaluate	Remission induction and maintenance therapy in acute leukemias Special considerations: bone marrow toxicity and GI toxicity are common; hyperuricemia is a true concern—ensure that the patient is well hydrated during therapy
 methotrexate (<i>Rheumatrex, Trexall</i>)	Dose varies with route and disease being treated; 15–30 mg PO or IM is common	Treatment of leukemias, psoriasis, rheumatoid arthritis, and choriocarcinomas Special considerations: hypersensitivity reactions can be severe; liver toxicity and GI complications are common; monitor for bone marrow suppression and increased susceptibility to infections; dose pack available for the oral treatment of psoriasis and rheumatoid arthritis
pemetrexed (<i>Alimta</i>)	500 mg/m ² IV over 10 min on day 1 with 75 mg/m ² cisplatin IV over 2 h; repeat cycle every 21 d	Treatment of malignant mesothelioma in patients whose disease is unresectable or who are not candidates for surgery; locally advanced or metastatic non–small cell lung cancer as a single agent after other chemotherapy Special considerations: pretreat with corticosteroids, folic acid, and vitamin B ₁₂ ; monitor for bone marrow suppression and GI effects.
pentostatin (<i>Nipent</i>)	4 mg/m ² IV every other week	Hairy cell leukemia in adults if refractory to interferon-alpha therapy Special considerations: Associated with severe renal, hepatic, CNS, and pulmonary toxicities—monitor patient closely and reduce dose accordingly; 3–6 mo of interferon-alpha therapy should be tried before using pentostatin
thioguanine (<i>Tabloid</i>)	2 mg/kg per day PO for 4 wk; then dose may be increased if tolerated well	Remission induction and maintenance of acute leukemias alone or as part of combination therapy Special considerations: bone marrow suppression, GI toxicity, miscarriage, and birth defects have been reported; monitor bone marrow status to determine dose and redosing; ensure that the patient is well hydrated during therapy to minimize hyperuricemia—patient may respond to allopurinol and urine alkalinization

which are needed for DNA synthesis. They are considered to be S phase specific in the cell cycle. They are most effective in rapidly dividing cells, preventing cell replication and leading to cell death (Figure 14.5). The antimetabolites are indicated for the treatment of various leukemias and some GI and

basal cell cancers (see Table 14.2 for usual indications for each agent). Use of these drugs has been somewhat limited because neoplastic cells rapidly develop resistance to these agents. For this reason, these drugs are usually administered as part of a combination therapy.

● **FIGURE 14.5** Sites of action of cell cycle–specific antineoplastic agents.

Pharmacokinetics

Methotrexate is absorbed well from the GI tract and is excreted unchanged in the urine. Patients with renal impairment may require reduced dose and increased monitoring when taking methotrexate. Methotrexate readily crosses the blood–brain barrier. Cytarabine, clofarabine, floxuridine, fluorouracil, gemcitabine, floxuridine, and pemetrexed are not absorbed well from the GI tract and need to be administered parenterally. They are metabolized in the liver and excreted in the urine, necessitating close monitoring of patients with hepatic or renal impairment who are receiving these drugs. Mercaptopurine and thioguanine are absorbed slowly from the GI tract and are metabolized in the liver and excreted in the urine.

Contraindications and Cautions

Antimetabolites are contraindicated for use during pregnancy and lactation *because of the potential for severe effects on the fetus and neonate*. Caution is necessary when administering antimetabolites to any individual with a known allergy to any of them; with bone marrow suppression, *which is often the index for redosing and dosing levels*; with renal or hepatic dysfunction, *which might interfere with the metabolism or excretion of these drugs and often indicates a need to change the dose*; and with known GI ulcerations or ulcerative diseases *that might be exacerbated by the effects of these drugs*.

Adverse Effects

Adverse effects frequently encountered with the use of the antimetabolites are listed here. To counteract the effects of treatment with one antimetabolite—methotrexate—the drug leucovorin or its isomer levoleucovorin is sometimes given (Box 14.6).

Hematological effects include bone marrow suppression, with leukopenia, thrombocytopenia, anemia, and pancytopenia, secondary to the effects of the drugs on the rapidly

multiplying cells of the bone marrow. Toxic GI effects include nausea, vomiting, anorexia, diarrhea, and mucous membrane deterioration, all of which are related to drug effects on the rapidly multiplying cells of the GI tract. CNS effects include headache, drowsiness, aphasia, fatigue, malaise, and dizziness. Patients should be advised to take precautions if these conditions occur. There is a risk of pulmonary toxicity, including interstitial pneumonitis with these drugs. As with alkylating agents, effects of the antimetabolites may include possible hepatic or renal toxicity, depending on the exact mechanism of action. Alopecia may also occur.

Clinically Important Drug–Drug Interactions

Antimetabolites that are known to cause hepatic or renal toxicity should be used with care with any other drugs known to have the same effect. In addition, drugs that are toxic to the

BOX 14.6 A Drug That Protects Against an Antimetabolite

Leucovorin (*Wellcovorin*) is an active form of folic acid that is used to “rescue” normal cells from the adverse effects of methotrexate therapy in the treatment of osteosarcoma. This drug is also used to treat folic acid deficiency conditions such as sprue, nutritional deficiency, pregnancy, and lactation. Leucovorin is given orally or intravenously at the time of methotrexate therapy and for the next 72 hours at a dose of 12 to 15 g/m² PO or IV followed by 10 mg/m² PO q6h for 72 hours. Use of this drug has been associated with pain at the injection site.

In 2008, levoleucovorin, an isomer of leucovorin, was also approved to diminish the toxicity and counteract the effects of impaired methotrexate elimination and of inadvertent overdose of folic acid antagonists after high-dose methotrexate therapy in osteosarcoma. The drug is given IV for up to 4 days, and dose is determined by the serum methotrexate level of the patient. There are high calcium levels in the solution, and the drug needs to be given slowly.

liver may adversely affect drugs that are metabolized in the liver or that act in the liver (e.g., oral anticoagulants). Check for specific drug–drug interactions for each agent in a nursing drug guide.

Prototype Summary: *Methotrexate*

Indications: Treatment of gestational choriocarcinoma, chorioadenoma destruens, hydatidiform, meningeal leukemia; symptomatic control of severe psoriasis; rheumatoid arthritis; juvenile rheumatoid arthritis.

Actions: Inhibits folic acid reductase, leading to inhibition of DNA synthesis and inhibition of cellular replication; affects the most rapidly dividing cells.

Pharmacokinetics:

Route	Onset	Peak
Oral	Varies	1–4 h
Intravenous	Rapid	0.5–2 h

$T_{1/2}$: 2–4 hours, excreted unchanged in the urine.

Adverse effects: Fatigue, malaise, rashes, alopecia, ulcerative stomatitis, hepatic toxicity, severe bone marrow suppression, interstitial pneumonitis, chills, fever, anaphylaxis.

Nursing Considerations for Patients Receiving Antimetabolites

Assessment: History and Examination

- Assess for contraindications and cautions: history of allergy to the specific antimetabolite *to avoid hypersensitivity reactions*; bone marrow suppression *to prevent further suppression*; renal or hepatic dysfunction *that might interfere with drug metabolism and excretion*; current status related to pregnancy or lactation *to prevent potentially serious effects to the fetus or nursing baby*; and a history of GI ulcerative disease, *which could be exacerbated with the use of these drugs.*
- Perform a physical assessment *to establish baseline data for determining the effectiveness of the drug and the occurrence of any adverse effects associated with drug therapy.*
- Assess orientation and reflexes *to evaluate any CNS effects*; respiratory rate and adventitious sounds *to monitor the disease and to evaluate for respiratory or hypersensitivity effects*; pulse, rhythm, and cardiac auscultation *to monitor for systemic or cardiovascular effects*; and bowel sounds and mucous membrane status *to monitor for GI effects.*
- Monitor the results of laboratory tests such as CBC with differential to identify possible bone marrow suppression and toxic drug effects; and renal and liver function tests *to determine the need for possible dose adjustment and toxic drug effects.*

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to GI, CNS, or skin effects of the drug
- Disturbed Body Image related to alopecia, skin effects, impaired fertility
- Fear, Anxiety related to diagnosis and treatment
- Imbalanced Nutrition, less than body requirements
- Risk for Infection
- Deficient Knowledge regarding drug therapy

Implementation with Rationale

- Arrange for blood tests to monitor bone marrow function before, periodically during, and for at least 3 weeks after therapy *to arrange to discontinue the drug or reduce the dose as needed.*
- Administer medication according to the scheduled protocol and in combination with other drugs as indicated *to improve the effectiveness of drug therapy.*
- Ensure that the patient is well hydrated *to decrease the risk of renal toxicity.*
- Provide small, frequent meals, frequent mouth care, and dietary consultation as appropriate *to maintain nutrition when GI effects are severe.* Anticipate the use of antiemetics as necessary. (See Box 14.4.)
- Arrange for proper head covering at extremes of temperature if alopecia occurs; a wig, scarf, or hat *is important for maintaining body temperature.* If alopecia is an anticipated effect of drug therapy, advise the patient to obtain a wig or head covering before the condition occurs *to promote self-esteem and a positive body image.*
- Protect the patient from exposure to infections *because bone marrow suppression will limit immune/inflammatory responses.*
- Provide support and encouragement to help the patient cope with the diagnosis and the effects of drug therapy.
- Provide the following patient teaching:
 - Follow the appropriate dosage regimen, including dates to return for further doses. Patients needed to be reminded to report all other drugs and alternative therapies that they might be using. Box 14.7 discusses alternative therapies often used by cancer patients that could interact with their drug regimen.
 - Maintain nutrition if GI effects are severe.
 - Cover the head at extremes of temperature if alopecia is anticipated.
 - Plan for appropriate rest periods because fatigue and weakness are common effects of the drugs.
 - Avoid situations that might lead to infection, including crowded places, sick people, and working in the soil.
 - Use safety measures such as not driving or using dangerous equipment, due to possible dizziness, headache, and drowsiness.

FOCUS ON
BOX 14.7 Cultural Considerations

Alternative Therapies and Cancer

The diagnosis of cancer and the sometimes devastating effects of cancer treatment often drive patients to seek out alternative therapies, either as adjuncts to traditional cancer therapy or sometimes instead of traditional therapy. Because Asian-Americans and Pacific Islanders often see drug therapy and other cancer therapies as part of a “yin/yang” belief system, they may turn to a variety of herbal therapies to “balance” their systems.

The nurse should be aware of some potential interactions that may occur when alternative therapies are used:

- *Echinacea*—may be hepatotoxic; increases the risk of hepatotoxicity when taken with antineoplastics that are hepatotoxic
- *Ginkgo*—inhibits blood clotting, which can cause problems after surgery or with bleeding neoplasms
- *Saw palmetto*—may increase the effects of various estrogen hormones and hormone modulators; advise patients taking such drugs to avoid this herb
- *St. John’s wort*—can greatly increase photosensitivity, which can cause problems with patients who have received radiation therapy or are taking drugs that cause other dermatological effects; has been shown to interfere with the effectiveness of some antineoplastic agents

If a patient has an unexpected reaction to a drug, ask about whether he or she is using alternative therapies. Many of these agents are untested, and interactions and adverse effects are not well documented.

- Think about consulting with a health care provider, if appropriate, due to the possibility of impaired fertility.
- Use barrier contraceptives to reduce the risk of pregnancy during therapy.

Evaluation

- Monitor patient response to the drug (alleviation of cancer being treated, palliation of signs and symptoms of cancer, palliation of rheumatoid arthritis or psoriasis).
- Monitor for adverse effects (bone marrow suppression, GI toxicity, neurotoxicity, alopecia, renal or hepatic dysfunction).
- Evaluate the effectiveness of the teaching plan (patient can name the drug, dosage, possible adverse effects to watch for, and specific measures to help avoid adverse effects).
- Monitor the effectiveness of comfort and safety measures and compliance with the regimen

KEY POINTS

- ▶ Antimetabolites inhibit DNA production by inhibiting metabolites needed for the synthesis of DNA in susceptible cells.
- ▶ Antimetabolites are S phase cell cycle specific and are used for some leukemias, as well as some GI and basal cell cancers.
- ▶ Bone marrow suppression, alopecia, and toxic GI effects are common adverse effects of antimetabolites.

ANTINEOPLASTIC ANTIBIOTICS

Antineoplastic antibiotics (Table 14.3), although selective for bacterial cells, are also toxic to human cells. Because these drugs tend to be more toxic to cells that are multiplying rapidly, they are more useful in the treatment of certain cancers. Antineoplastic antibiotics include bleomycin (*Blenoxane*), dactinomycin (*Cosmegen*), daunorubicin (*DaunoXome*), doxorubicin (*Adriamycin*, *Doxil*), epirubicin (*Elleence*), idarubicin (*Idamycin*), mitomycin (*Mutamycin*), mitoxantrone (*Novantrone*), and valrubicin (*Valstar*).

Therapeutic Actions and Indications

Some antineoplastic antibiotics break up DNA links, and others prevent DNA synthesis.

The antineoplastic antibiotics are cytotoxic and interfere with cellular DNA synthesis by inserting themselves between base pairs in the DNA chain. This, in turn, causes a mutant DNA molecule, leading to cell death (Figure 14.4). See Table 14.3 for usual indications for each antineoplastic antibiotic. Like other antineoplastics, the main adverse effects of these drugs are seen in cells that multiply rapidly, such as those in the bone marrow, GI tract, and skin. Their potentially serious adverse effects may limit their usefulness in patients with preexisting diseases and in those who are debilitated and, therefore, more susceptible to these effects.

Pharmacokinetics

The antineoplastic antibiotics are not absorbed well from the GI tract. They are given intravenously (IV) or injected into specific sites. They are metabolized in the liver and excreted in the urine at various rates. Many of them have very long half-lives (e.g., 45 hours for idarubicin; more than 5 days for mitoxantrone). Daunorubicin and doxorubicin do not cross the blood–brain barrier, but they are widely distributed in the body and are taken up by the heart, lungs, kidneys, and spleen. This can lead to toxic effects in these organs.

Contraindications and Cautions

All of these agents are contraindicated for use during pregnancy and lactation *because of the potential risk to the fetus and neonate*. Use caution when giving antineoplastic

TABLE 14.3 DRUGS IN FOCUS Antineoplastic Antibiotics

Drug Name	Dosage/Route	Usual Indications
bleomycin (<i>Blenoxane</i>)	0.25–0.5 units/kg IM, IV, or SC once or twice weekly	Palliative treatment of squamous cell carcinomas, testicular cancers, and lymphomas; used to treat malignant pleural effusion Special considerations: GI toxicity, severe skin reactions, and hypersensitivity reactions may occur; pulmonary fibrosis can be a serious problem—baseline and periodic chest radiographs and pulmonary function tests are necessary
dactinomycin (<i>Cosmegen</i>)	Adult: 0.5 mg/d IV for up to 5 d Pediatric: 0.015 mg/kg/d IV for up to 5 d or a total dose of 2.5 mg/m ² /wk	Part of combination drug regimen in the treatment of a variety of sarcomas and carcinomas; potentiates the effects of radiation therapy Special considerations: bone marrow suppression and GI toxicity, which may be severe, limit the dose; effects may not appear for 1–2 wk; local extravasation can cause necrosis and should be treated with injectable corticosteroids, ice to the area, and restarting of the IV line in a different vein
daunorubicin (<i>DaunoXome</i>)	40 mg/m ² IV, infused over 1 h; repeat every 2 wk	First-line treatment of advanced HIV infection and associated Kaposi sarcoma Special considerations: Complete alopecia is common, and GI toxicity and bone marrow suppression may also occur; severe necrosis may occur at sites of local extravasation—immediate treatment with corticosteroids, normal saline, and ice may help; if ulcerations occur, a plastic surgeon should be called
 doxorubicin (<i>Adriamycin, Doxil</i>)	60–75 mg/m ² as a single IV dose; repeat every 21 d Liposomal form: 30–50 mg/m ² IV over 1 hr once every 2–4 wk	Treatment of a number of leukemias and cancers; used to induce regression; available in a liposomal form for treatment of AIDS-associated Kaposi sarcoma Special considerations: complete alopecia is common; GI toxicity and bone suppression may occur; severe necrosis may occur at sites of local extravasation—immediate treatment with corticosteroids, normal saline, and ice may help; if ulcerations occur, a plastic surgeon should be called; toxicity is dose related—an accurate record of each dose received is important in determining dose; severe pulmonary toxicity, alopecia, and injection site and GI toxicity occur
epirubicin (<i>Ellence</i>)	100–120 mg/m ² IV given in repeated 3–4-wk cycles all on day 1 or divided on days 1 and 8	Adjunctive therapy in patients with evidence of axillary node tumor involvement after resection of primary breast cancer Special considerations: may cause cardiotoxicity and delayed cardiomyopathy; monitor for myelosuppression and hyperuricemia; severe local cellulitis and tissue necrosis can occur with extravasation
idarubicin (<i>Idamycin</i>)	12 mg/m ² per day IV for 3 d with cytarabine	Combination therapy for treatment of acute myeloid leukemia in adults Special considerations: may cause severe bone marrow suppression, which regulates dose; associated with cardiac toxicity, which can be severe; GI toxicity and local necrosis with extravasation are also common; severe necrosis may occur at sites of local extravasation—immediate treatment with corticosteroids, normal saline, and ice may help; if ulcerations occur, a plastic surgeon should be called; it is essential to monitor heart and bone marrow function to protect the patient from potentially fatal adverse effects
mitomycin (<i>Mutamycin</i>)	<i>Mutamycin</i> 20 mg/m ² IV as a single dose at 6–8-wk intervals	Treatment of disseminated adenocarcinoma of the stomach and pancreas Special considerations: severe pulmonary toxicity, alopecia, and injection-site and GI toxicity occur

Drug Name	Dosage/Route	Usual Indications
mitoxantrone (Novantrone)	12 mg/m ² per day IV for 1–3 d Multiple sclerosis: 12 mg/m ² IV as a short infusion every 3 mo	Part of combination therapy in the treatment of adult leukemias; treatment of bone pain in advanced prostatic cancer; reduction of neurological disability and frequency of relapses in chronic, progressive, relapsing multiple sclerosis Special considerations: severe bone marrow suppression may occur and limits dose; alopecia, GI toxicity, and congestive heart failure often occur; avoid direct skin contact with the drug—use gloves and goggles; monitor bone marrow activity and cardiac activity to adjust dose or discontinue drug as needed
valrubicin (Valstar)	800 mg intravesically once a week for 6 wk	Intravesical therapy for carcinoma in situ of the bladder if refractory to bacille Calmette-Guérin (BCG) therapy (orphan drug) Special considerations: use goggles and gloves when handling, avoid contact with eyes; severe bladder spasms have occurred; use caution with history of irritable bowel syndrome; do not clamp bladder catheter in place

antibiotics to an individual with a known allergy to the antibiotic or related antibiotics. Care is necessary when administering these agents to patients with the following conditions: bone marrow suppression, *which is often the index for redosing and dosing levels*; suppressed renal or hepatic function, *which might interfere with the metabolism or excretion of these drugs and often indicates a need to change the dose*; known GI ulcerations or ulcerative diseases, *which may be exacerbated by the effects of these drugs*; pulmonary problems with bleomycin or mitomycin, or cardiac problems with idarubicin or mitoxantrone, *which are specifically toxic to these organ systems*.

Adverse Effects

Adverse effects frequently encountered with the use of these antibiotics include bone marrow suppression, with leukopenia, thrombocytopenia, anemia, and pancytopenia, secondary to the effects of the drugs on the rapidly multiplying cells of the bone marrow. Toxic GI effects include nausea, vomiting, anorexia, diarrhea, and mucous membrane deterioration, all of which are related to drug effects on the rapidly multiplying cells of the GI tract. As with the alkylating agents and antimetabolites, effects of antineoplastic antibiotics may include renal or hepatic toxicity, depending on the exact mechanism of action. Alopecia may also occur. Specific antineoplastic antibiotics are toxic to the heart and lungs. Box 14.8 discusses a cardioprotective drug that interferes with the effects of doxorubicin.

Clinically Important Drug–Drug Interactions

Antimetabolites that are known to cause hepatic or renal toxicity should be used with care with any other drugs known to have the same effect. Drugs that result in toxicity to the heart

or lungs should be used with caution with any other drugs that produce that particular toxicity. Check for specific drug–drug interactions for each agent in a nursing drug guide.

Prototype Summary: Doxorubicin

Indications: To produce regression in acute lymphoblastic lymphoma, acute myeloblastic leukemia, Wilms tumor, neuroblastoma, soft tissue and bone sarcoma, breast carcinoma, ovarian carcinoma, thyroid carcinoma, Hodgkin and non-Hodgkin lymphomas, bronchogenic carcinoma; also to treat AIDS-related Kaposi sarcoma.

Actions: Binds to DNA and inhibits DNA synthesis in susceptible cells, causing cell death.

Pharmacokinetics:

Route	Onset	Peak	Duration
IV	Rapid	2 h	24–36 h

T_{1/2}: 12 minutes, then 3.3 hours, then 29.6 hours; metabolized in the liver and excreted in the bile, feces, and urine.

Adverse effects: Cardiac toxicity, complete but reversible alopecia, nausea, vomiting, mucositis, red urine, myelosuppression, fever, chills, rash.

Nursing Considerations for Patients Receiving Antineoplastic Antibiotics

Assessment: History and Examination

- Assess for contraindications and cautions: history of allergy to the antibiotic in use *to avoid hypersensitivity reactions*; bone marrow suppression *to prevent further*

BOX 14.8 A Cardioprotective Drug

Dexrazoxane (*Zinecard*), a powerful intracellular chelating agent, is a cardioprotective drug that interferes with the cardiotoxic effects of doxorubicin. The associated adverse effects are difficult to differentiate from those attributable to doxorubicin. This agent is approved for use to prevent the cardiomyopathy associated with doxorubicin in doses greater than 300 mg/m² in women with metastatic breast cancer. Dexrazoxane is given intravenously in a dose proportional to (10 times greater than) the doxorubicin dose 30 minutes before the doxorubicin is administered.

suppression; renal or hepatic dysfunction that might interfere with drug metabolism and excretion; respiratory or cardiac disease; current status related to pregnancy or lactation to prevent potentially serious adverse effects to the fetus or nursing baby; and GI ulcerative disease, which could be exacerbated by these drugs.

- Perform a physical assessment *to establish baseline data for determining the effectiveness of the drug and the occurrence of any adverse effects associated with drug therapy.*
- Assess orientation and reflexes *to evaluate any CNS effects; respiratory rate and adventitious sounds to monitor the disease and evaluate for respiratory or hypersensitivity effects; pulse, rhythm, cardiac auscultation, and baseline electrocardiogram to monitor for systemic or cardiovascular effects; and bowel sounds and mucous membrane status to monitor for GI effects.*
- Monitor the results of laboratory tests such as CBC with differential to identify possible bone marrow suppression and toxic drug effects, as well as renal and liver function tests, *to determine the need for possible dose adjustment.*

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to GI, CNS, or local effects of the drug
- Disturbed Body Image related to alopecia or skin effects
- Imbalanced Nutrition, less than body requirements
- Risk for Infection
- Fear, Anxiety related to diagnosis and treatment
- Deficient Knowledge regarding drug therapy

Implementation with Rationale

- Arrange for blood tests to monitor bone marrow function before, periodically during, and for at least 3 weeks after therapy *to arrange to discontinue the drug or reduce the dose as needed.*
- Monitor cardiac and respiratory function, as well as clotting times as appropriate for the drug being used, *to arrange to discontinue the drug or reduce the dose as needed.*
- Protect the patient from exposure to infection *because bone marrow suppression will decrease immune/inflammatory reactions.*

- Administer medication according to scheduled protocol and in combination with other drugs as indicated *to improve the effectiveness of drug therapy.*
- Ensure that the patient is well hydrated *to decrease the risk of renal toxicity.*
- Provide small, frequent meals, frequent mouth care, and dietary consultation as appropriate *to maintain nutrition when GI effects are severe.* Anticipate the need for antiemetics as necessary. (See Box 14.4.)
- Arrange for proper head covering at extremes of temperature if alopecia occurs; a wig, scarf, or hat *is important for maintaining body temperature.* If alopecia is an anticipated effect of drug therapy, advise the patient to obtain a wig or head covering before the condition occurs *to promote self-esteem and a positive body image.*
- Provide the following patient teaching:
 - Follow the appropriate dosage regimen, including dates to return for further doses.
 - Maintain nutrition if GI effects are severe.
 - Cover the head at extremes of temperature if alopecia is anticipated.
 - Plan for appropriate rest periods because fatigue and weakness are common effects of the drugs.
 - Avoid exposure to possible infection, including avoiding crowded places, sick people, and working in soil.
 - Use safety measures such as avoiding driving or using dangerous equipment to prevent injury due to possible dizziness, headache, and drowsiness.
 - Consult with a health care provider, if appropriate, related to the possibility of impaired fertility.
 - Use barrier contraceptives to reduce the risk of pregnancy during therapy.

Evaluation

- Monitor patient response to the drug (alleviation of cancer being treated and palliation of signs and symptoms of cancer).
- Monitor for adverse effects (bone marrow suppression, GI toxicity, neurotoxicity, alopecia, renal or hepatic dysfunction, and cardiac or respiratory dysfunction).
- Evaluate the effectiveness of the teaching plan (patient can name the drug, dosage, possible adverse effects to watch for, and specific measures to help avoid adverse effects).

KEY POINTS

- ▶ Antineoplastic antibiotics are toxic to rapidly dividing cells.
- ▶ These drugs are cell cycle specific, affecting the S phase.
- ▶ Bone marrow suppression, alopecia, and toxic GI effects are common adverse effects of the antineoplastic antibiotics.

MITOTIC INHIBITORS

Mitotic inhibitors (Table 14.4) are drugs that kill cells as the process of mitosis begins (see Figure 14.5). These cell cycle–specific agents inhibit DNA synthesis. Like other anti-neoplastics, the main adverse effects of the mitotic inhibitors

occur with cells that rapidly multiply: those in the bone marrow, GI tract, and skin. Mitotic inhibitors include docetaxel (*Taxotere*), etoposide (*Toposar*, *VePesid*), ixabepilone (*Ixempra*), paclitaxel (*Abraxane*, *Onxol*, *Taxol*), teniposide (*Vumon*), vinblastine (*Velban*), vincristine (*Oncovin*, *Vincasar*), and vinorelbine (*Navelbine*).

TABLE 14.4 DRUGS IN FOCUS Mitotic Inhibitors

Drug Name	Dosage/Route	Usual Indications
docetaxel (<i>Taxotere</i>)	60–100 mg/m ² IV over 1 h every 3 wk	Treatment of breast cancer and non–small cell lung cancer; androgen-dependent prostate cancer; gastric adenocarcinoma Special considerations: monitor patient closely—deaths have occurred during use; severe fluid retention can occur—premedicate with corticosteroids and monitor for weight gain; skin rash and nail disorders are usually reversible; monitor patients closely during use
etoposide (<i>Toposar</i> , <i>VePesid</i>)	35–100 mg/m ² per day IV for 4–5 d	Treatment of testicular cancers refractory to other agents; non–small cell lung carcinomas Special considerations: fatigue, GI toxicity, bone marrow depression, and alopecia are common side effects; avoid direct skin contact with the drug; use protective clothing and goggles; monitor bone marrow function to adjust dose; rapid fall in blood pressure can occur during IV infusion—monitor patient carefully
ixabepilone (<i>Ixempra</i>)	40 mg/m ² IV over 3 h every 3 wk	In combination with capecitabine for the treatment of patients with metastatic or locally advanced breast cancer Special considerations: peripheral neuropathies are common; monitor for bone marrow suppression and hepatic impairment; dose will need to be adjusted based on these tests
paclitaxel (<i>Abraxane</i> , <i>Onxol</i> , <i>Taxol</i>)	135–175 mg/m ² per day IV over 3 h every 3 wk	Treatment of advanced ovarian cancer, breast cancer, non–small cell lung cancer, and AIDS-related Kaposi sarcoma Special considerations: anaphylaxis and severe hypersensitivity reactions have occurred—monitor very closely during administration; also monitor for bone marrow suppression; cardiovascular toxicity and neuropathies have occurred
teniposide (<i>Vumon</i>)	165–250 mg/m ² IV weekly in combination with other drugs	In combination with other drugs for induction therapy in childhood acute lymphoblastic leukemia Special considerations: GI toxicity, CNS effects, bone marrow suppression, and alopecia are common effects; avoid direct skin contact with the drug—use protective clothing and goggles; monitor bone marrow function to adjust dose; rapid fall in blood pressure can occur during IV infusion—monitor patient carefully
vinblastine (<i>Velban</i>)	Adult: 3.7 mg/m ² IV once weekly Pediatric: 2.5 mg/m ² IV once weekly Dose may then be increased based on leukocyte count and patient response	Palliative treatment of various lymphomas and sarcomas; advanced Hodgkin disease; alone or as part of combination therapy for the treatment of advanced testicular germ cell cancers Special considerations: GI toxicity, CNS effects, and total loss of hair are common; antiemetics may help; avoid contact with drug; monitor injection sites for reactions

(drug table continues on page 216)

TABLE 14.4 DRUGS IN FOCUS Mitotic Inhibitors (continued)

Drug Name	Dosage/Route	Usual Indications
<p> vincristine (<i>Oncovin, Vincasar</i>)</p>	<p>Adult: 1.4 mg/m² IV at weekly intervals Pediatric: 1.5–2 mg/m² IV once weekly</p>	<p>Treatment of acute leukemia, various lymphomas, and sarcomas</p> <p>Special considerations: extensive CNS effects are common, GI toxicity, local irritation at injection IV site, and hair loss commonly occur; syndrome of inappropriate secretion of antidiuretic hormone (SIADH) has been reported—monitor urine output and arrange for fluid restriction and diuretics as needed</p>
<p>vinorelbine (<i>Navelbine</i>)</p>	<p>30 mg/m² IV once weekly, based on granulocyte count</p>	<p>First-line treatment of unresectable advanced non–small cell lung cancer; stage IV non–small-cell lung cancer and stage III non–small cell lung cancer with cisplatin</p> <p>Special considerations: GI and CNS toxicity are common; total loss of hair, local reaction at injection site, and bone marrow depression also occur; prepare a calendar with return dates for the series of injections; avoid extravasation but arrange for hyaluronidase infusion if it occurs; antiemetics may be helpful if reaction is severe</p>

Safe Medication Administration

Special care needs to be taken when administering these drugs. The nurse should avoid any skin, eye, or mucous membrane contact with the drug. This type of contact can cause serious reactions and toxicity.

Therapeutic Actions and Indications

The mitotic inhibitors interfere with the ability of a cell to divide; they block or alter DNA synthesis, thus causing cell death. They work in the M phase of the cell cycle. These drugs are used for the treatment of a variety of tumors and leukemias. See Table 14.4 for usual indications for each of these agents.

Pharmacokinetics

Generally, these drugs are given intravenously because they are not well absorbed from the GI tract. They are metabolized in the liver and excreted primarily in the feces, making them safer for use in patients with renal impairment than the antineoplastics that are cleared through the kidney.

Contraindications and Cautions

These drugs should not be used during pregnancy or lactation *because of the potential risk to the fetus or neonate*. Use caution when giving these drugs to anyone with a known allergy to the drug or related drugs. Care is necessary for patients with the following conditions: bone marrow suppression, *which is often the index for redosing and dosing levels*; renal or hepatic

dysfunction, *which could interfere with the metabolism or excretion of these drugs and often indicates a need to change the dose*; and known GI ulcerations or ulcerative diseases, *which may be exacerbated by the effects of these drugs*.

Adverse Effects

Adverse effects frequently encountered with the use of mitotic inhibitors include bone marrow suppression, with leukopenia, thrombocytopenia, anemia, and pancytopenia, secondary to the effects of the drugs on the rapidly multiplying cells of the bone marrow. GI effects include nausea, vomiting, anorexia, diarrhea, and mucous membrane deterioration. As with the other antineoplastic agents, effects of the mitotic inhibitors may include possible hepatic or renal toxicity, depending on the exact mechanism of action. Alopecia may also occur. These drugs also cause necrosis and cellulitis if extravasation occurs, so it is necessary to regularly monitor injection sites and take appropriate action as needed.

Safe Medication Administration

Preventing and Treating Extravasation

When an IV antineoplastic drug extravasates, or infiltrates into the surrounding tissue, serious tissue damage can occur. These drugs are toxic to cells, and the resulting tissue injury can result in severe pain, scarring, nerve and muscle damage, infection, and in very severe cases even amputation of the limb.

Prevention is the best way to deal with extravasation. Interventions that can help to prevent extravasation include the

following: use a distal vein, and avoid small veins on the wrist or digits; never use an existing line unless it is clearly open and running well; start the infusion with plain 5% dextrose in water (D5W) and monitor for any sign of extravasation; check the site frequently and ask the patient to report any discomfort in the area; and, if at all possible, do not use an infusion pump to administer one of these drugs because it will continue to deliver the drug under pressure and can cause a severe extravasation.

If extravasation occurs, there are specific antidotes to use with some antineoplastic drugs. The antidote is usually administered through the IV line to allow it to infiltrate the same tissue, but if the line has been pulled, a tuberculin syringe can be used to inject the antidote subcutaneously into the tissue surrounding the infiltrated area.

Drug	Antidote and Suggested Dosage
etoposide	hyaluronidase (<i>Wydase</i>), 0.2 mL
teniposide	subcutaneously; then apply heat to
vinblastine	disperse the drug and alleviate pain
vincristine	
daunorubicin	8.4% sodium bicarbonate, 5 mL; flush
doxorubicin	area with normal saline, apply cold
vinblastine	compress; local infiltration with
vincristine	corticosteroids may also be ordered
	at 25–50 mg/mL of extravasate; if ulcer-
	ation occurs, a plastic surgery consulta-
	tion should be obtained
mechlorethamine	isotonic sodium thiosulfate (1/6 M), 10 mL
	infused immediately, then apply an ice
	compress for 6–12 h
dactinomycin	50-mg ascorbic acid injection; flush area
	with normal saline and apply cold com-
	presses; consider the use of an injectable
	corticosteroid if reaction is severe

Clinically Important Drug–Drug Interactions

Mitotic inhibitors that are known to be toxic to the liver or the CNS should be used with care with any other drugs known to have the same adverse effect. Check specific drug–drug interactions for each agent in a nursing drug guide.

Prototype Summary: Vincristine

Indications: Acute leukemia, Hodgkin disease, non-Hodgkin lymphoma, rhabdomyosarcoma, neuroblastoma, Wilms tumor.

Actions: Arrests mitotic division at the stage of metaphase; the exact mechanism of action is not understood.

Pharmacokinetics:

Route	Onset	Peak
IV	Varies	15–30 min

$T_{1/2}$: 5 minutes, then 2.3 hours, then 85 hours; metabolized in the liver and excreted in the feces and urine.

Adverse effects: Ataxia, cranial nerve manifestations, neuritic pain, muscle wasting, constipation, leukopenia, weight loss, loss of hair, death.

Nursing Considerations for Patients Receiving Mitotic Inhibitors

Assessment: History and Examination

- Assess for contraindications or cautions: history of allergy to the drug used (or related drugs) *to avoid hypersensitivity reactions*; bone marrow suppression *to prevent further suppression*; renal or hepatic dysfunction *that might interfere with drug metabolism and excretion*; current status of pregnancy or lactation *to prevent potentially serious adverse effects on the fetus or nursing baby*; and GI ulcerative disease, *which could be exacerbated by these drugs*.
- Perform a physical assessment *to establish baseline data for determining the effectiveness of the drug and the occurrence of any adverse effects associated with drug therapy*.
- Assess orientation and reflexes *to evaluate any CNS effects*; skin *to evaluate for lesions*; hair and hair distribution *to monitor for adverse effects*; respiratory rate and adventitious sounds *to monitor the disease and to evaluate for respiratory or hypersensitivity effects*; and bowel sounds and mucous membrane status *to monitor for GI effects*.
- Monitor the results of laboratory tests such as CBC with differential *to identify possible bone marrow suppression and toxic drug effects*; and renal and liver function tests *to determine the need for possible dose adjustment as needed and to evaluate toxic drug effects*.
- Regularly inspect IV insertion sites *for signs of extravasation or inflammation, which need to be treated quickly*.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to GI, CNS, or local effects of the drug
- Disturbed Body Image related to alopecia, skin effects
- Risk for injury
- Fear, Anxiety related to diagnosis and treatment
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Arrange for blood tests to monitor bone marrow function before, periodically during, and for at least 3 weeks after therapy *to arrange to discontinue the drug or reduce the dose as needed*.
- Avoid direct skin or eye contact with the drug. Wear protective clothing and goggles while preparing and administering the drug *to prevent toxic reaction to the drug*.
- Administer medication according to scheduled protocol and in combination with other drugs as indicated *to improve the effectiveness of drug therapy*.
- Ensure that the patient is well hydrated *to decrease the risk of renal toxicity*.
- Monitor injection sites *to arrange appropriate treatment for extravasation, local inflammation, or cellulitis*.

- Protect the patient from exposure to infection *because bone marrow suppression will decrease immune/inflammatory responses.*
- Provide small, frequent meals, frequent mouth care, and dietary consultation as appropriate *to maintain nutrition if GI effects are severe.* Anticipate the need for antiemetics as necessary. (See Box 14.4.)
- Arrange for proper head covering at extremes of temperature if alopecia or epilation occurs; a wig, scarf, or hat *is important for maintaining body temperature.* If alopecia is an anticipated effect of drug therapy, advise the patient to obtain a wig or head covering before the condition occurs *to promote self-esteem and a positive body image.*
- Provide the following patient teaching:
 - Follow the appropriate dosage regimen, including dates to return for further doses.
 - Maintain nutrition if GI effects are severe.
 - Cover the head at extremes of temperature if alopecia is anticipated.
 - Plan for appropriate rest periods because fatigue and weakness are common effects of the drugs.
 - Avoid situations that might lead to infection, including crowded areas, sick people, and working in the soil.
 - Use safety measures such as avoiding driving or using dangerous equipment, due to possible dizziness, headache, and drowsiness.
 - Consult with a health care provider, as appropriate, related to the possibility of impaired fertility.
 - Use barrier contraceptives to reduce the risk of pregnancy during therapy.

Evaluation

- Monitor patient response to the drug (alleviation of cancer being treated and palliation of signs and symptoms of cancer).
- Monitor for adverse effects (bone marrow suppression, GI toxicity, neurotoxicity, alopecia, renal or hepatic dysfunction, and local reactions at the injection site).
- Evaluate the effectiveness of the teaching plan (patient can name the drug, dosage, possible adverse effects to watch for, and specific measures to help avoid adverse effects).

KEY POINTS

- ♦ Mitotic inhibitors kill cells during the M phase and are used to treat a variety of cancers.
- ♦ These drugs are usually given intravenously. Extravasation could be a serious problem
- ♦ Bone marrow suppression, alopecia, and toxic GI effects are common adverse effects of the mitotic inhibitors.

HORMONES AND HORMONE MODULATORS

Some cancers, particularly those involving the breast tissue, ovaries, uterus, prostate, and testes, are sensitive to estrogen stimulation. Estrogen-receptor sites on the tumor react with circulating estrogen, and this reaction stimulates the tumor cells to grow and divide. Several antineoplastic agents are used to block or interfere with these receptor sites to prevent growth of the cancer and in some situations to actually cause cell death. Some hormones are used to block the release of gonadotropic hormones in breast or prostate cancer if the tumors are responsive to gonadotropic hormones. Others may block androgen-receptor sites directly and are useful in the treatment of advanced prostate cancers. Hormones and hormone modulators include anastrozole (*Arimidex*), bicalutamide (*Casodex*), degarelix (*Degarelix for Injection*), estramustine (*Emcyt*), exemestane (*Aromasin*), flutamide (generic), fulvestrant (*Faslodex*), goserelin (*Zoladex*), histrelin (*Vantas*), letrozole (*Femara*), leuprolide (*Lupron*, *Eligard*), megestrol (*Megace*), mitotane (*Lysodren*), nilutamide (*Nilandron*), tamoxifen (*Nolvadex*, *Soltamox*), toremifene (*Fareston*) and triptorelin pamoate (*Trelstar Depot*) (Table 14.5).

Therapeutic Actions and Indications

The hormones and hormone modulators used as antineoplastics are receptor-site specific or hormone specific to block the stimulation of growing cancer cells that are sensitive to the presence of that hormone (see Figure 14.4). These drugs are indicated for the treatment of breast cancer in postmenopausal women or in other women without ovarian function. Some drugs are indicated for the treatment of prostatic cancers that are sensitive to hormone manipulation. Table 14.5 shows usual indications for each of the hormones and hormone modulators.

Pharmacokinetics

These drugs are readily absorbed from the GI tract, metabolized in the liver, and excreted in the urine. Caution must be used with any patient who has hepatic or renal impairment. These drugs cross the placenta and enter into breast milk.

Contraindications and Cautions

These drugs are contraindicated during pregnancy and lactation *because of toxic effects on the fetus and neonate.* Hypercalcemia is a contraindication to the use of toremifene, *which is known to increase calcium levels.* Use caution when giving hormones and hormone modulators to anyone with a known allergy to any of these drugs. Care is necessary in patients with bone marrow suppression, *which is often the index for redosing and dosing levels,* and in those with renal or hepatic dysfunction, *which could interfere with the metabolism or excretion of these drugs and often indicates a need to change the dose.*

TABLE 14.5 DRUGS IN FOCUS Hormones and Hormone Modulators

Drug Name	Dosage/Route	Usual Indications
anastrozole (<i>Arimidex</i>)	1 mg/d PO	Treatment of advanced breast cancer in postmenopausal women after tamoxifen therapy; first-line and adjunctive treatment of postmenopausal women with locally advanced breast cancer Actions: antiestrogen drug; blocks estradiol production without effects on adrenal hormones Special considerations: GI effects, signs and symptoms of menopause—hot flashes, mood swings, edema, vaginal dryness and itching—as well as bone pain and back pain, treatable with analgesics, may occur; monitor lipid concentrations in patients at risk for high cholesterol level
bicalutamide (<i>Casodex</i>)	50 mg/d PO	In combination with a luteinizing hormone for the treatment of advanced prostate cancer Actions: antiandrogen drug that competitively binds androgen-receptor sites Special considerations: gynecomastia and breast tenderness occur in 33% of patients; GI complaints are common; pregnancy category X
degarelix (<i>Degarelix for Injection</i>)	240 mg by subcutaneous injection given in two 120-mg injections, then 80 mg SC every 28 d for maintenance	Treatment of patients with advanced prostate cancer Actions: Gonadotropin-releasing hormone–receptor-site antagonist, leads to decreased follicle-stimulating hormone and luteinizing hormone and decreased testosterone levels Special considerations: pregnancy category X; risk of prolonged QT interval; injection-site reactions, hot flashes, increased weight are common
estramustine (<i>Emcyt</i>)	10–16 mg/kg per day PO in three to four divided doses for 30–90 d, then re-evaluate	Palliative for treatment of metastatic and progressive prostate cancer Actions: binds to estrogen steroid receptors, causing cell death Special considerations: GI toxicity, rash, bone marrow depression, breast tenderness, and cardiovascular toxicity are common adverse effects; 30–90 d of therapy may be required before effects are seen; monitor cardiovascular, liver, and bone marrow function throughout therapy
exemestane (<i>Aromasin</i>)	25 mg/d PO with meals	Treatment of advanced, metastatic breast cancer in postmenopausal women whose disease has progressed after tamoxifen therapy Actions: inactivates steroid aromatase, lowering circulating estrogen levels and preventing the conversion of androgens to estrogen Special considerations: avoid use in premenopausal women or in patients with liver or renal dysfunction; hot flashes, headache, GI upset, anxiety, and depression are common
flutamide (generic)	250 mg PO t.i.d. given 8 h apart	With a luteinizing hormone for treatment of locally confined and metastatic prostate cancer Actions: antiestrogenic drug, inhibits androgen uptake and binding on target cells Special considerations: may cause liver toxicity, so liver function should be monitored regularly; associated with impaired fertility and cancer development; urine may become greenish; protect patient from exposure to the sun—photosensitivity is common
fulvestrant (<i>Faslodex</i>)	250 mg IM at 1-mo intervals	Treatment of hormone receptor–positive metastatic breast cancer in postmenopausal women with disease progression after antiestrogen therapy Actions: competitively binds to estrogen receptors, downregulating the estrogen receptor protein in breast cancer cells Special considerations: pregnancy category X; hot flashes, depression, headache, and GI upset are common; mark calendar with monthly injection dates; injection-site reactions may occur

(drug table continues on page 220)

TABLE 14.5 DRUGS IN FOCUS Hormones and Hormone Modulators (continued)

Drug Name	Dosage/Route	Usual Indications
goserelin (<i>Zoladex</i>)	3.6–10.8 mg implant, SC, every 28 d to 12 wk, varies with diagnosis	Treatment of advanced prostatic and breast cancers; management of endometriosis Actions: synthetic luteinizing hormone that inhibits pituitary release of gonadotropic hormones Special considerations: a 3.6-mg dose is effective in decreasing the signs and symptoms of endometriosis; associated with hypercalcemia and bone density loss—monitor serum calcium levels regularly; impairs fertility and is carcinogenic; monitor male patients for possible ureteral obstruction, especially during the first month
histrelin (<i>Vantas</i>)	50-mg implant every 12 mo	Palliative treatment of advanced prostate cancer Actions: inhibits gonadotropic secretion; decreases follicle-stimulating hormone and luteinizing hormone levels and testosterone levels Special considerations: must be surgically implanted and removed; hot flashes very common; monitor implantation site
letrozole (<i>Femara</i>)	2.5 mg/d PO	Treatment of advanced breast cancer in postmenopausal women with disease after antiestrogen therapy; postsurgery adjunct for postmenopausal women with early hormone receptor–positive breast cancer. Actions: prevents the conversion of precursors to estrogens in all tissues Special considerations: GI toxicity, bone marrow depression, alopecia, hot flashes, and CNS depression are common effects; discontinue drug at any sign that the cancer is progressing
leuprolide (<i>Lupron</i> , <i>Eligard</i>)	3.7–30 mg by injection, implant, or depot every 1–4 mo, depending on preparation used	Treatment of advanced prostate cancer; also used to treat precocious puberty and endometriosis; depot form for uterine leiomyomata Actions: a natural luteinizing hormone that blocks the release of gonadotropic hormones Special considerations: Monitor cancer patient's prostate-specific antigen levels periodically; monitor bone density and serum calcium levels; warn patient that he may have difficulty voiding the first few weeks and may experience bone pain, hot flashes, and pain at injection site
megestrol (<i>Megace</i>)	Breast cancer: 160 mg/d PO Endometrial cancer: 40–320 mg/d PO Appetite stimulant: 400–800 mg/d suspension	Palliative treatment of advanced breast or endometrial cancer; appetite stimulant for HIV patients Actions: blocks luteinizing hormone release; efficacy not understood Special considerations: monitor for thromboembolic events and weight gain; not for use during pregnancy
mitotane (<i>Lysodren</i>)	2–6 mg PO in divided doses t.i.d. to q.i.d.; maximum dose 9–10 g/d	Treatment of inoperable adrenocortical carcinoma Actions: cytotoxic to corticosteroid-forming cells of the adrenal gland Special considerations: can cause GI toxicity, CNS toxicity with vision and behavioral changes, adrenal insufficiency; monitor adrenal function, and arrange for replacement therapy as indicated
nilutamide (<i>Nilandron</i>)	300 mg/d PO for 30 d, then 150 mg/d PO	With surgical castration for treatment of metastatic prostate cancer Actions: antiestrogenic drug, inhibits androgen uptake and binding on target cells Special considerations: may cause liver toxicity, and liver function test results should be monitored regularly; associated with interstitial pneumonitis—baseline and periodic chest radiographs should be obtained and drug discontinued at first sign of dyspnea

Drug Name	Dosage/Route	Usual Indications
 tamoxifen (<i>Nolvadex</i> , <i>Soltamox</i>)	20–40 mg/d PO	In combination therapy with surgery to treat breast cancer; treatment of advanced breast cancer in men and women; first drug approved for the prevention of breast cancer in women at high risk for breast cancer Actions: antiestrogen, competes with estrogen for receptor sites in target tissues Special considerations: signs and symptoms of menopause are common effects; CNS depression, bone marrow depression, and GI toxicity are also common; can change visual acuity and cause corneal opacities and retinopathy—pretherapy and periodic ophthalmic examinations are indicated
toremifene (<i>Fareston</i>)	60 mg/d PO	Treatment of advanced breast cancer in women with estrogen receptor–positive disease Actions: binds to estrogen receptors and prevents growth of breast cancer cells Special considerations: signs and symptoms of menopause are common effects; CNS depression and GI toxicity are also common
triptorelin pamoate (<i>Trelstar Depot</i>)	3.75-mg IM depot monthly or 11.25-mg IM depot every 3 mo	Treatment of advanced prostatic cancer. Actions: analogue of luteinizing hormone–releasing hormone; causes a decrease in follicle-stimulating hormone and luteinizing hormone levels, leading to a suppression of testosterone production. Special considerations: monitor prostate-specific antigen and testosterone levels regularly; sexual dysfunction, urinary tract symptoms, bone pain, and hot flashes are common; schedule depot injections and mark calendars for patient

Adverse Effects

Adverse effects frequently encountered with the use of these drugs involve the effects that are seen when estrogen is blocked or inhibited. Menopause-associated effects include hot flashes, vaginal spotting, vaginal dryness, moodiness, and depression. Other effects include bone marrow suppression and GI toxicity, including hepatic dysfunction. Hypercalcemia is also encountered as the calcium is pulled out of the bones without estrogen activity to promote calcium deposition. Many of these drugs increase the risk for cardiovascular disease because of their effects on the body.

Clinically Important Drug–Drug Interactions

If hormones and hormone modulators are taken with oral anticoagulants, there is often an increased risk of bleeding. Care is also necessary when administering these agents with any drugs that might increase serum lipid levels.

Prototype Summary: Tamoxifen

Indications: Treatment of metastatic breast cancer, reduction of risk of invasive breast cancer in women with ductal carcinoma in situ, reduction in occurrence of contralateral breast cancer in patients receiving adjuvant tamoxifen therapy, reduction in incidence of breast cancer in women at high risk for breast cancer, treatment of McCune–Albright syndrome,

and treatment of precocious puberty in female patients 2 to 10 years of age.

Actions: Competes with estrogen for binding sites in target tissues, such as the breast; a potent antiestrogenic agent.

Pharmacokinetics:

Route	Onset	Peak
Oral	Varies	4–7 h

$T_{1/2}$: 7 to 14 days; metabolized in the liver and excreted in the feces.

Adverse effects: Hot flashes, rash, nausea, vomiting, vaginal bleeding, menstrual irregularities, edema, pain, cerebrovascular accident, pulmonary emboli.

● Nursing Considerations for Patients Receiving Hormones and Hormone Modulators

Assessment: History and Examination

- Assess for contraindications or cautions: history of allergy to the drug in use or any related drugs *to avoid hypersensitivity reactions*; bone marrow suppression *to prevent further suppression*; renal or hepatic dysfunction *that might interfere with drug metabolism and excretion*; current status of pregnancy or lactation *to prevent potentially serious adverse effects on the fetus or nursing baby*; history

of hypercalcemia and hypercholesterolemia *to avoid further increases in levels.*

- Perform a physical assessment *to establish baseline data for determining the effectiveness of the drug and the occurrence of any adverse effects associated with drug therapy.*
- Assess orientation and reflexes *to evaluate any CNS effects;* skin *to evaluate for lesions;* hair and hair distribution *to monitor for adverse drug effects;* blood pressure, pulse, and perfusion *to evaluate the status of the cardiovascular system and monitor for adverse drug effects;* and bowel sounds and mucous membrane status *to monitor for GI effects.*
- Monitor the results of laboratory tests such as CBC with differential to identify bone marrow suppression and toxic drug effects, serum calcium levels to evaluate for hypercalcemia, and renal and liver function tests *to determine the need for possible dose adjustment to evaluate toxic drug effects.*

See the *Critical Thinking Scenario* for a full discussion of assessing and evaluating antineoplastic therapy for a patient with breast cancer.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to GI, CNS, or menopausal effects of the drug
- Disturbed Body Image related to antiestrogen effects, virilization
- Fear, Anxiety related to diagnosis and treatment
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Arrange for blood tests to monitor bone marrow function before and periodically during therapy *to discontinue the drug or reduce the dose as needed.*
- Provide small, frequent meals, frequent mouth care, and dietary consultation as appropriate *to maintain nutrition when GI effects are severe.*
- Provide comfort measures *to help the patient cope with menopausal signs and symptoms* such as hygiene measures, temperature control, and stress reduction. Expect to reduce the dose if these effects become severe or intolerable.
- Advise the patient of the need to use barrier contraceptive measures while taking these drugs *to avert serious fetal harm.*
- Provide the following patient teaching:
 - Follow the appropriate dosage regimen, including dates to return for further doses.
 - Maintain nutrition even if GI effects are severe.
 - Use barrier contraceptives to prevent pregnancy during therapy
 - Try using comfort measures such as staying in a cool environment.
 - Perform hygiene and skin care and use measures to reduce stress to help cope with menopausal effects.
 - You may need to have periodic blood tests to monitor the effects of this drug on your body.

Evaluation

- Monitor patient response to the drug (alleviation of cancer being treated and palliation of signs and symptoms of cancer being treated).
- Monitor for adverse effects (bone marrow suppression, GI toxicity, menopausal signs and symptoms, hypercalcemia, and cardiovascular effects).
- Evaluate the effectiveness of the teaching plan (patient can name the drug, dosage, possible adverse effects to watch for, and specific measures to help avoid adverse effects).

KEY POINTS

- ▶ Hormones and hormonal agents are used to treat specific cancers that respond to hormone stimulation such as breast cancer or prostate cancer.
- ▶ The adverse effects of hormones and hormonal agent used to treat cancers are increased or decreased effects of the hormones on the body: virilization, increased risk of cardiovascular disease, increased calcium levels.

CANCER CELL-SPECIFIC AGENTS

The goal of much of the current antineoplastic drug research is directed at finding drugs that are cancer cell specific. These drugs would not have the devastating effects on healthy cells in the body and would be more effective against particular cancer cells. Three groups of drugs are available for cancer cell-specific actions: protein tyrosine kinase inhibitors, an epidermal growth factor inhibitor, and a proteasome inhibitor (Table 14.6).

Protein Tyrosine Kinase Inhibitors

The protein kinase inhibitors (Table 14.6) act on specific enzymes that are needed for protein building by specific tumor cells. Blocking of these enzymes inhibits tumor cell growth and division.

Each drug that has been developed inhibits a very specific protein kinase and acts on very specific tumors. They do not affect healthy human cells, so the patient does not experience the numerous adverse effects associated with antineoplastic chemotherapy. Imatinib (*Gleevec*), the first drug approved in this class, is given orally and is approved to treat chronic myelocytic leukemia (CML). Patients who have CML and who have been switched to imatinib after traditional chemotherapy have been amazed at how good they feel and how much they have recovered from the numerous adverse effects of the traditional chemotherapy. Long-term effects are not yet known because the drug is relatively new. Unfortunately, this drug is expensive. It is estimated that 1 year of treatment with the drug (which needs to be taken continually) costs the patient between \$30,000 and \$35,000. Novartis, the drug company that manufactures *Gleevec*, has set up a patient assistance

CRITICAL THINKING SCENARIO

Antineoplastic Therapy and Breast Cancer

THE SITUATION

B.P., a 34-year-old white woman, is a schoolteacher with two young daughters. She noticed a slightly painful lump under her arm when showering. About 2 weeks later, she found a mass in her right breast. Initial patient assessment found that she had no other underlying medical problems, had no allergies, and took no medications. Her family history was most indicative: Many of the women in her family—her mother, two grandmothers, three aunts, two older sisters, and one younger sister—died of breast cancer when they were in their early 30s. All data from the initial examination, including an evaluation of the lump in the upper outer quadrant of her breast and the presence of a fixed axillary node, were recorded as baseline data for further drug therapy and treatment. B.P. underwent a radical mastectomy with biopsy report for grade IV infiltrating ductal carcinoma (28 of 35 lymph nodes were positive for tumor) and then radiation therapy. Then she began a 1-year course of doxorubicin, cyclophosphamide, and paclitaxel (AC/paclitaxel/sequential).

CRITICAL THINKING

What are the important nursing implications for B.P.? *Think about the outlook for B.P., based on her biopsy results and her family history.*

What are the effects of high levels of stress on the immune system and the body's ability to fight cancer?

What impact will this disease have on B.P.'s job and her family? *Think about the adverse drug effects that can be anticipated.* How can good patient teaching help B.P. to anticipate and cope with these many changes and unpleasant effects?

What future concerns should be addressed or at least approached at this point in the treatment of B.P.'s disease? What are the implications for her two daughters? How may a coordinated health team work to help the daughters cope with their mother's disease, as well as the prospects for their future?

DISCUSSION

The extent of B.P.'s disease, as evidenced by the biopsy results, does not signify a very hopeful prognosis. In this case, the overall nursing care plan should take into account not only the acute needs related to surgery and drug therapy, but also future needs related to potential debilitation and even the prospect of death. Immediate needs include comfort and teaching measures to help B.P. deal with the mastectomy and recovery from the surgery. She should be given an opportunity to vent her feelings and thoughts in a protected environment. Efforts should be made to help her to organize her life and plans around her radiation therapy and chemotherapy.

The adverse effects associated with the antineoplastic agents she will be given should be explained and possible ways to cope should be discussed. These effects include the following:

Alopecia. B.P. should be reassured that her hair will grow back, but she will need to cover her head in extremes of temperature. Purchasing a wig before the hair loss begins may be a good alternative to trying to remember later what her hair was like.

Nausea and vomiting. These effects will most often occur immediately after the drugs are given. Antiemetics may be ordered, but they are frequently not very effective.

Bone marrow suppression. This will make B.P. more susceptible to disease, which could be a problem for a teacher and a mother with young children. Ways to avoid contact and infection, as well as warning signs to report immediately, should be discussed.

Mouth sores. Stomatitis and mucositis are common problems. Frequent mouth care is important. The patient should be encouraged to maintain fluid intake and nutrition.

Because the antineoplastic therapy will be a long-term regimen, it might help to prepare a calendar of drug dates for use in planning other activities and events. All of B.P.'s treatment should be incorporated into a team approach that helps B.P. and her family deal with the impact of this disease and its therapy, as well as with the potential risk to her daughters. B.P.'s daughters are in a very high risk group for this disease, so the importance of frequent examinations as they grow up needs to be stressed. In some areas of the country, health care providers are encouraging prophylactic mastectomies for women in this very high risk group.

NURSING CARE GUIDE FOR B.P.: ANTINEOPLASTIC AGENTS

Assessment: History and Examination

Allergies to any of these drugs, renal or hepatic dysfunction, pregnancy or lactation, bone marrow suppression, or GI ulceration.

Concurrent use of ketoconazole, diazepam, verapamil, quinidine, dexamethasone, cisplatin, cyclosporine, teniposide, etoposide, vincristine, testosterone, or digoxin, which could interact with these drugs.

Local: evaluation of injection site.

CNS: orientation, affect, reflexes.

Skin: color, lesions, texture.

GI: abdominal, liver evaluation.

Laboratory tests: CBC with differential; renal and hepatic function tests.

Antineoplastic Therapy and Breast Cancer (continued)

Nursing Diagnoses

Acute Pain related to GI, CNS, or skin effects
 Imbalanced Nutrition: Less Than Body Requirements related to GI effects
 Disturbed Body Image related to diagnosis, therapy, adverse effects
 Deficient Knowledge regarding drug therapy
 Risk for infection

Implementation

Ensure safe administration of the drug.
 Provide comfort and safety measures: mouth and skin care, rest periods, safety precautions, antiemetics as needed, maintenance of nutrition, and head covering.
 Provide support and reassurance to deal with drug effects, body image changes, discomfort, and diagnosis.
 Provide patient teaching regarding drug name, dosage, adverse effects, precautions to take, signs and symptoms to report, and comfort measures to observe.

Evaluation

Evaluate drug effects: resolution of cancer.
 Monitor for adverse effects: GI toxicity, bone marrow suppression, CNS changes, renal and hepatic damage, alopecia, extravasation of drug.
 Monitor for drug–drug interactions as listed.
 Evaluate effectiveness of patient teaching program.
 Evaluate effectiveness of comfort and safety measures.

PATIENT TEACHING FOR B.P.

Antineoplastic agents work to destroy cells at various phases of their life cycle. The drugs are given in combination to affect the cells at these various stages. These drugs are prescribed to kill cancer cells that are growing in the body. Because these drugs also affect normal cells, they sometimes cause many adverse effects. Your drug combination includes doxorubicin, cyclophosphamide, and paclitaxel.

- These drugs are given in a 21-day cycle, followed by a rest period. You will need to mark your calendar with the treatment days and rest days. You will need to have regular blood tests to follow the effects of these drugs on your blood cells.
- Common adverse effects of these drugs include the following:
 - *Nausea and vomiting.* Antiemetic drugs and sedatives may help. Your health care provider will be with you to help if these effects occur.
 - *Loss of appetite.* It is very important to keep up your strength. Tell people if there is something that you would be interested in eating—anything that appeals to you.

Alert someone if you feel hungry, regardless of the time of day.

- *Loss of hair.* Your hair will grow back, although its color or consistency may be different from what it was originally. It may help to purchase a wig before you lose your hair so that you can match appearance if you would like to. Hats and scarves may also be worn. It is very important to keep your head covered in extremes of temperature and to protect yourself from sun, heat, and cold. Because much of the body's heat can be lost through the head, not protecting yourself could cause serious problems.
- *Mouth sores.* Frequent mouth care is very helpful. Try to avoid very hot or spicy foods.
- *Fatigue, malaise.* Frequent rest periods and careful planning of your day's activities can be very helpful.
- *Bleeding.* You may bruise more easily than you normally do, and your gums may bleed while you are brushing your teeth. Special care should be taken when shaving or brushing your teeth. Avoid activities that might cause an injury, and avoid medications that contain aspirin.
- *Susceptibility to infection.* Avoid people with infections or colds, and avoid crowded, public places. In some cases, the people who are caring for you may wear gowns and masks to protect you from their germs. Avoid working in your garden because soil can be full of bacteria.
- Report any of the following to your health care provider: bruising and bleeding, fever, chills, sore throat, difficulty breathing, flank pain, and swelling in your ankles or fingers.
- Take the full course of your prescription. It is very important to take the complete regimen that has been ordered for you. Cancer cells grow at different rates, and they go through rest periods during which they are not susceptible to the drugs. The disease must be attacked over time to eradicate the problem.
- Tell any doctor, nurse, or other health care provider that you are taking this drug.
- Try to maintain a balanced diet while you are taking this drug. Drink 10 to 12 glasses of water each day during the drug therapy.
- Use a barrier contraceptive while you are taking this drug. These drugs can cause serious effects to a developing fetus, and precautions must be taken to avoid pregnancy. If you think that you are pregnant, consult your health care provider immediately.
- You need to have periodic blood tests and examinations while you are taking this drug. These tests help to guard against serious adverse effects and may be needed to determine the next dose of your drug.

TABLE 14.6 DRUGS IN FOCUS Cancer Cell–Specific Agents

Drug Name	Dosage/Route	Usual Indications
Protein Tyrosine Kinase Inhibitors		
everolimus (<i>Afinitor</i>)	10 mg/d PO with food	Treatment of patients with advanced renal cell carcinoma after failure of treatment with sunitinib or sorafenib Special considerations: pneumonitis, serious-to-fatal infections, oral ulcerations, and elevations in blood glucose, lipid, and creatinine levels may occur; monitor patient very closely; do not use in pregnancy
gefitinib (<i>Iressa</i>)	250 mg/d PO	Monotherapy for treatment of patients with locally advanced or metastatic non–small cell lung cancer after failure with platinum-based or docetaxel chemotherapies; use limited to patients doing well on therapy—not for new use Special considerations: interstitial lung disease may occur; monitor pulmonary function closely; eye changes may require stopping the drug for a while; do not use during pregnancy; numerous drug–drug interactions are possible
 imatinib (<i>Gleevec</i>)	Chronic-phase chronic myelocytic leukemia (CML): 400 mg/d PO, may be increased to 600 mg/d if needed Blast-crisis CML: 600 mg/d PO, may be increased to 400 mg PO b.i.d. First-line CML treatment: 400 mg/d PO GI stromal tumors: 400–600 mg/d PO	Treatment of CML patients in blast crisis or in chronic phase after interferon-alpha therapy; treatment of patients with Kit-positive malignant GIST; first-line treatment of CML Special considerations: administer with a meal and a full glass of water; arrange for small, frequent meals if GI upset is a problem; provide analgesics for headache and muscle pain; monitor complete blood count and for edema to arrange for dose reduction if needed; patient should receive consultation to deal with high cost of drug
lapatinib (<i>Tykerb</i>)	1250 mg (5 tablets) orally once a daily on days 1–21 in combination with capecitabine 2000 mg/m ² per day PO in 2 doses approximately 12 h apart on days 1–14; give in a repeating 21-d cycle; reduce dose to 750 mg/d PO with severe hepatic dysfunction	In combination with capecitabine for the treatment of patients with advanced or metastatic breast cancer whose tumors overexpress HER2 and who have received prior treatment including an anthracycline, taxane, and trastuzumab Special considerations: monitor heart function closely and decrease dose as needed; monitor for rash, GI toxicity; avoid grapefruit juice; many drug–drug interactions are possible
nilotinib (<i>Tasigna</i>)	400 mg PO b.i.d., approximately 12 h apart without food	Treatment of chronic-phase and accelerated-phase Philadelphia chromosome–positive chronic myelogenous leukemia in adult patients resistant or intolerant to prior therapy that included imatinib Special considerations: monitor for prolonged QT interval, bone marrow suppression, and possible liver toxicity
sorafenib (<i>Nexavar</i>)	400 mg PO b.i.d. on an empty stomach	Treatment of patients with advanced renal cell carcinoma and unresectable hepatocellular carcinoma Special considerations: monitor for skin reactions, hand-foot syndrome, hypertension
sunitinib (<i>Sutent</i>)	50 mg/d PO for 4 wk, followed by 2 wk or rest; repeat cycle	Treatment of GI stromal tumor if patient is intolerant to or tumor progresses after imatinib therapy Special considerations: monitor for GI disturbances, bone marrow suppression; adjust dose as needed
temsirolimus (<i>Torisel</i>)	25 mg IV, infused over 30–60 min once per week	Treatment of advanced renal cell carcinoma Special considerations: monitor lung function, blood glucose, renal function; may experience slowed healing; avoid grapefruit juice, St. John's wort

(drug table continues on page 226)

TABLE 14.6 DRUGS IN FOCUS Cancer Cell–Specific Agents (continued)

Drug Name	Dosage/Route	Usual Indications
Epidermal Growth Factor Inhibitor		
erlotinib (<i>Tarceva</i>)	150 mg/d PO 1 h before or 2 h after meal	Treatment of locally advanced or metastatic non–small cell lung cancer after failure of at least one other drug regimen; first-line treatment of pancreatic cancer when used in combination with gemcitabine Special considerations: serious-to-fatal interstitial lung disease—monitor with hepatic impairment; do not use during pregnancy
Proteasome Inhibitor		
bortezomib (<i>Velcade</i>)	1.3 mg/m ² by bolus IV injection on days 1, 4, 8, and 11, followed by 10 d of rest, then repeat	Treatment of multiple myeloma in patients with disease progression after two other therapies Special considerations: may cause peripheral neuropathies, hypotension, and bone marrow suppression; do not use during pregnancy

program with a sliding-scale price reduction based on income. They do not want patients to have to pay more than 20% of their annual income for the drug. Patients prescribed this drug may need support and assistance in obtaining financial help. The protein tyrosine kinase inhibitors that are available include everolimus (*Afinitor*), gefitinib (*Iressa*), imatinib (*Gleevec*), lapatinib (*Tykerb*), nilotinib (*Tasigna*), sorafenib (*Nexavar*), sunitinib (*Sutent*), and temsirolimus (*Torisel*).

Epidermal Growth Factor Inhibitor

In late 2004, the U.S. Food and Drug Administration (FDA) approved erlotinib (*Tarceva*), a drug that inhibits cell epidermal growth factor receptors. This growth factor is found on normal and cancerous cells but is more abundant on rapidly growing cells.

Proteasome inhibitor

In 2003, the FDA approved bortezomib (*Velcade*) for the treatment of multiple myeloma in patients whose disease had progressed after two other standard therapies. This drug inhibits proteasome in human cells, a large protein complex that works to maintain cell homeostasis and protein production. Without it, the cell loses homeostasis and dies. This drug was shown to delay growth in selected tumors.

Therapeutic Actions and Indications

Imatinib is an oral antineoplastic drug is a protein tyrosine kinase inhibitor that selectively inhibits the Bcr-Abl tyrosine kinase created by the Philadelphia chromosome abnormality in CML. Blocking this enzyme inhibits proliferation and induces cell division in Bcr-Abl–positive cell lines, as well as in new leukemic cells, thereby inhibiting tumor growth in

CML patients in blast crisis. It also inhibits a specific receptor site in gastrointestinal stromal tumor (GIST) patients. Because of its specific effects on these tumor cells, it is not associated with adverse effects on normal human cells.

Gefitinib, lapatinib, nilotinib, sorafenib, sunitinib, and temsirolimus work by inhibiting various kinases in the cancer cell. Table 14.6 shows usual indications for all protein tyrosine kinase inhibitors.

Safe Medication Administration

Gefitinib was introduced in 2003. It inhibits tyrosine kinases, including ones associated with epidermal growth factor receptors. In 2005, the FDA announced that postmarketing studies did not support the use of gefitinib. Patients taking the drug did not live longer than patients using less toxic therapy. The *Iressa* Access Program was initiated in mid-2005 to ensure the proper use of the drug, limiting its availability to only those patients who had done well on gefitinib therapy. Initiation of *Iressa* therapy is no longer supported. Patients using it may stay on it, but new therapy regimens are not being started at this time.

Erlotinib is an oral drug that inhibits enzymes associated with epidermal growth factor. It is approved for the treatment of non–small cell lung cancer and for first-line treatment of pancreatic cancer when used in combination with gemcitabine.

Bortezomib blocks a large protein complex that is necessary for maintaining cell homeostasis, leading to cell death. It must be given IV and is approved for the treatment of mantle cell lymphoma and multiple myeloma.

Pharmacokinetics

Imatinib is slowly absorbed from the GI tract, reaching peak levels in 2 to 4 hours. It is extensively metabolized in the liver, with a half-life of 18 and then 40 hours. Gefitinib is

slowly absorbed from the GI tract, reaching peak levels in 3 to 7 hours. It is metabolized in the liver with a half-life of 48 hours. Lapatinib, given orally, is absorbed from the GI tract, reaching peak levels in 1 to 1.5 hours. Lapatinib is metabolized in the liver, with a half-life of 24 hours. Nilotinib, given orally, reach peak levels in 3 hours after GI absorption. Most of the drug is excreted unchanged in the stool with a half-life of 17 hours. Sorafenib is well absorbed from the GI tract after oral administration, reaching peak levels in 1 to 2 hours. Most of the drug is excreted unchanged in the stool with a half-life of 24 to 48 hours. Sunitinib, given orally, is slowly absorbed from the GI tract, reaching peak levels in 6 to 12 hours. After metabolism in the liver, it has a half-life of 40 to 60 hours and then 80 to 110 hours for its active metabolite. Temsirolimus, only available for IV use, reaches peak levels at the end of the infusion. It is metabolized in the liver and primarily excreted in the feces with a half-life of 17 hours and then 55 hours for its active metabolite.

Erlotinib is well absorbed orally from the GI tract, reaching peak levels in 4 hours. It is metabolized in the liver with a half-life of 36 hours.

Bortezomib, given IV, reaches peak effects at the end of the infusion. It is metabolized in the liver and has a half-life of 40 to 193 hours.

Contraindications and Cautions

All of these drugs are in pregnancy category D. Women of childbearing age should be advised to use barrier contraceptives while taking this drug. It can enter breast milk, and it should be used during lactation only if the benefits to the mother clearly outweigh the risks to the baby. With imatinib, caution should be used in patients with known hepatic dysfunction. Nilotinib is contraindicated with patients who have or who are at risk for prolonged QT intervals (hypokalemia, hypomagnesemia, or taking another drug that prolongs the QT interval) because it prolongs the QT interval, and sudden deaths could occur. These drugs should not be given to anyone who has a history of hypersensitivity to any component of the drug being given.

Adverse Effects

The adverse effects associated imatinib include GI upset, muscle cramps, heart failure, fluid retention, and skin rash. The severe bone marrow suppression, alopecia, and severe GI effects associated with more traditional antineoplastic therapy do not occur. Gefitinib has been associated with potentially severe interstitial lung disease and various eye symptoms. Nilotinib causes prolonged QT intervals and can impair liver and kidney function. Lapatinib causes diarrhea and can cause liver impairment and alter heart function. Erlotinib and bortezomib are associated with cardiovascular events and pulmonary toxicity. Bortezomib has also been associated with peripheral neuropathy and liver and kidney impairment.

Clinically Important Drug–Drug Interactions

Use caution when administering imatinib with other drugs affected by the cytochrome P450 enzyme system. In addition, St. John's wort decreases the effectiveness of many of these drug and should be avoided. When using nilotinib avoid any other drugs that are known to prolong the QT interval.

Prototype Summary: *Imatinib*

Indications: Treatment of adults with CML who are in blast crisis, accelerated phase, or chronic phase after failure with interferon-alpha therapy. It has since also been approved for use in the treatment of patients with CD117-positive unresectable or metastatic GIST.

Actions: Tyrosine kinase inhibitor that selectively inhibits the Bcr-Abl tyrosine kinase created by the Philadelphia chromosome abnormality in CML and certain tumor cells present in GIST; blocking this enzyme inhibits proliferation and induces cell division.

Pharmacokinetics:

Route	Onset	Peak
Oral	Slow	2–4 h

$T_{1/2}$: 18 to 40 hours; metabolized in the liver and excreted in the feces.

Adverse effects: Nausea, vomiting, bone marrow suppression, heart failure, headache, dizziness, edema, rash.

Nursing Considerations for Patients Receiving Cancer Cell-Specific Agents

These are similar to nursing care considerations for patients receiving alkylating agents.

KEY POINTS

- ▶ Cancer cell-specific drugs have been developed to target processes that occur in cancer cells but not in healthy cells. This specificity results in fewer toxic effects than with traditional antineoplastic therapy.
- ▶ Protein tyrosine kinase inhibitors, epidermal growth factor inhibitors, and proteasome inhibitors have been developed to target cancer cells specifically.

MISCELLANEOUS ANTINEOPLASTICS

Many other agents that do not fit into one of the previously discussed groups are used as antineoplastics to cause cell death. These drugs are used for treating a wide variety of cancers. Table 14.7 lists the unclassified antineoplastic drugs, their indications, and any special considerations associated with the drug. Specific information about each drug may be obtained in a nursing drug guide. (See Figure 14.4 for sites of action of the miscellaneous antineoplastic agents.)

TABLE 14.7 DRUGS IN FOCUS Miscellaneous Antineoplastics

Drug Name	Dosage/Route	Usual Indications
arsenic trioxide (<i>Trisenox</i>)	Induction: 0.15 mg/kg per day IV until remission Consolidation: continue 3–6 wk after inducing for up to 25 doses	Induction and consolidation in patients with acute promyelocytic leukemia (APL) who are refractory to or relapsed from standard therapy Actions: causes damage to fusion proteins and DNA failure, leading to cell death Special considerations: monitor for cardiac toxicity; do not use during pregnancy
asparaginase (<i>Elspar</i>)	1000–6000 units/m ² IM or IV and specific days as part of a specific combination regimen	As part of combination therapy to induce remission in children with acute lymphocytic leukemia Actions: an enzyme that hydrolyzes the amino acid asparagine, which is needed by malignant cells for protein synthesis; inhibits cell proliferation; most effective in G ₁ phase of the cell cycle Special considerations: can cause severe bone marrow depression, renal toxicity, and fatal hyperthermia; hypersensitivity reactions to this drug are common, and patients should be tested and desensitized, if necessary, before using the drug
azacitidine (<i>Vidaza</i>)	75 mg/m ² per day SC for 7 d q4wk	Treatment of patients with myelodysplastic syndrome Action: causes demethylation of DNA Special considerations: premedicate for nausea; monitor for bone marrow suppression; patient should avoid pregnancy and fathering children while on drug
bexarotene (<i>Targretin</i>)	300–400 mg/m ² PO daily	Treatment of cutaneous manifestations of cutaneous T cell lymphoma in patients refractory to at least one other systemic therapy Actions: binds and activates retinoid receptors Special considerations: risk of serious pancreatitis, photosensitivity
decitabine (<i>Dacogen</i>)	15 mg/m ² IV over 3 h q8h for 3 d; repeat q6wk for at least 4 cycles	Treatment of patients with myelodysplastic syndromes Action: affects DNA and inhibits DNA transfer Special considerations: premedicate with antiemetics; monitor for bone marrow suppression
hydroxyurea (<i>Hydrea</i>)	80 mg/kg PO every third day; 20–30 mg/kg PO daily for continual therapy	Inhibits enzymes essential for the synthesis of DNA, causing cell death Actions: treatment of melanoma, ovarian cancer, chronic myelocytic leukemia; in combination therapy for primary squamous cell cancers of the head and neck; also used in the treatment of sickle cell anemia Special considerations: can cause bone marrow depression, headache, rash, GI toxicity, and renal dysfunction; encourage patient to drink 10–12 glasses of water each day while taking this drug
irinotecan (<i>Camptosar</i>)	125 mg/m ² IV over 90 min, once a week for 4 wk, followed by 2 wk of rest; repeat every 6 wk	Treatment of metastatic colon or rectal cancer after treatment with fluorouracil (5-FU) or given with 5-FU Actions: disrupts DNA strands during DNA synthesis, causing cell death Special considerations: can cause severe bone marrow depression, which regulates dose of the drug; causes GI toxicity, dyspnea, and alopecia
nelarabine (<i>Arranon</i>)	1500 mg/m ² IV over 2 h on days 1, 3, and 5; repeat every 21 d	Treatment of T cell acute lymphoblastic leukemia and T cell lymphoblastic lymphoma when disease has progressed after standard therapy Actions: inhibits DNA synthesis and causes cell death Special considerations: watch for neurological toxicities, including neuropathies and demyelination disorders; bone marrow suppression is common

Drug Name	Dosage/Route	Usual Indications
pegaspargase (<i>Oncaspar</i>)	2500 International Units/m ² IM or IV q14d	<p>Treatment of acute lymphocytic leukemia in patients who are hypersensitive to asparaginase</p> <p>Actions: an enzyme that hydrolyzes the amino acid asparaginase, which is needed by malignant cells for protein synthesis; inhibits cell proliferation; most effective in G₁ phase of the cell cycle</p> <p>Special considerations: can cause potentially fatal hyperthermia, bone marrow depression, renal toxicity, and pancreatitis; monitor patient regularly, and arrange decreased dose as appropriate if toxic effects occur</p>
porfimer (<i>Photofrin</i>)	2 mg/kg IV over 3–5 min; may repeat in 40–50 h and again in 96–120 h	<p>Photosensitizing agent that is used with laser light to decrease tumor size in patients with obstructive esophageal cancers not responsive to laser treatment alone; transitional cell carcinoma in situ of urinary bladder; endothelial non–small cell lung cancer</p> <p>Actions: taken up by cells, causing radical reactions when cells are exposed to laser light, causing cell death</p> <p>Special considerations: has been associated with pleural effusion and fistula; associated with GI and cardiac toxicity; must be given in conjunction with scheduled laser treatment, with at least 30 d between treatments; protect patient from exposure to light with protective clothing for 30 d after treatment (sunscreens are not effective); avoid direct contact with the drug—protective clothing and goggles are suggested</p>
talc powder (<i>Sclerosol</i>)	4–8-g spray through open thoracotomy or during thoracoscopy	<p>Prevention of recurrence of malignant pleural effusion</p> <p>Actions: induces the inflammatory response, promoting adhesion of the pleura and preventing accumulation of fluid</p> <p>Special considerations: monitor for cardiac and respiratory effects; no actual antineoplastic actions</p>
topotecan (<i>Hycamtin</i>)	1.5 mg/m ² per day IV for 5 d; as part of a 21-d course; minimum of four courses	<p>Treatment of patients with metastatic ovarian cancer after failure of other agents</p> <p>Actions: damages DNA strand, causing cell death during cell division</p> <p>Special considerations: can cause severe bone marrow depression, which regulates the dose of the drug; total alopecia, GI toxicity, and CNS effects may also limit the use of the drug; analgesics may be helpful</p>
tretinoin (<i>Vesanoid</i>)	45 mg/m ² per day PO for 30 d	<p>Used to induce remission in APL; can cause severe respiratory and cardiac toxicity, including myocardial infarction and cardiac arrest</p> <p>Actions: promotes cell differentiation and the repopulation of the bone marrow with normal cells in patients with APL</p> <p>Special considerations: GI toxicity, pseudotumor cerebri (papilledema, headache, nausea, vomiting, visual changes), skin rash, and fragility may limit use in some patients; discontinue drug at first sign of toxic effects; use for induction of remission only—then other chemotherapeutic agents should be used</p>
vorinostat (<i>Zolinza</i>)	400 mg/d PO with food	<p>Treatment of cutaneous manifestations in patients with cutaneous T cell lymphoma</p> <p>Action: histone deacetylase inhibitor</p> <p>Special considerations: monitor for increased bleeding; excessive nausea and vomiting may occur; encourage fluid intake to prevent dehydration</p>

CHAPTER SUMMARY

- Cancers arise from a single abnormal cell that multiplies and grows.
- Cancers can manifest as diseases of the blood and lymph tissue or as growth of tumors arising from epithelial cells (carcinomas) or from mesenchymal cells and connective tissue (sarcomas).
- Cancer cells lose their normal function (anaplasia), develop characteristics that allow them to grow in an uninhibited way (autonomy), have the ability to travel to other sites in the body that are conducive to their growth (metastasis), and can stimulate the production of blood vessels to bring nutrients to the growing tumor (angiogenesis).
- Antineoplastic drugs affect both normal cells and cancer cells by disrupting cell function and division at various points in the cell cycle; new drugs are being developed, such as protein kinase inhibitors, to target cancer cell-specific functions.
- Cancer drugs are usually most effective against cells that multiply rapidly (i.e., proceed through the cell cycle quickly). These cells include most neoplasms, bone marrow cells, cells in the GI tract, and cells in the skin or hair follicles.
- The goal of cancer chemotherapy is to decrease the size of the neoplasm so that the human immune system can deal with it.
- Antineoplastic drugs are often given in combination so that they can affect cells in various stages of the cell cycle, including cells that are emerging from rest or moving to a phase of the cycle that is disrupted by these drugs.
- Adverse effects associated with antineoplastic therapy include effects caused by damage to the rapidly multiplying cells, such as bone marrow suppression, which may limit the drug use; GI toxicity, with nausea, vomiting, mouth sores, and diarrhea; and alopecia (hair loss).
- Chemotherapeutic agents should not be used during pregnancy or lactation because they may result in potentially serious adverse effects on the rapidly multiplying cells of the fetus and neonate.
- The newest drugs developed as antineoplastic agents target very specific enzyme systems or processes used by the cancer cells but not by healthy human cells. These drugs are not as toxic to the patient as traditional antineoplastic drugs.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-Rom in the front of the book.

MULTIPLE CHOICE

Select the best answer to the following.

- Some properties of neoplastic cells are the same as the properties of normal cells, including
 - anaplasia.
 - metastasis.
 - mitosis.
 - autonomy.
- Carcinomas are tumors that originate in
 - mesenchyme.
 - bone marrow.
 - striated muscle.
 - epithelial cells.
- The goal of traditional antineoplastic drug therapy is to
 - reduce the size of abnormal cell mass for immune system destruction.
 - eradicate all of the abnormal cells that have developed.
 - destroy all cells of the originating type.
 - stimulate the immune system to destroy the neoplastic cells.
- Cancer can be a difficult disease to treat because
 - cells no longer progress through the normal cell cycle.
 - cells can develop resistance to drug therapy.
 - cells remain dormant, emerging months to years later.
 - the exact cause of cancer is not known.
- Antineoplastic drugs destroy human cells. They are most likely to cause cell death among healthy cells that
 - have poor cell membranes.
 - are rapidly turning over.
 - are in dormant tissues.
 - are across the blood–brain barrier.
- Cancer treatment usually occurs in several different treatment phases. In assessing the appropriateness of another round of chemotherapy for a particular patient, the nurse would evaluate which of the following as most important?
 - hair loss
 - bone marrow function
 - anorexia
 - heart rate
- It is important to explain to women that chemotherapeutic agents should not be used during pregnancy because
 - the tendency to cause nausea and vomiting will be increased.
 - of potential serious adverse effects on the rapidly multiplying cells of the fetus.
 - bone marrow toxicity could alter hormone levels.
 - patients may be weakened by the drug regimen.
- Cancer drugs are given in combination and over a period of time because it is difficult to affect
 - slowly growing cells.
 - cells in the dormant phase of the cell cycle.
 - cells that multiply rapidly and go through the cell cycle quickly.
 - cells that have moved from their normal site in the body

MULTIPLE RESPONSE

Select all that apply.

- Which of the following points would be most important for the nurse to stress when developing a patient teaching plan for a patient receiving antineoplastic therapy?
 - The importance of keeping the head covered at extremes of temperature.
 - The need to use barrier contraceptives because of the risk of serious fetal effects.
 - The importance of avoiding exposure to infection because the ability to heal or to fight infection is impaired.
 - The importance of avoiding food if nausea or vomiting is a problem.
 - The importance of avoiding digging in the dirt without protective coverings because of the many pathogens that live in the dirt that could cause infection.
 - The importance of taking periodic rest periods during the day because you will feel tired when your red blood cell count falls.
- Hair loss, or alopecia, is an adverse effect of many antineoplastic agents. If a client is receiving a drug that usually causes alopecia, it is important that the nurse do which of the following?
 - Warn the patient that alopecia will occur.
 - Encourage the patient to arrange for an appropriate head covering at extremes of temperature.

- c. Advise the patient to lie with the legs elevated and head low to promote circulation and prevent hair loss.
- d. Encourage the patient to arrange for a wig or other head covering before the hair loss occurs.
- e. Advise the patient that people will stare and can be rude when hair loss occurs.
- f. Make arrangements for the patient to attend a support group before hair loss happens.

Introduction to the Immune Response and Inflammation

15

Learning Objectives

Upon completion of this chapter, you will be able to:

1. List four natural body defenses against infection.
2. Describe the cells associated with the body's fight against infection and their basic functions.
3. Outline the sequence of events in the inflammatory response.
4. Correlate the events in the inflammatory response with the clinical picture of inflammation.
5. Outline the sequence of events in an antibody-related immune reaction and correlate these events with the clinical presentation of such a reaction.

Glossary of Key Terms

antibodies: immunoglobulins; produced by B cell plasma cells in response to a specific protein; react with that protein to cause its destruction directly or through activation of the inflammatory response

antigen: foreign protein

arachidonic acid: released from injured cells to stimulate the inflammatory response through activation of various chemical substances

autoimmune disease: a disorder that occurs when the body responds to specific self-antigens to produce antibodies or cell-mediated responses against its own cells

B cells: lymphocytes programmed to recognize specific proteins; when activated, these cells cause the production of antibodies to react with that protein

calor: heat, one of the four cardinal signs of inflammation; caused by activation of the inflammatory response

chemotaxis: property of drawing neutrophils to an area

complement: series of cascading proteins that react with the antigen-antibody complex to destroy the protein or stimulate an inflammatory reaction

dolor: pain, one of the four cardinal signs of inflammation; caused by activation of the inflammatory response

Hageman factor: first factor activated when a blood vessel or cell is injured; starts the cascading reaction of the clotting factors, activates the conversion of plasminogen to plasmin to dissolve clots, and activates the kinin system responsible for activation of the inflammatory response

interferon: tissue hormone that is released in response to viral invasion; blocks viral replication

interleukins: chemicals released by white blood cells (WBCs) to communicate with other WBCs and to support the inflammatory and immune reactions

kinin system: system activated by Hageman factor as part of the inflammatory response; includes bradykinin

leukocytes: white blood cells; can be neutrophils, basophils, or eosinophils

lymphocytes: white blood cells with large, varied nuclei; can be T cells or B cells

macrophages: mature leukocytes that are capable of phagocytizing an antigen (foreign protein); also called monocytes or mononuclear phagocytes

major histocompatibility complex: the genetic identification code carried on a chromosome; produces several proteins or antigens that allow the body to recognize cells as being self-cells

mast cells: fixed basophils found in the respiratory and GI tracts and in the skin, which release chemical mediators of the inflammatory and immune responses when they are stimulated by local irritation

myelocytes: leukocyte-producing cells in the bone marrow that can develop into neutrophils, basophils, eosinophils, monocytes, or macrophages

phagocytes: neutrophils that are able to engulf and digest foreign material

phagocytosis: the process of engulfing and digesting foreign pyrogens

pyrogen: fever-causing substance

rubor: redness, one of the four cardinal signs of inflammation; caused by activation of the inflammatory response

T cells: lymphocytes programmed in the thymus gland to recognize self-cells; may be effector T cells, helper T cells, or suppressor T cells

tumor: swelling, one of the four cardinal signs of inflammation; caused by activation of the inflammatory response

The body has many defense systems in place to keep it intact and to protect it from external stressors. These stressors can include bacteria, viruses, other foreign pathogens or non-self-cells, trauma, and exposure to extremes of environmental conditions. The same defense systems that protect the body also help to repair it after cellular trauma or damage. Understanding the basic mechanisms involved in these defense systems helps to explain the actions of the drugs that affect the immune system and inflammation.

BODY DEFENSES

The body's defenses include barrier defenses, cellular defenses, the inflammatory response, and the immune response. Each of these defenses plays a major role in maintaining homeostasis and preventing disease.

Barrier Defenses

Certain anatomical barriers exist to prevent the entry of foreign pathogens and to serve as important lines of defense in protecting the body. These barriers include the skin and mucous membranes, gastric acid, and the major histocompatibility complex.

Skin

The skin is the first line of defense. The skin acts as a physical barrier to protect the internal tissues and organs of the body. Glands in the skin secrete chemicals that destroy or repel many pathogens. The top layer of the skin falls off daily, which makes it difficult for any pathogen to colonize on the skin. In addition, normal bacterial flora of the skin help to destroy many disease-causing pathogens.

Mucous Membranes

Mucous membranes line the areas of the body that are exposed to external influences but do not have the benefit of skin protection. These body areas include the respiratory tract, which is exposed to air; the gastrointestinal (GI) tract, which is exposed to anything ingested by mouth; and the genitourinary (GU) tract, which is exposed to many pathogens from the perineal and rectal area. Like the skin, the mucous membrane acts as a physical barrier to invasion. It also secretes a sticky mucus capable of trapping invaders and inactivating them for later destruction and removal by the body.

In the conducting airways of the respiratory tract, the mucous membrane is lined with tiny, hair-like processes called *cilia*. The cilia sweep any captured pathogens or foreign materials upward toward the mouth, where they will be swallowed. The cilia also can move the captured material to an area causing irritation, which leads to removal by coughing or sneezing.

In the GI tract, the mucous membrane serves as a protective coating, preventing erosion of GI cells by the acidic environment of the stomach, the digestive enzymes of the small intestine, and the waste products that accumulate in the

large intestine. The mucous membrane also secretes mucus that serves as a lubricant throughout the GI tract to facilitate movement of the food bolus and of waste products. The mucous membrane acts as a thick barrier to prevent foreign pathogens from penetrating the GI tract and entering the body.

In the GU tract, the mucous membrane provides direct protection against injury and trauma and traps any pathogens in the area for destruction by the body.

Gastric Acid

The stomach secretes acid in response to many stimuli. The acidity of the stomach not only aids digestion, but also destroys many would-be pathogens that are either ingested or swallowed after removal from the respiratory tract.

Major Histocompatibility Complex

The body's last barrier of defense is the ability to distinguish between self-cells and foreign cells. All of the cells and tissues of each person are marked for identification as part of that individual's genetic code. No two people have exactly the same code. In humans, the genetic identification code is carried on a chromosome and is called the **major histocompatibility complex** (MHC). The MHC produces several proteins called histocompatibility antigens, or human leukocyte antigens (HLAs). These **antigens** (proteins) are located on the cell membrane and allow the body to recognize cells as being self-cells. Cells that do not have these proteins are identified as foreign and are targeted for destruction by the body.

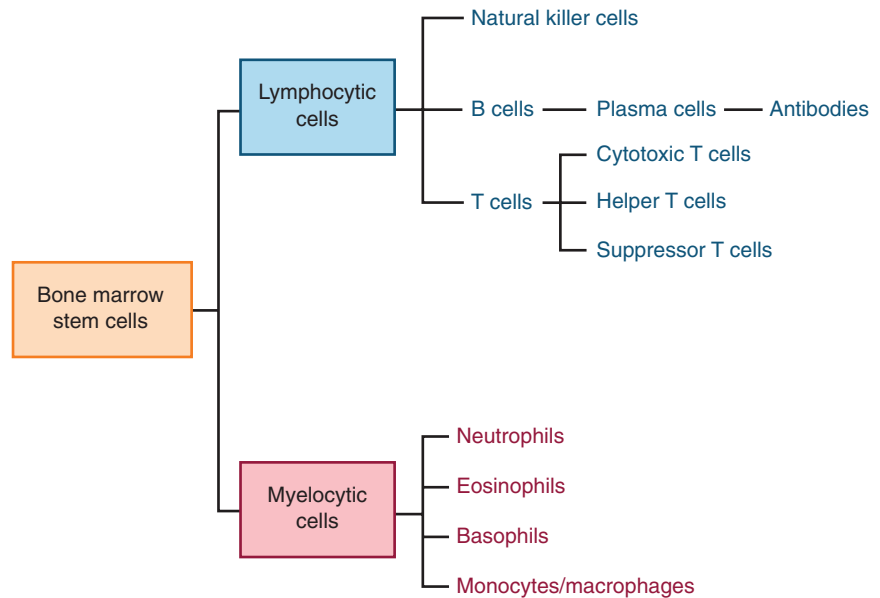

Cellular Defenses

Any foreign pathogen that manages to get past the barrier defenses will encounter the human inflammatory and immune systems, or mononuclear phagocyte system (MPS). Previously called the reticuloendothelial system, the MPS is composed primarily of leukocytes, lymphocytes, lymphoid tissues, and numerous chemical mediators.

Stem cells in the bone marrow produce two types of white blood cells or **leukocytes**: the lymphocytes and the myelocytes. The **lymphocytes** are the key components of the immune system and consist of T cells, B cells, and natural killer cells (see later discussion of the immune response). The **myelocytes** can develop into a number of different cell types that are important in both the basic inflammatory response and the immune response. Myelocytes include neutrophils, basophils, eosinophils, and monocytes, or macrophages (Figure 15.1).

Neutrophils

Neutrophils are polymorphonuclear leukocytes that are capable of moving outside of the blood stream (diapedesis) and engulfing and digesting foreign material (**phagocytosis**). When the body is injured or invaded by a pathogen, neutrophils are rapidly produced and move to the site of the insult to attack the foreign substance. Because neutrophils are able to engulf and digest foreign material, they are called **phagocytes**.

● **FIGURE 15.1** Types of white blood cells, or leukocytes, produced by the body.

Phagocytes are able to identify non–self-cells by use of the MHC, and they can engulf these cells or mark them for destruction by cytotoxic T lymphocytes.

Basophils

Basophils are myelocytic leukocytes that are not capable of phagocytosis. They contain chemical substances or mediators that are important for initiating and maintaining an immune or inflammatory response. These substances include histamine, heparin, and other chemicals used in the inflammatory response.

Basophils that are fixed and do not circulate are called **mast cells**. They are found in the respiratory and GI tracts and in the skin. They release many of the chemical mediators of the inflammatory and immune responses when they are stimulated by local irritation.

Eosinophils

Eosinophils are circulating myelocytic leukocytes whose exact function is not understood. They are often found at the site of allergic reactions and may be responsible for removing the proteins and active components of the immune reaction from the site of an allergic response.

Monocytes/Macrophages

Monocytes or mononuclear phagocytes are also called **macrophages**. They are mature leukocytes that are capable of phagocytizing an antigen. Macrophages help to remove foreign material from the body, including pathogens, debris from dead cells, and necrotic tissue from injury sites, so that the body can heal. They also can process antigens and present them to active lymphocytes for destruction.

Macrophages can circulate in the blood stream or they can be fixed in specific tissues, such as the Kupffer cells in the liver, the cells in the alveoli of the respiratory tract, and the

microglia in the central nervous system (CNS), GI, circulatory, and lymph tissues. As active phagocytes, macrophages release chemicals that are necessary to elicit a strong inflammatory reaction. These cells also respond to chemical mediators released by other cells that are active in the inflammatory and immune responses to increase the intensity of a response and to facilitate the body's reaction.

Lymphoid Tissues

Lymphoid tissues that play an important part in the cellular defense system include the lymph nodes, spleen, thymus gland (a bipolar gland located in the middle of the chest, which becomes smaller with age), bone marrow, and lymphoid tissue throughout the respiratory and GI tracts. The bone marrow and the thymus gland are important for creation of the cellular components of the MPS. The bone marrow has a role in the differentiation of these cellular components. The thymus gland is responsible for the final differentiation of the T cells and for regulating the actions of the immune system. The lymph nodes and lymphoid tissue store concentrated populations of neutrophils, basophils, eosinophils, and lymphocytes in areas of that body that facilitate their surveillance for and destruction of foreign proteins. Other cells travel through the cardiovascular and lymph systems to search for foreign proteins or to reach the sites of injury or pathogen invasion.

KEY POINTS

- ◆ The body has several defense mechanisms in place to protect it from injury or foreign invasion.
- ◆ Barrier defenses include the skin, mucous membranes, normal flora, and gastric acid.
- ◆ Cellular defenses include blood cells such as the lymphocytes (T and B cells) and the myelocytes (neutrophils, eosinophils, basophils, and macrophages).

The Inflammatory Response

The inflammatory response is the local reaction of the body to invasion or injury. Any insult to the body that injures cells or tissues sets off a series of events and chemical reactions.

Cell injury causes the activation of a chemical in the plasma called factor XII or **Hageman factor**. Hageman factor is responsible for activating at least three systems in the body: the **kinin system**, which is discussed here; the clotting cascade, which initiates blood clotting; and the plasminogen system, which initiates the dissolution of blood clots. The last two systems are discussed in Part VIII, Drugs Acting on the Cardiovascular System.

Kinin System

Hageman factor activates kallikrein, a substance found in the local tissues, which causes the precursor substance kininogen to be converted to bradykinin and other kinins. Bradykinin was the first kinin identified and remains the one that is best understood.

Bradykinin causes local vasodilation, which brings more blood to the injured area and allows white blood cells to escape into the tissues. It also stimulates nerve endings to cause pain, which alerts the body to the injury.

Bradykinin also causes the release of **arachidonic acid** from the cell membrane. Arachidonic acid causes the release of other substances called autacoids. These substances act like local hormones—they are released from cells, cause an effect in the immediate area, and then are broken down. These autacoids include the following:

- Prostaglandins, some of which augment the inflammatory reaction and some of which block it.
- Leukotrienes, some of which can cause vasodilation and increased capillary permeability, and some of which can block the reactions.
- Thromboxanes, which cause local vasoconstriction and facilitate platelet aggregation and blood coagulation.

Histamine Release

While this series of Hageman factor–initiated events is proceeding, another locally mediated response is occurring. Injury to a cell membrane causes the local release of histamine. Histamine causes vasodilation, which brings more blood and blood components to the area. It also alters capillary permeability, making it easier for neutrophils and blood chemicals to leave the bloodstream and enter the injured area. In addition, histamine stimulates pain perception. The vasodilation and changes in capillary permeability bring neutrophils to the area to engulf and get rid of the invader or to remove the cell that has been injured.

Chemotaxis

Some leukotrienes activated by arachidonic acid have a property called **chemotaxis**, which is the ability to attract neutrophils and to stimulate them and other macrophages in the area to be very aggressive. Activation of the neutrophils and

release of other chemicals into the area can lead to cell injury and destruction. When destroyed, the cell releases various lysosomal enzymes that dissolve or destroy cell membranes and cellular proteins. The lysosomal enzymes are an important part of biological recycling and the breakdown of once-living tissues after death. In the case of an inflammatory reaction, they can cause local cellular breakdown and further inflammation, which can develop into a vicious cycle leading to cell death.

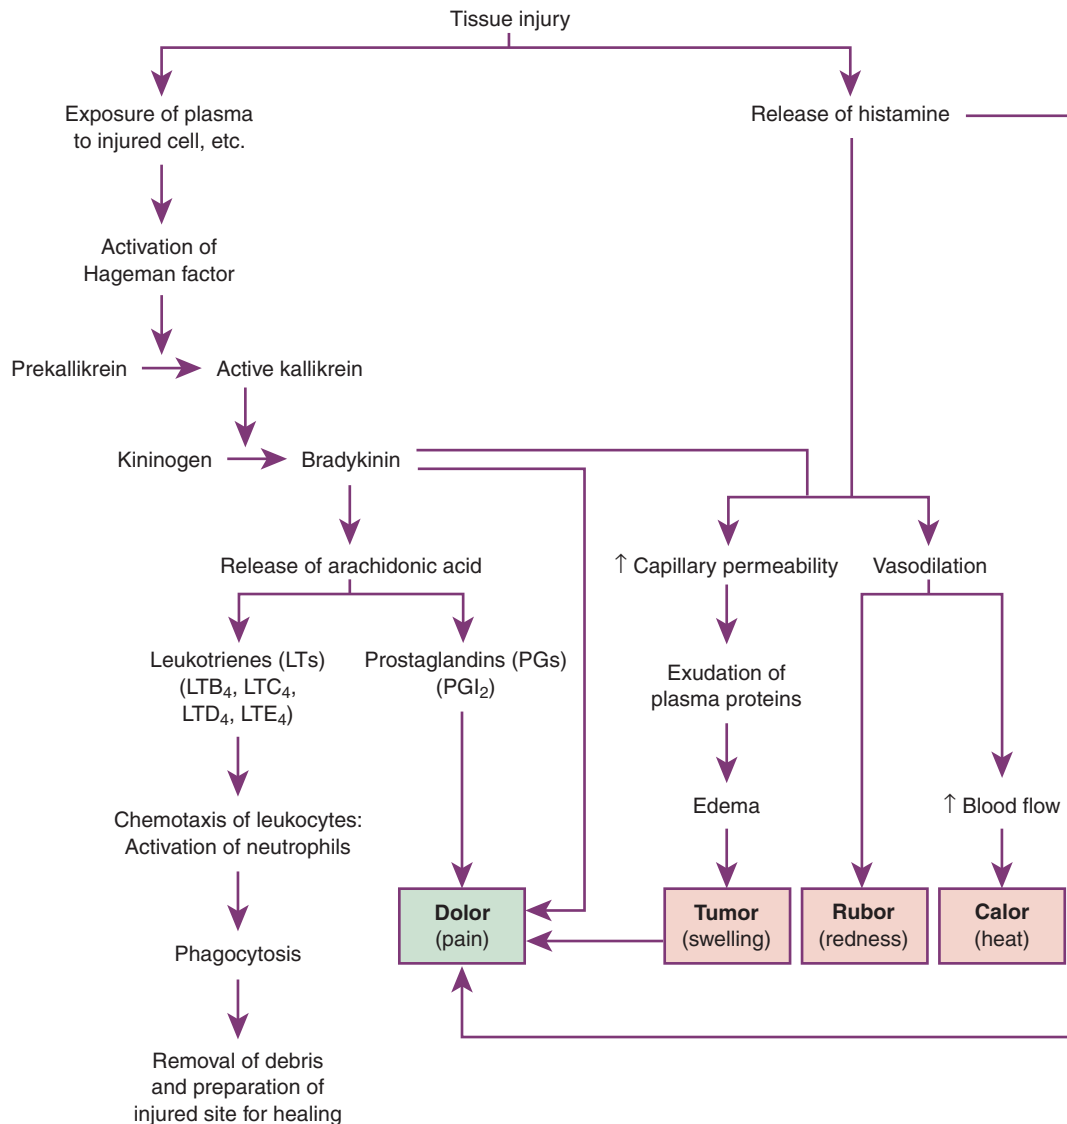

Many inflammatory diseases, such as rheumatoid arthritis and systemic lupus erythematosus, are examples of these uncontrolled cycles. The prostaglandins and leukotrienes are important to the inflammatory response because they act to moderate the reaction, thus preventing this destructive cycle from happening on a regular basis. Many of the drugs used to affect the inflammatory and immune systems modify or interfere with these inflammatory reactions.

Clinical Presentation

Activation of the inflammatory response produces a characteristic clinical picture. The Latin words *calor*, *tumor*, *rubor*, and *dolor* describe a typical inflammatory reaction. **Calor**, or heat, occurs because of the increased blood flow to the area. **Tumor**, or swelling, occurs because of the fluid that leaks into the tissues as a result of the change in capillary permeability. **Rubor**, or redness, is related again to the increase in blood flow caused by the vasodilation. **Dolor**, or pain, comes from the activation of pain fibers by histamine and the kinin system. These signs and symptoms occur any time a cell is injured (Figure 15.2). For example, if you scratch the top of your hand and wait for about a minute, the direct line of the scratch will be red (*rubor*) and raised (*tumor*). If you feel it gently, it will be warmer than the surrounding area (*calor*). You should also experience a burning sensation or discomfort at the site of the scratch (*dolor*). Invasion of the lungs by bacteria can produce pneumonia. If the lungs could be examined closely, they would also show the signs and symptoms of inflammation. They would be red from increased blood flow; fluid would start to leak out of the capillaries (often this can be heard as rales); the patient would complain of chest discomfort; and the increased blood flow to the area of infection would make it appear hot or very active on a scan. No matter what the cause of the insult, the body's local response is the same.

Once the inflammatory response is under way and neutrophils become active, engulfing and digesting injured cells or the invader, they release a chemical that is a natural **pyrogen**, or fever-causing substance. This pyrogen resets specific neurons in the hypothalamus to maintain a higher body temperature, seen clinically as a fever. The higher temperature acts as a catalyst to many of the body's chemical reactions, making the inflammatory and immune responses more effective. Treating fevers remains a controversial subject because lowering a fever decreases the efficiency of the immune and inflammatory responses.

The leukotrienes (autocoids activated through the kinin system) affect the brain to induce slow-wave sleep, which is believed to be an important energy conservation measure for

● **FIGURE 15.2** The inflammatory response in relation to the four cardinal signs of inflammation.

fighting the invader. They also cause myalgia and arthralgia (muscle and joint pain)—common signs and symptoms of various inflammatory diseases—which also cause reduced activity and save energy. All of these chemical responses make up the total clinical picture of an inflammatory reaction.

The Immune Response

More specific invasion can stimulate a more specific response through the immune system. As mentioned previously, stem cells in the bone marrow produce lymphocytes that can develop into T lymphocytes (so named because they migrate from the bone marrow to the thymus gland for activation and maturation) or B lymphocytes (so named because they are activated in the bursa of Fabricius in the chicken, although the specific point of activation in humans has not been identified). Other identified lymphocytes include natural killer cells and lymphokine-activated killer cells. Both of these cells are

aggressive against neoplastic or cancer cells and promote rapid cellular death. They do not seem to be programmed for specific identification of cells.

Research in the area of lymphocyte identification is relatively new and continues to grow. There may be other lymphocytes with particular roles in the immune response that have not yet been identified.

T Cells

T cells are programmed in the thymus gland and provide what is called cell-mediated immunity (Figure 15.3). T cells develop into at least three different cell types.

1. *Effector or cytotoxic T cells* are found throughout the body. These T cells are aggressive against non-self-cells, releasing cytokines, or chemicals, that can either directly destroy a foreign cell or mark it for aggressive destruction by phagocytes in the area via an inflammatory response.

● **FIGURE 15.3** Cell-mediated immune response. Cytotoxic T cells are activated when recognizing a non-self-cell. Memory T cells are formed. Cytokines are released to destroy the non-self-cell.

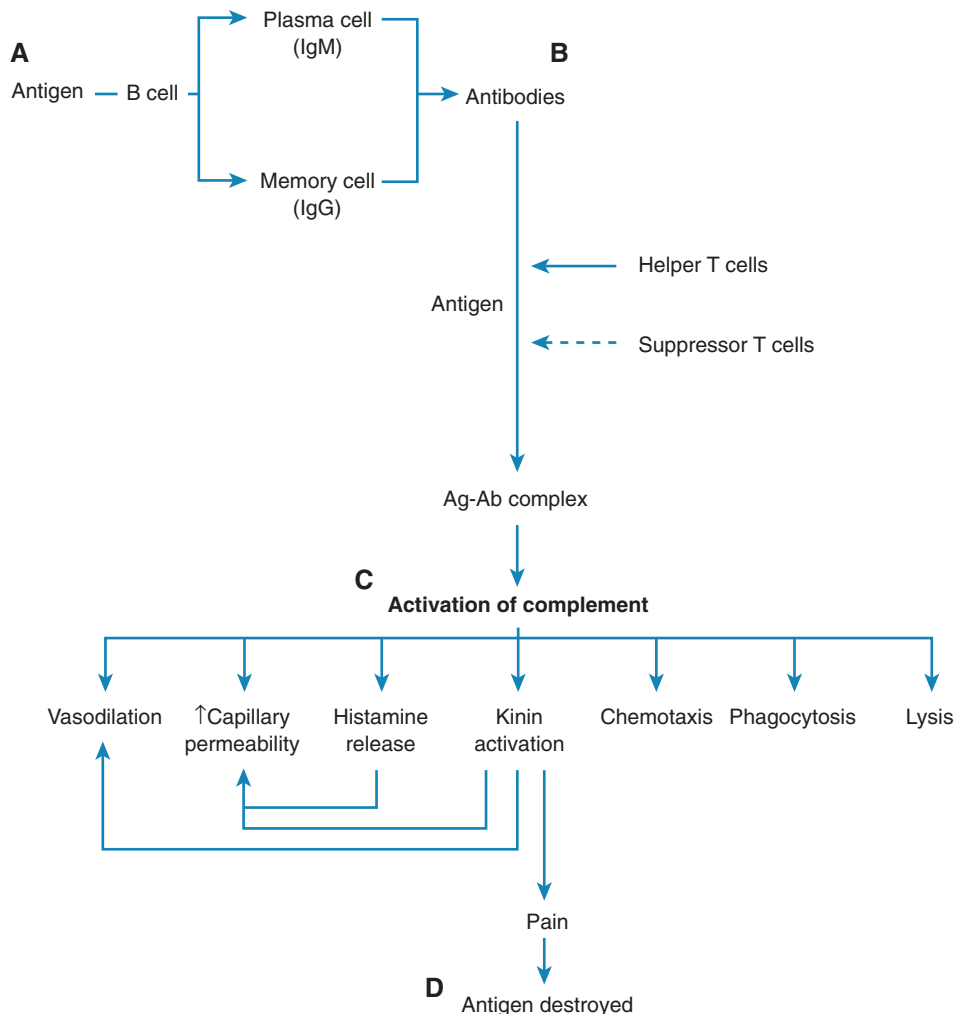

These non-self-cells have membrane-identifying antigens that are different from those established by the person's MHC. They may be the body's own cells that have been invaded by a virus, which changes the cell membrane; neoplastic cancer cells; or transplanted foreign cells.

2. *Helper T cells* respond to the chemical indicators of immune activity and stimulate other lymphocytes, including B cells, to be more aggressive and responsive.
3. *Suppressor T cells* respond to rising levels of chemicals associated with an immune response to suppress or slow the reaction. The balance of the helper and suppressor T cells allows for a rapid response to body injury or invasion by pathogens, which may destroy foreign antigens

immediately and then be followed by a slowing reaction if the invasion continues. This slowing allows the body to conserve energy and the components of the immune and inflammatory reaction necessary for basic protection and to prevent cellular destruction from a continued inflammatory reaction.

B Cells

B cells are found throughout the MPS in groups called clones. B cells are programmed to identify specific proteins, or antigens. They provide what is called humoral immunity (Figure 15.4). When a B cell reacts with its specific antigen, it changes to become a plasma cell. Plasma cells produce **antibodies**, or

● **FIGURE 15.4** The humoral immune response. **A.** A B cell reacts with a specific antigen to form plasma cells and memory cells, which produce antibodies. **B.** Circulating antibodies react with the antigen to form an antigen-antibody (Ag-Ab) complex. This process is facilitated by helper T cells and suppressed by suppressor T cells. **C.** The antigen-antibody complex activates circulating complement, which facilitates aggressive inflammatory reactions. **D.** This process destroys the antigen.

immunoglobulins, which circulate in the body and react with this specific antigen when it is encountered. This is a direct chemical reaction. When the antigen and antibody react, they form an antigen–antibody complex. This new structure reveals a new receptor site on the antibody that activates a series of plasma proteins in the body called complement proteins.

Complement Proteins

Complement Proteins react in a cascade fashion to form a ring around the antigen–antibody complex. The complement can destroy the antigen by altering the membrane, allowing an osmotic inflow of fluid that causes the cell to burst. They also induce chemotaxis (attraction of phagocytic cells to the area), increase the activity of phagocytes, and release histamine. Histamine release causes vasodilation, which increases blood flow to the area and brings in all of the components of the inflammatory reaction to destroy the antigen. The antigen–antibody–complement complex precipitates out of the circulatory system and deposits in various sites, including end arteries in joints, the eyes, the kidneys, and the skin. The signs and symptoms of the inflammatory response can be seen where the antigen–antibody complexes are deposited. Chickenpox eruptions are an example of an antigen–antibody–complement complex that deposits in the skin and causes a local inflammatory reaction.

Antibody Formation

The initial formation of antibodies, or primary response, takes several days. Once activated, the B cells form memory cells that will produce antibodies for immediate release in the future if the antigen is encountered. The antibodies are released in the form of immunoglobulins. Five different types of immunoglobulins have been identified:

- The first immunoglobulin released is M (IgM), which contains the antibodies produced at the first exposure to the antigen.
- IgG, another form of immunoglobulin, contains antibodies made by the memory cells that circulate and enter the tissue; most of the immunoglobulin found in the serum is IgG.
- IgA is found in tears, saliva, sweat, mucus, and bile. It is secreted by plasma cells in the GI and respiratory tracts and in epithelial cells. These antibodies react with specific pathogens that are encountered in exposed areas of the body.
- IgE is present in small amounts and seems to be related to allergic responses and to the activation of mast cells.
- IgD is another identified immunoglobulin whose role has not been determined.

This process of antibody formation, called acquired or active immunity, is a lifelong reaction. For example, a person exposed to chickenpox will have a mild respiratory reaction when the virus (varicella) first enters the respiratory tract. There will then be a 2- to 3-week incubation period as the body is forming IgM antibodies and preparing to attack any chickenpox virus that appears. The chickenpox virus enters a cell and multiplies. The cell eventually ruptures and ejects

more viruses into the system. When this happens, the body responds with the immediate release of antibodies, and a full-scale antigen–antibody response is seen throughout the body. Fever, myalgia, arthralgia, and skin lesions are all part of the immune response to the virus. Once all of the invading chickenpox viruses have been destroyed or have entered the CNS to safely hibernate away from the antibodies, the clinical signs and symptoms resolve. (Varicella can enter the CNS and stay dormant for many years. The antibodies are not able to cross into the CNS, and the virus remains unaffected while it stays there.)

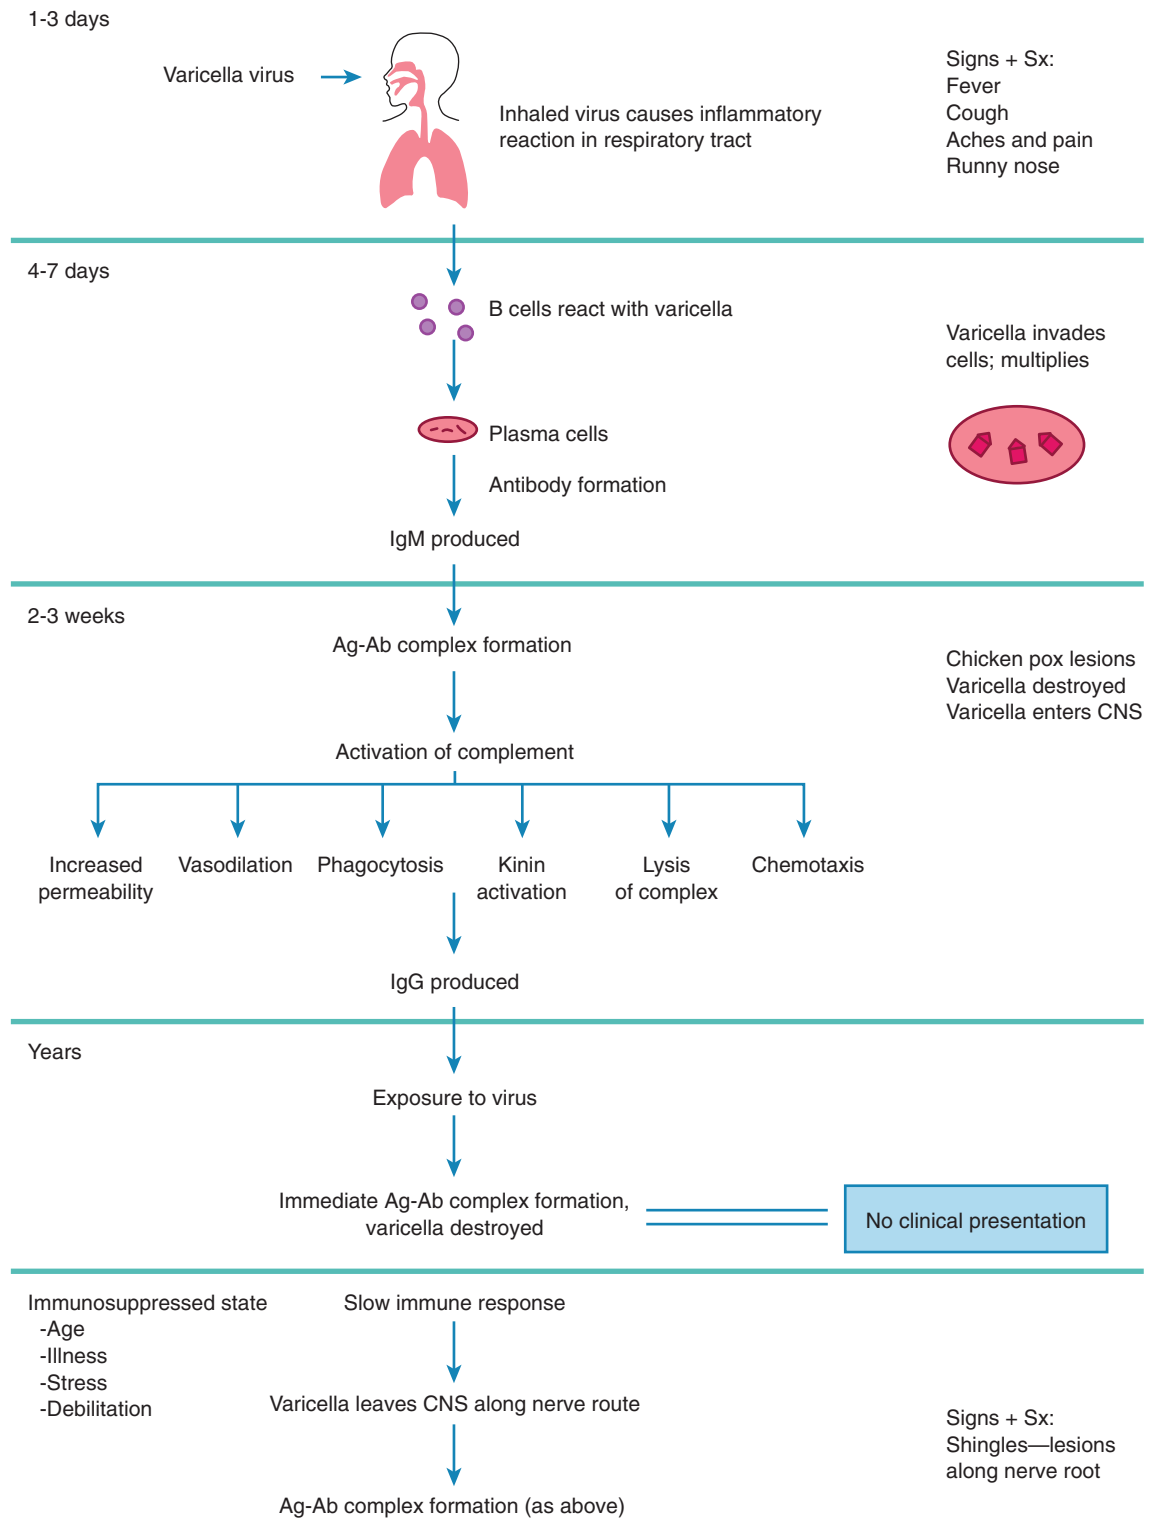

The B memory cells will continue to make a supply of immunoglobulin, IgG, for use on future exposure to the chickenpox virus. That exposure usually does not evolve into a clinical case because the viruses are destroyed immediately on entering the body and do not have a chance to multiply. Older patients with weakened immune systems, people who are immunosuppressed, and individuals who have depleted their immune system fighting an infection are at risk for development of shingles if they had chickenpox earlier in their lives. The dormant virus, which has aged and changed somewhat, is able to leave the CNS along a nerve root because the immunosuppressed body is slow to respond. The antibodies do eventually respond to the varicella, and the signs and symptoms of shingles occur as the virus is attacked along the nerve root. Figure 15.5 outlines this entire process.

B clones cluster in areas where they are most likely to encounter the specific antigen that they have been programmed to recognize. For example, pathogens or antigens that are introduced into the body via the respiratory tract will meet up with the B cells in the tonsils and upper respiratory tract; antigens that enter the body through the GI tract will meet their B cells situated in the esophagus and GI tract. Theorists believe that the B cells are programmed genetically and are formed by the time of birth. Clones of B cells contain similar cells. The introduction of an antigen to which there are no preprogrammed B cells could result in widespread disease because the body would have no way of responding. A major concern about space travel has always been the introduction of a completely new antigen to Earth; for this reason, long periods of decontamination have been used after rocks or debris are brought back to Earth. Germ warfare research is ongoing in some countries to develop an antigen that has not been seen before and to which people would have no response.

Other Mediators

Several other factors also play an important role in the immune reaction. **Interferons** are chemicals that are secreted by cells that have been invaded by viruses and possibly by other stimuli. The interferons prevent viral replication and also suppress malignant cell replication and tumor growth.

Interleukins are chemicals secreted by active leukocytes to influence other leukocytes. Interleukin 1 (IL-1) stimulates T and B cells to initiate an immune response. IL-2 is released from active T cells to stimulate the production of more T cells and to increase the activity of B cells, cytotoxic cells, and

● **FIGURE 15.5** Process of response to varicella exposure in humans. Ag-Ab, antigen–antibody complex; Ig, immunoglobulin.

natural killer cells. Interleukins also cause fever, arthralgia, myalgia, and slow-wave sleep induction—all things that help the body to conserve energy for use in fighting off the invader. Several other factors released by lymphocytes and basophils have been identified. These include interleukins such as B-cell growth factor, macrophage-activating factor, macrophage-

inhibiting factor, platelet-activating factor, eosinophil chemotactic factor, and neutrophil chemotactic factor.

The thymus gland also releases a number of hormones that aid in the maturation of T cells and that circulate in the body to stimulate and communicate with T cells. Thymosin, a thymus hormone that has been replicated, is important in

the maturation of T cells and cell-mediated immunity. Research is ongoing on the use of thymosin in certain leukemias and melanomas to stimulate the immune response.

Tumor necrosis factor (TNF), a cytokine, is a chemical released by macrophages that inhibits tumor growth and can actually cause tumor regression. It also works with other chemicals to make the inflammatory and immune responses more aggressive and efficient. Research is ongoing to determine the therapeutic effectiveness of TNF. TNF receptor sites are now available for injection into patients with acute rheumatoid arthritis. These receptor sites react with TNF released by the macrophages in this inflammatory disease. All of these chemicals act as communication factors within the immune system, allowing the coordination of the immune response.

Interrelationship of the Immune and Inflammatory Responses

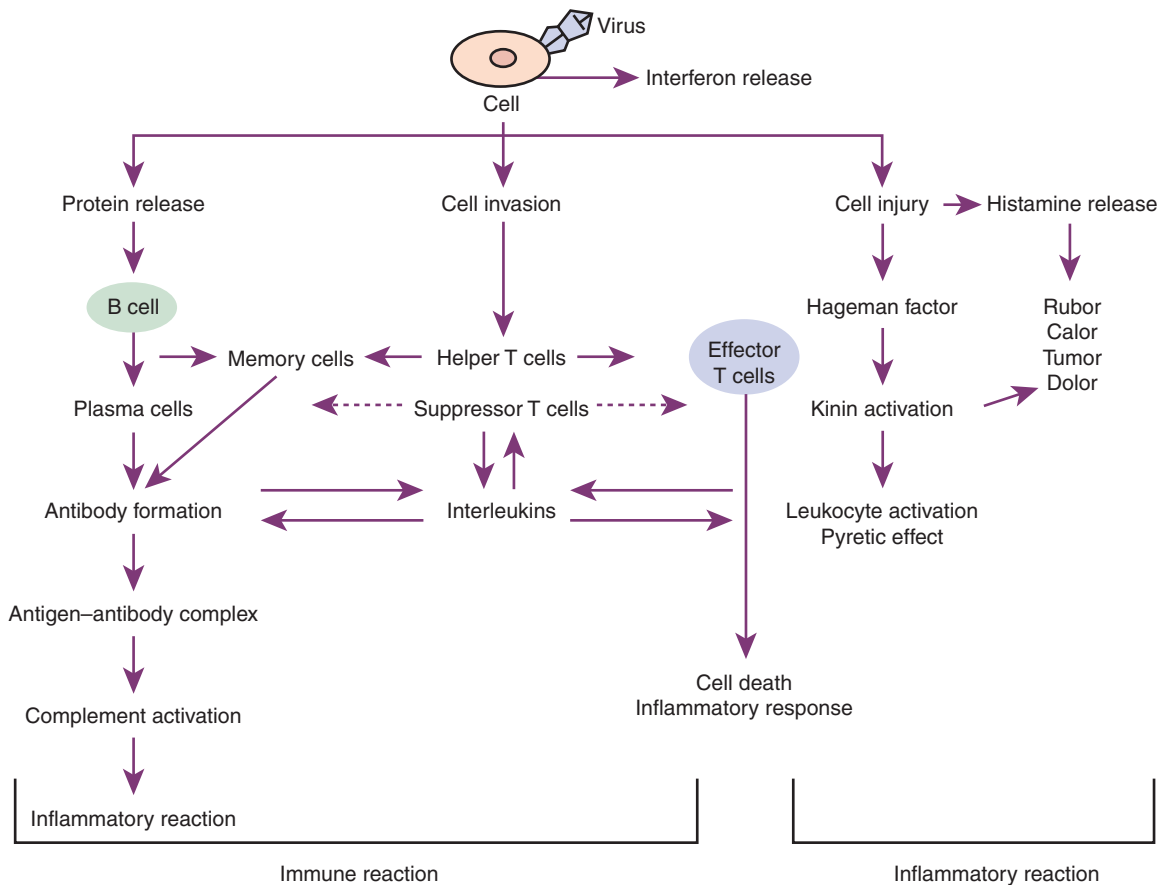

The immune and inflammatory responses work together to protect the body and to maintain a level of homeostasis within the body. Helper T cells stimulate the activity of B cells and effector T cells. Suppressor T cells monitor the chemical activity in the body and act to suppress B-cell and T-cell activity when the foreign antigen is under control. Both B cells and T cells ultimately depend on an effective inflammatory reaction to achieve the end goal of destruction of the foreign protein or cell (Figure 15.6).

KEY POINTS

- ▶ The response to the inflammatory stimuli involves local vasodilation, increased capillary permeability, and the stimulation of pain fibers. These reactions alert the person to the injury and bring an increased blood flow to the area.
- ▶ The immune response provides a specific reaction to foreign cells or proteins.
- ▶ T cells can be cytotoxic, destroying non-self-cells; helper, augmenting an immune reaction; or suppressor, dampening the immune response to save energy and prevent cell damage.
- ▶ B cells produce antibodies in response to exposure to specific antigens or proteins. Antibodies react with this antigen to produce an antigen-antibody complex that activates complement and will result in destruction of the antigen.
- ▶ Other mediators that affect the immune and inflammatory responses include interferons, tissue necrosis factor, and interleukins.
- ▶ The immune and inflammatory responses work together to protect the body from injury or foreign pathogens.

PATHOPHYSIOLOGY INVOLVING THE IMMUNE SYSTEM

Several conditions can arise that cause problems involving the immune system. These conditions, many of which are treated

● FIGURE 15.6 Interrelationship of immune and inflammatory reactions.

by drugs that stimulate or suppress the immune system, include neoplasm, viral invasion, autoimmune disease, and transplant rejection.

Neoplasms

Neoplasms occur when mutant cells escape the normal surveillance of the immune system and begin to grow and multiply. This can happen in many ways. For example, aging causes a decreased efficiency of the immune system, allowing some cells to escape detection. Location of the mutant cells can make it difficult for lymphocytes to get to an area to respond. Mutant cells in breast tissue, for example, are not well perfused with blood and may escape detection until they are quite abundant. Sometimes cells are able to avoid detection by the T cells until the growing mass of cells is so large that the immune system cannot deal with it. Tumors also can produce blocking antibodies that cover the antigen-receptor sites on the tumor and prevent recognition by cytotoxic T cells. In addition, a weakly antigenic tumor may develop; such a tumor elicits a mild response from the immune system and somehow tricks the T cells into allowing it to survive.

Viral Invasion of Cells

Viruses are parasites that can survive only by invading a host cell that provides the nourishment necessary for viral replication. Invasion of a cell alters the cell membrane and the antigenic presentation of the cell (the MHC). This change can activate cellular immunity, or it can be so subtle that the immune system's response to the cell is mild or absent. In some cases, the response activates a cellular immune reaction to normal cells similar to the one that was invaded. This is one theory for the development of autoimmune disease.

Autoimmune Disease

Autoimmune disease occurs when the body responds to specific self-antigens to produce antibodies or cell-mediated immune responses against its own cells. The cause of autoimmune disease is not known, but theories speculate that (1) it could be a result of response to a cell that was invaded by a virus, leading to antibody production to similar cells; (2) production of autoantibodies is a normal process that goes on all the time, but in a state of immunosuppression the suppressor T cells do not suppress autoantibody production; or (3) there is a genetic predisposition to develop autoantibodies.

Transplant Rejection

With the growing field of organ transplantation, more is being learned about the reaction to foreign cells that are introduced into the body. Typically, self-transplantation, or autotransplantation, results in no immune response. All other transplants produce an immune reaction. Therefore, matching a donor's HLA markers as closely as possible to those of the recipient for histocompatibility is essential. The more closely the foreign

cells can be matched, the less aggressive will the immune reaction be to the donated tissue.

CHAPTER SUMMARY

- The body has several defense mechanisms in place to protect it from injury or foreign invasion: the skin, mucous membranes, normal flora, gastric acid, and the inflammatory and immune responses.
- The inflammatory response is a general response to any cell injury and involves activation of Hageman factor to stimulate the kinin system and release of histamine from injured cells to generate local inflammatory responses.
- The clinical presentation of an inflammatory reaction is heat (calor), redness (rubor), swelling (tumor), and pain (dolor).
- The inflammatory response is a nonspecific reaction to any cellular injury and involves the activation of various chemicals and neutrophil activity. The immune response is specific to an antigen or protein that has entered the body and involves B cells, antibodies, and T cells.
- Several types of T cells exist: effector or cytotoxic T cells, helper T cells, and suppressor T cells. Effector or cytotoxic T cells immediately destroy foreign cells. Helper T cells stimulate the immune and inflammatory reactions. Suppressor T cells dampen the immune and inflammatory responses to conserve energy and prevent cellular damage.
- B cells are programmed to recognize specific proteins or foreign antigens. Once in contact with that protein, the B cell produces antibodies (immunoglobulins) that react directly with the protein.
- Reaction of an antibody with the specific receptor site on the protein activates the complement cascade of proteins and lyses the associated protein or precipitates an aggressive inflammatory reaction around it.
- Other chemicals are involved in communication among parts of the immune system and in local response to invasion. Any of these chemicals has the potential to alter the immune response.
- The T cells, B cells, and inflammatory reaction work together to protect the body from invasion, limit the response to that invasion, and return the body to a state of homeostasis.
- Patient problems that occur within the immune system include the development of neoplasms, viral invasions of cells that trigger immune responses, autoimmune diseases, and rejections of transplanted organs.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-Rom accompanying this book.

MULTIPLE CHOICE

Select the best answer to the following.

1. Antibodies
 - a. are carbohydrates.
 - b. are secreted by activated T cells.
 - c. are not found in circulating gamma globulins.
 - d. are effective only against specific antigens.
2. B and T cells are similar in that they both
 - a. secrete antibodies.
 - b. play important roles in the immune response.
 - c. are activated in the thymus gland.
 - d. release cytotoxins to destroy cells.
3. Which of the following is not a cytokine?
 - a. Interleukin 2
 - b. Antibody
 - c. Tumor necrosis factor
 - d. Interferon
4. As part of the nonspecific defense against infection,
 - a. blood flow and vascular permeability to proteins increase throughout the circulatory system.
 - b. particles in the respiratory tract are engulfed by phagocytes.
 - c. B cells are released from the bone marrow.
 - d. neutrophils release lysosomes, heparin, and kininogen into the extracellular fluid.
5. B cells respond to an initial antigen challenge by
 - a. reducing in size.
 - b. immediately producing antigen-specific antibodies.
 - c. producing a large number of cells that are unlike the original B cell.
 - d. producing new cells that become plasma cells and memory cells.
6. Treating fevers remains a controversial subject because
 - a. fevers make people feel ill.
 - b. higher temperatures act as catalysts to many of the body's chemical reactions.
 - c. higher temperatures can suppress the body's normal metabolism.
 - d. higher temperatures can alter the body's hormone levels, particularly that of progesterone.
7. After describing the function of T cells, the nurse would identify the need for additional teaching if the patient stated that T cells become which of the following?
 - a. Cytotoxic T cells
 - b. Helper T cells
 - c. Suppressor T cells
 - d. Antibody-secreting T cells
8. Interleukins are
 - a. chemicals released when a virus enters a cell.
 - b. chemicals secreted by activated leukocytes.
 - c. part of the kinin system.
 - d. activated by arachidonic acid.

MULTIPLE RESPONSE

Select all that apply.

1. Which of the following statements could be used to describe a neutrophil?
 - a. They possess the property of phagocytosis.
 - b. When activated, they release a pyrogen that causes fever.
 - c. When the body is injured, they are produced rapidly and in large numbers.
 - d. They are not capable of movement outside the circulatory system.
 - e. They are most often seen in response to an allergic reaction.
 - f. They float around in the blood and release chemicals in response to injury.
2. The inflammatory response is activated whenever cell injury occurs. An inflammatory response would involve which of the following activities?
 - a. Activation of Hageman factor.
 - b. Vasodilation in the area of the injury.
 - c. Generalized edema and tumor development.
 - d. Changes in capillary permeability to allow proteins to leak out of the capillaries.
 - e. Activation of complement.
 - f. Production of interferon.

Anti-Inflammatory, Antiarthritis, and Related Agents

16

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Describe the sites of action of the various anti-inflammatory agents.
2. Describe the therapeutic actions, indications, pharmacokinetics, contraindications, most common adverse reactions, and important drug–drug interactions associated with each class of anti-inflammatory agents.
3. Discuss the use of anti-inflammatory drugs across the lifespan.
4. Compare and contrast the prototype drugs for each class of anti-inflammatory drugs with the other drugs in that class.
5. Outline the nursing considerations and teaching needs for patients receiving each class of anti-inflammatory agents.

Glossary of Key Terms

analgesic: compounds with pain-blocking properties, capable of producing analgesia

anti-inflammatory agents: drugs that block the effects of the inflammatory response

antipyretic: blocking fever, often by direct effects on the thermoregulatory center in the hypothalamus or by blockade of prostaglandin mediators

chrysotherapy: treatment with gold salts; gold is taken up by macrophages, which then inhibit phagocytosis; it is reserved for use in patients who are unresponsive to conventional therapy, and can be very toxic

inflammatory response: the body's nonspecific response to cell injury, resulting in pain, swelling, heat, and redness in the affected area

(glossary continues on page 248)

SALICYLATES

- aspirin
- balsalazide
- choline magnesium trisalicylate
- diflunisal
- mesalamine
- olsalazine
- salsalate
- sodium thiosalicylate

NONSTEROIDAL ANTI-INFLAMMATORY AND RELATED AGENTS

Nonsteroidal Anti-inflammatory Agents (NSAIDs)

Propionic Acids

- fenoprofen
- flurbiprofen
- ibuprofen
- ketoprofen
- naproxen
- oxaprozin

Acetic Acids

- diclofenac
- etodolac

- indomethacin
- ketorolac
- nabumetone
- sulindac
- tolmetin

Fenamates

- meclofenamate
- mefenamic acid

Oxicam Derivatives

- meloxicam
- piroxicam

Cyclooxygenase-2 Inhibitor

- celecoxib

Related Agent

- acetaminophen

ANTIARTHRITIS AGENTS

Gold Compounds

- auranofin
- aurothioglucose
- gold sodium thiomalate

Other Antiarthritis Drugs

- anakinra
- etanercept
- hyaluronidase derivatives
- leflunomide
- penicillamine
- sodium hyaluronate

Glossary of Key Terms (continued)

nonsteroidal anti-inflammatory drugs (NSAIDs): drugs that block prostaglandin synthesis and act as anti-inflammatory, antipyretic, and analgesic agents

salicylates: salicylic acid compounds, used as anti-inflammatory, antipyretic, and analgesic agents; they block the prostaglandin system

salicylism: syndrome associated with high levels of salicylates—dizziness, ringing in the ears, difficulty hearing, nausea, vomiting, diarrhea, mental confusion, and lassitude

The inflammatory response is designed to protect the body from injury and pathogens. It employs a variety of potent chemical mediators to produce the reaction that helps to destroy pathogens and promote healing. As the body reacts to these chemicals, it produces signs and symptoms of disease, such as swelling, fever, aches, and pains. Occasionally, the inflammatory response becomes a chronic condition and can result in damage to the body, leading to increased inflammatory reactions. **Anti-inflammatory agents** generally block or alter the chemical reactions associated with the inflammatory response to stop one or more of the signs and symptoms of inflammation.

ANTI-INFLAMMATORY, ANTIARTHRITIS, AND RELATED AGENTS

Several different types of drugs are used as anti-inflammatory agents. Corticosteroids (discussed in Chapter 36) are used systemically to block the inflammatory and immune systems. Blocking these important protective processes may produce many adverse effects, including decreased resistance to infection and neoplasms. Corticosteroids also are used topically to produce a local anti-inflammatory effect without as many adverse effects. Antihistamines (discussed in Chapter 54) are used to block the release of histamine in the initiation of the inflammatory response. In this chapter, discussion of anti-inflammatory agents focuses on drugs that have a direct effect on the inflammatory response, including salicylates, nonsteroidal anti-inflammatory and related agents, and antiarthritis drugs.

Because many anti-inflammatory drugs are available over the counter (OTC), there is a potential for abuse and overdosing. In addition, patients may take these drugs and block the signs and symptoms of a present illness, thus potentially causing the misdiagnosis of a problem. Patients also may combine these drugs and unknowingly induce toxicity. All of these drugs have adverse effects that can be dangerous if toxic levels of drug circulate in the body. See Box 16.1 for information on using these drugs with various age groups and Box 16.2 for problems that some African Americans have with anti-inflammatory drugs.

SALICYLATES

Salicylates (Table 16.1) are popular anti-inflammatory agents not only because of their ability to block the inflammatory response, but also because of their **antipyretic** (fever-blocking)

and **analgesic** (pain-blocking) properties. Salicylates are some of the oldest anti-inflammatory drugs used. They were extracted from willow bark, poplar trees, and other plants by ancient peoples to treat fever, pain, and what we now call inflammation. They are generally available without prescription and are relatively nontoxic when used as directed. Aspirin (*Bayer*, *Empirin*, and others), which is available OTC, is one of the most widely used drugs for treating inflammatory conditions. Additional synthetic salicylates include balsalazide (*Colazal*), choline magnesium trisalicylate (*Tricosal*), diflunisal (*Dolobid*), mesalamine (*Pentasa* and others), olsalazine (*Dipentum*), sal-salate (*Argesic* and others), and sodium thiosalicylate (*Rexolate*). A person who does not respond to one salicylate may respond to a different one.

Therapeutic Actions and Indications

Salicylates inhibit the synthesis of prostaglandin, an important mediator of the inflammatory reaction (Figure 16.1). The antipyretic effect of salicylates may be related to blocking of a prostaglandin mediator of pyrogens (chemicals that cause an increase in body temperature and that are released by active white blood cells) at the thermoregulatory center of the hypothalamus. At low levels, aspirin also affects platelet aggregation by inhibiting the synthesis of thromboxane A₂, a potent vasoconstrictor that normally increases platelet aggregation and blood clot formation. At higher levels, aspirin inhibits the synthesis of prostacyclin, a vasodilator that inhibits platelet aggregation.

Salicylates are indicated for the treatment of mild to moderate pain, fever, and numerous inflammatory conditions, including rheumatoid arthritis and osteoarthritis. (See Box 16.3 and the Critical Thinking Scenario for more on rheumatoid arthritis.) See Table 16.1 for usual indications for each type of salicylate.

Pharmacokinetics

Salicylates are readily absorbed directly from the stomach, reaching peak levels within 5 to 30 minutes. They are metabolized in the liver and excreted in the urine, with a half-life of 15 minutes to 12 hours, depending on the salicylate. Salicylates cross the placenta and enter breast milk; they are not indicated for use during pregnancy or lactation because of the potential adverse effects on the neonate and associated bleeding risks for the mother.

BOX 16.1

Drug Therapy Across the Lifespan

Anti-Inflammatory Agents

CHILDREN

Children are more susceptible to the GI and CNS effects of these drugs. Care must be taken to make sure that the child receives the correct dose of any anti-inflammatory agent. This can be a problem because many of these drugs are available in OTC pain, cold, flu, and combination products. Parents need to be taught to read the label to find out the ingredients and the dose they are giving the child.

Aspirin and choline magnesium trisalicylate are the only salicylates recommended for children. They should not be used when any risk of Reye syndrome exists.

Ibuprofen, naproxen, tolmetin, meloxicam, and, in some cases, indomethacin are the NSAIDs approved for use in children.

Acetaminophen is the most used anti-inflammatory drug for children. Care must be taken to avoid overdose, which can cause severe hepatotoxicity.

Children with arthritis may receive treatment with gold salts or etanercept; they must be monitored very closely for toxic effects.

ADULTS

Adults need to be cautioned about the presence of these drugs in many OTC products and taught to be aware of exactly what they are taking to avoid serious toxic effects. They should also be cautioned to report OTC drug use to their health care provider when they are receiving any other

prescription drug to avoid possible drug–drug interactions and the masking of signs and symptoms of disease.

Pregnant and nursing women should not use these drugs unless the benefit clearly outweighs the potential risk to the fetus or neonate. The salicylates, NSAIDs, and gold products have potentially severe adverse effects on the neonate and possibly the mother. Acetaminophen can be used cautiously if a pain preparation or antipyretic is needed. Nondrug measures should be taken when at all possible to decrease the potential risk. These women also need to be urged to avoid OTC drugs unless they are suggested by their health care providers.

OLDER ADULTS

Older patients may be more susceptible to the CNS and GI effects of some of these drugs. Dose adjustment is not needed for many of these agents.

Geriatric warnings have been associated with naproxen, ketorolac, and ketoprofen because of reports of increased toxicity when they are used by older patients. These NSAIDs should be avoided if possible.

Gold salts, used to treat arthritis, which is more common in older patients, are particularly toxic for geriatric patients. Accumulations in tissues can lead to increased renal, GI, and even liver problems. If gold is used in this group, the dose should be reduced and the patient monitored very closely for toxic effects.

Contraindications and Cautions

Salicylates are contraindicated in the presence of known allergy to salicylates, other NSAIDs (more common with a history of nasal polyps, asthma, or chronic urticaria), or tartrazine (a

dye that has a cross-sensitivity with aspirin) *because of the risk of allergic reaction*; bleeding abnormalities *because of the changes in platelet aggregation associated with these drugs*; impaired renal function *because the drug is excreted in the urine*; chickenpox or influenza *because of the risk of Reye syndrome in children and teenagers*; surgery or other invasive procedures scheduled within 1 week *because of the risk of increased bleeding*; and pregnancy or lactation *because of the potential adverse effects on the neonate or mother*.

BOX 16.2

Cultural Considerations

Sensitivity to Anti-Inflammatory Drugs

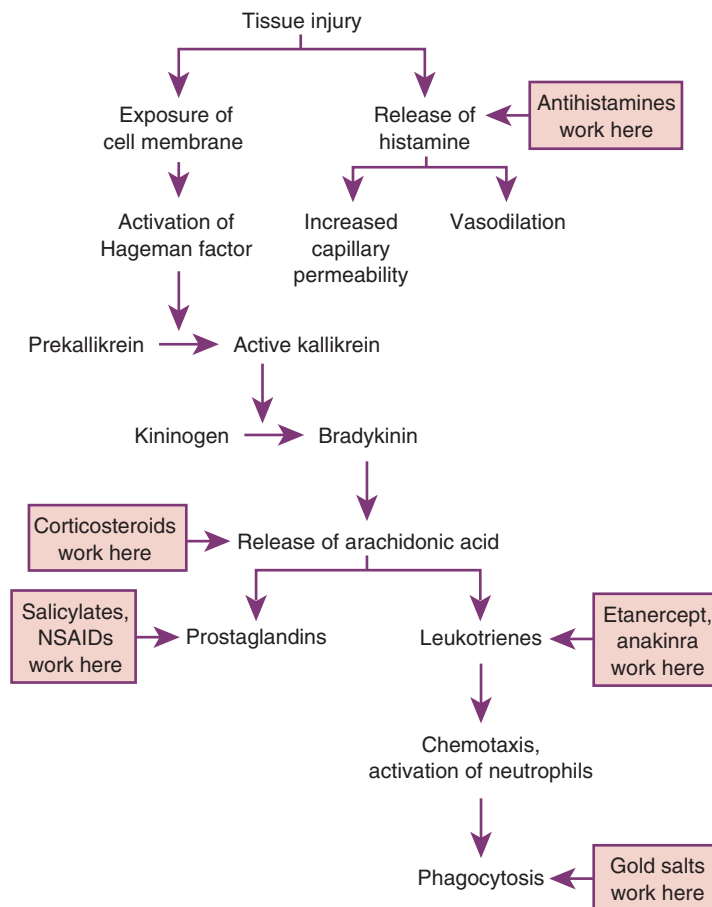

African Americans have a documented decreased sensitivity to the pain-relieving effects of many of the anti-inflammatory drugs. They do, however, have an increased risk of developing GI adverse effects to these drugs, including acetaminophen. This should be taken into consideration when using these drugs as analgesics. Increased doses may be needed to achieve a pain-blocking effect, but the increased dose will put these patients at an even greater risk for development of the adverse GI effects associated with these drugs. Monitor these patients closely, and use nondrug measures to decrease pain, such as positioning, environmental control, physical therapy, warm soaks, and so on. If African American patients are prescribed anti-inflammatory drugs, provide teaching about the signs and symptoms of GI bleeding and what to report, and monitor regularly for any adverse reactions to these drugs.

BOX 16.3 Pathophysiology of Rheumatoid Arthritis

Rheumatoid arthritis is a chronic, systemic disease that affects people of all ages. It is considered to be an autoimmune disease. Patients with rheumatoid arthritis have high levels of rheumatoid factor (RF), an antibody to immunoglobulin G (IgG). RF interacts with circulating IgG to form immune complexes, which tend to deposit in the synovial fluid of joints, as well as in the eye and other small vessels. The formation of the immune complex activates complement and precipitates an inflammatory reaction. During the immune reaction, lysosomal enzymes are released that destroy the tissues surrounding the joint. This destruction of normal tissue causes a further inflammatory reaction, and a cycle of destruction and inflammation ensues. Over time, the joint becomes severely damaged and the synovial space fills with scar tissue.

TABLE 16.1 DRUGS IN FOCUS Salicylates

Drug Name	Dosage/Route	Usual Indications
aspirin (<i>Bayer, Empirin, others</i>)	Adult: 325–650 mg PO or PR q4h Myocardial infarction (MI): 300–325 mg PO Pediatric: 65–100 mg/kg per day PO or PR in four to six divided doses; if <2 yr of age, consult with prescriber	Treatment of fever, pain, inflammatory conditions; at low dose to prevent the risk of death and MI in patients with history of MI, prevention of transient ischemic attacks
balsalazide (<i>Colazal</i>)	Three 750-mg capsules PO t.i.d. for 8 wk	Treatment of mildly to moderately acute ulcerative colitis in adults
choline magnesium trisalicylate (<i>Tricosal</i>)	Adult: 1.5–3 g/d PO in two to three divided doses Pediatric: 50 mg/kg per day PO in two divided doses	Relief of mild pain, fevers; treatment of arthritis
diflunisal (<i>Dolobid</i>)	500–1000 mg/d PO in two divided doses	Treatment of moderate pain, arthritis in adults
mesalamine (<i>Pentasa, others</i>)	800 mg PO t.i.d. for 6 wk; or 4 g/60 mL rectal suspension daily at bedtime or 500 mg suppository PR, retained for 1–3 h b.i.d.	Treatment of ulcerative colitis and other inflammatory bowel disease in adults
olsalazine (<i>Dipentum</i>)	1 g/d PO in two divided doses	Treatment of ulcerative colitis and other inflammatory bowel disease in adults
salsalate (<i>Argesic, others</i>)	3000 mg/d PO in divided doses	Treatment of pain, fever, inflammation in adults
sodium thiosalicylate (<i>Rexolate</i>)	50–150 mg IM q3–6h	Relief of gout, muscular pain; treatment of rheumatic fever in adults

● **FIGURE 16.1** Sites of action of anti-inflammatory agents.

CRITICAL THINKING SCENARIO

Aspirin and Rheumatoid Arthritis

THE SITUATION

G.T. is an 82-year-old man on a fixed income with a 14-year history of rheumatoid arthritis. He is seen in the clinic for evaluation of his arthritis and to address his complaint that his medicines are not helping him. On examination, it is found that G.T.'s range of motion, physical examination of joints, and overall presentation have not changed since his last visit. G.T. states that he had been taking aspirin, as prescribed, for his arthritis. But he read that aspirin can cause severe stomach problems, so he had switched to *Ecotrin* (an aspirin and antacid combination). This drug was much more expensive than he could handle on his fixed income, so he had started taking the drug only once every 3 days.

CRITICAL THINKING

Think about the pathophysiology of rheumatoid arthritis and how the drugs ordered act on the inflammatory process.

How can the nurse best explain the disease and the drug regimen to this patient?

What could be contributing to G.T.'s perception that his condition has worsened?

What nursing interventions would be appropriate to help G.T. cope with his disease and his need for medication?

DISCUSSION

G.T. should be offered encouragement and support to deal with his progressive disease and the drug regimen required. The fact that his physical status has not changed but he perceives that the disease is worse may reflect other underlying problems that are making it more difficult for him to cope with chronic pain and limitations. The nurse should explore his social situation, any changes in his living situation, and support services. An examination should be done to determine whether other physical problems have emerged that could be adding to his sense that things are getting worse. The actions of aspirin on the arthritic process should be reviewed in basic terms, with emphasis on the importance of preventing further damage and maintaining high enough levels of aspirin to control the arthritis signs and symptoms. Pictures of the process involved in rheumatoid arthritis may help—the simpler the better in most cases.

G.T. also should be taught that all aspirin is the same, so it is acceptable to buy the cheapest generic aspirin. He can check the expiration date to make sure that the drug is fresh and still therapeutic and check that it does not smell like vinegar. Tell G.T. that the expensive combination product that G.T. has been using has not been proven to be any

more effective at helping arthritis or at decreasing adverse effects than generic aspirin.

If G.T. has been having gastrointestinal complaints with the aspirin, he can be encouraged to take the drug with food and to have small, frequent meals to keep stomach acid levels at a more steady state. If G.T. has not been having any gastrointestinal complaints, he should be asked to report any immediately. The importance of the placebo effect cannot be overlooked with this patient. Many patients actually state that they feel better when they are using well-recognized, brand-name products. With support and encouragement, G.T. can be helped to follow his prescribed drug regimen and delay further damage from his arthritis.

NURSING CARE GUIDE FOR G.T.:
ASPIRIN AND RHEUMATOID ARTHRITIS**Assessment: History and Examination**

Allergies to aspirin; renal or hepatic impairment; ulcerative GI disease, peptic ulcer, hearing impairment, blood dyscrasias

Concurrent use of anticoagulants, steroids, ascorbic acid, phenylbutazone, alcohol, furosemide, acetazolamide, methazolamide, antacids, methotrexate, valproic acid, sulfonyleureas, insulin, captopril, beta-adrenergic blockers, probenecid, sulfinpyrazone, spironolactone, nitroglycerin

Neurologic: orientation, reflexes, affect

Musculoskeletal system: ROM, joint assessment

Skin: color, lesions

CV: pulse, cardiac auscultation, blood pressure, perfusion

GI: liver evaluation, bowel sounds

Lab tests: CBC, liver and renal function tests

Nursing Diagnoses

Acute Pain related to GI effects, headache

Disturbed Sensory Perception (Auditory, Kinesthetic) related to CNS effects

Deficient Knowledge regarding drug therapy

Implementation

Ensure proper administration of the drug.

Administer with food if GI upset occurs.

Provide support and comfort measures to deal with adverse effects: small, frequent meals; safety measures if CNS effects occur; measures for headache; bowel training as needed.

Provide patient teaching regarding drug name, dosage, side effects, precautions, and warnings to report; supplementary measures to help decrease arthritis pain.

Aspirin and Rheumatoid Arthritis (continued)**Evaluation**

Evaluate drug effects: decrease in signs and symptoms of inflammation.

Monitor for adverse effects: CNS changes, rash, GI upset, GI bleeding

Monitor for drug–drug interactions as listed.

Evaluate effectiveness of patient teaching program.

Evaluate effectiveness of comfort/safety measures.

PATIENT TEACHING FOR G.T.

- Your doctor has prescribed aspirin to help relieve the signs and symptoms of your rheumatoid arthritis. Aspirin works as an anti-inflammatory drug. It works in the body to decrease inflammation and to relieve the signs and symptoms of inflammation, such as pain, swelling, heat, tenderness, and redness. It does not cure your arthritis, but will help you to live with it more comfortably.
- Take your aspirin exactly as prescribed, every day. It is important to take the drug every day so that the blood levels of the aspirin are high enough to be effective. Do not use any aspirin that has a vinegar odor.

- Some of the following adverse effects may occur:
 - Nausea, vomiting, abdominal discomfort:* Taking the drug with food or eating small, frequent meals may help. If these effects persist, consult with your health care provider.
 - Diarrhea, constipation:* These effects may decrease over time; ensure ready access to bathroom facilities and consult with your health care provider for possible treatment.
 - Drowsiness, dizziness, blurred vision:* Avoid driving or performing tasks that require alertness if you experience any of these problems.
 - Headache:* If this becomes a problem, consult with your health care provider. Do not self-treat with more aspirin or other analgesics.
- Tell any health care provider who is taking care of you that you are taking this drug.
- Avoid using other over-the-counter preparations while you are taking this drug. If you feel that you need one of these drugs, consult with your health care provider for the most appropriate choice. Many of these drugs may also contain aspirin and could cause an overdose.
- Report any of the following to your health care provider: fever, rash, GI pain, nausea, itching, or black or tarry stools.
- Keep this drug and all medications out of the reach of children.

Adverse Effects

The adverse effects associated with salicylates may be the result of direct drug effects on the stomach (nausea, dyspepsia, heartburn, epigastric discomfort) and on clotting systems (blood loss, bleeding abnormalities). Salicylism can occur with high levels of aspirin; dizziness, ringing in the ears, difficulty hearing, nausea, vomiting, diarrhea, mental confusion, and lassitude can occur. Acute salicylate toxicity may occur at doses of 20 to 25 g in adults or 4 g in children. Signs of salicylate toxicity include hyperpnea, tachypnea, hemorrhage, excitement, confusion, pulmonary edema, convulsions, tetany, metabolic acidosis, fever, coma, and cardiovascular, renal, and respiratory collapse.

Clinically Important Drug–Drug Interactions

The salicylates interact with many other drugs, primarily because of alterations in absorption, effects on the liver, or extension of the therapeutic effects of the salicylate or the interacting drug (or both). The list of interacting drugs in each drug monograph in a nursing drug guide should be consulted and the prescriber consulted before adding or removing a salicylate from any drug regimen.

Prototype Summary: Aspirin

Indications: Treatment of mild to moderate pain, fever, inflammatory conditions; reduction of risk of transient ischemic attack (TIA) or stroke; reduction of risk of myocardial infarction (MI).

Actions: Inhibits the synthesis of prostaglandins; blocks the effects of pyrogens at the hypothalamus; inhibits platelet aggregation by blocking thromboxane A₂.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	5–30 min	0.25–2 h	3–6 h
Rectal	1–2 h	4–5 h	6–8 h

T_{1/2}: 15 minutes to 12 hours; metabolized in the liver and excreted in the urine.

Adverse effects: Nausea, vomiting, heartburn, epigastric discomfort, occult blood loss, dizziness, tinnitus, acidosis.

Nursing Considerations for Patients Receiving Salicylates**Assessment: History and Examination**

- Assess for contraindications or cautions: history of allergy to any salicylate or tartrazine *to avoid hypersensitivity reactions*; renal disease *because these drugs are excreted through the urine*; bleeding disorders *because of the drug effects on blood clotting*; chickenpox or influenza in children *to avoid the risk of Reye syndrome*; and pregnancy or lactation *to avoid adverse effects on the fetus or baby and risk of bleeding in the mother*.

- Perform physical assessment to establish baseline status before beginning therapy and to *monitor for any potential adverse effects*.
- Assess for the presence of any skin lesions *to monitor for dermatological effects*.
- Monitor temperature *to evaluate the drug's effectiveness in lowering temperature*.
- Evaluate central nervous system (CNS) status—orientation, reflexes, eighth cranial nerve function, and affect—*to assess CNS effects of the drug*.
- Monitor pulse, blood pressure, and perfusion *to assess for bleeding effects of cardiovascular effects of the drug*.
- Evaluate respirations and adventitious sounds *to detect hypersensitivity reactions*.
- Perform a liver evaluation and monitor bowel sounds *to detect hypersensitivity reactions, bleeding, and gastrointestinal (GI) effects of the drug*.
- Monitor laboratory tests for complete blood count (CBC), liver and renal function tests, urinalysis, stool guaiac, and clotting times *to detect bleeding or other adverse effects of the drug and changes in function that could interfere with drug metabolism and excretion*.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to CNS and gastrointestinal GI effects.
- Ineffective Breathing Pattern if toxic effects occur.
- Disturbed Sensory Perception (Auditory, Kinesthetic) if toxic effects occur.
- Deficient Knowledge regarding drug therapy.

Implementation With Rationale

- Administer with food if GI upset is severe; provide small, frequent meals *to alleviate GI effects*.
- Administer drug as indicated; check all drugs being taken for possible salicylate ingredients; monitor dose *to avoid toxic levels*.
- Monitor for severe reactions *to avoid problems and provide emergency procedures* (gastric lavage, induction of vomiting, administration of charcoal) if they occur.
- Arrange for supportive care and comfort measures (rest, environmental control) *to decrease body temperature or to alleviate inflammation*.
- Ensure that the patient is well hydrated during therapy *to decrease the risk of toxicity*.
- Provide thorough patient teaching, including measures to avoid adverse effects and warning signs of problems, as well as proper administration, *to increase knowledge about drug therapy and to increase compliance with the drug regimen*.
- Offer support and encouragement *to deal with the drug regimen*.

Evaluation

- Monitor patient response to the drug (improvement in condition being treated, relief of signs and symptoms of inflammation).
- Monitor for adverse effects (GI upset, CNS changes, bleeding).
- Evaluate the effectiveness of the teaching plan (patient can name drug, dosage, adverse effects to watch for, specific measures to avoid adverse effects).
- Monitor the effectiveness of comfort measures and compliance with the drug regimen.

KEY POINTS

- ▶ Salicylates block prostaglandin activity, which decreases the inflammatory response and relieves the signs and symptoms of inflammation.
- ▶ Salicylates can cause GI irritation, eighth cranial nerve stimulation, and salicylism—ringing in the ears, acidosis, nausea, vomiting, diarrhea, mental confusion, and lassitude.

NONSTEROIDAL ANTI-INFLAMMATORY AND RELATED AGENTS

Nonsteroidal anti-inflammatory drugs (NSAIDs) provide strong anti-inflammatory and analgesic effects without the adverse effects associated with the corticosteroids (Table 16.2). Acetaminophen (*Tylenol*) is a related drug and a widely used agent. It has antipyretic and analgesic properties but does not have the anti-inflammatory effects of the salicylates or the NSAIDs. It is discussed in this chapter because it is used for many of the same reasons that NSAIDs are used, and the nurse needs to understand the similarities and differences of these drugs.

Nonsteroidal Anti-Inflammatory Drugs

The NSAIDs are a drug class that has become one of the most commonly used drug types in the United States. Following unanticipated study results linking drugs in this class to an increased risk of cardiovascular events and death as well as increased bleeding in the GI tract, a black box warning was added to all of these drugs pointing out the cardiovascular and GI risks associated with taking them.

This group of drugs includes propionic acids, acetic acids, fenemates, oxicam derivatives, and cyclooxygenase-2 inhibitors. The classes are defined by chemical structural differences, but clinically, the NSAIDs are all-inclusive. See Table 16.2 for a list of these drugs by group, as well as their specific indications. The choice of NSAID depends on personal experience and the patient's response to the drug. A patient may have little response to one NSAID and a huge response to another. It may take several trials to determine the drug of choice for any particular patient (Box 16.4).

TABLE 16.2 DRUGS IN FOCUS Nonsteroidal Anti-Inflammatory Drugs (NSAIDs) and Related Agents

Drug Name	Dosage/Route	Usual Indications
NSAIDs		
Propionic Acids		
fenoprofen (<i>Nalfon</i>)	200–600 mg PO t.i.d. or q.i.d.	Treatment of pain, arthritis in adults
flurbiprofen (<i>Ansaid</i>)	200–300 mg PO in divided doses; ophthalmic solution: 1 drop (gtt) q30min beginning 2 h after surgery	Long-term management of arthritis; topically to manage pain after eye surgery in adults
 ibuprofen (<i>Motrin</i> , <i>Advil</i> , others)	Adult: 400–800 mg PO t.i.d. to q.i.d. Pediatric: 30–40 mg/kg per day PO in three to four divided doses for arthritis; 5–10 mg/kg PO q6–8h for fever	Treatment of pain, arthritis, dysmenorrhea, juvenile arthritis
ketoprofen (<i>Orudis</i>)	25–75 mg PO t.i.d. to q.i.d.; reduce dose with hepatic or renal impairment; sustained release (SR) form: 200 mg/d PO	Short-term management of pain; long-term management of arthritis (SR form); ophthalmic form to relieve ocular itching
naproxen (<i>Naprosyn</i>)	Adult: 250–500 mg PO b.i.d.; do not give >200 mg q12h for geriatric patients Pediatric: 10 mg/kg per day PO in two divided doses for juvenile arthritis; do not give OTC versions to children <12 yr without consulting health care provider	Treatment of pain, arthritis, dysmenorrhea, juvenile arthritis
oxaprozin (<i>Daypro</i>)	1200 mg PO daily	Treatment of arthritis in adults
Acetic Acids		
diclofenac (<i>Voltaren</i> , <i>Cataflam</i> , <i>Flector</i>)	100–200 mg/d PO 25–50 mg b.i.d. to q.i.d. PO Topical: apply one patch bid to most painful area	Treatment of acute and chronic pain associated with inflammatory conditions in adults
etodolac (<i>Lodine</i>)	800–1200 mg/d PO in divided doses; 200–400 mg q6–8h PO for pain management	Treatment of arthritis pain in adults; management of chronic pain (extended release [ER] formulation)
indomethacin (<i>Indocin</i>)	Adult: 75–150 mg/d PO in three to four divided doses Pediatric (>2 yr): in special circumstances, 2 mg/kg per day PO in divided doses	Relief of moderate to severe pain in PO, topical, and PR forms; closure of patent ductus arteriosus in premature infants (given IV)
ketorolac (<i>Toradol</i>)	10 mg PO q4–6h, or 30–60 mg IM, switching to oral form as soon as possible, or 30 mg IV as a single dose Ophthalmic: 1 gtt to affected eye q.i.d.; reduce dose with renal impairment and in patients >65 yr	Short-term management of pain in adults; topically to relieve ocular itching
nabumetone (<i>Relafen</i>)	1000 mg/d PO as a single dose	Treatment of acute and chronic arthritis pain in adults
sulindac (<i>Clinoril</i>)	150–200 mg PO b.i.d.	Treatment of various inflammatory conditions in adults
tolmetin (<i>Tolectin</i>)	Adult: 400 mg PO t.i.d.; 600–800 mg/d in three to four doses for maintenance Pediatric: 20 mg/kg per day PO in three to four divided doses	Treatment of acute flares of rheumatoid and juvenile arthritis
Fenamates		
meclofenamate	100–400 mg/d PO	Treatment of mild to moderate pain, primary dysmenorrheal, rheumatoid arthritis, osteoarthritis
mefenamic acid (<i>Ponstel</i>)	500 mg PO, then 250 mg PO q6h as needed	Short-term treatment of pain in adults and children >14 yr; primary dysmenorrhea

Drug Name	Dosage/Route	Usual Indications NSAIDs
Oxicam Derivative		
meloxicam (<i>Mobic</i>)	Adult: 7.5 mg/d PO to a maximum of 15 mg/d Pediatric: 0.125 mg/kg per day PO to a maximum of 7.5 mg/d	Treatment of osteoarthritis, rheumatoid arthritis, and juvenile arthritis
piroxicam (<i>Feldene</i>)	20 mg/d PO as a single dose	Treatment of acute and chronic arthritis in adults
Cyclooxygenase-2 Inhibitor		
celecoxib (<i>Celebrex</i>)	Initially: 100–200 mg PO b.i.d.; acute pain 400 mg PO then 200 mg PO b.i.d. for familial adenomatous polyposis (FAP)	Treatment of acute and chronic arthritis in adults; acute pain; primary dysmenorrhea; reduction of the number of colorectal polyps in FAP; ankylosing spondylitis
Related Agent		
 acetaminophen (<i>Tylenol</i>)	Adult: 1000 mg PO t.i.d. to q.i.d. or 325–650 mg PR q4–6h Pediatric: adjust dose based on age	Relief of pain and fever in a variety of situations

Therapeutic Actions and Indications

The anti-inflammatory, analgesic, and antipyretic effects of the NSAIDs are largely related to inhibition of prostaglandin synthesis (see Figure 16.1). The NSAIDs block two enzymes, known as cyclooxygenase-1 (COX-1) and cyclooxygenase-2 (COX-2). COX-1 is present in all tissues and seems to be involved in many body functions, including blood clotting, protecting the stomach lining, and maintaining sodium and water balance in the kidney. COX-1 turns arachidonic acid into prostaglandins as needed in a variety of tissues. COX-2 is active at sites of trauma or injury when more prostaglandins are needed, but it does not seem to be involved in the other tissue functions. By interfering with this part of the inflammatory reaction, NSAIDs block inflammation before all of the signs and symptoms can develop. Most NSAIDs also block various other functions of the prostaglandins, including protection of the stomach lining, regulation of blood clotting, and water and salt balance in the kidney. The COX-2 inhibitors are thought to act only at sites of trauma and injury to more specifically block the inflammatory reaction.

The adverse effects associated with most NSAIDs are related to blocking of both of these enzymes and changes in the functions that they influence—GI integrity, blood clotting, and sodium and water balance. The COX-2 inhibitors are designed to affect only the activity of COX-2, the enzyme that becomes active in response to trauma and injury. They do not interfere with COX-1, which is needed for normal functioning of these systems. Consequently, these drugs should not have the associated adverse effects seen when both COX-1 and COX-2 are inhibited. Experience has shown that the COX-2 inhibitors still have some effect on these other functions, and patients should still be evaluated for GI effects, changes in bleeding time, and water retention. Recent studies suggest that they may block some protective responses in the body, such as vasodilation and

inhibited platelet clumping, which is protective if vessel narrowing or blockage occurs; blocking this effect could lead to cardiovascular problems. Box 16.5 summarizes the actions and adverse effects of the COX-1 and COX-2 receptors.

The NSAIDs are indicated for relief of the signs and symptoms of rheumatoid arthritis and osteoarthritis, for relief of mild to moderate pain, for treatment of primary dysmenorrhea, and for fever reduction.

Pharmacokinetics

The NSAIDs are rapidly absorbed from the GI tract, reaching peak levels in 1 to 3 hours. They are metabolized in the liver and excreted in the urine. NSAIDs cross the placenta and cross into breast milk. Therefore, they are not recommended during pregnancy and lactation because of the potential adverse effects on the fetus or neonate.

Contraindications and Cautions

The NSAIDs are contraindicated in the presence of allergy to any NSAID or salicylate, and celecoxib is also contraindicated in the presence of allergy to sulfonamides. Additional contraindications are cardiovascular dysfunction or hypertension *because of the varying effects of the prostaglandins*; peptic ulcer or known GI bleeding *because of the potential to exacerbate the GI bleeding*; and pregnancy or lactation *because of potential adverse effects on the neonate or mother*. Caution should be used with renal or hepatic dysfunction, *which could alter the metabolism and excretion of these drugs*, and with any other known allergies, *which indicate increased sensitivity*.

Adverse Effects

Patients receiving NSAIDs often experience nausea, dyspepsia, GI pain, constipation, diarrhea, or flatulence caused by direct

BOX 16.4 **The Evidence**

Cyclooxygenase-2 Inhibitors

In late 2004, Merck voluntarily withdrew their cyclooxygenase-2 (COX-2) inhibitor, rofecoxib (*Vioxx*), from the market following release of a midstudy finding that the use of the drug over an 18-month period led to a significant increase in cardiovascular (CV) mortality in those taking the drug compared with a placebo group. The study, called the APPROVe study (Adenomatous Polyp Prevention on *Vioxx*), was targeted at testing whether the blocking of such growth factors as angiogenesis could decrease cancer risk in a specific population. The study participants took 25 mg of *Vioxx* each day for 18 months (the halfway point in the study) when the finding of increased CV events was announced and the study was stopped. The CV outcomes were not noted earlier than 18 months. Interestingly, other studies, including a 4-year study of the effects on Alzheimer's disease, did not show a significant difference in CV events between the placebo and drug groups. Yet, in the VIGOR (*Vioxx* Gastrointestinal Outcomes Research) study, in which rofecoxib was compared with naproxen (another NSAID) for 12 months, increased CV events were noted in the rofecoxib group after only 2 months.

The U.S. Food and Drug Administration (FDA) formed a committee to study the COX-2 inhibitors and then all of the NSAIDs on the market to see if there were any problems in oversight of drug safety and to make recommendations about the future use of these drugs.

Valdecoxib (*Bextra*) was withdrawn from the market at FDA request after the committee reviewed data. A small study did show an increase in CV events, including death, when *Bextra* was used immediately in postoperative patients recovering from coronary artery bypass graft (CABG) surgery. The drug was not proven to be especially more effective than other NSAIDs for relieving pain, and already had a black-box warning about the increased possibility of severe skin reactions, including Stevens–Johnson syndrome. With those facts in mind and the possibility of a COX-2 link to increased CV events, the FDA believed that the benefits of marketing the drug did not outweigh the potential risks for using the drug.

Celecoxib (*Celebrex*) remains on the market. The APC study (Adenoma Prevention with Celecoxib) did show a two- to threefold increase in CV events among patients using the drug compared with placebo over 33 months. There did seem to be a dose correlation, with more events in the group using a higher dose. A nearly identical study, the PreSAP trial

(Prevention of Spontaneous Adenomatous Polyps), showed no increase in CV events in the group using celecoxib. A small study, the ADAPT (Alzheimer's Disease Anti-inflammatory Prevention Trial), did not appear to show an increase in CV events in the patients in that study.

The media helped to fuel a real concern about the safety of any anti-inflammatory medication. The questions remain: Were the CV events related to dosage, length of drug use, or the underlying conditions of the patients being studied? Were the CV events a direct effect of the COX-2 inhibitor? Would these same events have occurred if the drug were used at the dosages approved and for the approved length of time? More long-term, controlled studies are needed to answer these questions. In the meantime, the FDA has recommended that valdecoxib and rofecoxib stay off the market until appropriate guidelines and controls are in place for their return; that all NSAIDs' packaging information include warnings that there is potential risk for increased CV events as well as the risk of gastrointestinal bleeding, and that health care providers use caution in recommending these drugs to anyone with an established CV risk; that all prescription NSAIDs be contraindicated in patients immediately after CABG surgery; and that the prescribing information for celecoxib include a black-box warning referencing the available data about increased CV risk. Two new COX-2 inhibitors being studied, lumiracoxib and etoricoxib, will be carefully reviewed for data on the incidence of increased CV events before they will be considered for approval.

Specialists treating patients with chronic pain have petitioned to have the FDA return rofecoxib and valdecoxib to the market, citing patients who could only obtain relief using those drugs. Some patients only respond to these particular NSAIDs, and these specialists feel that the patients should have a choice, being informed of the risks, to continue their use to relieve pain. Clearly, more long-term studies are needed. The nurse may be asked about this controversy and what recommendations are in place by patients who want relief from pain but really want to understand the risks to their health. To get a complete summary of the research, the report to the FDA, and current recommendations and research, go to www.fda.gov and click on NSAIDs under Hot Topics on the right side of the page. This site is updated regularly and offers information geared to patients and to health care professionals.

GI effects of the drug. The potential for GI bleeding often is a cause of discontinuation of the drug. Headache, dizziness, somnolence, and fatigue also occur frequently and could be related to prostaglandin activity in the CNS. Bleeding, platelet inhibition, and even bone marrow depression have been reported with chronic use and probably are related to the blocking of prostaglandin activity. Rash and mouth sores may occur, and anaphylactoid reactions ranging up to fatal anaphylactic shock have been reported in cases of severe hypersensitivity.

Clinically Important Drug–Drug Interactions

There often is a decreased diuretic effect when these drugs are taken with loop diuretics; there is a potential for decreased antihypertensive effect of beta-blockers if these drugs are combined; and there have been reports of lithium toxicity, especially when combined with ibuprofen. Patients who receive these combinations should be monitored closely, and appropriate dose adjustments should be made by the prescriber.

BOX 16.5 Comparison of Cyclooxygenase (COX) Receptors

COX-1	COX-2
Site of action Found in many tissues, important for homeostasis	Site of action Induced by inflammatory stimuli at the site of inflammation
Effects <ul style="list-style-type: none"> • Converts arachidonic acid to inflammatory prostaglandins • Maintains renal function • Provides for gastric mucosa integrity • Promotes vascular hemostasis, increases bleeding • Autocrine effects causing fever 	Effects <ul style="list-style-type: none"> • Increases pain, inflammation • Vasodilates • Blocks platelet clumping
Effects of blocking <ul style="list-style-type: none"> • Decreases swelling, pain, inflammation • Sodium retention, edema, increased blood pressure • Gastrointestinal erosion, bleeding • Decreases fever 	Effects of blocking <ul style="list-style-type: none"> • Decreases pain, inflammation • Prevents protective vasodilation, allows platelet clumping, which can lead to myocardial infarction, cerebrovascular accident • Myriad of skin reactions, including Stevens–Johnson syndrome

Prototype Summary: Ibuprofen

Indications: Relief of the signs and symptoms of rheumatoid arthritis and osteoarthritis; relief of mild to moderate pain; treatment of primary dysmenorrhea; fever reduction.

Actions: Inhibits prostaglandin synthesis by blocking cyclooxygenase-1 and -2 receptor sites, leading to an anti-inflammatory effect, analgesia, and antipyretic effects.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	30 min	1–2 h	4–6 h

$T_{1/2}$: 1.8 to 2.5 hours; metabolized in the liver and excreted in the urine.

Adverse effects: Headache, dizziness, somnolence, fatigue, rash, nausea, dyspepsia, bleeding, constipation.

Acetaminophen

Acetaminophen (*Tylenol*) is used to treat moderate to mild pain and fever and often is used in place of the NSAIDs or salicylates. It is the most frequently used drug for managing pain and fever in children. It is widely available over the counter and is found in many combination products. It can be extremely toxic. It causes severe liver toxicity that can lead to death when taken in high doses. Every year children die from inadvertent acetaminophen overdose when parents give their child more than one OTC drug containing acetaminophen or administer a high dose of acetaminophen. The FDA and drug manufac-

turers have joined forces to produce mass media ads warning parents about this possibility.

Therapeutic Actions and Indications

Acetaminophen acts directly on the thermoregulatory cells in the hypothalamus to cause sweating and vasodilation; this in turn causes the release of heat and lowers fever. The mechanism of action related to the analgesic effects of acetaminophen has not been identified.

Acetaminophen is indicated for the treatment of pain and fever associated with a variety of conditions, including influenza; for the prophylaxis of children receiving diphtheria–pertussis–tetanus (DPT) immunizations (aspirin may mask Reye syndrome in children); and for the relief of musculoskeletal pain associated with arthritis (see Table 16.2).

Pharmacokinetics

Acetaminophen is rapidly absorbed from the GI tract, reaching peak levels in 0.5 to 2 hours. It is extensively metabolized in the liver and excreted in the urine, with a half-life of about 2 hours. Caution should be used in patients with hepatic or renal impairment, which could interfere with metabolism and excretion of the drug, leading to toxic levels. Acetaminophen crosses the placenta and enters breast milk; it should be used cautiously during pregnancy or lactation because of the potential adverse effects on the fetus or neonate.

Contraindications and Cautions

Acetaminophen is contraindicated in the presence of allergy to acetaminophen. It should be used cautiously in pregnancy or lactation and in hepatic dysfunction or chronic alcoholism *because of associated toxic effects on the liver.*

Adverse Effects

Adverse effects associated with acetaminophen use include headache, hemolytic anemia, renal dysfunction, skin rash, and fever. Hepatotoxicity is a potentially fatal adverse effect that is usually associated with chronic use and overdose and is related to direct toxic effects on the liver. The dose that could prove toxic varies with the age of the patient, other drugs that the patient might be taking, and the underlying hepatic function of that patient. When overdose occurs, acetylcysteine can be used as an antidote. Life support measures may also be necessary.

Clinically Important Drug–Drug Interactions

There is an increased risk of bleeding with oral anticoagulants because of effects on the liver; of toxicity with chronic ethanol ingestion because of toxic effects on the liver; and of hepatotoxicity with barbiturates, carbamazepine, hydantoins, rifampin, or sulfapyrazone. These combinations should be avoided, but if they must be used, appropriate dose adjustment should be made and the patient should be monitored closely.

P Prototype Summary: *Acetaminophen*

Indications: Treatment of mild to moderate pain, fever, or signs and symptoms of the common cold or flu; musculoskeletal pain associated with arthritis and rheumatic disorders.

Actions: Acts directly on the hypothalamus to cause vasodilation and sweating, which will reduce fever; mechanism of action as an analgesic is not understood.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	Varies	0.5–2 h	3–6 h

$T_{1/2}$: 1 to 3 hours; metabolized in the liver and excreted in the urine.

Adverse effects: Rash, fever, chest pain, liver toxicity and failure, bone marrow suppression.

Nursing Considerations for Patients Receiving NSAIDs and Related Agents

Assessment: History and Examination

(Refer to the section on salicylates for nursing diagnoses, implementation with rationale, and evaluation.)

- Assess for *contraindications or cautions*: known allergies to any salicylates, NSAIDs, or tartrazine; pregnancy or lactation; hepatic or renal disease; cardiovascular dysfunction; hypertension; and GI bleeding or peptic ulcer.
- Assess for *baseline status before beginning therapy and for any potential adverse effects*: presence of any skin lesions; temperature; orientation, reflexes, and affect; pulse, blood pressure, and perfusion; respirations and adventitious sounds; liver evaluation; bowel sounds; and CBC, liver and renal function tests, urinalysis, stool guaiac, and serum electrolytes.

KEY POINTS

- ◆ NSAIDs block prostaglandin synthesis at COX-1 and COX-2 sites. This blocks inflammation but also blocks protection of the stomach lining, as well as the kidneys' regulation of water.
- ◆ There are many different NSAIDs. If one does not work for a particular patient, another one might.
- ◆ Acetaminophen causes vasodilation and heat release, lowering fever and working to relieve pain.
- ◆ Acetaminophen can cause liver failure. It is found in many OTC products. Teach patients to avoid toxic doses of acetaminophen.

ANTIARTHRITIS AGENTS

Other drugs that are used to block the inflammatory process include the antiarthritis drugs. Arthritis is potentially debilitating

inflammatory process in the joints that cause pain and bone deformities. Antiarthritis drugs include the gold compounds, which are used to prevent and suppress arthritis in selected patients with rheumatoid arthritis. The other antiarthritis drugs are specifically used to block the inflammation and tissue damage of rheumatoid arthritis. (See Table 16.3.)

Gold Compounds

Some patients with rheumatic inflammatory conditions do not respond to the usual anti-inflammatory therapies, and their conditions worsen despite weeks or months of standard pharmacological treatment. Some of these patients respond to treatment with gold salts, also known as **chrysotherapy**, in which gold is taken up by macrophages, which then inhibit phagocytosis; it is reserved for use in patients who are unresponsive to conventional therapy and can be very toxic. The gold salts available for use include auranofin (*Ridaura*), aurothioglucose (*Solganal*), and gold sodium thiomalate (*Aurolate*).

Therapeutic Actions and Indications

Chrysotherapy results in inhibition of phagocytosis (see Figure 16.1). Because phagocytosis is blocked, the release of lysosomal enzymes is inhibited and tissue destruction is decreased. This action allows gold salts to suppress and prevent some arthritis and synovitis. Gold salts are indicated to treat selected cases of rheumatoid and juvenile rheumatoid arthritis in patients whose disease has been unresponsive to standard therapy (see Table 16.3 for usual indications). These drugs do not repair damage; they prevent further damage and so are most effective if used early in the disease.

Pharmacokinetics

The gold salts are absorbed at varying rates, depending on their route of administration. They are widely distributed throughout the body but seem to concentrate in the hypothalamic–pituitary–adrenocortical (HPA) system and in the adrenal and renal cortices. The gold salts are excreted in urine and feces. These drugs cross the placenta and cross into breast milk. They have been shown to be teratogenic in animal studies and should not be used during pregnancy or lactation. Barrier contraceptives should be recommended to women of child-bearing age, and another method of feeding the baby should be used if gold therapy is needed in a lactating woman.

Contraindications and Cautions

Gold salts can be quite toxic and are contraindicated in the presence of any known allergy to gold, severe diabetes, congestive heart failure, severe debilitation, renal or hepatic impairment, hypertension, blood dyscrasias, recent radiation treatment, history of toxic levels of heavy metals, and pregnancy or lactation.

TABLE 16.3 DRUGS IN FOCUS Antiarthritis Agents

Drug Name	Dosage/Route	Usual Indications
Gold Compounds		
auranofin (<i>Ridaura</i>)	Adult: 6 mg/d PO; monitor geriatric patients carefully Pediatric: 0.1–0.15 mg/kg per day PO	Oral agent for long-term therapy of rheumatic disorders
 aurothioglucose (<i>Solganal</i>)	Adult: 10 mg IM, then two doses of 25 mg IM, then two doses of 50 mg IM; then 50 mg IM every 3–4 wk; monitor geriatric patients carefully Pediatric: one-fourth the adult dose	Injected drug for early treatment of rheumatic disorders
gold sodium thiomalate (<i>Aurolate</i>)	Adult: 10 mg IM, then 25 mg IM every other week; use caution in geriatric patients Pediatric: 10 mg IM, then 1 mg/kg IM every other week	Injected drug for early treatment of rheumatic disorders
Other Antiarthritis Drugs		
anakinra (<i>Kineret</i>)	Adult: 100 mg/d SQ	Reduction of signs and symptoms of rheumatoid arthritis in patients ≥ 18 yr if one or more other arthritis agents have failed
etanercept (<i>Enbrel</i>)	Adult: 25 mg SQ two times per week or 50 mg SQ once a week Pediatric (4–17 yr): 0.4 mg/kg SQ two times per week with 72–96 h between doses; not recommended for patients <4 yr	Reduction of signs and symptoms of severe rheumatoid arthritis in patients whose disease is unresponsive to other therapy; prevention of damage early in the disease; ankylosing spondylosis; psoriatic arthritis
hyaluronidase derivatives (hylan G-F 20, <i>Synvisc</i>)	2 mL once a week for 3 wk injected into the affected knee	Relief of pain in the knees of arthritis patients whose disease is unresponsive to conventional treatment
leflunomide (<i>Arava</i>)	100 mg PO daily for 3 d, then 20 mg PO daily	Treatment of active rheumatoid arthritis, to relieve signs and symptoms and to slow the progression of disease in adults
penicillamine (<i>Depen</i>)	125–250 mg PO daily	Treatment of severe, active rheumatoid arthritis in adults whose disease is unresponsive to conventional therapy
sodium hyaluronate (<i>Hyalgan</i>)	2 mg once a week for 5 wk injected into the affected knee	Relief of pain in the knees of arthritis patients whose disease is unresponsive to conventional treatment

Adverse Effects

A variety of adverse effects is common with the use of gold salts, and they are probably related to their deposition in the tissues and effects at that local level: stomatitis, glossitis, gingivitis, pharyngitis, laryngitis, colitis, diarrhea, and other GI inflammation; gold bronchitis and interstitial pneumonitis; bone marrow depression; vaginitis and nephrotic syndrome; dermatitis, pruritus, and exfoliative dermatitis; and allergic reactions ranging from flushing, fainting, and dizziness to anaphylactic shock.

Clinically Important Drug–Drug Interactions

These drugs should not be combined with penicillamine, antimalarials, cytotoxic drugs, or immunosuppressive agents other than low-dose corticosteroids because of the potential for severe toxicity.

Prototype Summary: Aurothioglucose

Indications: Treatment of selected cases of adult and juvenile rheumatoid arthritis, most effective early in disease.

Actions: Taken up by macrophages, which inhibits phagocytosis and release of lysosomal enzymes that cause damage associated with inflammation.

Pharmacokinetics:

Route	Onset	Peak
IM	Slow	4–6 h

$T_{1/2}$: 3 to 7 days; excreted in the urine and feces.

Adverse effects: Dermatitis, nausea, vomiting, stomatitis, anemia, interstitial pneumonitis, acute tubular necrosis.

Disease-Modifying Antirheumatic Drugs

Other antiarthritis drugs, called disease-modifying antirheumatic drugs (DMARDs), are available for treating arthritis and aggressively affect the process of inflammation. Because they alter the course of the inflammatory process, many rheumatologists are selecting to DMARDs early in the diagnosis, before damage to the joints has occurred. Adverse effects associated with these drugs (see adverse effects) can be severe to life-threatening because they alter the ability of the body to initiate or carry on an inflammatory reaction.

DMARDs discussed in this chapter include drugs used when patients do not respond to conventional therapy—anakinra (*Kineret*), etanercept (*Enbrel*), leflunomide (*Arava*), and penicillamine (*Depen*)—and drugs used to directly decrease pain in joints affected by arthritis, including hyaluronidase derivative (*Synvisc*) and sodium hyaluronate (*Hyalgan*).

Additional drugs also used to modify the disease process in rheumatoid arthritis include the antineoplastic drug methotrexate (see Chapter 14), the monoclonal antibodies infliximab (*Remicade*) and adalimumab (*Humira*) (see Chapter 17), the T cell suppressor abatacept (*Orencia*) (see Chapter 17), certain antimalarial drugs (see Chapter 12), some additional antineoplastic drugs such as cyclophosphamide (see Chapter 14), and the immune modulators cyclosporine A and azathioprine (Chapter 17).

Therapeutic Actions and Indications

Anakinra is one of the newest of the antiarthritis drugs. This drug is an interleukin-1 receptor antagonist. It blocks the increased interleukin-1, which is responsible for the degradation of cartilage in rheumatoid arthritis. This drug must be given each day by subcutaneous injection and is often used in combination with other antiarthritis drugs.

Etanercept contains genetically engineered tumor necrosis factor (TNF) receptors derived from Chinese hamster ovary cells. These receptors react with free-floating TNF released by active leukocytes in autoimmune inflammatory disease to prevent the damage caused by TNF. See Table 16.3 for usual indications.

Hyaluronidase derivatives, such as hylan G-F 20 and sodium hyaluronate, have elastic and viscous properties. These drugs are injected directly into the joints of patients with severe rheumatoid arthritis of the knee. They seem to cushion and lubricate the joint and relieve the pain associated with degenerative arthritis. They are given weekly for 3 to 5 weeks.

Leflunomide directly inhibits an enzyme, dihydroorotate dehydrogenase (DHODH), that is active in the autoimmune process that leads to rheumatoid arthritis, relieving signs and symptoms of inflammation and blocking the structural damage this inflammation can cause, slowing disease progression.

Penicillamine lowers the immunoglobulin M (IgM) rheumatoid factor levels in patients with acute rheumatoid arthritis, relieving the signs and symptoms of inflammation. It may take 2 to 3 months of therapy before a response is noted.

Pharmacokinetics

Anakinra is slowly absorbed from the subcutaneous tissue, reaching peak levels in 3 to 7 hours. It is metabolized in the tissues and excreted in the urine. It has a half-life of 4 to 6 hours. Etanercept is very slowly absorbed after subcutaneous injection, reaching peak levels in 72 hours. It is metabolized and destroyed in the tissues with a half-life of 115 hours. The hyaluronidase derivatives are not absorbed systemically. Leflunomide is slowly absorbed from the GI tract, reaching peak levels in 6 to 12 hours. It undergoes hepatic metabolism and excretion in the urine. The half-life of leflunomide is 14 to 18 days. Penicillamine is an oral drug that reaches peak levels in 1 to 3 hours after administration. It is extensively metabolized in the liver and excreted in the urine with a half-life of 2 to 3 hours.

Contraindications and Cautions

These drugs are contraindicated in the presence of allergy to the drugs or to the animal products from which they were derived (Chinese hamster products in etanercept; chicken products in hylan G-F 20 and sodium hyaluronate); pregnancy or lactation *because of the potential for adverse effects on the fetus or neonate*; acute infection *because of the blocking of normal inflammatory pathways*; and liver or renal impairment, *which could be exacerbated by these drugs*.

Adverse Effects

A variety of adverse effects are common with the use of these drugs, including local irritation at injection sites (anakinra, etanercept, hyaluronidase derivatives, and sodium hyaluronate), pain with injection, and increased risk of infection. Leflunomide is associated with potentially fatal hepatic toxicity and rashes. Penicillamine is associated with a potentially fatal myasthenic syndrome, bone marrow depression, and assorted hypersensitivity reactions. Etanercept is associated with severe bone marrow suppression, and a warning has been issued stating that the drug has been associated with the development of serious CNS problems, including multiple sclerosis. It can also cause severe myelosuppression and increased risk of infections and cancer development. Patients who use this drug need to be monitored very closely. Leflunomide has been associated with severe hepatic toxicity, and the patient's liver function needs to be monitored closely.

Clinically Important Drug–Drug Interactions

Hyaluronidase derivatives such as sodium hyaluronate should not be injected at the same time as local anesthetics.

Because leflunomide can cause severe liver dysfunction if it is combined with other hepatotoxic drugs, this combination should be avoided.

The absorption of penicillamine is decreased if it is taken with iron salts or antacids; if these are both being given, they should be separated by at least 2 hours.

Anakinra and etanercept should not be used together because of an increased risk of serious infections.

Nursing Considerations for Patients Receiving Antiarthritis Agents

Nursing considerations for patients receiving the drugs listed in this section are similar to those for patients receiving NSAIDs and related agents. Details related to each individual drug can be found in the specific drug monograph in your nursing drug guide.

KEY POINTS

- ▶ Gold salts prevent macrophage phagocytosis, lysosomal release, and tissue damage because the gold salts are taken up by phagocytes, which then are not able to function in a normal way.
- ▶ Gold salts are deposited in the tissues and cause an assortment of inflammatory reactions, including stomatitis, glossitis, gingivitis, pharyngitis, laryngitis, colitis, diarrhea, and other GI inflammation; gold bronchitis and interstitial pneumonitis; bone marrow depression; vaginitis and nephrotic syndrome; dermatitis, pruritus, and exfoliative dermatitis; and allergic reactions ranging from flushing, fainting, and dizziness to anaphylactic shock.
- ▶ Drugs used to alter the inflammatory process involved in arthritis are called disease-modifying antirheumatic drugs (DMARDs) and can be associated with serious to potentially fatal infections. If used early in the disease, they can prevent or slow down the damage caused to the joints.
- ▶ The DMARDs can cause local irritation at the injection site to liver impairment and a variety of CNS problems, including demyelinating disorders.

CHAPTER SUMMARY

- The inflammatory response, which is important for protecting the body from injury and invasion, produces many of the signs and symptoms associated with disease, including fever, aches and pains, and lethargy.

- Chronic or excessive activity by the inflammatory response can lead to the release of lysosomal enzymes and tissue destruction.
- Anti-inflammatory drugs block various chemicals associated with the inflammatory reaction. Anti-inflammatory drugs also may have antipyretic (fever-blocking) and analgesic (pain-blocking) activities.
- Salicylates block prostaglandin activity. NSAIDs block prostaglandin synthesis. Acetaminophen causes vasodilation and heat release, lowering fever and working to relieve pain. Gold salts prevent macrophage phagocytosis, lysosomal release, and tissue damage. DMARDs alter the course of the inflammatory process and treats arthritis by aggressively affecting the process of inflammation.
- Salicylates can cause acidosis and eighth cranial nerve damage. NSAIDs are most associated with GI irritation and bleeding. Acetaminophen can cause serious liver toxicity. The gold salts cause many systemic inflammatory reactions. Other antiarthritis drugs are associated with local injection-site irritation and increased susceptibility to infection; leflunomide is associated with severe hepatic toxicity.
- Many anti-inflammatory drugs are available OTC, and care must be taken to prevent abuse or overuse of these drugs.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-Rom in the front of the book.

MULTIPLE CHOICE

Select the best answer to the following.

1. A drug could be classified as an analgesic if it:
 - a. reduces fever.
 - b. reduces swelling.
 - c. reduces redness.
 - d. reduces pain.
2. An antipyretic is a drug that can
 - a. block pain.
 - b. block swelling.
 - c. block fever.
 - d. block inflammation.
3. A nurse might not see a salicylate used as an anti-inflammatory if a drug was needed for its
 - a. antipyretic properties.
 - b. analgesic properties.
 - c. OTC availability.
 - d. parenteral availability.

4. The NSAIDs affect the COX-1 and COX-2 enzymes. By blocking COX-2 enzymes, the NSAIDs block inflammation and the signs and symptoms of inflammation at the site of injury or trauma. By blocking COX-1 enzymes, these drugs block
 - a. fever regulation.
 - b. prostaglandins that protect the stomach lining.
 - c. swelling in the periphery.
 - d. liver function.
5. Your patient has been receiving ibuprofen for many years to relieve the pain of osteoarthritis. Assessment of the patient should include
 - a. an electrocardiogram.
 - b. CBC with differential.
 - c. respiratory auscultation.
 - d. renal evaluation.
6. Patients taking NSAIDs should be taught to avoid the use of OTC medications without checking with their prescriber because
 - a. many of the OTC preparations contain NSAIDs, and inadvertent toxicity could occur.
 - b. no one should take more than one type of pain reliever at a time.
 - c. increased GI upset could occur.
 - d. there is a risk of Reye syndrome.
7. Chronic or excessive activity by the inflammatory response can lead to
 - a. loss of white blood cells.
 - b. coagulation problems.
 - c. release of lysosomal enzymes and tissue destruction.
 - d. adrenal suppression.
8. A patient with rheumatoid arthritis who is on a fixed income and who is being treated with aspirin should be advised
 - a. to use only brand-name aspirin.
 - b. to use only enteric-coated aspirin.
 - c. to use generic aspirin.
 - d. to switch to one of the NSAIDs.

MULTIPLE RESPONSE

Select all that apply.

1. A client is being treated for severe rheumatoid arthritis. The nurse could anticipate treatment with which of the following.
 - a. Etanercept—tumor necrosis factor
 - b. Gold therapy
 - c. Hylan G-F 20—hyalans with elastic properties
 - d. Ketoprofen
 - e. Interferon beta-2a
 - f. Methotrexate
2. The nurse notes an order for oxaprozin (*Daypro*) for the treatment of arthritis. Before administering the drug, the nurse would assess the patient for which problems that could be cautions or contraindications?
 - a. Headaches
 - b. Dysmenorrhea
 - c. Active peptic ulcer disease
 - d. Chronic obstructive pulmonary disease
 - e. Renal impairment
 - f. Bleeding disorders

Immune Modulators

17

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Describe the sites of actions of the various immune modulators.
2. Describe the therapeutic actions, indications, pharmacokinetics, contraindications, most common adverse effects, and important drug–drug interactions associated with each class of immune stimulants and immune suppressants.
3. Discuss the use of immune modulators across the lifespan.
4. Compare and contrast the prototype drugs for each class of immune modulators with the other drugs in that class and with drugs in other classes.
5. Outline the nursing considerations and teaching needs for patients receiving each class of immune modulator.

Glossary of Key Terms

immune stimulant: drug used to energize the immune system when it is exhausted from fighting prolonged invasion or needs help fighting a specific pathogen or cancer cell

immune suppressant: drug used to block or suppress the actions of the T cells and antibody production; used to prevent transplant rejection and to treat autoimmune diseases

monoclonal antibodies: specific antibodies produced by a single clone of B cells to react with a very specific antigen

recombinant DNA technology: use of bacteria to produce chemicals normally produced by human cells

IMMUNE STIMULANTS

Interferons

- interferon alfa-2b
- interferon alfacon-1
- interferon alfa-n3
- interferon beta-1a
- interferon beta-1b
- interferon gamma-1b
- peginterferon alfa-2a
- peginterferon alfa-2b

Interleukins

- aldesleukin
- oprelvekin

IMMUNE SUPPRESSANTS

T- and B-Cell Suppressors

- abatacept
- alefacept
- azathioprine
- cyclosporine
- glatiramer acetate
- mycophenolate
- pimecrolimus
- sirolimus
- tacrolimus

Interleukin-Receptor Antagonist

anakinra

Monoclonal Antibodies

- adalimumab
- alemtuzumab
- basiliximab
- bevacizumab
- certolizumab
- cetuximab
- daclizumab
- eculizumab
- erlotinib

gemtuzumab

ibritumomab

infliximab

muromonab-CD3

natalizumab

omalizumab

palivizumab

pegaptanib

rituximab

tocilizumab

tositumomab

trastuzumab

ustekinumab

As the name implies, immune modulators are used to modify the actions of the immune system. **Immune stimulants** are used to energize the immune system when it is exhausted from fighting prolonged invasion or when the immune system needs help fighting a specific pathogen or cancer cell. **Immune suppressants** are used to block the normal effects of the immune system in cases of organ transplantation (in which non-self-cells are transplanted into the body and destroyed by the immune reaction) and in autoimmune disorders (in which the body's defenses recognize self-cells as foreign and work to destroy them) in some cancers. Each group acts at various sites within the immune response (Figure 17.1).

The knowledge base about the actions and components of the immune system is continually growing and changing. As new discoveries are made and the actions and interactions of the various components of the system become better understood, new applications will be found for modulating the immune system in a variety of disorders. Box 17.1 discusses the use of immune modulators across the lifespan. Box 17.2 discusses use of these agents during pregnancy.

IMMUNE STIMULANTS

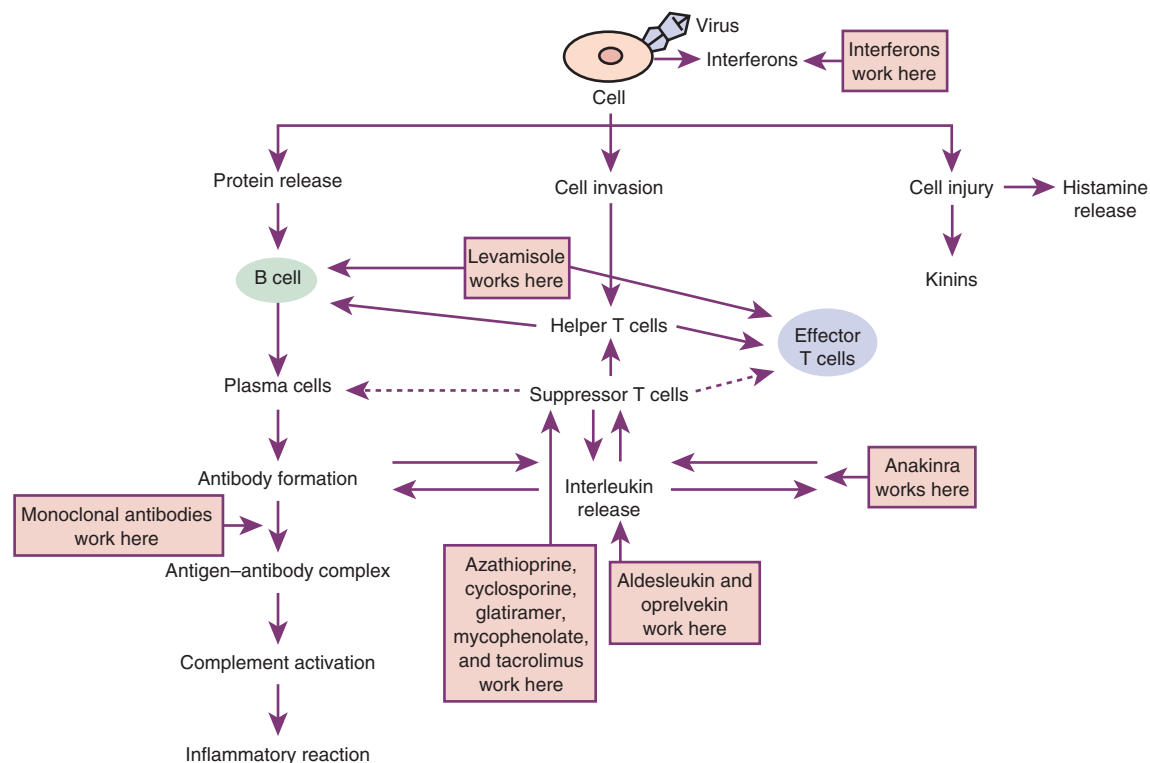

Immune stimulants (Table 17.1) include the interferons, which are naturally released from human cells in response to viral invasion; and interleukins, which are chemicals produced by T cells to communicate between leukocytes.

Interferons

Interferons are substances naturally produced and released by human cells that have been invaded by viruses. They may also be released from cells in response to other stimuli, such as cytotoxic T cell activity. A number of interferons are available for use. Several are produced by **recombinant DNA technology**, including interferon alfa-2b (*Intron-A*), interferon alfacon-1 (*Infergen*), peginterferon alfa-2a (*Pegasys*), peginterferon alfa-2b (*Peg-Intron*), and interferon beta-1b (*Betaseron*). Interferon alfa-n3 (*Alferon N*) is produced by harvesting human leukocytes. Interferon beta-1a (*Avonex*) is produced from Chinese hamster ovary cells. Interferon gamma-1b (*Actimmune*) is produced by *Escherichia coli* bacteria. The interferon of choice depends on the condition being treated (see Table 17.1).

Therapeutic Actions and Indications

Interferons act to prevent virus particles from replicating inside cells. They also stimulate interferon-receptor sites on noninvaded cells to produce antiviral proteins, which prevent viruses from entering the cell. In addition, interferons have been found to inhibit tumor growth and replication, to stimulate cytotoxic T-cell activity, and to enhance the inflammatory response. Of interest, interferon gamma-1b also acts like an interleukin, stimulating phagocytes to be more aggressive. See Table 17.1 for usual indications for each interferon.

● FIGURE 17.1 Sites of action of the immune modulators.

BOX 17.1

Drug Therapy Across the Lifespan

Immune Modulators

CHILDREN

Most of the drugs that affect the immune system are not recommended for use in children or have not been tested in children. The exceptions—interferon alfa-2b, azathioprine, cyclosporine, tacrolimus, and palivizumab—should be used cautiously, monitoring the child frequently for infection, GI, renal, hematological, or CNS effects.

The immune suppressants (azathioprine, cyclosporine, and tacrolimus) are usually needed in higher doses for children than for adults to achieve the same therapeutic effect.

Protecting the child from infection and injury is a very important part of the care of a child taking an immune modulator. This can be a great challenge with an active child.

ADULTS

Both the adult patient who is receiving a parenteral immune modulator and a significant other should learn the proper technique for injection, disposal of needles, and special storage precautions for the drug. It is important to stress ways to avoid exposure to infection and injury to prevent further complications. The patient should be encouraged to seek regular follow-up and medical care.

Immune modulators are contraindicated during pregnancy and lactation because of the potential for adverse effects on the fetus or neonate and complications for the mother. Women of childbearing age should be advised to use barrier contraceptives while taking these drugs and, if breast-feeding, should be counseled to find another method of feeding the baby. Some of these drugs impair fertility, and the patient should be advised of this fact before taking the drug.

OLDER ADULTS

Older patients may be more susceptible to the effects of the immune modulators, partly because the aging immune system is less efficient and less responsive.

These patients need to be monitored closely for infection, GI, renal, hepatic, and CNS effects. Baseline renal and liver function tests can help to determine whether a decreased dosage will be needed before beginning therapy.

Because these patients are more susceptible to infection, they need to receive extensive teaching about ways to avoid infection and injury.

Pharmacokinetics

The interferons are generally well absorbed after subcutaneous or intramuscular injection. They have a rapid onset of action and peak within 3 to 8 hours, with a half-life ranging from 3 to 8 hours, with the exception of interferon beta-1a, which

has an onset of action of 12 hours and reaches peak levels in 48 hours, with a half-life of 10 hours. They are broken down in the liver and kidneys and seem to be excreted primarily through the kidneys.

BOX 17.2

Gender Considerations

Immune Modulators and Pregnancy

Generally, immune modulators are contraindicated for use during pregnancy and lactation, largely because these drugs have been associated with fetal abnormalities, increased maternal and fetal infections, and suppressed immune responses in nursing babies. Female patients should be informed of the risk of using these drugs during pregnancy and receive counseling in the use of barrier contraceptives. (The use of barrier contraceptives is advised because the effects of oral contraceptives may be altered by liver changes or by changes in the body's immune response, potentially resulting in unexpected pregnancy.)

If a patient taking immune modulators becomes pregnant or decides that she wants to become pregnant, she should discuss this with her health care provider and review the risks associated with use of the drug or drugs being taken. The monoclonal antibodies should be used with caution during pregnancy and lactation. Because long-term studies of most of these drugs are not yet available, it may be prudent to advise patients taking these drugs to avoid pregnancy if possible.

Contraindications and Cautions

The use of interferons is contraindicated in the presence of known allergy to any interferon or product components. Many of the interferons are teratogenic in animals and therefore should not be used during pregnancy. Use of barrier contraceptives is advised for women of childbearing age. It is not known whether these drugs cross into breast milk, but because of the potential adverse effects on the baby, it is advised that the drugs not be used during lactation unless the benefits to the mother clearly outweigh any risks to the baby. Caution should be used in the presence of known cardiac disease *because hypertension and arrhythmias have been reported with the use of these drugs*; with myelosuppression *because these drugs may further suppress the bone marrow*; and with central nervous system (CNS) dysfunction of any kind *because of the potential for CNS depression and personality changes that have been reported*.

Adverse Effects

The adverse effects associated with the use of interferons are related to the immune or inflammatory reaction that is being stimulated (stimulating the immune and inflammatory response causes a flu-like syndrome with lethargy, myalgia, arthralgia,

TABLE 17.1 DRUGS IN FOCUS Immune Stimulants

Drug Name	Dosage/Route	Usual Indications
Interferons		
 interferon alfa-2b (Intron-A)	Adult: dose varies widely based on indication Pediatric: for hepatitis B, adjust adult dose to weight	Treatment of leukemias, Kaposi sarcoma, warts, hepatitis B, malignant melanoma
interferon alfacon-1 (Infergen)	9 mcg SQ as a single dose three times per week for 24 wk	Treatment of chronic hepatitis C in adults
interferon alfa-n3 (Alferon N)	250,000 IU intralesionally two times per week for 8 wk	Intralesional treatment of warts; AIDS-related complex; AIDS orphan drug indication
interferon beta-1a (Avonex)	30 mcg IM once a week	Treatment of multiple sclerosis in adults
interferon beta-1b (Betaseron)	0.25 mg SQ every other day; discontinue if disease is unremitting >6 mo	Treatment of multiple sclerosis in adults
interferon gamma-1b (Actimmune)	50 mcg/m ² SQ three times per week	Treatment of serious, chronic granulomatous disease in adults; delaying time to disease progression in severe, malignant osteopetrosis
peginterferon alfa-2b (Peg-Intron)	1 mcg/kg SQ once a week for 1 y	Treatment of chronic hepatitis C in adults
Interleukins		
 aldesleukin (Proleukin)	Two 5-d cycles of 600,000 IU/kg IV q8h given over 15 min	Treatment of specific renal carcinomas in adults; also, drug is being investigated for use in the treatment of AIDS and AIDS-related disorders
oprelvekin (Neumega)	50 mcg/kg per day SQ starting 1 d after chemotherapy and continuing for 14–21 d	Prevention of severe thrombocytopenia (an abnormal decrease in the number of platelets) after myelosuppressive chemotherapy

anorexia, nausea). Other commonly seen adverse effects include headache, dizziness, bone marrow depression, depression and suicidal ideation, photosensitivity, and liver impairment.

Clinically Important Drug–Drug Interactions

There are no reported clinically important drug–drug interactions with the interferons.

Prototype Summary: Interferon Alfa-2b

Indications: Hairy cell leukemia, malignant melanoma, AIDS-related Kaposi sarcoma, chronic hepatitis B and C, intralesional treatment of condylomata acuminata in patients 18 years of age or older.

Actions: Inhibits the growth of tumor cells and enhances the immune response

Pharmacokinetics:

Route	Onset	Peak
IM, SQ	Rapid	3–12 h
IV	Rapid	End of infusion

$T_{1/2}$: 2 to 3 hours; metabolized in the kidney, excretion is unknown.

Adverse effects: Dizziness, confusion, rash, dry skin, anorexia, nausea, bone marrow suppression, flu-like syndrome.

Interleukins

Interleukins are synthetic compounds much like the interferons; they communicate between lymphocytes, which stimulate cellular immunity and inhibit tumor growth. Interleukin-2 stimulates cellular immunity by increasing the activity of natural killer cells, platelets, and cytokines. Two interleukin preparations are available for use. Aldesleukin (*Proleukin*) is a human interleukin produced by recombinant DNA technology using *E. coli* bacteria. Oprelvekin (*Neumega*) is a newer agent that is also produced by DNA technology (see Table 17.1).

Therapeutic Actions and Indications

Natural interleukin-2 is produced by various lymphocytes to activate cellular immunity and inhibit tumor growth by increasing lymphocyte numbers and their activity. When interleukins

are administered, there are increases in the numbers of natural killer cells and lymphocytes, in cytokine activity, and in the number of circulating platelets. See Table 17.1 for usual indications.

Pharmacokinetics

The interleukins are rapidly distributed after injection. Aldesleukin, given IV, reaches peak levels in 13 minutes and has a half-life of 85 minutes. Oprelvekin, which is given subcutaneously, reaches peak levels in 3 to 5 hours and had a half-life of 7 to 8 hours. They are primarily cleared from the body by the kidneys.

Contraindications and Cautions

Interleukins are contraindicated in the presence of any allergy to an interleukin or *E. coli*-produced product. They were shown to be embryocidal and teratogenic in animal studies and should not be used during pregnancy. Use of barrier contraceptives is recommended for women of childbearing age who require one of these drugs. It is not clear whether the drugs cross into breast milk, but it is recommended that they not be used during lactation; if they must be used, another method of feeding the baby must be chosen because of the potential for adverse effects in the baby. Caution should be used with renal, liver, or cardiovascular impairment *because of the adverse effects of the drugs*.

Adverse Effects

The adverse effects associated with the interleukins can be attributed to their effect on the body during inflammation (flu-like effects: lethargy, myalgia, arthralgia, fatigue, fever). Respiratory difficulties, CNS changes, and cardiac arrhythmias also have been reported, and the patient should be monitored for these effects and the drug stopped if they do occur. Oprelvekin has been associated with severe hypersensitivity reactions, and patients should be closely watched when beginning therapy and encouraged to report any difficulty breathing or swallowing, chest tightness, or swelling.

Clinical Important Drug–Drug Interactions

There are no reported drug–drug interactions with the interleukins.

Prototype Summary: Aldesleukin

Indications: Metastatic renal cell carcinoma in adults; treatment of metastatic melanomas (orphan drug use).

Actions: Activates human cellular immunity and inhibits tumor growth through increases in lymphocytes, platelets, and cytokines.

Pharmacokinetics:

Route	Onset	Peak	Duration
IV	5 min	13 min	3–4 h

$T_{1/2}$: 85 minutes; metabolized in the kidney and excreted in the urine.

Adverse effects: Mental status changes, dizziness, hypotension, sinus tachycardia, arrhythmias, pruritus, nausea, vomiting, diarrhea, anorexia, gastrointestinal (GI) bleed, bone marrow suppression, respiratory difficulties, fever, chills, pain.

Nursing Considerations for Patients Receiving Immune Stimulants

Assessment: History and Examination

- Assess for contraindications and cautions: known allergies to any of these drugs or their components *to prevent hypersensitivity reactions*; current status related to pregnancy or lactation *to avoid serious adverse effects on the fetus or baby*; history of hepatic, renal, or cardiac disease, bone marrow depression, and CNS disorders, including seizures, *all of which could be exacerbated by the effects of these drugs*.
- Perform a physical assessment to determine *baseline status before beginning therapy and for any potential adverse effects*: inspect for the presence of any skin lesions *to detect early dermatological effects*; obtain weight *to monitor for fluid retention*; monitor temperature *to detect any infection*; check heart rate and rhythm and blood pressure *to monitor for any cardiac effects of the drug*; assess level of orientation and reflexes *to evaluate CNS effects of the drug*.
- Obtain a baseline electrocardiogram (ECG) *to evaluate cardiac function and monitor adverse effects of the drugs*.
- Assess patient's renal and liver function, including renal and liver function tests, *to determine the appropriateness of therapy and to determine the need for possible dose adjustment and toxic drug effects*.
- Monitor the results of laboratory tests such as complete blood count (CBC) *to identify changes in bone marrow function*.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to CNS, GI, and flu-like effects
- Imbalanced Nutrition: Less Than Body Requirements related to flu-like effects
- Anxiety related to diagnosis and drug therapy
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Arrange for laboratory tests before and periodically during therapy, including CBC and differential, *to monitor for drug effects and adverse effects*.

- Administer drug as indicated; instruct the patient and a significant other if injections are required *to ensure that the drug will be given even if the patient is not able to administer it.*
- Monitor for severe reactions, such as severe hypersensitivity reactions, and *arrange to discontinue the drug immediately if they occur.*
- Arrange for supportive care and comfort measures for flu-like symptoms (e.g., rest, environmental control, acetaminophen) *to help the patient cope with the drug effects.* Ensure that the patient is well hydrated during therapy *to prevent severe adverse effects.*
- Instruct female patients in the use of barrier contraceptives *to avoid pregnancy during therapy because of the potential for adverse effects on the fetus.*
- Offer support and encouragement *to deal with the diagnosis and the drug regimen.*
- Provide patient teaching about measures to avoid adverse effects; warning signs of problems; and proper administration technique.

Evaluation

- Monitor patient response to the drug (improvement in condition being treated).
- Monitor for adverse effects (flu-like symptoms, GI upset, CNS changes, bone marrow depression).
- Evaluate the effectiveness of the teaching plan (patient can name drug, dosage, adverse effects to watch for, specific measures to avoid adverse effects).
- Monitor the effectiveness of comfort measures and compliance with the regimen.

KEY POINTS

- ▶ Immune stimulants assist the immune system to fight specific pathogens or cancer cells; in doing so they cause flu-like symptoms (lethargy, muscle and joint aches and pains, anorexia, nausea).
- ▶ Interferons are used to treat various cancers and warts.
- ▶ Interleukins stimulate cellular immunity and inhibit tumor growth.

IMMUNE SUPPRESSANTS

Immune suppressants (Table 17.2) often are used in conjunction with corticosteroids, which block the inflammatory reaction and decrease initial damage to cells. They are especially beneficial in cases of organ transplantation and in the treatment of autoimmune diseases. The immune suppressants include T- and B-cell suppressors, an interleukin-receptor antagonist, and **monoclonal antibodies**—antibodies produced by a single clone of B cells that react with specific antigens.

T- and B-Cell Suppressors

Several T- and B-cell immune suppressors are available for use. Of the numerous agents available, cyclosporine is the

most commonly used immune suppressant. Additional agents include abatacept (*Orencia*), alefacept (*Amevive*), azathioprine (*Imuran*), cyclosporine (*Sandimmune*, *Neoral*), glatiramer (*Copaxone*), mycophenolate (*CellCept*), pimecrolimus (*Elidel*), sirolimus (*Rapamune*), and tacrolimus (*Prograf*).

Therapeutic Actions and Indications

The exact mechanism of action of the T- and B-cell suppressors is not clearly understood. It has been shown that they block antibody production by B cells, inhibit suppressor and helper T cells, and modify the release of interleukins and of T-cell growth factor (see Figure 17.1).

The T- and B-cell suppressors are indicated for the prevention and treatment of specific transplant rejections. See Table 17.2 for usual indications of each agent.

Pharmacokinetics

Cyclosporine is well absorbed from the GI tract, reaching peak levels in 1 to 2 hours. It is extensively metabolized in the liver by the cytochrome P450 system and is primarily excreted in the bile. The half-life of the drug is about 19 hours for *Sandimmune* and 8.4 hours for *Neoral*. It is available as an oral solution that can be mixed with milk, chocolate milk, or orange juice for ease of administration. Abatacept must be given as a 30-minute infusion every 2 to 4 weeks, depending on the patient's response. Peak levels are reached at the end of the infusion. Abatacept has a half-life of 12 to 23 days and usually reaches a steady state by 60 days of treatment. The drug is cleared from the body by the kidneys.

Alefacept is rapidly absorbed and can be given IM or IV. It reaches peak levels in 4 to 6 hours and has a half-life of 270 hours.

Azathioprine is rapidly absorbed from the GI tract, reaching peak levels in 1 to 2 hours. This drug is catabolized in the liver and red blood cells.

Little is known about the pharmacokinetics of glatiramer. Some of it is immediately hydrolyzed on injection, some enters the lymph system, and some may actually reach the systemic circulation.

Mycophenolate is readily absorbed and immediately metabolized to its active metabolite. Most of the metabolized drug is then excreted in the urine.

Sirolimus is rapidly absorbed from the GI tract, reaching peak levels in 1 hour. It is extensively metabolized in the liver, partly by the cytochrome P450 system. The drug is then excreted primarily in the feces.

Tacrolimus is rapidly absorbed from the GI tract, reaching peak levels in 1.5 to 3.5 hours. It is extensively metabolized in the liver by the cytochrome P450 system and is excreted in the urine.

Contraindications and Cautions

The use of T- and B-cell suppressors is contraindicated in the presence of any known allergy to the drug or its components

TABLE 17.2 DRUGS IN FOCUS Immune Suppressants

Drug Name	Dosage/Route	Usual Indications
T- and B-Cell Suppressors		
abatacept (<i>Orencia</i>)	<60 kg: 500 mg IV repeated at 2 and 4 wk, then every 4 wk 60–100 kg: 750 mg IV, repeated at 2 and 4 wk, then every 4 wk >100 kg: 1 g IV, repeated at 2 and 4 wk, then every 4 wk	Reduction of the signs and symptoms and slowing structural damage in adults with rheumatoid arthritis who have inadequate response to other drugs
alefacept (<i>Amevive</i>)	7.5-mg IV bolus once a week or 15 mg IM once a week, in 12-wk cycles	Treatment of adults with moderate to severe chronic plaque psoriasis who are candidates for systemic therapy
azathioprine (<i>Imuran</i>)	Adult: 3–5 mg/kg day PO for prevention of rejection; maintenance: 1–3 mg/kg per day PO Rheumatoid arthritis: 1–2.5 mg/kg per day PO; reduce dose with renal impairment Pediatric: 3–5 mg/kg per day IV or PO to prevent rejection; maintenance: 1–3 mg/kg per day PO	Prevention of rejection in renal homotransplants; treatment of rheumatoid arthritis
 cyclosporine (<i>Sandimmune</i>)	15 mg/kg PO as a single oral dose 4–12 h before transplantation, then 5–10 mg/kg per day PO Pediatric: larger doses may be needed to achieve therapeutic levels	Suppression of rejection in a variety of transplant situations
(<i>Neoral</i>)	9–15 mg/kg PO as a single oral dose 4–12 h before transplantation, then 5–10 mg/kg per day PO—titrate down Rheumatoid arthritis: 2.5 mg/kg per day PO in two divided doses Psoriasis: 2.5 mg/kg PO b.i.d.	Treatment of rheumatoid arthritis, psoriasis
glatiramer acetate (<i>Copaxone</i>)	20 mg/d SQ	Reduction of the number of relapses in multiple sclerosis in adults
mycophenolate (<i>CellCept</i>)	1–1.5 mg PO b.i.d.; may be started IV during transplantation, with switch to oral route as soon as possible	Prevention of rejection after renal, hepatic, or heart transplantation in adults; not for use in pregnancy
sirolimus (<i>Rapamune</i>)	6 mg PO as soon after transplant as possible; then 2 mg/d PO Children <13 yr: 3 mg/m ² PO loading dose, then 1 mg/m ² per day PO	Prevention of rejection after renal transplantation
Interleukin-Receptor Antagonist		
anakinra (<i>Kineret</i>)	0.10–0.2 mg/kg per day PO in two divided doses; may begin as continuous IV infusion of 0.03–0.05 mg/kg per day, with switch to oral form as soon as possible Pediatric: may require higher doses to achieve therapeutic levels 100 mg/day SQ	Prevention of rejection after renal or liver transplantation; reduction of the signs and symptoms and slowing structural damage in adults with rheumatoid arthritis who have inadequate response to other drugs
Monoclonal Antibodies		
adalimumab (<i>Humira</i>)	40 mg SQ every other week; if also taking methotrexate, may require 40 mg SQ once a week	Reduction of signs and symptoms and inhibition of structural damage in adults who have moderate to severe rheumatoid arthritis and who have not responded to other drugs

(drug table continues on page 270)

TABLE 17.2 DRUGS IN FOCUS Immune Suppressants (continued)

Drug Name	Dosage/Route	Usual Indications
Monoclonal Antibodies (continued)		
alemtuzumab (<i>Campath</i>)	3 mg/d IV as a 2-h infusion; increase slowly to maintenance dose of 30 mg/d IV three times per week for up to 12 wk	Treatment of B-cell chronic lymphocytic leukemia in patients who have been treated with alkylating agents and have failed fludarabine therapy
basiliximab (<i>Simulect</i>)	20 mg IV twice—first dose within 24 h of transplantation, then at 4 d	Prevention of renal transplant rejection
certolizumab (<i>Cimzia</i>)	400 mg subcutaneously, repeated at weeks 2 and 4, then every 4 wk	Reduction of the signs and symptoms of Crohn disease in adults with moderate to severe disease not controlled by standard therapy
daclizumab (<i>Zenapax</i>)	1 mg/kg IV for 5 doses, the first within 24 h of transplantation and the last within 14 d after transplantation	Prevention of renal transplant rejection
eculizumab (<i>Soliris</i>)	600 mg IV every 7 d for 4 wk, then 900 mg every 7 d, followed by 900 mg every 14 d	Treatment of paroxysmal nocturnal hemoglobinuria, a rare genetic condition in which patients have generations of abnormal blood cells that are lysed by the body, to reduce hemolysis
gemtuzumab (<i>Mylotarg</i>)	9 mg/m ² IV over 2 h, 2 doses given 14 d apart	Treatment of CD33-positive acute myelogenous leukemia in the first relapse in patients >60 years who are not candidates for cytotoxic chemotherapy
ibritumomab (<i>Zevalin</i>)	2 mg of antibody labeled with 0.3 or 0.4 mCi/kg of yttrium-90 IV	Treatment of B-cell non-Hodgkin lymphoma in conjunction with rituximab
infliximab (<i>Remicade</i>)	5 mg/kg IV over 2 h; may be repeated at 2 and 6 wk	Decreases signs and symptoms of Crohn disease in patients who do not respond to other therapy; treatment of fistulating Crohn disease; also approved for use with methotrexate in the treatment of progressing moderate to severe rheumatoid arthritis
 muromonab-CD3 (<i>Orthoclone OKT3</i>)	5 mg/d IV for 10–14 d infused as an IV bolus over <1 min	Prevention of renal transplant rejection; treatment of steroid-resistant rejection of heart and liver transplants in adults
omalizumab (<i>Xolair</i>)	0.15 mg/kg per day SQ	Treatment of asthma with a very strong allergic component and seasonal allergic rhinitis not well controlled with traditional medications
palivizumab (<i>Synagis</i>)	15 mg/kg IM as a single dose at the start of respiratory syncytial virus (RSV) season	Prevention of serious RSV infection in high-risk children
pegaptanib (<i>Macugen</i>)	Injected into the intravitreal fluid of the eye once every 6 wk	Treatment of neovascular (wet) age-related macular degeneration
rituximab (<i>Rituxan</i>)	375 mg/m ² IV once weekly for 4 doses	Treatment of relapsed follicular B-cell non-Hodgkin lymphoma
tocilizumab (<i>Actemra</i>)	4–8 mg/kg IV every 4 wk, with methotrexate	Relief of signs and symptoms of moderate to severe rheumatoid arthritis in adults
tositumomab with I 131 tositumomab (<i>Bexxar</i>)	450 mg IV in 50 mL of 0.9% sodium chloride over 60 min, then 35 mg of I-131 tositumomab over 30 min; repeat based on response	CD-20–positive follicular non-Hodgkin lymphoma when disease is refractory to rituximab and relapsed following chemotherapy
trastuzumab (<i>Herceptin</i>)	4 mg/kg IV over 90 min, then 2 mg/kg IV once a week over at least 30 min	Treatment of metastatic breast cancer with tumors that overexpress human epidermal growth factor receptor 2 (HER2)
Ustekinumab (<i>Stelara</i>)	45–90 mg by SQ injection once a week, progressing to once a month, then once every 3 mo as determined by patient condition and response	Treatment of recalcitrant plaque psoriasis in adults not responsive to traditional therapy

and during pregnancy and lactation *because of the potential serious adverse effects on the fetus or neonate*. Caution should be used with renal or hepatic impairment, *which could interfere with the metabolism or excretion of the drug*, and in the presence of known neoplasms, *which potentially could spread with immune system suppression*.

Adverse Effects

Patients receiving these drugs are at increased risk for infection and for the development of neoplasms due to their blocking effect on the immune system. Other potentially dangerous adverse effects include hepatotoxicity, renal toxicity, renal dysfunction, and pulmonary edema. Patients may experience headache, tremors, secondary infections such as acne, GI upset, diarrhea, and hypertension.

Clinically Important Drug–Drug Interactions

There is an increased risk of toxicity if these drugs are combined with other drugs that are hepatotoxic or nephrotoxic. Extreme care should be used if such combinations are necessary. Other reported drug–drug interactions are drug specific; consult a drug guide or drug handbook.

Prototype Summary: Cyclosporine

Indications: Prophylaxis for organ rejection in kidney, liver, and heart transplants (used with corticosteroids); treatment of chronic rejection in patients previously treated with other immunosuppressants; treatment of rheumatoid arthritis and recalcitrant psoriasis.

Actions: Reversibly inhibits immunocompetent lymphocytes; inhibits T helper cells and T suppressor cells, lymphokine production, and release of interleukin-2 and T-cell growth factor.

Pharmacokinetics:

Route	Onset	Peak
PO	Varies	3.5 h
IV	Rapid	1–2 h

$T_{1/2}$: 19 to 27 hours; metabolized in the liver and excreted in the bile and urine.

Adverse effects: Tremor, hypertension, gum hyperplasia, renal dysfunction, diarrhea, hirsutism, acne, bone marrow suppression.

Interleukin-Receptor Antagonist

An interleukin-receptor antagonist works to block the activity of the interleukins that are released in an inflammatory or immune response. The only available interleukin receptor

antagonist is anakinra (*Kineret*). See Table 17.2 for additional information about this drug.

Therapeutic Actions and Indications

Anakinra specifically antagonizes human interleukin-1 receptors, blocking the activity of interleukin-1. Interleukin-1 levels are elevated in response to inflammation or immune reactions and are thought to be responsible for the degradation of cartilage that occurs in rheumatoid arthritis. Anakinra is used to reduce the signs and symptoms of moderately to severely active rheumatoid arthritis in patients 18 years of age and older who have not responded to the traditional antirheumatic drugs.

Pharmacokinetics

The recommended dosage is 100 mg/d by subcutaneous injection. Anakinra is administered by subcutaneous injection and is absorbed slowly, reaching peak effects in 3 to 7 hours. It is metabolized in the tissues with a 4- to 6-hour half-life and is excreted in the urine.

Contraindications and Cautions

Anakinra is contraindicated with any known allergy to *E. coli*-produced products or to anakinra itself. It should be used with caution during pregnancy and lactation *because the drug may cross the placenta and enter breast milk*. It also is used cautiously in patients with renal impairment, immunosuppression, or any active infection *because these could be exacerbated by the effects of the drug*. There is an increased risk of infection whenever this drug is used, and the patient needs to be protected from exposure to infections and monitored closely after any invasive procedures. Immunizations cannot be given while the patient is on this drug.

Adverse Effects

Headache, sinusitis, nausea, diarrhea, upper respiratory and other infections, and injection-site reactions are among the most common adverse effects.

Clinically Important Drug–Drug Interactions

Patients who are also receiving etanercept (*Enbrel*) must be monitored very closely because severe and even life-threatening infections have occurred. Anakinra should not be combined with abatacept because of the potential for serious infections.

Monoclonal Antibodies

Antibodies that attach to specific receptor sites are being developed to respond to very specific situations. Every year,

several new monoclonal antibodies are marketed, showing the rapid pace with which these agents are being developed and approved for clinical use. Monoclonal antibodies include adalimumab (*Humira*), alemtuzumab (*Campath*), basiliximab (*Simulect*), bevacizumab (*Avastin*), cetuximab (*Erbix*), certolizumab (*Cimzia*), daclizumab (*Zenapax*), eculizumab (*Soliris*), erlotinib (*Tarceva*), gemtuzumab (*Mylotarg*), ibritumomab (*Zevalin*), infliximab (*Remicade*), natalizumab (*Tysabri*), omalizumab (*Xolair*), palivizumab (*Synagis*), pegaptanib (*Macugen*), rituximab (*Rituxan*), tocilizumab (*Actemra*), tositumomab combined with iodine-131 tositumomab (*Bexxar*), trastuzumab (*Herceptin*), and ustekinumab (*Stelara*).

Therapeutic Actions and Indications

Muromonab-CD3, the first monoclonal antibody approved for use, is a T-cell-specific antibody that is available as an IV agent. It reacts as an antibody to human T cells, disabling the T cells and acting as an immune suppressor (see Figure 17.1). Muromonab is indicated for the treatment of acute allograft rejection in patients undergoing renal transplantation. It also is indicated for the treatment of steroid-resistant acute allograft rejection in those receiving heart or liver transplants.

Adalimumab, certolizumab, and infliximab are antibodies specific for human tumor necrosis factor. It keeps the inflammatory reaction in check by reacting with and deactivating the free-floating tumor necrosis factor released by active leukocytes.

Alemtuzumab is an antibody specific for lymphocyte-receptor sites.

Basiliximab and daclizumab are specific to interleukin-2 receptor sites on activated T lymphocytes; they react with those sites and block cellular response to allograft transplants.

Cetuximab is an antibody specific to epidermal growth factor receptor sites. Trastuzumab also reacts with human epidermal growth factor receptor 2 (HER2), a genetic defect that is seen in certain metastatic breast cancers. It is used in the treatment of metastatic breast cancer in tumors that overexpress HER2.

Eculizumab binds to complement proteins and prevents the formation of the complement complex.

Erlotinib, bevacizumab, pegaptanib, and tositumomab combined with iodine-131 tositumomab are effective against specific malignant receptor sites.

Gemtuzumab is an antibody to CD33 sites found in acute myelocytic leukemia. It is given IV to treat the first relapse in patients 60 years of age or older who are not candidates for cytotoxic chemotherapy.

Ibritumomab and rituximab are antibodies specific to sites on activated B lymphocytes.

Natalizumab is an antibody specific to surface receptors on all leukocytes except neutrophils.

Omalizumab is an antibody to immunoglobulin E, an important factor in allergic reactions. It has not had a great deal of success because of related respiratory adverse effects.

Palivizumab is specific to the antigenic site on respiratory syncytial virus (RSV); it inactivates that virus. It is used to prevent RSV disease in high-risk children.

Tocilizumab and ustekinumab are antibodies specific to interleukins.

Pharmacokinetics

With the exception of erlotinib (an oral agent), all of the monoclonal antibodies have to be injected. They can be given IV, IM, or SQ. Because antibodies are proteins, they are rapidly broken down in the GI tract. They are processed by the body like naturally occurring antibodies.

Contraindications and Cautions

Monoclonal antibodies are contraindicated in the presence of any known allergy to the drug or to murine products and in the presence of fluid overload. They should be used cautiously with fever (treat the fever before beginning therapy) and in patients who have had previous administration of the monoclonal antibody (*serious hypersensitivity reactions can occur with repeat administration*). Because of the potential for adverse effects, they should not be used during pregnancy or lactation unless the benefit clearly outweighs the potential risk to the fetus or neonate.

Adverse Effects

The most serious adverse effects associated with the use of monoclonal antibodies are acute pulmonary edema (dyspnea, chest pain, wheezing), which is associated with severe fluid retention, and cytokine release syndrome (flu-like symptoms that can progress to third-spacing of fluids and shock). Other adverse effects that can be anticipated include fever, chills, malaise, myalgia, nausea, diarrhea, vomiting, and increased susceptibility to infection.

Eculizumab can lead to intravascular hemolysis with resultant fatigue, pain, dark urine, shortness of breath, and blood clots.

Erlotinib is reserved for patients whose disease has progressed after other therapies.

Gemtuzumab is commonly associated with fever after infusion of the drug, and it is important to make sure that the patient is well hydrated.

The manufacturer of natalizumab stopped marketing the drug weeks after its release because of reports of CNS complications. It was returned to the market in June 2006 with warnings about the potential for CNS complications.

Clinically Important Drug–Drug Interactions

Use caution and arrange to reduce the dose if a monoclonal antibody is combined with any other immunosuppressant drug because severe immune suppression with increased infections and neoplasms can occur.

Prototype Summary: Muromonab-CD3

Indications: Treatment of acute allograft rejection in renal transplant patients; treatment of steroid-resistant acute allograft rejection in cardiac and hepatic transplant patients.

Actions: Monoclonal antibody to the antigen of human T cells; functions as an immunosuppressant by enabling T cells.

Pharmacokinetics:

Route	Onset	Peak	Duration
IV	Minutes	2–7 d	7 d

$T_{1/2}$: 47 to 100 hours; metabolized in the tissues.

Adverse effects: Malaise, tremors, vomiting, nausea, diarrhea, acute pulmonary edema, dyspnea, fever, chills, increased susceptibility to infection.

Nursing Considerations for Patients Receiving Immune Suppressants

Assessment: History and Examination

- Assess for contraindications and cautions: any known allergies to any of these drugs or their components to prevent hypersensitivity reactions; current status related to pregnancy or lactation because of the potential risk to the fetus or baby; history of renal or hepatic impairment that might interfere with drug metabolism and excretion; and history of neoplasm, which could be exacerbated with the use of these drugs.
- Perform a physical assessment to determine baseline status before beginning therapy and for any potential adverse effects: Inspect the skin to detect the presence of any lesions; obtain weight to monitor for fluid retention; monitor temperature to monitor for potential infection; monitor pulse and blood pressure to assess the cardiac effects of these drugs; assess level of orientation and reflexes to monitor for any CNS changes associated with drug use.
- Obtain a baseline ECG to evaluate cardiac function.
- Assess the patient's renal and liver function, including renal and liver function tests, to determine the appropriateness of therapy and determine the need for possible dose adjustment and toxic drug effects.
- Monitor the results of laboratory tests such as CBC to identify changes in bone marrow function.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include:

- Acute Pain related to CNS, GI, and flu-like effects
- Risk for Infection related to immune suppression
- Imbalanced Nutrition: Less Than Body Requirements, related to nausea and vomiting
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Arrange for laboratory tests before and periodically during therapy, including CBC, differential, and liver and renal function tests, to monitor for drug effects and adverse effects.
- Administer the drug as indicated; instruct the patient and a significant other if injections are required to ensure proper administration of the drug.
- Protect the patient from exposure to infections and maintain strict aseptic technique for any invasive procedures to prevent infections during immunosuppression.
- Arrange for supportive care and comfort measures for flu-like symptoms (rest, environmental control, acetaminophen) to decrease patient discomfort and increase therapeutic compliance.
- Monitor nutritional status during therapy; provide small, frequent meals, mouth care, and nutritional consultation as necessary to ensure adequate nutrition.
- Instruct female patients in the use of barrier contraceptives to avoid pregnancy during therapy because of the risk of adverse effects to the fetus.
- Offer support and encouragement to help the patient deal with the diagnosis and the drug regimen.
- Provide thorough patient teaching, including measures to avoid adverse effects, warning signs of problems, and proper administration, to increase knowledge about drug therapy and to increase compliance with the drug regimen.
- Offer support and encouragement to help the patient deal with the diagnosis and the drug regimen.

Evaluation

- Monitor patient response to the drug (prevention of transplant rejection; improvement in autoimmune disease or cancer; prevention of RSV disease; improvement in signs and symptoms of Crohn disease or rheumatoid arthritis).
- Monitor for adverse effects (flu-like symptoms, GI upset, increased infections, neoplasms, fluid overload).
- Evaluate the effectiveness of the teaching plan (patient can name drug, dosage, adverse effects to watch for, specific measures to avoid adverse effects, proper administration technique).
- Monitor the effectiveness of comfort measures and compliance to the regimen (see Critical Thinking Scenario).

KEY POINTS

- Immune suppressants are used to depress the immune system when needed to prevent transplant rejection or severe tissue damage associated with autoimmune disease. Research is ongoing to extend the use of various immune suppressants to other situations, including various autoimmune disorders.
- Increased susceptibility to infection and increased risk of neoplasm are potentially dangerous effects associated with the use of immune suppressants. Patients need to be protected from infection, injury, and invasive procedures.

CRITICAL THINKING SCENARIO

Holistic Care for a Transplantation Patient

THE SITUATION

After waiting on a transplant list for 4 years, T.B. received a human heart transplant to replace his heart, which had been severely damaged by cardiomyopathy. Before getting the transplant, T.B. was bedridden, on oxygen, and near death. The transplant has given T.B. a “new lease on life,” and he is determined to do everything possible to stay healthy and improve his activity and lifestyle. Currently, he is being maintained on cyclosporine, mycophenolate, and corticosteroids.

CRITICAL THINKING

- What important teaching facts would help T.B. to achieve his goal? *Think about the psychological impact of the heart transplant and the “new lease on life.”*
- What activity, dietary, and supportive guidelines should be outlined for T.B.?
- What impact will T.B.’s drug regimen have on his plans? How can all of the aspects of his condition and medical care be coordinated to give T.B. the best possible advantages for the future?

DISCUSSION

T.B.’s medical regimen will include a very complicated combination of rehabilitation, nutrition, drug therapy, and prevention. T.B. should know the risks of transplant rejection and the measures that will be used to prevent it. He also should know the names of his medications and when to take them, the signs and symptoms of rejection to watch for, and what to do if they occur. T.B. must understand the need to prevent exposure to infections and the precautions required, such as avoiding crowded areas and people with known diseases, avoiding injury, and taking steps to maintain cleanliness and avoid infection if an injury occurs.

The medications that T.B. is taking may cause him to experience flu-like symptoms, which can be quite unpleasant. A restful, quiet environment may help to decrease his stress. Acetaminophen may be ordered to help alleviate the fever, aches, and pains.

T.B. also may experience gastrointestinal upset, nausea, and vomiting related to drug effects. A nutritional consultation may be requested to help T.B. maintain a good nutritional state. Frequent mouth care and small, frequent meals may help. Proper nutrition will help T.B. to recover, heal, and maintain his health.

T.B.’s primary health care provider will need to work with the transplantation surgeon, rehabilitation team, nutritionist, and cardiologist to coordinate a total program that will help T.B. to avoid problems and make the most of his transplanted heart.

NURSING CARE GUIDE FOR T.B.: CYCLOSPORINE, MYCOPHENOLATE, AND CORTICOSTEROIDS

Assessment: History and Examination

- Assess for history of allergies to any immune suppressant, renal or hepatic impairment, history of neoplasm, concurrent use of cholestyramine, theophylline, phenytoin, other nephrotoxic drugs, digoxin, lovastatin, diltiazem, metoclopramide, nicardipine, amiodarone, androgens, azole antifungals, macrolides; grapefruit juice.
- Review physical examination findings, including orientation, reflexes, affect (neurological); temperature and weight (general); pulse, cardiac auscultation, blood pressure, edema, electrocardiogram (cardiovascular); liver evaluation (GI); and laboratory test results (complete blood count, liver and renal function tests, condition being treated)

Nursing Diagnoses

- Acute Pain related to CNS, GI, flu-like symptoms
 Risk for Infection related to immune suppression
 Imbalanced Nutrition: Less Than Body Requirements related to GI effects
 Activity Intolerance related to fatigue, drug effects
 Deficient Knowledge regarding drug therapy

Implementation

- Arrange for laboratory tests before and periodically during therapy.
- Administer drug as indicated.
- Protect patient from exposure to infection.
- Provide supportive and comfort measures to deal with adverse effects.
- Monitor nutritional status and intervene as needed.
- Provide patient teaching regarding the drugs and their dosage, adverse effects, precautions, and warning signs to report to care provider.

Evaluation

- Evaluate drug effects: prevention of transplant rejection, improvement of autoimmune disease.
- Monitor for adverse effects: infection, flu-like symptoms, GI upset, fluid overload, neoplasm.
- Monitor for drug–drug interactions and drug–food interactions.
- Evaluate effectiveness of patient teaching program and of comfort and safety measures.

PATIENT TEACHING FOR T.B.: CYCLOSPORINE, MYCOPHENOLATE, AND CORTICOSTEROIDS

- You will need to take a combination of drugs to prevent your body from rejecting your new organ. These drugs

Holistic Care for a Transplantation Patient (continued)

include cyclosporine, mycophenolate, and corticosteroids. They suppress the activity of your immune system and prevent your body from rejecting any transplanted tissue.

- You should never stop taking your drugs without consulting your health care provider. If your prescription is low or you are unable to take the medication for *any* reason, notify your health care provider.
- You should not take your cyclosporine with grapefruit juice.
- Some of the following adverse effects may occur:
 - *Nausea, vomiting:* Taking the drug with food and eating small frequent meals may help. It is very important that you maintain good nutrition. A consult with a nutritionist may be needed to help you if these GI problems are severe.
 - *Diarrhea:* This may not decrease; ensure ready access to bathroom facilities.
 - *Flu-like symptoms:* Rest and a cool, peaceful environment may help; acetaminophen may be ordered to help relieve discomfort.
- *Rash, mouth sores:* Frequent skin and mouth care may ease these effects.
- You will be more susceptible to infection because your body's normal defenses will be decreased. You should avoid crowded places, people with known infections, and working in soil. If you notice any signs of illness or infection, notify your health care provider immediately.
- Tell any doctor, nurse, or other health care provider involved in your care that you are taking these drugs.
- You will need to schedule periodic blood tests and perhaps biopsies while you are being treated with these drugs.
- Report any of the following to your health care provider: unusual bleeding or bruising, fever, sore throat, mouth sores, fatigue, and any other signs of infection or injury.
- Keep your medications safely out of the reach of children and pets and do not share medications with anyone else.

CHAPTER SUMMARY

- Immune stimulants boost the immune system when it is exhausted from fighting off prolonged invasion or needs help to fight a specific pathogen or cancer cell. They include interferons and interleukins.
- Interferons are naturally released from cells in response to viral invasion; they are used to treat various cancers and warts.
- Interleukins stimulate cellular immunity and inhibit tumor growth; they are used to treat very specific cancers.
- Adverse effects seen with immune stimulants are related to the immune response (flu-like symptoms, including fever, myalgia, lethargy, arthralgia, and fatigue).
- Immune suppressants are used to depress the immune system when needed to prevent transplant rejection or severe tissue damage associated with autoimmune disease. Research is ongoing to extend the use of various immune suppressants to other situations, including various autoimmune disorders.
- Increased susceptibility to infection and increased risk of neoplasm are potentially dangerous effects associated with

the use of immune suppressants. Patients need to be protected from infection, injury, and invasive procedures.

**WEB LINKS**

Health care providers and patients may want to consult the following Internet sources:

<http://www.oncolink.upenn.edu>

Information on cancers (including leukemias and Kaposi sarcoma) and treatments.

<http://www.nmss.org>

Information on multiple sclerosis (updates, treatments, contact groups).

<http://www.fda.gov/cber>

Information on drug research and development, new approvals, alerts, and warnings.

http://www.accessexcellence.org/RC/AB/IE/Monoclonal_Antibodies

Information on the process of monoclonal antibody production and uses.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-Rom in the front of the book.

MULTIPLE CHOICE

Select the best answer to the following.

- In which situation would the nurse least likely expect to administer an immune suppressant?
 - Treatment of transplant rejection
 - Treatment of autoimmune disease
 - Reduction of number of relapses in multiple sclerosis
 - Treatment of aggressive cancers
- The nurse would expect to administer Interferon alfa-n3 (*Alferon N*) as the drug of choice for
 - treatment of leukemias.
 - treatment of multiple sclerosis.
 - intralesional treatment of warts.
 - treatment of Kaposi sarcoma.
- Patient teaching for a patient receiving an interferon would include
 - proper use of oral contraceptives.
 - use of aspirin to control adverse effects.
 - importance of cardiovascular workouts.
 - proper methods injecting the drug.
- Patients who are receiving an immune stimulant may experience any of the clinical signs of immune response activity, including
 - flu-like symptoms.
 - diarrhea.
 - constipation.
 - headache.
- Organ transplants are often rejected by the body because the T cells recognize the transplanted cells as
 - foreign and try to destroy them. Treatment with an immune suppressant would
 - activate antibody production.
 - stimulate interleukin release.
 - stimulate thymus secretions.
 - block the initial damage to the transplanted cells.
- You might use a monoclonal antibody in treating
 - warts.
 - herpes zoster.
 - tumors that overexpress HER2.
 - Kaposi sarcoma.

MULTIPLE RESPONSE

Select all that apply.

- The nurse is assigned to care for a client who is receiving immune suppressants. The nurse would continually assess the client for which of the following anticipated adverse effects?
 - Development of cancers
 - Increased risk of infection
 - Cardiac standstill
 - Development of secondary infections
 - Increased bleeding tendencies
 - Hepatomegaly
- Teaching points that the nurse would incorporate into the care of a client receiving cyclosporine would include which of the following?
 - Use barrier contraceptives to avoid pregnancy.
 - If mouth sores occur, try to restrict eating as much as possible.
 - Dilute the solution with milk, chocolate milk, or orange juice and drink immediately.
 - Avoid drinking grapefruit juice when on this drug.
 - Stop taking the drug if GI upset or fever occurs.
 - Refrigerate the oral solution.

Vaccines and Sera

18

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Define the terms active immunity and passive immunity.
2. Describe the therapeutic actions, indications, pharmacokinetics, contraindications, most common adverse effects, and important drug–drug interactions associated with each vaccine, immune serum, antitoxin, and antivenin.
3. Discuss the use of vaccines and sera across the lifespan, including recommended immunization schedules.
4. Compare and contrast the prototype drugs for each class of vaccine and immune serum with others in that class.
5. Outline the nursing considerations and teaching needs for patients receiving a vaccine or immune serum.

VACCINES

Bacterial Vaccines

bacille Calmette-Guérin (BCG)

Haemophilus influenzae b conjugate vaccine

Haemophilus influenzae b conjugate vaccine and hepatitis B surface antigen

meningococcal polysaccharide vaccine

meningococcal polysaccharide diphtheria toxoid conjugate vaccine

pneumococcal vaccine, polyvalent

pneumococcal 7-valent conjugate vaccine

typhoid vaccine

Toxoids

diphtheria and tetanus toxoids, combined, absorbed

diphtheria and tetanus toxoids and acellular pertussis vaccine, absorbed

diphtheria and tetanus toxoids and acellular pertussis and

Haemophilus influenzae b conjugate vaccines
diphtheria and tetanus toxoids and acellular pertussis and poliovirus vaccine

diphtheria and tetanus toxoids and acellular pertussis, poliovirus and *Haemophilus influenzae* b conjugate vaccines

diphtheria and tetanus toxoids and acellular pertussis, absorbed, and hepatitis B (recombinant) and inactivated poliovirus vaccines, combined tetanus toxoid

Viral Vaccines

H5N1 influenza vaccine
hepatitis A vaccine, inactivated

hepatitis A vaccine, inactivated, with hepatitis B recombinant vaccine

hepatitis B vaccine
human papillomavirus recombinant vaccine
influenza virus vaccine,

influenza virus vaccine, intranasal

Japanese encephalitis vaccine

measles virus vaccine, live attenuated

 measles, mumps, rubella vaccine

measles, mumps, rubella, varicella virus vaccine

mumps virus vaccine, live poliovirus vaccine,

inactivated

rabies vaccine

rotavirus vaccine, live, oral

rubella and mumps virus vaccine, live

smallpox vaccine

varicella virus vaccine

yellow fever vaccine

zoster vaccine, live

IMMUNE SERA

antithymocyte immune globulin

botulism immune globulin

cytomegalovirus immune globulin

hepatitis B immune globulin

 immune globulin, intramuscular
immune globulin, intravenous
lymphocyte immune globulin
rabies immune globulin
respiratory syncytial virus immune globulin
RHO immune globulin
RHO immune globulin, microdose
tetanus immune globulin
vaccinia immune globulin IV
varicella zoster immune globulin

ANTITOXINS AND ANTIVENINS

antivenin (Crotalidae) polyvalent

antivenin (*Micrurus fulvius*)

black widow spider antivenin

Crotalidae polyvalent immune fab

Glossary of Key Terms

active immunity: the formation of antibodies secondary to exposure to a specific antigen; leads to the formation of plasma cells, antibodies, and memory cells to immediately produce antibodies if exposed to that antigen in the future; imparts lifelong immunity

antitoxins: immune sera that contain antibodies to specific toxins produced by invaders; may prevent the toxin from adhering to body tissues and causing disease

antivenins: immune sera that contain antibodies to specific venins produced by poisonous snakes or spiders; may prevent the venom from causing cell death

biologicals: vaccines, immune sera, and antitoxins that are used to stimulate the production of antibodies, to provide preformed antibodies to facilitate an immune reaction, or to react specifically with the toxins produced by an invading pathogen

immune sera: preformed antibodies found in immune globulin from animals or humans who have had a specific disease and developed antibodies to it

immunization: the process of stimulating active immunity by exposing the body to weakened or less toxic proteins associated with specific disease-causing organisms; the goal is to stimulate immunity without causing the full course of a disease

passive immunity: the injection of preformed antibodies into a host at high risk for exposure to a specific disease; immunity is limited by the amount of circulating antibody

serum sickness: reaction of a host to injected antibodies or foreign sera; host cells make antibodies to the foreign proteins, and a massive immune reaction can occur

vaccine: immunization containing weakened or altered protein antigens to stimulate a specific antibody formation against a specific disease; refers to a product used to stimulate active immunity

Vaccines and immune sera, including antivenins and antitoxins, are usually referred to as **biologicals**. They are used to stimulate the production of antibodies, to provide preformed antibodies to facilitate an immune reaction, or to react specifically with the toxins produced by an invading pathogen or venins injected by poisonous snakes or spiders. Stimulating the production of antibodies to specific antigens with vaccines provides the person with immunity to that antigen. Vaccines are frequently called immunizations because they stimulate immunity. Many diseases that were once devastating or fatal can now be prevented by stimulating an immune response and the development of antibodies without the need for the patient to actually contract the disease. Prudent, prophylactic medical care requires the routine administration of certain vaccines to prevent diseases. The immune sera provide treatments for specific antigens, toxins, or venins and are used after exposure to antigens or toxins or after bites from poisonous snakes or spiders to make diseases less invasive and aggressive or to prevent clinical problems from developing at all. Box 18.1 discusses the use of biologicals among various age groups.

IMMUNITY

Immunity is a state of relative resistance to a disease that develops after exposure to the specific disease-causing agent. People are not born with immunity to diseases, so they must acquire immunity by stimulating B-cell clones to form plasma cells and then antibodies.

Active immunity occurs when the body recognizes a foreign protein and begins producing antibodies to react with

that specific protein or antigen. After plasma cells are formed to produce antibodies, specific memory cells that produce the same antibodies are created. If the specific foreign protein is introduced into the body again, these memory cells react immediately to release antibodies. This type of immunity is thought to be lifelong.

Passive immunity occurs when preformed antibodies are injected into the system and react with a specific antigen. These antibodies come from animals that have been infected with the disease or from humans who have had the disease and have developed antibodies. The circulating antibodies act in the same manner as those produced from plasma cells, recognizing the foreign protein and attaching to it, rendering it harmless. Unlike active immunity, passive immunity is limited. It lasts only as long as the circulating antibodies last because the body does not produce its own antibodies.

In some cases, the host human responds to the circulating injected antibodies, which are foreign proteins to the host's body, by producing its own antibodies to the injected antibodies. This results in **serum sickness**, a massive immune reaction manifested by fever, arthritis, flank pain, myalgia, and arthralgia.

IMMUNIZATION

Immunization is the process of artificially stimulating active immunity by exposing the body to weakened or less toxic proteins associated with specific disease-causing organisms. The proteins could be a weakened bacterial cell membrane, the protein coat of a virus, or a virus (protein coat with the genetic fragment that makes up the virus) that has been chemically

BOX 18.1

Drug Therapy Across the Lifespan

Biologicals

CHILDREN

Routine immunization for children has become a standard of care in this country. Parents should receive written records of immunizations given to their children to assure continuity of care. The parent should be asked to report adverse reactions to any immunization. Sensitive children may receive divided doses of their immunizations to help prevent adverse reactions.

Simple comfort measures—warm soaks at the injection site, acetaminophen to reduce fever or aches and pains, comfort from parents or caregivers—will help the child to deal with the immunization experience.

Parent education is a very important aspect of the immunization procedure. Parents may need reassurance and educational materials when concerns about the safety of immunizations arise.

Immune sera are used for specific exposures. Botulism immune globulin is specific for treatment of infants younger than 1 year of age with botulism.

ADULTS

There are a number of reasons why adults should receive certain immunizations. For example, adults who are traveling to areas with high risk for particular diseases—and who may not have previously been exposed to those diseases—are advised to be immunized.

In addition, adults with chronic diseases are advised to be immunized yearly with an influenza vaccine and once with a pneumococcal pneumonia vaccine. These vaccines

provide some protection against diseases that can prove dangerous for people with chronic lung, cardiovascular, or endocrine disorders. The influenza vaccine changes yearly, depending on predictions of which flu strain might be emergent in that year. The pneumonia vaccine contains 23 strains and is believed to offer lifetime protection.

Tetanus shots also are recommended for adults every 10 years or with any injury that potentially could precipitate a tetanus infection.

Immune sera are used for specific exposures.

OLDER ADULTS

Older patients are at greater risk for severe illness from influenza and pneumococcal infections. The yearly flu shot and the pneumococcal vaccine should be stressed for this group.

A tetanus booster every 10 years will also help to protect older adults from exposure to that illness. Ask the patient about any adverse reaction to previous tetanus boosters, and weigh the risk against the possible exposure to tetanus.

If an older patient is traveling to an area where a particular disease is endemic and the risk of exposure is great, the Centers for Disease Control and Prevention should be contacted to determine whether the appropriate vaccine is acceptable for use in the older patient.

Immune sera are used for specific exposures. Older adults are at increased risk for severe reactions and should be monitored closely.

weakened so that it cannot cause disease. The goal is to cause an immune response without having the patient suffer the full course of a disease. Adults may require immunizations in certain situations: exposure, travel to an area endemic for a disease they have not had and have not been immunized against, and occupations that are considered high risk (Figure 18.1). Children routinely are immunized against many infections that were once quite devastating (Figure 18.2 and Box 18.2). For example, smallpox was one of the first diseases against which children were immunized. Today, smallpox is considered to be eradicated worldwide. Concerns over biological terrorism have renewed interest in this disease, and smallpox vaccine is now available for people who might be at high risk for exposure to a potential attack by terrorists using smallpox.

Diphtheria, pertussis, tetanus, *Haemophilus influenzae* B, hepatitis B, hepatitis A, chickenpox, poliovirus, meningitis, measles, mumps, rotavirus, and rubella are all standard childhood immunizations today. The bacille Calmette-Guérin (BCG) vaccine for tuberculosis is widely used throughout the world in countries with a high incidence of tuberculosis to limit the spread of the disease. However, it is not routinely used in the United States because the incidence of tuberculosis is relatively low and it can induce false-positive tuberculin skin test results. The human papillomavirus (HPV) vaccine is

now recommended for girls to protect against several of the viruses that cause many cervical cancers.

The use of vaccines is not without controversy. Severe reactions, although rare, have occurred, resulting in concerns about the safety of vaccines and their administration, especially in children (Box 18.3). The central reporting of adverse effects or suspected adverse effects may help to clarify concerns about reactions to immunizations.

Antigens are also processed and injected to help some people who have severe allergic reactions. People who receive allergy shots to help them cope with the signs and symptoms of allergic reactions are receiving antigenic proteins that stimulate antibody production to prevent the allergic response by stimulating production of another antibody in the body.

Safe Medication Administration

Use of Allergenic Extracts

Many people receive “allergy shots” or injections of allergenic extracts. These extracts contain various antigens based on specific standardizations. The exact action of these extracts is not completely understood, but it has been shown that after

(continued)

VACCINE ▼	AGE GROUP ►	19–26 years	27–49 years	50–59 years	60–64 years	≥65 years
Tetanus, diphtheria, pertussis (Td/Tdap) ^{1,*}		Substitute 1-time dose of Tdap for Td booster; then boost with Td every 10 yr				Td booster every 10 yrs
Human papillomavirus (HPV) ^{2,*}		3 doses (females)				
Varicella ^{3,*}		2 doses				
Zoster ⁴					1 dose	
Measles, mumps, rubella (MMR) ^{5,*}		1 or 2 doses		1 dose		
Influenza ^{6,*}		1 dose annually				
Pneumococcal (polysaccharide) ^{7,8}		1 or 2 doses				1 dose
Hepatitis A ^{9,*}		2 doses				
Hepatitis B ^{10,*}		3 doses				
Meningococcal ^{11,*}		1 or more doses				

* Covered by the Vaccine Injury Compensation Program.

 For all persons in this category who meet the age requirements and who lack evidence of immunity (e.g., lack documentation of vaccination or have no evidence of prior infection)
 Recommended if some other risk factor is present (e.g., on the basis of medical, occupational, lifestyle, or other indications)
 No recommendation

VACCINE ▼	INDICATION ►	Pregnancy	Immuno-compromising conditions (excluding human immunodeficiency virus [HIV]) ¹³	HIV infection ^{3,12,13} CD4+ T lymphocyte count		Diabetes, heart disease, chronic lung disease, chronic alcoholism	Asplenia ¹² (including elective splenectomy and terminal complement deficiencies)	Chronic liver disease	Kidney failure, end-stage renal disease, receipt of hemodialysis	Health-care personnel
				<200 cells/μL	≥200 cells/μL

injection, specific immunoglobulin G (IgG) antibodies appear in the serum. These antibodies compete with IgE for the receptor site on a specific antigen that is the cause of the allergy (IgE is the immune globulin that is associated with allergic reactions; these antibodies react with mast cells, causing the release of histamine and other inflammatory chemicals when they have combined with the antigen). After repeated exposure to the antigens, the levels of IgG antibodies increase and the circulating levels of IgE seem to decrease, leading to less allergic response. It may take 4 to 6 months of subcutaneous injections of the allergenic extract every 3 to 14 days to achieve relief from the symptoms of the allergic reaction. The IgG levels remain high for weeks or sometimes months, but the individual response varies widely. Many people are

maintained with a weekly injection once the desired response has been achieved.

VACCINES

The word **vaccine** comes from the Latin word for smallpox, *vaccinia*. Vaccines are immunizations containing weakened or altered protein antigens that stimulate the formation of antibodies against a specific disease (Figure 18.3). They are used to promote active immunity (see Table 18.1).

Due to recent events and the fear of terrorist activities, concern has risen about the use of various diseases as

The table below provides catch-up schedules and minimum intervals between doses for children whose vaccinations have been delayed. A vaccine series does not need to be restarted, regardless of the time that has elapsed between doses. Use the section appropriate for the child's age.

CATCH-UP SCHEDULE FOR PERSONS AGED 4 MONTHS THROUGH 6 YEARS					
Vaccine	Minimum Age for Dose 1	Minimum Interval Between Doses			
		Dose 1 to Dose 2	Dose 2 to Dose 3	Dose 3 to Dose 4	Dose 4 to Dose 5
Hepatitis B ¹	Birth	4 weeks	8 weeks (and at least 16 weeks after first dose)		
Rotavirus ²	6 wks	4 weeks	4 weeks ²		
Diphtheria, Tetanus, Pertussis ³	6 wks	4 weeks	4 weeks	6 months	6 months ³
Haemophilus influenzae type b ⁴	6 wks	4 weeks if first dose administered at younger than age 12 months 8 weeks (as final dose) if first dose administered at age 12-14 months No further doses needed if first dose administered at age 15 months or older	4 weeks ⁴ if current age is younger than 12 months 8 weeks (as final dose) ⁴ if current age is 12 months or older and second dose administered at younger than age 15 months No further doses needed if previous dose administered at age 15 months or older	8 weeks (as final dose) This dose only necessary for children aged 12 months through 59 months who received 3 doses before age 12 months	
Pneumococcal ⁵	6 wks	4 weeks if first dose administered at younger than age 12 months 8 weeks (as final dose for healthy children) if first dose administered at age 12 months or older or current age 24 through 59 months No further doses needed for healthy children if first dose administered at age 24 months or older	4 weeks if current age is younger than 12 months 8 weeks (as final dose for healthy children) if current age is 12 months or older No further doses needed for healthy children if previous dose administered at age 24 months or older	8 weeks (as final dose) This dose only necessary for children aged 12 months through 59 months who received 3 doses before age 12 months or for high-risk children who received 3 doses at any age	
Inactivated Poliovirus ⁶	6 wks	4 weeks	4 weeks	4 weeks ⁶	
Measles, Mumps, Rubella ⁷	12 mos	4 weeks			
Varicella ⁸	12 mos	3 months

Hepatitis B ¹	Birth	4 weeks	8 weeks (and at least 16 weeks after first dose)		
Inactivated Poliovirus ⁶	6 wks	4 weeks	4 weeks	4 weeks ⁶	
Measles, Mumps, Rubella ⁷	12 mos	4 weeks			
Varicella ⁸	12 mos	3 months if the person is younger than age 13 years 4 weeks if the person is aged 13 years or older			

● FIGURE 18.2 (Continued)

BOX 18.2

Patient Teaching

Pediatric Immunization

It is well-documented that by preventing potentially devastating diseases, society prevents unneeded suffering and death, and saves valuable citizens for the future. Pediatric immunization has helped to greatly decrease the incidence of most childhood diseases and has prevented associated complications. In the United States, routine immunization is considered standard medical practice.

Ensuring that every child has the opportunity to receive the recommended immunizations has become a political as well as a social issue. The cost of preventing a disease that most people have never even seen may be difficult to justify to families who have trouble putting food on the table. Widespread campaigns to provide free immunizations and health screening to all children have addressed this problem but have not been totally successful.

In addition, periodic reports of severe or even fatal reactions to standard immunizations alarm many parents about the risks of immunizations. These parents need facts as well as reassurance about modern efforts to prevent and screen for these reactions.

Public education efforts should be directed at providing parents with information about pediatric immunization and encouraging them to act on that information. Nurses are often in the ideal position to provide this information, during prenatal visits, while screening for other problems, or even standing in line at a grocery store. It is important for nurses to be well versed on the need for standard immunizations and screening to prevent severe reactions. The Centers for Disease Control and Prevention (<http://www.cdc.gov>) offers current information and updates for health care providers, as well as patient teaching materials that can be printed for easy reference.

BOX 18.3 *The Evidence*

Studies Find No Link Between MMR Vaccine and Autism

The Immunization Safety Review Committee Board of Health Promotion and Disease Prevention of the Institute of Medicine under the auspices of the Centers for Disease Control and Prevention and the National Institutes of Health has concluded that there is no evidence to support a linkage between the use of measles–mumps–rubella (MMR) vaccine and the development of autism (a psychiatric neurological impairment affecting children and marked by deficits in communication and social attachment). The media, however, continue to pursue this possible connection, raising concerns for parents about the use of vaccines in children.

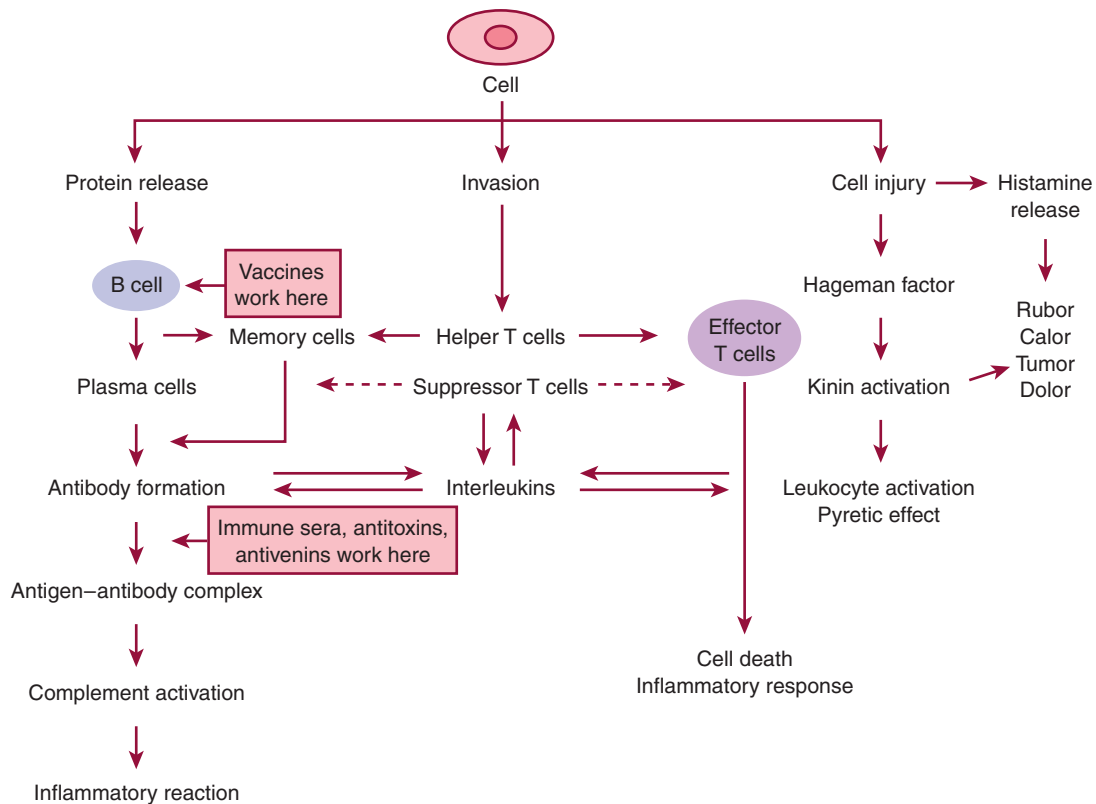

Among materials studied by the Institute of Medicine were questionnaires about reported symptoms and the timing of the vaccination and Vaccine Adverse Event Reporting System (VAERS) reports. The information obtained will help determine a need for other research, and it will also be used to educate parents. Parents can be referred to www.cdc.gov; click on vaccine safety to get current information and to review the research that has been done.

biological weapons. Box 18.4 discusses vaccines and the use of biological weapons.

Vaccines can be made from chemically inactivated microorganisms or from live, weakened viruses or bacteria. Toxoids are vaccines that are made from the toxins produced by the microorganism. The toxins are altered so that they are no longer poisonous but still have the recognizable protein antigen that will stimulate antibody production.

The particular vaccine that is used depends on the possible exposure a person will have to a particular disease and the age of the person. Some vaccines are used only in children, and some cannot be used in infants. Some vaccines require booster doses—doses that are given a few months after the initial dose to further stimulate antibody production. For example, Box 18.5 discusses the new human papillomavirus (HPV) vaccine, which protects young women from many

● **FIGURE 18.3** Sites of action of biologicals.

TABLE 18.1 DRUGS IN FOCUS Vaccines

Drug Name	Dosage/Route	Usual Indications
Bacterial Vaccines		
bacille Calmette-Guérin [BCG] (<i>TICE</i>)	0.2–0.3 mL percutaneously	Prevention of tuberculosis with high risk of exposure
<i>Haemophilus influenzae</i> b conjugate vaccine (<i>HibTITER</i> , <i>Liquid PedvaxHIB</i> , <i>ActHIB</i>)	0.5 mL IM; ages vary with preparation	Active immunization against <i>Haemophilus influenzae</i> type b infection in infants and children
<i>Haemophilus influenzae</i> b conjugate vaccine and hepatitis B surface antigen (<i>Comvax</i>)	Three 0.5-mL IM injections at 2, 4, and 6 mo, with 0.5-mL booster at 15–18 mo	Immunization of children against <i>H. influenzae</i> type b and hepatitis B infections
meningococcal polysaccharide vaccine (<i>Menomune-A/C/Y/W-135</i>)	0.5 mL SQ	Immunization against meningococcal infections in endemic areas
meningococcal polysaccharide diphtheria toxoid conjugate vaccine (<i>Menactra</i>)	0.5 mL IM	Active immunization of people aged 11–55 yr to prevent invasive meningococcal disease
pneumococcal vaccine, polyvalent (<i>Pneumovax 23</i>)	0.5 mL SQ or IM, not recommended for children <2 yr of age	Immunization against pneumococcal infections
pneumococcal 7-valent conjugate vaccine (<i>Prevnar</i>)	7–11 mo: three 0.5-mg IM doses at least 4 wk apart and the last one at >1 yr 12–23 mo: two 0.5-mg IM doses 2 mo apart 24 mo–9 yr: one 0.5-mg IM dose	Prevention of invasive pneumococcal disease in infants and children
typhoid vaccine (<i>Vivotif Berna Typhim Vi</i>)	Two doses of 0.5 mL SQ at intervals of ≥ 4 wk with booster given every 3 yr, or one capsule PO on days 1, 3, 5, and 7	Immunization against typhoid fever
Toxoids		
diphtheria and tetanus toxoids, combined, adsorbed [DT, Td]	Two IM injections of 0.5 mL at intervals of 4–8 wk, with booster of 0.5 mL in 6–12 mo	Immunization of adults and children >7 yr of age against diphtheria and tetanus
diphtheria and tetanus toxoids and acellular pertussis vaccine, adsorbed [DTaP] (<i>Tripedia</i> , <i>Infanrix</i> , <i>Adacel</i> , <i>Boostrix</i>)	3 IM doses of 0.5 mL at 4–6 wk intervals starting by 6–8 wks of age; fourth dose of 0.5 mL IM at 15–20 mo; then 0.5 mL at 4–6 yr Booster at 10–18 yr <i>Boostrix</i> : 0.5 mL IM; at 11–64 yr <i>Adacel</i> : 0.5 mL IM	Immunization of children against diphtheria, tetanus, and pertussis as the fourth and fifth doses of the immunization series Booster for adolescents and adults
diphtheria and tetanus toxoids and acellular pertussis and <i>Haemophilus influenzae</i> type b conjugate vaccines [DTaP-HIB] (<i>TriHIBit</i>)	0.5 mL IM at 15–18 mo	Active immunization of children aged 15–18 mo as the fourth dose when being immunized with <i>ActHIB</i> , <i>DTaP</i> or DTP

Drug Name	Dosage/Route	Usual Indications NSAIDs
Toxoids (continued)		
diphtheria and tetanus toxoids and acellular pertussis, adsorbed, and hepatitis B (recombinant) and inactivated poliovirus vaccine, combined (<i>Pediarix</i>)	0.5 mL IM, three doses at 8-wk intervals or completion of series in combined form, beginning at 2 mo of age	Active immunization against diphtheria, tetanus, pertussis, hepatitis B, and poliovirus in infants with hepatitis B surface antigen (HBsAg)-negative mothers
diphtheria and tetanus toxoids and acellular pertussis, adsorbed and poliovirus vaccine (<i>Kinrix</i>)	0.5 ml IM children 4–6 yr, to complete the series started with <i>Infranix</i> or <i>Pediarix</i>	Active immunization against diphtheria, tetanus, pertussis, and poliovirus in children needing to complete the series
diphtheria and tetanus toxoids and acellular pertussis, poliovirus and <i>Haemophilus influenzae</i> b conjugate vaccines	0.5 mL IM given as a 4-dose series At 2, 4, 6 and 15–18 mo, may be started as early as 6 wk of age	Active immunization against diphtheria, tetanus, pertussis, poliovirus and <i>Haemophilus influenzae</i> b
tetanus toxoid	Adults and children ≥ 7 yr: 0.5 mL IM, second dose in 4–8 wk, third dose 6–12 mo later	Active immunization of adults and children ≥ 7 yr against tetanus when combined preparations are not indicated

Viral Vaccines

H5Ni influenza vaccine	Patients 18–64 yr: 1 mL IM, then 1 mL IM 21–35 d later	Active immunization of patients 18–64 yr of age at increased risk for exposure to avian flu
hepatitis A vaccine, inactivated (<i>Havrix</i> , <i>Vaqta</i>)	Adult: 1 mL IM with a booster dose in 6–12 mo Pediatric: 0.5 mL IM with a repeat dose in 6–12 mo	Immunization of adults and children against hepatitis A infection
hepatitis A vaccine, inactivated, with hepatitis B recombinant vaccine (<i>Twinrix</i>)	1 mL IM followed by booster doses at 1 and 6 mo	Immunization against hepatitis A and hepatitis B infections in people ≥ 18 yr of age
hepatitis B vaccine (<i>Energix-B</i> , <i>Recombivax HB</i>)	0.5–1 mL IM, followed by 0.5–1 mL IM at 1 and 6 mo	Immunization against hepatitis B infections in susceptible people and in infants born to mothers with hepatitis B
human papillomavirus, recombinant, quadrivalent (<i>Gardasil</i>)	Females 9–26 yr: 0.5 mL IM, then 0.5 mL IM 2 mo later, followed by 0.5 mL IM 6 mo after the first dose	Active immunization against human papillomavirus responsible for causing genital warts and many cervical cancers
influenza virus vaccine (<i>Fluzone</i> , <i>Fluvirin</i>)	Adult: 0.5 mL IM Pediatric: 0.25–0.5 mL IM, repeated in 4 wk	Prophylaxis in adults and children at high risk for complications of influenza infections
influenza virus vaccine, intranasal (<i>FluMist</i>)	9–49 yr: 0.5 mL intranasal once each flu season 5–8 yr not previously vaccinated with <i>FluMist</i> : two doses of 0.5 mL each intranasally given 60 d apart 5–8 yr previously vaccinated with <i>FluMist</i> : 0.5 mL intranasally once per flu season	Active immunization to prevent disease caused by influenza A and B viruses
Japanese encephalitis vaccine (<i>JE-VAX</i>)	1 mL SQ on days 0, 7, and 30 1–3 yr: 0.5 mL SQ on days 0, 7 and 30	Immunization of persons >1 yr of age who reside in or will travel to endemic areas
measles virus vaccine (<i>Attenuvax</i>)	0.5 mL SQ	Immunization against measles

(drug table continues on page 286)

TABLE 18.1 DRUGS IN FOCUS Vaccines (continued)

Drug Name	Dosage/Route	Usual Indications
Viral Vaccines (continued)		
 measles, mumps, rubella vaccine (<i>M-M-R-II</i>)	0.5 mL SQ	Immunization against measles, mumps, and rubella in adults and children >15 mo of age
measles, mumps, rubella, varicella virus vaccine (<i>ProQuad</i>)	0.5 mL SQ	Simultaneous immunization against measles, mumps, rubella, and varicella in children aged 12 mo–12 yr
measles and rubella virus vaccine, live (<i>M-R-Vax II</i>)	0.5 mg SQ	Immunization against measles and rubella in children ≥15 mo of age
mumps virus vaccine (<i>MumpsVax</i>)	0.5 mL SQ	Immunization against mumps in persons >12 mo of age
poliovirus vaccine, inactivated (<i>IPOL</i>)	0.5 mL SQ at 2, 4, and 12–15 mo; booster when starting school Adult: 0.5 mL SQ, two doses at intervals of 1–2 mo, with a third dose 6–12 mo later	Immunization against polio infections in adults and children
rabies vaccine (<i>Imovax Rabies, RabAvert</i>)	Pre-exposure: 1 mL IM on days 0, 7, 21, and 28 Postexposure: 1 mL IM on days 0, 3, 7, 21, and 28	Pre-exposure immunization against rabies for high-risk people; postexposure antirabies regimen with rabies immune globulin
rotavirus vaccine, live, oral pentavalent (<i>RotaTeq</i>)	Three doses of 2 mL PO starting at age 6–12 wk, with subsequent doses at 4- to 10-wk intervals (third dose should be given at 32 wk)	Prevention of rotavirus gastroenteritis in infants and children
rubella virus vaccine (<i>Meruvax II</i>)	One dose SQ (>1000 times the median tissue culture infective dose [TCID ₅₀])	Immunization against rubella in adults and children >12 mo of age
rubella and mumps vaccine, live (<i>Biavax II</i>)	0.5 mg SQ	Immunization against rubella and mumps in children >12 mo, preferably at 15 mo
smallpox vaccine (<i>Dryvax</i>)	One drop of live virus in two to three prepared punctures on the upper arm; inspect after 6–8 d; a scab should form, leaving a scar; if only a mild reaction occurs, repeat vaccination using 15 punctures in the area where a drop of vaccine is placed	Active immunization against smallpox disease
varicella virus vaccine (<i>Varivax</i>)	0.5 mL SQ, followed by 0.5 mL SQ 4–8 wk later	Immunization against chickenpox infections in adults and children ≥12 mo of age
yellow fever vaccine (<i>YF-Vax</i>)	Children 1–12 yr: 0.5 mL SQ 0.5 mL SQ booster every 10 yr	Immunization of travelers to areas where yellow fever is endemic
zoster vaccine (<i>Zostavax</i>)	Adults ≥60 yr: 0.5 mL by subcutaneous injection	Prevention of herpes zoster (shingles) in persons ≥60 yr

cervical cancers This vaccine is given in a series of three injections to achieve full protection. In many cases, antibody titers (levels of the antibody in the serum) can be used to evaluate a person's response to an immunization and determine the need for a booster dose.

Therapeutic Actions and Indications

Vaccines stimulate active immunity in people who are at high risk for development of a particular disease. The vaccine needed for a patient depends on the exposure that person will

have to the pathogen. Exposure is usually determined by where the person lives and his or her travel plans and work or family environment exposures. Vaccines are thought to provide lifelong immunity to the disease against which the patient is being immunized. Table 18.1 lists the various vaccines available along with usual indications.

Pharmacokinetics

There is no pharmacokinetic information on these biologicals, which are treated like endogenous antibodies in the body.

BOX 18.4 Vaccines and Biological Weapons

The events of September 11, 2001, and the subsequent war on terrorism have heightened awareness of several diseases that might be in development as biological weapons. Anthrax, plague, tularemia, smallpox, botulism, and a variety of viral hemorrhagic fevers are all considered to be likely biological warfare weapons.

ANTHRAX

A vaccine is available in the United States made from inactivated cell-free filtrate of an avirulent strain of the anthrax bacillus. It is available only for military use. Active production stopped in 1998, but production and supply issues were made high priorities. Ciprofloxacin and, in sensitive cases, doxycycline and penicillins are effective in treating postexposure cases. The vaccine is given and repeated in 2 and 4 weeks, along with the appropriate antibiotic, to patients who have been exposed.

PLAGUE

Plague is easily spread from person to person, and without treatment can progress rapidly to respiratory failure and death. There is currently no vaccine for plague; a whole-cell vaccine that was used for many years is no longer available. Research is ongoing using a pneumonic plague vaccine that has successfully protected animals. Several drugs have been found to be life-saving with plague—streptomycin, doxycycline, ciprofloxacin, and chloramphenicol.

SMALLPOX

Smallpox was considered eradicated since no new cases had been seen in 20 years. Smallpox is highly transmissible and has a 30% mortality rate in unvaccinated people. Immunization against smallpox ended in the 1970s. There is now a commercially available vaccine, but use is somewhat limited because of questions raised during studies of the vaccine. It is given to military personnel and people thought to be at high risk. It is currently thought that the vaccine is no longer effective after 20 years, although there is no definite evidence that previously vaccinated people have no protection. The smallpox vaccine

uses live virus, placed in punctures made in the skin. After exposure, vaccination given within the first 3 to 4 days can prevent the disease. If it has been 7 days or longer since exposure, the vaccine and a vaccinia immune globulin should be used, if any are available. So far no drugs are thought to be effective in treating smallpox. Early studies have, however, shown cidofovir to be effective in vitro.

TULAREMIA

Tularemia in an aerosolized form can cause systemic and respiratory illness with a 35% mortality rate. It is not passed from person to person. There is no vaccine available, but doxycycline and ciprofloxacin can be used after exposure, and gentamicin has been effective after symptoms appear.

BOTULISM

Botulism, produced by *Clostridium botulinum*, can be aerosolized or used to contaminate food. The toxin it produces causes cranial nerve palsies that can result in muscle paralysis and respiratory failure. A botulinum toxoid is available through the Centers for Disease Control and Prevention for the military and high-risk workers. Antitoxin is also available for patients with specific exposures, and research is ongoing with an equine antitoxin effective against all seven serotypes of botulism that is thought to cause fewer hypersensitivity reactions than what is currently available.

VIRAL HEMORRHAGIC FEVER

Lassa, Marburg, Junin, and Ebola viruses cause hemorrhagic fevers with mortality rates as high as 90%. No vaccines are currently available for these agents, although the United States Army has had success with a vaccine for Junin. Ribavirin has been effective in some cases of Lassa fever and has been effective orally for postexposure prophylaxis. It is being studied for effectiveness with these other viruses. Currently there is no established treatment, and this area is one of the highest priorities for combating possible biological warfare.

Contraindications and Cautions

The use of vaccines is contraindicated in the presence of immune deficiency *because the vaccine could cause disease, and the body would not be able to respond as anticipated if it is in an immunodeficient state*; during pregnancy *because of potential effects on the fetus and on the success of the pregnancy*; in patients with known allergies to any of the components of the vaccine (refer to each individual vaccine for specifics, sometimes including eggs, where some pathogens are cultured); or in patients who are receiving immune globulin or who have received blood or blood products within the last 3 months *because a serious immune reaction could occur*.

Caution should be used any time a vaccine is given to a child with a history of febrile convulsions or cerebral injury, or in any condition in which a potential fever would be

dangerous. Caution also should be used in the presence of any acute infection.

Adverse Effects

Adverse effects of vaccines are associated with the immune or inflammatory reaction that is being stimulated: moderate fever, rash, malaise, chills, fretfulness, drowsiness, anorexia, vomiting, and irritability. Pain, redness, swelling, and even nodule formation at the injection site are also common. In rare instances, severe hypersensitivity reactions have been reported.

Clinically Important Drug–Drug Interactions

Vaccines should not be given with any immunosuppressant drugs, including corticosteroids, which could alter the body's response to the vaccine.

FOCUS ON BOX 18.5 The Evidence

Vaccine to Protect Against Cervical Cancer

In 2006, the U.S. Food and Drug Administration (FDA) approved the first vaccine to protect against cancer caused by a virus. The human papillomavirus (HPV) is the most common sexually transmitted infection in the United States. The Centers for Disease Control and Prevention estimates that 6 million Americans become infected with genital HPV each year and that half of sexually active men and women become infected at some time during their lifetime. Most of the time, the body's defense system will clear the virus, but some types of HPV can be more virulent. There are many types of HPV; some cause genital warts, and others are known to cause abnormal cells on the lining of the cervix, which can lead to cervical cancer years later.

The vaccine *Gardasil* is effective against HPV types 16 and 18 (which account for 70% of cervical cancers) and against types 6 and 11 (which are responsible for 90% of genital warts). The vaccine is recommended for girls and women ages 9 to 26 years. Studies have shown that it is only effective if it is given before HPV infection occurs, so it is best given before the girl or woman becomes sexually active. The vaccine is given as a series of three injections. The second injection given about 2 months after the first, and the last injection given about 6 months later. Tests are being done to evaluate the effectiveness of the vaccine in males and to monitor the long-term effectiveness of the vaccine. Because it is new, it is not yet known whether a booster injection will be needed later and its effects if given inadvertently to a pregnant

woman. Side effects that have been reported include the usual flu-like symptoms seen with immunization and pain at the injection site.

The vaccine is not without controversy. In 2007, it cost approximately \$360 for the three-shot series, making it an expensive injection. In February, 2007, the governor of Texas issued an executive order mandating that the vaccine be given to all schoolgirls entering the sixth grade. A group resenting the mandate for a vaccine sued, and the order was overruled. New Hampshire and Alaska have adopted voluntary programs that supply the vaccine free of charge to girls 11 to 18 years (New Hampshire) or 9 to 18 years (Alaska). Those debating the use of the drug cite the potential for preventing more than 9700 new cases and 3700 deaths from cervical cancer every year, whereas others question the long-term effects and effectiveness of the vaccine, stating that it is poor judgment to mandate something with such a short track record. Others fear that women who have had the vaccine will stop getting an annual pelvic exam and Pap smear, which is still needed because cervical cancer can be caused by other things. Others fear that the protection offered by the vaccine will lead to earlier or more frequent sexual activity among women who have had the vaccination.

This is the first vaccine to protect against cancer, and it is hoped that more such vaccines will be developed in the future. The willingness of parents to listen to the pros and cons and accept the need for this vaccine will have a big impact on the success of this and other such vaccines.

Nursing Considerations for Patients Receiving Vaccines

Assessment: History and Examination

- Assess for contraindications or cautions: known allergies to any vaccines or to the components of the one being used *to prevent hypersensitivity reactions*; current status related to pregnancy, *which is a contraindication to the use of vaccines*; recent administration of immune globulin or blood products, *which could alter the response to the vaccine*; history of immune deficiency, *which could alter immune reactions*; and evidence of acute infection, *which could be exacerbated by the introduction of other antigens*.
- Perform a physical assessment *to determine baseline status before beginning therapy and for any potential adverse effects*: Inspect for the presence of any skin lesions *to monitor for hypersensitivity reactions*; check temperature *to monitor for possible infection*; monitor pulse, respirations, and blood pressure; auscultate lungs for adventitious sounds; and assess level of orientation and affect *to monitor for hypersensitivity reactions to the vaccine*.

- Evaluate the range of motion of the extremity to be used for vaccine administration *to assure adequate blood flow to deal with the antigen and inflammatory reaction*.
- Assess tissue perfusion to establish a baseline *to monitor for potential hypersensitivity reactions*.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to injection, gastrointestinal (GI), and flu-like effects
- Ineffective Tissue Perfusion if severe reaction occurs
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Do not use to treat acute infection; *a vaccine is only used to prevent infection with future exposures*.
- Do not administer if the patient exhibits signs of acute infection or immune deficiency *because the vaccine can cause a mild infection and can exacerbate acute infections*.
- Do not administer if the patient has received blood, blood products, or immune globulin within the last 3 months *because a severe immune reaction could occur*.

- Arrange for proper preparation and administration of the vaccine; check on the timing and dose of each injection *because dose, preparation, and timing vary with individual vaccines.*
- Maintain emergency equipment on standby, including epinephrine, *in case of severe hypersensitivity reaction.*
- Arrange for supportive care and comfort measures for flu-like symptoms (rest, environmental control, acetaminophen) and for injection discomfort (local heat application, anti-inflammatories, resting arm) *to promote patient comfort.*
- Do not administer aspirin to children for the treatment of discomforts associated with the immunization. *Aspirin can mask warning signs of Reye syndrome, a potentially serious disease.*
- Provide thorough patient teaching, including measures to avoid adverse effects, warning signs of problems, and the need to keep a written record of immunizations, *to increase knowledge about drug therapy and to increase compliance with the drug regimen.*
- Provide a written record of the immunization, including the need to return for booster immunizations and timing of the boosters, if necessary, *to increase patient compliance with medical regimens.*

Evaluation

- Monitor patient response to the drug (prevention of disease, appropriate antibody titer levels).
- Monitor for adverse effects (flu-like symptoms; GI upset; local pain, swelling, nodule formation at the injection site).
- Evaluate the effectiveness of the teaching plan (patient can name drug, dosage, adverse effects to watch for; has written record of immunizations; can state when to return for the next immunization or booster if needed).

- Monitor the effectiveness of comfort measures and adherence to the regimen.

See *Critical Thinking Scenario* for additional information on educating a parent about vaccines.

Prototype Summary: Measles, Mumps, and Rubella Vaccine

Indications: Active immunization against measles, mumps, and rubella in children older than 15 months and adults.

Actions: Attenuated measles, mumps, and rubella viruses produce a modified infection and stimulate an active immune reaction with the production of antibodies to these viruses.

Pharmacokinetics:

Route	Onset	Peak
IM	Rapid	3–12 h

$T_{1/2}$: Unknown; metabolized in the tissues, excretion is unknown.

Adverse effects: Moderate fever, rash, or burning or stinging wheal or flare at the site of injection; rarely, febrile convulsions and high fever; Guillain-Barré syndrome, ocular palsies.

KEY POINTS

- ▶ Immunity is a state of relative resistance to a disease that develops only after exposure to the specific disease-causing agent.
- ▶ Vaccines provide active immunity by stimulating the production of antibodies to a specific protein, which may produce the signs and symptoms of a mild immune reaction but protects the person from the more devastating effects of disease.

CRITICAL THINKING SCENARIO

Educating a Parent About Vaccines

THE SITUATION

S.D. is a 25-year-old, first-time mother who has brought her 2-month-old daughter to the well-baby clinic for a routine evaluation. The baby is found to be healthy, growing well, and within normal parameters for her age. At the end of the visit, the nurse prepares to give the baby the first of her routine immunizations. S.D. becomes concerned and expresses fears about paralysis and infant deaths associated with immunizations.

CRITICAL THINKING

- What information should S.D. be given about immunizations?
- What nursing interventions would be appropriate at this time? *Think of ways to explain the importance of immunizations to S.D. while supporting her concerns for the welfare of her baby.*
- How can this experience be incorporated into a teaching plan for S.D. and her baby?

(scenario continues on page 290)

Educating a Parent About Vaccines (continued)

DISCUSSION

S.D. should be reassured before the baby is immunized. The nurse can tell her that in the past, paralysis and infant deaths were reported, but that efforts continue to make the vaccines pure. Careful monitoring of the child and the child's response to each immunization can help avoid such problems. Reassure S.D. that the immunizations will prevent her daughter from contracting many, sometimes deadly, diseases. Praise S.D.'s efforts for researching information that might affect her baby and for asking questions that could have an impact on her child and her understanding of her care.

The recommended schedule of immunizations should be given to S.D. so that she is aware of what is planned and how the various vaccines are spaced and combined. She should be encouraged to monitor the baby after each injection for fever, chills, and flu-like reactions. When she gets home, she can medicate the baby with acetaminophen to avert many of these symptoms before they happen. (S.D. should be advised not to give the baby aspirin, which could cover up Reye's syndrome, a potentially serious disorder.) S.D. also should be told that the injection site might be sore, swollen, and red, but that this will pass in a couple of days. S.D. can ease the baby's discomfort by applying warm soaks to the area for about 10 to 15 minutes every 2 hours.

S.D. should be encouraged to write down all of the immunizations that the baby has had and to keep this information handy for easy reference. She should also be encouraged to record any adverse effects that occur after each immunization. If reactions are uncomfortable, it is possible to split doses of future immunizations.

The nurse should give S.D. a chance to vent her concerns and fears. First-time parents may be more anxious than experienced ones when dealing with issues involving a new baby. To alleviate S.D.'s anxiety, the nurse should provide a telephone number that S.D. can call if the baby seems to be having a severe reaction or if S.D. wants to discuss any questions or concerns. She should feel that support is available for any concern that she may have. Because this interaction is likely to form the basis for future interactions with S.D., it is important to establish a sense of respect and trust.

NURSING CARE GUIDE FOR S.D.'S BABY: VACCINES**Assessment: History and Examination**

Allergies to the serum base, acute infection, immunosuppression

General: temperature

CV: pulse, cardiac auscultation, blood pressure, edema, perfusion

Respiratory: respirations, adventitious sounds

Skin: lesions

Joints: range of motion

Nursing Diagnoses

Acute Pain related to infection and flu-like symptoms

Ineffective Tissue Perfusion if severe reaction occurs

Deficient Knowledge regarding drug therapy

Implementation

Ensure proper preparation and administration of vaccine within appropriate time frame.

Provide supportive and comfort measures to deal with adverse effects: anti-inflammatory/antipyretic, local heat application, small meals, rest, and a quiet environment.

Provide parent teaching regarding drug name, adverse effects and precautions, and warning signs to report.

Provide emergency life support if needed for acute reaction.

Evaluation

Evaluate drug effects: serum titers reflecting immunization (if appropriate).

Monitor for adverse effects: pain, flu-like symptoms, local discomfort.

Evaluate effectiveness of parent teaching program.

Evaluate effectiveness of comfort and safety measures.

Evaluate effectiveness of emergency measures if needed.

PATIENT TEACHING FOR S.D.

- This immunization will help your baby to develop antibodies to protect her against diphtheria, tetanus, and pertussis. The baby will develop antibodies to these diseases, and this will prevent the baby from contracting one of these potentially deadly diseases in the future.
- The injection site might be sore and painful. Heat applied to the area may help this discomfort and speed the baby's recovery.
- Adverse effects that the baby might experience include fever, muscle aches, joint aches, fatigue, malaise, crying, and fretfulness. Acetaminophen may help these discomforts; check with your health care provider for the correct dose to use for the baby. Rest, small meals, and a quiet environment may also help the baby to feel better.
- The adverse effects should pass within 2 to 3 days. If they seem to be causing undue discomfort or persist longer than a few days, notify your health care provider.
- Booster immunizations are required for this immunization. Your baby should receive a booster immunization at your next well-baby checkup. Keep a written record of this immunization.
- Please contact your health care provider if you have any questions or concerns.

IMMUNE SERA

As explained earlier, passive immunity can be achieved by providing preformed antibodies to a specific antigen. These antibodies are found in immune sera, which may contain antibodies to toxins, venins, bacteria, viruses, or even red blood cell antigenic factors. The term **immune sera** is usually used to refer to sera that contain antibodies to specific bacteria or viruses. The term **antitoxin** refers to immune sera that have antibodies to very specific toxins that might be released by invading pathogens. The term **antivenin** is used to refer to immune sera that have antibodies to venom that might be injected through spider or snake bites. These drugs are used to provide early treatment following exposure to known antigens. They are very specific for antigens to which they can respond (see Table 18.2).

Therapeutic Actions and Indications

Immune sera are used to provide passive immunity to a specific antigen, which could be a pathogen, venom, or toxin. They also may be used as prophylaxis against specific diseases after exposure in patients who are immunosuppressed. In addition, immune sera may be used to lessen the severity of a disease after known or suspected exposure (see Figure 18.3 for sites of action of immune sera and antitoxins). Table 18.2 lists the various available immune sera, antitoxins, and antivenins, as well as usual indications.

Pharmacokinetics

No pharmacokinetic data are available for these biologicals.

Contraindications and Cautions

Immune sera are contraindicated in patients with a history of severe reaction to any immune sera or to products similar to the components of the sera *to prevent potential serious hypersensitivity reactions*. They should be used with caution during pregnancy *because of potential risk to the fetus*; with coagulation defects or thrombocytopenia; or in patients with a known history of previous exposure to the immune sera *because increased risk of hypersensitivity reaction occurs with each use*.

Adverse Effects

Adverse effects can be attributed either to the effect of immune sera on the immune system (rash, nausea, vomiting, chills, fever) or to allergic reactions (chest tightness, falling blood pressure, difficulty breathing). Local reactions, such as swelling, tenderness, pain, or muscle stiffness at the injection site, are very common.

Clinically Important Drug–Drug Interactions

Caution should be used if these drugs are combined with any immune suppressant drugs, including corticosteroids. These can alter the body's response to the biologicals.

Prototype Summary: Immune Globulin, Intramuscular

Indications: Prophylaxis against hepatitis A, measles, varicella, rubella; prophylaxis for patients with immunoglobulin deficiency.

Actions: Provides preformed antibodies to hepatitis A, measles, varicella, rubella, and perhaps other antigens, providing a passive, short-term immunity.

Pharmacokinetics:

Route	Onset	Peak
IM	Slow	2–5 days

$T_{1/2}$: Unknown; metabolized in the tissues, excretion is unknown.

Adverse effects: Tenderness, muscle stiffness at site of THE injection; urticaria, angioedema, nausea, vomiting, chills, fever, chest tightness.

Nursing Considerations for Patients Receiving Immune Sera

Assessment: History and Examination

- Assess for contraindications or cautions: any known allergies to any of these drugs or their components *to prevent hypersensitivity reactions*; current status related to pregnancy, *which would be a contraindication for immune sera*; previous exposure to the serum being used *because hypersensitivity reactions become worse with repeated exposure*; evidence of thrombocytopenia or coagulation disorders, *which could be exacerbated by the effects of immune sera*; and immunization history *to determine the potential for hypersensitivity reactions*.
- Perform a physical assessment *to determine baseline status before beginning therapy and for any potential adverse effects*: inspect for the presence of any skin lesions *to monitor for hypersensitivity reactions*; check temperature *to monitor for possible infection*; monitor pulse, respirations, and blood pressure; auscultate lungs for adventitious sounds; and assess level of orientation and affect *to monitor for hypersensitivity reactions to the vaccine*.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to local, GI, and flu-like effects
- Ineffective Tissue Perfusion related to possible severe reactions
- Deficient Knowledge regarding drug therapy

TABLE 18.2 DRUGS IN FOCUS Immune Sera

Drug Name	Dosage/Route	Usual Indications
Immune Sera		
antithymocyte immune globulin (<i>Thymoglobulin</i>)	1.5 mg/kg per day for 7–14 d as 6-h infusion for the first dose and ≥ 4 h for each subsequent dose	Treatment of renal transplant acute rejection in conjunction with immunosuppression
botulism immune globulin (<i>Baby BIG</i>)	Pediatric <1 yr: 50 mg/kg IV as an infusion	Treatment of patients <1 yr with infant botulism caused by toxin type A or B
cytomegalovirus immune globulin (<i>CytoGam</i>)	15 mg/kg IV over 30 min, increased to 30 mg/kg IV over 30 min, then 60 mg/kg IV to a max of 150 mg/kg; infuse at 72 h, at 2 wk, and then at 4, 6, 8, 12, and 16 wk after transplantation	Attenuation of primary cytomegalovirus disease after renal transplantation
hepatitis B immune globulin (<i>BayHep B, Nabi-HB</i>)	0.06 mL/kg IM, repeated at 3 and 6 mo	Postexposure prophylaxis against hepatitis B
 immune globulin, intramuscular (<i>BayGam, others</i>)	Dose varies with exposure; check manufacturer's instructions	Prophylaxis after exposure to hepatitis A, measles, varicella, or rubella
immune globulin, intravenous (<i>Gamimune N, Octagam, and others</i>)	Dose varies with indication and preparation; always check manufacturer's instructions	Prophylaxis after exposure to hepatitis A, measles, varicella, or rubella; bone marrow and other transplants; Kawasaki disease; chronic lymphocytic leukemia; treatment of patients with immunoglobulin deficiency
lymphocyte immune globulin (<i>Atgam</i>)	Adult: 10–30 mg/kg per day IV Pediatric: 5–25 mg/kg per day IV for aplastic anemia	Management of allograft rejection in renal transplantation; treatment of aplastic anemia
rabies immune globulin (<i>HyperRAB S/D, Imogam Rabies</i>)	20 International Units/kg IM	Protection against rabies in nonimmunized patients exposed to rabies
respiratory syncytial virus immune globulin (<i>RespiGam</i>)	1.5 mL/kg per hour for 15 min, then 3 mL/kg per hour for 15 min, then 6 mL/kg per hour to a total monthly infusion of 750 mg/kg	Prevention of respiratory syncytial virus infection in children <24 mo of age with bronchopulmonary dysplasia or premature birth
RHO immune globulin (<i>BayRho-D Full Dose, RhoGAM</i>)	One vial IM within 72 h after delivery	Prevention of sensitization to the Rh factor
RHO immune globulin, microdose (<i>BayRho-D Mini-Dose, MICRhoGAM</i>)	One vial IV within 72 h after delivery	Prevention of sensitization to the Rh factor
tetanus immune globulin (<i>BayTet</i>)	250 units IM	Passive immunization against tetanus at time of injury
vaccinia immune globulin IV (<i>VIGIV</i>)	2 mL/kg (100 mg/kg) IV	Treatment and management of vaccinia infections
varicella zoster immune globulin (<i>Varicella Zoster Immune Globulin</i>)	125 units/10 kg IM, to a maximum of 625 units	Passive immunization against varicella zoster in immunosuppressed patients exposed to disease
Antitoxins and Antivenins		
antivenin (Crotalidae) polyvalent (generic)	20–40 mL IV, up to 100–150 mL in severe cases	Neutralizes the venom of pit vipers, rattlesnakes, and copperheads
antivenin (<i>Micrurus fulvius</i>) (generic)	30–50 mL IV, flush with fluids after antivenin has infused	Neutralizes the venom of coral snakes
Black widow spider antivenin (generic)	25 mL IM or IV in 10- to 50-mL saline over 15 min	Treatment of symptoms of black widow spider bites
Crotalidae polyvalent immune fab (<i>CroFab</i>)	Four to six vials IV given diluted over 60 min	Treatment of rattlesnake bites

Implementation With Rationale

- Do not administer to any patient with a history of severe reaction to immune globulins or to the components of the drug being used *because severe immune reactions can occur.*
- Administer the drug as indicated. *Preparation varies with each product; always check the manufacturer's guidelines.*
- Monitor for severe reactions and have emergency equipment ready *to allow prompt intervention should a severe reaction occur.*
- Arrange for supportive care and comfort measures for flu-like symptoms (rest, environmental control, acetaminophen) and for the local reaction (heat to injection site, anti-inflammatories) *to promote patient comfort.*
- Provide thorough patient teaching, including measures to avoid adverse effects and warning signs of problems, *to improve patient compliance.*
- Provide a written record of immune sera use, and encourage the patient or family to keep that information *to ensure proper medical treatment and to avert future reactions.*

Evaluation

- Monitor the patient's response to the drug (improvement in disease signs and symptoms, prevention of severe disease).
- Monitor for adverse effects (flu-like symptoms, GI upset, local inflammation and pain).
- Evaluate the effectiveness of the teaching plan (patient can name drug, dosage, adverse effects to watch for, and specific measures to avoid adverse effects and to promote comfort and acknowledge the need to retain a written record of injection).
- Monitor the effectiveness of comfort measures and compliance with the regimen.

KEY POINTS

- ▶ Immune sera provide preformed antibodies to specific proteins for people who have been exposed to them or are at high risk for exposure.
- ▶ The term immune sera typically refers to sera that contain antibodies to specific bacteria or viruses.

CHAPTER SUMMARY

- Immunity (relative resistance to a disease) may be active or passive. Active immunity results from the body making

antibodies against specific proteins for immediate release if that protein re-enters the body. Passive immunity results from preformed antibodies to a specific protein, which offers protection against the protein only for the life of the circulating antibodies.

- Immunizations are given to stimulate active immunity in a person who is at high risk for exposure to specific diseases. Immunizations are a standard part of preventive medicine.
- Vaccines can be made from chemically inactivated microorganisms or from live, weakened viruses or bacteria. Toxoids are vaccines that are made from the toxins produced by the microorganism that are altered so that they are no longer poisonous but still have the recognizable protein antigen that will stimulate antibody production.
- Immune sera provide preformed antibodies to specific proteins for people who have been exposed to them or are at high risk for exposure.
- The term immune sera typically refers to sera that contain antibodies to specific bacteria or viruses. Antitoxins are immune sera that have antibodies to very specific toxins that might be released by invading pathogens. Antivenins are immune sera that have antibodies to venom that might be injected through spider or snake bites.
- Serum sickness—a massive immune reaction—occurs more frequently with immune sera than with vaccines. Patients need to be monitored for any history of hypersensitivity reactions, and emergency equipment should be available.
- Patients should be advised to keep a written record of all immunizations or immune sera used. Booster doses for various vaccines may be needed to further stimulate antibody production.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-Rom accompanying this book.

MULTIPLE CHOICE

Select the best answer to the following.

- When preparing a presentation for a local parent group about vaccines, the nurse would describe vaccines as being used to stimulate
 - passive immunity to a foreign protein.
 - active immunity to a foreign protein.
 - serum sickness.
 - a mild disease in healthy people.
- After teaching a parent about common adverse effects associated with routine immunizations, which of the following, if stated by the parent, would indicate the need for additional teaching?
 - Difficulty breathing and fainting
 - Fever and rash
 - Drowsiness and fretfulness
 - Swelling and nodule formation at the site of injection
- Which vaccine would the nurse be least likely to recommend for a 6-month-old child?
 - Diphtheria, tetanus, pertussis (DTaP) vaccine
 - Haemophilus influenzae* b vaccine
 - Poliovirus vaccine
 - Chickenpox vaccine
- The nurse recommends that older adults and people who are at high risk for complications of influenza should receive a flu vaccine every fall based on the understanding that the vaccine is repeated because
 - the immunity wears off after a year.
 - the strains of virus predicted to cause the flu change every year.
 - a booster shot will activate the immune system.
 - older people do not produce good antibodies.
- The nurse reviews a patient's record to make sure that tetanus booster shots have been given
 - only with exposure to anaerobic bacteria.
 - every 2 years.
 - every 5 years.
 - every 10 years.
- A nurse suffers a needle stick after injecting a patient with suspected hepatitis B. The nurse should
 - have repeated titers to determine whether she was exposed to hepatitis B and, if she was, have hepatitis immune globulin.
 - immediately receive hepatitis immune globulin and begin hepatitis B vaccines if she has not already received them.
 - start antibiotic therapy immediately.
 - go on sick leave until all screening tests are negative.
- A patient is to receive immune globulin after exposure to hepatitis A. The patient has a previous history of allergies to various drugs. Before giving the immune globulin, the nurse should
 - have emergency equipment readily available.
 - premedicate the patient with aspirin.
 - make sure all of the patient's vaccinations are up to date.
 - make sure the patient has a ride home.

MULTIPLE RESPONSE

Select all that apply.

- A public education campaign to stress the importance of childhood immunizations should include which of the following points?
 - Prevention of potentially devastating diseases outweighs the discomfort and risks of immunization.
 - Routine immunization is standard practice in the United States.
 - The practice of routine immunizations has virtually wiped out many previously deadly or debilitating diseases.
 - The risk of severe adverse reactions is on the rise and is not being addressed.
 - If there is a family history of autism, that person should avoid immunizations.
 - The temporary discomfort associated with the immunization can be treated with over-the-counter drugs.

2. A mother brings her child to his 18-month well-baby visit. The nurse would not give the child his routine immunizations in which of the following situations?
- He cried at his last immunization.
 - He developed a fever or rash after his last immunization.
 - He currently has a fever and symptoms of a cold.
 - He is allergic to aspirin.
 - He is currently taking oral corticosteroids.
 - His siblings are all currently being treated for a viral infection.
3. When assessing the medical record of an older adult to evaluate the status of his immunizations, the nurse would be looking for evidence of which of the following?
- Yearly pneumococcal vaccination
 - Yearly flu vaccination
 - Tetanus booster every 10 years
 - Tetanus booster every 5 years
 - Measles, mumps, rubella (MMR) vaccine if the patient was born after 1957
 - Varicella vaccine only if there is evidence that the patient had chickenpox as a child

Introduction to Nerves and the Nervous System

19

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Label the parts of a neuron and describe the functions of each part.
2. Describe an action potential, including the roles of the various electrolytes involved in the action potential.
3. Explain what a neurotransmitter is, including its origins and functions at the synapse.
4. Describe the function of the cerebral cortex, cerebellum, hypothalamus, thalamus, midbrain, pituitary gland, medulla, spinal cord, and reticular activating system.
5. Discuss what is known about learning and the impact of emotion on the learning process.

Glossary of Key Terms

action potential: sudden change in electrical charge of a nerve cell membrane; the electrical signal by which neurons send information

afferent: neurons or groups of neurons that bring information to the central nervous system; sensory nerve

axon: long projection from a neuron that carries information from one nerve to another nerve or effector

dendrite: short projection on a neuron that transmits information

depolarization: opening of the sodium channels in a nerve membrane to allow the influx of positive sodium ions, reversing the membrane charge from negative to positive

effector cell: cell stimulated by a nerve; may be a muscle, a gland, or another nerve cell

efferent: neurons or groups of neurons that carry information from the central nervous system to an effector; motor neurons are efferent

engram: short-term memory made up of a reverberating electrical circuit of action potentials

forebrain: upper level of the brain; consists of the two cerebral hemispheres, where thinking and coordination of sensory and motor activity occur

ganglia: a group of nerve bodies

hindbrain: most primitive area of the brain, the brainstem; consists of the pons and medulla, which control basic, vital

functions and arousal, and the cerebellum, which controls motor functions that regulate balance

limbic system: area in the midbrain that is rich in epinephrine, norepinephrine, and serotonin and seems to control emotions

midbrain: the middle area of the brain; it consists of the hypothalamus and thalamus and includes the limbic system

neuron: structural unit of the nervous system

neurotransmitter: chemical produced by a nerve and released when the nerve is stimulated; reacts with a specific receptor site to cause a reaction

repolarization: return of a membrane to a resting state, with more sodium ions outside the membrane and a relatively negative charge inside the membrane

Schwann cell: insulating cell found on nerve axons; allows “leaping” electrical conduction to speed the transmission of information and prevent tiring of the neuron

soma: cell body of a neuron; contains the nucleus, cytoplasm, and various granules

synapse: junction between a nerve and an effector; consists of the presynaptic nerve ending, a space called the synaptic cleft, and the postsynaptic cell

The nervous system is responsible for controlling the functions of the human body, analyzing incoming stimuli, and integrating internal and external responses. The nervous system is composed of the central nervous system (CNS; the brain and spinal cord) and the peripheral nervous system (PNS). The PNS is composed of sensory receptors that bring information into the CNS and motor nerves that carry information away from the CNS to facilitate response to stimuli. The autonomic nervous system, which is discussed in Chapter 29, uses components of the CNS and PNS to regulate automatic or unconscious responses to stimuli.

The structural unit of the nervous system is the nerve cell, or **neuron**. The billions of nerve cells that make up the nervous system are organized to allow movement realization of various sensations; response to internal and external stimuli; and learning, thinking, and emotion. The mechanisms that are involved in all of these processes are not clearly understood. The actions of drugs that are used to affect the functioning of the nerves and the responses that these drugs cause throughout the nervous system provide some of the current theories about the workings of the nervous system.

PHYSIOLOGY OF THE NERVOUS SYSTEM

The nervous system operates through the use of electrical impulses and chemical messengers to transmit information throughout the body and to respond to internal and external stimuli. The properties and functions of the neuron provide the basis for all nervous system function.

Neurons

As noted previously, the neuron is the structural unit of the nervous system. The human body contains about 14 billion neurons. About 10 billion of these are located in the brain, and the remainder make up the spinal cord and PNS.

Neurons have several distinctive cellular features (Figure 19.1). Each neuron is made up of a cell body, or **soma**, which contains the cell nucleus, cytoplasm, and various granules and other particles. Short, branch-like projections that cover most of the surface of a neuron are known as **dendrites**. These structures, which provide increased surface

area for the neuron, bring information into the neuron from other neurons.

One end of the nerve body extends into a long process that does not branch out until the very end of the process. This elongated process is called the nerve **axon**, and it emerges from the soma at the axon hillock, a slightly enlarged area of the soma from which the axon emerges. The axon of a nerve can be extremely tiny, or it can extend for several feet. The axon carries information from a nerve to be transmitted to **effector** cells—cells stimulated by a nerve, which may include a muscle, gland, or another nerve. This transmission occurs at the end of the axon, where the axon branches out in what is called the axon terminal.

The axons of many nerves are packed closely together in the nervous system and look like cable or fiber tracts. **Afferent** fibers are nerve axons that run from peripheral receptors into the CNS. In contrast, **efferent** fibers are nerve axons that carry nerve impulses from the CNS to the periphery to stimulate muscles or glands. (An easy way to remember the difference between afferent and efferent is to recall that efferent fibers exit from the CNS.)

It is currently thought that neurons are unable to reproduce; so, if nerves are destroyed, they are lost. If dendrites and axons are lost, nerves regenerate those structures; however, for this regeneration to occur, the soma and the axon hillock must remain intact. For a clinical example, consider a person who has closed a car door on his or her finger. Sensation and movement may be lost or limited for a certain period, but because the nerve bodies for most of the nerves in the hand are located in **ganglia** (groups of nerve bodies) in the wrist, they are able to regenerate the damaged axon or dendrites. Over time, sensation and full movement should return.

Research on possible ways to stimulate the reproduction of nerves is under way. Although scientists have used nerve growth factor with fetal cell implants to stimulate some nerve growth, it is currently assumed that nerves are unable to reproduce.

Action Potential

Nerves send messages by conducting electrical impulses called **action potentials**.

● **FIGURE 19.1** The neuron, functional unit of the nervous system.

Nerve membranes, which are capable of conducting action potentials along the entire membrane, send messages to nearby neurons or to effector cells that may be located inches to feet away via this electrical communication system. Like all cell membranes, nerve membranes have various channels or pores that control the movement of substances into and out of the cell. Some of these channels allow the movement of sodium, potassium, and calcium. When cells are at rest, their membranes are impermeable to sodium. However, the membranes are permeable to potassium ions.

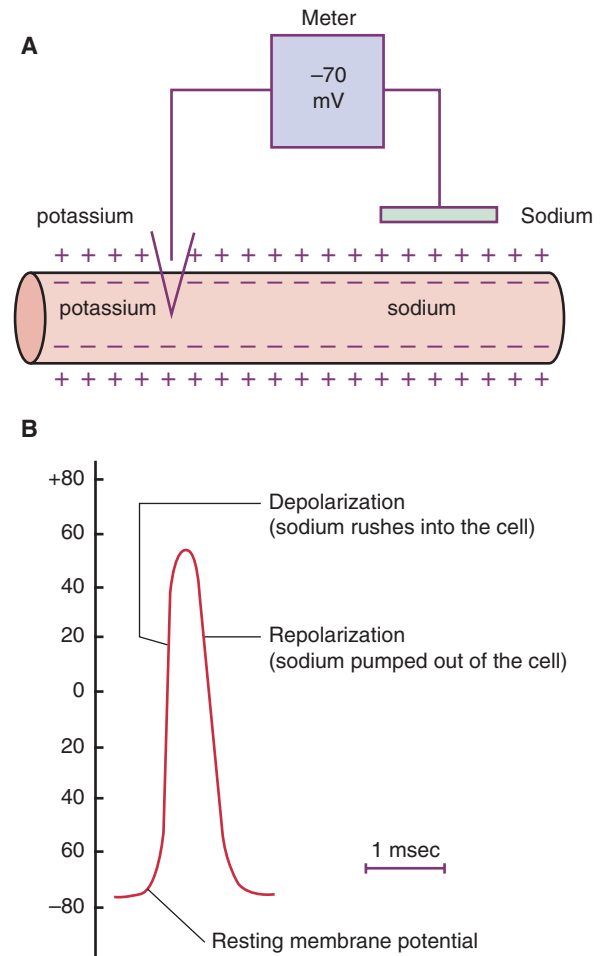

The sodium–potassium pump that is active in the membranes of neurons is responsible for this property of the membrane. This system pumps sodium ions out of the cell and potassium ions into the cell. At rest, more sodium ions are outside the cell membrane, and more potassium ions are inside. Electrically, the inside of the cell is relatively negative compared with the outside of the membrane, which establishes an electrical potential along the nerve membrane. When nerves are at rest, this is referred to as the resting membrane potential of the nerve.

Stimulation of a neuron causes **depolarization** of the nerve, which means that the sodium channels open in response to the stimulus, and sodium ions rush into the cell, following the established concentration gradient. If an electrical monitoring device is attached to the nerve at this point, a positive rush of ions is recorded. The electrical charge on the inside of the membrane changes from relatively negative to relatively positive. This sudden reversal of membrane potential, called the action potential (Figure 19.2), lasts less than a microsecond. Using the sodium–potassium pump, the cell then returns that section of membrane to the resting membrane potential, a process called **repolarization**. The action potential generated at one point along a nerve membrane stimulates the generation of an action potential in adjacent portions of the cell membrane, and the stimulus travels the length of the cell membrane.

Nerves can respond to stimuli several hundred times per second, but for a given stimulus to cause an action potential, it must have sufficient strength and must occur when the nerve membrane is able to respond—that is, when it has repolarized. A nerve cannot be stimulated again while it is depolarized. The balance of sodium and potassium across the cell membrane must be re-established.

Nerves require energy (i.e., oxygen and glucose) and the correct balance of the electrolytes sodium and potassium to maintain normal action potentials and transmit information into and out of the nervous system. If an individual has anoxia or hypoglycemia, the nerves might not be able to maintain the sodium–potassium pump, and that individual may become severely irritable or too stable (not responsive to stimuli).

Long nerves are myelinated: they have a myelin sheath that speeds electrical conduction and protects the nerves from the fatigue that results from frequent formation of action potentials. Even though many of the tightly packed nerves in the brain do not need to travel far to stimulate another nerve,

● **FIGURE 19.2** The action potential. **A.** A segment of an axon showing that, at rest, the inside of the membrane is relatively negatively charged and the outside is positively charged. A pair of electrodes placed as shown would record a potential difference of about -70 mV; this is the resting membrane potential. **B.** An action potential of about 1 msec that would be recorded if the axon shown in panel A were brought to threshold. At the peak of the action potential, the charge on the membrane reverses polarity.

they are myelinated. The effect of this myelination is not understood.

Myelinated nerves have **Schwann cells**, which are located at specific intervals along nerve axons and are very resistant to electrical stimulation (Figure 19.1). The Schwann cells wrap themselves around the axon in jellyroll fashion (Figure 19.3). Between the Schwann cells are areas of uncovered nerve membrane called the nodes of Ranvier. So-called “leaping” nerve conduction occurs along these exposed nerve fibers. An action potential excites one section of nerve membrane, and the electrical impulse then “skips” from one node to the next, generating an action potential. Because the membrane is forming fewer action potentials, the speed of conduction is much faster and the nerve is protected from being exhausted or using up energy to form multiple action potentials. This node-to-node mode of conduction is termed *saltatory* or leaping conduction (Figure 19.1).

● **FIGURE 19.3** Formation of a myelin sheath. **A.** Schwann cells wrap around the axon, creating a myelin coating. **B.** The outermost layer of the Schwann cell forms the neurilemma. Spaces between the cells are the nodes of Ranvier.

If the Schwann cells become enlarged or swollen and block the nodes of Ranvier, which is what occurs in the neuromuscular disease multiple sclerosis, conduction does not occur because the electrical impulse has a limited firing range. A stimulus may simply be “lost” along the nerve. Believed to be an autoimmune disorder that attacks Schwann cells and leads to swelling and scarring of these cells, multiple sclerosis is characterized by a progressive loss of nerve response and muscle function.

Nerve Synapse

When the electrical action potential reaches the end of an axon, the electrical impulse comes to a halt. At this point the stimulus no longer travels at the speed of electricity. The transmission of information between two nerves or between a nerve and a gland or muscle is chemical. Nerves communicate with other nerves or effectors at the nerve **synapse** (Figure 19.4). The synapse is made up of a presynaptic nerve, the synaptic cleft, and the postsynaptic effector cell. The nerve axon, called the presynaptic nerve, releases a chemical called a **neurotransmitter** into the synaptic cleft, and the

neurotransmitter reacts with a very specific receptor site on the postsynaptic cell to cause a reaction.

Neurotransmitters

Neurotransmitters stimulate postsynaptic cells either by exciting or by inhibiting them. The reaction that occurs when a neurotransmitter stimulates a receptor site depends on the specific neurotransmitter that it releases and the receptor site it activates. A nerve may produce only one type of neurotransmitter, using building blocks such as tyrosine or choline from the extracellular fluid, often absorbed from dietary sources. The neurotransmitter, packaged into vesicles, moves to the terminal membrane of the axon, and when the nerve is stimulated, the vesicles contract and push the neurotransmitter into the synaptic cleft. The calcium channels in the nerve membrane are open during the action potential, and the presence of calcium causes the contraction. When the cell repolarizes, calcium leaves the cell, and the contraction stops. Once released into the synaptic cleft, the neurotransmitter reacts with very specific receptor sites to cause a reaction.

To return the effector cell to a resting state so that it can be stimulated again, if needed, neurotransmitters must be inactivated. Neurotransmitters may be either reabsorbed by the presynaptic nerve in a process called reuptake (a recycling effort by the nerve to reuse the materials and save resources) or broken down by enzymes in the area (e.g., monoamine oxidase breaks down the neurotransmitter norepinephrine; the enzyme acetylcholinesterase breaks down the neurotransmitter acetylcholine). Several neurotransmitters have been identified. As research continues, other neurotransmitters may be discovered, and the actions of known neurotransmitters will be better understood.

The following are selected neurotransmitters:

- *Acetylcholine*, which communicates between nerves and muscles, is also important as the preganglionic neurotransmitter throughout the autonomic nervous system and as the postganglionic neurotransmitter in the parasympathetic nervous system and in several pathways in the brain.
- *Norepinephrine* and *epinephrine* are catecholamines, which are released by nerves in the sympathetic branch of the autonomic nervous system and are classified as hormones when they are released from cells in the adrenal medulla. These neurotransmitters also occur in high levels in particular areas of the brain, such as the limbic system.
- *Dopamine*, which is found in high concentrations in certain areas of the brain, is involved in the coordination of impulses and responses, both motor and intellectual.
- *Gamma-aminobutyric acid (GABA)*, which is found in the brain, inhibits nerve activity and is important in preventing overexcitability or stimulation such as seizure activity.
- *Serotonin*, which is also found in the limbic system, is important in arousal and sleep, as well as in preventing depression and promoting motivation.

Many of the drugs that affect the nervous system involve altering the activity of the nerve synapse. These drugs have

● **FIGURE 19.4** The sequence of events in synaptic transmission: **(1)** Synthesis of the neurotransmitter; **(2)** uptake of the neurotransmitter into storage vesicles; **(3)** release of the neurotransmitter by an action potential in the presynaptic nerve; **(4)** diffusion of the neurotransmitter across the synaptic cleft; **(5)** combination of the neurotransmitter with a receptor; **(6)** a sequence of events leading to activation of second messengers within the postsynaptic nerve; **(7)** change in permeability of the postsynaptic membrane to one or more ions, causing **(8a)** an inhibitory postsynaptic potential or **(8b)** an excitatory postsynaptic potential. Characteristic responses of the postsynaptic cell are as follows: **(9a)** The gland secretes hormones; **(9b)** the muscle cells have an action potential; and **(10)** the muscle contracts. The action of the neurotransmitter is terminated by one or more of the following processes. **(A)** inactivation by an enzyme; **(B)** diffusion out of the synaptic cleft and removal by the vascular system; and **(C)** reuptake into the presynaptic nerve followed by storage in a synaptic vesicle or deactivation by an enzyme.

several functions, including blocking the reuptake of neurotransmitters so that they are present in the synapse in greater quantities and cause more stimulation of receptor sites; blocking receptor sites so that the neurotransmitter cannot stimulate the receptor site; blocking the enzymes that break down neurotransmitters to cause an increase in neurotransmitter concentration in the synapse; stimulating specific receptor sites when the neurotransmitter is not available; and causing the presynaptic nerve to release greater amounts of the neurotransmitter.

KEY POINTS

- ▶ The nervous system controls the body, analyzes external stimuli, and integrates internal and external responses to stimuli.
- ▶ The neuron, comprising a cell body, dendrites and an axon, is the functional unit of the nervous system. Dendrites route information to the nerve, and axons take the information away.
- ▶ Nerves transmit information by way of action potentials. An action potential is a sudden change in membrane charge from negative to positive that is triggered when stimulation of a nerve opens sodium channels and allows positive sodium ions to flow into the cell.
- ▶ When sodium ions flow into a nerve, the nerve membrane depolarizes. Mechanically, this is recorded as a flow of positive electrical charges. Repolarization immediately follows, with the sodium–potassium pump in the cell membrane pumping sodium and potassium ions out of the cell, leaving the inside of the membrane relatively negative to the outside.
- ▶ At the end of the axon, neurons communicate with chemicals called neurotransmitters, which are produced by the nerve. Neurotransmitters are released into the synapse when the nerve is stimulated; they react with a very specific receptor site to cause a reaction and are immediately broken down or removed from the synapse.

CENTRAL NERVOUS SYSTEM

The CNS consists of the brain and the spinal cord, the two parts of the body that contain the vast majority of nerves. The bones of the vertebrae protect the spinal cord; and the bones of the skull, which are corrugated much like an egg carton and serve to absorb impact, protect the brain (Figure 19.5). In addition, the meninges, which are membranes that cover the nerves in the brain and spine, furnish further protection.

The blood–brain barrier, a functioning boundary, also plays a defensive role. It keeps toxins, proteins, and other large structures out of the brain and prevents their contact with the sensitive and fragile neurons. The blood–brain barrier represents a therapeutic challenge to drug treatment of brain-related disorders because a large percentage of drugs

● FIGURE 19.5 Bony and membranous protection of the brain.

are carried bound to plasma proteins and are unable to cross into the brain. When a patient is suffering from a brain infection, antibiotics cannot cross into the brain until the infection is so severe that the blood–brain barrier can no longer function.

The brain has a unique blood supply to protect the neurons from lack of oxygen and glucose. Two arteries—the carotids—branch off the aortic arch and go up into each side of the brain at the front of the head, and two other arteries—the vertebrals—enter the back of the brain to become the basilar arteries. These arteries all deliver blood to a common vessel at the bottom of the brain called the circle of Willis, which distributes the blood to the brain as it is needed (Figure 19.6). The role of the circle of Willis becomes apparent when an individual has an occluded carotid artery. Although the passage of blood through one of the carotid arteries may be negligible, the areas of the brain on that side will still have a full blood supply because of the blood sent to those areas via the circle of Willis.

Anatomy of the Brain

The brain has three major divisions: the hindbrain, the midbrain, and the forebrain (Figure 19.7).

The **hindbrain**, which runs from the top of the spinal cord into the midbrain, is the most primitive area of the brain and contains the brainstem, where the pons and medulla oblongata are located. These areas of the brain control basic, vital functions, such as the respiratory centers, which control breathing; the cardiovascular centers, which regulate blood

● **FIGURE 19.6** The protective blood supply of the brain: the carotid, vertebral, and basilar arteries join to form the circle of Willis.

pressure; the chemoreceptor trigger zone and emetic zone, which control vomiting; the swallowing center, which coordinates the complex swallowing reflex; and the reticular activating system (RAS), which controls arousal and awareness of stimuli and contains the sleep center. The RAS filters the billions of incoming messages, selecting only the most significant for response. When levels of serotonin become high in the RAS, the system shuts down, and sleep occurs. The medulla absorbs serotonin from the RAS; when the levels are low enough, consciousness or arousal results.

The cranial nerves (see Figure 19.7), which also emerge from the hindbrain, involve *specific* senses (sight, smell, hearing, balance, taste) and some muscle activity of the head and neck (e.g., chewing, eye movement). The cerebellum—a part of the brain that looks like a skein of yarn and lies behind the other parts of the hindbrain—coordinates the motor function that regulates posture, balance, and voluntary muscle activity.

The **midbrain** contains the thalamus, the hypothalamus, and the limbic system (see Figure 19.7). The thalamus sends direct information into the cerebrum to transfer sensations, such as cold, heat, pain, touch, and muscle sense. The hypothalamus, which is poorly protected by the blood–brain barrier, acts as a major sensor for activities in the body. Areas of the hypothalamus are responsible for temperature control, water balance, appetite, and fluid balance. In addition, the hypothalamus plays a central role in the endocrine system and in the autonomic nervous system.

The **limbic system** is an area of the brain that contains high levels of three neurotransmitters: epinephrine, norepinephrine, and serotonin. Stimulation of this area, which

● **FIGURE 19.7** Anatomy of the brain. **A.** A view of the underside of the brain. **B.** The medial or midsagittal view of the brain.

appears to be responsible for the expression of emotions, may lead to anger, pleasure, motivation, stress, and so on. This part of the brain seems to be largely responsible for the “human” aspect of brain function. Drug therapy aimed at alleviating emotional disorders such as depression and anxiety often involves attempting to alter the levels of epinephrine, norepinephrine, and serotonin.

The **forebrain** is made up of two cerebral hemispheres joined together by an area called the corpus callosum. These two hemispheres contain the sensory neurons, which receive nerve impulses, and the motor neurons, which send them. They also contain areas that coordinate speech and communication and seem to be the area where learning takes place (see Figure 19.7). Different areas of the brain appear to be responsible for receiving and sending information to specific areas of the body. When the brain is viewed at autopsy, it looks homogeneous, but scientists have mapped the general areas that are responsible for sensory response, motor function, and other functions (see Figure 19.8). In conjunction with the cerebellum, groups of ganglia or nerve cell bodies called the basal ganglia, located at the bottom of the brain, make up the extrapyramidal motor system. This system coordinates motor activity for unconscious activities such as posture and gait.

● **FIGURE 19.8** Functional areas of the brain. **A.** Topographical organization of functions of control and interpretation in the cerebral cortex. **B.** Areas of the brain that control specific areas of the body. Size indicates relative distribution of control.

Anatomy of the Spinal Cord

The spinal cord is made up of 31 pairs of spinal nerves. Each spinal nerve has two components or roots. These mixed nerve parts include a sensory fiber (called the dorsal root) and a motor fiber (called the ventral root). The spinal sensory fibers bring information into the CNS from the periphery. The motor fibers cause movement or reaction.

Functions of the Central Nervous System

The brain is responsible for coordinating reactions to the constantly changing external and internal environment. In all animals, the function of this organ is essentially the same. The human component involving emotions, learning, and conscious response takes the human nervous system beyond a simple reflex system and complicates the responses seen to any stimulus.

Sensory Functions

Millions of sensory impulses are constantly streaming into the CNS from peripheral receptors. Many of these impulses go directly to specific areas of the brain designated to deal with input from particular areas of the body or from the senses. The responses that occur as a result of these stimuli can be altered by efferent neurons that respond to emotions through the limbic system, to learned responses stored in the cerebral cortex, or to autonomic input mediated through the hypothalamus.

The intricacies of the human brain can change the response to a sensation depending on the situation. People may react differently to the same stimulus. For example, if an individual drops a can on his or her foot, the physiological response is one of pain and a stimulation of the sympathetic

branch of the autonomic nervous system. If the person is alone or in a very comfortable environment (e.g., fixing dinner at home), he or she may scream, swear, or jump around. However, if that person is in the company of other people (e.g., a cooking teacher working with a class), he or she may be much more dignified and quiet, even though the physiological effect on the body is the same.

Motor Functions

The sensory nerves that enter the brain react with related motor nerves to cause a reaction mediated by muscles or glands. The motor impulses that leave the cortex are further regulated or coordinated by the pyramidal system, which coordinates voluntary movement, and the extrapyramidal system, which coordinates unconscious motor activity that regulates control of position and posture. For example, some drugs may interfere with the extrapyramidal system and cause tremors, shuffling gait, and lack of posture and position stability. Motor fibers from the cortex cross to the other side of the spinal cord before emerging to interact with peripheral effectors. In this way, motor stimuli coming from the right side of the brain affect motor activity on the left side of the body. For example, an area of the left cortex may send an impulse down to the spinal cord that reacts with an interneuron, crosses to the other side of the spinal cord, and causes a finger on the right hand to twitch.

Intellectual and Emotional Functions

The way that the cerebral cortex uses sensory information is not clearly understood, but research has demonstrated that the two hemispheres of the brain process information in different ways. The right side of the brain is the more artistic

side, concerned with forms and shapes, and the left side is more analytical, concerned with names, numbers, and processes. Why the two hemispheres are different and how they develop differently is not known.

When learning takes place, distinct layers of the cerebral cortex are affected, and an actual membrane change occurs in a neuron to store information in the brain permanently. Learning begins as an electrical circuit called an **engram**, a reverberating circuit of action potentials that eventually becomes a long-term, permanent memory in the presence of the proper neurotransmitters and hormones. Scientists do not understand exactly how this happens, but it is known that the nerve requires oxygen, glucose, and sleep to process an engram into a permanent memory, and during that processing structural changes occur to the cells involved in the engram. This reverberating circuit is responsible for short-term memory. When patients have a decreased blood supply to the brain, short-term memory may be lost, and they are not able to remember new things. Because they are unable to remember new things, the brain falls back on long-term, permanent memory for daily functioning. For example, a patient may be introduced to a nurse and have no recollection of the nurse 2 hours later and yet be able to recall the events of several years ago vividly.

Several substances appear to affect learning. Antidiuretic hormone (ADH), which is released during reactions to stress, is one such substance. Although too much stress prevents learning, feeling slightly stressed may increase a person's ability to learn. A patient who is a little nervous about upcoming surgery, for example, seems to display a better mastery of facts about the surgery and postoperative procedures than a patient who is very stressed and scared or one who appears to show no interest or concern. Oxytocin is another substance that seems to increase actual learning. Because childbirth is the only known time that oxytocin levels increase, the significance of this is not understood. Nurses who work with maternity patients should know that women in labor will very likely remember the smallest details about the whole experience and should use whatever opportunity is made available to do teaching.

In addition, the limbic system appears to play an important role in how a person learns and reacts to stimuli. The emotions associated with a memory as well as with the present have an impact on stimulus response. The placebo effect is a documented effect of the mind on drug therapy: If a person perceives that a drug will be effective, it is much more likely to actually be effective. This effect, which uses the actions of the cerebrum and the limbic system, can have a tremendous impact on drug response. Events that are perceived as stressful by some patients may be seen as positive by other patients.

KEY POINTS

◆ The CNS consists of the brain and spinal cord, which are protected by bone and meninges. To ensure blood flow to the brain if a vessel should become damaged, the brain also has a protective blood supply moderated by the circle of Willis.

- ◆ The hindbrain, the most primitive area of the brain, contains the centers that control basic, vital functions. The pons, the medulla, and the reticular activating system (RAS), which regulates arousal and awareness, are all located in the hindbrain. The cerebellum, which helps to coordinate motor activity, is found at the back of the hindbrain.
- ◆ The midbrain consists of the hypothalamus, the thalamus, and the limbic system. The limbic system is responsible for the expression of emotion, and the thalamus and hypothalamus coordinate internal and external responses and direct information into the cerebral cortex.
- ◆ The cerebral cortex consists of two hemispheres, which regulate the communication between sensory and motor neurons and are the sites of thinking and learning.

CLINICAL SIGNIFICANCE OF DRUGS THAT ACT ON THE NERVOUS SYSTEM

The features of the human nervous system, including the complexities of the human brain, sometimes make it difficult to predict the exact reaction of a particular patient to a given drug. When a drug is used to affect the nervous system, the occurrence of many systemic effects is always a possibility because the nervous system affects the entire body. The chapters in this section address the individual classes of drugs used to treat disorders of the nervous system, including their adverse effects. An understanding of the actions of specific drugs makes it easier to anticipate what therapeutic and adverse effects might occur. In addition, nurses should consider all of the learned, cultural, and emotional aspects of the patient's situation in an attempt to provide optimal therapeutic benefit and minimal adverse effects.

CHAPTER SUMMARY

- Although nerves do not reproduce, they can regenerate injured parts if the soma and axon hillock remain intact.
- Efferent nerves take information out of the CNS to effector sites; afferent nerves are sensory nerves that take information into the CNS.
- When the transmission of action potentials reaches the axon terminal, it causes the release of chemicals called neurotransmitters, which cross the synaptic cleft to stimulate an effector cell, which can be another nerve, a muscle, or a gland.
- A neurotransmitter must be produced by a nerve (each nerve can produce only one kind); it must be released into the synapse when the nerve is stimulated; it must react with a very specific receptor site to cause a reaction; and it must be immediately broken down or removed from the synapse so that the cell can be ready to be stimulated again.
- Much of the drug therapy in the nervous system involves receptor sites and the release or reuptake and breakdown of neurotransmitters.

- The CNS consists of the brain and spinal cord, which are protected by bone and meninges. To ensure blood flow to the brain if a vessel should become damaged, the brain also has a protective blood supply moderated by the circle of Willis.
- The hindbrain, the most primitive area of the brain, contains the centers that control basic, vital functions. The pons, the medulla, and the reticular activating system (RAS), which regulates arousal and awareness, are all located in the hindbrain. The cerebellum, which helps to coordinate motor activity, is found at the back of the hindbrain.
- The midbrain consists of the hypothalamus, the thalamus, and the limbic system. The limbic system is responsible for the expression of emotion, and the thalamus and hypothalamus coordinate internal and external responses and direct information into the cerebral cortex.
- The cerebral cortex consists of two hemispheres, which regulate the communication between sensory and motor neurons and are the sites of thinking and learning.
- The mechanisms of learning and processing learned information are not understood. Emotion-related factors influence the human brain, which handles stimuli and responses in complex ways.
- Much remains to be learned about the human brain and how drugs influence it. The actions of many drugs that have known effects on human behavior are not understood.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-Rom in the front of the book.

MULTIPLE CHOICE

Select the best answer to the following.

- The cerebellum
 - initiates voluntary muscle movement.
 - helps regulate the tone of skeletal muscles.
 - if destroyed, would result in the loss of all voluntary skeletal activity.
 - contains the centers responsible for the regulation of body temperature.
- At those regions of the nerve membrane where myelin is present, there is
 - low resistance to electrical current.
 - high resistance to electrical current.
 - high conductance of electrical current.
 - energy loss for the cell.
- The nerve synapse
 - is not resistant to electrical current.
 - cannot become exhausted.
 - has a synaptic cleft.
 - transfers information at the speed of electricity.
- Which of the following could result in the initiation of an action potential?
 - Depolarizing the membrane
 - Decreasing the extracellular potassium concentration
 - Increasing the activity of the sodium–potassium active transport system
 - Stimulating the nerve with a threshold electrical stimulus during the absolute refractory period of the membrane
- Neurotransmitters are
 - produced in the muscle to communicate with nerves.
 - the chemicals used to stimulate or suppress effectors at the nerve synapse.
 - usually found in the diet.
 - nonspecific in their action on various nerves.
- The limbic system is an area of the brain that
 - is responsible for coordination of movement.
 - is responsible for the special senses.
 - is responsible for the expression of emotions.
 - controls sleep.
- The most primitive area of the brain, the brainstem, contains areas responsible for
 - vomiting, swallowing, respiration, arousal, and sleep.
 - learning.
 - motivation and memory.
 - taste, sight, hearing, and balance.

8. A clinical indication of poor blood supply to the brain, particularly to the higher levels where learning takes place, would be
- loss of long-term memory.
 - loss of short-term memory.
 - loss of coordinated movement.
 - insomnia.

- Little glucose is stored in nerve cells, so a constant supply is needed.
- The brain needs a constant supply of insulin and thyroid hormone.
- The brain swells easily and needs the blood supply to reduce swelling.
- Circulating aldosterone levels maintain the fluid balance in the brain.

MULTIPLE RESPONSE

Select all that apply.

1. In explaining the importance of a constant blood supply to the brain, the nurse would tell the student which of the following?
- Energy is needed to maintain nerve membranes and cannot be produced without oxygen.
 - Carbon dioxide must constantly be removed to maintain the proper pH.

2. The blood–brain barrier could be described by which of the following?
- It is produced by the cells that make up the meninges.
 - It is regulated by the microglia in the CNS.
 - It is weaker in certain parts of the brain.
 - It is uniform in its permeability throughout the CNS.
 - It is an anatomical structure that can be punctured.
 - It is more likely to block the entry of proteins into the CNS.

Anxiolytic and Hypnotic Agents

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Define the states that are affected by anxiolytic or hypnotic agents.
2. Describe the therapeutic actions, indications, pharmacokinetics, contraindications, most common adverse reactions, and important drug–drug interactions associated with each class of anxiolytic or hypnotic agent.
3. Discuss the use of anxiolytic or hypnotic agents across the lifespan.
4. Compare and contrast the prototype drugs for each class of anxiolytic or hypnotic drug with the other drugs in that class.
5. Outline the nursing considerations and teaching needs for patients receiving each class of anxiolytic or hypnotic agent.

Glossary of Key Terms

anxiety: unpleasant feeling of tension, fear, or nervousness in response to an environmental stimulus, whether real or imaginary

anxiolytic: drug used to depress the central nervous system (CNS); prevents the signs and symptoms of anxiety

barbiturate: former mainstay drug used for the treatment of anxiety and for sedation and sleep induction; associated with potentially severe adverse effects and many drug–drug interactions, which makes it less desirable than some of the newer agents

benzodiazepine: drug that acts in the limbic system and the reticular activating system to make gamma-aminobutyric

acid (GABA), an inhibitory neurotransmitter, more effective, causing interference with neuron firing; depresses CNS to block the signs and symptoms of anxiety, and may cause sedation and hypnosis in higher doses

hypnosis: extreme sedation resulting in CNS depression and sleep

hypnotic: drug used to depress the CNS; causes sleep

sedation: loss of awareness of and reaction to environmental stimuli

sedative: drug that depresses the CNS; produces a loss of awareness of and reaction to the environment

BENZODIAZEPINES USED AS ANXIOLYTICS

alprazolam
chlordiazepoxide
clorazepate
diazepam
estazolam
flurazepam
lorazepam
oxazepam

quazepam
temazepam
triazolam

BARBITURATES USED AS ANXIOLYTIC-HYPNOTICS

amobarbital
butobarbital
mephobarbital

pentobarbital
phenobarbital
secobarbital

OTHER ANXIOLYTIC AND HYPNOTIC DRUGS

bupirone
chloral hydrate
dexmedetomidine

diphenhydramine
eszopiclone
meprobamate
promethazine
ramelteon
zaleplon
zolpidem

The drugs discussed in this chapter are used to alter an individual's responses to environmental stimuli. They have been called **anxiolytics** because they can prevent feelings of tension or fear; **sedatives** because they can calm patients and make them unaware of their environment; **hypnotics** because they can cause sleep; and minor tranquilizers because they can produce a state of tranquility in anxious patients. In the past, a given drug would simply be used at different doses to yield each of these effects. Further research into how the brain reacts to outside stimuli has resulted in the increased availability of specific agents that produce particular goals and avoid unwanted adverse effects. Use of these drugs also varies across the lifespan (Box 20.1).

STATES AFFECTED BY ANXIOLYTIC AND HYPNOTIC DRUGS

Anxiety

Anxiety is a feeling of tension, nervousness, apprehension, or fear that usually involves unpleasant reactions to a stimulus, whether actual or unknown. Anxiety is often accompanied by

signs and symptoms of the sympathetic stress reaction (see Chapter 29), which may include sweating, fast heart rate, rapid breathing, and elevated blood pressure. Mild anxiety, a not uncommon reaction, may serve as a stimulus or motivator in some situations. A person who feels anxious about being alone in a poorly lit parking lot at night may be motivated to take extra safety precautions. When anxiety becomes overwhelming or severe, it can interfere with the activities of daily living and lead to medical problems related to chronic stimulation of the sympathetic nervous system. A severely anxious person may, for example, be afraid to leave the house or to interact with other people. In these cases, treatment is warranted. Anxiolytic drugs are drugs that are used to lyse or break the feeling of anxiety.

Sedation

The loss of awareness and reaction to environmental stimuli is termed **sedation**. This condition may be desirable in patients who are restless, nervous, irritable, or overreacting to stimuli. Although sedation is anxiolytic, it may frequently lead to drowsiness. For example, sedative-induced drowsiness is a concern for outpatients who need to be alert and responsive in

BOX 20.1 Drug Therapy Across the Lifespan

Anxiolytic and Hypnotic Agents

CHILDREN

Use of anxiolytic and hypnotic drugs with children is challenging. The response of the child to the drug may be unpredictable; inappropriate aggressiveness, crying, irritability, and fearfulness are common.

Of the benzodiazepines, only chlordiazepoxide, clonazepam, clorazepate, and diazepam have established pediatric dosages. Some of the others are used in pediatric settings, and dosage may be calculated using age and weight.

The barbiturates, being older drugs, have established pediatric dosages. These drugs must be used with caution because of the often unexpected responses. Children must be monitored very closely for CNS depression and excitability.

Chloral hydrate is approved for use in children. The potential for adverse effects and the unpleasant taste and odor make the drug less desirable as a sleep agent. The antihistamines diphenhydramine and promethazine are more popular for use in helping to calm children and to induce rest and sleep. Care must be taken to assess for possible dried secretions and effects on breathing. Dosage must be calculated carefully.

ADULTS

Adults using these drugs for the treatment of insomnia need to be cautioned that they are for short-term use only. The reason for the insomnia should be sought (e.g., medical, hormonal, or anxiety problems). Other methods for helping to induce sleep—established routines, quiet activities before bed, a back-rub or warm bath—should be encouraged

before drugs are prescribed. Adults receiving anxiolytics also may need referrals for counseling and diagnosis of possible causes. Adults should be advised to avoid driving and making legal decisions when taking these drugs.

Liver function should be evaluated before and periodically during therapy.

These drugs are contraindicated during pregnancy and lactation because of the potential for adverse effects on the fetus and possible sedation of the baby. The antihistamines, which have not been associated with congenital malformations, may be the safest to use, with caution, if an anxiolytic or hypnotic drug must be used.

OLDER ADULTS

Older patients may be more susceptible to the adverse effects of these drugs, from unanticipated CNS effects to increased sedation, dizziness, and even hallucinations. Dosages of all of these drugs should be reduced and the patient should be monitored very closely for toxic effects and to provide safety measures if CNS effects do occur.

Baseline liver and renal function tests should be performed, and these values should be monitored periodically for any changes that would indicate a need to decrease dosage further or to stop the drug.

Nondrug measures to reduce anxiety and to help induce sleep are important with older patients. The patient should be screened for physical problems, neurological deterioration, or depression, which could contribute to the insomnia or anxiety.

their normal lives. On the other hand, this tiredness may be desirable for patients who are about to undergo surgery or other procedures and who are receiving medical support. The choice of an anxiolytic drug depends on the situation in which it will be used, keeping the related adverse effects in mind.

Hypnosis

Extreme sedation results in further central nervous system (CNS) depression and sleep, or **hypnosis**. Hypnotics are used to help people fall asleep by causing sedation. Drugs that are effective hypnotics act on the reticular activating system (RAS) and block the brain's response to incoming stimuli. Hypnosis, therefore, is the extreme state of sedation, in which the person no longer senses or reacts to incoming stimuli.

BENZODIAZEPINES USED AS ANXIOLYTICS

Benzodiazepines, the most frequently used anxiolytic drugs, prevent anxiety without causing much associated sedation. In addition, they are less likely to cause physical dependence than many of the older sedatives/hypnotics that are used to relieve anxiety. Table 20.1 lists the available benzodiazepines, including common indications and specific information about each drug. The benzodiazepines used as anxiolytics include alprazolam (*Xanax*), chlordiazepoxide (*Librium*), clorazepate (*Tranxene*), diazepam (*Valium*), estazolam (*ProSom*), flurazepam (*Dalmane*), lorazepam (*Ativan*), oxazepam (*Serax*), quazepam (*Doral*), temazepam (*Restoril*), and triazolam (*Halcion*). Box 20.2 provides an exercise in calculating dose for a pediatric patient receiving a sedative/hypnotic.

FOCUS BOX 20.2 Calculations

Your 3-year-old patient, weighing 25 kg, is prescribed chloral hydrate as a hypnotic at bedtime. The order reads: 50 mg/kg/day PO at bedtime. The drug comes in a syrup form as 500 mg/5 mL. How much syrup would you give as the bedtime dose?

First, figure out what the correct dose would be:

$$50 \text{ mg/kg} \times 25 \text{ kg} = 1250 \text{ mg}$$

Set up the equation using available form = prescribed dose:

$$500 \text{ mg}/5 \text{ mL} = 1250 \text{ mg}/\text{dose}$$

Then, cross-multiply:

$$\begin{aligned} 500 \text{ mg (dose)} &= 6250 \text{ mg (mL)} \\ \text{dose} &= 6250 \text{ mg (mL)}/500 \text{ mg} \\ \text{dose} &= 12.5 \text{ mL} \end{aligned}$$

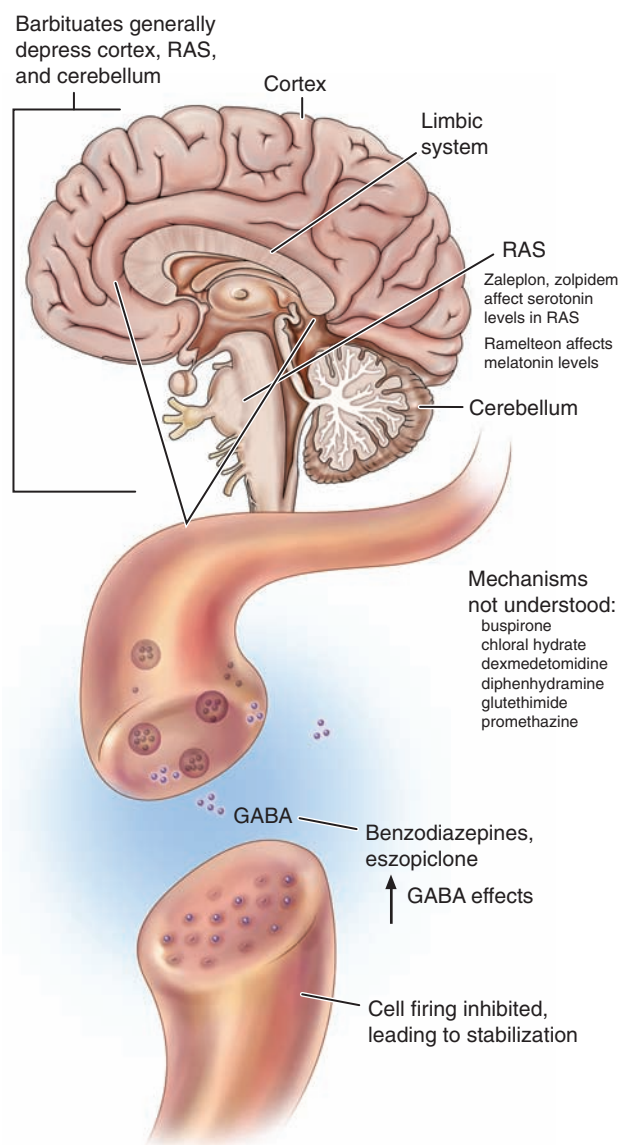

Because this is a child, it is good practice to ask another nurse to calculate the correct dosage and then compare your work, so you can double-check the accuracy of your calculations.

Therapeutic Actions and Indications

The benzodiazepines are indicated for the treatment of the following conditions: anxiety disorders, alcohol withdrawal, hyperexcitability and agitation, and preoperative relief of anxiety and tension to aid in balanced anesthesia. These drugs act in the limbic system and the RAS to make gamma-aminobutyric acid (GABA) more effective, causing interference with neuron firing (Figure 20.1). GABA stabilizes the postsynaptic cell. This leads to an anxiolytic effect at doses lower than those required to induce sedation and hypnosis. The exact mechanism of action is not clearly understood.

Pharmacokinetics

The benzodiazepines are well absorbed from the gastrointestinal (GI) tract, with peak levels achieved in 30 minutes

● **FIGURE 20.1** Sites of action of the benzodiazepines, barbiturates, and other anxiolytics.

TABLE 20.1 DRUGS IN FOCUS Benzodiazepines* Used as Anxiolytics

Drug Name	Dosage/Route	Usual Indications
alprazolam (<i>Xanax</i>)	0.25–0.5 mg PO t.i.d. up to 1–10 mg/day PO have been used; reduced dosage in elderly	Anxiety; panic attacks Onset: 30 min Duration: 4–6 h Special considerations: Taper after long-term therapy
chlordiazepoxide (<i>Librium</i>)	Adult: 5–25 mg PO t.i.d. to q.i.d.; or 50–100 mg IV or IM; may be repeated; reduce dosage with older patients Pediatric (>6 yr): 5 mg PO b.i.d. to q.i.d.; 25–50 mg IV or IM	Anxiety; alcohol withdrawal; preoperative anxiolytic Onset: 10–15 min Duration: 2–3 days Special considerations: Monitor injection sites
clorazepate (<i>Tranxene</i>)	Adult: 15–60 mg/day in divided doses; 7.5–15 mg/day PO for elderly patients Pediatric: (9–12 yr): 7.5 mg PO b.i.d. as adjunct therapy for epilepsy	Anxiety; alcohol withdrawal; partial seizures Onset: rapid Duration: days Special considerations: Taper dosage
 diazepam (<i>Valium</i>)	Adult: 2–10 mg PO b.i.d. to q.i.d.; or 0.2 mg/kg PR; or 2–30 mg IM b.i.d. or IV; 2–2.5 mg PO b.i.d. for elderly patients Pediatric: 1–2.5 mg PO t.i.d. to q.i.d.; 0.3–0.5 mg/kg PR; or 1–3 mg IM or IV	Anxiety; alcohol withdrawal; muscle relaxant; antiepileptic; antitetanous; preoperative anxiolytic Onset: 5–60 min Duration: 3 h Special considerations: Monitor injection sites; drug of choice if route change is anticipated; taper after long-term therapy
estazolam (<i>ProSom</i>)	1 mg PO at bedtime; start with 0.5 mg for elderly or debilitated patient	Hypnotic; treatment of insomnia Onset: 45–60 min Duration: 2 h Special considerations: Monitor liver and renal function, CBC if used long-term
flurazepam (<i>Dalmane</i>)	30 mg PO at bedtime; 15 mg PO at bedtime for elderly or debilitated patients	Hypnotic; treatment of insomnia Onset: varies Duration: 30–60 min Special considerations: Monitor liver and renal function, CBC in long-term use
lorazepam (<i>Ativan</i>)	2–6 mg/day PO in divided doses; or 0.05 mg/kg IM; or 0.044 mg/kg IV	Anxiety; preanesthesia anxiolytic Onset: 1–30 min Duration: 12–24 h Special considerations: Monitor injection sites; reduce dosage of narcotics given with this drug
oxazepam (<i>Serax</i>)	10–15 mg PO t.i.d. to q.i.d.	Anxiety; alcohol withdrawal Onset: slow Duration: 2–4 h Special considerations: Preferred for elderly
quazepam (<i>Doral</i>)	15 mg PO at bedtime	Hypnotic; treatment of insomnia Onset: varies Duration: 4–6 h Special considerations: Monitor liver and renal function, CBC if used for long-term therapy; taper after long-term therapy
temazepam (<i>Restoril</i>)	15–30 mg PO at bedtime	Hypnotic; treatment of insomnia Onset: varies Duration: 4–6 h Special considerations: Taper after long-term therapy
triazolam (<i>Halcion</i>)	0.125–0.5 mg PO at bedtime	Hypnotic; treatment of insomnia Onset: varies Duration: 2–4 h Special considerations: Monitor liver and renal function, CBC; taper after long-term therapy

*Onset of action and duration are important in selecting the correct drug for a particular use.

to 2 hours. They are lipid soluble and well distributed throughout the body, crossing the placenta and entering breast milk. The benzodiazepines are metabolized extensively in the liver. Patients with liver disease must receive a smaller dose and be monitored closely. Excretion is primarily through the urine.

Contraindications and Cautions

Contraindications to benzodiazepines include allergy to any benzodiazepine; psychosis, *which could be exacerbated by sedation*; and acute narrow-angle glaucoma, shock, coma, or acute alcoholic intoxication, *all of which could be exacerbated by the depressant effects of these drugs*.

In addition, these sedative/hypnotics are contraindicated in pregnancy *because a predictable syndrome of cleft lip or palate, inguinal hernia, cardiac defects, microcephaly, or pyloric stenosis occurs when they are taken in the first trimester*. Neonatal withdrawal syndrome may also result. Breast-feeding is also a contraindication *because of potential adverse effects on the neonate (e.g., sedation)*.

Use with caution in elderly or debilitated patients *because of the possibility of unpredictable reactions* and in cases of renal or hepatic dysfunction, *which may alter the metabolism and excretion of these drugs, resulting in direct toxicity*. Dose adjustments usually are needed for such patients. Box 20.3 provides information about the effect of benzodiazepines in African American patients.

Adverse Effects

The adverse effects of benzodiazepines are associated with the impact of these drugs on the central and peripheral nervous systems. Nervous system effects include sedation, drowsiness, depression, lethargy, blurred vision, headaches,

apathy, light-headedness, and confusion. In addition, mild paradoxical excitatory reactions may occur during the first 2 weeks of therapy.

Several other kinds of adverse effects may occur. GI conditions such as dry mouth, constipation, nausea, vomiting, and elevated liver enzymes may result. Cardiovascular problems may include hypotension, hypertension, arrhythmias, palpitations, and respiratory difficulties. Hematological conditions such as blood dyscrasias and anemia are possible. Genitourinary (GU) effects include urinary retention and hesitancy, loss of libido, and changes in sexual functioning. Because phlebitis, local reactions, and thrombosis may occur at local injection sites, such sites should be monitored. Abrupt cessation of these drugs may lead to a withdrawal syndrome characterized by nausea, headache, vertigo, malaise, and nightmares.

Clinically Important Drug–Drug Interactions

The risk of CNS depression increases if benzodiazepines are taken with alcohol or other CNS depressants, so such combinations should be avoided. In addition, the effects of benzodiazepines increase if they are taken with cimetidine, oral contraceptives, or disulfiram. If any of these drugs is used with benzodiazepines, patients should be monitored and the appropriate dose adjustments made.

Finally, the impact of benzodiazepines may be decreased if they are given with theophyllines or ranitidine. If either of these drugs is used, dose adjustment may be necessary.

Prototype Summary: Diazepam

Indications: Management of anxiety disorders, acute alcohol withdrawal, muscle relaxation, treatment of tetanus, antiepileptic adjunct in status epilepticus, preoperative relief of anxiety and tension.

Actions: Acts in the limbic system and reticular formation to potentiate the effects of GABA, an inhibitory neurotransmitter; may act in spinal cord and supraspinal sites to produce muscle relaxation.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	30–60 min	1–2 h	3 h
IM	15–30 min	30–45 min	3 h
IV	1–5 min	30 min	15–60 min
Rectal	Rapid	1.5 h	3 h

$T_{1/2}$: 20 to 80 hours, metabolized in the liver, excreted in urine.

Adverse effects: Mild drowsiness, depression, lethargy, apathy, fatigue, restlessness, bradycardia, tachycardia, constipation, diarrhea, incontinence, urinary retention, changes in libido, drug dependence with withdrawal syndrome.

BOX 20.3 Cultural Considerations

Benzodiazepine Levels

Special care should be taken when anxiolytic or hypnotic drugs are given to African Americans. About 15% to 20% of African Americans are genetically predisposed to delayed metabolism of benzodiazepines. As a result, they may develop high serum levels of these drugs, with increased sedation and an increased incidence of adverse effects.

If an anxiolytic or hypnotic agent is the drug of choice for an African American individual, the smallest possible dose should be used, and the patient should be monitored very closely during the first week of treatment. Dosage adjustments are necessary to achieve the most effective dose with the fewest adverse effects.

Nursing Considerations for Patients Receiving Benzodiazepines

Assessment: History and Examination

- Assess for contraindications or cautions: known allergies to benzodiazepines *to prevent hypersensitivity reactions*; impaired liver or kidney function, *which could alter the metabolism and excretion of a particular drug*; any condition *that might be exacerbated by the depressant effects of the drugs* (e.g., glaucoma, coma, psychoses, shock, acute alcohol intoxication); and pregnancy and lactation.
- Assess for baseline status before beginning therapy *to check for occurrence of any potential adverse effects*. Assess for the following: temperature and weight; skin color and lesions; affect, orientation, reflexes, and vision; pulse, blood pressure, and perfusion; respiratory rate, adventitious sounds, and presence of chronic pulmonary disease; and bowel sounds on abdominal examination.
- Perform laboratory tests, including renal and liver function tests and complete blood count (CBC).

Refer to the Critical Thinking Scenario for a full discussion of nursing care for a patient dealing with anxiety.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Disturbed Thought Processes and Disturbed Sensory Perception (Visual, Kinesthetic) related to CNS effects
- Risk for Injury related to CNS effects
- Disturbed Sleep Pattern related to CNS effects
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Do not administer intra-arterially *because serious arteriospasm and gangrene could occur*. Monitor injection sites carefully for local reactions to institute treatment as soon as possible.
- Do not mix intravenous (IV) drugs in solution with any other drugs *to avoid potential drug–drug interactions*.
- Give parenteral forms only if oral forms are not feasible or available, and switch to oral forms, *which are safer and less likely to cause adverse effects*, as soon as possible.
- Give IV drugs slowly *because these agents have been associated with hypotension, bradycardia, and cardiac arrest*.

CRITICAL THINKING SCENARIO

Benzodiazepines

THE SITUATION

P.P., a 43-year-old mother of three teenage sons, comes to the outpatient department for a routine physical examination. Results are unremarkable except for blood pressure of 145/90, pulse rate of 98, and apparent tension—she is jittery, avoids eye contact, and sometimes appears teary-eyed. She says that she is having some problems dealing with “life in general.” Her sons present many stresses and her husband, who is busy with his career, has little time to deal with issues at home. When he *is* home, he is very demanding. In addition, she thinks she is beginning menopause and is having trouble coping with the idea of menopause as well as with some of the symptoms. Overall, she feels lonely and has no outlet for her anger, tension, or stress. A health care provider, who reassures P.P. that this problem is common in women of her age, prescribes the benzodiazepine diazepam (*Valium*) to help P.P. deal with her anxiety.

CRITICAL THINKING

What sort of crisis intervention would be most appropriate for P.P.?

What nursing interventions are helpful at this point?

What nondrug interventions might be helpful?

What other support systems could be used to help P.P. deal with all that is going on in her life?

Think about the overwhelming problems that P.P. has to deal with on a daily basis and how the anxiolytic effects of diazepam might change her approach to these problems.

Could the problems actually get worse?

Develop a care plan for the long-term care of P.P.

DISCUSSION

Anxiolytics are useful for controlling the unpleasant signs and symptoms of anxiety. The diazepam prescribed for P.P. may provide some immediate relief, enabling her to survive the “crisis” period and plan changes in her life in general. However, the associated drowsiness and sedation may make coping with the problems in her life even more difficult. She should be taught the adverse effects of diazepam, the warning signs of serious adverse effects, and the health problems to report.

A follow-up evaluation should be scheduled. Additional meetings with the same health care provider are important for the long-term solution to P.P.’s anxiety. Her need for drug therapy should be re-evaluated once she can discover other support systems and develop other ways of coping. Although anxiolytic therapy may be beneficial initially, it will not solve the problems that are causing anxiety, and in

Benzodiazepines (continued)

this case, the causes for the anxiety are specific. The anxiolytic should be considered only as a short-term aid.

Unlike P.P., many patients in severe crisis do not consciously identify the many causes of stress, or stressors. However, P.P. has identified a list of factors that makes her life stressful. This facilitates the development of coping strategies. She may find the following support systems helpful:

- Referral to a counselor and involvement of the entire family in identifying problems and ways to deal with them.
- Support groups for women in various stages of life (e.g., entering menopause, mothers of children who are entering the teens). Just having the opportunity to discuss problems and explore ways of dealing with them helps many people.

NURSING CARE GUIDE FOR P.P.: DIAZEPAM**Assessment: History and Examination**

Allergies to diazepam, psychoses, acute narrow angle glaucoma, acute alcohol intoxication, impaired liver or kidney function, pregnancy, breast-feeding, concurrent use of alcohol, omeprazole, cimetidine, disulfiram, oral contraceptives, theophylline, ranitidine

CV: blood pressure, pulse, perfusion

CNS: orientation, affect, reflexes, vision

Skin: color, lesions, texture

Respiratory: respiration, adventitious sounds

GI: abdominal examination, bowel sounds

Laboratory tests: hepatic and renal function tests, complete blood count

Nursing Diagnoses

Disturbed Thought Processes and Disturbed Sensory

Perception (Visual, Kinesthetic) related to CNS effects

Risk for Injury related to CNS effects

Disturbed Sleep Patterns related to CNS effects

Deficient Knowledge regarding drug therapy

Implementation

Provide comfort and safety measures, small meal, drug with food if GI upset occurs, bowel program as needed; taper dosage after long-term use; reduce dosage if other medications include narcotics; lower dose with renal or hepatic impairment.

Provide support and reassurance to deal with drug effects.

Provide patient teaching regarding drug, dosage, adverse effects, safety precautions and unusual symptoms to report.

Evaluation

Evaluate drug effects: relief of signs and symptoms of anxiety.

Monitor for adverse effects, particularly sedation, dizziness, insomnia, blood dyscrasia, GI upset, hepatic or renal dysfunction, cardiovascular effects.

Monitor for drug–drug interactions.

Evaluate effectiveness of patient teaching program.

Evaluate effectiveness of comfort and safety measures.

PATIENT TEACHING FOR P.P.

- The drug that has been prescribed for you is called diazepam, or *Valium*. It belongs to a class of drugs called benzodiazepines, which are used to relieve tension and nervousness. Exactly how the drug works is not completely understood, but it does relax muscle spasms, relieve insomnia, and promote calm. Common side effects of this drug include:
 - *Dizziness and drowsiness*: Avoid driving or performing hazardous or delicate tasks that require concentration if these effects occur.
 - *Nausea, vomiting, and weight loss*: Small frequent meals may help to relieve nausea. If weight loss occurs, monitor the loss; if the loss is extensive, consult your health care provider. Do not take this drug with antacids.
 - *Constipation or diarrhea*: These reactions usually pass with time. If they do not, consult with your health care provider for appropriate therapy.
 - *Vision changes, slurred speech, unsteadiness*: These effects also subside with time. Take extra care in your activities for the first few days. If these reactions do not go away after 3 or 4 days, consult your health care provider.
 - Report any of the following conditions to your health care provider: *rash, fever, sore throat, insomnia, depression, clumsiness, or nervousness*.
- Tell any doctor, nurse, or other health care provider involved in your care that you are taking this drug.
- Keep this drug and all medications safely away from children or pets.
- Avoid the use of over-the-counter medications or herbal therapies while you are taking this drug. If you think that you need one of these products, consult with your health care provider about the best choice because many of these products can interfere with your medication.
- Avoid alcohol while you are taking this drug. Combining alcohol and a benzodiazepine can cause serious problems.
- If you have been taking this drug for a prolonged time, do not stop taking it suddenly. Your body will need time to adjust to the loss of the drug, and the dosage will need to be reduced gradually to prevent serious problems. When discontinuing use of this drug, tell your health care provider if the following occurs: trembling, muscle cramps, sweating, irritability, confusion, or seizures.

- Arrange to reduce the dose of narcotic analgesics in patients receiving a benzodiazepine *to decrease potentiated effects and sedation.*
- Maintain patients who receive parenteral benzodiazepines in bed for a period of at least 3 hours. Do not permit ambulatory patients to operate a motor vehicle after an injection *to ensure patient safety.*
- Monitor hepatic and renal function, as well as CBC, during long-term therapy *to detect dysfunction and to arrange to taper and discontinue the drug if dysfunction occurs.*
- Taper dose gradually after long-term therapy, especially in epileptic patients. *Acute withdrawal could precipitate seizures in these patients. It may also cause withdrawal syndrome.*
- Provide comfort measures *to help patients tolerate drug effects*, such as having them void before dosing, instituting a bowel program as needed, giving food with the drug if GI upset is severe, providing environmental control (lighting, temperature, stimulation), taking safety precautions (use of side rails, assistance with ambulation), and aiding orientation.
- Provide thorough patient teaching, including drug name, prescribed dose, measures for avoidance of adverse effects, and warning signs that may indicate possible problems. Instruct patients about the need for periodic monitoring and evaluation *to enhance patient knowledge about drug therapy and to promote compliance.*
- Offer support and encouragement *to help the patient cope with the diagnosis and the drug regimen.*
- If necessary, use flumazenil (Box 20.4), the benzodiazepine antidote, *for the treatment of overdose.*

Evaluation

- Monitor patient response to the drug (alleviation of signs and symptoms of anxiety; sleep; sedation).
- Monitor for adverse effects (sedation, hypotension, cardiac arrhythmias, hepatic or renal dysfunction, blood dyscrasias).
- Evaluate the effectiveness of the teaching plan (patient can give the drug name, dosage, possible adverse effects to watch for, specific measures to help avoid adverse effects, and the importance of continued follow-up).
- Monitor the effectiveness of comfort measures and compliance with the regimen.

KEY POINTS

- ▶ Anxiety is a feeling of tension, nervousness, apprehension, or fear. In the extreme, anxiety may produce physiological manifestations and may interfere with activities of daily life. Anxiolytic drugs, such as the benzodiazepines, depress the CNS to diminish these feelings.
- ▶ CNS depressants, such as sedatives, block the awareness of and reaction to environmental stimuli. They induce drowsiness, as do hypnotic drugs, which also depress the CNS and inhibit neuronal arousal.

BOX 20.4 A Benzodiazepine Antidote

Flumazenil (*Romazicon*), a benzodiazepine antidote, acts by inhibiting the effects of the benzodiazepines at the gamma-aminobutyric acid (GABA) receptors. It is used for three purposes: to treat benzodiazepine overdose, to reverse the sedation caused by benzodiazepines that are used as adjuncts for general anesthesia, and to reverse sedation produced for diagnostic tests or other medical procedures.

Flumazenil, which is available for IV use only, is injected into the tubing of a running IV. The drug has a rapid onset of action that peaks 5 to 10 minutes after administration. It is metabolized in the liver. Because this drug has a half-life of about 1 hour, it may be necessary to repeat injections of flumazenil if a long-acting benzodiazepine was used.

Patients who receive flumazenil should be monitored continually, and life-support equipment should be readily available. If the patient has been taking a benzodiazepine for a long period, administration of flumazenil may precipitate a rapid withdrawal syndrome that necessitates supportive measures. Headache, dizziness, vertigo, nausea, and vomiting may be associated with use of flumazenil.

- ▶ Hypnotics react with GABA-inhibitory sites to depress the CNS. They can cause drowsiness, lethargy, and other CNS effects.

BARBITURATES USED AS ANXIOLYTIC/HYPNOTICS

The **barbiturates** were once the sedative/hypnotic drugs of choice. Not only is the likelihood of sedation and other adverse effects greater with these drugs than with newer sedative/hypnotic drugs, but the risk of addiction and dependence is also greater. For these reasons, newer anxiolytic drugs have replaced the barbiturates in most instances. The barbiturates used as anxiolytic/hypnotics include amobarbital (*Amytal Sodium*), butabarbital (*Butisol*), mephobarbital (*Mebaral*), pentobarbital (*Nembutal*), phenobarbital (*Luminal*) and secobarbital (*Seconal*). Table 20.2 lists the available barbiturates, including common indications and specific information about each drug.

Therapeutic Actions and Indications

The barbiturates are general CNS depressants that inhibit neuronal impulse conduction in the ascending RAS, depress the cerebral cortex, alter cerebellar function, and depress motor output (see Figure 20.1). Thus, they can cause sedation, hypnosis, anesthesia, and, in extreme cases, coma. In general, barbiturates are indicated for the relief of the signs and symptoms of anxiety and for sedation, insomnia, pre-anesthesia, and the treatment of seizures (Table 20.2). Parenteral forms, which reach peak levels faster and have a

TABLE 20.2 DRUGS IN FOCUS Barbiturates Used as Anxiolytics–Hypnotics*

Drug Name	Dosage/Route	Usual Indications
amobarbital (<i>Amytal sodium</i>)	Adult: 65–500 mg IM or IV; reduce dosage with older patients Pediatric: (6–12 yr): 65–500 mg IM or IV; monitor very closely	Sedative–hypnotic; convulsions; manic reactions Onset: 15–60 min Duration: 3–8 h Special considerations: Monitor carefully if administered by IV
butobarbital (<i>Butisol</i>)	Adult: 15–30 mg PO t.i.d. to q.i.d.; 50–100 mg PO at bedtime for sedation; reduce dosage in elderly Pediatric: 7.5–30 mg PO based on age and weight	Short-term sedative–hypnotic Onset: 45–60 min Duration: 6–8 h Special considerations: Taper gradually after long-term use; use caution in children, may produce aggressiveness, excitability
mephobarbital (<i>Mebaral</i>)	Adult: 32–100 mg PO t.i.d. to q.i.d.; 400–600 mg/day PO for seizures; reduce dosage in elderly patients Pediatric: 16–32 mg PO t.i.d. to q.i.d.; 16–64 mg PO t.i.d. to q.i.d. for seizures	Anxiolytic; antiepileptic Onset: 30–60 min Duration: 10–16 h Special considerations: Taper gradually after long-term use; use caution in children, may produce aggressiveness, excitability
pentobarbital (<i>Nembutal</i>)	Adult: 20 mg PO t.i.d. to q.i.d.; 100 mg at bedtime for insomnia; 120–200 mg PR; 150–200 mg IM or 100 mg IV; reduce dosage in elderly patients Pediatric: 2–6 mg/kg/day; adjust dosage based on age and weight	Sedative–hypnotic; preanesthetic Onset: 10–15 min Duration: 2–4 h Special considerations: Taper gradually after long-term use; give IV slowly; monitor injection sites
 phenobarbital (<i>Luminal</i>)	Adult: 30–120 mg/day PO, IM, or IV; reduce dosage in elderly patients Pediatric: 1–3 mg/kg IV or IM	Sedative–hypnotic; control of seizures; preanesthetic Onset: 10–60 min Duration: 4–16 h Special considerations: Taper gradually after long-term use; give IV slowly; monitor injection sites
secobarbital (<i>Seconal</i>)	Adult: 100–300 mg PO; reduce dosage in elderly patients Pediatric: 2–6 mg/kg PO	Preanesthetic sedation; convulsive seizures of tetanus Onset: rapid Duration: 1–4 h Special considerations: Taper gradually after long-term use

*Onset of action and duration are important in selecting the correct drug for a particular use.

faster onset of action, may be used for the treatment of acute manic reactions and many forms of seizures (see Chapter 23).

Pharmacokinetics

The barbiturates are absorbed well, reaching peak levels in 20 to 60 minutes. They are metabolized in the liver to varying degrees, depending on the drug, and excreted in the urine. The longer-acting barbiturates tend to be metabolized slower and excreted to a greater degree unchanged in the urine. The barbiturates are known to induce liver enzyme systems, increasing the metabolism of the barbiturate broken down by that system, as well as that of any other drug that may be metabolized by that enzyme system. Patients with hepatic or renal dysfunction require lower doses of the drug to avoid toxic effects and should be monitored closely. Barbiturates are lipid soluble; they readily cross the placenta and enter breast milk.

Contraindications and Cautions

Contraindications to barbiturates include allergy to any barbiturate and a previous history of addiction to sedative/hypnotic drugs *because the barbiturates are more addicting than most other anxiolytics*. Other contraindications are latent or manifest porphyria, *which may be exacerbated*; marked hepatic impairment or nephritis, *which may alter the metabolism and excretion of these drugs*; and respiratory distress or severe respiratory dysfunction, *which could be exacerbated by the CNS depression caused by these drugs*. Pregnancy is a contraindication *because of potential adverse effects on the fetus*; congenital abnormalities have been reported with barbiturate use.

Use with caution in patients with acute or chronic pain *because barbiturates can cause paradoxical excitement, masking other symptoms*; with seizure disorders *because abrupt withdrawal of a barbiturate can precipitate status epilepticus*; and with chronic hepatic, cardiac, or respiratory diseases,

which could be exacerbated by the depressive effects of these drugs. Care should be taken with lactating women because of the potential for adverse effects on the infant.

Adverse Effects

As previously stated, the adverse effects caused by barbiturates are more severe than those associated with other, newer sedatives/hypnotics. For this reason, barbiturates are no longer considered the mainstay for the treatment of anxiety. In addition, the development of physical tolerance and psychological dependence is more likely with the barbiturates than with other anxiolytics.

The most common adverse effects are related to general CNS depression. CNS effects may include drowsiness, somnolence, lethargy, ataxia, vertigo, a feeling of a “hangover,” thinking abnormalities, paradoxical excitement, anxiety, and hallucinations. GI signs and symptoms such as nausea, vomiting, constipation, diarrhea, and epigastric pain may occur. Associated cardiovascular effects may include bradycardia, hypotension (particularly with IV administration), and syncope. Serious hypoventilation may occur, and respiratory depression and laryngospasm may also result, particularly with IV administration. Hypersensitivity reactions, including rash, serum sickness, and Stevens–Johnson syndrome, which is sometimes fatal, may also occur.

Clinically Important Drug–Drug Interactions

Increased CNS depression results if these agents are taken with other CNS depressants, including alcohol, antihistamines, and other tranquilizers. If other CNS depressants are used, dose adjustments are necessary.

There often is an altered response to phenytoin if it is combined with barbiturates; evaluate the patient frequently if this combination cannot be avoided. If barbiturates are combined with monoamine oxidase (MAO) inhibitors, increased serum levels and effects occur. If the older sedatives/hypnotics are combined with MAO inhibitors, patients should be monitored closely and necessary dose adjustments made.

In addition, because of an enzyme induction effect of barbiturates in the liver, the following drugs may not be as effective as desired: oral anticoagulants, digoxin, tricyclic antidepressants (TCAs), corticosteroids, oral contraceptives, estrogens, acetaminophen, metronidazole, phenmetrazine, carbamazepine, beta-blockers, griseofulvin, phenylbutazones, theophyllines, quinidine, and doxycycline. If these agents are given in combination with barbiturates, patients should be monitored closely; frequent dose adjustments may be necessary to achieve the desired therapeutic effect.

Prototype Summary: Phenobarbital

Indications: Sedation, short-term treatment of insomnia, long-term treatment of tonic–clonic seizures and cortical focal seizures, emergency control of certain acute convulsive episodes, preanesthetic.

Actions: Inhibits conduction in the ascending RAS; depresses the cerebral cortex; alters cerebellar function; depresses motor output; can produce excitation, sedation, hypnosis, anesthesia, and deep coma; and has anticonvulsant activity.

Pharmacokinetics:

Route	Peak	Onset	Duration
Oral	15 min	30–60 min	10–16 h
IM, SQ		10–30 min	4–6 h
IV	up to 15 min	5 min	4–6 h

$T_{1/2}$: 79 hours; metabolized in the liver, excreted in urine.

Adverse effects: Somnolence, agitation, confusion, hyperkinesias, ataxia, vertigo, CNS depression, hallucinations, bradycardia, hypotension, syncope, nausea, vomiting, constipation, diarrhea, hypoventilation, apnea, withdrawal syndrome, rash, Stevens–Johnson syndrome.

● Nursing Considerations for Patients Receiving Barbiturates

Assessment: History and Examination

- Assess for contraindications or cautions: known allergies to barbiturates *to prevent hypersensitivity reactions* or a history of addiction to sedative/hypnotic drugs *to avert a similar problem with these drugs*; impaired hepatic or renal function *that could alter the metabolism and excretion of the drug*; cardiac dysfunction or respiratory dysfunction; seizure disorders, *which could be exacerbated by these drugs*; acute or chronic pain disorders, *which should be evaluated before using these drugs*; and pregnancy or lactation, *which would indicate a need for caution when using these drugs*.
- Assess for baseline status *before beginning therapy and for the occurrence of any potential adverse effects*. Assess the following: temperature and weight; blood pressure and pulse, including perfusion; skin color and lesions; affect, orientation, and reflexes; respiratory rate and adventitious sounds; and bowel sounds.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Disturbed Thought Processes and Disturbed Sensory Perception (Visual, Auditory, Kinesthetic, Tactile) related to CNS effects
- Risk for Injury related to CNS effects
- Impaired Gas Exchange related to respiratory depression
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Do not administer these drugs intra-arterially *because serious arteriospasm and gangrene could occur*. Monitor injection sites carefully *for local reactions*.

- Do not mix IV drugs in solution with any other drugs to avoid potential drug–drug interactions.
- Give parenteral forms only if oral forms are not feasible or available, and switch to oral forms as soon as possible to avoid serious reactions or adverse effects.
- Give IV medications slowly because rapid administration may cause cardiac problems.
- Provide standby life-support facilities in case of severe respiratory depression or hypersensitivity reactions.
- Taper dose gradually after long-term therapy, especially in patients with epilepsy. Acute withdrawal may precipitate seizures or cause withdrawal syndrome in these patients.
- Provide comfort measures to help patients tolerate drug effects, including small, frequent meals; access to bathroom facilities; bowel program as needed; consuming food with the drug if GI upset is severe; and environmental control, safety precautions, orientation, and appropriate skin care as needed.
- Provide thorough patient teaching, including drug name, prescribed dosage, measures for avoidance of adverse effects, and warning signs that may indicate possible problems. Instruct patients about the need for periodic monitoring and evaluation to enhance patient knowledge about drug therapy and to promote compliance.
- Offer support and encouragement to help the patient cope with the diagnosis and the drug regimen.

TABLE 20.3 DRUGS IN FOCUS Other Anxiolytic/Hypnotic Drugs

Drug Name	Usual Indications
bupirone (<i>BuSpar</i>)	Oral drug for anxiety disorders; off-label use; signs and symptoms of premenstrual syndrome Special considerations: may cause dry mouth, headache; use with caution in patients with hepatic or renal impairment and in elderly patients
chloral hydrate (<i>Aquachloral</i>)	Administered PO or PR for nocturnal sedation, preoperative sedation Special considerations: withdraw gradually over 2 wk in patients maintained for weeks or months
dexmedetomidine (<i>Precedex</i>)	IV drug used for newly intubated and mechanically ventilated patients in the intensive care unit Special considerations: do not use longer than 24 h; monitor patient continually
diphenhydramine (<i>Benadryl</i>)	PO, IM, or IV for sleep aid, motion sickness, allergic rhinitis; oral drug for short-term treatment of insomnia (up to 1 wk) Special considerations: antihistamine, drying effects common; monitor patients for thickened respiratory secretions and breathing difficulties, a problem that can cause concern after anesthesia
eszopiclone (<i>Lunesta</i>)	Oral drug for the treatment of insomnia Special considerations: tablet must be swallowed whole; instruct the patient to take this drug just before bed and allow 8 h for sleep
meprobamate (<i>Miltown</i>)	Oral drug used for the short-term management of anxiety disorders Special considerations: supervise dose in patients who are addiction prone; withdraw gradually over 2 wk if patient has been maintained on the drug for weeks or months
promethazine (<i>Phenergan</i>)	PO, IM, or IV use to decrease the need for postoperative pain relief and for preoperative sedation Special considerations: an antihistamine; monitor injection sites carefully; monitor patients for thickened respiratory secretions and breathing difficulties, a problem that can cause concern after anesthesia
ramelteon (<i>Rozerenm</i>)	Oral drug for the treatment of insomnia characterized by difficulty falling asleep Special considerations: patient should take 30 min before bed and allow 8 h for sleep; monitor for depression and suicidal ideation
zaleplon (<i>Sonata</i>)	Oral drug for the short-term treatment of insomnia Special considerations: patient should take before bed and devote 4–8 h to sleep; use with caution in patients with hepatic or renal impairment; elderly patients are especially sensitive to these drugs—administer a lower dose and monitor these patients carefully
zolpidem (<i>Ambien</i>)	Oral drug for short-term treatment of insomnia Special considerations: dispense the least amount possible to depressed and/or suicidal patients; withdraw gradually if used for prolonged period; patient should take before bed and devote 4–8 h to sleep; use with caution in patients with hepatic or renal impairment; elderly patients are especially sensitive to these drugs—administer a lower dose and monitor these patients carefully

Evaluation

- Monitor patient response to the drug (alleviation of signs and symptoms of anxiety, sleep, sedation, reduction in seizure activity).
- Monitor for adverse effects (sedation, hypotension, cardiac arrhythmias, hepatic or renal dysfunction, skin reactions, dependence).
- Evaluate the effectiveness of the teaching plan (patient can give the drug name, dosage, possible adverse effects to watch for, specific measures to help avoid adverse effects, and the importance of continued follow-up).
- Monitor the effectiveness of comfort measures and compliance with the regimen.

KEY POINTS

- ▶ Barbiturates are an older class of drugs used as anxiolytics, sedatives, and hypnotics. Because they are associated with potentially serious adverse effects and interact with many other drugs, they are less desirable than the benzodiazepines or other anxiolytics.

OTHER ANXIOLYTIC AND HYPNOTIC DRUGS

Other drugs are used to treat anxiety or to produce hypnosis that do not fall into either the benzodiazepine or the barbiturate group. See Table 20.3 for a list of other anxiolytic/hypnotic drugs, including usual indications and special considerations. Such medications include the following:

- Antihistamines (promethazine [*Phenergan*], diphenhydramine [*Benadryl*]) can be very sedating in some people. They are used as preoperative medications and postoperatively to decrease the need for narcotics.
- Buspirone (*BuSpar*), a newer antianxiety agent, has no sedative, anticonvulsant, or muscle relaxant properties, and its mechanism of action is unknown. However, it reduces the signs and symptoms of anxiety without many of the CNS effects and severe adverse effects associated with other anxiolytic drugs. It is rapidly absorbed from the GI tract, metabolized in the liver, and excreted in urine.
- Chloral hydrate (*Aquachloral*) is frequently used to produce nocturnal sedation or preoperative sedation. Its mechanism of action is unknown. It is rapidly absorbed from the GI tract and metabolized in the liver and kidney for excretion in the bile and urine.
- Dexmedetomidine (*Precedex*) is given intravenously at a starting dose of 1 mcg/kg over 10 minutes and then a controlled infusion for up to 24 hours. It is used for the sedation of newly intubated and mechanically ventilated patients in an intensive care unit.

- Eszopiclone (*Lunesta*) is a new agent used to treat insomnia. It is thought to react with GABA sites near benzodiazepine receptors. It is rapidly absorbed, metabolized in the liver, and excreted in the urine.
- Meprobamate (*Miltown*) is an older drug that is used to manage acute anxiety for up to 4 months. It works in the limbic system and thalamus and has some anticonvulsant properties and central nervous system muscle-relaxing effects. It is rapidly absorbed and is metabolized in the liver and excreted in urine.
- Ramelteon (*Rozarem*), introduced in 2005, is the first of a new class of sedatives/hypnotics, the melatonin-receptor agonists. This drug stimulates melatonin receptors, which are thought to be involved in the maintenance of circadian rhythm and the sleep–wake cycle. Ramelteon is used for the treatment of insomnia characterized by difficulty with sleep onset. It is rapidly absorbed, with peak levels in 30 to 90 minutes. It is metabolized in the liver and excreted in the feces and urine.
- Zaleplon (*Sonata*) and zolpidem (*Ambien*), both of which cause sedation, are used for the short-term treatment of insomnia. They are thought to work by affecting serotonin levels in the sleep center near the RAS. These drugs are metabolized in the liver and excreted in the urine.

CHAPTER SUMMARY

- Anxiolytics, or minor tranquilizers, are drugs used to treat anxiety by depressing the CNS. When given at higher doses, these drugs may be sedatives or hypnotics.
- Sedatives block the awareness of and reaction to environmental stimuli, resulting in associated CNS depression that may cause drowsiness, lethargy, and other effects. This action can be beneficial when a patient is very excited or afraid.
- Hypnotics further depress the CNS, particularly the RAS, to inhibit neuronal arousal and induce sleep.
- Benzodiazepines are a group of drugs used as anxiolytics. They react with GABA-inhibitory sites to depress the CNS. They can cause drowsiness, lethargy, and other CNS effects.
- Barbiturates are an older class of drugs used as anxiolytics, sedatives, and hypnotics. Because they are associated with potentially serious adverse effects and interact with many other drugs, they are less desirable than the benzodiazepines or other anxiolytics.
- Buspirone, a newer anxiolytic drug, does not cause sedation or muscle relaxation. Because of the absence of CNS effects, it is much preferred in certain circumstances (e.g., when a person must drive, go to work, or maintain alertness).
- Newer hypnotic agents act in the RAS to affect serotonin levels (zaleplon and zolpidem) or to affect melatonin levels in the brain (ramelteon).

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-Rom in the front of the book.

MULTIPLE CHOICE

Select the best answer to the following.

- Drugs that are used to alter a patient's response to the environment are called
 - hypnotics.
 - sedatives.
 - antiepileptics.
 - anxiolytics.
- The benzodiazepines are the most frequently used anxiolytic drugs because
 - they are anxiolytic at doses much lower than those needed for sedation or hypnosis.
 - they can also be stimulating.
 - they are more likely to cause physical dependence than older anxiolytic drugs.
 - they do not affect any neurotransmitters.
- Barbiturates cause liver enzyme induction, which could lead to
 - rapid metabolism and loss of effectiveness of other drugs metabolized by those enzymes.
 - increased bile production.
 - CNS depression.
 - the need to periodically lower the barbiturate dose to avoid toxicity.
- A person who could benefit from an anxiolytic drug for short-term treatment of insomnia would *not* be prescribed
 - zolpidem.
 - chloral hydrate.
 - buspirone.
 - meprobamate.
- Anxiolytic drugs block the awareness of and reaction to the environment. This effect would *not* be beneficial
 - to relieve extreme fear.
 - to moderate anxiety related to unknown causes.
 - in treating a patient who must drive a vehicle for a living.
 - in treating a patient who is experiencing a stress reaction.
- Mr. Jones is the chief executive officer of a large company and has been experiencing acute anxiety attacks. His physical examination was normal, and he was diagnosed with anxiety. Considering his occupation and his need to be alert and present to large groups on a regular basis, the following anxiolytic would be a drug of choice for Mr. Jones:
 - phenobarbital
 - diazepam
 - clorazepate
 - buspirone
- The benzodiazepines react with
 - GABA-receptor sites in the RAS to cause inhibition of neural arousal.
 - norepinephrine-receptor sites in the sympathetic nervous system.
 - acetylcholine-receptor sites in the parasympathetic nervous system.
 - monoamine oxidase to increase norepinephrine breakdown.
- A pediatric patient is prescribed phenobarbital preoperatively to relieve anxiety and produce sedation. After giving the injection, you should assess the patient for
 - acute Stevens-Johnson syndrome.
 - bone marrow depression.
 - paradoxical excitement.
 - withdrawal syndrome.

MULTIPLE RESPONSE

Select all that apply.

1. In assessing a client who is experiencing anxiety, the nurse would expect to find which of the following?
 - a. Rapid breathing
 - b. Rapid heart rate
 - c. Fear and apprehension
 - d. Constricted pupils
 - e. Decreased abdominal sounds
 - f. Hypotension
2. Your client has a long history of anxiety and has always responded well to diazepam. She has just learned that she is pregnant and feels very anxious. She would like a prescription for diazepam to get her through her early anxiety. What rationale would the nurse use in explaining why this is not recommended?
 - a. This drug is known to cause a predictable syndrome of birth defects, including cleft lip and pyloric stenosis.
 - b. Babies born to mothers taking benzodiazepines may progress through a neonatal withdrawal syndrome.
 - c. Cardiac defects and small brain development may occur if this drug is taken in the first trimester.
 - d. This drug almost always causes loss of the pregnancy.
 - e. The hormones the body produces during pregnancy will make you unresponsive to diazepam.
 - f. This drug could have adverse effects on your baby; we should explore nondrug measures to help you deal with the anxiety.

Antidepressant Agents

21

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Describe the biogenic theory of depression.
2. Describe the therapeutic actions, indications, pharmacokinetics, contraindications, most common adverse reactions, and important drug–drug interactions associated with each class of antidepressant.
3. Discuss the use of antidepressants across the lifespan.
4. Compare and contrast the prototype drugs for each class of antidepressant with the other drugs in that class and with drugs in the other classes of antidepressants.
5. Outline the nursing considerations and teaching needs for patients receiving each class of antidepressant.

Glossary of Key Terms

affect: feeling that a person experiences when he or she responds emotionally to the environment

biogenic amine: one of the neurotransmitters norepinephrine, serotonin, or dopamine; it is thought that a deficiency of these substances in key areas of the brain results in depression

depression: affective disorder in which a person experiences sadness that is much more severe and longer lasting than is warranted by the event that seems to have precipitated it, with a more intense mood; the condition may not even be traceable to a specific event or stressor

monoamine oxidase inhibitor (MAOI): drug that prevents the enzyme monoamine oxidase from breaking down norepinephrine (NE), leading to increased NE levels in the

synaptic cleft; relieves depression and also causes sympathomimetic effects

selective serotonin reuptake inhibitor (SSRI): drug that specifically blocks the reuptake of serotonin and increases its concentration in the synaptic cleft; relieves depression and is not associated with anticholinergic or sympathomimetic adverse effects

tricyclic antidepressant (TCA): drug that blocks the reuptake of norepinephrine and serotonin; relieves depression and has anticholinergic and sedative effects

tyramine: an amine found in food that causes vasoconstriction and raises blood pressure; ingesting foods high in tyramine while taking an MAOI poses the risk of a severe hypertensive crisis

TRICYCLIC ANTIDEPRESSANTS

amitriptyline
amoxapine
clomipramine
desipramine
doxepin
P imipramine
maprotiline
nortriptyline

protriptyline
trimipramine

MONOAMINE OXIDASE INHIBITORS

P isocarboxazid
phenelzine
tranylcypromine

SELECTIVE SEROTONIN REUPTAKE INHIBITORS

P citalopram
duloxetine
escitalopram
fluoxetine
fluvoxamine
paroxetine
sertraline

OTHER ANTIDEPRESSANTS

bupropion
desvenlafaxine
mirtazapine
nefazodone
selegiline
trazodone
venlafaxine

When you ask people how they feel, they may say “pretty good” or “not so great.” People’s responses are usually appropriate to what is happening in their lives, and they describe themselves as being in a good mood or a bad mood. Some days are better than others.

Affect is a term that is used to refer to people’s feelings in response to their environment, whether positive and pleasant or negative and unpleasant. All people experience different affective states at various times in their lives. These states of mind, which change in particular situations, usually do not last very long and do not often involve extremes of happiness or depression. If a person’s mood goes far beyond the usual normal “ups and downs,” he or she is said to have an affective disorder.

DEPRESSION AND ANTIDEPRESSANTS

Depression is a very common affective disorder involving feelings of sadness that are much more severe and longer lasting than the suspected precipitating event, and the mood of affected individuals is much more intense. The depression may not even be traceable to a specific event or stressor (i.e., there are no external causes). Patients who are depressed may have little energy, sleep disturbances, a lack of appetite, limited libido, and inability to perform activities of daily living. They may describe overwhelming feelings of sadness, despair, hopelessness, and disorganization.

In many cases, the depression is never diagnosed, and the patient is treated for physical manifestations of the underlying disease, such as fatigue, malaise, obesity, anorexia, or alcoholism and drug dependence. Clinical depression is a disorder that can interfere with a person’s family life, job, and social interactions. Left untreated, it can produce multiple physical problems that can lead to further depression or, in extreme cases, even suicide.

Biogenic Amine Theory of Depression

Research on the development of the drugs known to be effective in relieving depression led to formulation of the current hypothesis regarding the cause of depression. Scientists have theorized that depression results from a deficiency of **biogenic amines** in key areas of the brain; these biogenic amines include norepinephrine (NE), dopamine, and serotonin (5HT). Both NE and 5HT are released throughout the brain by neurons that react with multiple receptors to regulate arousal, alertness, attention, moods, appetite, and sensory processing. Deficiencies of these neurotransmitters may develop for three known reasons. First, monoamine oxidase (MAO) may break them down to be recycled or restored in the neurons. Second, rapid fire of the neurons may lead to their depletion. Third, the number or sensitivity of postsynaptic receptors may increase, thus depleting neurotransmitter levels.

Depression also may occur as a result of other, yet unknown causes. This condition may be a syndrome that reflects either

activity or lack of activity in a number of sites in the brain, including the arousal center (reticular activating system [RAS]), the limbic system, and basal ganglia.

Drug Therapy

The use of agents that alter the concentration of neurotransmitters in the brain is the most effective means of treating depression with drugs. The antidepressant drugs used today counteract the effects of neurotransmitter deficiencies in three ways. First, they may inhibit the effects of MAO, leading to increased NE or 5HT in the synaptic cleft. Second, they may block reuptake by the releasing nerve, leading to increased neurotransmitter levels in the synaptic cleft. Third, they may regulate receptor sites and the breakdown of neurotransmitters, leading to an accumulation of neurotransmitter in the synaptic cleft.

Antidepressants may be classified into three groups: the tricyclic antidepressants (TCAs), the MAOIs, and the selective serotonin reuptake inhibitors (SSRIs). Other drugs that are used as antidepressants similarly increase the synaptic cleft concentrations of these neurotransmitters (Figure 21.1). For information on how antidepressants affect people from young to old, see Box 21.1.

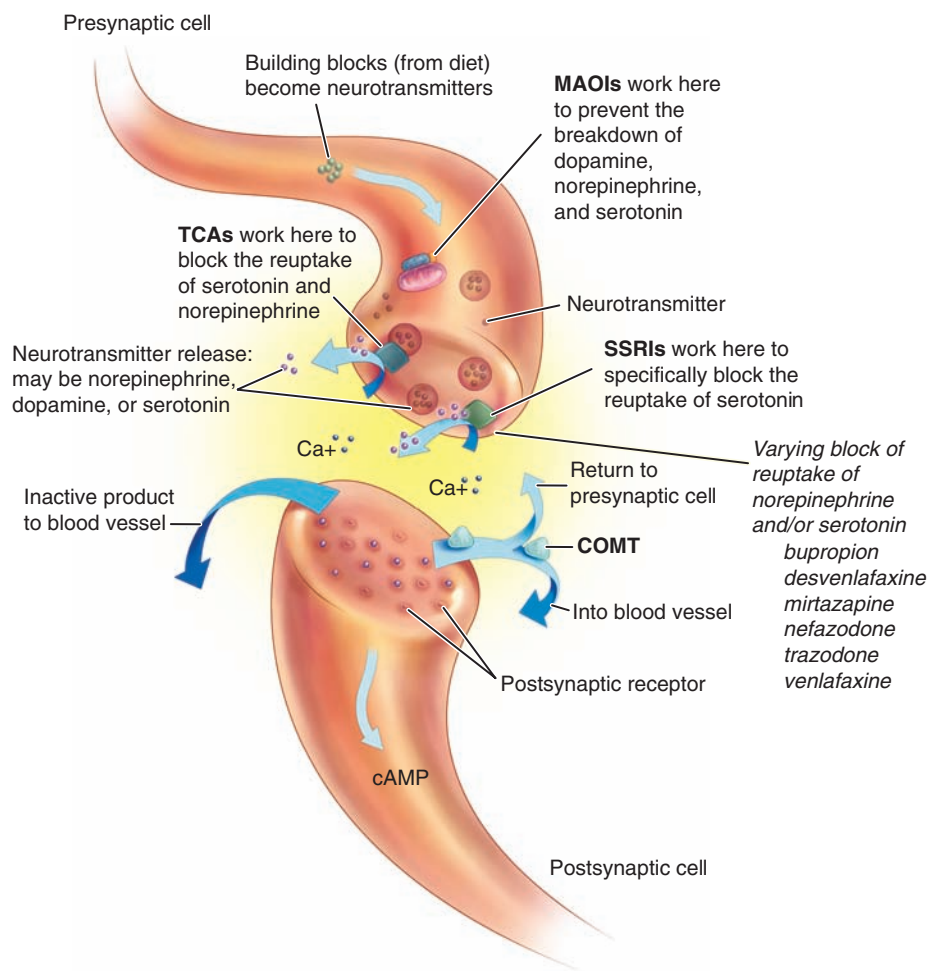

TRICYCLIC ANTIDEPRESSANTS

The **tricyclic antidepressants (TCAs)**, including the amines, secondary amines, and tetracyclics, all reduce the reuptake of 5HT and NE into nerves. Because all TCAs are similarly effective, the choice of TCA depends on individual response to the drug and tolerance of adverse effects. A patient who does not respond to one TCA may respond to another drug from this class. TCAs that are available include the amines amitriptyline (generic), amoxapine (*Asendin*), clomipramine (*Anafranil*), doxepin (*Sinequan*), imipramine (*Tofranil*), and trimipramine (*Surmontil*); the secondary amines desipramine (*Norpramin*), nortriptyline (*Aventyl*, *Pamelor*), and protriptyline (*Vivactil*); and the tetracyclic drug maprotiline (generic). Table 21.1 shows the relative frequency of the occurrence of adverse effects by specific type of TCA.

Therapeutic Actions and Indications

The TCAs inhibit presynaptic reuptake of the neurotransmitters 5HT and NE, which leads to an accumulation of these neurotransmitters in the synaptic cleft and increased stimulation of the postsynaptic receptors. The exact mechanism of action in decreasing depression is not known but is thought to be related to the accumulation of NE and 5HT in certain areas of the brain.

TCAs are indicated for the relief of symptoms of depression. The sedative effects of these drugs may make them more effective in patients whose depression is characterized by

● **FIGURE 21.1** Sites of action for the antidepressants: monoamine oxidase inhibitors (MAOIs), tricyclic antidepressants (TCAs), selective serotonin reuptake inhibitors (SSRIs), and other agents. camp, cyclic adenosine monophosphate; COMT, catecholamine-*O*-methyltransferase.

anxiety and sleep disturbances. They are effective for treating enuresis in children older than 6 years (see Box 21.1). Some of these drugs are being investigated for the treatment of chronic, intractable pain. In addition, the TCAs are anticholinergic. Clomipramine is now also approved for use in the treatment of obsessive-compulsive disorders (OCDs).

Pharmacokinetics

The TCAs are well absorbed from the gastrointestinal (GI) tract, reaching peak levels in 2 to 4 hours. They are highly bound to plasma proteins and are lipid soluble; this allows them to be distributed widely in the tissues, including the brain. TCAs are metabolized in the liver and excreted in the urine, with relatively long half-lives, ranging from 8 to 46 hours. The TCAs cross the placenta and enter breast milk (see contraindications and cautions).

Contraindications and Cautions

One contraindication to the use of TCAs is the presence of allergy to any of the drugs in this class *because of the risk of hypersensitivity reactions*. Other contraindications include

recent myocardial infarction *because of the potential occurrence of reinfarction or extension of the infarct with the cardiac effects of the drug*; myelography within the previous 24 hours or in the next 48 hours *because of a possible drug-drug interaction with the dyes used in these studies*; and concurrent use of an MAOI *because of the potential for serious adverse effects or toxic reactions*. In addition, pregnancy and lactation are contraindications *because of the potential for adverse effects in the fetus and neonate*; TCAs should not be used unless the benefit to the mother clearly outweighs the potential risk to the neonate.

Caution should be used with TCAs in patients with pre-existing cardiovascular (CV) disorders *because of the cardiac stimulatory effects of the drug* and with any condition that would be exacerbated by the anticholinergic effects, such as angle-closure glaucoma, urinary retention, prostate hypertrophy, or GI or genitourinary (GU) surgery. Care should also be taken with psychiatric patients, *who may exhibit a worsening of psychoses or paranoia*, and with manic-depressive patients, *who may shift to a manic stage*. There is a black box warning on all of the TCAs bringing attention to a risk of suicidality, especially in children and adolescents; caution should be used, and the amount of drug dispensed at any

Antidepressant Agents

CHILDREN

Use of antidepressant drugs with children poses a challenge. The response of the child to the drug may be unpredictable, and the long-term effects of many of these agents are not clearly understood. Studies have not shown efficacy in using these drugs to treat depression in children and also indicate that there may be an increase in suicidal ideation and suicidal behavior when antidepressants are used to treat depression in children.

Of the tricyclic drugs (TCAs), clomipramine, imipramine, nortriptyline, and trimipramine have established pediatric doses in children older than 6 years. Children should be monitored closely for adverse effects, and dose changes should be made as needed.

Monoamine oxidase (MAO) inhibitors should be avoided in children if at all possible because of the potential for drug–food interactions and the serious adverse effects.

The selective serotonin reuptake inhibitors (SSRIs) can cause serious adverse effects in children. Fluvoxamine and sertraline have established pediatric dose guidelines for the treatment of obsessive–compulsive disorders. Fluoxetine is widely used to treat depression in adolescents, and a 2000 survey of off-label uses of drugs showed that it was being used in children as young as 6 months. Dosage regimens must be established according to the child's age and weight, and a child receiving an antidepressant should be monitored very carefully. Underlying medical reasons for the depression should be ruled out before antidepressant

therapy is begun. Again, these children should be monitored for any suicidal ideation.

ADULTS

Adults using these drugs should have medical causes for their depression ruled out before therapy is begun. Thyroid disease, hormonal imbalance, and cardiovascular disorders can all lead to the signs and symptoms of depression.

The patient needs to understand that the effects of drug therapy may not be seen for 4 weeks and that it is important to continue the therapy for at least that long.

These drugs should be used very cautiously during pregnancy and lactation because of the potential for adverse effects on the fetus and possible neurological effects on the baby. Use should be reserved for situations in which the benefits to the mother far outweigh the potential risks to the neonate.

OLDER ADULTS

Older patients may be more susceptible to the adverse effects of these drugs, from unanticipated central nervous system (CNS) effects to increased sedation, dizziness, and even hallucinations. Doses of all of these drugs need to be reduced and the patient monitored very closely for toxic effects. Safety measures should be provided if CNS effects do occur.

Patients with hepatic or renal impairment should be monitored very closely while taking these drugs. Decreased doses may be needed. Because many older patients also have renal or hepatic impairment, they need to be screened carefully.

given time should be limited with potentially suicidal patients. In addition, caution is necessary in patients with a history of seizures *because the seizure threshold may be decreased secondary to stimulation of the receptor sites* and in elderly patients. The presence of hepatic or renal disease, *which could interfere with metabolism and excretion of these drugs and lead to toxic levels*, also necessitates caution and the need for need a lower dose of the drug.

Adverse Effects

The adverse effects of TCAs are associated with the effects of the drugs on the central nervous system (CNS) and on the peripheral nervous system. Sedation, sleep disturbances, fatigue, hallucinations, disorientation, visual disturbances, difficulty in concentrating, weakness, ataxia, and tremors may occur.

Use of TCAs may lead to GI anticholinergic effects, such as dry mouth, constipation, nausea, vomiting, anorexia, increased salivation, cramps, and diarrhea. Resultant GU effects may include urinary retention and hesitancy, loss of libido, and changes in sexual functioning. CV effects such as orthostatic hypotension, hypertension, arrhythmias, myocardial infarction, angina, palpitations, and stroke may also pose

problems. Miscellaneous reported effects include alopecia, weight gain or loss, flushing, chills, and nasal congestion.

These adverse effects may be intolerable to some patients, who then stop taking the particular TCA. Abrupt cessation of all TCAs causes a withdrawal syndrome characterized by nausea, headache, vertigo, malaise, and nightmares.

Clinically Important Drug–Drug Interactions

If TCAs are given with cimetidine, fluoxetine, or ranitidine, an increase in TCA levels results, with an increase in both therapeutic and adverse effects, especially anticholinergic conditions. Patients should be monitored closely, and appropriate dose reductions should be made.

Other drug combinations may also pose problems. The combination of TCAs and oral anticoagulants leads to higher serum levels of the anticoagulants and increased risk of bleeding. Blood tests should be done frequently, and appropriate dose adjustments in the oral anticoagulant should be made.

If TCAs are combined with sympathomimetics or clonidine, the risk of arrhythmias and hypertension is increased. This combination should be avoided, especially in patients with underlying cardiovascular disease.

TABLE 21.1 DRUGS IN FOCUS Tricyclic Antidepressants

Drug Name	Common Side Effects				Usual Dosage
	Sedation	Anticholinergic	Hypotension	Cardiovascular	
Amines					
amitriptyline (generic)	++++	++++	++++	++	75–150 mg/d PO
amoxapine (<i>Asendin</i>)	+	+	++	++	50–100 mg PO b.i.d. to t.i.d.
clomipramine (<i>Anafranil</i>)	+++	+++	+++	+++	Adult: 25–50 mg PO q.i.d. Pediatric: 25 mg PO q.i.d. to a maximum of 3 mg/kg per day
doxepin (<i>Sinequan</i>)	+++	+++	++	++	25–50 mg PO t.i.d.
 imipramine (<i>Tofranil</i>)	++	++	+++	++	Adult: 50–200 mg/d PO Pediatric: 30–40 mg/d PO
trimipramine (<i>Surmontil</i>)	+++	++	++	++	Adult: 75–150 mg/d PO Pediatric: 50 mg/d PO Geriatric: 50–100 mg/d PO
Secondary Amines					
desipramine (<i>Norpramin</i>)	+	+	++	++	100–200 mg/d PO
nortriptyline (<i>Aventyl, Pamelor</i>)	+	+	+	+	Adult: 25–50 mg PO t.i.d. to q.i.d. Pediatric: 30–50 mg/d PO in divided doses Geriatric: 30–50 mg/d PO in divided doses
protriptyline (<i>Vivactil</i>)	+	+++	+	+	15–40 mg/d PO in three or four divided doses; 5 mg PO t.i.d. for elderly patients
Tetracyclic					
maprotiline (generic)	++	+	++	++	75–150 mg/d PO; reduce dose in elderly patients

++++, marked effects; ++++, moderate effects; ++, mild effects; +, negligible effects.

The combination of TCAs with MAOIs leads to a risk of severe hyperpyretic crisis with severe convulsions, hypertensive episodes, and death. This combination should be avoided. Although TCAs and MAOIs have been used together in selected patients who do not respond to a single agent, the risk of severe adverse effects is very high.

Prototype Summary: Imipramine

Indications: Relief of symptoms of depression; enuresis in children older than 6 years; off-label consideration—control of chronic pain.

Actions: Inhibits presynaptic reuptake of norepinephrine and serotonin; anticholinergic at CNS and peripheral receptors; sedating.

Pharmacokinetics:

Route	Onset	Peak
Oral	Varies	2–4 h

$T_{1/2}$: 8 to 16 hours, metabolized in the liver, excretion in the urine.

Adverse effects: sedation, anticholinergic effects, confusion, anxiety, orthostatic hypotension, dry mouth, constipation, urinary retention, rash, bone marrow depression.

● Nursing Considerations for Patients Receiving Tricyclic Antidepressants

Assessment: History and Examination

- Assess for any known allergies to these drugs *to avoid hypersensitivity reactions*; impaired liver or kidney function, *which could alter metabolism and excretion of the drug*; glaucoma, benign prostatic hypertrophy, cardiac dysfunction, GI obstruction, surgery, or recent myocardial infarction, *all of which could be exacerbated by the effects of the drug*; and pregnancy or lactation *to avoid potential adverse effects on the fetus or baby*.
- Assess whether the patient has a history of seizure disorders or a history of psychiatric problems or suicidal thoughts, or myelography within the past 24 hours or in the next 48 hours, or is taking an MAOI, *to avoid potentially serious adverse reactions*.
- Assess temperature and weight; skin color and lesions; affect, orientation, and reflexes; vision; blood pressure, including orthostatic blood pressure; pulse and perfusion; respiratory rate and adventitious sounds; and bowel sounds on abdominal examination. *This determines baseline status before beginning therapy and for any potential adverse effects*. Also obtain an electrocardiogram, as well as renal and liver function tests.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to anticholinergic effects, headache, and CNS effects
- Decreased Cardiac Output related to CV effects
- Disturbed Thought Processes and Disturbed Sensory Perception (Visual, Auditory, Kinesthetic, Tactile, or Olfactory) related to CNS effects
- Risk for Injury related to CNS effects
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Limit drug access if the patient is suicidal *to decrease the risk of overdose to cause harm*.
- Maintain the initial dose for 4 to 8 weeks *to evaluate the therapeutic effect*.
- Administer parenteral forms of the drug only if oral forms are not feasible or available; switch to an oral form, *which is less toxic and associated with fewer adverse effects, as soon as possible*.
- Administer a major portion of the dose at bedtime if drowsiness and anticholinergic effects are severe *to decrease the risk of patient injury*. *Elderly patients may not be able to tolerate larger doses*.
- Reduce dose if minor adverse effects occur, and discontinue the drug slowly if major or potentially life-threatening adverse effects occur *to ensure patient safety*.

- Provide comfort measures *to help the patient tolerate drug effects*. These measures may include voiding before dosing, instituting a bowel program as needed, taking food with the drug if GI upset is severe, and environmental control (lighting, temperature, stimuli).
- Provide thorough patient teaching, including drug name, prescribed dosage, measures for avoidance of adverse effects, and warning signs that may indicate possible problems. Instruct the patient about the need for periodic monitoring and evaluation *to enhance patient knowledge about drug therapy and to promote compliance*.
- Offer support and encouragement *to help the patient cope with the diagnosis and the drug regimen*.

Evaluation

- Monitor patient response to the drug (alleviation of signs and symptoms of depression).
- Monitor for adverse effects (sedation, anticholinergic effects, hypotension, cardiac arrhythmias, suicidal thoughts).
- Evaluate the effectiveness of the teaching plan (patient can give the drug name, dosage, possible adverse effects to watch for, specific measures to help avoid adverse effects, and importance of continued follow-up).
- Monitor the effectiveness of comfort measures and compliance with the regimen.

KEY POINTS

- ◆ Affect is a term that refers to the feelings that people experience when they respond emotionally.
- ◆ Depression is an affective disorder characterized by inappropriate sadness, despair, and hopelessness.
- ◆ According to the biogenic amine theory, depression is caused by a brain deficiency of the biogenic amines. Antidepressant drugs are thought to raise the level of the biogenic amines.

MONOAMINE OXIDASE INHIBITORS

Monoamine oxidase inhibitors (MAOIs) (Table 21.2) irreversibly inhibits MAO, an enzyme found in nerves and other tissues (including the liver), to break down the biogenic amines NE, dopamine, and 5HT and relieve depression. At one time, MAOIs were used more often, but now they are used rarely because they require a specific dietary regimen to prevent toxicity. There are some patients, however, who only seem to respond to these particular drugs, so they remain available. Agents still in use include isocarboxazid (*Marplan*), phenelzine (*Nardil*), and tranylcypromine (*Parnate*). The choice of an MAOI depends on the prescriber's experience and individual response. A patient who does not respond to one MAOI may respond to another.

TABLE 21.2 DRUGS IN FOCUS Monoamine Oxidase Inhibitors

Drug Name	Dosage/Route	Usual Indications
isocarboxazid (<i>Marplan</i>)	10 mg PO b.i.d., may reach a maximum of 40 mg/day	Treatment of depression not responsive to other agents
 phenelzine (<i>Nardil</i>)	15 mg PO t.i.d.; maintenance 15 mg/day PO	Treatment of depression not responsive to other agents
tranylcypromine (<i>Parnate</i>)	30 mg/day PO in divided doses; maximum 60 mg/day	Treatment of adult reactive depression

Therapeutic Actions and Indications

Blocking the breakdown of the biogenic amines NE, dopamine, and 5HT allows these amines to accumulate in the synaptic cleft and in neuronal storage vesicles, causing increased stimulation of the postsynaptic receptors. It is thought that this increased stimulation of the receptors causes relief of depression. The MAOIs are generally indicated for treatment of the signs and symptoms of depression in patients who cannot tolerate or do not respond to other, safer antidepressants (see Table 21.2).

Pharmacokinetics

The MAOIs are well absorbed from the GI tract, reaching peak levels in 2 to 3 hours. They are metabolized in the liver primarily by acetylation and are excreted in the urine. Patients with liver or renal impairment and those known as “slow acetylators” may require lowered doses to avoid exaggerated effects of the drugs. The MAOIs cross the placenta and enter breast milk (see contraindications and cautions).

Contraindications and Cautions

Contraindications to the use of MAOIs include allergy to any of these antidepressants *because of the risk of hypersensitivity reactions*; pheochromocytoma *because the sudden increases in NE levels could result in severe hypertension and CV emergencies*; CV disease, including hypertension, coronary artery disease, angina, and congestive heart failure, *which could be exacerbated by increased NE levels*; and known abnormal CNS vessels or defects *because the potential increase in blood pressure and vasoconstriction associated with higher NE levels could precipitate a stroke*. A history of headaches may also be a contraindication.

Other contraindications include renal or hepatic impairment, *which could alter the metabolism and excretion of these drugs and lead to toxic levels*, and myelography within the past 24 hours or in the next 48 hours *because of the risk of severe reaction to the dye used in myelography*.

In addition, caution should be used with psychiatric patients, *who could be overstimulated or shift to a manic*

phase as a result of the stimulation associated with MAOIs, and in patients with seizure disorders or hyperthyroidism, both of which could be exacerbated by the stimulation of these drugs. There is a black box warning on all drugs of this class to bring awareness to a possible risk of suicidality, especially with children and adolescents, in patients using these drugs. Care should also be taken with patients who are soon to undergo elective surgery *because of the potential for unexpected effects with NE accumulation during the stress reaction*, and with female patients who are pregnant or breast-feeding *because of potential adverse effects on the fetus and neonate*; these drugs should be used during pregnancy and lactation only if the benefit to the mother clearly outweighs the potential risk to the neonate.

Adverse Effects

The MAOIs are associated with more adverse effects, more of which are fatal, than most other antidepressants. The effects relate to the accumulation of NE in the synaptic cleft. Dizziness, excitement, nervousness, mania, hyperreflexia, tremors, confusion, insomnia, agitation, and blurred vision may occur.

MAOIs can cause liver toxicity. Other GI effects can include nausea, vomiting, diarrhea or constipation, anorexia, weight gain, dry mouth, and abdominal pain. Urinary retention, dysuria, incontinence, and changes in sexual function may also occur. Cardiovascular effects can include orthostatic hypotension, arrhythmias, palpitations, angina, and the potentially fatal hypertensive crisis. This last condition is characterized by occipital headache, palpitations, neck stiffness, nausea, vomiting, sweating, dilated pupils, photophobia, tachycardia, and chest pain. It may progress to intracranial bleeding and fatal stroke.

Clinically Important Drug–Drug Interactions

Drug interactions of MAOIs with other antidepressants include hypertensive crisis, coma, and severe convulsions with TCAs and a potentially life-threatening serotonin syndrome with SSRIs. A period of 6 weeks should elapse after stopping an SSRI before beginning therapy with an MAOI.

TABLE 21.3 Tyramine-Containing Foods

FOODS HIGH IN TYRAMINE	FOODS WITH MODERATE AMOUNTS OF TYRAMINE	FOODS WITH LOW AMOUNTS OF TYRAMINE
Aged cheeses: cheddar cheese, blue cheese, Swiss cheese, Camembert Aged or fermented meats, fish or poultry: chicken paté, beef liver paté, caviar Brewer's yeast Fava beans Red wines: Chianti, burgundy, sherry, vermouth Smoked or pickled meats, fish or poultry: herring, sausage, corned beef, salami, pepperoni	Meat extracts: consommé, bouillon Pasteurized light and pale beer Avocados	Distilled liquors: vodka, gin, Scotch, rye Cheeses: American, mozzarella, cottage cheese, cream cheese Chocolate Fruits: figs, raisins, grapes, pineapple, oranges Sour cream Soy sauce Yogurt

If MAOIs are given with other sympathomimetic drugs (e.g., methyl dopa, guanethidine), sympathomimetic effects increase. Combinations with insulin or oral antidiabetic agents result in additive hypoglycemic effects. Patients who receive these combinations must be monitored closely, and appropriate dose adjustments should be made.

Clinically Important Drug–Food Interactions

Tyramine and other pressor amines that are found in food, which are normally broken down by MAO enzymes in the GI tract, may be absorbed in high concentrations in the presence of MAOIs, resulting in increased blood pressure. In addition, tyramine causes the release of stored NE from nerve terminals, which further contributes to high blood pressure and hypertensive crisis. Patients who take MAOIs should avoid the tyramine-containing foods listed in Table 21.3.

Prototype Summary: *Phenelzine*

Indications: Treatment of patients with depression who are unresponsive to other antidepressive therapy or in whom other antidepressive therapy is contraindicated.

Actions: Irreversibly inhibits MAO, allowing norepinephrine, serotonin, and dopamine to accumulate in the synaptic cleft; this accumulation is thought to be responsible for the clinical effects.

Pharmacokinetics:

Route	Onset	Duration
Oral	Slow	48–96 h

$T_{1/2}$: Unknown; metabolized in the liver, excreted in urine.

Adverse effects: Dizziness, vertigo, headache, overactivity, hyperreflexia, tremors, mania, weakness, drowsiness, fatigue, sweating, orthostatic hypotension, constipation, diarrhea, dry mouth, edema, anorexia, potential for hypertensive crisis.

Nursing Considerations for Patients Receiving Monoamine Oxidase Inhibitors

Assessment: History and Examination

- Assess for any known allergies to these drugs *to avoid hypersensitivity reactions*; impaired liver or kidney function *that could alter the metabolism and excretion of the drug*; cardiac dysfunction; GI or GU obstruction, *which could be exacerbated by the drug*; surgery, including elective surgery, *because the effects of changes in NE levels are unpredictable following surgery*; seizure disorders; psychiatric conditions or suicidality; and occurrence of myelography within the past 24 hours or in the next 48 hours *to avoid the possibility of severe reactions*.
- Determine whether female patients are pregnant or breast-feeding *because these drugs should not be used during pregnancy or lactation*.
- Assess temperature and weight; skin color and lesions; affect, orientation, and reflexes; vision; blood pressure, including orthostatic blood pressure; pulse and perfusion; respiratory rate and adventitious sounds; and bowel sounds on abdominal examination *to determine baseline status and for any potential adverse effects before beginning therapy*. Also obtain an electrocardiogram and renal and liver function tests.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to sympathomimetic effects, headache, and CNS effects
- Decreased Cardiac Output related to CV effects
- Disturbed Thought Processes and Disturbed Sensory Perception (Visual, Kinesthetic) related to CNS effects
- Risk for Injury related to CNS effects
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Limit drug access to a potentially suicidal patient *to decrease the risk of overdose.*
- Monitor the patient for 2 to 4 weeks *to ascertain the onset of the full therapeutic effect.*
- Monitor blood pressure and orthostatic blood pressure carefully *to arrange for a slower increase in dose as needed for patients who show a tendency toward hypotension.*
- Monitor liver function before and periodically during therapy and *arrange to discontinue the drug at the first sign of liver toxicity.*
- Discontinue drug and monitor the patient carefully at any complaint of severe headache *to decrease the risk of severe hypertension and cerebrovascular effects.*
- Have phentolamine or another adrenergic blocker on standby *as treatment in case of hypertensive crisis.*
- Provide comfort measures *to help the patient tolerate drug effects.* These include voiding before dosing, instituting a bowel program as needed, taking food with the drug if GI upset is severe, and environmental control (lighting, temperature, decreased stimulation).
- Provide a list of potential drug–food interactions that can cause severe toxicity *to decrease the risk of a serious drug–food interaction.* Provide a diet that is low in tyramine-containing foods.
- Provide thorough patient teaching, including drug name, prescribed dosage, measures for avoidance of adverse effects, and warning signs that may indicate possible problems. Instruct the patient about the need for periodic monitoring and evaluation *to enhance patient knowledge about drug therapy and to promote compliance.*
- Offer support and encouragement *to help the patient cope with the disease and the drug regimen.*

Evaluation

- Monitor patient response to the drug (alleviation of signs and symptoms of depression).
- Monitor for adverse effects (sedation, sympathomimetic effects, hypotension, cardiac arrhythmias, GI disturbances, hypertensive crisis).
- Evaluate the effectiveness of the teaching plan (patient can give the drug name, dosage, possible adverse effects to watch for, specific measures to help avoid adverse effects, importance of continued follow-up, and importance of avoiding foods high in tyramine).
- Monitor the effectiveness of comfort measures and compliance with the regimen.

KEY POINTS

- ▶ The MAO inhibitors (MAOIs) prevent the breakdown of NE and 5HT by monoamine oxidase, leading to an increased level of these biogenic amines in the synaptic cleft. This accumulation of the amines is thought to relieve the signs and symptoms of depression.

- ▶ Patients taking MAOIs need to avoid foods high in tyramine to prevent serious increases in blood pressure and hypertensive crises.

SELECTIVE SEROTONIN REUPTAKE INHIBITORS

Selective serotonin reuptake inhibitors (SSRIs) (Table 21.4), the newest group of antidepressant drugs, specifically block the reuptake of 5HT, with little to no known effect on NE. Because SSRIs do not have the many adverse effects associated with TCAs and MAOIs, they are a better choice for many patients. SSRIs include fluoxetine (*Prozac*), the first SSRI; citalopram (*Celexa*); duloxetine (*Cymbalta*), the newest SSRI; escitalopram (*Lexapro*), fluvoxamine (*Luvox*); paroxetine (*Paxil*); and sertraline (*Zoloft*).

Therapeutic Actions and Indications

The action of SSRIs blocking the reuptake of 5HT increases the levels of 5HT in the synaptic cleft and may contribute to the antidepressant and other effects attributed to these drugs.

SSRIs are indicated for the treatment of depression, OCDs, panic attacks, bulimia, premenstrual dysphoric disorder (PMDD), posttraumatic stress disorders, social phobias, and social anxiety disorders. A period of up to 4 weeks is necessary for realization of the full therapeutic effect. Patients may respond well to one SSRI and yet show little or no response to another one. The choice of drug depends on the indications and individual response. Box 21.2 provides more information. Ongoing investigations are focusing on the use of these antidepressant drugs in the treatment of other psychiatric disorders (see Table 21.4).

Pharmacokinetics

The SSRIs are well absorbed from the GI tract, metabolized in the liver, and excreted in the urine and feces. The half-life varies widely with the drug being used.

Contraindications and Cautions

The SSRIs are contraindicated in the presence of allergy to any of these drugs *because of the risk of hypersensitivity reactions.* Caution should be used in patients with impaired renal or hepatic function *that could alter the metabolism and excretion of the drug, leading to toxic effects,* or with diabetes, *which could be exacerbated by the stimulating effects of these drugs.* Caution should also be used with severely depressed or suicidal patients, especially children and adolescents, *because of a risk of increased suicidality.* The SSRIs have been associated with congenital abnormalities in animal studies and should be used during pregnancy only if the benefits to the mother clearly outweigh the potential risks to the fetus. The SSRIs enter breast milk and can cause

TABLE 21.4 DRUGS IN FOCUS Selective Serotonin Reuptake Inhibitors

Drug Name	Usual Dosage	Usual Indications
citalopram (<i>Celexa</i>)	20 mg/d PO b.i.d., up to 40 mg/d may be needed	Treatment of depression in adults has also been used to treat panic disorder, premenstrual dysphoric disorder (PMDD), obsessive-compulsive disorders (OCDs), social phobias, trichotillomania, and posttraumatic stress disorders
duloxetine (<i>Cymbalta</i>)	20 mg PO b.i.d., up to 60 mg/d if needed	Treatment of major depressive disorder and management of neuropathic pain associated with diabetic peripheral neuropathy
escitalopram (<i>Lexapro</i>)	10 mg/d PO as a single dose; 10–20 mg/d PO maintenance	Treatment of major depressive disorder, maintenance of patients with major depressive disorder and generalized anxiety disorder
 fluoxetine (<i>Prozac, Sarafem</i>)	20 mg/d PO in the AM; do not exceed 60 mg/d; reduce dose with hepatic impairment; also available in a 90-mg, once-a-week formulation	Treatment of depression, bulimia, OCDs, panic disorders, PMDD in adults; also under investigation for treatment of other psychiatric disorders, including obesity, alcoholism, chronic pain, and various neuropathies
fluvoxamine (<i>Luvox</i>)	Adult: 50 mg PO at bedtime to a maximum of 300 mg/d; reduce dose with hepatic impairment Pediatric (8–17 yr): 25 mg PO at bedtime; do not exceed 250 mg/d	Treatment of OCDs; also under investigation for treatment of depression, bulimia, panic disorder, and social phobia
paroxetine (<i>Paxil</i>)	10–20 mg/d PO; do not exceed 50 mg/d; or 62.5 mg/d controlled-release tablets; reduce dose in hepatic or renal dysfunction and with the elderly	Treatment of depression, OCDs, PMDD, posttraumatic stress reaction, social anxiety disorders, general anxiety disorders, and various panic disorders in adults; also under investigation for treatment of chronic headache, diabetic neuropathy, and hot flashes
sertraline (<i>Zoloft</i>)	Adult: 25–50 mg/d PO; reduce dose with hepatic dysfunction, OCD Pediatric: 25–50 mg/d PO based on age and severity of OCD	Treatment of depression, OCDs, social anxiety disorder, posttraumatic stress disorder, panic disorders, PMDD

FOCUS ON BOX 21.2 Cultural Considerations

The Popularity of Prozac

A rise in the diagnosis of depression began in the 1990s, with that decade's fast-paced lifestyle, high-stress jobs, explosion of information, and rapid change. Many people who have high expectations of both themselves and others are overworked and overstimulated to a point at which they become clinically depressed.

There is now a selection of relatively safe and nontoxic drugs that can be used to treat depression—the selective serotonin reuptake inhibitors (SSRIs). For several years, the SSRIs remained in the top-selling category of prescription drugs. Fluoxetine (*Prozac*), in particular, has been the subject of numerous talk shows, books, and movies. In many ways, *Prozac* was the “in” drug of the 1990s. This societal phenomenon put pressure on health care providers to prescribe a drug even if it was not appropriate to a given patient's situation. In some instances, patients just wanted

the drug that helped their friend. They may not have been willing to listen to their health care provider or to take the time to be properly diagnosed; they just wanted an SSRI. *Prozac* is not the solution to everyone's problem, and it is often difficult to explain this fact to a patient. It also may be hard to get the patient to understand that this drug is not a quick fix; it takes 4 to 6 weeks to achieve full therapeutic effectiveness. Fortunately, the SSRIs have the least adverse effects of the antidepressants, and such fads usually pass in a few years.

It is important to remember the powerful effects of the media on health care-seeking behavior. As more and more drugs are advertised in magazines and on television, patients are becoming aware of options and “cures” that they might like to try. Patient education is a tricky yet important part of any health care intervention and an extremely important aspect of health care in our society.

adverse effects in the baby, so a different method of feeding the baby should be selected if an SSRI is required by the mother.

FOCUS ON Safe Medication Administration

When administering medications, confusion about similar drug names may present a hazard, for example with *Celexa* (citalopram), *Celebrex* (celecoxib), *Xanax* (alprazolam), and *Cerebyx* (fosphenytoin). Use caution. Serious adverse effects have been reported, as well as important loss of therapeutic effects, when the wrong drug is given. If any of these drugs is ordered for your patient, make sure you know the indication for the drug, as well as the generic name of the prescribed drug.

FOCUS ON Safe Medication Administration

Because antidepressants have varied uses, it is essential that the patient know generic and trade names to avoid unintentional overdose from drugs prescribed by different providers. *Wellbutrin* (bupropion) for example, may be prescribed for depression to a patient taking *Zyban* (bupropion) for smoking cessation, leading to an overdose of bupropion. Another example is prescribing *Prozac* (fluoxetine) for depression to a patient taking *Sarafem* (fluoxetine) for PMDD, leading to an overdose of fluoxetine. To prevent serious medication errors, provide generic and brand names of drugs in writing, and instruct the patient to share complete drug information with all health care providers.

BOX 21.3 The Evidence

Childhood Suicide and Antidepressants

The Food and Drug Administration (FDA) issued a talk paper in late spring 2003 after reports from the British press cited an increase in suicidal behavior in children being treated with paroxetine (*Paxil*). The FDA compiled a review of reports for eight different antidepressant drugs—citalopram, fluoxetine, fluvoxamine, mirtazapine, nefazodone, paroxetine, sertraline, and venlafaxine—that were being studied for use in pediatric populations.

The data from these studies did not clearly establish a link between increased suicidal ideation and the use of these antidepressants, but the data also did not establish effectiveness in major depressive disorder in children for any of the drugs, except fluoxetine. Many journals and news reports have discussed an increase in suicide attempts and completed suicides in pediatric patients being treated with antidepressants. Many anecdotal reports have been submitted to Medwatch reporting the same events. The FDA points out, however, that these reports are hard to interpret and, without a control group, it

Adverse Effects

The adverse effects associated with SSRIs, which are related to the effects of increased 5HT levels, include CNS effects such as headache, drowsiness, dizziness, insomnia, anxiety, tremor, agitation, and seizures. GI effects such as nausea, vomiting, diarrhea, dry mouth, anorexia, constipation, and changes in taste often occur, as do GU effects, including painful menstruation, cystitis, sexual dysfunction, urgency, and impotence. Respiratory changes may include cough, dyspnea, upper respiratory infections, and pharyngitis. Other reported effects are sweating, rash, fever, and pruritus. Recent studies have linked the incidence of suicidal ideation and suicide attempts to the use of these drugs in pediatric patients and adolescents (see Box 21.3).

Clinically Important Drug–Drug Interactions

Because of the risk of serotonin syndrome if SSRIs are used with MAOIs, this combination should be avoided, and at least 2 to 4 weeks should be allowed between use of the two types of drugs if one is switching from one to the other. In addition, the use of SSRIs with TCAs results in increased therapeutic and toxic effects. If these combinations are used, patients should be monitored closely, and appropriate dose adjustments should be made. For more information see Box 21.4.

Prototype Summary: Fluoxetine

Indications: Treatment of depression, OCDs, bulimia, PMDD, panic disorders; off-label uses include chronic pain, alcoholism, neuropathies, obesity.

is difficult to know whether these effects are also seen in this age group of children even when they are not being treated with antidepressants. In 20 placebo-controlled studies involving these eight drugs and more than 4100 pediatric patients, there were no reports of completed suicides.

In fall 2004, the FDA issued an advisory to all prescribers noting the studies that had been done and concluding that there was not enough evidence at that point that suicidal ideation was inherent to many major depressive disorders. In 2006, a black box warning was added to all antidepressants bringing attention to the increase in suicidality, especially in children and adolescents, when these drugs were used. All of these drugs should be used with caution and prescriptions written in the smallest quantity feasible, and parents should be educated about the warning signs of suicide. Continued research is being carried out to study the actual cause and effect relation. The FDA has issued guidelines based on a review of all studies. See <http://www.fda.gov>; under A in the Index, click on Antidepressants.

Actions: Inhibits CNS neuronal reuptake of serotonin, with little effect on norepinephrine and little affinity for cholinergic, histaminic, or alpha-adrenergic sites.

Pharmacokinetics:

Route	Onset	Peak
Oral	Slow	6–8 h

$T_{1/2}$: 2 to 4 weeks; metabolized in the liver, excreted in urine and feces.

Adverse effects: Headache, nervousness, insomnia, drowsiness, anxiety, tremor, dizziness, sweating, rash, nausea, vomiting, diarrhea, dry mouth, anorexia, sexual dysfunction, upper respiratory infections, weight loss, fever.

FOCUS ON BOX 21.4 Herbal and Alternative Therapies

Patients being treated with SSRIs are at an increased risk of developing a severe reaction, including serotonin syndrome, as well as an increased sensitivity to light if they are also taking St. John's wort. Because this herbal therapy is often used to self-treat depression, it is important to forewarn any patient who is taking an SSRI not to combine it with taking St. John's wort.

Also caution patients that there is an increased risk of seizures if evening primrose is used with antidepressants, and patients should be cautioned against this combination. Interactions have also been reported when antidepressants are combined with ginkgo, ginseng, and valerian. Patients should be cautioned against using these herbs while taking antidepressants.

Nursing Considerations for Patients Receiving Selective Serotonin Reuptake Inhibitors

Assessment: History and Examination

- Assess for any known allergies to SSRIs *to avoid hypersensitivity reactions*; severe depression or suicidality, *which could be exacerbated by these drugs*; impaired liver or kidney function, *which could alter metabolism and excretion of the drug*; and diabetes mellitus. Find out whether female patients are pregnant or breast-feeding *because caution should be used in these situations and drug use limited*.
- Assess temperature and weight; skin color and lesions; affect, orientation, and reflexes; vision; blood pressure and pulse; respiratory rate and adventitious sounds; and bowel sounds on abdominal examination *for baseline status before beginning therapy and for any potential adverse effects*. Also obtain renal and liver function tests.

Refer to *Critical Thinking Scenario* for a full discussion of nursing care for a patient who is dealing with depression.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to GI, GU, and CNS effects
- Disturbed Thought Processes and Disturbed Sensory Perception (Kinesthetic, Tactile) related to CNS effects
- Imbalanced Nutrition related to GI effects
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Arrange for lower dose in elderly patients and in those with renal or hepatic impairment *because of the potential for severe adverse effects*.
- Monitor the patient for up to 4 weeks *to ascertain the onset of full therapeutic effect before adjusting dose*.
- Establish suicide precautions for severely depressed patients and limit the quantity of the drug dispensed *to decrease the risk of overdose to cause harm*.
- Administer the drug once a day in the morning *to achieve optimal therapeutic effects*. If dose is increased or if the patient is having severe GI effects, the dose can be divided. Serious name confusion has been reported with some of the SSRIs (see Focus on Safe Medication Administration in the section Contraindications and Cautions).
- Suggest that the patient use barrier contraceptives *to prevent pregnancy while taking this drug because serious fetal abnormalities can occur*.
- Provide comfort measures *to help the patient tolerate drug effects*. These may include voiding before dosing, instituting a bowel program as needed, taking food with the drug if GI upset is severe, or environmental control (lighting, temperature, stimuli).
- Provide thorough patient teaching, including the drug name, prescribed dosage, measures for avoidance of adverse effects, and warning signs that may indicate possible problems. Instruct patients about the need for periodic monitoring and evaluation *to enhance patient knowledge about drug therapy and to promote compliance*.
- Offer support and encouragement *to help the patient cope with the disease and the drug regimen*.

Evaluation

- Monitor patient response to the drug (alleviation of signs and symptoms of depression, OCD, bulimia, panic disorder).
- Monitor for adverse effects (sedation, dizziness, GI upset, respiratory dysfunction, GU problems, skin rash).
- Evaluate the effectiveness of the teaching plan (patient can give the drug name, dosage, possible adverse effects to watch for, specific measures to help avoid adverse effects, importance of continued follow-up, and importance of avoiding pregnancy).
- Monitor the effectiveness of comfort measures and compliance with the regimen.

CRITICAL THINKING SCENARIO

Selective Serotonin Reuptake Inhibitors

THE SITUATION

D.J., a 46-year-old married woman, complains of weight gain, malaise, fatigue, sleeping during the day, loss of interest in daily activities, and bouts of crying for no apparent reason. On examination, she weighs 8 pounds more than the standard weight for her height; all other findings are within normal limits. In conversation with a nurse, D.J. says that in the past 10 months, several events have occurred. She lost both of her parents, her only child graduated from high school and went away to college, her nephew died of renal failure, her one sister learned she had metastatic breast cancer, and she lost her job as a day care provider when the client family moved out of town. In addition, the family cat of 17 years was diagnosed with terminal leukemia. D.J. is prescribed fluoxetine (*Prozac*) and is given an appointment with a counselor.

CRITICAL THINKING

What nursing interventions are appropriate at this time?

What sort of crisis intervention would be most appropriate? *Balance the benefits of pointing out all of the losses and points of grief that you detect in D.J.'s story with the risks of upsetting her strained coping mechanisms.* What can D.J. expect to experience as a result of the SSRI therapy? How can you help D.J. cope during the lengthy period it takes to reach therapeutic effects? What other future interventions should be planned with D.J.?

DISCUSSION

Many patients in severe crisis do not consciously identify the many things that are causing them stress. They have developed coping mechanisms to help them survive and cope with their day-to-day activities. However, D.J. seems to have reached her limit, and she exhibits many of the signs and symptoms of depression. However, it is important to make sure that she does not have some underlying medical condition that could be contributing to her complaints. Because of her age, she may also be perimenopausal, which could account for some of her problems.

It is hoped that the fluoxetine, an SSRI, will enable D.J. to regain her ability to cope and her normal affect. The drug should give her brain a chance to reach a new biochemical balance. Before she begins taking the fluoxetine, she should receive a written sheet listing the pertinent drug information, adverse effects to watch for, warning signs to report, and a telephone number to call in case she has questions later or just needs to talk. The written information is especially

important because she may not remember drug-related discussions or instructions clearly.

Once the SSRI reaches therapeutic levels, which can take as long as 4 weeks, D.J. may start to feel like her “old self” and may be strong enough to begin dealing with all her grief. She may recover from her need for the SSRI over time, and use of the medication can then be discontinued.

NURSING CARE GUIDE FOR D.J.: FLUOXETINE

Assessment: History and Examination

Allergies to fluoxetine or any other antidepressant SSRI; renal or hepatic dysfunction; pregnancy or lactation; diabetes

Concurrent use of TCAs, cyproheptadine, lithium, MAO inhibitors, benzodiazepines, alcohol, other SSRIs

CV: blood pressure, pulse

CNS: orientation, affect, reflexes, vision

Skin: color, lesions, texture

Respiratory: respiration, adventitious sounds

GI: abdominal examination, bowel sounds

Laboratory tests: hepatic and renal function tests

Nursing Diagnoses

Acute Pain related to GI, GU, CNS effects

Disturbed Thought Processes related to CNS effects

Imbalanced Nutrition related to GI effects

Deficient Knowledge regarding drug therapy

Implementation

Administer drug in morning; divide doses if GI upset occurs.

Provide comfort, safety measures; small meals; void before dosing; side rails; pain medication as needed; suggest barrier contraceptive; limit dosage with potentially suicidal patients; lower dose with renal or hepatic impairment.

Provide support and reassurance to help D.J. deal with drug effects (4-week delay in full effectiveness).

Provide patient teaching regarding drug dosage, adverse effect conditions to report, and the need to use barrier contraceptives.

Evaluation

Evaluate drug effects: relief of signs and symptoms of depression.

Monitor for adverse effects: sedation, dizziness, insomnia; respiratory dysfunction; GI upset; GU problems; rash.

Monitor for drug–drug interactions.

Evaluate effectiveness of patient teaching program.

Evaluate effectiveness of comfort and safety measures.

Selective Serotonin Reuptake Inhibitors (continued)

PATIENT TEACHING FOR D.J.

- The drug that has been prescribed is called a selective serotonin reuptake inhibitor or SSRI. SSRIs change the concentration of serotonin in specific areas of the brain. An increase in serotonin level is believed to relieve depression.
- The drug should be taken once a day in the morning. If your dosage has been increased or if you are having stomach upset, the dose may be divided.
- It may take as long as 4 weeks before you feel the full effects of this drug. Continue to take the drug every day during that time so that the concentration of the drug in your body eventually reaches effective levels.
- Common side effects of SSRIs include the following:
 - *Dizziness, drowsiness, nervousness, and insomnia:* If these effects occur, avoid driving or performing hazardous or delicate tasks that require concentration.
 - *Nausea, vomiting and weight loss:* Small frequent meals may help. Monitor your weight loss; if it becomes excessive, consult your health care provider.
 - *Sexual dysfunction and flu-like symptoms:* These effects may be temporary. Consult with your health care provider if these conditions become bothersome.
- Report any of the following conditions to your health care provider: *rash mania, seizures, and severe weight loss.*
- Tell your doctors, nurses, and other health care providers that you are taking this drug. Keep this drug and all medications out of the reach of children and pets. Do not take this drug during pregnancy because severe fetal abnormalities could occur. The use of barrier contraceptives is recommended while you are taking this drug. If you think that you are pregnant or would like to become pregnant, consult with your health care provider.

KEY POINTS

- ◆ The SSRIs prevent the reuptake of serotonin into the presynaptic nerve, leading to an accumulation of these biogenic amines in the synaptic cleft. This accumulation causes increased stimulation of the postsynaptic nerve and may be responsible for the antidepressant effects of these drugs.
- ◆ The SSRIs are not associated with many of the CNS, CV, and anticholinergic effects of other antidepressants.

OTHER ANTIDEPRESSANTS

Some other effective antidepressants do not fit into any of the three groups that have been discussed in this chapter. These drugs have varying effects on NE, 5HT, and dopamine. Although it is not known how their actions are related to clinical efficacy, these agents may be most effective in treating depression in patients who do not respond to other antidepressants. They may even be used before MAOIs or TCAs, which have many more adverse effects. As with the other antidepressants, these drugs have a black box warning to be alert for the possibility of increased suicidality, especially in children and adolescents, whenever the drugs are used. Other antidepressants include the following (see Table 21.5 for usual indications):

- Bupropion (*Wellbutrin, Zyban*) weakly blocks the reuptake of NE, 5HT, and dopamine. At lower doses, this drug is effective in smoking cessation. It is well absorbed from the GI tract, metabolized in the liver, and excreted in the urine. There are no adequate studies done in pregnancy, and the drug should be used during pregnancy only if the

benefits to the mother clearly outweigh the potential risks to the fetus. Bupropion does enter breast milk and should not be used by nursing mothers. The drug is available in a sustained-release formulation, as well as an extended-release formula, which some patients find to be more convenient.

- Desvenlafaxine (*Pristiq*) is the newest of the SSRIs. It blocks the reuptake of NE and 5HT. It is readily absorbed from the GI tract, reaching peak levels in 7.5 hours. It is metabolized in the liver and excreted through urine within about 72 hours. It passes into breast milk and should not be used by nursing mothers. As with other SSRIs, it should be used in pregnancy only if the benefit clearly outweighs the risk. It is taken orally, once a day.
- Mirtazapine (*Remeron*) is rapidly absorbed from the GI tract, extensively metabolized in the liver, and excreted in the urine. Mirtazapine has a half-life of 20 to 40 hours. How its many anticholinergic effects relate to its antidepressive effects is not known. Little is known about its effects in pregnancy and lactation, and it should be used during those times only if the benefit to the mother clearly outweighs the potential risk to the neonate.
- Nefazodone (generic) has a short half-life of 2 to 4 hours. It is well absorbed from the GI tract, metabolized in the liver, and excreted in the urine. It has been associated with severe liver toxicity in some patients and because of this, its use has become limited. Little is known about its effects in pregnancy and breast-feeding, and it should be used during those times only if the benefit to the mother clearly outweighs the potential risk to the fetus or neonate.
- Selegiline (*Emsam*) is a MAO type B inhibitor that has been used for many years in the treatment of Parkinson disease and is now available as a transdermal system,

TABLE 21.5 DRUGS IN FOCUS Other Antidepressants

Drug Name	Usual Dosage	Usual Indications
bupropion (<i>Wellbutrin</i> , <i>Wellbutrin SR</i> , <i>Wellbutrin XL</i> , <i>Zyban</i>)	300 mg/d PO given in three doses; or 150 mg PO b.i.d. in sustained-release form or 150–300 mg/d as a single dose of extended-release form	Treatment of depression in adults, smoking cessation
desvenlafaxine (<i>Pristiq</i>)	50 mg/d PO with or without food; range 50–400 mg/d	Treatment of major depressive disorder in adults
mirtazapine (<i>Remeron</i>)	15 mg/d PO, may be increased to a maximum of 45 mg/d; reduce dose in elderly patients and those with renal or hepatic dysfunction	Treatment of depression in adults
nefazodone (generic)	100 mg PO b.i.d., to a maximum of 600 mg/d; reduce dose in elderly	Treatment of depression in adults
selegiline (<i>Emsam</i>)	Initially, one 6 mg/24 h transdermal system applied to dry, intact skin on the upper thigh, upper torso, or upper arm; may be increased to a maximum 12 mg/24 h system; geriatric patients, maximum 6 mg/2 h.	Treatment of major depressive disorder
trazodone (<i>Desyrel</i>)	150 mg/d PO in divided doses; up to 600 mg/d, reduce dose with the elderly Pediatric: 1.5–2 mg/kg per day PO in divided doses; do not exceed 6 mg/kg per day	Treatment of depression in adults and children 6–18 yr
venlafaxine (<i>Effexor</i> , <i>Effexor XR</i>)	75 mg/d PO in divided doses, to 375 mg/d; 75 mg/d PO sustained-release formulation to a maximum 225 mg/d; reduce dose with hepatic and renal impairment	Treatment and prevention of depression in generalized anxiety disorder; social anxiety disorder; decreases addictive behavior

Emsam, for the treatment of major depressive disorder. The drug is slowly absorbed into the bloodstream over 24 hours. It is metabolized in the liver and excreted through urine. The drug does cross the placenta and enters breast milk, so it should only be used during pregnancy and lactation if the benefit outweighs the potential risk to the neonate. This drug is associated with CNS effects, as well as GI effects including nausea, vomiting, dry mouth, and abdominal pain. Patients need to be taught to apply the patch to dry, intact skin on the upper torso, upper thigh, or upper arm. They should always remove the old patch before applying a new one to avoid inadvertent overdose.

- Trazodone (*Desyrel*), which blocks 5HT and some 5HT precursor reuptake, is effective in some forms of depression but has many CNS effects associated with its use. It is readily absorbed from the GI tract, extensively metabolized in the liver, and excreted in urine and feces. Trazodone caused fetal abnormalities in animal studies and crosses into breast milk. It should be used during pregnancy and lactation only if the benefits to the mother clearly outweigh the potential risks to the fetus. A black box warning has been added to this drug, cautioning about the need to limit the quantity of the drug to depressed patients, the risk for low blood pressure, and a risk for

priapism. Because of these warnings, the use of this drug has also become limited.

- Venlafaxine (*Effexor*) mildly blocks the reuptake of NE, 5HT, and dopamine and has fewer adverse CNS effects than trazodone. Its popularity has increased with the introduction of an extended-release form that does away with the multiple daily doses that are required with the regular form. Venlafaxine is readily absorbed from the GI tract, extensively metabolized in the liver, and excreted in urine. Adequate studies have not been done in pregnancy and lactation, and it should be used during those times only if the benefit to the mother clearly outweighs the potential risk to the neonate.

CHAPTER SUMMARY

- Depression is a very common affective disorder; it is associated with many physical manifestations and is often misdiagnosed. It could be that depression is caused by a series of events that are not yet understood.
- Antidepressant drugs—TCAs, MAOIs, and SSRIs— increase the concentrations of the biogenic amines in the brain.

- Selection of an antidepressant depends on individual drug response and tolerance of associated adverse effects. The adverse effects of TCAs are sedating and anticholinergic; those of MAOIs are CNS related and sympathomimetic. The adverse effects of SSRIs are fewer, but they do cause CNS changes.
- Other antidepressants with unknown mechanisms of action are also effective in treating depression.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-Rom in the front of the book.

MULTIPLE CHOICE

Select the best answer to the following.

- The biogenic amine theory of depression states that depression is a result of
 - an unpleasant childhood.
 - GABA inhibition.
 - deficiency of NE, dopamine, or 5HT in key areas of the brain.
 - blockages within the limbic system, which controls emotions and affect.
- When teaching a patient receiving tricyclic antidepressants (TCAs), it is important to remember that TCAs are associated with many anticholinergic adverse effects. Teaching about these drugs should include anticipation of
 - increased libido and increased appetite.
 - polyuria and polydipsia.
 - urinary retention, arrhythmias, and constipation.
 - hearing changes, cataracts, and nightmares.
- Adverse effects may limit the usefulness of TCAs with some patients. Nursing interventions that could alleviate some of the unpleasant aspects of these adverse effects include
 - always administering the drug when the patient has an empty stomach.
 - reminding the patient not to void before taking the drug.
 - increasing the dose to override the adverse effects.
 - taking the major portion of the dose at bedtime to avoid experiencing drowsiness and the unpleasant anticholinergic effects.
- You might question an order for an MAOI as a first step in the treatment of depression, remembering that these drugs are reserved for use in cases in which there has been no response to other agents because
 - MAOIs can cause hair loss.
 - MAOIs are associated with potentially serious drug-food interactions.
 - MAOIs are mostly recommended for use in surgical patients.
 - MAOIs are more expensive than other agents.
- Your patient is being treated for depression and is started on a regimen of *Prozac* (fluoxetine). She calls you 10 days after the drug therapy has started to report that nothing has changed and she wants to try a different drug. You should
 - tell her to try sertraline (*Zoloft*) because some patients respond to one SSRI and not another.
 - ask her to try a few days without the drug to see whether there is any difference.
 - add an MAOI to her drug regimen to get an increased antidepressant effect.
 - encourage her to keep taking the drug as prescribed because it usually takes up to 4 weeks to see the full antidepressant effect.

6. The drug of choice for a patient with a documented obsessive-compulsive disorder who is also suffering from depression and occasional panic disorder would be
- Celexa*.
 - Paxil*.
 - Luvox*.
 - Prozac*.
7. Venlafaxine (*Effexor*) is a relatively new antidepressant that might be very effective for use in patients who
- have proven to be responsive to other antidepressants.
 - can tolerate multiple side effects.
 - are reliable at taking multiple daily dosings.
 - have not responded to other antidepressants and would benefit from once-a-day dosing.
8. Depression is an affective disorder that is
- always precipitated by a specific event.
 - most common in patients with head injuries.
 - characterized by overwhelming sadness, despair, and hopelessness.
 - very evident and easy to diagnose in the clinical setting.

MULTIPLE RESPONSE

Select all that apply.

- Depression is a very common affective disorder that strikes many people. In assessing a client who might be suffering from depression, the nurse would expect to find which of the following?
 - Lack of energy
 - Hyperactivity
 - Sleep disturbances
 - Libido problems
 - Confusion
 - Decreased reflexes
- A client reports that he thinks he is taking an antidepressant, but he is not sure. In reviewing his medication history, which of the following drugs would be considered antidepressants?
 - Tetracyclic drugs
 - Cholinergics
 - SSRIs
 - MAOIs
 - Angiotensin II receptor blockers (ARBs)
 - Benzodiazepines

Psychotherapeutic Agents

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Define the term psychotherapeutic agent and list conditions that the psychotherapeutic agents are used to treat.
2. Describe the therapeutic actions, indications, pharmacokinetics, contraindications, most common adverse reactions, and important drug–drug interactions associated with each class of psychotherapeutic agent.
3. Discuss the use of psychotherapeutic agents across the lifespan.
4. Compare and contrast the prototype drugs for each class of psychotherapeutic agent with other drugs in that class and with drugs in the other classes of psychotherapeutic agents.
5. Outline the nursing considerations and teaching needs for patients receiving each class of psychotherapeutic agents.

Glossary of Key Terms

antipsychotic: drug used to treat disorders involving thought processes; dopamine-receptor blocker that helps affected people to organize their thoughts and respond appropriately to stimuli

attention-deficit disorder: behavioral syndrome characterized by an inability to concentrate for longer than a few minutes and excessive activity

bipolar disorder: behavioral disorder that involves extremes of depression alternating with hyperactivity and excitement

major tranquilizer: former name of antipsychotic drugs; the name is no longer used because it implies that the primary effect of these drugs is sedation, which is no longer thought to be the desired therapeutic action

mania: state of hyperexcitability; one phase of bipolar disorders, which alternate between periods of severe depression and mania

narcolepsy: mental disorder characterized by daytime sleepiness and periods of sudden loss of wakefulness

neuroleptic: a drug with many associated neurological adverse effects that is used to treat disorders that involve thought processes (e.g., schizophrenia)

schizophrenia: the most common type of psychosis; characteristics include hallucinations, paranoia, delusions, speech abnormalities, and affective problems

ANTIPSYCHOTIC/ NEUROLEPTIC DRUGS

Typical Antipsychotics

-  chlorpromazine
- fluphenazine
- haloperidol
- loxapine
- molindone
- perphenazine
- pimozide
- prochlorperazine

- thioridazine
- thiothixene
- trifluoperazine

Atypical Antipsychotics

-  aripiprazole
- clozapine
- olanzapine
- paliperidone
- quetiapine

- risperidone
- ziprasidone

ANTIMANIC DRUGS

-  aripiprazole
- lamotrigine
- lithium
- olanzapine
- quetiapine
- ziprasidone

CENTRAL NERVOUS SYSTEM STIMULANTS

-  armodafinil
- atomoxetine
- dexmethylphenidate
- dextroamphetamine
- lisdexamfetamine
- methylphenidate
- modafinil

The drugs discussed in this chapter are used to treat psychoses—perceptual and behavioral disorders. These psychotherapeutic agents are targeted at thought processes rather than affective states. Although they do not cure any psychotic disorders, psychotherapeutic agents do help both adult and child patients to function in a more acceptable manner and carry on activities of daily living (Box 22.1).

MENTAL DISORDERS AND THEIR CLASSIFICATION

Mental disorders were once attributed to environmental influences and life experiences such as poor parenting or trauma. Mental disorders are now thought to be caused by some inherent dysfunction within the brain that leads to abnormal thought processes and responses. Most theories attribute these disorders to some sort of chemical imbalance in specific areas within the brain. Diagnosis of a mental disorder is often based on distinguishing characteristics as described in the *Diagnostic and Statistical Manual of Mental Disorders*, 4th edition, text revision (DSM-IV-TR). Because no diagnostic laboratory tests

are available, patient assessment and response must be carefully evaluated to determine the basis of a particular problem. Selected disorders are discussed here.

Schizophrenia, the most common type of psychosis, can be very debilitating and prevents affected individuals from functioning in society. Characteristics of schizophrenia include hallucinations, paranoia, delusions, speech abnormalities, and affective problems. This disorder, which seems to have a very strong genetic association, may reflect a fundamental biochemical abnormality.

Mania, with its associated bipolar illness (i.e., manic-depressive illness), is characterized by periods of extreme overactivity and excitement. **Bipolar disorder** involves extremes of depression alternating with hyperactivity and excitement. This condition may reflect a biochemical imbalance followed by overcompensation on the part of neurons and their inability to re-establish stability.

Narcolepsy is characterized by daytime sleepiness and sudden periods of loss of wakefulness. This disorder may reflect problems with stimulation of the brain by the reticular activating system (RAS) or problems with response to that stimulation.

BOX 22.1

Drug Therapy Across the Lifespan

Psychotherapeutic Agents

CHILDREN

Many of these agents are used in children, often in combination with other central nervous system (CNS) drugs in an attempt to control symptoms and behavior. Long-term effects of many of these agents are not known, and parents should be informed of this fact.

Of the antipsychotics, chlorpromazine, haloperidol, pimozide, prochlorperazine, risperidone, thioridazine, and trifluoperazine are the only ones with established pediatric regimens. Aripiprazole has doses for children 13 to 17 years of age. The dose is often higher than that required for adults. The child should be monitored carefully for adverse effects and developmental progress.

Lithium does not have a recommended pediatric dose, and the drug should not ordinarily be used in children. If it is used, the dose should be carefully calculated from the child's age and weight, and the child should be monitored very closely for renal, CNS, cardiovascular, and endocrine function.

The CNS stimulants are often used in children to manage various attention-deficit disorders. Caution should be used with extended-release preparations because they differ markedly in timing and effectiveness. The child should be assessed carefully and challenged periodically for the necessity of continuing the drug.

ADULTS

Adults using these drugs should be under regular care and should be monitored regularly for adverse effects. The QT_c interval should be evaluated before thioridazine or ziprasidone is prescribed and periodically during use.

Patients receiving lithium should be encouraged to maintain hydration and salt intake. They need to understand the importance of periodic monitoring of serum lithium levels.

These drugs should be used very cautiously during pregnancy and lactation because of the potential for adverse effects on the fetus or neonate. A woman maintained on one of these drugs needs to be counseled about the risk to the fetus versus the risk of returning symptoms if the drug is stopped. Use should be reserved for situations in which the benefits to the mother far outweigh the potential risks to the neonate. Women of childbearing age who need to take lithium should be advised to use barrier contraceptives while taking the drug because of the potential for serious congenital abnormalities.

OLDER ADULTS

Older patients may be more susceptible to the adverse effects of these drugs. All doses need to be reduced and patients monitored very closely for toxic effects and to provide safety measures if CNS effects do occur. They should not be used to control behavior with dementia.

Patients with renal impairment should be monitored very closely while taking lithium. Decreased doses may be needed. Because many older patients may also have renal impairment, they need to be screened carefully. They should be urged to maintain hydration and salt intake, which can be a challenge with some older patients.

Prolongation of the QT_c interval—associated with use of thioridazine or ziprasidone—may be a concern in elderly patients with coronary disease. Careful screening and monitoring should be done if these drugs are needed for such patients.

Attention-deficit disorders involve various conditions characterized by an inability to concentrate on one activity for longer than a few minutes and a state of hyperkinesis. These conditions are usually diagnosed in school-aged children but can occur in adults.

ANTIPSYCHOTIC/NEUROLEPTIC DRUGS

The **antipsychotic** drugs, which are essentially dopamine-receptor blockers, are used to treat disorders that involve thought processes. Because of their associated neurological adverse effects, these medications are also called **neuroleptic** agents. At one time, these drugs were known as **major tranquilizers**. However, that name is no longer used because the primary action of these drugs is not sedation but a change in neuron stimulation and response (Figure 22.1).

Antipsychotics are classified as either typical or atypical: Typical antipsychotics include chlorpromazine (*Thorazine*),

fluphenazine (*Prolixin*), haloperidol (*Haldol*), loxapine (*Loxitane*), molindone (*Moban*), perphenazine (*Trilafon*), pimozide (*Orap*), prochlorperazine (*Compazine*), thiothixene (*Navane*), and trifluoperazine (*generic*). Atypical antipsychotics include aripiprazole (*Abilify*), clozapine (*Clozaril*), olanzapine (*Zyprexa*, *Zyprexa Zydis*), paliperidone (*Invega*), quetiapine (*Seroquel*, *Seroquel XR*), risperidone (*Risperdal*, *Risperdal Conta*), and ziprasidone (*Geodon*). Table 22.1 lists both typical and antipsychotic agents, including the specific type and the occurrence of sedation and other adverse effects.

FOCUS NO Safe Medication Administration

Name confusion has been reported between chlorpromazine (an antipsychotic) and chlorpropamide (an antidiabetic agent). Serious adverse effects have occurred. Manufacturers of these two drugs have been working to make the labels of

(continued)

● **FIGURE 22.1** Sites of action of the drugs used to treat mental disorders: antipsychotics, central nervous system stimulants, lithium.

the drugs very distinctive to help eliminate some of these errors. If your patient is prescribed chlorpromazine, make sure the patient is aware of the name of the drug, its intended use, and what it should look like.

Therapeutic Actions and Indications

The typical antipsychotic drugs block dopamine receptors, preventing the stimulation of the postsynaptic neurons by dopamine. They also depress the RAS, limiting the stimuli

coming into the brain. They also have anticholinergic, anti-histamine, and alpha-adrenergic blocking effects, all related to the blocking of the dopamine-receptor sites. Newer atypical antipsychotics block both dopamine and serotonin receptors. This dual action may help to alleviate some of the unpleasant neurological effects and depression associated with the typical antipsychotics (see Table 22.1).

The antipsychotics are indicated for schizophrenia and for manifestations of other psychotic disorders, including hyperactivity, combative behavior, and severe behavioral problems in children (short-term control); some of them are also approved

TABLE 22.1 DRUGS IN FOCUS Antipsychotic/Neuroleptic Drugs

Drug Name	Potency	Common Side Effects				Usual Dosage
		Sedation	Anticholinergic	Hypotension	Extrapyramidal	
Typical Antipsychotics						
 chlorpromazine (Thorazine)	Low	++++	++++	+++	++	Adult: 25 mg IM for acute episode, may be repeated; switch to 25–50 mg PO t.i.d. Pediatric: 0.5–1 mg/kg q4–8h PO, IM, or PR
fluphenazine (Prolixin)	High	+	+	+	++++	Adult: 0.5–10 mg/day PO in divided doses; 1.25–10 mg/day IM in divided doses Geriatric: 1–2.5 mg/day PO, adjust dose based on response
haloperidol (Haldol)	High	+	+/-	+	++++	Adult: 0.5–2 mg PO t.i.d. or 2–5 mg IM, may be repeated in 1 h, 4–8 h more common Geriatric: reduce dose Pediatric (3–12 yr): 0.5 mg/d PO; 0.05–0.075 mg/kg per day PO for Tourette syndrome and behavioral syndromes
loxapine (Loxitane)	Medium	+++	++	++	+++	Adult: 20–60 mg/day PO; 12.5–50 mg IM or IV for acute states
molindone (Moban)	Medium	+	++	+/-	+	Adult: initially 50–75 mg/d PO, maintenance at 5–25 mg PO t.i.d. to q.i.d.
perphenazine (Trilafon)	Medium	++	+	++	+++	Adult: 4–8 mg PO t.i.d. or 5–10 mg IM q6h; switch to oral as soon as possible Geriatric: 1/2–1/3 of adult dose
pimozide (Orap)	High	+	+	++	+++	Adult: 1–2 mg/d PO in divided doses Pediatric (>12 yr): 0.05 mg/kg PO at bedtime; do not exceed 10 mg/d

Drug Name	Potency	Common Side Effects				Usual Dosage
		Sedation	Anticholinergic	Hypotension	Extrapyramidal	
Typical Antipsychotics (continued)						
prochlorperazine (Compazine)	Low	+	++	+	+++	Adult: 5–10 mg PO t.i.d. to q.i.d.; 10–20 mg IM for acute states Geriatric: reduce dose Pediatric: 2.5 mg PO t.i.d.; 0.03 mg/kg IM for acute states; 20–25 mg/d PR
thioridazine (generic)	Low	++++	++++	+++	+	Adult: 50–100 mg PO t.i.d., monitor QT _c intervals Pediatric: up to 3 mg/kg per day PO
thiothixene (Navane)	High	+	+	+	++++	Adult: 2 mg PO t.i.d.; up to a maximum 60 mg/d in severe cases
trifluoperazine (generic)	High	+	+	+	++++	Adult: 2–5 mg PO b.i.d.; 1–2 mg IM q4–6h in severe cases Geriatric: reduce dose Pediatric (6–12 yr): 1 mg PO daily or b.i.d.; 1 mg IM daily or b.i.d. for severe cases

Atypical Antipsychotics						
aripiprazole (Abilify)	Medium	+	+	++	+	Adult: 10–15 mg/d PO Pediatric (13–17 yr): 10–30 mg/d PO
 clozapine (Clozaril)	Low	++++	++++	+++	+/-	Adult: initially 25 mg PO b.i.d. to t.i.d.; up to 500 mg/d; available only through the <i>Clozaril</i> Patient Management System, which monitors white blood cell count and compliance issues, only 1-wk supply given at a time
olanzapine (Zyprexa, Zyprexa Zydys)	High	++++	++++	+++	+	Adult: 5–10 mg/d PO, up to 20 mg/d PO for bipolar mania; available in disintegrating tablets, which can be taken without swallowing
paliperidone (Invega)	Medium	+	+	++	++	Adult: 6 mg/d PO; maximum dose 12 mg/d Renal impairment: maximum dose 6 mg/d with moderate impairment, maximum dose 3 mg/d with severe impairment
quetiapine (Seroquel, Seroquel XR)	Medium	++++	++++	++	+/-	Adult: initially 25 mg PO b.i.d., up to 300–400 mg/d; 400–900 mg/d PO (XR) Geriatric, hepatic impairment, or hypotensives: reduce dose and titrate very slowly

(drug table continues on page 346)

TABLE 22.1 DRUGS IN FOCUS Antipsychotic/Neuroleptic Drugs (continued)

Drug Name	Potency	Common Side Effects				Usual Dosage
		Sedation	Anticholinergic	Hypotension	Extrapyramidal	
Atypical Antipsychotics (continued)						
risperidone (Risperdal, Risperdal Cona)	High	+++	+	++	++	Adult: 1 mg PO b.i.d. up to 8 mg/d or 25 mg IM once every 2 wk Pediatric: 10–17 yr: 0.5–6 mg/d PO (bipolar disorders) 13–17 yr: 1–6 mg/d PO (schizophrenia) Geriatric, renal impaired, or hypotensives: 0.5 mg PO b.i.d. initially, titrate slowly
ziprasidone (Geodon)	Medium	+++	++	+	+	Adult: 20–80 mg PO b.i.d.; rapid control of as-stated behavior: 10–20 mg IM, maximum dose 40 mg/d IM; monitor QT _c intervals

Each plus sign indicates increased incidence of the given adverse effect.

b.i.d., twice daily; IM, intramuscularly; PO, orally; PR, rectally; q.i.d., four times daily; q4–6h, every 4–6 hours; q4–8h, every 4–8 hours; q6h, every 6 hours; t.i.d., three times daily; XR, extended release.

for the treatment of bipolar disorder. Chlorpromazine, one of the older antipsychotics, is also used to decrease preoperative restlessness and apprehension, to treat intermittent porphyria, as an adjunct in the treatment of tetanus, and to control nausea, vomiting, and intractable hiccups. Haloperidol is frequently used to treat acute psychiatric situations and is available for intravenous (IV) use when prolonged parenteral therapy is required because of swallowing difficulties or the acuity of the behavioral problems. Prochlorperazine is also frequently used to control severe nausea and vomiting associated with surgery and chemotherapy. It has the advantage of being available in oral, rectal, and parenteral forms. Aripiprazole, one of the newer atypical antipsychotics, has been found to be effective in treating schizophrenia, major depressive disorder, and bipolar disorders and has been used parenterally for the treatment of acute agitation associated with these disorders. Olanzapine and ziprasidone are also used for bipolar disorders and parenterally to treat acute agitation. Quetiapine is also approved for short-term treatment of acute manic episodes associated with bipolar disease. Risperidone is used frequently to treat irritability and aggression associated with autistic disorders in children and adolescents, as well as for acute manic episodes of bipolar disease. Any of these drugs may be effective in a particular patient; the selection of a specific drug depends on the desired potency and patient tolerance of the associated adverse effects. A patient who does not respond to one drug may react successfully to another agent. (Responses may also vary because of cultural

issues [Box 22.2].) To determine the best therapeutic regimen for a particular patient, it may be necessary to try more than one drug.

Pharmacokinetics

The antipsychotics are erratically absorbed from the gastrointestinal (GI) tract, depending on the drug and the preparation of the drug. Intramuscular doses provide four to five times the active dose as oral doses, and caution is required if one is switching between routes. The antipsychotics are widely distributed in the tissues and are often stored there, being released for up to 6 months after the drug is stopped. They are metabolized in the liver and excreted through the bile and urine. Children tend to metabolize these drugs faster than do adults, and elderly patients tend to metabolize them more slowly, making it necessary to carefully monitor these patients and adjust doses as needed. Clinical effects may not be seen for several weeks, and patients should be encouraged to continue taking the drugs even if they see no immediate effectiveness. The antipsychotics cross the placenta and enter breast milk (see contraindications and cautions).

Contraindications and Cautions

Antipsychotic drugs are contraindicated in the presence of underlying diseases *that could be exacerbated by the*

FOCUS ON BOX 22.2 Cultural Considerations

Antipsychotic Drugs

The ways in which patients in certain cultural groups respond to antipsychotic drugs—either physiologically or emotionally—may vary. Therefore, when a pharmacological regimen is incorporated into overall patient care, health care providers must consider and respect an individual patient's cultural beliefs and needs.

- African Americans respond more rapidly to antipsychotic medications and have a greater risk for development of disfiguring adverse effects, such as tardive dyskinesia. Consequently, these patients should be started off at the lowest possible dose and monitored closely. African Americans also display a higher red blood cell plasma lithium ratio than Caucasians do, and they report more adverse effects from lithium therapy. These patients should be monitored closely because they have a higher potential for lithium toxicity at standard therapeutic ranges.
- Patients in Asian countries, such as India, Turkey, Malaysia, China, Japan, and Indonesia, receive lower doses of neuroleptics and lithium to achieve the same therapeutic response as seen in patients in the United States. This may be related to these individuals' lower body mass as well as metabolic differences, and it may have implications for dosing protocols for patients in these ethnic groups who undergo therapy in the United States.
- Arab American patients metabolize antipsychotic medications more slowly than Asian Americans do and may require lower doses to achieve the same therapeutic effects as in Caucasians.
- Individuals in some cultures use herbs and other folk remedies, and the use of herbs may interfere with the metabolism of Western medications. The nurse should carefully assess for herbal use and be aware of potential interactions.

dopamine-blocking effects of these drugs. They are also contraindicated in the following conditions, which can be exacerbated by the drugs: central nervous system (CNS) depression, circulatory collapse, Parkinson disease, coronary disease, severe hypotension, bone marrow suppression, and blood dyscrasias. Prolongation of the QT_c interval is a contraindication to the use of mesoridazine, thioridazine, and ziprasidone, all of which can further prolong the QT_c interval, leading to increased risk of serious cardiac arrhythmias. Antipsychotics are contraindicated for use in elderly patients with dementia because this use is associated with an increased risk of cardiovascular events and death. In 2005, the U.S. Food and Drug Administration (FDA) issued a public health advisory regarding the use of antipsychotics after postmarketing studies showed that when these drugs were used to control behavioral symptoms of dementia in older adults, the patients being treated experienced increased car-

diovascular events and death. None of these drugs is approved for this use, but it was common practice in many settings to use them, off-label, to establish behavioral control of patients with dementia. The manufacturers of all of these drugs sent out “Dear Health Care Provider” letters to remind health care providers that this is not an approved use and to alert them of the risk for death if they used the drug in this way. Antipsychotics now have a black-box warning on the prescribing information outlining this safety information and contraindication.

Caution should be used in the presence of medical conditions *that could be exacerbated by the anticholinergic effects of the drugs*, such as glaucoma, peptic ulcer, and urinary or intestinal obstruction. In addition, care should be taken in patients with seizure disorders *because the threshold for seizures could be lowered*; in patients with thyrotoxicosis *because of the possibility of severe neurosensitivity*; and in patients with active alcoholism *because of potentiation of the CNS depression*.

Other situations that warrant caution include myelography within the last 24 hours or scheduled within the next 48 hours *because severe neuron reaction to the dye used in these tests can occur* and pregnancy or lactation *because of the potential of adverse effects on the fetus or neonate*; antipsychotic agents should be used only if the benefit to the mother clearly outweighs the potential risk to the fetus or baby. Because children are more apt to develop dystonia from the drugs, *which could confuse the diagnosis of Reye syndrome*, caution should be used with children younger than 12 years of age who have a CNS infection or chickenpox. *The use of antipsychotics may result in bone marrow suppression, leading to blood dyscrasias*, so care should be taken with patients who are immunosuppressed and those who have cancer.

Adverse Effects

The adverse effects associated with the antipsychotic drugs are related to their dopamine-blocking, anticholinergic, antihistamine, and alpha-adrenergic activities. The most common CNS effects are sedation, weakness, tremor, drowsiness, extrapyramidal side effects (EPS), pseudoparkinsonism, dystonia, akathisia, tardive dyskinesia, and potentially irreversible neuroleptic malignant syndrome (Box 22.3). Anticholinergic effects include dry mouth, nasal congestion, flushing, constipation, urinary retention, impotence, glaucoma, blurred vision,

FOCUS ON BOX 22.3 Herbal and Alternative Therapies

Evening Primrose

Patients with schizophrenia should be advised to avoid the use of evening primrose. This herb has been associated with increased symptoms and CNS hyperexcitability.

and photophobia. Cardiovascular (CV) effects, which are probably related to the dopamine-blocking effects, include hypotension, orthostatic hypotension, cardiac arrhythmias, congestive heart failure, and pulmonary edema. Several of these agents (thioridazine, mesoridazine, ziprasidone) are associated with prolongation of the QT_c interval, which could lead to serious or even fatal cardiac arrhythmias. Patients receiving these drugs should have a baseline and periodic electrocardiogram (ECG) during therapy. In late 2003, the FDA issued a requirement that all of the atypical antipsychotics include warnings that there is a risk for the development of diabetes mellitus when these drugs are used. Consequently, when patients are maintained on any of the atypical antipsychotics, they should be monitored regularly for the signs and symptoms of diabetes mellitus.

Respiratory effects such as laryngospasm, dyspnea, and bronchospasm may also occur. The phenothiazines (chlorpromazine, fluphenazine, prochlorperazine, promethazine, and thioridazine) often turn the urine pink to reddish-brown as a result of their excretion. Although this effect may cause great patient concern, it has no clinical significance. In addition, bone marrow suppression is a possibility with some antipsychotic agents.

Clinically Important Drug–Drug Interactions

Because the combination of antipsychotics with beta-blockers may lead to an increase in the effect of both drugs, this combination should be avoided if possible. Antipsychotic–alcohol combinations result in an increased risk of CNS depression, and antipsychotic–anticholinergic combinations lead to increased anticholinergic effects, so dose adjustments are necessary. Patients who take either of these combinations should be monitored closely for adverse effects, and supportive measures should be provided. Patients should not take thioridazine or ziprasidone with any other drug that is associated with prolongation of the QT_c interval.

Prototype Summary: *Chlorpromazine*

Indications: Management of manifestations of psychotic disorders; relief of preoperative restlessness; adjunctive treatment of tetanus; acute intermittent porphyria; severe behavioral problems in children; control of hiccups, nausea, and vomiting.

Actions: Blocks postsynaptic dopamine receptors in the brain; depresses those parts of the brain involved in wakefulness and emesis; anticholinergic; antihistaminic; alpha-adrenergic blocking.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	30–60 min	2–4 h	4–6 h
Intramuscular	10–15 min	15–20 min	4–6 h

*T*_{1/2}: 2 hours, then 30 hours; metabolized in the liver, excreted in the urine.

Adverse effects: Drowsiness, insomnia, vertigo, extrapyramidal symptoms, orthostatic hypotension, photophobia, blurred vision, dry mouth, nausea, vomiting, anorexia, urinary retention, photosensitivity.

Prototype Summary: *Clozapine*

Indications: Management of severely ill patients with schizophrenia who are unresponsive to standard drugs; reduction of risk of recurrent suicidal behavior in patients with schizophrenia or schizoaffective disorder.

Actions: Blocks dopamine and serotonin receptors; depresses the RAS; anticholinergic; antihistaminic; alpha-adrenergic blocking.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	Varies	1–6 h	Weeks

*T*_{1/2}: 4–12 hours; metabolized in the liver, excreted in the urine and feces.

Adverse effects: Drowsiness, sedation, seizures, dizziness, syncope, headache, tachycardia, nausea, vomiting, fever, neuroleptic malignant syndrome.

Nursing Considerations for Patients Receiving Antipsychotic/Neuroleptic Drugs

Assessment: History and Examination

- Assess for *contraindications or cautions for the use of the drug* including any known allergies to these drugs, severe CNS depression, circulatory collapse, coronary disease including prolonged QT_c interval, brain damage, severe hypotension, glaucoma, respiratory depression, urinary or intestinal obstruction, thyrotoxicosis, seizure disorder, bone marrow suppression, pregnancy or lactation, and myelography within the last 24 hours or scheduled in the next 48 hours. In children younger than 12 years of age, screen for CNS infections.
- Assess temperature; skin color and lesions; CNS orientation, affect, reflexes, and bilateral grip strength; bowel sounds and reported output; pulse, auscultation, and blood pressure, including orthostatic blood pressure; respiration rate and adventitious sounds; and urinary output to determine baseline status before beginning therapy and for any potential adverse effects. Also obtain liver and renal function tests, thyroid function tests, ECG if appropriate, and complete blood count (CBC).

Refer to the Critical Thinking Scenario for a full discussion of nursing care for a patient who is prescribed antipsychotic drugs.

CRITICAL THINKING SCENARIO

Antipsychotic Drugs

THE SITUATION

B.A., a 36-year-old, single, professional woman, was diagnosed with chronic schizophrenia when she was a senior in high school. Her condition has been well controlled with chlorpromazine (*Thorazine*), and she is able to maintain steady employment, live in her own home, and carry on a fairly active social life. At her last evaluation, she appeared to be developing bone marrow suppression, and her physician decided to try to taper the drug dosage. As the dosage was being lowered, B.A. became withdrawn and listless, missed several days of work, and canceled most of her social engagements. Afraid of interacting with people, she stayed in bed most of the time. She reported having thoughts of death and paranoid ideation about her neighbors that she was beginning to think might be true.

CRITICAL THINKING

- What nursing interventions are appropriate at this time?
- What supportive measures might be useful to help B.A. cope with this crisis and allow her to function normally again?
- What happens to brain chemistry after long-term therapy with phenothiazines?
- What drug options should be tried?
- Are there any other options that might be useful?

DISCUSSION

Schizophrenia is not a disorder that can be resolved simply with proper counseling. B.A., an educated woman with a long history of taking phenothiazines, realizes the necessity of drug therapy to correct the chemical imbalance in her brain. She may need a high-potency antipsychotic to return her to the level of functioning she had reached before experiencing this setback. Her knowledge of her individual responses can be used to help select an appropriate drug and dosage. Her experiences may also facilitate her care planning and new drug regimen.

B.A. will need support to cope with problems at work—from her inability to go in to work, to coping with feelings about not meeting her social obligations, to finding the motivation to get up and become active again. She might do well with behavior modification techniques that give her some control over her activities and allow her to use her knowledge and experience with her own situation to her advantage in forming a new medical regimen. She may need support in explaining her problem to her employer and her social contacts in ways that will help her avoid the prejudice associated with mental illness and will allow her every opportunity to return to her regular routine as soon as she can.

Because it may take several months to find the drug or drugs that will bring B.A. back to a point of stabilization, it is important to have a consistent, reliable health care team in place to support her through this stabilization period. She should have a reliable contact person to call when she has questions and when she needs support.

NURSING CARE GUIDE FOR B.A.: ANTIPSYCHOTIC/NEUROLEPTIC DRUGS

Assessment: History and Examination

- Allergies to any of these drugs; CNS depression; CV disease; pregnancy or lactation; myelography; glaucoma; hypotension; thyrotoxicosis; seizures
- Concurrent use of anticholinergics, barbiturate anesthetics, alcohol, meperidine, beta blockers, epinephrine, norepinephrine, guanethidine
- CV: blood pressure, pulse, orthostatic blood pressure
- CNS: orientation, affect, reflexes, vision
- Skin: color, lesions, texture
- Respiratory: respiration, adventitious sounds
- GI: abdominal examination, bowel sounds
- Laboratory tests: thyroid, liver and renal function tests, CBC

Nursing Diagnoses

- Impaired Physical Mobility related to extrapyramidal effects
- Risk for Injury related to CNS effects
- Decreased Cardiac Output related to CV effects
- Impaired Urinary Elimination related to anticholinergic effects
- Deficient knowledge regarding drug therapy

Implementation

- Give drug in evening; do not allow patient to chew or crush sustained-release capsules.
- Provide comfort and safety measures: void before dosing; raise siderails; provide sugarless lozenges, mouth care; institute safety measures if CNS effects occur; position patient to relieve dyskinesia discomfort; taper dosage after long-term therapy.
- Provide support and reassurance to help patient cope with drug effects.
- Teach patient about drug, dosage, adverse effects, conditions to report, and precautions.

Evaluation

- Evaluate drug effects: relief of signs and symptoms of psychotic disorders.
- Monitor for adverse effects: sedation, dizziness, insomnia; anticholinergic effects; extrapyramidal effects; bone marrow suppression; skin rash.
- Monitor for drug–drug interactions as listed.

Antipsychotic Drugs (continued)

Evaluate effectiveness of patient teaching program.
Evaluate effectiveness of comfort and safety measures.

PATIENT TEACHING FOR B.A.

- The drugs that are useful for treating schizophrenia are called antipsychotic or neuroleptic drugs. These drugs affect the activities of certain chemicals in your brain and are used to treat certain mental disorders.
- Drugs in this group should be taken exactly as prescribed. Because these drugs affect many body systems, it is important that you have medical checkups regularly.
- Common effects of these drugs include:
 - *Dizziness, drowsiness, and fainting:* Avoid driving or performing hazardous tasks or delicate tasks that require concentration if these occur. Change position slowly. The dizziness usually passes after 1 to 2 weeks of drug use.
 - *Pink or reddish urine (with phenothiazines):* These drugs sometimes cause urine to change color. Do not be alarmed by this change; it does not mean that your urine contains blood.
 - *Sensitivity to light:* Bright light might hurt your eyes and sunlight might burn your skin more easily. Wear sunglasses and protective clothing when you must be out in the sun.
- *Constipation:* Consult with your health care provider if this becomes a problem.
- Report any of the following conditions to your health care provider: *sore throat, fever, rash, tremors, weakness, and vision changes.*
- Tell any doctor, nurse, or other health care provider that you are taking this drug.
- Keep this drug and all medications out of the reach of children.
- Avoid the use of alcohol or other depressants while you are taking this drug. You also may want to limit your use of caffeine if you feel very tense or cannot sleep.
- Avoid the use of over-the-counter drugs while you are on this drug. Many of them contain ingredients that could interfere with the effectiveness of your drug. If you feel that you need one of these preparations, consult with your health care provider about the most appropriate choice.
- Take this drug exactly as prescribed. If you run out of medicine or find that you cannot take your drug for any reason, consult your health care provider. After this drug has been used for a period of time, additional adverse effects may occur if it is suddenly stopped. This drug dosage will need to be tapered over time.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Impaired Physical Mobility related to extrapyramidal effects.
- Decreased Cardiac Output related to hypotensive effects.
- Risk for Injury related to CNS effects and sedation.
- Impaired Urinary Elimination related to anticholinergic effects.
- Deficient Knowledge regarding drug therapy.

Implementation With Rationale

- Do not allow patient to crush or chew sustained-release capsules, *which will speed up their absorption and may cause toxicity.*
- If administering parenteral forms, keep patient recumbent for 30 minutes *to reduce the risk of orthostatic hypotension.*
- Consider warning the patient or the patient's guardians about the risk of development of tardive dyskinesias with continued use *so they are prepared for that neurological change.*
- Monitor CBC *to arrange to discontinue the drug at signs of bone marrow suppression.*

- Monitor blood glucose levels with long-term use *to detect the development of glucose intolerance.*
- Arrange for gradual dose reduction after long-term use. *Abrupt withdrawal has been associated with gastritis, nausea, vomiting, dizziness, arrhythmias, and insomnia.*
- Provide positioning of legs and arms *to decrease the discomfort of dyskinesias.*
- Provide sugarless candy and ice chips *to increase secretions and frequent mouth care to prevent dry mouth from becoming a problem.*
- Encourage patient to void before taking a dose *if urinary hesitancy or retention is a problem.*
- Provide safety measures such as side rails and assistance with ambulation if CNS effects or orthostatic hypotension occurs *to prevent patient injury.*
- Provide for vision examinations *to determine ocular changes and arrange appropriate dose change.*
- Provide thorough patient teaching, including drug name, prescribed dosage, measures for avoidance of adverse effects, cautions that it may take weeks to see the desired clinical effects, warning signs that may indicate possible problems, and the need for monitoring and evaluation *to enhance patient knowledge about drug therapy and to promote compliance.* (Refer to Critical

- Thinking Scenario.) Warn patient that urine may have a pink to reddish-brown color.
- Offer support and encouragement to *help the patient to cope with the drug regimen.*

Evaluation

- Monitor patient response to the drug (decrease in signs and symptoms of psychotic disorder).
- Monitor for adverse effects (sedation, anticholinergic effects, hypotension, extrapyramidal effects, bone marrow suppression).
- Evaluate the effectiveness of the teaching plan (patient can give the drug name and dosage, possible adverse effects to watch for, specific measures to prevent adverse effects, and warning signs to report).
- Monitor the effectiveness of comfort measures and compliance with the regimen.

KEY POINTS

- ▶ Mental disorders are thought-process disorders that may be caused by some inherent dysfunction within the brain. A psychosis is a thought disorder, and schizophrenia is the most common psychosis in which delusions and hallucinations are hallmarks.
- ▶ Antipsychotic drugs are dopamine-receptor blockers that are effective in helping people to organize thought patterns and to respond appropriately to stimuli.

- ▶ Antipsychotics can cause hypotension, anticholinergic effects, sedation, and extrapyramidal effects, including parkinsonism, ataxia, and tremors.

ANTIMANIC DRUGS

Mania, at the opposite pole from depression, occurs in individuals with bipolar disorder, who experience a period of depression followed by a period of mania. The cause of mania is not understood, but it is thought to be an overstimulation of certain neurons in the brain. The mainstay for treatment of mania has always been lithium (*Lithotabs, Lithobid*). Today, many other drugs are used successfully in treating bipolar disorders, including aripiprazole (*Abilify*), olanzapine (*Zyprexa, Zyprexa Zydys*), quetiapine (*Seroquel*), and ziprasidone (*Geodon*), which are atypical antipsychotics; and lamotrigine (*Lamictal*), an antiepileptic agent discussed in greater detail in Chapter 23. These new approvals were the first advances since the 1970s in the treatment of bipolar disorder (see Table 22.2).

Lithium salts (*Lithane, Lithotabs*) are taken orally for the management of manic episodes and prevention of future episodes. These very toxic drugs can cause severe CNS, renal, and pulmonary problems that may lead to death. Despite the potential for serious adverse effects, lithium is used with caution because it is consistently effective in the treatment of mania. The therapeutically effective serum level is 0.6 to 1.2 mEq/L.

TABLE 22.2 DRUGS IN FOCUS Antimanic Drugs

Drug Name	Dose/Route	Usual Indications
aripiprazole (<i>Abilify</i>)	30 mg/d PO	Treatment of acute manic and mixed episodes of bipolar disorders
lamotrigine (<i>Lamictal</i>)	25 mg/d PO	Long-term maintenance of patients with bipolar disorders; decreases occurrence of acute mood episodes
 Lithium salts (<i>Lithotabs, Lithobid</i>)	600 mg PO t.i.d. for acute episodes; 300 mg PO t.i.d. to q.i.d. for maintenance; reduce dose with elderly patients	Treatment of manic episodes of manic-depressive or bipolar illness; maintenance therapy to prevent or diminish the frequency and intensity of future manic episodes; currently being studied for improvement of neutrophil counts in patients with cancer chemotherapy—induced neutropenia and as prophylaxis of cluster headaches and migraine headaches; not recommended for children <12 yr
olanzapine (<i>Zyprexa, Zyprexa Zydys</i>)	10 mg/d PO; range 5–20 mg/d	Management of acute manic episodes associated with bipolar disorder, in combination with lithium or valproate, or as monotherapy
quetiapine (<i>Seroquel</i>)	50 mg PO b.i.d., titrate to a maximum 800 mg/d	Adjunct or monotherapy for the treatment of manic episodes associated with bipolar disorder
ziprasidone (<i>Geodon</i>)	40 mg PO b.i.d. with food; maximum 80 mg b.i.d.	Treatment of acute manic and mixed episodes of bipolar disorders

b.i.d., twice daily; PO, orally; q.i.d., four times daily; t.i.d., three times daily.

Therapeutic Actions and Indications

Lithium functions in several ways. It alters sodium transport in nerve and muscle cells; inhibits the release of norepinephrine and dopamine, but not serotonin, from stimulated neurons; increases the intraneuronal stores of norepinephrine and dopamine slightly; and decreases intraneuronal content of second messengers. This last mode of action may allow it to selectively modulate the responsiveness of hyperactive neurons that might contribute to the manic state. Although the biochemical actions of lithium are known, the exact mechanism of action in decreasing the manifestations of mania are not understood.

Pharmacokinetics

Lithium is readily absorbed from the GI tract, reaching peak levels in 30 minutes to 3 hours. It follows the same distribution pattern in the body as water. It slowly crosses the blood–brain barrier. Lithium is excreted from the kidney, although about 80% is reabsorbed. During periods of sodium depletion or dehydration, the kidney reabsorbs more lithium into the serum, often leading to toxic levels. Therefore, patients must be encouraged to maintain hydration while taking this drug. Lithium crosses the placenta and enters breast milk, and has been associated with congenital abnormalities (see contraindications and cautions).

Contraindications and Cautions

Lithium is contraindicated in the presence of hypersensitivity to lithium. In addition, it is contraindicated in the following conditions: significant renal or cardiac disease *that could be exacerbated by the toxic effects of the drug*; a history of leukemia; metabolic disorders, including sodium depletion; dehydration; and diuretic use *because lithium depletes sodium reabsorption, and severe hyponatremia may occur*. (Hyponatremia leads to lithium retention and toxicity.) Pregnancy and lactation are also contraindications *because of the potential for adverse effects on the fetus or neonate*; breast-feeding should be discontinued while using lithium, and women of childbearing age should be advised to use birth control while taking this drug. Caution should be used in any condition *that could alter sodium levels*, such as protracted diarrhea or excessive sweating; with suicidal or impulsive patients; and in patients who have infection with fever, *which could be exacerbated by the toxic effects of the drug*.

Adverse Effects

The adverse effects associated with lithium are directly related to serum levels of the drug.

- *Serum levels of less than 1.5 mEq/L*: CNS problems, including lethargy, slurred speech, muscle weakness, and fine tremor; polyuria, which relates to renal toxicity; and beginning of gastric toxicity, with nausea, vomiting, and diarrhea.

- *Serum levels of 1.5 to 2 mEq/L*: Intensification of all of the foregoing reactions, with ECG changes.
- *Serum levels of 2 to 2.5 mEq/L*: Possible progression of CNS effects to ataxia, clonic movements, hyperreflexia, and seizures; possible CV effects such as severe ECG changes and hypotension; large output of dilute urine secondary to renal toxicity; fatalities secondary to pulmonary toxicity.
- *Serum levels greater than 2.5 mEq/L*: Complex multiorgan toxicity, with a significant risk of death.

Clinically Important Drug–Drug Interactions

Some drug–drug combinations should be avoided. A lithium–haloperidol combination may result in an encephalopathic syndrome, consisting of weakness, lethargy, confusion, tremors, extrapyramidal symptoms, leukocytosis, and irreversible brain damage (Box 22.4).

If lithium is given with carbamazepine, increased CNS toxicity may occur, and a lithium–iodide salt combination results in an increased risk of hypothyroidism. Patients who receive either of these combinations should be monitored carefully. In addition, a thiazide diuretic–lithium combination increases the risk of lithium toxicity because of the loss of sodium and increased retention of lithium. If this combination is used, the dose of lithium should be decreased and the patient should be monitored closely.

In the following instances, the serum lithium level should be monitored closely and appropriate dose adjustments made. With the combination of lithium and some urine-alkalinizing drugs, including antacids and tromethamine, there is a possibility of decreased effectiveness of lithium. If lithium is combined with indomethacin or with some nonsteroidal anti-inflammatory drugs, higher plasma levels of lithium occur.

Prototype Summary: Lithium

Indications: Treatment of manic episodes of bipolar, manic-depressive illness.

Actions: Alters sodium transport in nerve and muscle cells; inhibits the release of norepinephrine and dopamine, but not serotonin, from stimulated neurons; increases the intraneuronal stores of norepinephrine and dopamine slightly; and decreases the intraneuronal content of second messengers.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	Unknown	0.5–3 h	8–12 h
Oral, extended release	Unknown	4–12 h	12–18 h

$T_{1/2}$: 24 hours; excreted in the urine.

Adverse effects: CNS problems, including lethargy, slurred speech, muscle weakness, and fine tremor; polyuria, gastric toxicity, with nausea, vomiting, and diarrhea progressing; CV collapse, coma; adverse effects are related to serum drug levels.

BOX 22.4

Herbal and Alternative Therapies

Psyllium

Patients being treated with lithium should be encouraged not to use the herbal therapy psyllium, which is used to treat constipation and to lower cholesterol levels. If this agent is combined with lithium, the absorption of the lithium may be blocked, and the patient will not receive therapeutic levels. If the patient feels a need for a drug to relieve constipation or is concerned about cholesterol levels, he or she should be encouraged to discuss alternative measures with the health care provider.

Nursing Considerations for Patients Receiving Lithium

Assessment: History and Examination

- Assess for *contraindications or cautions for the use of the drug*, including any known allergies to lithium; renal or CV disease; dehydration; sodium depletion, use of diuretics, protracted sweating, or diarrhea; suicidal or impulsive patients with severe depression; pregnancy or lactation; and infection with fever.
- Assess temperature; skin color and lesions; CNS orientation, affect, and reflexes; bowel sounds and reported output; pulse, auscultation, and blood pressure, including orthostatic blood pressure; respiration rate and adventitious sounds; and urinary output *for baseline status before beginning therapy and for any potential adverse effects*. Also obtain liver and renal function tests, thyroid function tests, CBC, and baseline ECG, and obtain serum lithium levels as appropriate.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to GI, CNS, and vision effects.
- Risk for Injury related to CNS effects.
- Impaired Urinary Elimination related to renal toxic effects.
- Disturbed Thought Processes related to CNS effects.
- Deficient Knowledge regarding drug therapy.

Implementation With Rationale

- Administer drug cautiously, with daily monitoring of serum lithium levels, to patients with significant renal or CV disease, dehydration, or debilitation, as well as those taking diuretics, *to monitor for toxic levels and to arrange for appropriate dose adjustment*.
- Administer drug with food or milk *to alleviate GI irritation if GI upset is severe*.
- Arrange to decrease dose after acute manic episodes. *Lithium tolerance is greatest during acute episodes and decreases when the acute episode is over.*

- Ensure that the patient maintains adequate intake of salt and fluid *to decrease toxicity*.
- Monitor patient's clinical status closely, especially during the initial stages of therapy, *to provide appropriate supportive management as needed*.
- Arrange for small, frequent meals, sugarless lozenges to suck, and frequent mouth care, *to increase secretions and decrease discomfort as needed*.
- Provide safety measures such as side rails and assistance with ambulation if CNS effects occur *to prevent patient injury*.
- Provide thorough patient teaching, including drug name, prescribed dosage, measures for avoidance of adverse effects, cautions that it may take time to see the desired therapeutic effects, warning signs that may indicate possible problems, and the need to avoid pregnancy while taking lithium *to enhance patient knowledge about drug therapy and to promote compliance*.
- Offer support and encouragement *to help the patient to cope with the drug regimen*.

Evaluation

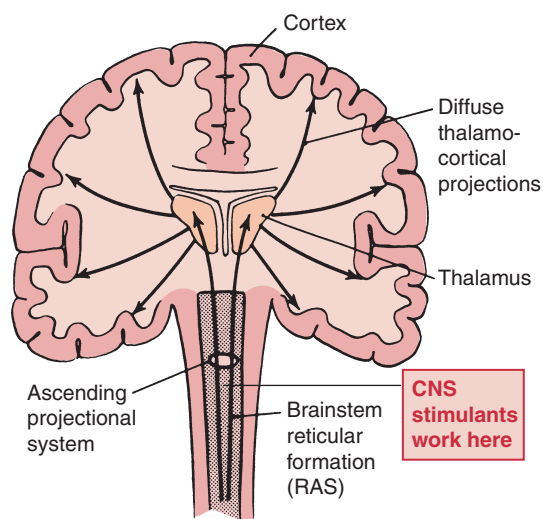

- Monitor patient response to the drug (decreased manifestations and frequency of manic episodes).
- Monitor for adverse effects (CV toxicity, renal toxicity, GI upset, respiratory complications).
- Evaluate effectiveness of the teaching plan (patient can give the drug name and dosage and describe the possible adverse effects to watch for, specific measures to help avoid adverse effects, warning signs to report, and the need to avoid pregnancy).
- Monitor effectiveness of comfort measures and compliance with the regimen.

KEY POINTS

- ▶ Lithium, a membrane stabilizer, is the standard antimanic drug. Because it is a very toxic salt, serum levels must be carefully monitored to prevent severe toxicity.
- ▶ Many other CNS drugs, including many of the atypical antipsychotics, are now approved for use in bipolar disorder. Many patients respond to a combination of these drugs to control their bipolar signs and symptoms.

CENTRAL NERVOUS SYSTEM STIMULANTS

CNS stimulants are used clinically to treat both attention-deficit disorders and narcolepsy. Paradoxically, these drugs calm hyperkinetic children and help them to focus on one activity for a longer period. They also redirect and excite the arousal stimuli from the RAS (Figure 22.2; see also Figure 22.1). The CNS stimulants that are used to treat attention-deficit disorder and narcolepsy include methylphenidate (*Ritalin*,

● **FIGURE 22.2** Site of action of the central nervous system (CNS) stimulants in the reticular activating system (RAS).

Concerta, and others); dexamethylphenidate (*Focalin*), an isomer of methylphenidate used in lower doses than methylphenidate; dextroamphetamine (*Dexedrine*); modafinil (*Provigil*), which is not associated with many of the systemic stimulatory effects of some of the other CNS stimulants; as well as three newer drugs—armodafinil (*Nuvigil*), which is thought to act through dopaminergic mechanisms but it is not associated with the cardiac and systemic stimulatory effects seen with other CNS stimulants; atomoxetine (*Strattera*), which is a selective norepinephrine reuptake inhibitor with anticholinergic effects but without the CV and stimulatory effects, making it preferable in patients who cannot tolerate the systemic stimulatory effects; and lisdexamfetamine (*Vyvanse*), an amphetamine (see Table 22.3).

Therapeutic Actions and Indications

The CNS stimulants act as cortical and RAS stimulants, possibly by increasing the release of catecholamines from presynaptic

TABLE 22.3 DRUGS IN FOCUS Central Nervous System Stimulants

Drug Name	Dose/Route	Usual Indications
armodafinil (<i>Nuvigil</i>)	150–250 mg/d PO as a single dose in the morning Shift work sleep disorder: 150 mg/d PO at 1 h before the start of shift	Management of patients with obstructive sleep disorders (including sleep apnea), narcolepsy, and shift work sleep disorders to improve wakefulness
atomoxetine (<i>Strattera</i>)	Adults and children >70 kg: 40 mg/d PO, slowly increase to a target daily dose of 80 mg Children ≤70 kg: 0.5 mg/kg per day, increase to a target daily dose of 1.2 mg/kg per day Hepatic impairment: decrease dose by 50%	Treatment of attention-deficit/hyperactivity disorders as part of a total treatment program
dexamethylphenidate (<i>Focalin</i>)	2.5–5 mg PO b.i.d.; do not exceed 10 mg PO b.i.d.	Treatment of attention-deficit/hyperactivity disorder in patients age ≥6 yr
dextroamphetamine (<i>Dexedrine</i>)	Narcolepsy: 5–60 mg/d PO in divided doses Attention-deficit disorders: 2.5–5 mg/day PO taken in the morning Obesity: 5–30 mg/d PO (not recommended for children <12 yr)	Treatment of narcolepsy, attention-deficit disorders, behavioral syndromes, exogenous obesity
lisdexamfetamine (<i>Vyvanse</i>)	Pediatric (6–12 yr): 30 mg/d PO; maximum dose 70 mg/d	Treatment of attention-deficit/hyperactivity disorder in children 6–12 yr of age
 methylphenidate (<i>Ritalin</i> , <i>Concerta</i> , and others)	Adult: 10–60 mg/day PO in divided doses, depending on preparation Pediatric: 5 mg PO b.i.d.; increase gradually, do not exceed 60 mg/d	Treatment of attention-deficit disorders and other behavioral syndromes associated with hyperactivity, as well as narcolepsy; currently available in various forms allowing for dosing one, two, or three times a day
modafinil (<i>Provigil</i>)	200 mg/d PO as a single dose; reduce dose with hepatic impairment and in the elderly	Treatment of narcolepsy in adults, for improving wakefulness in various sleep disorders, and for improving wakefulness in people with obstructive sleep apnea/hypopnea syndrome

b.i.d., twice daily; PO, orally.

neurons, leading to an increase in stimulation of the postsynaptic neurons. The paradoxical effect of calming hyperexcitability through CNS stimulation seen in attention-deficit syndrome is believed to be related to increased stimulation of an immature RAS, which leads to the ability to be more selective in response to incoming stimuli.

The CNS stimulants are indicated, as part of a comprehensive treatment program, for the treatment of attention-deficit syndromes, including behavioral syndromes characterized by hyperactivity and distractibility, as well as for narcolepsy and improvement of wakefulness in people with various sleep disorders.

Pharmacokinetics

These drugs are rapidly absorbed from the GI tract, reaching peak levels in 2 to 4 hours. They are metabolized in the liver and excreted in the urine, with half-lives ranging from 2 to 15 hours, depending on the drug. Safety for use during pregnancy and lactation has not been established; during those periods, these drugs should be used only if the benefit to the mother clearly outweighs the potential risk to the fetus or neonate.

Contraindications and Cautions

The CNS stimulants are contraindicated in the presence of known allergy to the drug, *which could lead to hypersensitivity reactions*. Other contraindications include the following conditions: marked anxiety, agitation, or tension and severe fatigue or glaucoma, *which could be exacerbated by the CNS stimulation caused by these drugs*; cardiac disease, *which could be aggravated by the stimulatory effects of these drugs, making it important to rule out congenital heart problems*; and pregnancy and lactation *because of the potential for adverse effects on the fetus or neonate*.

Caution should be used in patients with a history of seizures, *which could be potentiated by the CNS stimulation*; in patients with a history of drug dependence, including alcoholism, *because these drugs may result in physical and psychological dependence*; and in patients with hypertension, *which could be exacerbated by the stimulatory effects of these drugs*.

Adverse Effects

The adverse effects associated with these drugs are related to the CNS stimulation they cause. CNS effects can include nervousness, insomnia, dizziness, headache, blurred vision, and difficulty with accommodation. GI effects such as anorexia, nausea, and weight loss may occur. CV effects can include hypertension, arrhythmias, and angina. Skin rashes are a common reaction to some of these drugs. Physical and psychological dependence may also develop. Because CNS stimulants have this effect, the drugs are controlled substances. Atomoxetine, which does not show dependence development, is not a controlled substance. The adverse effects associated with this drug are mainly anticholinergic (dry mouth, constipation, nausea, urinary hesitancy).

Clinically Important Drug–Drug Interactions

The combination of a CNS stimulant with a monoamine oxidase (MAO) inhibitor leads to an increased risk of adverse effects and increased toxicity and should be avoided if possible. Likewise, the combination of a CNS stimulant with guanethidine, which results in a decrease in antihypertensive effects, should be avoided.

In addition, the combination of CNS stimulants with tricyclic antidepressants or phenytoin leads to a risk of increased drug levels. Patients who receive such a combination should be monitored for toxicity.

Prototype Summary: *Methylphenidate*

Indications: Narcolepsy and attention-deficit disorder.

Actions: Mild cortical stimulant with CNS actions similar to those of amphetamines.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	Varies	1–3 h	4–6 h

$T_{1/2}$: 1–3 hours; metabolized in the liver; excreted in the urine.

Adverse effects: Nervousness, insomnia, increased or decreased pulse rate and blood pressure, tachycardia, loss of appetite, nausea, abdominal pain.

Nursing Considerations for Patients Receiving Central Nervous System Stimulants

Assessment: History and Examination

- Assess for *contraindications or cautions for the use of the drug*, including any known allergies to the drug; glaucoma, anxiety, tension, fatigue, or seizure disorder; cardiac disease and hypertension; pregnancy or lactation; a history of leukemia; and a history of drug dependency, including alcoholism.
- Assess temperature; skin color and lesions; CNS orientation, affect, and reflexes; ophthalmic examination; bowel sounds and reported output; pulse, auscultation, and blood pressure, including orthostatic blood pressure; respiration rate and adventitious sounds; and urinary output *to determine baseline status before beginning therapy and for any potential adverse effects*. Also obtain a CBC.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Disturbed Thought Processes related to CNS effects of the drug.
- Decreased Cardiac Output related to CV effects of the drug.
- Risk for Injury related to CNS and visual effects of the drug.
- Deficient Knowledge regarding drug therapy.

Implementation With Rationale

- Ensure proper diagnosis of behavioral syndromes and narcolepsy *because these drugs should not be used until underlying medical causes of the problem are ruled out.*
- Arrange to interrupt the drug periodically in children who are receiving the drug for behavioral syndromes *to determine whether symptoms recur and therapy should be continued.*
- Arrange to dispense the least amount of drug possible *to minimize the risk of overdose and abuse.*
- Administer drug before 6 P.M. *to reduce the incidence of insomnia.*
- Monitor weight, CBC, and ECG *to ensure early detection of adverse effects and proper interventions.*
- Consult with the school nurse or counselor *to ensure comprehensive care of school-aged children receiving CNS stimulants* (Box 22.5).
- Provide safety measures such as side rails and assistance with ambulation if CNS effects occur *to prevent patient injury.*
- Provide thorough patient teaching, including drug name, prescribed dosage, the need to secure the drug as a controlled substance, measures for avoidance of adverse effects, warning signs that may indicate possible problems, and the need for monitoring and evaluation *to enhance patient knowledge about drug therapy and to promote compliance.* Offer support and encouragement to help the patient to cope with the drug regimen.

Evaluation

- Monitor patient response to the drug (decrease in manifestations of behavioral syndromes, decrease in daytime sleep and narcolepsy).
- Monitor for adverse effects (CNS stimulation, CV effects, rash, physical or psychological dependence, GI dysfunction).
- Evaluate effectiveness of the teaching plan (patient can give the drug name and dosage, name possible adverse effects to watch for and specific measures to help avoid adverse effects, and describe the need for follow-up and evaluation).
- Monitor effectiveness of comfort measures and compliance with the regimen.

KEY POINTS

- ▶ An attention-deficit disorder is a behavioral syndrome characterized by hyperactivity and a short attention span.
- ▶ Narcolepsy is a disorder characterized by daytime sleepiness and sudden loss of wakefulness.
- ▶ CNS stimulants, which stimulate cortical levels and the RAS to increase RAS activity, are used to treat attention-deficit disorders and narcolepsy. These drugs improve concentration and the ability to filter and focus incoming stimuli.

BOX 22.5

The Evidence

School Nursing and Ritalin Administration

In the last several years, the number of schoolchildren receiving diagnoses of attention-deficit disorder or minimal brain dysfunction and being prescribed methylphenidate (*Ritalin*) has increased dramatically. Because this drug needs to be given two or three times each day, it has become the responsibility of the school nurse to dispense the drug during the day. Some school nurses reportedly spend between 50% and 70% of their time administering these drugs and completing the necessary paperwork. In 2000–2001, several long-acting formulations of methylphenidate became available.

Concerta, previously available in an extended-release tablet in 18- and 36-mg strengths, is now also available in a 54-mg strength. This form is suggested for every-12-hours dosing. *Metadate CD* is approved as a 20-mg extended-release capsule that is suggested as a once-daily treatment for children with attention-deficit disorder. *Ritalin SR* is another extended-release formulation that is designed to be given every 8 hours. These extended-release forms are not interchangeable, and the instructions that come with the drug that is prescribed should be checked carefully. The advantage of these extended-release forms is expected to be a decrease in the number of students who must see the nurse for medication during the school day and, perhaps, a

decrease in the stigma that may be associated with needing this drug.

The school nurse has additional responsibilities besides administering the drug. The school nurse is responsible for assessing children's response to the drug and for coordinating the teacher's and health care providers' input into each individual case, including the incidence of adverse effects and the appropriateness of the drug therapy. The nurse should:

- Ensure that the proper diagnosis is made before supporting the use of the drug.
- Constantly evaluate and work with the primary health care provider to regularly challenge children without the drug to see whether the drug is doing what is expected or whether the child is maturing and no longer needs the drug therapy.

The school nurse needs to be prepared to be an advocate for the best therapeutic intervention for a particular child. Because long-term methylphenidate therapy is associated with many adverse effects, use of the drug should not be taken lightly. A federal review of the *Ritalin* issues facing the country today can be found at <http://commdocs.house.gov/committees/edu/hedcew6-109.000/hedcew6-109.htm>.

CHAPTER SUMMARY

- Schizophrenia, the most common psychosis, is characterized by delusions, hallucinations, and inappropriate responses to stimuli.
- Mania is a state of hyperexcitability, one pole of bipolar disorder.
- An attention-deficit disorder is a behavioral syndrome characterized by hyperactivity and a short attention span.
- Narcolepsy is a disorder characterized by daytime sleepiness and sudden loss of wakefulness.
- Lithium, a membrane stabilizer, is the standard antimanic drug. Because it is a very toxic salt, serum levels must be carefully monitored to prevent severe toxicity. Many other CNS drugs are now approved for use in bipolar disorder.
- CNS stimulants, which stimulate cortical levels and the RAS to increase RAS activity, are used to treat attention-deficit disorders and narcolepsy. These drugs improve concentration and the ability to filter and focus incoming stimuli.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-Rom accompanying this book.

MULTIPLE CHOICE

Select the best answer to the following.

1. Mental disorders are now thought to be caused by some inherent dysfunction within the brain that leads to abnormal thought processes and responses. They include
 - a. depression.
 - b. anxiety.
 - c. seizures.
 - d. schizophrenia.
2. Antipsychotic drugs are basically
 - a. serotonin reuptake inhibitors.
 - b. norepinephrine blockers.
 - c. dopamine-receptor blockers.
 - d. acetylcholine stimulators.
3. Adverse effects associated with antipsychotic drugs are related to the drugs' effects on receptor sites and can include
 - a. insomnia and hypertension.
 - b. dry mouth, hypotension, and glaucoma.
 - c. diarrhea and excessive urination.
 - d. increased sexual drive and improved concentration.
4. Lithium toxicity can be dangerous. Patient assessment to evaluate for appropriate lithium levels would look for
 - a. serum lithium levels greater than 3 mEq/L.
 - b. serum lithium levels greater than 4 mEq/L.
 - c. serum lithium levels less than 1.5 mEq/L.
 - d. undetectable serum lithium levels.
5. Your patient, a 6-year-old boy, is starting a regimen of *Ritalin* (methylphenidate) to control an attention-deficit disorder. Family teaching should include which of the following?
 - a. This drug can be shared with other family members who might seem to need it.
 - b. This drug may cause insomnia, weight loss, and GI upset.
 - c. Do not alert the school nurse to the fact that this drug is being taken because the child could have problems later on.
 - d. This drug should not be stopped for any reason for several years.
6. Antipsychotic drugs are also known as neuroleptic drugs because
 - a. they cause numerous neurological effects.
 - b. they frequently cause epilepsy.
 - c. they are also minor tranquilizers.
 - d. they are the only drugs known to directly affect nerves.

7. Attention-deficit disorders (the inability to concentrate or focus on an activity) and narcolepsy (sudden episodes of sleep) are both most effectively treated with the use of
- neuroinhibitors.
 - dopamine-receptor blockers.
 - major tranquilizers.
 - CNS stimulants.
8. Haloperidol (*Haldol*) is a potent antipsychotic that is associated with
- severe extrapyramidal effects.
 - severe sedation.
 - severe hypotension.
 - severe anticholinergic effects.
2. Dyskinesias are a common side effect of antipsychotic drugs. Nursing interventions for the patient receiving antipsychotic drugs should include which of the following?
- Positioning to decrease discomfort of dyskinesias
 - Implementing safety measures to prevent injury
 - Encouraging the patient to chew tablets to prevent choking
 - Careful teaching to alert the patient and family about this adverse effect
 - Applying ice to the joints to prevent damage
 - Pureeing all food to decrease the risk of aspiration
- following drugs, which could cause serious adverse effects?
- Ibuprofen
 - Haloperidol
 - Thiazide diuretics
 - Antacids
 - Ketoconazole
 - Theophylline

MULTIPLE RESPONSE

Select all that apply.

- Before administering lithium to a client, the nurse should check for the concomitant use of which of the

Anti-seizure Agents

23

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Define the terms generalized seizure, tonic-clonic seizure, absence seizure, partial seizure, and status epilepticus.
2. Describe the therapeutic actions, indications, pharmacokinetics, contraindications, most common adverse reactions, and important drug-drug interactions associated with each class of antiseizure agents.
3. Discuss the use of antiepileptic drugs across the lifespan.
4. Compare and contrast the prototype drugs for each class of antiepileptic drug with the other drugs in that class and with drugs from the other classes.
5. Outline the nursing considerations and teaching needs for patients receiving each class of antiepileptic agents.

Glossary of Key Terms

absence seizure: type of generalized seizure that is characterized by sudden, temporary loss of consciousness, sometimes with staring or blinking for 3 to 5 seconds; formerly known as a petit mal seizure

antiepileptic: drug used to treat the abnormal and excessive energy bursts in the brain that are characteristic of epilepsy

convulsion: tonic-clonic muscular reaction to excessive electrical energy arising from nerve cells in the brain

epilepsy: collection of various syndromes, all of which are characterized by seizures

generalized seizure: seizure that begins in one area of the brain and rapidly spreads throughout both hemispheres

partial seizures: also called focal seizures; seizures involving one area of the brain that do not spread throughout the entire organ

seizure: sudden discharge of excessive electrical energy from nerve cells in the brain

status epilepticus: state in which seizures rapidly recur; most severe form of generalized seizure

tonic-clonic seizure: type of generalized seizure that is characterized by serious clonic-tonic muscular reactions and loss of consciousness, with exhaustion and little memory of the event on awakening; formerly known as a grand mal seizure

DRUGS FOR TREATING GENERALIZED SEIZURES

Hydantoins

ethotoin
fosphenytoin
phenytoin

Barbiturates and Barbiturate-Like Drugs

mephobarbital

tiagabine
topiramate

DRUGS FOR TREATING PARTIAL SEIZURES

carbamazepine
clorazepate
felbamate
gabapentin

Epilepsy, the most prevalent of the neurological disorders, is not a single disease but a collection of different syndromes characterized by the same feature: sudden discharge of excessive electrical energy from nerve cells located within the brain, which leads to a **seizure**. In some cases, this release stimulates motor nerves, resulting in convulsions, with tonic–clonic muscle contractions that have the potential to cause injury, tics, or spasms. Other discharges may stimulate autonomic or sensory nerves and cause very different effects, such as a barely perceptible, temporary lapse in consciousness or a sympathetic reaction. Because epilepsy involves a loss of control, it can be very frightening to patients when they are first diagnosed (Box 23.1).

The treatment of epilepsy varies widely, depending on the exact problem and its manifestations. The drugs that are used to manage epilepsy are called **antiepileptics**, or antiseizure agents, and are sometimes referred to as anticonvulsants; however, because not all types of epilepsy involve **convulsions**, this term is not generally applicable. The drug of choice for any given situation depends on the type of epilepsy, patient age (Box 23.2), specific patient characteristics such as cultural variations (Box 23.3), and patient tolerance for associated adverse effects. Drugs can be used to treat more than one type of seizure. Table 23.1 lists drugs and the types of seizures that they can be used to treat.

NATURE OF SEIZURES

The form that a particular seizure takes depends on the location of the cells that initiate the electrical discharge and the neural pathways that are stimulated by the initial volley of electrical impulses. For the most part, epilepsy seems to be caused by abnormal neurons that are very sensitive to stimulation or overrespond for some reason. They do not appear to be different from other neurons in any other way. Seizures caused by these abnormal cells are called primary seizures because no underlying cause can be identified. In some cases, however, outside factors—head injury, drug overdose, environmental exposure, and so on—may precipitate seizures. Such seizures are often referred to as secondary seizures.

Classification of Seizures

Accurate diagnosis of seizure type is very important for determining the correct medication to prevent future seizures while causing the fewest problems and adverse effects. Seizures were formerly categorized as grand mal (tonic–clonic seizures) or petit mal (absence seizures), but the International Classification of Seizures currently refers to seizures in a more systematic approach (based on the description of symptoms and characteristics), grouping them into two main categories: generalized

BOX 23.1

Patient and Family Teaching

Teaching and Counseling Patients With Epilepsy

Epilepsy, with its stigma, is frightening to people who know little about the disease. This condition has long been associated with some sort of brain dysfunction or possession by the devil or evil spirits. In some eras, exorcism was the first choice of treatment for a person with a seizure disorder. A person who receives a diagnosis of epilepsy must deal with this stigma as well as the significance of the diagnosis. What does having epilepsy mean? Individuals who are newly diagnosed with epilepsy must consider restrictions on their independence as well as the prospect of chronic therapy for control of this problem.

In our society, the ability to be readily mobile—to drive to appointments, work, or religious obligations—is very important to many people. Most states require physicians to report new diagnoses of epilepsy. In most cases, the driving privileges of affected individuals are revoked, at least temporarily. The conditions for recovering the license vary with the diagnosis and the laws of each state.

The person who is newly diagnosed with epilepsy has to cope not only with the stigma of epilepsy, but also with the loss of a driver's license. The nurse may be in the best position to help the patient adjust to both of these problems through patient education and referrals to community

resources. Thorough patient teaching should include the following:

- Explanations of old stigmas
- Ways in which people may react to the diagnosis
- Ways in which patients can educate family, friends, and employers about the realities of the condition and its treatment
- Actions to take if a seizure happens so that no injuries occur and no panic develops
- Information about the availability of public transportation
- The importance of encouraging patients with epilepsy to carry or wear a MedicAlert identification, to alert any emergency caregivers to their condition and to what drugs they are taking if they are not able to speak for themselves.
- Contact information regarding other community support services

Many communities have epilepsy support groups that can supply information on valuable resources as well as updated facts about the laws in each area. While patients are first adjusting to epilepsy and its implications, it may help to put them in contact with such organizations. The local chapter of the Epilepsy Foundation of America may be able to offer support groups, lists of resources, and support. Individuals with epilepsy should have several options for getting around without feeling that they are being a burden or an imposition.

BOX 23.2

Drug Therapy Across the Lifespan

Anti-Seizure Agents

CHILDREN

Antiepileptic drugs can have an impact on a child's learning and social development. Children may also be more sensitive to the sedating effects of some of these drugs. Children should be monitored very closely and often require a switch to a different agent or dosage adjustments based on their response.

Newborns (1 to 10 days of age) respond best to intramuscular phenobarbital if an antiepileptic is needed.

Older children (2 months to 6 years of age) absorb and metabolize many of these drugs more quickly than adults do and require a larger dosage per kilogram to maintain therapeutic levels. Careful calculation of drug dosage using both weight and age are important in helping the child to receive the best therapeutic effect with the least toxicity. After the age of 10 to 14 years, many of these drugs can be given in the standard adult dose.

Parents of children receiving these drugs should receive consistent support and education about the seizure disorder and the medications being used to treat it. Many communities have local support groups that can offer lots of educational materials and support programs. It is a very frightening experience to watch your child have a tonic-clonic seizure, and parents should be supported with this in mind.

ADULTS

Adults using these drugs should be under regular care and should be monitored regularly for adverse effects. They should be encouraged to carry or wear a Medic-Alert identification to alert emergency personnel that antiepileptic drugs are being taken. Adults also need education and support to deal with the old stigma of seizures as well as the

lifestyle changes and drug effects that they may need to cope with.

Most of these drugs have been associated with fetal abnormalities in animal studies. Some of them are clearly associated with predictable congenital effects in humans. Women of childbearing age should be encouraged to use contraceptives while taking these drugs. If a pregnancy does occur, or if a woman taking one of these drugs desires to become pregnant, the importance of the drug to the mother should be weighed against the potential risk to the fetus. Stopping an antiepileptic can precipitate seizures that could cause anoxia and its related problems for the mother and the baby. Women who are nursing should be encouraged to find another way of feeding the baby to avoid the sedating and central nervous system effects that the drugs can have on the infant.

OLDER ADULTS

Older patients may be more susceptible to the adverse effects of these drugs. Dosages of all of these drugs may need to be reduced, and the patient should be monitored very closely for toxic effects and to provide safety measures if central nervous system effects do occur.

Patients with renal or hepatic impairment should be monitored very closely. Baseline renal and liver function tests should be done and dosages adjusted as appropriate. Serum levels of the drug should be monitored closely in such cases to prevent serious adverse effects.

The older patient should also be encouraged to wear or carry a Medic-Alert identification in case there is an emergency and the patient is not able to communicate information about the drug or disorder.

BOX 23.3

Cultural Considerations

Altered Metabolism of Anti-seizure Agents

Because of differences in liver enzyme functioning among Arab Americans and Asian Americans, patients in these ethnic groups may not metabolize anti-seizure agents in the same way as patients in other ethnic groups. They may require not only lower doses to achieve the same therapeutic effects, but also frequent dose adjustment.

Nurses need to be aware that the therapeutic range for patients in these ethnic groups may differ from standard norms and that these patients may be more apt to show adverse or toxic reactions to antiepileptic drugs at lower doses. As with all medications, the lowest possible dose should be used. Serum drug levels should be closely monitored and titrated carefully and slowly to achieve the maximum benefits with the fewest adverse effects.

or partial seizures. Each of these categories can be further subdivided (see Figure 23.1).

Generalized Seizures

Generalized seizures begin in one area of the brain and rapidly spread throughout both hemispheres of the brain. Patients who have a generalized seizure usually experience a loss of consciousness resulting from this massive electrical activity throughout the brain.

Generalized seizures are further classified into the following five types:

1. **Tonic-clonic seizures** involve dramatic tonic-clonic muscle contractions (involuntary muscle contraction followed by relaxation appearing as an aggressive spasm), loss of consciousness, and a recovery period characterized by confusion and exhaustion.
2. **Absence seizures** involve abrupt, brief (3- to 5-second) periods of loss of consciousness. Absence seizures occur commonly in children, starting at about 3 years of age,

TABLE 23.1 Antiepileptic Drug Therapy Grouped by Seizure Class

PARTIAL SEIZURES	GENERALIZED SEIZURES (EXCEPT STATUS EPILEPTICUS)	STATUS EPILEPTICUS
Carbamazepine	Carbamazepine	Diazepam
Clonazepam	Clonazepam	Fosphenytoin
Clorazepate	Ethosuximide	Lorazepam
Ethotoin	Ethotoin	Midazolam
Felbamate	Felbamate	Pentobarbital
Gabapentin	(Lennox-Gastaut syndrome)	Phenobarbital
Lamotrigine	Lamotrigine	Phenytoin
Levetiracetam	Levetiracetam	Propofol
Oxcarbazepine	Methsuximide	
Phenytoin	Oxcarbazepine	
Pregabalin	Phensuximide	
Tiagabine	Phenytoin	
Topiramate	Topiramate	
valproic acid	valproic acid	
Zonisamide	Zonisamide	

From Aschenbrenner, *Drug Therapy in Nursing*, 3rd edition (LWW), p. 331.

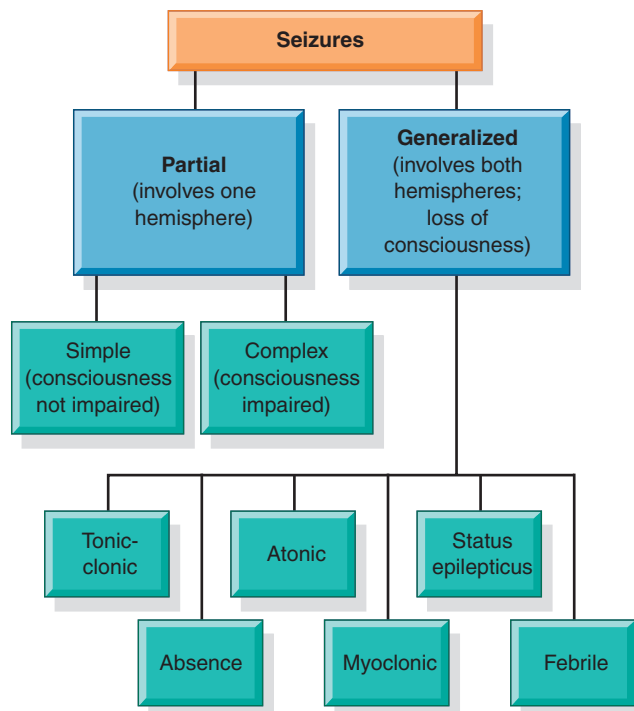

and frequently disappear by puberty. Absence seizures do not usually involve muscle contractions.

- Myoclonic seizures involve short, sporadic periods of muscle contractions that last for several minutes. They are relatively rare and are often secondary seizures.
- Febrile seizures are related to very high fevers and usually involve tonic–clonic seizures. Febrile seizures most frequently occur in children; they are usually self-limited and do not reappear.
- Jacksonian seizures are seizures that begin in one area of the brain and involve one part of the body, and then progressively spread to other parts of the body; they can develop into generalized tonic–clonic seizures.
- Psychomotor seizures are complex seizures that involve sensory, motor, and psychic components. They usually begin with a loss of consciousness, and patients have no memory of the event. Patients may exhibit automatic movements, emotional outbursts, and motor or psychological disturbances.
- Status epilepticus**, potentially the most dangerous of seizure conditions, is a state in which seizures rapidly recur again and again with no recovery between seizures.

Partial Seizures

Partial seizures, or focal seizures, are so called because they involve one area of the brain, usually originate from one site or focus, and do not spread throughout the entire organ. The presenting symptoms depend on exactly where in the brain the excessive electrical discharge is occurring. Partial seizures can be further classified as follows:

- Simple partial seizures, which occur in a single area of the brain and may involve a single muscle movement or sensory alteration.

● **FIGURE 23.1** Classification of seizures. [From Aschenbrenner, D. S., & Venable, S. J. (2008). *Drug therapy in nursing* (3rd ed.). Philadelphia: Lippincott Williams & Wilkins; p. 332, Figure 21.2.]

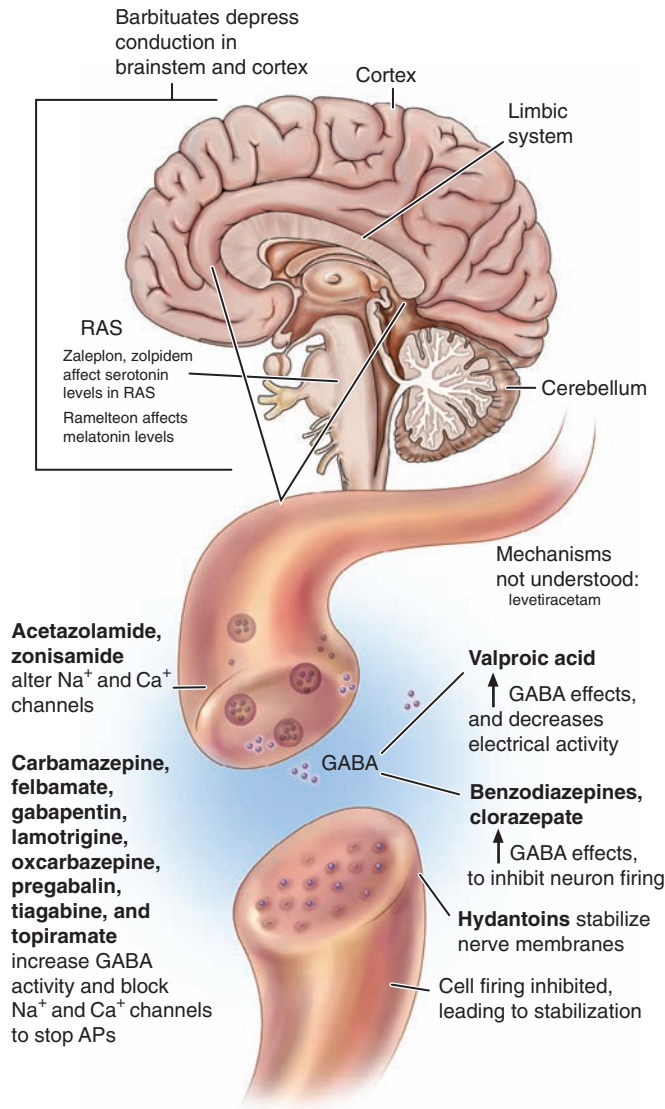

- Complex partial seizures, which involve a series of reactions or emotional changes and complex sensory changes such as hallucinations, mental distortion, changes in personality, loss of consciousness, and loss of social inhibitions. Motor changes may include involuntary urination, chewing motions, diarrhea, and so on. The onset of complex partial seizures usually occurs by the late teens.

KEY POINTS

- ▶ Epilepsy is characterized by seizures that result from sudden discharge of excessive electrical energy from nerve cells in the brain.
- ▶ There are two major categories of seizures: generalized and partial seizures.
- ▶ Generalized seizures include the following types: tonic–clonic, absence, myoclonic, febrile, Jacksonian, psychomotor, and rapid recurring (status epilepticus).
- ▶ Partial seizures may be simple or complex.

DRUGS FOR TREATING GENERALIZED SEIZURES

Drugs typically used to treat generalized seizures stabilize the nerve membranes by blocking channels in the cell membrane or altering receptor sites. Because they work generally on the central nervous system (CNS), sedation and other CNS effects often result. Various drugs are used to treat generalized seizures, including hydantoins, barbiturates, barbiturate-like

● **FIGURE 23.2** Sites of action of drugs used to treat various types of epilepsy. AP, action potential; GABA, gamma-aminobutyric acid; RAS, reticular activating system.

drugs, benzodiazepines, and succinimides. These drugs affect the entire brain and reduce the chance of sudden electrical outburst. Associated adverse effects are often related to total brain stabilization (Figure 23.2).

Absence seizures, another type of generalized seizure, may require drugs that are different than those used to treat or prevent other types of generalized seizures. The succinimides and drugs that modulate the inhibitory neurotransmitter gamma-aminobutyric acid (GABA) are most frequently used (see Table 23.2).

Hydantoin

Hydantoin include ethotoin (*Peganone*), fosphenytoin (*Cerebix*), and phenytoin (*Dilantin*). Because hydantoin are generally less sedating than many other antiepileptics, they

may be the drugs of choice for patients who are not willing to tolerate sedation and drowsiness. They do have significant adverse effects; thus, less toxic drugs, such as benzodiazepines, have replaced them in many situations.

FOCUS ON Safe Medication Administration

Be aware that name confusion has been reported among *Cerebix* (fosphenytoin), *Celebrex* (celecoxib; a nonsteroidal anti-inflammatory agent), *Celexa* (citalopram, a selective serotonin reuptake inhibitor antidepressant), and *Xanax* (alprazolam, an anti-anxiety drug). Because these drugs have sound-alike, look-alike names, if your patient is prescribed any of these drugs, make sure you know what the drug is being used for and that the patient is getting the correct prescribed drug.

Therapeutic Actions and Indications

The hydantoin stabilize nerve membranes throughout the CNS directly by influencing ionic channels in the cell membrane, thereby decreasing excitability and hyperexcitability to stimulation. By decreasing conduction through nerve pathways, they reduce the tonic-clonic, muscular, and emotional responses to stimulation. See Table 23.2 for usual indications.

Pharmacokinetics

Phenytoin and ethotoin are well absorbed from the gastrointestinal (GI) tract, metabolized in the liver, and excreted in the urine. Therapeutic serum phenytoin levels range from 10 to 20 mcg/mL. The therapeutic serum levels of ethotoin are from 15 to 50 mcg/mL. Fosphenytoin is given intramuscularly or intravenously. It is metabolized in the liver and excreted in the urine. The therapeutic serum levels peak about 10 to 20 minutes after the infusion. Phenytoin is available in oral and parenteral forms.

Contraindications and Cautions

Hydantoin are generally contraindicated in the presence of allergy to any of these drugs *to avoid hypersensitivity reactions*. Many of these agents are associated with specific birth defects and should not be used in pregnancy or lactation unless the risk of seizures outweighs the potential risk to the fetus. In such cases, the mother should be informed of the potential risks. The risk of taking a woman with a seizure disorder off of an antiepileptic drug that has stabilized her condition may be greater than the risk of the drug to the fetus. Discontinuing the drug could result in status epilepticus, which has a high risk of hypoxia for the mother and the fetus. Research has not been able to show the effects of even a minor seizure during pregnancy on the fetus, making it important to prevent seizures during pregnancy if at

TABLE 23.2 DRUGS IN FOCUS Drugs for Treating Generalized Seizures

Drug Name	Dosage/Route	Usual Indications
Hydantoins		
ethotoin (<i>Peganone</i>)	Adult: 2–3 g/d PO in four to six divided doses Pediatric: 500 mg to 1 g/d PO; consider age and weight	Treatment of tonic–clonic and psychomotor seizures
fosphenytoin (<i>Cerebyx</i>)	Adult: loading dose, 15–20 mg phenytoin equivalent (PE) per kg IV given as 100–150 mg PE per minute; maintenance, 4–6 mg PE per kg per day; reduce dose with renal or hepatic impairment	Short-term control of status epilepticus, prevention of seizures after neurosurgery
 phenytoin (<i>Dilantin</i>)	Adult: 100 mg PO t.i.d., up to 300–400 mg/d; 10–15 mg/kg IV Pediatric: 5–8 mg/kg per day PO; 5–10 mg/kg IV in divided doses	Treatment of tonic–clonic seizures, prevention of status epilepticus, and treatment of seizures after neurosurgery
Barbiturates and Barbiturate-like Drugs		
mephobarbital (<i>Mebaral</i>)	Adult: 400–600 mg/d PO; decrease dose and monitor elderly patients and debilitated patients closely Pediatric (≤ 5 yr): 16–32 mg PO t.i.d. to q.i.d. Pediatric (> 5 yr): 32–64 mg PO t.i.d. to q.i.d.	Treatment of tonic–clonic and absence seizures; also used as sedative/hypnotic
 phenobarbital (<i>Solfoton, Luminal</i>)	Adult: 60–100 mg/d PO; 200–320 mg IM or IV for acute episodes, may be repeated in 6 h; reduce dose with elderly and with renal or hepatic impairment Pediatric: 3–6 mg/kg per day PO; 4–6 mg/kg per day IM or IV; 15–20 mg/kg IV over 10–15 min for status epilepticus	Long-term treatment of tonic–clonic seizures localized in the cortex; treatment of cortical focal seizures, simple partial seizures, febrile seizures; used as a sedative/hypnotic; emergency control of status epilepticus and acute seizures associated with eclampsia, tetanus, and other conditions
primidone (<i>Mysoline</i>)	Adult: 250 mg PO five to six times per day Pediatric (> 8 yr): 250 mg PO five to six times per day Pediatric (< 8 yr): 125–250 mg PO t.i.d.	Alternative choice in treatment of tonic–clonic, partial, febrile, and refractory seizures; may be combined with other agents to treat seizures that cannot be controlled by any other antiseizure agents
Benzodiazepines		
clonazepam (<i>Klonopin</i>)	Adult: initially 1.5 mg/d PO in three divided doses, up to a maximum 20 mg/d Pediatric (> 10 yr): 0.01–0.03 mg/kg per day PO initially, then up to 0.1–0.2 mg/kg per day PO	Treatment of absence and myoclonic seizures; administered to patients who do not respond to succinimides; being studied for use in the treatment of panic attacks, restless leg movements during sleep, hyperkinetic dysarthria, acute manic episodes, multifocal tic disorders, and neuralgias and as an adjunct in the treatment of schizophrenia
 diazepam (<i>Valium</i>)	Adult: 2–10 mg PO b.i.d. to q.i.d.; or 0.2 mg/kg PR, may repeat in 4–12 h; 2–20 mg IM or IV Geriatric or debilitated patients: 2–2.5 mg PO daily to b.i.d.; or 2–5 mg IM or IV Pediatric: 1–2.5 mg PO t.i.d. to q.i.d.; or 0.3–0.5 mg/kg PR with a repeat in 4–12 h if needed; 0.25 mg/kg IV over 3 min, may repeat in 15–30 min for up to three doses	Treatment of severe convulsions, clonic–tonic seizures, status epilepticus; treatment of alcohol withdrawal and tetanus; relieves tension, preoperative anxiety; being studied for use in treatment of panic attacks; this drug is no longer used for long-term management of epilepsy

Drug Name	Dosage/Route	Usual Indications
Succinimides		
 ethosuximide (Zarontin)	Adult and pediatric >6 yr: 500 mg/d PO Pediatric (3–6 yr): 250 mg/d PO, increase cautiously as needed	Drug of choice for treatment of absence seizures
methsuximide (Celontin)	Adult: 300 mg/d PO, up to 1.2 g/d Pediatric: determine dose by age and weight considerations	Treatment of absence seizures refractory to other agents
Drugs that Modulate the Inhibitory Neurotransmitter Gamma-aminobutyric Acid		
acetazolamide (Diamox)	8–30 mg/kg per day PO regardless of age; 250 mg PO daily if used with other antiepileptics	Treatment of absence seizures, especially in children; open-angle and secondary glaucoma; to decrease edema associated with heart failure and drug use; and as a prophylaxis and for mountain sickness
 valproic acid (Depakene)	Adult: 10–15 mg/kg per day PO up to a maximum 60 mg/kg per day Pediatric: use extreme caution, determine dose by age and weight	Drug of choice for myoclonic seizures; second-choice drug for treatment of absence seizures; also effective in mania, migraine headaches, and complex partial seizures
zonisamide (Zonegran)	Adults (>16 yr): 100 mg PO daily up to 600 mg/d	Adjunct for treatment of absence seizures

all possible. Women of childbearing age should be urged to use barrier contraceptives while taking these drugs. If a pregnancy does occur, the woman should receive educational materials and counseling.

Caution should be used with elderly or debilitated patients, *who may respond adversely to the CNS depression*, and with patients who have impaired renal or liver function *that may interfere with drug metabolism and excretion*. Patients with hepatic impairment are at risk for increased toxicity from phenytoin. Caution should be used when giving ethosuximide to diabetic patients and patients with severe cardiovascular problems. Patients receiving fosphenytoin intravenously require careful monitoring of their cardiovascular status during the infusion period. Some potentially serious name confusion has occurred with fosphenytoin (see prior Focus on Safe Medication Administration). Other contraindications include coma, depression, or psychoses, *which could be exacerbated by the generalized CNS depression*.

Adverse effects

The most common adverse effects relate to CNS depression and its effects on body function: depression, confusion, drowsiness, lethargy, fatigue, constipation, dry mouth, anorexia, cardiac arrhythmias and changes in blood pressure, urinary retention, and loss of libido.

Specifically, the hydantoins may cause severe liver toxicity, bone marrow suppression, gingival hyperplasia, and potentially serious dermatological reactions (e.g., hirsutism, Steven–Johnson syndrome) may occur, all of which are directly related to cellular toxicity.

Clinically Important Drug–Drug Interactions

Because the risk of CNS depression is increased with hydantoins taken with alcohol, patients should be advised not to drink alcohol while they are taking these agents. Always consult a drug reference before any drug is added TO or withdrawn from a therapeutic regimen that involves any of these agents. Box 23.4 describes a hazardous drug–herbal therapy interaction associated with antiepileptic medications.

Prototype Summary: Phenytoin

Indications: Control of tonic–clonic and psychomotor seizures; prevention of seizures during neurosurgery; control of status epilepticus.

Actions: Stabilizes neuronal membranes and prevents hyperexcitability caused by excessive stimulation; limits the spread of seizure activity from an active focus; has cardiac antiarrhythmic effects similar to those of lidocaine.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	Slow	2–12 h	6–12 h
IV	1–2 h	Rapid	12–24 h

$T_{1/2}$: 6 to 24 hours; metabolized in the liver, excreted in the urine.

Adverse effects: Nystagmus, ataxia, dysarthria, slurred speech, mental confusion, dizziness, fatigue, tremor, headache, dermatitis, Stevens–Johnson syndrome, nausea, gingival hyperplasia, liver damage, hematopoietic complications, sometimes fatal.

FOCUS
BOX 23.4 *Herbal and Alternative Therapies*

Patients being treated for epilepsy should be advised not to use the herb evening primrose because it increases the risk of having seizures. Patients being treated with barbiturates or phenytoin should be advised not to use ginkgo, which could cause serious adverse effects.

Barbiturates and Barbiturate-Like Drugs

Barbiturates and barbiturate-like drugs include mephobarbital (*Mebaral*), phenobarbital (*Solfoton*, *Luminal*), and primidone (*Mysoline*). These drugs are associated with significant central nervous system depression.

Therapeutic Actions and Indications

The barbiturates and barbiturate-type drugs inhibit impulse conduction in the ascending reticular activating system (RAS), depress the cerebral cortex, alter cerebellar function, and depress motor nerve output. They stabilize nerve membranes throughout the CNS directly by influencing ionic channels in the cell membrane, thereby decreasing excitability and hyperexcitability to stimulation. By decreasing conduction through nerve pathways, they reduce the tonic-clonic, muscular, and emotional responses to stimulation. Phenobarbital depresses conduction in the lower brainstem and the cerebral cortex and depresses motor conduction.

Mephobarbital is used for the treatment of tonic-clonic and absence seizures. It is also used as an anxiolytic/hypnotic agent. See Table 23.2 for usual indications for each of these agents.

Pharmacokinetics

Phenobarbital, which is available in oral and parenteral forms, is well absorbed from the GI tract, metabolized in the liver, and excreted in the urine. This drug has very low lipid solubility, giving it a slow onset and a very long duration of activity. The therapeutic serum level range is 15 to 40 mcg/mL.

Primidone, available only as an oral agent, is well absorbed from the GI tract, metabolized in the liver to phenobarbital metabolites, and excreted in the urine. It tends to have a longer half-life than phenobarbital. The therapeutic serum levels are 5 to 12 mcg/mL.

Mephobarbital, an oral drug, is well absorbed from the GI tract, metabolized in the liver, and excreted in the urine. It has a long half-life of 11 to 67 hours.

Contraindications and Cautions

Contraindications and cautions for barbiturates are the same as those discussed for hydantoins.

Adverse effects

The most common adverse effects associated with barbiturates relate to CNS depression and its effects on body function: depression, confusion, drowsiness, lethargy, fatigue, constipation, dry mouth, anorexia, cardiac arrhythmias and changes in blood pressure, urinary retention, and loss of libido. Because barbiturates and barbiturate-like drugs depress nerve function, they can produce sedation, hypnosis, anesthesia, and deep coma. The degree of depression is dose related. At doses below those needed to cause hypnosis, these drugs block seizure activity.

In addition, phenobarbital may be associated with physical dependence and withdrawal syndrome. The drug has also been linked to severe dermatological reactions and the development of drug tolerance related to changes in drug metabolism over time.

Mephobarbital is commonly associated with CNS and GI effects. Its cardiovascular effects (hypotension, bradycardia, circulatory collapse) and respiratory effects (apnea, hypoventilation) make it less desirable than many of the other antiepileptic agents.

Clinically Important Drug-Drug Interactions

Because the risk of CNS depression is increased when barbiturates are taken with alcohol, patients should be advised not to drink alcohol while they are taking these agents. Always consult a drug reference before any drug is added or withdrawn from a therapeutic regimen that involves any of these agents.

Prototype Summary: Phenobarbital

Indications: Long-term treatment of generalized tonic-clonic and cortical focal seizures; emergency control of certain acute convulsive episodes (status epilepticus, tetanus, eclampsia, meningitis); anticonvulsant treatment of generalized tonic-clonic seizures and focal seizures (parenteral).

Actions: General CNS depressant; inhibits impulse conduction in the ascending RAS; depresses the cerebral cortex; alters cerebellar function; depresses motor output; and can produce excitation, sedation, hypnosis, anesthesia, and deep coma.

Pharmacokinetics:

Route	Onset	Duration
Oral	30–60 min	10–16 h
IM, SC	10–30 min	4–6 h
IV	5 min	4–6 h

$T_{1/2}$: 79 hours; metabolized in the liver, excreted in the urine.

Adverse effects: Somnolence, insomnia, vertigo, nightmares, lethargy, nervousness, hallucinations, insomnia, anxiety, dizziness, bradycardia, hypotension, syncope, nausea, vomiting, constipation, diarrhea, hypoventilation, respiratory depression, tissue necrosis at injection site, withdrawal syndrome.

Benzodiazepines

Some benzodiazepines are used as antiepileptic agents. These include clonazepam (*Klonopin*) and diazepam (*Valium*).

Therapeutic Actions and Indications

The benzodiazepines may potentiate the effects of GABA, an inhibitory neurotransmitter that stabilizes nerve cell membranes. These drugs, which appear to act primarily in the limbic system and the RAS, also cause muscle relaxation and relieve anxiety without affecting cortical functioning substantially. The benzodiazepines stabilize nerve membranes throughout the CNS to decrease excitability and hyperexcitability to stimulation. By decreasing conduction through nerve pathways, they reduce the tonic-clonic, muscular, and emotional responses to stimulation. In general, these drugs have limited toxicity and are well tolerated by most people. (See Chapter 20 for the use of benzodiazepines as sedatives and anxiolytics.) See Table 23.2 for usual indications for each of these agents. Clonazepam may lose its effectiveness within 3 months (affected patients may respond to dose adjustment).

Pharmacokinetics

Diazepam is available in oral, rectal, and parenteral forms. Clonazepam is now available in an orally disintegrating tablet, making it a good choice for patients who have difficulty swallowing capsules or tablets. These agents are well absorbed from the GI tract, metabolized in the liver, and excreted in the urine. They have a long half-life of 18 to 50 hours.

Contraindications and Cautions

Contraindications for benzodiazepines are the same as those discussed for hydantoin.

Adverse Effects

The most common adverse effects associated with benzodiazepines relate to CNS depression and its effects on body function: depression, confusion, drowsiness, lethargy, fatigue, constipation, dry mouth, anorexia, cardiac arrhythmias, and changes in blood pressure, urinary retention, and loss of libido. Benzodiazepines may be associated with physical dependence and withdrawal syndrome.

Clinically Important Drug–Drug Interactions

Because the risk of CNS depression is increased when benzodiazepines are taken with alcohol, patients should be advised not to drink alcohol while they are taking these agents. Always consult a drug reference before any drug is added or withdrawn from a therapeutic regimen that involves any of these agents.

Prototype Summary: Diazepam

Indications: Management of anxiety disorders; acute alcohol withdrawal; muscle relaxant; treatment of tetanus; adjunct in status epilepticus and severe recurrent convulsive seizures; preoperative relief of anxiety and tension; management of epilepsy in patients who require intermittent use to control bouts of increased seizure activity.

Actions: Acts in the limbic system and reticular formation; potentiates the effects of GABA; has little effect on cortical function.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	30–60 min	1–2 h	3 h
IM	15–30 min	30–45 min	3 h
IV	1–5 min	30 min	15–60 min
Rectal	Rapid	1.5 h	3 h

$T_{1/2}$: 20 to 80 hours; metabolized in the liver, excreted in the urine.

Adverse effects: Drowsiness, sedation, depression, lethargy, apathy, fatigue, disorientation, bradycardia, tachycardia, paradoxical excitatory reactions, constipation, diarrhea, incontinence, urinary retention, drug dependence with withdrawal syndrome.

Succinimides

The succinimides include ethosuximide (*Zarontin*) and methsuximide (*Celontin*). The succinimides are most frequently used to treat absence seizures, a form of generalized seizure.

Therapeutic Actions and Indications

Although the exact mechanism of action is not understood, the succinimides suppress the abnormal electrical activity in the brain that is associated with absence seizures. The action may be related to activity in inhibitory neural pathways in the brain (see Figure 23.2).

Ethosuximide and methsuximide are indicated for the control of absence seizures (see Table 23.2). Ethosuximide should be tried first; methsuximide should be reserved for the treatment of seizures that are refractory to other agents because it is associated with more severe adverse effects.

Pharmacokinetics

Ethosuximide and methsuximide are available for oral use. These drugs cross the placenta and enter breast milk (see contraindications and cautions). The succinimides are readily absorbed from the GI tract, reaching peak levels in 1 to 7 hours, depending on the drug. They are metabolized in the liver and excreted in the urine. The half-life of ethosuximide is 30 hours in children and 60 hours in adults; the half-life of methsuximide is 2.6 to 4 hours. The established therapeutic serum level for ethosuximide is 40 to 100 mcg/mL.

Contraindications and Cautions

The succinimides are contraindicated in the presence of allergy to any of these drugs *to avoid hypersensitivity reactions*. Caution should be used with succinimides in patients with intermittent porphyria, *which could be exacerbated by the adverse effects of these drugs*, and those with renal or hepatic disease, *which could interfere with the metabolism and excretion of these drugs and lead to toxic levels*. Use during pregnancy should be discussed with the woman because of the potential for adverse effects on the fetus. Another method of feeding the baby should be used if one of these drugs is needed during lactation.

Adverse Effects

Ethosuximide has relatively few adverse effects compared with many other antiepileptic drugs. Many of the adverse effects associated with the succinimides are related to their depressant effects in the CNS. These may include depression, drowsiness, fatigue, ataxia, insomnia, headache, and blurred vision. Decreased GI activity with nausea, vomiting, anorexia, weight loss, GI pain, and constipation or diarrhea may also occur. Bone marrow suppression, including potentially fatal pancytopenia, and dermatological reactions such as pruritus, urticaria, alopecia, and Stevens–Johnson syndrome may occur as a result of direct chemical irritation of the skin and bone marrow.

Clinically Important Drug–Drug Interactions

Use of succinimides with primidone may cause a decrease in serum levels of primidone. Patients should be monitored and appropriate dose adjustments made if these two agents are used together.

Prototype Summary: Ethosuximide

Indications: Control of absence seizures.

Actions: May act in inhibitory neuronal systems; suppresses the electroencephalographic pattern associated with absence seizures; reduces frequency of attacks.

Pharmacokinetics:

Route	Peak
Oral	3–7 h

$T_{1/2}$: 30 hours (children), 60 hours (adults); metabolized in the liver, excreted in the urine and bile.

Adverse effects: Drowsiness, ataxia, dizziness, irritability, nervousness, headache, blurred vision, pruritus, Stevens–Johnson syndrome, nausea, vomiting, epigastric pain, anorexia, diarrhea, and pancytopenia.

Other Drugs for Treating Absence Seizures

Three other drugs that are used in the treatment of absence seizures do not fit into a specific drug class (Table 23.2). These include acetazolamide (*Diamox*), valproic acid (*Depakene*), and zonisamide (*Zonegran*).

Therapeutic Actions and Indications

Valproic acid reduces abnormal electrical activity in the brain and may also increase GABA activity at inhibitory receptors. Acetazolamide—a sulfonamide—alters electrolyte movement, stabilizing nerve cell membranes. Another sulfonamide—zonisamide—is a newer agent that inhibits voltage-sensitive sodium and calcium channels, thus stabilizing nerve cell membranes and modulating calcium-dependent presynaptic release of excitatory neurotransmitters. See Table 23.2 for usual indications related to these drugs.

Pharmacokinetics

Valproic acid, available for oral and IV use, is readily absorbed from the GI tract, reaching peak levels in 1 to 4 hours. It is metabolized in the liver and excreted in the urine with a half-life of 6 to 16 hours.

Acetazolamide, which can be given orally, IM, or IV, is readily absorbed from the GI tract and is excreted unchanged in the urine with a half-life of 2.5 to 6 hours.

Zonisamide, an oral drug, is well absorbed from the GI tract, reaching peak levels in 2 to 6 hours. It is primarily excreted unchanged in the urine, with a half-life of 63 hours.

Contraindications and Cautions

These drugs are contraindicated with known allergy to any component of the drug. The sulfonamides are also contraindicated with known allergy to antibacterial sulfonamides and thiazide diuretics *to avoid hypersensitivity reactions*. When it is discontinued, zonisamide should be tapered over 2 weeks because of a risk of precipitating seizures. Patients who take this drug should be very well hydrated *due to risk of renal calculi development*.

Caution should be used in patients with hepatic or renal impairment, *which could alter metabolism and excretion of*

the drug. These drugs should not be used during pregnancy or lactation unless the benefit clearly outweighs the risk to the fetus or neonate *because of the potential for serious adverse effects on the baby.*

Adverse Effects

Valproic acid is associated with liver toxicity. All of these drugs cause CNS effects related to CNS suppression—weakness, fatigue, drowsiness, dizziness, and paresthesias. Acetazolamide and zonisamide may cause rash and dermatological changes. Zonisamide is associated with bone marrow suppression, renal calculi development, and GI upset.

Clinically Important Drug–Drug Interactions

Acetazolamide increases the serum levels of quinidine, tricyclic antidepressants, and amphetamines and may increase salicylate toxicity when given with salicylates. Valproic acid can increase serum levels and potential toxicity of phenobarbital, ethosuximide, diazepam, primidone, and zidovudine. If any of these drugs are used in combination, the patient should be monitored carefully and doses adjusted appropriately. Breakthrough seizures have been reported when valproic acid is combined with phenytoin, and extreme care should be taken if this combination must be used. Zonisamide levels and toxicity are increased if it is combined with carbamazepine, and the patient should be monitored and zonisamide dose reduced as needed.

● Nursing Considerations for Patients Receiving Drugs for Treating Generalized Seizures

The information that follows primarily relates to drug therapy with hydantoins and succinimides, acetazolamide, valproic acid, and zonisamide. See Chapter 20 for nursing considerations for patients receiving barbiturates or benzodiazepines.

Assessment: History and Examination

- Assess for *contraindications or cautions* to the use of hydantoins, including known history of allergy to hydantoins *to avoid hypersensitivity reactions*; cardiac arrhythmias, hypotension, diabetes, coma, or psychoses, *which could be exacerbated by the use of the drug*; history of renal or hepatic dysfunction *that might interfere with drug metabolism or excretion*; and current status related to pregnancy and lactation.
- Assess for *contraindications or cautions* to the use of succinimides, including any known allergies to these drugs; history of intermittent porphyria, *which could be exacerbated by these drugs*; history of renal or hepatic dysfunction *that might interfere with drug metabolism or excretion*; and current status related to pregnancy or lactation.

- Obtain a description of seizures, including onset, aura, duration, and recovery, *to determine type of seizure and establish a baseline.*
- Perform a physical assessment *to establish baseline data for determining the effectiveness of therapy and the occurrence of any potential adverse effect.*
- Inspect the skin for color and lesions *to determine evidence of possible skin effects*; assess pulse and blood pressure and auscultate heart *to evaluate for possible cardiac effects*; assess level of orientation, affect, reflexes, and bilateral grip strength *to evaluate any CNS effects*; monitor bowel sounds and urine output *to determine possible gastrointestinal or genitourinary effects*; and evaluate gums and mucous membranes *to establish baseline and monitor changes associated with adverse effects.*
- Obtain a baseline electroencephalogram if appropriate *to evaluate brain function.*
- Assess the patient's renal and liver function, including renal and liver function tests, *to determine appropriateness of therapy and determine the need for possible dose adjustment.*

Refer to the Critical Thinking Scenario for a full discussion of nursing care for a patient who is being prescribed antiepileptic drugs.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Discomfort related to GI, CNS, and genitourinary effects
- Disturbed Thought Processes related to CNS effects
- Risk for Infection related to bone marrow suppression (succinimides, zonisamide)
- Risk for Injury related to CNS effects or toxic drug levels
- Impaired Skin Integrity related to dermatological effects
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Discontinue the drug at any sign of hypersensitivity reaction, liver dysfunction, or severe skin rash *to limit reaction and prevent potentially serious reactions.*
- Administer the drug with food *to alleviate GI irritation if GI upset is a problem.*
- Monitor for adverse effects and provide appropriate supportive care as needed *to help the patient cope with these effects.*
- Monitor complete blood count (CBC) before and periodically during therapy *to detect bone marrow suppression early and provide appropriate interventions.*
- Discontinue the drug if skin rash, bone marrow suppression, or unusual depression or personality changes occur *to prevent the development of more serious adverse effects.*
- Discontinue the drug slowly, and never withdraw the drug quickly, *because rapid withdrawal may precipitate absence seizures.*

CRITICAL THINKING SCENARIO

Antiepileptic Drugs

THE SITUATION

J.M., an athletic, 18-year-old high school senior, suffered his first seizure during math class. He seemed attentive and alert, and then he suddenly slumped to the floor and suffered a full tonic-clonic (grand mal) seizure. The other students were frightened and did not know what to do. Fortunately, the teacher was familiar with seizures and quickly reacted to protect J.M. from hurting himself and to explain what was happening.

J.M. was diagnosed with idiopathic generalized epilepsy with tonic-clonic (grand mal) seizures. The combination of phenytoin and phenobarbital that he began taking made him quite drowsy during the day. These drugs were unable to control the seizures, and he suffered three more seizures in the next month—one at school and two at home. J.M. is now undergoing re-evaluation for possible drug adjustment and counseling.

CRITICAL THINKING

What teaching implications should be considered when meeting with J.M.? *Consider his age and the setting of his first seizure.*

What problems might J.M. encounter in school and in athletics related to the diagnosis and the prescribed medication? *Consider measures that may help him avoid some of the unpleasant side effects related to this particular drug therapy. Driving a car may be a central social focus in the life of a high school senior.*

What problems can be anticipated and confronted before they occur concerning laws that forbid individuals with newly diagnosed epilepsy from driving?

Develop a teaching protocol for J.M. How will you involve the entire family in the teaching plan?

DISCUSSION

On their first meeting, it is important for the nurse to establish a trusting relationship with J.M. and his family. J.M., who is at a sensitive stage of development, requires a great deal of support and encouragement to cope with the diagnosis of epilepsy and the need for drug therapy. He may need to ventilate his feelings and concerns and discuss how he can re-enter school without worrying about having a seizure in class. The nurse should implement a thorough drug teaching program, including a description of warning signs to watch for that should be reported to a health care profes-

sional. J.M. should be encouraged to take the following preventive measures:

- Have frequent oral hygiene to protect the gums.
- Avoid operating dangerous machinery or performing tasks that require alertness while drowsy and confused.
- Pace activities as much as possible to help deal with any fatigue and malaise.
- Take the drugs with meals if gastrointestinal upset is a problem.

This information should be given to both J.M. and his family in written form for future reference, along with the name of a health care professional and a telephone number to call with questions or comments. The importance of continuous medication to suppress the seizures should be stressed. The adverse effects of many of these drugs make it difficult for some patients to remain compliant with their drug regimen.

After the discussion with J.M., the nurse should meet with his family members, who also need support and encouragement to deal with his diagnosis and its implications. They need to know what seizures are, how the prescribed antiepileptic drugs affect the seizures, what they can do when seizures occur, and complete information about the drugs he must take and their anticipated drug effects. In addition, it is important to work with family members to determine whether any particular thing precipitated the seizures. In other words, was there any warning or aura? This may help with adjustment of drug dosages or avoidance of certain situations or stimuli that precipitate seizures. Family members should be encouraged to report and record any seizure activity that occurs.

Most states do not permit individuals with newly diagnosed epilepsy to drive, and states have varying regulations about the return of the driver's license after a seizure-free interval. If driving makes up a major part of J.M.'s social activities, this news may be even more unacceptable than his diagnosis. J.M. and his family should be counseled and helped to devise other ways of getting places and coping with this restriction. J.M. may be interested in referral to a support group for teens with similar problems, where he can share ideas, support, and frustrations.

J.M.'s condition is a chronic one that will require continual drug therapy and evaluation. He will need periodic reteaching and should have the opportunity to ask additional questions and to ventilate his feelings. J.M. should be encouraged to wear or carry a MedicAlert tag so that

Antiepileptic Drugs (continued)

emergency medical personnel are aware of his diagnosis and the medications he is taking.

**NURSING CARE GUIDE FOR J.M.:
ANTIEPILEPTIC AGENTS****Assessment: History and Examination**

Allergies to any of these drugs; hypotension; arrhythmias; bone marrow suppression; coma; psychoses; pregnancy or lactation; hepatic or renal dysfunction

Concurrent use of valproic acid, cimetidine, disulfiram, isoniazid, phenacemide, sulfonamides, diazoxide, folic acid, rifampin, sucralfate, theophylline, primidone, acetaminophen

CV: blood pressure, pulse, peripheral perfusion

CNS: orientation, reflexes, affect, strength, EEG

Skin: color, lesions, texture, temperature

GI: abdominal evaluation, bowel sounds

Respiratory: respiration, adventitious sounds

Laboratory tests: CBC, liver and renal function tests

Nursing Diagnoses

Acute Pain related to GI, CNS, and GU effects

Risk for Injury related to CNS effects

Disturbed Thought Processes related to CNS effects

Deficient Knowledge regarding drug therapy

Impaired Skin Integrity related to dermatological effects

Implementation

Discontinue drug at first sign of liver dysfunction or skin rash.

Provide comfort and safety measures: positioning; give with meals; skin care.

Provide support and reassurance to cope with diagnosis, restrictions, and drug effects.

Provide patient teaching regarding drug name, dosage, side effects, symptoms to report, and the need to wear MedicAlert information; other drugs to avoid.

Evaluation

Evaluate drug effects: decrease in incidence and frequency of seizures; serum drug levels within therapeutic range.

Monitor for adverse effects: CNS effects (multiple); bone marrow suppression; rash, skin changes; GI effects—nausea, anorexia; arrhythmias.

Monitor for drug–drug interactions: increased depression with CNS depressants, alcohol; drugs as listed.

Evaluate effectiveness of patient teaching program.

Evaluate effectiveness of comfort/safety measures.

PATIENT TEACHING FOR J.M.

- The drugs that are being evaluated for you are called antiepileptic agents. They are used to stabilize abnormal cells in the brain that have been firing excessively and causing seizures.
- The timing of these doses is very important. To be effective, this drug must be taken regularly.
- Do not stop taking this drug suddenly. If for any reason you are unable to continue taking the drug, notify your health care provider at once. This drug must be slowly withdrawn when its use is discontinued.
- Common effects of these drugs include:
 - *Fatigue, weakness, and drowsiness:* Try to space activities evenly throughout the day and allow rest periods to avoid these effects. Take safety precautions and avoid driving or operating dangerous machinery if these conditions occur.
 - *Headaches and difficulty sleeping:* These usually disappear as your body adjusts to the drug. If they persist and become too uncomfortable, consult with your health care provider.
 - *Gastrointestinal upset, loss of appetite, and diarrhea or constipation:* Taking the drug with food or eating small, frequent meals may help alleviate this problem.
 - Report any of the following conditions to your health care provider: *skin rash, severe nausea and vomiting, impaired coordination, yellowing of the eyes or skin, fever, sore throat, personality changes, and unusual bleeding or bruising.*
- It is advisable to wear or carry a Medic-Alert warning so that any person who takes care of you in an emergency will know that you are taking this drug.
- Tell any doctor, nurse, or other health care provider involved in your care that you are taking this drug.
- Keep this drug and all medications out of the reach of children.
- Do not take any other drug, including over-the-counter medications and alcohol, without consulting with your health care provider. Many of these preparations interact with the drug and could cause adverse effects.
- Report and record any seizure activity that you have while you are taking this drug.
- Take this drug exactly as prescribed. Regular medical follow-up, which may include blood tests, will be necessary to evaluate the effects of this drug on your body.

- Monitor for drug–drug interactions *to arrange to adjust doses appropriately if any drug is added to or withdrawn from the drug regimen.*
- Arrange for counseling for women of childbearing age who are taking these drugs. *Because these drugs have the potential to cause serious damage to the fetus, women should understand the risk of birth defects and use barrier contraceptives to avoid pregnancy.*
- Offer support and encouragement *to help the patient cope with the drug regimen.*
- Provide thorough patient teaching, including drug name and prescribed dosage, as well as measures for avoidance of adverse effects and warning signs that may indicate possible problems *to enhance patient knowledge about drug therapy and to promote compliance; and the need for periodic blood tests to evaluate blood counts to reduce the risk for infection and for drug levels to evaluate therapeutic effectiveness and minimize the risk for toxicity.*
- Suggest the wearing or carrying of a MedicAlert bracelet *to alert emergency workers and health care providers about the use of an antiepileptic drug.*

Evaluation

- Monitor patient response to the drug (decrease in incidence or absence of seizures; serum drug levels within the therapeutic range); evaluate for therapeutic blood levels (40 to 100 mcg/mL) for ethosuximide *to ensure the most appropriate dose of the drug.*
- Monitor for adverse effects (CNS changes, GI depression, urinary retention, arrhythmias, blood pressure changes, liver toxicity, bone marrow suppression, severe dermatological reactions).
- Evaluate the effectiveness of the teaching plan (patient can give the drug name and dosage and name possible adverse effects to watch for and specific measures to prevent them; patient is aware of the risk of birth defects and the need to carry information about the diagnosis and use of this drug).
- Monitor the effectiveness of comfort measures and compliance with the regimen.

KEY POINTS

- ◆ Drugs used to treat generalized seizures include the hydantoins, barbiturates, and benzodiazepines.
- ◆ Drugs used to treat absence seizures—a particular type of generalized seizure—include the hydantoins, succinimides, acetazolamide, valproic acid, and zonisamide.
- ◆ All of these drugs stabilize nerve membranes throughout the CNS to decrease excitability and hyperexcitability to stimulation.
- ◆ Adverse effects associated with these drugs reflect the CNS depression—lethargy, somnolence, fatigue, dry mouth, constipation, and dizziness. Serious liver, bone marrow, and dermatological problems can occur with specific drugs

DRUGS FOR TREATING PARTIAL SEIZURES

Partial seizures may be simple (involving only a single muscle or reaction) or complex (involving a series of reactions or emotional changes). Drugs used in the treatment of partial seizures include carbamazepine (*Tegretol*, *Atretol*, and others), clorazepate (*Tranxene*, *Gen-Xene*, and others), felbamate (*Felbatol*), gabapentin (*Neurontin*), lamotrigine (*Lamictal*), levetiracetam (*Keppra*), oxcarbazepine (*Trileptal*), pregabalin (*Lyrica*), tiagabine (*Gabitril*), and topiramate (*Topamax*) (see Table 23.3). Some of the drugs used to treat generalized seizures have also been found to be useful in treating partial seizures (see Table 23.1).

Safe Medication Administration

Name confusion has been reported between *Keppra* (levetiracetam) and *Kaletra* (lopinavir/ritonavir), an HIV antiviral combination drug. Both drugs come in a liquid form, and confusion has been reported in the administration of the two drugs, causing serious adverse effects. Use extreme caution when administering these drugs.

Therapeutic Actions and Indications

The drugs used to control partial seizures stabilize nerve membranes in either of two ways—directly, by altering sodium and calcium channels, or indirectly, by increasing the activity of GABA, an inhibitory neurotransmitter, and thereby decreasing excessive activity (see Figure 23.2). Carbamazepine, felbamate, and oxcarbazepine are used as monotherapy, and the remaining drugs are used as adjunctive therapy (see Table 23.3 for usual indications for each agent). Each of the drugs used for treating partial seizures has a slightly different mechanism of action:

Carbamazepine is chemically related to the tricyclic antidepressants. It has the ability to inhibit polysynaptic responses and to block sodium channels to prevent the formation of repetitive action potentials in the abnormal focus.

Clorazepate and felbamate are thought to potentiate the effects of the inhibitory neurotransmitter GABA.

Gabapentin inhibits polysynaptic responses and blocks stimulus increases in certain situations.

Lamotrigine may inhibit voltage-sensitive sodium and calcium channels, stabilize nerve cell membranes, and modulate calcium-dependent presynaptic release of excitatory neurotransmitters. Levetiracetam is a newer drug, and its mechanism of action is not understood; its antiepileptic action does not seem to be associated with any known mechanisms of inhibitory or excitatory neurotransmission. (See also the prior Focus on Safe Medication Administration for information about potentially serious name confusion that has occurred with levetiracetam.)

TABLE 23.3 DRUGS IN FOCUS Drugs for Treating Partial Seizures

Drug Name	Dosage/Route	Usual Indications
 carbamazepine (<i>Tegretol, Atritol</i>)	Adult: 800–1200 mg/d PO in divided doses q6–8h Pediatric (>12 yr): adult doses, do not exceed 1000 mg/d Pediatric (6–12 yr): 20–30 mg/kg per day PO in divided doses t.i.d. to q.i.d. Pediatric (<6 yr): 35 mg/kg per day PO	Drug of choice for treatment of partial seizures and tonic-clonic seizures; treatment of trigeminal neuralgia, bipolar disorder
clorazepate (<i>Tranxene, Gen-Xene</i>)	Adult: 7.5 mg PO t.i.d., up to 90 mg/d Pediatric (9–12 yr): 7.5 mg PO b.i.d., up to 60 mg/d	Used as adjunct for treatment of partial seizures; also used for anxiety disorders, acute symptoms of alcohol withdrawal
felbamate (<i>Felbatol</i>)	Adult and children >14 yr: 2600 mg/d PO Pediatric (2–14 yr): 15 mg/kg per day PO in divided doses three to four times per day	Used as monotherapy or adjunctive therapy for treatment of partial seizures; adjunctive therapy for Lennox–Gastaut syndrome in children; however, drug is reserved for those cases that are unresponsive to other therapies due to its risks for severe adverse effects
gabapentin (<i>Neurontin</i>)	Adult: 900–1800 mg/d PO in divided doses t.i.d. Pediatric (3–12 yr): 10–15 mg/kg per day PO in divided doses	Used as adjunct in treating partial seizures; treatment of postherpetic pain in adults and children ages 3–12 yr of age; has orphan drug status for the treatment of amyotrophic lateral sclerosis; treatment of postherpetic pain, migraines, bipolar disorders, tremors of multiple sclerosis, and nerve-generated pain states
lamotrigine (<i>Lamictal</i>)	Adult: 300–500 mg/d PO in divided doses b.i.d. Pediatric (2–12 yr): 1–5 mg/kg per day PO in divided doses b.i.d. Pediatric (>12 yr): 100–400 mg/d PO in divided doses b.i.d.	Used as adjunct or for monotherapy in treating partial seizures and in treatment of seizures associated with Lennox–Gastaut syndrome in adults and children ≥ 2 years of age; long-term treatment of bipolar disorders
levetiracetam (<i>Keppra</i>)	Adult: 500 mg PO b.i.d. up to 3000 mg/d Pediatric (4–16 yr): 10 mg/kg PO b.i.d. to a maximum of 1500–3000 mg/d	Newer drug approved for adjunctive treatment of partial seizures in adults and children ≥ 4 years of age; in 2007, it was also approved for the treatment of primary generalized tonic-clonic seizures in adults and treatment of children ≥ 6 years of age with idiopathic generalized epilepsy; being studied for use in absence seizures, myoclonic seizures, and drug-resistant seizures of multiple types
oxcarbazepine (<i>Trileptal</i>)	Adult: 600 mg PO b.i.d. Pediatric (4–16 yr): 8–10 mg/kg per day PO	Used for monotherapy or adjunctive therapy in treatment of partial seizures in adults and children 4–16 yr of age; also being studied as an alternate treatment of bipolar disease
pregabalin (<i>Lyrica</i>)	150–600 mg/d PO in divided doses Neuropathic pain: 100 mg PO t.i.d. Postherpetic neuralgia: 75–150 mg PO t.i.d.	Used for adjunctive treatment of adults with partial-onset seizures; management of neuropathic pain associated with diabetic peripheral neuropathy and postherpetic neuralgia; fibromyalgia
tiagabine (<i>Gabitril</i>)	Adult: 4 mg PO daily up to 56 mg/d in two to four divided doses Pediatric (12–18 yr): 4 mg PO daily up to a maximum 32 mg/d in two to four divided doses	Used as adjunct in treating partial seizures in adults and in children 12–18 yr of age
topiramate (<i>Topamax</i>)	Adult: 400 mg PO daily in two divided doses; reduce dose in renal impairment Pediatric (2–16 yr): 5–9 mg/kg per day PO in two divided doses	Used as adjunct in treating partial seizures in adults and children 2–16 yr of age; also approved for treatment of tonic-clonic seizures, for prevention of migraine headaches, and as adjunct therapy in Lennox–Gastaut syndrome; being studied for use in cluster headaches, infantile spasms, alcohol dependence, bulimia nervosa, and weight loss

Oxcarbazepine was approved in 2000, and its exact mechanism of action is also unknown. It inhibits voltage-sensitive sodium channels, stabilizing hyperexcited nerve cell membranes. It also increases potassium conductance and modulates calcium-dependent presynaptic release of excitatory neurotransmitters. Any or all of these effects may be responsible for the antiseizure effects of the drug.

Pregabalin, which was introduced in the United States in 2005, has a high binding affinity for voltage-gated calcium channels in the cerebrovascular system. It seems to modulate the calcium function in these neurons, leading to a decreased release of neurotransmitters into the synaptic cleft and a decrease in cell activity. In 2007, pregabalin became the first drug approved for the treatment of fibromyalgia.

Tiagabine binds to GABA reuptake receptors, causing an increase in GABA levels in the brain. Because GABA is an inhibitory neurotransmitter, the result is a stabilizing of nerve membranes and a decrease in excessive activity.

Topiramate is another newer drug that blocks sodium channels in neurons with sustained depolarization and increases GABA activity, inhibiting nerve activity.

Pharmacokinetics

These drugs are all given orally. Levetiracetam is also available for IV use.

Carbamazepine is absorbed from the GI tract and metabolized in the liver by the cytochrome P450 system. It is excreted in the urine with a half-life of 25 to 65 hours.

Clorazepate is rapidly absorbed from the GI tract, reaching peak levels in 1 to 2 hours. After metabolism in the liver, it is excreted in the urine with a half-life of 30 to 100 hours.

Felbamate is absorbed well from the GI tract and is primarily excreted unchanged in the urine with a half-life of 20 to 23 hours.

Gabapentin is well absorbed from the GI tract and widely distributed in the body. It is excreted unchanged in the urine with a half-life of 5 to 7 hours.

Lamotrigine is rapidly absorbed from the GI tract, metabolized in the liver, and primarily excreted in the urine. The half-life of lamotrigine is approximately 25 hours.

Levetiracetam is rapidly absorbed from the GI tract, reaching peak levels in 1 hour. It goes through very little metabolism, with most of the drug being excreted unchanged in the urine with a half-life of 6 to 8 hours.

Oxcarbazepine is completely absorbed from the GI tract and extensively metabolized in the liver. It is excreted in the urine with a half-life of 2 and then 9 hours.

Pregabalin is rapidly absorbed orally, reaching peak levels in 1.5 hours. It is not metabolized but is eliminated unchanged in the urine with a half-life of 6.3 hours.

Tiagabine is rapidly absorbed from the GI tract, reaching peak levels in 45 minutes. It is metabolized in the liver by the cytochrome P450 system. It is excreted in the urine with a half-life of 4 to 7 hours.

Topiramate is rapidly absorbed from the GI tract, reaching peak levels in 2 hours. It is widely distributed and is excreted unchanged in the urine.

Contraindications and Cautions

Contraindications to the drugs used to control partial seizures include the following conditions: presence of any known allergy to the drug; bone marrow suppression, *which could be exacerbated by the drug effects*; and severe hepatic dysfunction, *which could be exacerbated and could interfere with the metabolism of the drugs*.

Carbamazepine, clorazepate, gabapentin, and oxcarbazepine have been shown to be dangerous to a fetus and should not be used during pregnancy. Women of childbearing age should be advised to use contraception. These drugs enter breast milk and can cause serious adverse effects in the baby. If any of these drugs is needed during lactation, another method of feeding the baby should be used.

There are no clear studies about the effects of felbamate, lamotrigine, levetiracetam, pregabalin, tiagabine, or topiramate use during pregnancy and lactation. Therefore, these drugs should not be used during pregnancy or lactation unless the benefits to the mother clearly outweigh potential adverse effects in the fetus or neonate. Men considering fathering a child should be advised that in animal studies, males receiving pregabalin had decreased fertility and associated birth defects in offspring.

Caution should also be used in the following situations: with renal or hepatic dysfunction, *which could alter the metabolism and excretion of the drugs*; and with renal stones, *which could be exacerbated by the effects of some of these agents*.

Adverse Effects

The most frequently occurring adverse effects associated with the drugs used for partial seizures relate to the CNS depression that results. The following conditions may occur: drowsiness, fatigue, weakness, confusion, headache, and insomnia; GI depression, with nausea, vomiting, and anorexia; and upper respiratory infections. These antiepileptics can also be directly toxic to the liver and the bone marrow, causing dysfunction. The exact effects of each drug vary.

Felbamate has been associated with severe liver failure and aplastic anemia. Lamotrigine has been associated with very serious to life-threatening rashes, and the drug should be discontinued at the first sign of any rash. Patients with renal dysfunction are more likely to experience toxic effects of levetiracetam, and the dose for these patients needs to be decreased accordingly.

The adverse effects most commonly seen with pregabalin are related to CNS depression—tremor, dizziness, somnolence, and visual changes. This drug does have a controlled

substance rating as Category V. It can cause feelings of well-being and euphoria. Because of this, its use should be limited in patients who have a history of abuse of medications or alcohol.

A reduced dose of topiramate is recommended for patients with renal impairment. The drug also has been associated with marked CNS depression. Tiagabine has also been associated with serious skin rash.

Clinically Important Drug–Drug Interactions

If any of these drugs is taken with other CNS depressants or alcohol, a potential for increased CNS depression exists. Caution patients to avoid alcohol while taking drugs for partial seizures or to take extreme precautions if such combinations cannot be avoided.

In addition, numerous drug–drug interactions are associated with carbamazepine. Always consult a drug reference whenever a drug is added or withdrawn from a carbamazepine-containing regimen. Dose adjustments may be necessary.

Prototype Summary: Carbamazepine

Indications: Treatment of seizure disorders, including partial seizures with complex patterns; tonic–clonic seizures; mixed seizures; trigeminal neuralgia.

Actions: Inhibits polysynaptic responses and blocks postsynaptic potentiators; mechanism of action is not understood; related to the tricyclic antidepressants.

Pharmacokinetics:

Route	Onset	Peak
Oral	Slow	4–5 h
Extended release oral	Slow	3–12 h

$T_{1/2}$: 25 to 65 hours, then 12 to 17 hours; metabolized in the liver, excreted in the urine and feces.

Adverse effects: Drowsiness, ataxia, dizziness, nausea, vomiting, CV complications, hepatitis, hematological disorders, Stevens–Johnson syndrome.

Nursing Considerations for Patients Receiving Drugs to Treat Partial Seizures

Assessment: History and Examination

- Assess for contraindications and cautions: any known allergies to these drugs to avoid hypersensitivity reactions; history of bone marrow suppression or renal stones, which could be exacerbated by these drugs; history of renal or hepatic dysfunction that might interfere with drug

metabolism and excretion; and current status of pregnancy or lactation, which are contraindicated or require caution when using these drugs.

- Perform a physical assessment to establish baseline data for determining the effectiveness of therapy and the occurrence of any potential adverse effects.
- Inspect the skin for color and lesions to determine evidence of possible skin effects; assess pulse and blood pressure and auscultate heart to evaluate for possible cardiac effects; assess level of orientation, affect, reflexes, and bilateral grip strength to evaluate any CNS effects; monitor bowel sounds and urine output to determine possible gastrointestinal or genitourinary effects.
- Obtain a baseline electroencephalogram if appropriate to evaluate brain function.
- Assess the patient's renal and liver function, including renal and liver function tests, to determine the appropriateness of therapy and determine the need for possible dose adjustment.
- Monitor the results of laboratory tests such as urinalysis and CBC with differential to identify changes in bone marrow function.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to GI and CNS effects
- Disturbed Thought Processes related to CNS effects
- Risk for Injury related to CNS effects
- Risk for Infection related to bone marrow suppression effects
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Administer the drug with food to alleviate GI irritation if GI upset is a problem.
- Monitor CBC before and periodically during therapy to detect and prevent serious bone marrow suppression.
- Protect the patient from exposure to infection if bone marrow suppression occurs.
- Discontinue the drug if skin rash, bone marrow suppression, unusual depression, or personality changes occur to prevent further serious adverse effects.
- Discontinue the drug slowly, and never withdraw the drug quickly, because rapid withdrawal may precipitate seizures.
- Arrange for counseling for women of childbearing age who are taking these drugs. Because these drugs have the potential to cause serious damage to the fetus, women should understand the risk of birth defects and use barrier contraceptives to avoid pregnancy.

- Evaluate for therapeutic blood levels of carbamazepine (4 to 12 mcg/mL) *to ensure that the most effective dose is being used.*
- Provide safety measures to protect the patient from injury or falls *if CNS changes occur.*
- Provide patient teaching, including drug name and prescribed dosage, as well as measures for avoidance of adverse effects, warning signs that may indicate possible problems, and the need for periodic laboratory testing and monitoring and evaluation *to enhance patient knowledge about drug therapy and to promote compliance.*
- Suggest that the patient wear or carry a MedicAlert bracelet *to alert emergency workers and health care providers about the use of an antiepileptic drug.*
- Offer support and encouragement *to help the patient cope with the drug regimen.*

Evaluation

- Monitor patient response to the drug (decrease in incidence or absence of seizures).
- Monitor for adverse effects (CNS changes, GI depression, bone marrow suppression, severe dermatological reactions, liver toxicity, renal stones).
- Evaluate the effectiveness of the teaching plan (patient can give the drug name and dosage and name possible adverse effects to watch for and specific measures to prevent them; patient is aware of the risk of birth defects and the need to carry information about the diagnosis and use of this drug).

KEY POINTS

- ♦ Drugs used in the treatment of partial seizures include drugs that stabilize the nerve membrane by altering electrolyte movement or increasing GABA activity.
- ♦ Some of the drugs used to treat generalized seizures have also been found to be useful in treating partial seizures.
- ♦ Adverse effects associated with the use of drugs used in treating partial seizures include CNS depressive effects and dermatological disorders.

CHAPTER SUMMARY

- Epilepsy is a collection of different syndromes, all of which have the same characteristic: a sudden discharge of excessive electrical energy from nerve cells located within the brain. This event is called a seizure.
- Seizures can be divided into two groups: generalized and partial (focal).
- Generalized seizures can be further classified as tonic-clonic (grand mal); absence (petit mal); myoclonic; febrile; and rapidly recurrent (status epilepticus).
- Partial (focal) seizures can be further classified as simple or complex.
- Drug treatment depends on the type of seizure that the patient has experienced and the toxicity associated with the available agents.
- Drug treatment is directed at stabilizing the overexcited nerve membranes and/or increasing the effectiveness of GABA, an inhibitory neurotransmitter.
- Adverse effects associated with antiepileptics (e.g., insomnia, fatigue, confusion, GI depression, bradycardia) reflect the CNS depression caused by the drugs.
- Patients being treated with an antiepileptic should be advised to wear or carry a MedicAlert notification to alert emergency medical professionals to their epilepsy and their use of antiepileptic drugs.
- Patients being treated with antiepileptic are often on long-term therapy, which requires compliance with their drug regimen and restrictions associated with their disorder and the drug effects.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-Rom in the front of the book.

MULTIPLE CHOICE

Select the best answer to the following.

- When teaching a group of students about epilepsy, which of the following should the nurse include?
 - Always characterized by grand mal seizures.
 - Only a genetic problem.
 - The most prevalent neurological disorder.
 - The name given to one brain disorder.
- Which of the following would the nurse be least likely to include as a type of generalized seizure?
 - Petit mal seizures.
 - Febrile seizures.
 - Grand mal seizures.
 - Complex seizures.
- Which instruction would the nurse encourage a patient receiving an antiepileptic drug to do?
 - Give up his or her driver's license.
 - Wear or carry a MedicAlert identification.
 - Take antihistamines to help dry up secretions.
 - Keep the diagnosis a secret to avoid prejudice.
- Drugs that are commonly used to treat grand mal seizures include
 - barbiturates, benzodiazepines, and hydantoins.
 - barbiturates, antihistamines, and local anesthetics.
 - hydantoins, phenobarbital, and phensuximide.
 - benzodiazepines, phensuximide, and valproic acid.
- The drug of choice for the treatment of absence seizures is
 - valproic acid.
 - methsuximide.
 - phensuximide.
 - ethosuximide.
- Focal or partial seizures
 - start at one point and spread quickly throughout the brain.
 - are best treated with benzodiazepines.
 - involve only part of the brain.
 - are easily diagnosed and recognized.
- One drug that is used alone in the treatment of partial seizures is
 - carbamazepine.
 - topiramate.
 - lamotrigine.
 - gabapentin.
- Treatment of epilepsy is directed at
 - blocking the transmission of nerve impulses into the brain.
 - stabilizing overexcited nerve membranes
 - blocking peripheral nerve terminals.
 - thickening the meninges to dampen brain electrical activity.

MULTIPLE RESPONSE

Select all that apply.

- A client has been stabilized on phenytoin (*Dilantin*) for several years and has not experienced a grand mal seizure in more than 3 years. The client decides to stop the drug because it no longer seems to be needed. In counseling the client, the nurse should include which of the following points?
 - He will always need this drug.
 - This drug needs to be slowly tapered to avoid potentially serious adverse effects.
 - He is probably correct and the drug is not needed.
 - The drug should not be stopped until appropriate blood tests are done.
 - Stopping the drug suddenly could precipitate seizures because the nerves will be more sensitive.
 - His insurance company won't cover any problems that might occur if he stops the drug without physician approval.
- The most common adverse effects associated with antiepileptic therapy reflect the depression of the CNS. In assessing a client on antiepileptic therapy, the nurse would monitor the patient for which of the following?
 - Hypertension
 - Insomnia
 - Confusion
 - GI depression
 - Increased salivation
 - Tachycardia

Antiparkinsonism Agents

24

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Describe the current theory of the cause of Parkinson disease and correlate this with the clinical presentation of the disease.
2. Describe the therapeutic actions, indications, pharmacokinetics, contraindications, most common adverse reactions, and important drug–drug interactions associated with antiparkinsonism agents.
3. Discuss the use of antiparkinsonism agents across the lifespan.
4. Compare and contrast the prototype drugs for each class of antiparkinsonism agents with the other drugs in that class and with drugs from the other classes used to treat the disease.
5. Outline the nursing considerations and teaching needs for patients receiving each class of antiparkinsonism agents.

Glossary of Key Terms

anticholinergic: drug that opposes the effects of acetylcholine at acetylcholine-receptor sites

bradykinesia: difficulty in performing intentional movements and extreme slowness and sluggishness; characteristic of Parkinson disease

corpus striatum: part of the brain that reacts with the substantia nigra to maintain a balance of suppression and stimulation

dopaminergic: drug that increases the effects of dopamine at receptor sites

Parkinson disease: debilitating disease, characterized by progressive loss of coordination and function, which results from the degeneration of dopamine-producing cells in the substantia nigra

parkinsonism: Parkinson disease–like extrapyramidal symptoms that are adverse effects associated with particular drugs or brain injuries.

substantia nigra: a part of the brain rich in dopamine and dopamine receptors; site of degenerating neurons in Parkinson disease

DOPAMINERGIC AGENTS

amantadine
apomorphine
bromocriptine

carbidopa–levodopa
levodopa
pramipexole
rasagiline
ropinirole

ANTICHOLINERGIC AGENTS

benztropine
biperiden
diphenhydramine
trihexyphenidyl

ADJUNCTIVE AGENTS

entacapone
selegiline
tolcapone

In the 1990s, several prominent figures—former heavyweight boxing champion Muhammad Ali, former U.S. Attorney General Janet Reno, and actor Michael J. Fox—revealed that they had **Parkinson disease**, a progressive, chronic neurological disorder. In general, Parkinson disease may develop in people of any age, but it usually affects those who are past middle age and entering their 60s or even later years. Therefore,

the occurrence of Parkinson disease in these well-known individuals who were relatively young at the time of diagnosis is that much more interesting. The cause of the condition is not known.

At this time, there is no cure for Parkinson disease. Therapy is aimed at management of signs and symptoms to provide optimal functioning for as long as possible.

PARKINSON DISEASE AND PARKINSONISM

Lack of coordination is characteristic of Parkinson disease. Rhythmic tremors develop, insidiously at first. In some muscle groups, these tremors lead to rigidity, and in others, weakness. Affected patients may have trouble maintaining position or posture, and they may develop the condition known as **bradykinesia**, marked by difficulties in performing intentional movements and extreme slowness or sluggishness.

As Parkinson disease progresses, walking becomes a problem; a shuffling gait is a hallmark of the condition. In addition, patients may drool, and their speech may be slow and slurred. As the cranial nerves are affected, they may develop a mask-like expression. Parkinson disease does not affect the higher levels of the cerebral cortex, so a very alert and intelligent person may be trapped in a progressively degenerating body.

Parkinsonism is a term used to describe the Parkinson disease–like extrapyramidal symptoms that are adverse effects associated with particular drugs or brain injuries. Patients typically exhibit tremors and bradykinesia.

Pathophysiology

Although the cause of Parkinson disease is not known, it is known that the signs and symptoms of the disease relate to damaged neurons in the basal ganglia of the brain. Theories about the cause of the degeneration of these neurons range from viral infection, blows to the head, brain infection, atherosclerosis, and exposure to certain drugs and environmental factors.

Even though the actual cause is not known, the mechanism that causes the signs and symptoms of Parkinson disease is understood. In a part of the brain called the **substantia nigra**, a dopamine-rich area, nerve cell bodies begin to degenerate. This process results in a reduction of the number of impulses sent to the **corpus striatum** in the basal

ganglia. This area of the brain, in conjunction with the substantia nigra, helps to maintain muscle tone not related to any particular movement. The corpus striatum is connected to the substantia nigra by a series of neurons that use gamma-aminobutyric acid (GABA), an inhibitory neurotransmitter. The substantia nigra sends nerve impulses back into the corpus striatum using the inhibitory neurotransmitter dopamine. The two areas then mutually inhibit activity in a balanced manner.

Higher neurons originating in the cerebral cortex secrete acetylcholine (an excitatory neurotransmitter) in the area of the corpus striatum to coordinate intentional movements of the body. When dopamine decreases in the area, a chemical imbalance occurs that allows the cholinergic or excitatory cells to dominate. This affects the functioning of the basal ganglia and of the cortical and cerebellar components of the extrapyramidal motor system. The extrapyramidal system is one that provides coordination for unconscious muscle movements, including those that control position, posture, and movement. The result of this imbalance in the motor system is apparent as the manifestations of Parkinson disease (Figure 24.1).

Treatment

At this time, there is no treatment that arrests the neuron degeneration of Parkinson disease and the eventual decline in patient function. Surgical procedures involving the basal ganglia have been tried with varying success at prolonging the degeneration caused by this disease. Drug therapy remains the primary treatment.

Therapy is aimed at restoring the balance between the declining levels of dopamine, which has an inhibitory effect on the neurons in the basal ganglia, and the now-dominant cholinergic neurons, which are excitatory. This may help to reduce the signs and symptoms of parkinsonism and restore normal function for a time (Figure 24.2).

Total management of patient care in individuals with Parkinson disease presents a challenge. Patients should be

● **FIGURE 24.1** Schematic representation of the degeneration of neurons that leads to Parkinson disease. Cells in the corpus striatum send impulses to the substantia nigra using gamma-aminobutyric acid (GABA) to inhibit activity. In turn, the substantia nigra sends impulses to the corpus striatum, using dopamine, to inhibit activity. Cortical areas use acetylcholine (Ach) to stimulate intentional movements.

● **FIGURE 24.2** Drug therapy in treating Parkinson disease is aimed at achieving a balance between the stimulating cholinergic effects and the inhibitory effects of dopamine in the basal ganglia. Type 1 drugs affect dopamine and are inhibitory. Type 2 drugs block cholinergic effects, preventing stimulation.

encouraged to be as active as possible, to perform exercises to prevent the development of skeletal deformities, and to attend to their care as long as they can. Both the patient and family need instruction about following drug protocols and monitoring adverse effects, as well as encouragement and support for

coping with the progressive nature of the disease (Box 24.1). Because of the degenerative effects of this disease, patients may experience episodes of depression or emotional upset. Psychological support, as well as physical support, is a crucial aspect of care.

BOX 24.1 Drug Therapy Across the Lifespan

Antiparkinsonism Agents

CHILDREN

The safety and effectiveness of most of these drugs has not been established in children. The incidence of Parkinson disease in children is very small. Children do, however, experience parkinsonian symptoms as a result of drug effects.

If a child needs an antiparkinsonian drug, diphenhydramine is the drug of choice. If further relief is needed and another drug is tried, careful dosage calculations should be done based on age and weight, and the child should be monitored very closely for adverse effects.

ADULTS

The eventual dependence and lack of control that accompany Parkinson disease are devastating to all patients and their families but may be particularly overwhelming to individuals in their prime of life who value high degrees of autonomy, self-determination, and independence. Although these characteristics are not associated with any particular ethnic group, they are valued more highly among certain cultures than others. For example, Latinos—who traditionally have strong extended family ties—may not have the same problems adjusting to a chronic, debilitating illness in a relative as members of other ethnic groups. It is important for the nurse to assess all families with sensitivity to determine what convictions they hold and plan nursing care accordingly.

Adults diagnosed with Parkinson disease require extensive teaching and support and help coping with the disease as well as with the effects of the drugs.

With the increasing interest in herbal and alternative therapies, it is important to stress the need to inform the health

care provider about any other treatment being used. Vitamin B₆ can pose a serious problem for patients who are taking some of these drugs.

Women of childbearing age should be advised to use contraception when they are on these drugs. If a pregnancy does occur, or is desired, they need counseling about the potential for adverse effects. Women who are nursing should be encouraged to find another method of feeding the baby because of the potential for adverse drug effects on the baby.

OLDER ADULTS

Although Parkinson disease may affect individuals of any age, gender, or nationality, the frequency of the disease increases with age. This debilitating condition, which affects more men than women, may be one of many chronic problems associated with aging.

The drugs that are used to manage Parkinson disease are associated with more adverse effects in older people with long-term problems. Both anticholinergic and dopaminergic drugs aggravate glaucoma, benign prostatic hypertrophy, constipation, cardiac problems, and chronic obstructive pulmonary diseases. Special precautions and frequent follow-up visits are necessary for older patients with Parkinson disease, and their drug dosages may need to be adjusted frequently to avoid serious problems. In many cases, other agents are given to counteract the effects of these drugs, and patients then have complicated drug regimens with many associated adverse effects and problems. Consequently, it is essential for these patients to have extensive written drug-teaching protocols.

KEY POINTS

- ▶ Parkinson disease is a progressive nervous system disease characterized by tremors, changes in posture and gait, and a mask-like facial expression.
- ▶ The loss of dopamine-secreting cells results in a loss of the inhibitory dopamine effect and is thought to be responsible for Parkinson disease.

DOPAMINERGIC AGENTS

Dopaminergics—drugs that increase the effects of dopamine at receptor sites—have been proven to be even more effective than anticholinergics in the treatment of parkinsonism (see Table 24.1). Dopaminergic agents include amantadine (*Symmetrel*), apomorphine (*Apokyn*), bromocriptine (*Parlodel*), levodopa (*Dopar*), carbidopa–levodopa (*Sinemet*), pramipexole (*Mirapex*), rasagiline (*Azilect*), and ropinirole (*Requip*).

Therapeutic Actions and Indications

Dopamine does not cross the blood–brain barrier. Therefore, other drugs that act like dopamine or increase dopamine concentrations indirectly must be used to increase dopamine levels in the substantia nigra or to directly stimulate the dopamine receptors in that area. This action helps to restore the balance between the inhibitory and stimulating neurons. Dopaminergic agents are effective as long as enough intact neurons remain in the substantia nigra to respond to increased

levels of dopamine. After the neural degeneration has progressed beyond a certain point, these agents are no longer effective.

The dopaminergics are indicated for the relief of the signs and symptoms of idiopathic Parkinson disease (see Table 24.1 for usual indications for each of these agents). Levodopa is the mainstay of treatment for Parkinson disease. This precursor of dopamine crosses the blood–brain barrier and is converted into dopamine. In this way, it acts like a replacement therapy. Although levodopa is almost always given in combination form with carbidopa as a fixed-combination drug (*Sinemet*), other drugs besides carbidopa may be used (see Adjunctive Therapy). When used with carbidopa, the enzyme dopa decarboxylase is inhibited in the periphery, diminishing the metabolism of levodopa in the gastrointestinal (GI) tract and in peripheral tissues, thereby leading to higher levels crossing the blood–brain barrier. Because the carbidopa decreases the amount of levodopa needed to reach a therapeutic level in the brain, the dose of levodopa can be decreased, which reduces the incidence of adverse side effects.

Amantadine is an antiviral drug that also seems to increase the release of dopamine, being effective as long as there is a possibility of more dopamine release.

Apomorphine is a newer adjunctive therapy for Parkinson disease that directly binds with postsynaptic dopamine receptors. Similar to apomorphine, bromocriptine and pramipexol act as direct dopamine agonists on dopamine-receptor sites in the substantia nigra. Because bromocriptine does not depend on cells in the area to biotransform it or to increase the release

TABLE 24.1 DRUGS IN FOCUS Dopaminergic Agents

Drug Name	Dosage/Route	Usual Indications
amantadine (<i>Symmetrel</i>)	100 mg PO b.i.d.; up to 400 mg/d has been used	Antiviral; treatment of idiopathic and drug-induced parkinsonism in adults
apomorphine (<i>Apokyn</i>)	2–6 mg SC t.i.d.; given with trimethobenzamide: 300 mg PO t.i.d.	Intermittent treatment of hypomobility “off” episodes of advanced Parkinson disease
bromocriptine (<i>Parlodel</i>)	1.25 mg PO b.i.d.; titrate up to 10–40 mg/d	Treatment of idiopathic Parkinson disease; may be beneficial in later stages when response to levodopa decreases
carbidopa–levodopa (<i>Sinemet</i>)	100 mg levodopa with 10–25 mg carbidopa PO t.i.d.	Treatment of idiopathic Parkinson disease
 levodopa (<i>Dopar</i>)	0.5–1 g/d PO in two divided doses; titrate up to 8 g/d; most often given in combination with carbidopa as <i>Sinemet</i> : 25 mg carbidopa/100 mg levodopa PO t.i.d.	Treatment of idiopathic Parkinson disease
pramipexole (<i>Mirapex</i>)	0.125 mg PO t.i.d., titrate up to 1.5 mg PO t.i.d.	Treatment of idiopathic Parkinson disease
rasagiline (<i>Azilect</i>)	1 mg/d PO; 0.5 mg/d PO if used with levodopa	Initial monotherapy and as adjunct to levodopa to treat idiopathic Parkinson disease
ropinirole (<i>Requip</i>)	0.25 mg PO t.i.d.; titrate up to maximum dose of 24 mg/d	Treatment of idiopathic Parkinson disease in early stages and in later stages when combined with levodopa; treatment of restless legs syndrome

of already produced dopamine, it may be effective longer than levodopa or amantadine.

Ropinirole is newer drug that directly stimulates dopamine receptors. It is also used to treat restless leg syndrome.

Rasagiline is another newer dopamine agonist that increases dopamine in the nerve synapse, particularly in areas of the brain responsible for controlling movement and coordination. It inhibits monoamine oxidase type B, which is found primarily in the central nervous system (CNS). Because this drug works on an enzyme found mostly inside the CNS, it has fewer peripheral adverse effects. It can be used as initial monotherapy or as an adjunct therapy with levodopa.

Pharmacokinetics

The dopaminergics are usually given orally and are generally well absorbed from the GI tract and widely distributed in the body. Apomorphine, however, must be given subcutaneously. The dopaminergics are metabolized in the liver and peripheral cells and excreted in the urine. They cross the placenta and enter breast milk.

Contraindications and Cautions

The dopaminergics are contraindicated in the presence of any known allergy to the drug or drug components *to prevent hypersensitivity reactions*, and in angle-closure glaucoma, *which could be exacerbated by these drugs*. Dopaminergics enter breast milk and should not be used during lactation because of the potential for adverse effects in the baby. In addition, levodopa is contraindicated in patients with a history or presence of suspicious skin lesions *because this drug has been associated with the development of melanoma*.

Administer dopaminergic agents cautiously with patients who have *any condition that could be exacerbated by dopamine receptor stimulation*, such as cardiovascular disease, including myocardial infarction, arrhythmias, and hypertension; bronchial asthma; history of peptic ulcers; urinary tract obstruction; and psychiatric disorders. Care also is necessary during pregnancy *because these drugs cross the placenta and could adversely affect the fetus*, and in patients with renal and hepatic disease, *which could interfere with the metabolism and excretion of the drug*. Closely monitor cardiac status in patients receiving apomorphine because of the associated risk for hypotension and prolonged QT interval.

Adverse Effects

The adverse effects associated with the dopaminergics usually result from stimulation of dopamine receptors. CNS effects may include anxiety, nervousness, headache, malaise, fatigue, confusion, mental changes, blurred vision, muscle twitching, and ataxia. Peripheral effects may include anorexia, nausea, vomiting, dysphagia, and constipation or diarrhea; cardiac arrhythmias, hypotension, and palpitations; bizarre breathing

patterns; urinary retention; and flushing, increased sweating, and hot flashes. Bone marrow depression and hepatic dysfunction have also been reported.

Clinically Important Drug–Drug Interactions

If dopaminergics are combined with monoamine oxidase inhibitors (MAOIs), therapeutic effects increase and a risk of hypertensive crisis exists. The MAOI should be stopped 14 days before beginning therapy with a dopaminergic.

The combination of levodopa with vitamin B₆ or with phenytoin may lead to decreased efficacy of the levodopa (see Critical Thinking Scenario). Reduced effectiveness of both drugs may also result if dopaminergics are combined with dopamine antagonists. In addition, patients who take dopaminergics should be cautioned to avoid over-the-counter vitamins; if such medications are used, the patient should be monitored closely because a decrease in dopaminergic effectiveness can result.

Patients using rasagiline should avoid tyramine-containing foods, as well as St. John's wort, meperidine, and other analgesics, to avoid potentially serious reactions.

Prototype Summary: Levodopa

Indications: Treatment of parkinsonism and Parkinson disease.

Actions: Precursor of dopamine, which is deficient in parkinsonism; crosses the blood–brain barrier, where it is converted to dopamine and acts as a replacement neurotransmitter; effective for 2 to 5 years in relieving the symptoms of Parkinson disease.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	Varies	0.5–2 h	5 h

T_{1/2}: 1 to 3 hours; metabolized in the liver, excreted in the urine.

Adverse effects: Adventitious movements, ataxia, increased hand tremor, dizziness, numbness, weakness, agitation, anxiety, anorexia, nausea, dry mouth, dysphagia, urinary retention, flushing, cardiac irregularities.

Nursing Considerations for Patients Receiving Dopaminergic Agents

Assessment: History and Examination

- Assess for contraindications or cautions: any known allergies to these drugs *to avoid hypersensitivity reactions*; GI depression or obstruction, urinary hesitancy or obstruction, benign prostatic hypertrophy, or glaucoma, *which may be exacerbated by these drugs*; cardiac arrhythmias, hypertension, or respiratory disease, *which may be exacerbated by dopamine receptor stimulation*; current status of pregnancy

CRITICAL THINKING SCENARIO

Effects of Vitamin B₆ Intake on Levodopa Levels

THE SITUATION

S.S., a 58-year-old man with well-controlled Parkinson disease, presents with severe nausea, anorexia, fainting spells, and heart palpitation. He has been maintained on levodopa for the Parkinson disease, and he claims to have followed his drug regimen religiously.

According to S.S. the only change in his lifestyle has been the addition of several health foods and vitamins. His daughter, who recently returned from her freshman year in college, has begun a new health regimen, including natural foods and plenty of supplemental vitamins. She was so enthusiastic about her new approach that everyone in the family agreed to give this diet a try.

CRITICAL THINKING

Based on S.S.'s signs and symptoms, what has probably occurred?

In Parkinson disease, is it possible to differentiate a deterioration of illness from a toxic reaction to a drug?

What nursing implications should be considered when teaching S.S. and his family about the effects of vitamin B₆ on levodopa levels?

In what ways can the daughter cope with her role in this crisis?

Develop a new care plan for S.S. that involves all family members and that includes drug teaching.

DISCUSSION

The presenting symptoms reflect an increase in Parkinson symptoms, as well as an increase in peripheral dopamine reactions (e.g., palpitations, fainting, anorexia, nausea). It is necessary to determine whether the problem involves a further degeneration in the neurons in the substantia nigra or the particular medication that S.S. has been taking. In many patients, responsiveness to levodopa is lost as neural degeneration continues.

The explanation of the new lifestyle—full of grains, natural foods, and vitamins—alerted the nurse to the possibility of excessive vitamin B₆ intake. In reviewing the vitamin bottles and some of the food packages supplied by S.S., it seemed that too much vitamin B₆, which speeds the conversion of levodopa to dopamine before it can cross the blood–brain barrier, might be the reason the patient's symptoms recurred.

The status of S.S.'s Parkinson disease should be evaluated, and then he can be restarted on levodopa. The smallest dose possible should be used initially, with gradual increases to achieve the maximum benefit with the fewest side effects.

It would be wise to consider combining the drug with carbidopa to prevent some of the patient's recent problems.

In addition, S.S. should receive thorough drug teaching in written form for future reference. The need to avoid vitamin B₆ should be emphasized. The entire family should be involved in an explanation of what happened and how this situation can be avoided in the future. Because the daughter may feel guilty about her role, she should have the opportunity to discuss her feelings and explore the positive impact of healthy food on nutrition and quality of life. This situation can serve as a good teaching example for staff, as well as present them with an opportunity to review drug therapy in Parkinson disease and the risks and benefits of more extreme diets.

NURSING CARE GUIDE FOR S.S.: LEVODOPA

Assessment: History and Examination

Allergies to levodopa; chronic obstructive pulmonary disease (COPD); dysrhythmias, hypotension, hepatic or renal dysfunction; psychoses; peptic ulcer; glaucoma
Concurrent use of monoamine oxidase inhibitors (MAOIs), phenytoin, pyridoxine, papaverine, or tricyclic antidepressants (TCAs)

Focus physical examination on

CV: blood pressure, pulse rate, peripheral perfusion, electrocardiogram results

CNS: orientation, affect, reflexes, grip strength

Renal: output, bladder palpation

GI: abdominal examination, bowel sounds

Respiratory: respiration, adventitious sounds

Laboratory tests: renal and liver function tests, complete blood count

Nursing Diagnoses

Risk for Injury related to CNS effects

Disturbed Thought Processes related to CNS effects

Deficient Knowledge regarding drug therapy

Constipation related to GI effects

Implementation

Ensure safe and appropriate administration of drug.

Provide comfort and safety: slow positioning changes; assess orientation, provide pain medication as needed; give drug with food; administer with carbidopa; have patient void before each dose.

Provide support and reassurance to deal with disease and drug effects.

Instruct the patient regarding drug dose, effects, and adverse symptoms to report.

Effects of Vitamin B₆ Intake on Levodopa Levels (continued)**Evaluation**

Evaluate drug effects: relief of signs and symptoms of Parkinson disease

Monitor for adverse effects: CNS effects; renal changes, urinary retention; GI effects (constipation); increased sweating or flushing.

Monitor for drug–drug interactions: hypertensive crisis with MAOIs, decreased effects with vitamin B₆ or phenytoin.

Evaluate the effectiveness of the patient teaching program.

Evaluate the effectiveness of comfort and safety measures.

PATIENT TEACHING FOR S.S.

- The drug that has been prescribed is called levodopa. It increases the levels of dopamine in the central areas of the brain and helps to reduce the signs and symptoms of Parkinson disease.
- Often, this drug is combined with carbidopa, which allows the correct levels of levodopa to reach the brain.
- People who take this drug must have their individual dose needs adjusted over time. Common effects of this drug include:
 - *Fatigue, weakness, and drowsiness:* Try to space activities evenly through the day; allow rest periods to avoid these side effects. Take safety precautions, and avoid driving or operating dangerous machinery if these conditions occur.
 - *Dizziness, fainting:* Change position slowly to avoid dizzy spells.

- *Increased sweating, darkened urine:* This is a normal reaction. Avoid very hot environments.
- *Headaches, difficulty sleeping:* These usually pass as the body adjusts to the drug. If they become too uncomfortable and persist, consult with your health care provider.
- Report any of the following to your health care provider: *uncontrolled movements of any body part, chest pain or palpitations, depression or mood changes, difficulty in voiding, or severe or persistent nausea and vomiting.*
- Be aware that vitamin B₆ interferes with the effects of levodopa. If you feel that you need a vitamin product, consult with your health care provider about using an agent that does not contain vitamin B₆.
- Avoid eating large quantities of health foods that contain vitamin B₆, such as grains and brans. If you are taking a carbidopa–levodopa combination, these precautions are not as important.
- Tell any doctor, nurse, or other health care provider involved in your care that you are taking this drug.
- Keep this drug and all medications out of the reach of children.
- Do not overexert yourself when you begin to feel better. Pace yourself.
- Take this drug exactly as directed, and schedule regular medical checkups to evaluate its effects.

or lactation, which are cautions or contraindications to use of the drug; and renal or hepatic dysfunction, which could interfere with the drug's excretion or metabolism.

- Perform a physical assessment to determine baseline status before beginning therapy, to determine the effectiveness of drug therapy, and to monitor for any potential adverse effects.
- Inspect the skin for evidence of skin lesions or history of melanoma if the patient is to receive levodopa, which could cause or exacerbate melanoma.
- Assess for a history of prolonged QT interval and obtain an electrocardiogram if apomorphine is to be administered to avoid further prolonged QT interval and serious arrhythmias.
- Assess level of orientation and neurological status, including affect, reflexes, bilateral grip strength, gait, tremors, and spasticity, to evaluate any CNS effects.
- Auscultate lungs and assess respiratory status to evaluate for changes that could be exacerbated by the drug's effect.
- Monitor pulse, blood pressure, and cardiac output to evaluate for possible adverse effects
- Auscultate bowel sounds to evaluate GI motility to assess for adverse effects.

- Assess urine output and palpate bladder to determine adequate bladder and renal function.
- Monitor the results of laboratory tests, such as liver and renal function studies, to determine need for possible dose adjustment, and complete blood count (CBC) with differential to evaluate for possible bone marrow suppression.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Disturbed Thought Processes related to CNS effects
- Risk for urinary retention related to dopaminergic effects
- Constipation related to dopaminergic effects
- Risk for Injury related to CNS effects and incidence of orthostatic hypertension
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Arrange to decrease the dose of the drug if therapy has been interrupted for any reason to prevent systemic dopaminergic effects.

- Evaluate disease progress and signs and symptoms periodically and record *for reference of disease progress and drug response*.
- Give the drug with meals *to alleviate GI irritation if GI upset is a problem*.
- Monitor bowel function and institute a bowel program *if constipation is severe*.
- Ensure that the patient voids before taking the drug *if urinary retention is a problem*.
- Monitor urinary output, palpate bladder, and check for residual urine *if urinary retention becomes a problem*.
- Establish safety precautions if CNS or vision changes occur *to prevent patient injury*.
- Monitor hepatic, renal, and hematological tests periodically during therapy *to detect early signs of dysfunction and consider re-evaluation of drug therapy*.
- Provide support services and comfort measures as needed *to improve patient compliance*.
- Provide thorough patient teaching about topics such as the drug name and prescribed dose, measures to help avoid adverse effects, warning signs that may indicate problems, and the need for periodic monitoring and evaluation *to enhance patient knowledge about drug therapy and to promote compliance*.
- Offer support and encouragement *to help the patient cope with the disease and drug regimen*.

Evaluation

- Monitor patient response to the drug (improvement in signs and symptoms of Parkinson disease).
- Monitor for adverse effects (CNS changes, urinary retention, GI depression, tachycardia, increased sweating, flushing).

- Evaluate the effectiveness of the teaching plan (patient can give the drug name and dosage, name possible adverse effects to watch for and specific measures to prevent them, and discuss the importance of continued follow-up).
- Monitor the effectiveness of support measures and compliance with the regimen.

KEY POINTS

- ▶ Dopaminergic drugs are used to increase the effects of dopamine at receptor sites, restoring the balance of neurotransmitters in the basal ganglia.
- ▶ The adverse effects associated with these drugs are related to the systemic effects of dopamine, increased heart rate, increased blood pressure, decreased GI activity, and urinary retention.
- ▶ Levodopa is the standard dopaminergic used to treat parkinsonism and Parkinson disease. Several other dopaminergics are now used as adjuncts to levodopa to increase the dopamine effects as long as possible.

ANTICHOLINERGIC AGENTS

Anticholinergics (Table 24.2) are drugs that oppose the effects of acetylcholine at receptor sites in the substantia nigra and the corpus striatum, thus helping to restore chemical balance in the area. Anticholinergics used to treat Parkinson disease include benztropine (*Cogentin*), biperiden (*Akineton*), diphenhydramine (*Benadryl*), and trihexyphenidyl (*Artane*).

TABLE 24.2 DRUGS IN FOCUS Anticholinergic Agents

Drug Name	Dosage/Route	Usual Indications
benztropine (<i>Cogentin</i>)	0.5–6 mg/d PO may be needed; 1–2 mg IM or IV; reduce dose in older patients	Adjunctive treatment of parkinsonism, and drug-induced parkinsonism resulting from drug effects of phenothiazines
 biperiden (<i>Akineton</i>)	2 mg PO t.i.d. to q.i.d. to a maximum of 16 mg/d; 2 mg IM or IV, repeated in 12 h as needed; do not give more than four doses per day	Adjunctive treatment of parkinsonism, and drug-induced parkinsonism resulting from drug effects of phenothiazines
diphenhydramine (<i>Benadryl</i>)	Adult: 25–50 mg PO t.i.d. to q.i.d.; 10–50 mg IM or IV, maximum dose 400 mg/d Pediatric: 12.5–25 mg PO t.i.d. to q.i.d.; do not exceed 300 mg/d; 5 mg/kg per day IM or IV divided into four equal doses; maximum daily dose 300 mg	Adjunctive agent for treatment of Parkinson disease; treatment of parkinsonism, including drug-induced disease particularly in the elderly and in patients at the early stages of disease
trihexyphenidyl (<i>Artane</i>)	1–2 mg PO daily initially, titrate up to 6–10 mg/d; up to 15 mg/d may be needed	Adjunct to levodopa in treatment of parkinsonism; can be used alone for the control of drug-induced extrapyramidal disorders

Therapeutic Actions and Indications

The anticholinergics used to treat parkinsonism are synthetic drugs that have been developed to have a greater affinity for cholinergic receptor sites in the CNS than for those in the peripheral nervous system. However, they still block, to some extent, the cholinergic receptors that are responsible for stimulation of the parasympathetic nervous system's postganglionic effectors. This blockage is associated with the adverse effects (see Chapter 33), including slowed gastrointestinal (GI) motility and secretions, with dry mouth and constipation, urinary retention, blurred vision, and dilated pupils.

Anticholinergic drugs are indicated for the treatment of parkinsonism, whether idiopathic, atherosclerotic, or postencephalitic, and for the relief of symptoms of extrapyramidal disorders associated with the use of some drugs, including phenothiazines. Although these drugs are not as effective as levodopa in the treatment of advancing cases of the disease, they may be useful as adjunctive therapy and for patients who no longer respond to levodopa. See Table 24.2 for usual indications.

Pharmacokinetics

The anticholinergic drugs are variably absorbed from the GI tract, reaching peak levels in 1 to 4 hours. They are metabolized in the liver and excreted by cellular pathways. All of them cross the placenta and enter breast milk (see contraindications and cautions). Benztropine, diphenhydramine, and biperiden are available in oral and intramuscular/intravenous forms. Trihexyphenidyl is only available in an oral form.

Contraindications and Cautions

Anticholinergics are contraindicated in the presence of allergy to any of these agents *to avoid hypersensitivity reactions*. In addition, they are contraindicated in narrow-angle glaucoma, GI obstruction, genitourinary (GU) obstruction, and prostatic hypertrophy, *all of which could be exacerbated by the peripheral anticholinergic effects of these drugs*, and in myasthenia gravis, *which could be exacerbated by the blocking of acetylcholine-receptor sites at neuromuscular synapses*. The safety and efficacy for use in children have not been established.

Administer these agents cautiously in the following conditions: tachycardia and other dysrhythmias and hypertension or hypotension *because the blocking of the parasympathetic system may cause a dominance of sympathetic stimulatory activity*, and hepatic dysfunction, *which could interfere with the metabolism of the drugs and lead to toxic levels*. They should be used during pregnancy and lactation only if the benefit to the mother clearly outweighs the potential risk to the fetus or neonate. In addition, use caution in individuals who work in hot environments *because reflex*

sweating may be blocked, placing the individuals at risk for heat prostration.

Adverse Effects

The use of anticholinergics for Parkinson disease and parkinsonism is associated with CNS effects that relate to the blocking of central acetylcholine receptors, such as disorientation, confusion, and memory loss. Agitation, nervousness, delirium, dizziness, light-headedness, and weakness may also occur.

Anticipated peripheral anticholinergic effects include dry mouth, nausea, vomiting, paralytic ileus, and constipation related to decreased GI secretions and motility. In addition, other adverse effects may occur, including the tachycardia, palpitations, and hypotension related to the blocking of the suppressive cardiac effects of the parasympathetic nervous system; urinary retention and hesitancy related to a blocking of bladder muscle activity and sphincter relaxation; blurred vision and photophobia related to pupil dilation and blocking of lens accommodation; and flushing and reduced sweating related to a blocking of the cholinergic sites that stimulate sweating and blood vessel dilation in the skin.

Clinically Important Drug–Drug Interactions

When these anticholinergic drugs are used with other drugs that have anticholinergic properties, including the tricyclic antidepressants and the phenothiazines, there is a risk of potentially fatal paralytic ileus and an increased risk of toxic psychoses. If such combinations must be given, monitor patients closely and implement supportive measures. Dose adjustments often are necessary. In addition, when antipsychotic drugs are combined with anticholinergics, a risk for decreased antipsychotic therapeutic effectiveness may occur, possibly as a result of a central antagonism of the two agents.

Prototype Summary: Biperiden

Indications: Adjunctive therapy for Parkinson disease; relief of symptoms of extrapyramidal disorders (parkinsonism) that accompany phenothiazine therapy.

Actions: Acts as an anticholinergic, principally in the CNS, returning balance to the basal ganglia and reducing the severity of rigidity, akinesia, and tremors; peripheral anticholinergic effects help to reduce drooling and other secondary effects of parkinsonism.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	1 h	1–1.5 h	6–12 h
IM	15 min	Unknown	Unknown

$T_{1/2}$: 18.4 to 24.3 hours; metabolized in the liver.

Adverse effects: Disorientation, confusion, memory loss, nervousness, light-headedness, dizziness, depression, blurred vision, mydriasis, dry mouth, constipation, urinary retention, urinary hesitation, flushing, decreased sweating.

Nursing Considerations for Patients Receiving Anticholinergic Agents

Assessment: History and Examination

- Assess for contraindications or cautions: any known allergies to these drugs *to avoid hypersensitivity reactions*; GI depression or obstruction, urinary hesitancy or obstruction, benign prostatic hypertrophy, or glaucoma, *which may be exacerbated by the peripheral anticholinergic effect of the drug*; cardiac arrhythmias, hypertension, or hypotension, *which may be increased due to the dominance of sympathetic stimulatory activity due to blockage of parasympathetic activity*; myasthenia gravis, *which may be exacerbated by blockage of acetylcholine receptors*; current status related to pregnancy or lactation *due to risk of fetal or infant adverse effects*; hepatic dysfunction, *which could interfere with drug metabolism and increase risk for toxicity*; and exposure to a hot environment, *which may block the individual's reflex sweating*.
- Perform a physical assessment *to determine baseline data for determining the effectiveness of the drug and the occurrence of adverse effects associated with drug therapy*.
- Assess level of orientation and neurological status, including affect, reflexes, bilateral grip strength, gait, tremors, and spasticity, *to evaluate any CNS effects*.
- Monitor pulse, blood pressure, and cardiac output *to evaluate for possible adverse effects related to blocking of suppressive action on the heart*.
- Auscultate bowel sounds *to evaluate GI motility and detect possible indications of paralytic ileus*.
- Assess urine output and palpate bladder *to determine adequate renal and bladder function*.
- Monitor the results of laboratory tests such as renal and liver function tests *to determine the need for possible dose adjustment and identify potential toxic effects*.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Impaired oral mucous membranes related to anticholinergic effects
- Risk for impaired thermoregulation related to anticholinergic effects
- Impaired urinary elimination related to GU effects
- Constipation related to GI effects
- Disturbed Thought Processes related to CNS effects
- Risk for Injury related to CNS effects
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Arrange to decrease dose or discontinue the drug *if dry mouth becomes so severe that swallowing becomes difficult*. Provide sugarless lozenges to suck and frequent mouth care to help with this problem.
- Give drug with caution and arrange for a decrease in dose in hot weather or with exposure to hot environments *because patients are at increased risk for heat prostration because of decreased ability to sweat*.
- Give drug with meals if GI upset is a problem, before meals if dry mouth is a problem, and after meals if drooling occurs and the drug causes nausea *to facilitate compliance with drug therapy*.
- Monitor bowel function and institute a bowel program *if constipation is severe*.
- Ensure that the patient voids before taking the drug; monitor urinary output and palpate for bladder distention and residual urine *if urinary retention is a problem*.
- Establish safety precautions if CNS or vision changes occur *to prevent patient injury*.
- Provide thorough patient teaching about topics such as the drug name and prescribed dose, measures to help avoid adverse effects, warning signs that may indicate problems, and the need for periodic monitoring and evaluation *to enhance patient knowledge about drug therapy and to promote compliance*.
- Offer support and encouragement *to help the patient cope with the progressive nature of the disease and long-term drug regimen*.

Evaluation

- Monitor patient response to the drug (improvement in signs and symptoms of Parkinson disease or parkinsonism).
- Monitor for adverse effects (CNS changes, urinary retention, GI slowing, tachycardia, decreased sweating, flushing).
- Evaluate the effectiveness of the teaching plan (patient can give the drug name and dosage, name possible adverse effects to watch for and specific measures to prevent them, and discuss the importance of continued follow-up).
- Monitor the effectiveness of support measures and compliance with the regimen.

KEY POINTS

- ◆ Anticholinergic agents are used to suppress the stimulatory effects of acetylcholine in the substantia nigra, bringing balance into the control of movement.
- ◆ The adverse effects associated with the anticholinergic drugs are related to blocking of the acetylcholine in the parasympathetic nervous system—dry mouth, constipation, urinary retention, increased heart rate, decreased sweating.

TABLE 24.3 DRUGS IN FOCUS Adjunctive Antiparkinsonism Drugs

Drug Name	Dosage/Route	Usual Indications
entacapone (<i>Comtan</i>)	200 mg PO taken with levodopa–carbidopa, maximum of eight doses per day	Adjunctive treatment of idiopathic Parkinson disease with levodopa–carbidopa for patients who are experiencing “wearing off” of drug effects
tolcapone (<i>Tasmar</i>)	100 mg PO t.i.d.; maximum daily dose 600 mg	Adjunctive treatment of idiopathic Parkinson disease with levodopa–carbidopa
selegiline (<i>Carbex, Eldepryl</i>)	5 mg PO b.i.d. (at breakfast and lunch); attempt to decrease levodopa–carbidopa dose after 2–3 d Orally disintegrating tablet: 1.25 mg/d PO with breakfast	Adjunctive treatment of idiopathic Parkinson disease with levodopa–carbidopa in patients whose response to that therapy has decreased

ADJUNCTIVE AGENTS

Adjunctive agents used to improve patient response to traditional therapy include entacapone (*Comtan*), tolcapone (*Tasmar*), and selegiline (*Carbex, Eldepryl*). See Table 24.3 for additional information.

Entacapone is used with carbidopa–levodopa to increase the plasma concentration and duration of action of levodopa. It does this by inhibiting catecholamine-*O*-methyl transferase (COMT), a naturally occurring enzyme that eliminates catecholamines, including dopamine. It is given with the carbidopa–levodopa at a dose of 200 mg PO, with a maximum of eight doses a day. It is readily absorbed from the GI tract, metabolized in the liver, and excreted in urine and feces. Women of childbearing age should be encouraged to use barrier contraceptives while taking this drug, which crosses the placenta and could have adverse effects on the fetus.

Tolcapone works in a similar way with carbidopa–levodopa to further increase plasma levels of levodopa. Tolcapone also blocks the enzyme COMT, which is responsible for the breakdown of dopamine. Because this drug has been associated with fulminant and potentially fatal liver damage, it is contraindicated in the presence of liver disease. Tolcapone is reserved for use in later stages of Parkinson disease, when carbidopa–levodopa is losing its effectiveness. It undergoes hepatic metabolism after GI absorption and is excreted in the urine and feces. It is given in doses of 100 or 200 mg PO three times a day, up to a maximum of 600 mg/d. Women of childbearing age should be encouraged to use barrier contraceptives while taking this drug, which crosses the placenta and could have adverse effects on the fetus.

Selegiline is used with carbidopa–levodopa after patients have shown signs of deteriorating response to this treatment. Its mechanism of action is not understood. It does irreversibly inhibit monoamine oxidase (MAO), which has an important role in the breakdown of catecholamines, including dopamine. It is also approved in a dermal system for the treatment of depression. The maximum daily dose of the drug is 10 mg, and the dose of levodopa needs to be reduced when this drug

is started. It is well absorbed from the GI tract, extensively metabolized in the liver, and excreted in urine. It is not known whether this drug crosses the placenta, but it should be used in pregnancy only if the benefits to the mother clearly outweigh any potential risks to the fetus. Because of the risk of MAO inhibitor–induced hypertensive effects, patients should be urged to immediately report severe headache and any other unusual symptoms that they have not experienced before.

Nursing Considerations for Patients Receiving Adjunctive Agents

Nursing considerations for patients receiving the drugs listed in this section are similar to those for patients receiving the dopaminergic drugs. Details related to each individual drug can be found in the specific drug monograph in your nursing drug guide.

KEY POINTS

- ▶ Adjunctive drugs are used to increase the responsiveness of the cells to dopamine. They act to decrease the breakdown of dopamine, leaving it on the receptor for longer periods of time.
- ▶ Adjunctive drugs are only used in combination with carbidopa–levodopa and are usually reserved for use when the patient stops responding adequately to traditional therapy.

CHAPTER SUMMARY

- Parkinson disease is a progressive, chronic neurological disorder for which there is no cure.
- Loss of dopamine-secreting neurons in the substantia nigra is characteristic of Parkinson disease. Destruction of dopamine-secreting cells leads to an imbalance between excitatory cholinergic cells and inhibitory dopaminergic cells.

- Signs and symptoms of Parkinson disease include tremor, changes in posture and gait, slow and deliberate movements (bradykinesia), and eventually drooling and changes in speech.
- Drug therapy for Parkinson disease is aimed at restoring the dopamine–acetylcholine balance. The signs and symptoms of the disease can be managed until the degeneration of neurons is so extensive that a therapeutic response no longer occurs.
- Anticholinergic drugs are used to block the excitatory cholinergic receptors, and dopaminergic drugs are used to increase dopamine levels or to directly stimulate dopamine receptors.
- Many adverse effects are associated with the drugs used for treating Parkinson disease, including CNS changes, anticholinergic effects when using the anticholinergics (atropine-like or parasympathetic blocking effects), and dopamine stimulation (sympathetic-type effects) in the peripheral nervous system when using the dopaminergics.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-Rom in the front of the book.

MULTIPLE CHOICE

Select the best answer to the following.

1. Parkinson disease is a progressive, chronic neurological disorder that is usually
 - a. associated with severe head injury.
 - b. associated with chronic diseases.
 - c. associated with old age.
 - d. known to affect people of all ages with no known cause.
2. Parkinson disease reflects an imbalance between inhibitory and stimulating activity of nerves in the
 - a. reticular activating system.
 - b. cerebellum.
 - c. basal ganglia.
 - d. limbic system.
3. The main underlying problem with Parkinson disease seems to be a decrease in the neurotransmitter
 - a. acetylcholine.
 - b. norepinephrine.
 - c. dopamine.
 - d. serotonin.
4. Anticholinergic drugs are effective in early Parkinson disease. They act
 - a. to block stimulating effects of acetylcholine in the brain to bring activity back into balance.
 - b. to block the signs and symptoms of the disease, making it more acceptable.
 - c. to inhibit dopamine effects in the brain and increase neuron activity
 - d. to increase the effectiveness of the inhibitory neurotransmitter GABA.
5. A patient receiving an anticholinergic drug for Parkinson disease is planning a winter trip to Tahiti. The temperature in Tahiti is 70 degrees warmer than at home. What precautions should the patient be urged to take?
 - a. Take the drug with plenty of water to stay hydrated.
 - b. Reduce dose and take precautions to reduce the risk for heat stroke.
 - c. Wear sunglasses and use sunscreen because of photophobia that will develop.
 - d. Avoid drinking the water to prevent gastric distress.
6. Replacing dopamine in the brain would seem to be the best treatment for Parkinson disease. This is difficult because dopamine
 - a. is broken down in gastric acid.
 - b. is not available in drug form.
 - c. cannot cross the blood–brain barrier.
 - d. is used peripherally before reaching the brain.

7. A patient taking levodopa and over-the-counter megavitamins might experience
 - a. cure from Parkinson disease.
 - b. return of Parkinson symptoms
 - c. improved health and well-being.
 - d. a resistance to viral infections.
8. A patient who has been diagnosed with Parkinson disease for many years and whose symptoms were controlled using *Sinemet* has started to exhibit increasing signs of the disease. Possible treatment might include
 - a. increased exercise program.
 - b. addition of diphenhydramine to the drug regimen.
 - c. combination therapy with an anticholinergic drug.
 - d. changes in diet to eliminate vitamin B₆.

MULTIPLE RESPONSE

Select all that apply.

1. A client asks the nurse to explain parkinsonism to him. Which of the following possible causes of parkinsonism might be included in the explanation?
 - a. Adverse effect of drug therapy
 - b. Brain injury

- c. Viral infection
- d. Dementia
- e. Bacterial infection
- f. Birth defect

2. No therapy is available that will stop the loss of neurons and the eventual decline of function in clients with Parkinson disease. As a result, nursing care should involve which of the following interventions?
 - a. Regular exercises to slow loss of function
 - b. Supportive education as drugs fail and new therapy is needed
 - c. Community and family support networking
 - d. Discontinuation of drug therapy to test for a cure
 - e. Special vitamin therapy to slow the loss of the neurons
 - f. Explanations of the adjunctive drug therapy that may be used

Muscle Relaxants

25

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Describe a spinal reflex and discuss the pathophysiology of muscle spasm and muscle spasticity.
2. Describe the therapeutic actions, indications, pharmacokinetics, contraindications, most common adverse reactions, and important drug–drug interactions associated with the centrally acting and the direct-acting skeletal muscle relaxants.
3. Discuss the use of muscle relaxants across the lifespan.
4. Compare and contrast the prototype drugs baclofen and dantrolene with other muscle relaxants in their classes.
5. Outline the nursing considerations, including important teaching points for patients receiving muscle relaxants as adjunct to anesthesia.

Glossary of Key Terms

basal ganglia: lower area of the brain, associated with coordination of unconscious muscle movements that involve movement and position

cerebellum: lower portion of the brain, associated with coordination of muscle movements, including voluntary motion, as well as extrapyramidal control of unconscious muscle movements

extrapyramidal tract: cells from the cortex and subcortical areas, including the basal ganglia and the cerebellum, which coordinate unconsciously controlled muscle activity; allows the body to make automatic adjustments in posture or position and balance

hypertonia: state of excessive muscle response and activity

interneuron: neuron in the CNS that communicates with other neurons, not with muscles or glands

pyramidal tract: fibers within the CNS that control precise, intentional movement

spasticity: sustained muscle contractions

spindle gamma loop system: simple reflex arcs that involve sensory receptors in the periphery that respond to stretch and spinal motor nerves and cause muscle fiber contraction; responsible for maintaining muscle tone and keeping an upright position against the pull of gravity

CENTRALLY ACTING SKELETAL MUSCLE RELAXANTS

baclofen
carisoprodol
chlorzoxazone

metaxalone
methocarbamol
orphenadrine
tizanidine

DIRECT-ACTING SKELETAL MUSCLE RELAXANTS

botulinum toxin type A
botulinum toxin type B
dantrolene

Many injuries and accidents result in local damage to muscles or the skeletal anchors of muscles. These injuries may lead to muscle spasm and pain, which may be of long duration and may interfere with normal functioning. Damage to central nervous system (CNS) neurons may cause a permanent state of muscle **spasticity**—sustained muscle contractions—as a result of loss of nerves that help to maintain balance in controlling muscle activity.

Neuron damage, whether temporary or permanent, may be treated with skeletal muscle relaxants. Most skeletal muscle relaxants work in the brain and spinal cord, where they interfere with the cycle of muscle spasm and pain. However, the botulinum toxins and dantrolene enter muscle fibers directly. See Box 25.1 for discussion of the use of these muscle relaxants in various age groups.

NERVES AND MOVEMENT

Posture, balance, and movement are the result of a constantly fluctuating sequence of muscle contraction and relaxation. The nerves that regulate these actions are the spinal motor

neurons. These neurons are influenced by higher-level brain activity in the lower areas of the brain, the **cerebellum** (associated with conscious muscle movements) and **basal ganglia** (associated with unconscious muscle movements). This brain activity provides coordination of contractions, and the cerebral cortex allows conscious thought to regulate movement.

Spinal Reflexes

The spinal reflexes are the simplest nerve pathways that monitor movement and posture (Figure 25.1). Spinal reflexes can be simple, involving an incoming sensory neuron and an outgoing motor neuron, or more complex, involving **interneurons** that communicate with the related centers in the brain. Simple reflex arcs involve sensory receptors in the periphery and spinal motor nerves. Such reflex arcs make up what is known as the **spindle gamma loop system**; they respond to stretch receptors or spindles on muscle fibers to cause a muscle fiber contraction that relieves the stretch. In this system, nerves from stretch receptors form a synapse with gamma nerves in the spinal cord, which send an impulse to the stretched muscle fibers to stimulate their contraction. These reflexes are

BOX 25.1 *Drug Therapy Across the Lifespan*

Skeletal Muscle Relaxants

CHILDREN

The safety and effectiveness of most of these drugs have not been established in children. If a child older than 12 years of age requires a skeletal muscle relaxant after an injury, metaxalone has an established pediatric dosage. Other agents have been used, with adjustments to the adult dosage based on the child's age and weight.

Baclofen is often used to relieve the muscle spasticity associated with cerebral palsy. A caregiver needs intensive education in the use of the intrathecal infusion pump and how to monitor the child for therapeutic as well as adverse effects.

Methocarbamol is the drug of choice if a child needs to be treated for tetanus.

Dantrolene is used to treat upper motor neuron spasticity in children. The dosage is based on body weight and increases over time. The child should be screened regularly for central nervous system (CNS) and gastrointestinal (including hepatic) toxicity.

ADULTS

Adults being treated for acute musculoskeletal pain should be cautioned to avoid driving and to take safety precautions against injury because of the related CNS effects, including dizziness and drowsiness.

Adults complaining of muscle spasm pain that may be related to anxiety often respond very effectively to diazepam, which is a muscle relaxant and anxiolytic.

Women of childbearing age should be advised to use contraception when they are taking these drugs. If a preg-

nancy does occur, or is desired, they need counseling about the potential for adverse effects. Women who are nursing should be encouraged to find another method of feeding the baby because of the potential for adverse drug effects on the baby.

Perimenopausal women are also at increased risk for the hepatotoxicity associated with dantrolene and should be monitored very closely for any change in hepatic function and given written information about the prodrome syndrome that often occurs with the hepatic toxicity.

OLDER ADULTS

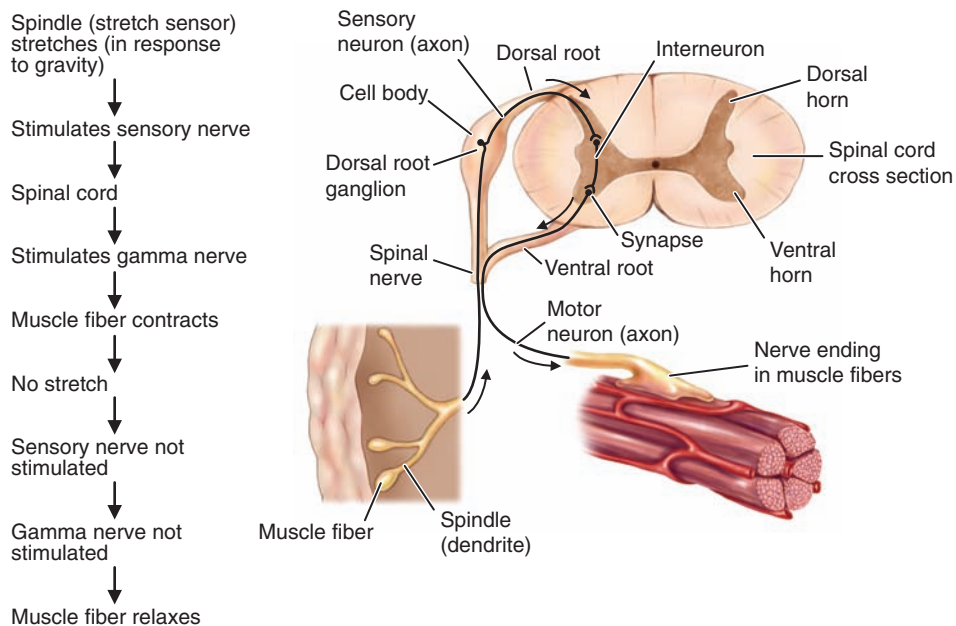

Older patients are more likely to experience the adverse effects associated with these drugs—CNS, gastrointestinal, and cardiovascular. Because older patients often also have renal or hepatic impairment, they are also more likely to have toxic levels of the drug related to changes in metabolism and excretion.

Carisoprodol is the centrally acting skeletal muscle relaxant of choice for older patients and for those with hepatic or renal impairment.

If dantrolene is required for an older patient, lower doses and more frequent monitoring are needed to assess for potential cardiac, respiratory, and liver toxicity.

Older women who are receiving hormone replacement therapy are at the same risk for development of hepatotoxicity as premenopausal women and should be monitored accordingly.

Relaxed muscle fiber

● **FIGURE 25.1** Reflex arc showing the pathway of impulses. The spindle gamma loop reflex arc: The relaxing and contracting of muscle fibers causes muscle tone and ability to stand upright and promotes venous return.

responsible for maintaining muscle tone and keeping an upright position against the pull of gravity and are important in helping venous return when the contracting muscle fibers massage veins to help move the blood toward the heart. Other spinal reflexes may involve synapses with interneurons within the spinal cord, which adjust movement and response based on information from higher brain centers to coordinate movement and position.

Brain Control

Many areas within the brain influence the spinal motor nerves. Areas of the brainstem, the basal ganglia, and the cerebellum modulate spinal motor nerve activity and help to coordinate activity among various muscle groups, thereby allowing coordinated movement and control of body muscle motions. Nerve areas within the cerebral cortex allow conscious, or intentional, movement. Nerves within the cortex send signals down the spinal cord, where they cross to the opposite side of the spinal cord before sending out nerve impulses to cause muscle contraction. In this way, each side of the cortex controls muscle movement on the opposite side of the body.

Different fibers control different types of movements. Those fibers that control precise, intentional movement make up the **pyramidal tract** within the CNS. The **extrapyramidal tract** is composed of cells from the cerebral cortex, as well as those from several subcortical areas, including the basal ganglia and the cerebellum. This tract modulates or coordinates unconsciously controlled muscle activity, and it allows the body to make automatic adjustments in posture or position and balance. The extrapyramidal tract controls lower-level, or crude, movements.

NEUROMUSCULAR ABNORMALITIES

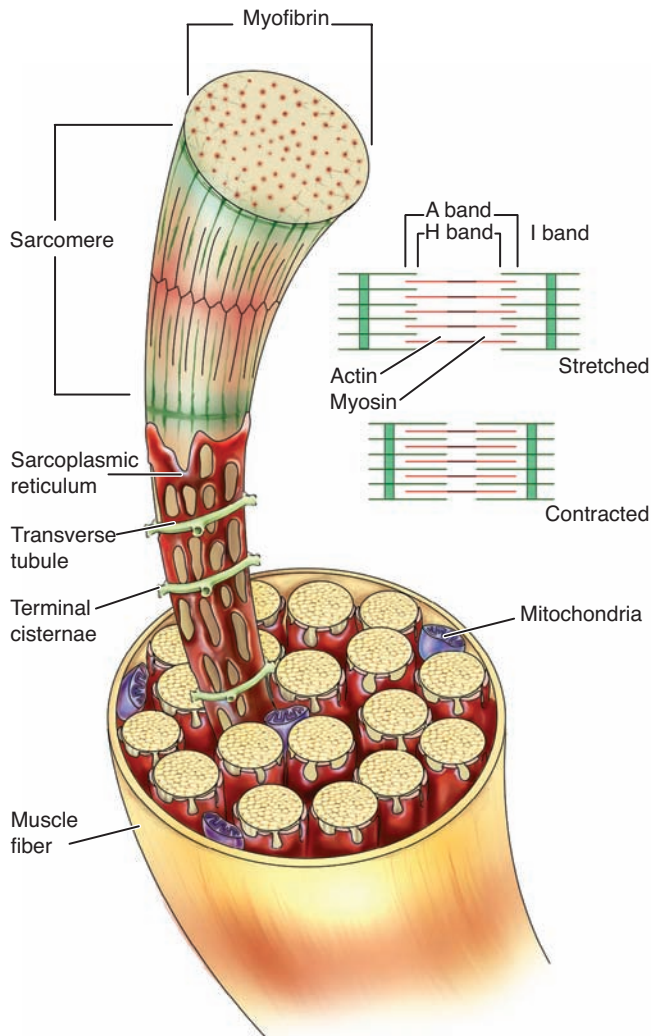

All of the areas mentioned work together to allow for a free flow of impulses into and out of the CNS to coordinate posture, balance, and movement. When injuries, diseases, and toxins affect the normal flow of information into and out of the CNS motor pathways, many clinical signs and symptoms may develop, ranging from simple muscle spasms to spasticity—or sustained muscle spasm—and paralysis.

Muscle Spasm

Muscle spasms often result from injury to the musculoskeletal system—for example, overstretching a muscle, wrenching a joint, or tearing a tendon or ligament. These injuries can cause violent and painful involuntary muscle contractions. It is thought that these spasms are caused by the flood of sensory impulses coming to the spinal cord from the injured area. These impulses can be passed through interneurons to spinal motor nerves, which stimulate an intense muscle contraction. The contraction cuts off blood flow to the muscle fibers in the injured area, causing lactic acid to accumulate and resulting in pain. The new flood of sensory impulses caused by the pain may lead to further muscle contraction, and a vicious cycle may develop (Figure 25.2).

Muscle Spasticity

Muscle spasticity is the result of damage to neurons within the CNS rather than injury to peripheral structures. Because the spasticity is caused by nerve damage in the CNS, it is a permanent condition. Spasticity may result from an increase

● **FIGURE 25.2** When stimulation stops, calcium ions are actively transported back into the sarcoplasmic reticulum, resulting in decreased calcium ions in the sarcoplasm. The removal of calcium ions restores the inhibitory action of troponin–tropomyosin; cross-bridge action is impossible in this state.

in excitatory influences or a decrease in inhibitory influences within the CNS. The interruption in the balance among all of these higher influences within the CNS may lead to excessive stimulation of muscles, or **hypertonia**, in opposing muscle groups at the same time, a condition that may cause contractions and permanent structural changes. This control imbalance also results in a loss of coordinated muscle activity.

For example, the signs and symptoms of cerebral palsy and paraplegia are related to the disruption in the nervous control of the muscles. The exact presentation of any chronic neurological disorder depends on the specific nerve centers and tracts that are damaged and how the control imbalance is manifested.

KEY POINTS

- ◆ Movement and muscle control are regulated by spinal reflexes and the upper CNS, including the basal ganglia, cerebellum, and cerebral cortex.

- ◆ Spinal reflexes can be simple, involving an incoming sensory neuron and an outgoing motor neuron, or more complex, involving interneurons that communicate with the related centers in the brain.
- ◆ The pyramidal tract in the cerebellum coordinates intentional muscle movement, and the extrapyramidal tract in the cerebellum and basal ganglia coordinates involuntary muscle activity.
- ◆ Muscle or skeletal damage may send a multitude of stimuli to the spinal cord and result in muscle spasms or extended contraction.
- ◆ Damaged motor neurons can cause muscle spasticity and impaired movement and coordination.

CENTRALLY ACTING SKELETAL MUSCLE RELAXANTS

Centrally acting skeletal muscle relaxants (Table 25.1) include baclofen (*Lioresal*), carisoprodol (*Soma*), chlorzoxazone (*Paraflex*), cyclobenzaprine (*Flexeril*, *Amrix*), metaxalone (*Skelaxin*), methocarbamol (*Robaxin*), orphenadrine (*Banflex*, *Flexoject*), and tizanidine (*Zanaflex*). Diazepam (*Valium*), a drug widely used as an anxiety agent (see Chapter 20), also has been shown to be an effective centrally acting skeletal muscle relaxant. It may be advantageous in situations in which anxiety may be precipitating the muscle spasm.

Other measures in addition to these drugs should be used to alleviate muscle spasm and pain. Such modalities as rest of the affected muscle, heat applications to increase blood flow to the area to remove the pain-causing chemicals, physical therapy to return the muscle to normal tone and activity, and anti-inflammatory agents (including nonsteroidal anti-inflammatory drugs [NSAIDs]) if the underlying problem is related to injury or inflammation may help (Box 25.2).

Therapeutic Actions and Indications

The centrally acting skeletal muscle relaxants work in the CNS to interfere with the reflexes that are causing the muscle spasm. Because these drugs lyse or destroy spasm, they are often referred to as spasmolytics. Although the exact mechanism of action of these skeletal muscle relaxants is not known, it is thought to involve action in the upper or spinal interneurons. Tizanidine is an alpha-adrenergic agonist and is thought to increase inhibition of presynaptic motor neurons in the CNS. The primary indication for the use of centrally acting skeletal muscle agents is the relief of discomfort associated with acute, painful musculoskeletal conditions as an adjunct to rest, physical therapy, and other measures. Because these drugs work in the upper levels of the CNS, possible depression must be anticipated with their use. See Table 25.1 for usual indications for each of these agents.

Pharmacokinetics

Baclofen is available in oral and intrathecal forms and can be administered via a delivery pump for the treatment of central

TABLE 25.1 DRUGS IN FOCUS Centrally Acting Skeletal Muscle Relaxants

Drug Name	Dosage/Route	Usual Indications
 baclofen (<i>Lioresal</i>)	Adult: 40–80 mg PO daily, 12–1500 mcg/d per intrathecal infusion pump Pediatric: intrathecal infusion pump, 24–1199 mcg/day—base dose on patient response	Treatment of muscle spasticity associated with neuromuscular diseases such as multiple sclerosis, muscle rigidity, and spinal cord injuries
carisoprodol (<i>Soma</i>)	350 mg PO t.i.d. to q.i.d.	Relief of discomfort of acute musculoskeletal conditions in adults
chlorzoxazone (<i>Paraflex</i>)	250 mg PO t.i.d. to q.i.d.	Relief of discomfort of acute musculoskeletal conditions in adults
cyclobenzaprine (<i>Flexeril</i>)	10 mg PO t.i.d., do not exceed 60 mg/d	Relief of discomfort of acute musculoskeletal conditions in adults
metaxalone (<i>Skelaxin</i>)	Adults and children >12 yr: 800 mg PO t.i.d. to q.i.d.; reduce dose with hepatic impairment	Relief of discomfort of acute musculoskeletal conditions; one of the few skeletal muscle relaxants with an established pediatric dose for children >12 yr
methocarbamol (<i>Robaxin</i>)	Adult: 1.5 g PO q.i.d., up to 30–60 mg/d; 1–2 g IV or IM for tetanus Pediatric: 15 mg/kg IV for tetanus; 0.4 mg/kg per day PO initially; maintenance 0.2 mg/kg per day	Relief of discomfort of acute musculoskeletal conditions in adults; treatment of tetanus in children to alleviate signs and symptoms of tetanus
orphenadrine (<i>Banflex, Flexoject</i>)	100 mg PO, AM and at bedtime, or 60 mg IV or IM q12h	Relief of discomfort of acute musculoskeletal conditions in adults; under investigation for relief of quinidine-induced leg cramps
tizanidine (<i>Zanaflex</i>)	8 mg PO as a single dose may be repeated q6–8h as needed	Relief of discomfort of acute musculoskeletal conditions in adults; provides acute and intermittent management of increased muscle tone associated with spasticity

spasticity. Cyclobenzaprine is available in a controlled release form for continual control of the discomfort without repeated dosings. Methocarbamol is available in both oral and parenteral forms. Most of these agents are rapidly absorbed and metabolized in the liver. Baclofen is not metabolized, but like the other skeletal muscle relaxants, it is excreted in the urine.

Contraindications and Cautions

Centrally acting skeletal muscle relaxants are contraindicated in the presence of any known allergy to any of these

drugs and with skeletal muscle spasms resulting from rheumatic disorders. In addition, baclofen should not be used to treat any spasticity that contributes to locomotion, upright position, or increased function. *Blocking this spasticity results in loss of these functions.* All centrally acting skeletal muscle relaxants should be used cautiously in the following circumstances: with a history of epilepsy *because the CNS depression and imbalance caused by these drugs may exacerbate the seizure disorder*; with cardiac dysfunction *because muscle function may be depressed*; with any condition marked by muscle weakness, *which the drugs*

BOX 25.2 Fixed-Combination Centrally Acting Skeletal Muscle Relaxants

Some products are available that combine a centrally acting muscle relaxant with an anti-inflammatory or analgesic agent. These products tend to facilitate relief of the discomfort associated with acute painful musculoskeletal conditions. They should be used as adjuncts to rest, physical therapy, and other measures.

Drug Name	Composition	Dosage
<i>Soma Compound, Sodol compound</i>	200 mg carisoprodol/325 mg aspirin	1–2 tablets PO q.i.d.
<i>Soma Compound with codeine</i>	200 mg carisoprodol/325 mg aspirin/16 mg codeine	1–2 tablets PO q.i.d.
<i>Flexaphen</i> ^a	250 mg chlorzoxazone/300 mg acetaminophen	2 capsules PO q.i.d.
<i>Lobac</i> ^a	200 mg salicylamide/20 mg phenyltoloxamine/300 mg acetaminophen	2 capsules PO q.i.d.
<i>Norgesic</i> ^a	25 mg orphenadrine/385 mg aspirin/30 mg caffeine	1–2 tablets PO t.i.d. to q.i.d.
<i>Norgesic Forte</i> ^a	50 mg orphenadrine/770 mg aspirin/60 mg caffeine	1 tablet PO t.i.d. to q.i.d.

^a Rated by the U.S. Food and Drug Administration as “possibly effective” for this indication.

could make much worse; and with hepatic or renal dysfunction (especially with metaxalone and tizanidine), which could interfere with the metabolism and excretion of the drugs, leading to toxic levels. Carisoprodol may be safer than the other spasmolytics in older patients and in patients with renal or hepatic dysfunction. No good studies exist regarding the effects of these agents during pregnancy and lactation; therefore, use should be limited to those situations in which the benefit to the mother clearly outweighs any potential risk to the fetus or neonate.

Adverse Effects

The most frequently seen adverse effects associated with these drugs relate to the associated CNS depression: drowsiness, fatigue, weakness, confusion, headache, and insomnia. Gastrointestinal (GI) disturbances, which may be linked to CNS depression of the parasympathetic reflexes, include nausea, dry mouth, anorexia, and constipation. In addition, hypotension and arrhythmias may occur, again as a result of depression of normal reflex arcs. Urinary frequency, enuresis, and feelings of urinary urgency reportedly may occur. Chlorzoxazone may discolor the urine, becoming orange to purple-red when metabolized and excreted. Patients should be warned about this effect to prevent any fears of blood in the urine. Tizanidine has been associated with liver toxicity and hypotension in some patients.

Clinically Important Drug–Drug Interactions

If any of the centrally acting skeletal muscle relaxants are taken with other CNS depressants or alcohol, CNS depression may increase. Patients should be cautioned to avoid alcohol while taking these muscle relaxants; if this combination cannot be avoided, they should take extreme precautions.

Prototype Summary: Baclofen

Indications: Alleviation of signs and symptoms of spasticity; may be of use in spinal cord injuries or spinal cord diseases.

Actions: Gamma-aminobutyric acid (GABA) analogue; exact mechanism of action is not understood; inhibits monosynaptic and polysynaptic spinal reflexes; CNS depressant.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	1 h	2 h	4–8 h
Intrathecal	30–60 min	4 h	4–8 h

$T_{1/2}$: 3 to 4 hours; not metabolized; excreted in the urine.

Adverse effects: Transient drowsiness, dizziness, weakness, fatigue, constipation, headache, insomnia, hypotension, nausea, urinary frequency.

Nursing Considerations for Patients Receiving Centrally Acting Skeletal Muscle Relaxants

Assessment: History and Examination

- Assess for *contraindications or cautions for the use of the drug*, including any known allergies, *to prevent hypersensitivity reactions*; cardiac depression, epilepsy, muscle weakness, or rheumatic disorder, *which could be exacerbated by the effects of these drugs*; pregnancy or lactation, *which would be contraindications to use of the drugs*; and renal or hepatic dysfunction, *which alter metabolism and excretion of the drugs*.
- Assess temperature; skin color and lesions; CNS orientation, affect, reflexes, bilateral grip strength, and spasticity evaluation; bowel sounds and reported output; and liver and renal function tests *to determine baseline status before beginning therapy and for any potential adverse effects*.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to GI and CNS effects
- Disturbed Thought Processes related to CNS effects
- Risk for Injury related to CNS effects
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Provide additional measures to relieve discomfort—heat, rest for the muscle, NSAIDs, positioning— *to augment the effects of the drug at relieving the musculoskeletal discomfort*.
- Discontinue drug at any sign of hypersensitivity reaction or liver dysfunction *to prevent severe toxicity*.
- If using baclofen, taper the drug slowly over 1 to 2 weeks *to prevent the development of psychoses and hallucinations*. Use baclofen cautiously in patients whose spasticity contributes to mobility, posture, or balance *to prevent loss of this function*.
- If patient is receiving baclofen through a delivery pump, the patient should understand the pump, the reason for frequent monitoring, and how to adjust the dose and program the unit *to enhance patient knowledge and promote compliance*.
- Monitor respiratory status *to evaluate adverse effects and arrange for appropriate dose adjustment or discontinuation of the drug*.
- Provide thorough patient teaching, including drug name, prescribed dosage, measures for avoidance of adverse effects, warning signs that may indicate possible problems, and the need for monitoring and evaluation *to enhance patient knowledge about drug therapy and to promote compliance*.
- Offer support and encouragement *to help the patient cope with the drug regimen*.

Evaluation

- Monitor patient response to the drug (improvement in muscle spasm and relief of pain; improvement in muscle spasticity).
- Monitor for adverse effects (CNS changes, GI depression, urinary urgency).
- Evaluate the effectiveness of the teaching plan (patient can give the drug name and dosage, name possible adverse effects to watch for and specific measures to prevent them, and describe, if necessary, proper intrathecal administration).
- Monitor the effectiveness of comfort measures and compliance with the regimen.

KEY POINTS

- ▶ The centrally acting skeletal muscle relaxants interfere with the reflexes that are causing the muscle spasm
- ▶ The centrally acting skeletal muscle relaxants cause central CNS depression, and the adverse effects associated with them are related to the CNS depression (insomnia, dizziness, confusion, anticholinergic effects).
- ▶ The centrally acting muscle relaxants are used for the relief of discomfort associated with acute, painful musculoskeletal conditions as an adjunct to rest, physical therapy, and other measures

DIRECT-ACTING SKELETAL MUSCLE RELAXANTS

The direct-acting skeletal muscle relaxants enter the muscle to prevent muscle contraction directly. Direct-acting skeletal muscle relaxants (Table 25.2) include dantrolene (*Dantrium*), botulinum toxin type A (*Botox Cosmetic*), and botulinum toxin type B (*Myobloc*).

Therapeutic Actions and Indications

Dantrolene directly affects peripheral muscle contraction and has become important in the management of spasticity associated with neuromuscular diseases. Dantrolene acts within skeletal muscle fibers, interfering with the release of calcium from the muscle tubules (see Figure 25.2). This action prevents the fibers from contracting. Dantrolene does not interfere with neuromuscular transmissions, and it does not affect the surface membrane of skeletal muscle. The botulinum toxins A and B bind directly to the receptor sites of motor nerve terminals and inhibit the release of acetylcholine, leading to local muscle paralysis. These two drugs are injected locally and used to paralyze or prevent the contractions of specific muscle groups.

Long-term use of dantrolene commonly results in a decrease of the amount and intensity of required nursing care. Continued long-term use is justified as long as the drug reduces painful and disabling spasticity. This agent is not used for the treatment of muscle spasms associated with musculoskeletal injury or

TABLE 25.2 DRUGS IN FOCUS Direct-Acting Skeletal Muscle Relaxants

Drug Name	Dosage/Route	Usual Indications
botulinum toxin type A (<i>Botox Cosmetic</i>)	Adult: 20 units (0.5 mL solution) injected as divided doses of 0.1 mL (4 units) into each of five sites (two in each corrugator muscle and one in the procerus muscle) repeated every 3–4 mo; local injection associated with particular disorder—see manufacturer's guidelines	Improvement of appearance in glabellar (frown) lines associated with corrugator or procerus muscle activity in adults; treatment of cervical dystonia; approved in 2004 for treatment of strabismus and blepharospasm associated with dystonia in patients ≥ 12 yr of age; treatment of severe primary axillary hyperhidrosis (sweating) when injected into the axillary area
botulinum toxin type B (<i>Myobloc</i>)	2500–5000 units IM injected locally into affected muscles	Reduction of severity of abnormal head position and neck pain associated with cervical dystonia
 dantrolene (<i>Dantrium</i>)	Adult: initially 25 mg PO; increase based on spinal cord injuries; prevention and management of response to a maximum 400 mg/d for spasticity Prevention of malignant hyperthermia: 4–8 mg/kg per day PO for 1–2 d before surgery, or 2.5 mg/kg IV over 1 h, given 1 h before surgery; postcrisis, 4–8 mg/kg per day PO for 1–3 d Pediatric: initially 0.5 mg/kg per day PO b.i.d., titrate to a maximum 100 mg PO q.i.d. for spasticity; for malignant hyperthermia, follow adult dose	Management of upper motor neuron–associated muscle spasticity such as spinal cord injury, myasthenia gravis, cerebral palsy, multiple sclerosis, muscular dystrophy, polio, tetanus, quadriplegia, and amyotrophic lateral sclerosis (ALS); prevention or treatment of malignant hyperthermia—a state of intense muscle contraction and resulting hyperpyrexia; used orally as preoperative prophylaxis in susceptible patients who must undergo anesthesia and after acute episodes to prevent recurrence

rheumatic disorders. Table 25.2 presents additional information about these agents, including usual indications.

Pharmacokinetics

Dantrolene is used in oral or parenteral forms. Dantrolene is slowly absorbed from the GI tract and metabolized in the liver with a half-life of 4 to 8 hours. Excretion is through the urine. Dantrolene crosses the placenta and was found to be embryotoxic in animal studies. Use should be reserved for those situations in which the benefit to the mother clearly outweighs the risk to the fetus. Dantrolene enters breast milk and is contraindicated for use during lactation. Safety for use in children younger than 5 years of age has not been established; because the long-term effects are not known, careful consideration should be given to use of the drug in children.

The botulinum toxins are not generally absorbed systemically, and there is no pharmacokinetic information available.

Contraindications and Cautions

Dantrolene is contraindicated in the presence of any known allergy to the drug. It is also contraindicated in the following conditions: spasticity that contributes to locomotion, upright position, or increased function, *which would be lost if that spasticity were blocked*; active hepatic disease, *which might interfere with metabolism of the drug and because of known liver toxicity*; and lactation *because the drug may cross into breast milk and cause adverse effects in the infant*. The botulinum toxins are contraindicated in the presence of allergy to any component of the drug or with active infection at the site of the injection *because injecting the drug could aggravate the infection*.

Caution should be used with dantrolene in the following circumstances: in women and in all patients older than 35 years *because of increased risk of potentially fatal hepatocellular disease* (Box 25.3); in patients with a history of liver disease or previous dysfunction, *which could make the liver more susceptible to cellular toxicity*; in patients with respiratory depression, *which could be exacerbated by muscular weakness*; in patients with cardiac disease *because cardiac muscle depression may be a risk*; and during pregnancy *because of the potential for adverse effects on the fetus*. Caution should be used with the botulinum toxins with any peripheral neuropathic disease; with neuromuscular disorders, *which could be exacerbated by the effects of the drug*; with pregnancy and lactation; and with any known cardiovascular disease.

Adverse Effects

The most frequently seen adverse effects associated with dantrolene relate to drug-caused CNS depression: drowsiness, fatigue, weakness, confusion, headache and insomnia, and visual disturbances. GI disturbances may be linked to direct irritation or to alterations in smooth muscle function caused by the drug-induced calcium effects. Such adverse GI effects

FOCUS ON BOX 25.3 Gender Considerations

Understanding the Risks of Liver Damage With Dantrolene

Dantrolene (*Dantrium*) is associated with potentially fatal hepatocellular injury. When liver damage begins to occur, patients often experience a prodrome, or warning syndrome, which includes anorexia, nausea, and fatigue. The incidence of such hepatic injury is greater in women and in patients older than 35 years of age.

In women, a combination of dantrolene and estrogen seems to affect the liver, thus posing a greater risk. Women of all ages may be at increased risk, because those entering menopause may be taking hormone replacement therapy. Patients older than 35 years of age are at increasing risk of liver injury because of the changing integrity of the liver cells that comes with age and exposure to toxins over time.

If a particular woman needs dantrolene for relief of spasticity, she should not be taking any estrogens (e.g., birth control pills, hormone replacement therapy), and she should be monitored closely for any sign of liver dysfunction. For safer relief of spasticity in these patients, baclofen may be helpful.

may include GI irritation, diarrhea, constipation, and abdominal cramps. Dantrolene may also cause direct hepatocellular damage and hepatitis that can be fatal. Urinary frequency, enuresis, and feelings of urinary urgency reportedly occur, and crystalline urine with pain or burning on urination may result. In addition, several unusual adverse effects may occur, including acne, abnormal hair growth, rashes, photosensitivity, abnormal sweating, chills, and myalgia.

The botulinum toxins have been associated with anaphylactic reactions; with headache, dizziness, muscle pain, and paralysis; and with redness and edema at the injection site. Adverse effects associated with use of botulinum toxin type A for cosmetic purposes include headache, respiratory infections, flu-like syndrome, and droopy eyelids in severe cases. Pain, redness, and muscle weakness also have been reported. The reactions tended to be temporary, but there have been reports of reactions that lasted several months. The U.S. Food and Drug Administration (FDA) strongly reminds providers that this is a prescription drug and should be used only under close medical supervision and not injected at trendy “Botox parties.”

Clinically Important Drug–Drug Interactions

If dantrolene is combined with estrogens, the incidence of hepatocellular toxicity is apparently increased. If possible, this combination should be avoided. If the botulinum toxins are used with other drugs that interfere with neuromuscular transmission—neuromuscular junction (NMJ) blockers, lincosamides, quinidine, magnesium sulfate, anticholinesterases, succinylcholine, or polymyxin—or with aminoglycosides, there is a risk of additive effects. If any of these must be given in combination, extreme caution should be used.

P Prototype Summary: *Dantrolene*

Indications: Control of clinical spasticity resulting from upper motor neuron disorders; preoperatively to prevent or attenuate the development of malignant hyperthermia in susceptible patients; IV for management of fulminant malignant hyperthermia.

Actions: Interferes with the release of calcium from the sarcoplasmic reticulum within skeletal muscles, preventing muscle contraction; does not interfere with neuromuscular transmission.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	Slow	4–6 h	8–10 h
IV	Rapid	5 h	6–8 h

T_{1/2}: 9 hours (oral), 4 to 8 hours (IV); excreted in the urine.

Adverse effects: Drowsiness, dizziness, weakness, fatigue, diarrhea, hepatitis, myalgia, tachycardia, transient blood pressure changes, rash, urinary frequency.

Nursing Considerations for Patients Receiving a Direct-Acting Skeletal Muscle Relaxant

Assessment: History and Examination

- Assess for *contraindications or cautions for the use of the drug* including any known allergies *to prevent hypersensitivity reactions*; cardiac depression; epilepsy; muscle weakness; respiratory depression, *which could be exacerbated by the effects of these drugs*; pregnancy and lactation, *which require cautious use*; renal or hepatic dysfunction, *which could alter the metabolism and excretion of the drug*; and local infections (if using botulinum toxins) *to prevent exacerbation of the infections*.
- Assess temperature; skin color and lesions; CNS orientation, affect, reflexes, bilateral grip strength, and spasticity; respiration and adventitious sounds; pulse, electrocardiogram (ECG), and cardiac output; bowel sounds and reported output; and liver and renal function tests *to determine baseline status before beginning therapy and for any potential adverse effects*.

Refer to the *Critical Thinking Scenario* for a full discussion of nursing care for a patient who is receiving a direct-acting skeletal muscle relaxant.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to GI and CNS effects
- Disturbed Thought Processes related to CNS effects

- Risk for Injury related to CNS effects
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Discontinue the drug at any sign of liver dysfunction. *Early diagnosis of liver damage may prevent permanent dysfunction. Arrange for the drug to be discontinued if signs of liver damage appear.* A prodrome, with nausea, anorexia, and fatigue, is present in 60% of patients with evidence of hepatic injury.
- Do not administer botulinum toxins into any area with an active infection *because of the risk of exacerbation of the infection*.
- Monitor intravenous access sites for potential extravasation *because the drug is alkaline and very irritating to tissues*.
- Institute other supportive measures (e.g., ventilation, anticonvulsants as needed, cooling blankets) for the treatment of malignant hyperthermia *to support the patient through the reaction*.
- Periodically discontinue the drug for 2 to 4 days *to monitor therapeutic effectiveness*. A clinical impression of exacerbation of spasticity indicates a positive therapeutic effect and justifies continued use of the drug.
- Establish a therapeutic goal before beginning oral therapy (e.g., to gain or enhance the ability to engage in a therapeutic exercise program; to use braces; to accomplish transfer maneuvers) *to promote patient compliance and a sense of success with therapy*.
- Discontinue the drug if diarrhea becomes severe *to prevent dehydration and electrolyte imbalance*. The drug may be restarted at a lower dose.
- Provide thorough patient teaching, including drug name, prescribed dosage, measures for avoidance of adverse effects, warning signs that may indicate possible problems, and the need for monitoring and evaluation *to enhance patient knowledge about drug therapy and to promote compliance*.
- Offer support and encouragement to help the patient cope with the drug regimen.

Evaluation

- Monitor patient response to the drug (improvement in spasticity, improvement in movement and activities; improvement in dystonia, facial lines, sweating with botulinum toxins).
- Monitor for adverse effects (CNS changes, diarrhea, liver toxicity, urinary urgency).
- Evaluate the effectiveness of the teaching plan (patient can give the drug name and dosage, possible adverse effects to watch for and specific measures to prevent adverse effects, and therapeutic goals).
- Monitor the effectiveness of comfort measures and compliance with the regimen.

CRITICAL THINKING SCENARIO

Skeletal Muscle Relaxants for Cerebral Palsy

THE SITUATION

L.G. is 26 years old. He was diagnosed with cerebral palsy shortly after his birth. He lives in the community in a group home with six other affected people. Two adult caregivers provide supervision. In the past few months, L.G.'s spasticity has progressed severely, making it impossible for him to carry on his daily activities without extensive assistance.

Following a clinical evaluation, his health care team suggests trying a course of dantrolene therapy. After learning about the risks of dantrolene-related hepatic dysfunction, L.G. decides that the benefits of dantrolene therapy are more important to him than the risks of hepatotoxicity. The health care team proceeds with a complete physical examination, including liver enzyme analysis. Therapy begins and a clinic staff member schedules L.G. for a visit by a public health nurse in 4 days.

CRITICAL THINKING

What basic principles must be included in the nursing care plan for L.G. for the visiting nurses? *Think about the importance of including the adult caregivers in any teaching or evaluation programs. Consider specific problems that could develop that L.G. would be unable to handle on his own.*

What therapeutic goals might the nurse set with L.G. and his caregiver? How might these be evaluated?

What additional drug-related information should be posted in the group home and reviewed with L.G. and his caregivers?

DISCUSSION

In the first visit to the home, the nurse needs to establish a relationship with L.G. and his caregivers. They should all realize that drug therapy, and other measures, are needed to help L.G. attain his full potential and make use of his existing assets. Step-by-step therapeutic goals should be established and written down for future reference. Small reachable goals, such as partially dressing himself, walking to the table for meals, and managing parts of his daily hygiene routine are best at the beginning. Written goals provide a good basis for future evaluation when drug therapy is stopped briefly to determine its therapeutic effectiveness. It also helps L.G. to see progress and improvement.

In addition, the nurse should perform a complete examination to obtain baseline data. The patient should be asked about any noticeable changes or problems since starting the drug. If improvement appears to have occurred, the dosage may be slowly increased until the optimal level of functioning

has been achieved. The nurse is in a position to evaluate this and report it to the primary caregiver.

While in the home, the nurse can also evaluate resources and environmental limitations and suggest improvements (e.g., use of leg braces). L.G. and his caregivers should receive a drug teaching card that includes a telephone number to call with questions or concerns; warning signs of liver disease; and a list of findings to report. The nurse should discuss anticipated appointments for liver function tests to ensure that L.G. can keep the appointments. The health care team should work closely with L.G. to maximize his involvement in his care and to minimize unnecessary problems and confusion. Because the treatment involves a long-term commitment, a good working relationship among all members of the health care team is important to ensure continuity of care and optimal results.

NURSING CARE GUIDE FOR L.G.: MUSCLE RELAXANTS

Assessment: History and Examination

Concentrate the health history on allergies to any skeletal muscle relaxants, respiratory depression, muscle weakness, hepatic or renal dysfunction, and concurrent use of verapamil or alcohol.

Focus the physical examination on the following:

CV: blood pressure pulse rate, peripheral perfusion, ECG

CNS: orientation, affect, reflexes, grip strength

Skin: color, lesions, texture, temperature

GI: abdominal examination, bowel sounds

Respiratory: respiration, adventitious sounds

Laboratory tests: renal and hepatic function

Nursing Diagnoses

Acute Pain related to GI, GU, and CNS effects

Risk for Injury related to CNS effects

Disturbed Thought Processes related to CNS effects

Deficient Knowledge regarding drug therapy

Implementation

Discontinue drug at first sign of liver dysfunction.

Provide comfort and safety measures: positioning, orientation, safety measures, pain medication as needed.

Provide support and reassurance to help L.G. deal with spasticity and drug effects.

Teach L.G. about drug, dosage, drug effects and symptoms of reportable serious adverse effects.

Evaluation

Evaluate drug effects: relief of spasticity, improved daily function.

Skeletal Muscle Relaxants for Cerebral Palsy (continued)

Monitor for adverse effects: multiple CNS effects, respiratory depression, rash, skin changes, GI problems (diarrhea, hepatotoxicity), urinary urgency or weakness.

Monitor for drug–drug interactions: myocardial suppression with verapamil or alcohol.

Evaluate effectiveness of patient teaching program.

PATIENT TEACHING FOR L.G.

- The drug prescribed for you is a direct-acting skeletal muscle relaxant called dantrolene (*Dantrium*). This drug makes spastic muscles relax. Because this drug may cause liver damage, it is important that you have regular medical check-ups.
- Common side effects of skeletal muscle relaxants, such as dantrolene, include:
 - *Fatigue, weakness, and drowsiness*: Try to pace activities evenly throughout the day and allow rest periods to

avoid discouraging side effects. If they become too severe, consult your health care provider.

- *Dizziness and fainting*: Change position slowly to avoid dizzy spells. If these effects should occur, avoid activities that require coordination and concentration.
- *Diarrhea*: Be sure to be near bathroom facilities if this occurs. This effect usually subsides after a few weeks.
- Report any of the following to your health care provider: *fever, chills, rash, itching, changes in the color of your urine or stool, or a yellowish tint to the eyes or skin.*
- Keep this drug and all medications out of the reach of children.
- Do not overexert yourself when you begin to feel better. Pace yourself.
- Take this drug exactly as directed and schedule regular medical checkups to evaluate the effects of this drug on your body.

KEY POINTS

- Centrally acting skeletal muscle relaxants are used to relieve the effects of muscle spasm. Dantrolene, a direct-acting skeletal muscle relaxant, is used to control spasticity and prevent malignant hyperthermia.
- The botulinum toxin type B is used to reduce the severity of abnormal head position and neck pain associated with cervical dystonia. Botulinum toxin type A is used to improve the appearance of moderate to severe glabellar lines and to treat cervical dystonia, severe primary axillary hyperhidrosis, and strabismus and blepharospasm associated with dystonia.

form intentional tasks and maintain posture, position, and locomotion.

- Centrally acting skeletal muscle relaxants are used to relieve the effects of muscle spasm. Dantrolene, a direct-acting skeletal muscle relaxant, is used to control spasticity and prevent malignant hyperthermia.
- The botulinum toxin type B is used to reduce the severity of abnormal head position and neck pain associated with cervical dystonia. Botulinum toxin type A is used to improve the appearance of moderate to severe glabellar lines and to treat cervical dystonia, severe primary axillary hyperhidrosis, and strabismus and blepharospasm associated with dystonia.

CHAPTER SUMMARY

- Upper-level controls of muscle activity include the pyramidal tract in the cerebellum, which regulates coordination of intentional muscle movement, and the extrapyramidal tract in the cerebellum and basal ganglia, which coordinates crude movements related to unconscious muscle activity.
- Damage to a muscle or anchoring skeletal structure may result in the arrival of a flood of impulses to the spinal cord. Such overstimulation may lead to a muscle spasm or a state of increased contraction.
- Damage to motor neurons can cause muscle spasticity, with a lack of coordination between muscle groups and loss of coordinated activity, including the ability to per-

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-Rom in the front of the book.

MULTIPLE CHOICE

Select the best answer to the following.

1. A muscle spasm often results from
 - a. damage to the basal ganglia.
 - b. central nervous system damage.
 - c. injury to the musculoskeletal system.
 - d. chemical imbalance within the CNS.
2. Muscle spasticity is the result of
 - a. direct damage to a muscle cell.
 - b. overstretching of a muscle.
 - c. tearing of a ligament.
 - d. damage to neurons within the CNS.
3. Signs and symptoms of tetanus, which includes severe muscle spasm, are best treated with
 - a. baclofen.
 - b. diazepam.
 - c. carisoprodol.
 - d. methocarbamol.
4. The drug of choice for a patient experiencing severe muscle spasms and pain precipitated by anxiety is
 - a. methocarbamol.
 - b. baclofen.
 - c. diazepam.
 - d. carisoprodol.
5. Dantrolene (*Dantrium*) differs from the other skeletal muscle relaxants because
 - a. it acts in the highest levels of the CNS.
 - b. it is used to treat muscle spasms as well as muscle spasticity.
 - c. it cannot be used to treat neuromuscular disorders.
 - d. it acts directly within the skeletal muscle fiber and not within the CNS.
6. The use of neuromuscular junction blockers may sometimes cause a condition known as malignant hyperthermia. The drug of choice for prevention or treatment of this condition is
 - a. baclofen.
 - b. diazepam.
 - c. dantrolene.
 - d. methocarbamol.
7. Dantrolene is associated with potentially fatal cellular damage. If your patient's condition is being managed with dantrolene, the patient should
 - a. have repeated CBCs during therapy.
 - b. have renal function tests done monthly.
 - c. be monitored for signs of liver damage and have liver function tests done regularly.
 - d. have a thorough eye examination before and periodically during therapy.

MULTIPLE RESPONSE

Select all that apply.

1. Spasmolytics, or centrally acting muscle relaxants, block the reflexes in the central nervous system that lead to spasm. While a patient is taking one of these drugs, which of the following interventions should be implemented?
 - a. Rest for the affected muscle
 - b. Heat to the affected area
 - c. Ice packs to the affected area
 - d. Use of anti-inflammatory agents
 - e. Body temperature check every 2 hours to watch for malignant hyperthermia
 - f. Positioning to decrease pain and spasm
2. Muscle relaxants would be used in which of the following circumstances?
 - a. To treat spasticity related to spinal cord injury
 - b. To treat spasticity that contributes to locomotion, upright position, or increase in function
 - c. To treat spasticity that is related to toxins, such as tetanus
 - d. To treat spasticity that is a result of neuromuscular degeneration
 - e. To reduce the severity of head position associated with cervical dystonia
 - f. To reduce the appearance of frown lines (glabellar lines)

Narcotics, Narcotic Antagonists and Antimigraine Agents

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Outline the gate theory of pain and explain therapeutic ways to block pain using the gate theory.
2. Describe the therapeutic actions, indications, pharmacokinetics, contraindications, most common adverse reactions, and important drug–drug interactions associated with narcotics and antimigraine agents.
3. Discuss the use of the different classes of narcotics, narcotic antagonists, and antimigraine agents across the lifespan.
4. Compare and contrast the prototype drugs morphine, pentazocine, naloxone, ergotamine, and sumatriptan with other drugs in their respective classes.
5. Outline the nursing considerations, including important teaching points, for patients receiving a narcotic, a narcotic antagonist, or an antimigraine drug.

Glossary of Key Terms

A fibers: large-diameter nerve fibers that carry peripheral impulses associated with touch and temperature to the spinal cord

A-delta fibers: small-diameter nerve fibers that carry peripheral impulses associated with pain to the spinal cord

C fibers: unmyelinated, slow-conducting fibers that carry peripheral impulses associated with pain to the spinal cord

ergot derivative: drug that causes a vascular constriction in the brain and the periphery; relieves or prevents migraine headaches but is associated with many adverse effects

gate control theory: theory that states that the transmission of a nerve impulse can be modulated at various points along its path by descending fibers from the brain that close the “gate” and block transmission of pain information and by A fibers that are able to block transmission in the dorsal horn by closing the gate for transmission for the A-delta and C fibers

Glossary of Key Terms (continued)

migraine headache: headache characterized by severe, unilateral, pulsating head pain associated with systemic effects, including GI upset and sensitization to light and sound; related to a hyperperfusion of the brain from arterial dilation

narcotics: drugs, originally derived from opium, that react with specific opioid receptors throughout the body

narcotic agonists: drugs that react at opioid receptor sites to stimulate the effects of the receptors

narcotic agonists–antagonists: drugs that react at some opioid receptor sites to stimulate their activity and at other opioid receptor sites to block activity

narcotic antagonists: drugs that block the opioid receptor sites; used to counteract the effects of narcotics or to treat an overdose of narcotics

opioid receptors: receptor sites on nerves that react with endorphins and enkephalins, which are receptive to narcotic drugs

pain: a sensory and emotional experience associated with actual or potential tissue damage

spinothalamic tract: nerve pathway from the spine to the thalamus along which pain impulses are carried to the brain

triptan: selective serotonin receptor blocker that causes a vascular constriction of cranial vessels; used to treat acute migraine attacks

Pain, by definition, is a sensory and emotional experience associated with actual or potential tissue damage. The perception of pain is part of the clinical presentation in many disorders and is one of the hardest sensations for patients to cope with during the course of a disease or dysfunction. The drugs involved in the management of severe pain, whether acute or chronic, are discussed in this chapter. These agents all work in the central nervous system (CNS)—the brain and the spinal cord—to alter the way that pain impulses arriving from peripheral nerves are processed. These agents can change the perception and tolerance of pain. Two major types of drugs are considered here: the narcotics—the opium derivatives that are used to treat many types of pain; and the antimigraine drugs, which are reserved for the treatment of **migraine headache**, a type of severe headache. Narcotic antagonists, which are used to block the effects of the narcotics in cases of overdose, also are discussed.

PAIN

Pain is described as an unpleasant sensation and emotional experience. In many ways it is a subjective experience. The physiological processes that cause pain are perceived and reacted to in different ways because of learned experiences, cultural differences, and environmental stimuli. Pain occurs whenever tissues are damaged. The injury to cells releases many chemicals, including kinins and prostaglandins, which stimulate specific sensory nerves. Pain can be acute or chronic. Acute pain occurs in response to recent tissue damage or injury. This type of pain makes a person aware of an injury and should lead to measures to care for the injury and teaches the person to avoid similar situations that could cause this pain. Chronic pain is constant or intermittent pain that keeps occurring long past the time the injured area would be expected to heal. Chronic pain can cause a stress reaction,

interrupt much-needed sleep, and interfere with all of the activities of daily living. Pain can also be classified by location. “Where does it hurt?” is a common question in assessing pain. Sometimes the location of the pain is a direct indicator of where the tissue damage has occurred. In some cases so-called referred pain occurs. A person experiencing pain from damage to heart muscle may actually feel the pain in the neck or jaw. The sensation of pain is experienced in a different area of the body. Referred pain often follows predictable pathways, which helps health care providers figure out where the injury has occurred. Pain can be further classified by originating source as nociceptive, neuropathic, or psychogenic. Nociceptive pain is caused by a direct stimulus to a pain receptor. Neuropathic pain is caused by nerve injury. Psychogenic pain is pain that is associated with emotional, psychological, or behavioral stimuli.

Pain Impulse Transmission and Perception

Two small-diameter sensory nerves, called the **A-delta and C fibers**, respectively, respond to stimulation by generating nerve impulses that produce pain sensations. The A-delta fibers are small, myelinated fibers that respond quickly to acute pain. The C fibers are unmyelinated and are slow conducting. Pain impulses from the skin, subcutaneous tissues, muscles, and deep visceral structures are conducted to the dorsal, or posterior, horn of the spinal cord on these fibers. In the spinal cord, these nerves form synapses with spinal cord nerves that then send impulses to the brain (Figure 26.1).

In addition, large-diameter sensory nerves enter the dorsal horn of the spinal cord. These so-called **A fibers** do not transmit pain impulses; instead, they transmit sensations associated with touch and temperature. The A fibers, which are larger and conduct impulses more rapidly than do the smaller fibers, can actually block the ability of the smaller fibers to transmit their signals to the secondary neurons in the spinal

● FIGURE 26.1 Neural pathways of pain.

cord. The dorsal horn, therefore, can be both excitatory and inhibitory with regard to pain impulses that are transmitted from the periphery.

The impulses reaching the dorsal horn are transmitted upward toward the brain by a number of specific ascending nerve pathways. These pathways run from the spinal cord into the thalamus, where they form synapses with various nerve cells that transmit the information to the cerebral cortex, along the **spinothalamic tracts**. According to the **gate control theory**, the transmission of these impulses can be modulated or adjusted all along these tracts. All along the spinal cord, the interneurons can act as “gates” by blocking the ascending transmission of pain impulses. It is thought that the gates can be closed by stimulation of the larger A fibers and by descending impulses coming down the spinal cord from higher levels in such areas as the cerebral cortex, the limbic system, and the reticular activating system.

The inhibitory influence of the higher brain centers on the transmission of pain impulses helps to explain much of the mystery associated with pain. Several factors, including learned experiences, cultural expectations, individual tolerance, and the placebo effect, can activate the descending

inhibitory nerves from the upper central nervous system. These other factors need to be considered and incorporated into pain management strategies, which usually involve the use of drugs. For example, the placebo effect, stress reduction, acupuncture, and back rubs (which stimulate the A fibers) all can play important roles in the effective management of pain.

Pain Receptors

Opioid receptors are receptor sites that respond to naturally occurring peptides, the endorphins and the enkephalins. These receptor sites are found in the CNS, on nerves in the periphery, and on cells in the gastrointestinal (GI) tract. In the brainstem, opioid receptors help to control blood pressure, pupil diameter, GI secretions, and the chemoreceptor trigger zone (CTZ) that regulates nausea and vomiting, cough, and respiration. In the spinal cord and thalamus, these receptors help to integrate and relate incoming information about pain. The endorphins and enkephalins normally modulate the pain information coming into the brain. Endorphins are released during stress to block the sensation of pain. Professional

athletes may be injured during an important game and have no sensation of pain or injury because their stress reaction is highly activated, and the endorphins are blocking pain transmission into the brain. In the hypothalamus, stimulation of the opioid receptors may interrelate the endocrine and neural responses to pain. In the limbic system, the receptors incorporate emotional aspects of pain and response to pain. At peripheral nerve sites, they may block the release of neurotransmitters that are related to pain and inflammation.

Pain Perception

Many factors play a role in the patient's perception of pain. Past experience has a big impact on how pain is perceived. Having experienced pain in the past, a patient may fear the intensity it could reach and the overall impact of that pain. Learned response to pain also plays a large role. Children learn the accepted response to painful stimuli when growing up. Some children are taught to ignore pain and deal with it without showing emotion. Some children learn that reacting to pain can lead to much-wanted attention. The environmental setting in which the pain occurs also has an influence on perception and response to pain. A parent may not be willing to admit pain when the children are present, feeling that the role of the parent is to be strong. If you cut your finger when you are alone, you may perceive pain and react loudly. If you cut your finger when you are surrounded by young children, you may show no reaction and just go on with your activities. These varied influences on pain perception and response often make it very difficult to effectively evaluate and manage pain.

Pain Management

Accurately assessing pain can lead to effective pain management. Because so many factors play a role in pain perception and it is very subjective, assessment has to depend on the patient's report of pain. Health care providers often use a scale system to evaluate a patient's pain. Patients may be asked to rank their pain on a scale from 0 to 10, with 0 being no pain and 10 being the worst possible pain. Some pain scales use drawings of faces and ask the patient to pick the face that most reflects the pain they feel. Numerous methods, both nonpharmacological and pharmacological, may be used to manage pain. Nonpharmacological treatments can include warmth, massage, positioning, acupuncture, or meditation. Pharmacological methods often include the use of nonsteroidal anti-inflammatory drugs (NSAIDs) or acetaminophen (Chapter 15) for tissue-related pain or atypical antipsychotics or other CNS depressants for the treatment of neurogenic pain. These methods can be used individually or in combination. The goal is to achieve maximum pain relief.

One major method of pain management involves the use of **narcotics**. The narcotics, or opioids, were first derived from the opium plant. Although most narcotics are now synthetically prepared, their chemical structure resembles that of

the original plant alkaloids. All drugs in this class are similar, in that they occupy specific opioid receptors in the CNS. Their actions in the body are related to the stimulation of the various opioid receptors that they occupy.

KEY POINTS

- ▶ When tissue is injured, various chemicals are released and pain results.
- ▶ A-delta and C fibers carry pain impulses to the spinal cord.
- ▶ According to the gate theory of pain, impulses travel from the spine to the cortex via tracts that can be modulated along the way at specific gates. These gates can be closed to block the transmission of pain impulses by descending nerves from the upper CNS, which relate to emotion, culture, placebo effect, and stress, and by large-diameter sensory fibers, which are associated with touch.
- ▶ Endogenous endorphins and enkephalins react with opioid receptors to regulate the transmission of pain.
- ▶ Narcotics are derived from the opium plant; they bind to opioid receptors to relieve pain and promote feelings of well-being or euphoria.

NARCOTICS

The narcotic drugs used vary with the type of opioid receptors with which they react. This accounts for a change in pain relief, as well as a variation in the side effects that can be anticipated. Four types of opioid receptors have been identified: mu (μ), kappa (κ), beta (β), and sigma (σ). The mu-receptors are primarily pain-blocking receptors. Besides analgesia, mu-receptors also account for respiratory depression, a feeling of euphoria, decreased GI activity, pupil constriction, and the development of physical dependence. The kappa-receptors are associated with some analgesia and with pupillary constriction, sedation, and dysphoria. The beta-receptors react with enkephalins in the periphery to modulate pain transmission. The sigma-receptors cause pupillary dilation and may be responsible for the hallucinations, dysphoria, and psychoses that can occur with narcotic use. The administration of narcotics requires specific considerations related to age (Box 26.1).

Narcotic Agonists

The **narcotic agonists** (Table 26.1) are drugs that react with the opioid receptors throughout the body to cause analgesia, sedation, or euphoria (Figure 26.2). Anticipated effects other than analgesia are mediated by the types of opioid receptors affected by each drug. Because of the potential for the

BOX 26.1

Drug Therapy Across the Lifespan

Narcotics

CHILDREN

The safety and effectiveness of many of these drugs have not been established in children. If a narcotic is used, the dose should be calculated very carefully, and the child should be monitored closely for the adverse effects associated with narcotic use.

Narcotics that have an established pediatric dose include codeine, fentanyl (but not transdermal fentanyl), hydrocodone, meperidine, and morphine. Narcotics that are not recommended for children are levorphanol, oxycodone, and propoxyphene.

Methadone is not recommended as an analgesic in children. If a child older than 13 years of age requires a narcotic agonist-antagonist, buprenorphine is the drug of choice. Naloxone is the drug of choice for reversal of narcotic effects and narcotic overdose in children.

ADULTS

Adults being treated for acute pain should be reassured that the risk of addiction to a narcotic during treatment is remote. They should be encouraged to ask for pain medication before the pain is acute, to get better coverage for their pain. Many institutions allow patients to self-regulate intravenous drips to control their pain postoperatively.

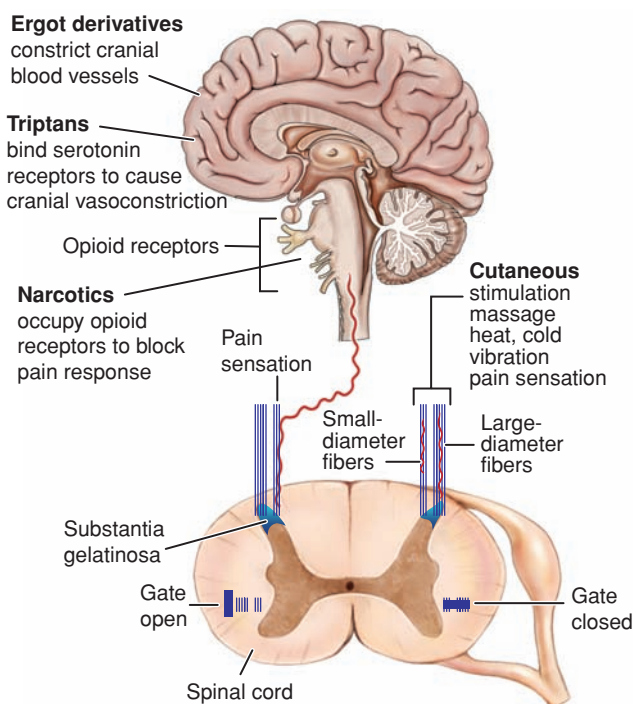

The narcotics are contraindicated or should only be used with caution during pregnancy because of the potential for adverse effects on the fetus. These drugs enter breast milk and can cause opioid effects in the baby, so caution should be used during lactation. Morphine, meperidine, and oxycodone are often used for analgesia during labor. The mother should be monitored closely for adverse reactions, and, if the drug is used over a prolonged labor, the newborn infant should be monitored for opioid effects.

OLDER ADULTS

Elderly patients should be specifically asked whether they require pain medication. Because many older patients can recall a time when nurses were able to spend more time with patients, they may tend to believe that the nurse will meet their needs.

Older patients are more likely to experience the adverse effects associated with these drugs, including central nervous system, gastrointestinal, and cardiovascular effects.

Because older patients often have renal or hepatic impairment, they are also more likely to have toxic levels of the drug related to changes in metabolism and excretion. The older patient should have safety measures in effect—side rails, call light, assistance to ambulate—when receiving one of these drugs in the hospital setting.

● **FIGURE 26.2** Sites of action. Narcotics occupy opioid receptors to block pain response. Ergot derivatives constrict cranial blood vessels, and triptans bind serotonin receptors to cause cranial vasoconstriction.

development of physical dependence while taking these drugs, the narcotic agonists are classified as controlled substances. The degree of control is determined by the relative ability of each drug to cause physical dependence. Narcotic agonists include codeine, fentanyl (*Actiq*, *Duragesic*, *Ionsys*), hydrocodone (*Hycodan*), hydromorphone (*Dilaudid*), levorphanol (*Levo-Dromoran*), meperidine (*Demerol*), methadone (*Dolophine*), morphine (*Roxanol*, *Astramorph*), opium (*Paregoric*), oxycodone (*OxyContin*), oxycodone (*Numorphan*), propoxyphene (*Darvon*, *Darvon-N*), remifentanyl (*Ultiva*), sufentanyl (*Sufental*), and tramadol (*Ultram*).

Therapeutic Actions and Indications

The narcotic agonists act at specific opioid receptor sites in the CNS to produce analgesia, sedation, and a sense of well-being. They also are used as antitussives and as adjuncts to general anesthesia to produce rapid analgesia, sedation, and respiratory depression. Indications for narcotic agonists include relief of severe acute or chronic pain, preoperative medication, analgesia during anesthesia, and specific individual indications, depending on their receptor affinity. (See Table 26.1 for usual indications for each narcotic agonist). Accurate calculation of a dose is crucial to prevent overdosing patients.

TABLE 26.1 DRUGS IN FOCUS Narcotics

Drug Name	Dosage/Route	Usual Indications
Narcotic Agonists		
codeine	Adult: 15–60 mg PO, IM, IV, or SQ q4–6h; 10–20 mg PO q4–6h for cough Pediatric: 0.5 mg/kg PO, IM, or SQ q4–6h; 2.5–10 mg PO q4–6h for cough	Relief of mild to moderate pain; relief of coughing induced by mechanical or chemical irritation of the respiratory tract
fentanyl (<i>Actiq, Duragesic, Ionsys</i>)	Adult: 0.05–0.1 mg IM, 30–60 min before surgery; 0.002 mg/kg IV or IM during surgery; 0.05–0.1 mg postoperatively; 5 mcg/kg transmucosally; for transdermal patch, calculate the previous day's narcotics need and use table to convert to patch strength; ionic delivery system, 40 mcg over 10 min Pediatric (>2 yr): 2–3 mcg/kg IM or IV; base transmucosal dose on weight and do not exceed 400 mcg	For analgesia before, during, and after surgery; transdermal patch for management of chronic pain; control of breakthrough pain
hydrocodone (<i>Hycodan</i>)	Adult: 5–10 mg PO q4h in combination products for pain; 5–10 mg PO q4–6h for cough Pediatric (2–12 yr): 1.25–5 mg PO q4–6h	Relief of cough; relief of moderate pain in combination products
hydromorphone (<i>Dilaudid</i>)	2–4 mg PO q4–6h, or 3 mg PR q6–8h, or 1–4 mg SQ or IM q4–6h	Relief of moderate to severe pain in adults
levorphanol (<i>Levo-Dromoran</i>)	1 mg IV by slow injection or 1–2 mg IM or SQ q6–8h, or 2 mg PO q6–8h	Management of moderate to severe pain in adults; postoperative pain in adults
meperidine (<i>Demerol</i>)	Adult: 50–150 mg PO, IM, or SQ q3–4h; during labor, 100 mg IM or SQ q1–3h Pediatric: 1–1.8 mg/kg IM, SQ, or PO q3–4h	Relief of moderate to severe pain, preoperative analgesia and support of anesthesia, and obstetrical analgesia
methadone (<i>Dolophine</i>)	2.5–10 mg IM, SQ, or PO q3–4h for pain; 15–20 mg PO for withdrawal, then 20 mg PO q4–8h for maintenance treatment	Relief of severe pain; detoxification and temporary maintenance treatment of narcotic addiction in adults
 morphine (<i>Roxanol, Astramorph</i>)	Adult: 10 to 20-mg solution PO or 15- to 30-mg tablets PO q4h, or 10 mg SQ or IM q4h, or 2–10 mg/70 kg IV over 4–5 min, or 10–20 mg PR q4h Pediatric: 0.1–0.2 mg/kg IM or SQ q4h	Relief of moderate to severe chronic and acute pain; preoperatively and postoperatively and during labor
opium (<i>Paregoric</i>)	Adult: 0.6 mL liquid PO q.i.d. or 5–10 mL camphorated tincture one to four times per day PO Pediatric: 0.005–0.02 mg/kg PO q3–4h or 0.25–0.5 mL/kg PO q1–4h of camphorated tincture	Treatment of diarrhea, relief of moderate pain
oxycodone (<i>OxyContin</i>)	10–30 mg PO q4h as needed	Relief of moderate to severe pain in adults
oxymorphone (<i>Numorphan</i>)	0.5 mg IV initially; 1–1.5 mg IM or SQ q4–6h as needed; 0.5–1 mg IM for labor; 5 mg PR q4–6h	Relief of moderate to severe pain in adults; preoperative medication; obstetrical analgesia
propoxyphene (<i>Darvon, Darvon-N</i>)	65 mg PO q4h as needed; <i>Darvon-N</i> , 100 mg PO q4h as needed	Relief of mild to moderate pain in adults Special considerations: limit use in suicidal or addiction-prone patients
remifentanyl (<i>Ultiva</i>)	Adult and children >2 yr: dose determined by general anesthetic being used	Analgesic for use during general anesthesia Special considerations: must be under the direct supervision of anesthesia practitioner
sufentanyl (<i>Sufental</i>)	Adult: 1–2 mcg/kg IV with general anesthesia Pediatric: 10–25 mcg/kg IV	Analgesic for use during general anesthesia; used as an epidural agent in labor and delivery Special considerations: must be under the direct supervision of anesthesia practitioner

Drug Name	Dosage/Route	Usual Indications
tramadol (<i>Ultram</i>)	Adults: rapid relief of pain: 50-100 mg PO q4-6h to a maximum 400 mg/d; Chronic pain: 25 mg/d PO titrated slowly to a maximum 400 mg/d	Relief of moderate to moderately severe pain Special considerations: limit use in patients with a history of addictions

Narcotic Agonists-Antagonists

buprenorphine (<i>Buprenex</i>)	Adults and children >13 yr: 0.3 mg IM or slow IV q6h as needed	Treatment of mild to moderate pain
butorphanol (<i>Stadol</i>)	Adult: 0.5-2 mg IV q3-4h or 1-4 mg IM q3-4h; 1 mg nasal spray, repeated in 60-90 min, then in 3-4 h as needed Geriatric: use one-half of the adult dose at twice the usual interval Pediatric: not recommended for children <18 yr	Used as preoperative medication to relieve moderate to severe pain; treatment of migraine headaches, with fewer peripheral adverse effects than many of the traditional antimigraine drugs
nalbuphine (<i>Nubain</i>)	10 mg/70 kg IM, SC, or IV q3-6h as needed; do not exceed 160 mg/d	Relief of pain during labor and delivery; used as adjunct to general anesthesia; treatment of moderate to severe pain in adults
 pentazocine (<i>Talwin</i>)	Adults and children >12 yr: 30 mg IM, SQ, or IV q3-4h as needed or 50 mg PO q3-4h as needed; do not exceed 360 mg/d; 30 mg IM most common for labor	Relief of moderate to severe pain during labor and delivery; treatment of postpartum pain; used as adjunct to general anesthesia

Narcotic Antagonists

nalmefene (<i>Revex</i>)	Adult: for reversal of postoperative opioid depression, 0.25 mcg/kg IV every 2-5 min until desired reversal is obtained; for management of overdose, 0.5 mg/70 kg IV, then 1 mg IV 2-5 min later; reduce dose in renal and hepatic disease	Reversal of opioid effects, management of narcotic overdose
 naloxone (<i>Narcan</i>)	Adult: for overdose, 0.4-2 mg IV, may repeat at 2- to 3-min intervals; for reversal of opioid effects, 0.1-0.2 mg IV, may repeat at 2- to 3-min intervals Pediatric: for overdose, 0.01 mg/kg IV, repeat as needed; for reversal of opioid effects, 0.005-0.01 mg IV at 2- to 3-min intervals	Diagnosis of narcotic overdose, reversal of opioid effects
naltrexone (<i>ReVia</i>)	Adult: 50 mg/d PO	Adjunct treatment of alcohol or narcotic dependence in adults

Box 26.2 describes how to calculate dose for one narcotic agonist.

In deciding which narcotic to use in any particular situation, it is important to consider all of these aspects of the patient's condition and to select the drug that will be most effective in each situation with the fewest adverse effects for the patient. Each patient is different, and his or her response to a drug also is different (Box 26.3). For instance, if an analgesic that is long acting but not too sedating is desired for an outpatient, hydrocodone might fit those objectives. Fentanyl, which is available for injection, is also available as a lozenge for treating breakthrough pain, as a buccal tablet, as a transdermal patch, and in an ionic delivery system, which allows the patient to activate the release of the drug as needed for treating breakthrough pain in cancer patients. See the Critical

Thinking Scenario for information about using morphine to relieve pain.

Pharmacokinetics

Intravenous (IV) administration is the most reliable way to achieve therapeutic levels of narcotics. Intramuscular (IM) and subcutaneous (SQ) administration offer varying rates of absorption, and absorption is slower in female than in male patients because of the normal fat content of female muscles and tissue. These drugs undergo hepatic metabolism and are generally excreted in the urine and bile. Half-life periods vary widely, depending on the drug being used. These agents cross the placenta and are known to enter breast milk.

FOCUS BOX 26.2 Calculations

You are taking care of a 4-year-old child after surgery. An order has been written for 1.5 mg/kg meperidine IM q3–4h as needed. The child is waking up and crying, so you decide to start the pain medication. The meperidine is available as 10 or 50 mg/mL. You note that the child weighs 20 kg. How much meperidine would you inject?

$$20 \text{ kg} \times 1.5 \text{ mg/kg} = 30 \text{ mg needed}$$

You could give 3 mL of the 10-mg/mL preparation:

$$(x \text{ mL}/30 \text{ mg} = 1 \text{ mL}/10 \text{ mg}; x = 3)$$

Or you could give 0.6 mL of the 50-mg/mL preparation:

$$(x \text{ mL}/30 \text{ mg} = 1 \text{ mL}/50 \text{ mg}; x = 0.6 \text{ mL})$$

In this case, you might prefer to give the child the smaller volume, using 0.6 mL of the 50-mg/mL solution to deliver the 30 mg of meperidine.

Contraindications and Cautions

The narcotic agonists are contraindicated in the following conditions: presence of any known allergy to any narcotic agonist *to avoid hypersensitivity reactions*; diarrhea caused by toxic poisons *because depression of GI activity could lead to increased absorption and toxicity*; and after biliary surgery or surgical anastomoses *because of the adverse effects associated with slowed GI activity due to narcotics*.

FOCUS BOX 26.3 Cultural Considerations

Differences in Responses to Narcotic Therapy

Because of physical and cultural differences among various ethnic groups, patients from certain groups respond differently to particular medications. Nurses should keep in mind that patients in some ethnic groups are genetically predisposed to metabolize medications differently. For example, Arab Americans may not achieve the same pain relief from narcotics as patients in other ethnic groups; their inborn differences in metabolism may require larger doses to achieve therapeutic effects.

Some African American patients seem to have a decreased sensitivity to the pain-relieving qualities of some narcotics, although the reason for this is unknown. Moreover, increasing the dosage of these medications may not increase the level of pain relief and actually may be toxic. In such cases, another class of medication might be used to “boost” the pain-relieving qualities of the narcotic.

Among some immigrant and first-generation Asian Americans, it may not be socially acceptable to show strong emotion, such as that associated with pain. The sensitive nurse will frequently ask such patients if they are comfortable or require additional medication.

Oxycodone is classified as pregnancy category B, whereas all of the other narcotic agonists are in category C, so it might be the drug of choice if one is needed during pregnancy. Extended-release oxycodone (*OxyContin*) has been associated with abuse because when the tablet is cut, crushed, or chewed, the entire dose of the drug is released at once. Pregnant women must be cautioned not to cut, crush, or chew these tablets if they are prescribed this drug. Many sources recommend waiting 4 to 6 hours after receiving a narcotic before breast-feeding the baby if a narcotic is needed for pain control.

Caution should be used in patients with respiratory dysfunction, *which could be exacerbated by the respiratory depression caused by these drugs*; recent GI or genitourinary (GU) surgery, acute abdomen or ulcerative colitis, *which could become worse with the depressive effects of the narcotics*; head injuries, alcoholism, delirium tremens, or cerebral vascular disease, *which could be exacerbated by the CNS effects of the drugs*; liver or renal dysfunction, *which could alter the metabolism and excretion of the drugs*; and during pregnancy, labor, or lactation *because of potential adverse effects on the fetus or neonate, including respiratory depression*.

Adverse Effects

The most frequently seen adverse effects associated with narcotic agonists relate to their effects on various opioid receptors. Respiratory depression with apnea, cardiac arrest, and shock may result from narcotic-induced respiratory center depression. Orthostatic hypotension is commonly seen with some narcotics. Gastrointestinal effects such as nausea, vomiting, constipation, and biliary spasm may occur as a result of CTZ stimulation and negative effects on GI motility. Box 26.4 discusses a drug approved to treat opioid-induced constipation. Neurological effects such as light-headedness, dizziness, psychoses, anxiety, fear, hallucinations, pupil constriction, and impaired mental processes may occur as a result of the stimulation of CNS opioid receptors in the cerebrum, limbic system, and hypothalamus. GU effects, including ureteral spasm, urinary retention, hesitancy, and loss of libido, may be related to direct receptor stimulation or to CNS activation of sympathetic pathways. In addition, sweating and dependence (both physical and psychological) are possible, more so with some agents than with others.

Clinically Important Drug–Drug Interactions

When narcotic agonists are given with barbiturate general anesthetics or with some phenothiazines and MAOIs, the likelihood of respiratory depression, hypotension, and sedation or coma is increased. If these drug combinations cannot be avoided, patients should be monitored closely and appropriate supportive measures taken.

CRITICAL THINKING SCENARIO

Using Morphine to Relieve Pain

THE SITUATION

L.M., a 25-year-old businessman, was in a car crash and suffered a fractured pelvis, a fractured left tibia, a fractured right humerus, and multiple contusions and abrasions. For the first 2 days after surgery to reduce the fractures, L.M. was heavily sedated. As healing progressed, he was taught to use a patient-controlled analgesia (PCA) system using morphine. PCA provides a baseline, constant infusion of morphine and gives the patient control of the system to add bolus doses of morphine if he feels that pain is not being controlled. The system prevents overdose by locking out extra doses until a specific period of time has elapsed. L.M. became agitated when he was not able to give himself a bolus because the appropriate time between boluses had not elapsed. The nurse working with L.M. noted an increase in blood pressure, pulse, and respirations. L.M. had no fever. He did seem very anxious and rated his pain at 10. The nurse tried several nonpharmacological measures to alleviate the pain and spent time talking with L.M. and reassuring him. By day 5, L.M. was switched to an oral morphine and plans were made to wean him from then narcotics.

CRITICAL THINKING

- What basic principles must be included in the nursing care plan for this patient? *Think about the difficult position the floor nurse is in when L.M. begins demanding pain relief before the prescribed time limit.*
- What implications will L.M.'s agitation have on the way that the staff responds to him and on other patients in the area?
- What other nursing measures could be used to help relieve pain and make the narcotic more effective?
- What plans could the health team make with L.M. to give him more control over his situation and increase the chances that the pain relief will be effective?

DISCUSSION

In assessing L.M.'s response to drug therapy, you suspect that the morphine was not providing the desired therapeutic effect. Numerous research studies have shown that, in general, the dose of narcotics prescribed for acute pain relief provides inadequate analgesic coverage. It could be that the dose of morphine ordered for L.M. was just not sufficient to relieve his pain. This patient has many causes of acute pain and will heal more quickly if the pain is managed better. He has requested more drugs because the dose is too small or the intervals between doses are too long to effectively relieve his pain. Other measures may be successful in helping the morphine relieve the pain. Back rubs, environmental controls to decrease excessive stimuli (e.g., noise, lighting,

temperature, interruptions), and stress reduction may all be useful. Discussing the possibility of increasing the drug dose with the physician would be appropriate.

L.M. may be very anxious about his injuries, and the opportunity to vent his feelings and concerns may alleviate some of the tension associated with pain. He may fear that if he does not cover the pain before it gets too bad, it will be very hard to get any pain relief. The nursing staff can work on this concern and figure out a way to reassure him.

The health care team should try to discuss the concerns with L.M., including the concern about the physical dependency. L.M. is a businessman and may respond positively to having some input into his care; he may even offer suggestions as to how he could cope better and adjust to his situation. Cortical impulses can close gates as effectively as descending inhibitory pathways, and stimulation of the cortical pathways through patient education and active involvement should be considered an important aspect of pain relief. Because L.M.'s injuries are extensive, a long-term approach should be taken to his care. The sooner that L.M. can be involved, the better the situation will be for everyone involved.

NURSING CARE GUIDE FOR L.M.: NARCOTICS

Assessment: History and Examination

Assess history of allergies to any narcotic drug, respiratory depression, GI or biliary surgery, hepatic or renal dysfunction, alcoholism, or convulsive disorders.

Focus the physical examination on the following:

CV: blood pressure, pulse rate, peripheral perfusion, ECG

CNS: orientation, affect, reflexes, grip strength

Skin: color, lesions, texture, temperature

GI: abdominal examination, bowel sounds

Respiratory: respiration, adventitious sounds

Laboratory tests: renal and liver function tests

Nursing Diagnoses

Acute Pain related to injuries, GI, CNS, GU effects

Disturbed Sensory Perceptions (Visual, Auditory, Kinesthetic) related to CNS effects

Impaired Gas Exchange related to respiratory depression

Deficient Knowledge regarding drug therapy

Anxiety related to injuries, drug regimen

Constipation

Implementation

Provide a narcotic antagonist, facilities for assisted ventilation during IV administration.

Provide comfort and safety measures: orientation, accurate timing of doses, monitoring for extravasation, and additional measures for pain relief to increase effects.

Using Morphine to Relieve Pain (continued)

Provide support and reassurance to deal with drug effects and addiction potential.

Provide patient teaching about the drug, dosage, drug effects, and symptoms of serious reactions to report.

Evaluation

Evaluate drug effects: relief of pain, sedation.

Monitor for adverse effects: CNS effects (multiple), respiratory depression, rash, skin changes, GI depression, constipation.

Monitor drug–drug interactions: increased respiratory depression, sedation, coma with barbiturate anesthetics, monoamine oxidase inhibitors, phenothiazines.

Evaluate the effectiveness of the patient teaching program.

Evaluate the effectiveness of comfort and safety measures.

PATIENT TEACHING FOR L.M.

- A narcotic is used to relieve pain. Do not hesitate to take this drug if you feel uncomfortable. Remember that it is important to use the drug before the pain becomes severe and thus more difficult to treat.
- Common effects of these drugs include:
 - *Constipation*: Your health care provider will suggest appropriate measures to alleviate this common problem.

- *Dizziness, drowsiness, and visual changes*: If any of these occur, avoid driving, operating complex machinery, or performing delicate tasks. If these effects occur in the hospital, the side rails on the bed may be raised for your protection.
- *Nausea and loss of appetite*: Taking the drug with food may help. Lying quietly until these sensations pass may also help to alleviate this problem.
- Report any of the following to your health care provider: *severe nausea or vomiting, skin rash, or shortness of breath or difficulty breathing*.
- Avoid the use of alcohol, antihistamines, and other over-the-counter drugs while taking this drug. Many of these drugs could interact with this narcotic.
- Tell any doctor, nurse, dentist, or other health care provider involved in your care that you are taking this drug.
- Keep this drug and all medications out of the reach of children.
- Do not take any leftover medication for other disorders, and do not let anyone else take your medication.
- Take this drug exactly as prescribed. Regular medical follow-up is necessary to evaluate the effects of this drug on your body.

Prototype Summary: Morphine

Indications: Relief of moderate to severe acute or chronic pain; preoperative medication; component of combination therapy for severe chronic pain; intraspinal to reduce intractable pain.

Actions: Acts as an agonist at specific opioid receptors in the CNS to produce analgesia, euphoria, and sedation.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	Varies	60 min	5–7 h
PR	Rapid	20–60 min	5–7 h
SQ	Rapid	50–90 min	5–7 h
IM	Rapid	30–60 min	5–6 h
IV	Immediate	20 min	5–6 h

$T_{1/2}$: 1.5 to 2 hours; metabolized in the liver, excreted in the urine and bile.

Adverse effects: Light-headedness, dizziness, sedation, nausea, vomiting, dry mouth, constipation, ureteral spasm, respiratory depression, apnea, circulatory depression, respiratory arrest, shock, cardiac arrest.

Narcotic Agonists-Antagonists

The **narcotic agonists-antagonists** (Table 26.1) stimulate certain opioid receptors but block other such receptors. These

drugs, which have less abuse potential than the pure narcotic agonists, exert a similar analgesic effect as morphine. Like morphine, they may cause sedation, respiratory depression, and constipation. They have also been associated with more psychotic-like reactions, and they may even induce a withdrawal syndrome in patients who have been taking narcotics for a long period.

BOX 26.4 Laxative for Dealing With Narcotic-Induced Constipation

One of the most uncomfortable side effects of narcotic use is constipation. Frequently, when ordering a narcotic for pain, a prescriber will also order a laxative to avert serious constipation discomfort. When a patient is on long-term narcotics for controlling pain in cases of cancer or in hospice settings where palliative care uses narcotics to make patients comfortable, constipation can be a real problem. In 2008, methylnaltrexone bromide (*Relistor*) was approved for the treatment of opioid-induced constipation in patients who are receiving palliative care and who no longer respond to traditional laxatives. *Relistor* is a peripherally acting, mu-specific opioid antagonist. It blocks the mu-receptors responsible for constipation related to opioid use. *Relistor* given by subcutaneous injection once each day. It is rapidly absorbed from the tissues, reaching peak levels in 30 minutes. It is excreted primarily unchanged in the urine with a half-life of 8 hours. The adverse effects associated with the drug are related to the increase in GI activity that occurs—diarrhea, abdominal pain, flatulence, and nausea.

Available narcotic agonists-antagonists include buprenorphine (*Buprenex*), butorphanol (*Stadol*), nalbuphine (*Nubain*), and pentazocine (*Talwin*).

Therapeutic Actions and Indications

The narcotic agonists-antagonists act at specific opioid receptor sites in the CNS to produce analgesia, sedation, euphoria, and hallucinations. In addition, they block opioid receptors that may be stimulated by other narcotics. These drugs have three functions: (1) relief of moderate to severe pain, (2) adjuncts to general anesthesia, and (3) relief of pain during labor and delivery. See Table 26.1 for usual indications for each narcotic agonist-antagonist agent.

Pharmacokinetics

Narcotic agonists-antagonists are readily absorbed after IM administration and reach peak levels rapidly when given IV. They are metabolized in the liver and are excreted in urine or feces. They are known to cross the placenta and enter breast milk.

Buprenorphine is available for use in IM and IV forms. Butorphanol is available for IM or IV administration and as a nasal spray. Nalbuphine is administered parenterally (SQ, IM, or IV). Pentazocine is available in parenteral and oral forms, making it the preferred drug for patients who will be switched from parenteral to oral forms after surgery or labor.

Contraindications and Cautions

Narcotic agonists-antagonists are contraindicated in the presence of any known allergy to any narcotic agonist-antagonist to avoid hypersensitivity reactions.

Nalbuphine should not be given to patients who are allergic to sulfites to avoid a cross-hypersensitivity reaction.

Caution should be used in cases of physical dependence on a narcotic because a withdrawal syndrome may be precipitated; the narcotic antagonistic properties can block the analgesic effect and intensify the pain. Narcotic agonists-antagonists may be desirable for relieving chronic pain in patients who are susceptible to narcotic dependence, but extreme care must be used if patients are switched directly from a narcotic agonist to one of these drugs.

Caution should also be exercised in the following conditions: chronic obstructive pulmonary disease or other respiratory dysfunction, which could be exacerbated by respiratory depression; acute myocardial infarction (MI), documented coronary artery disease (CAD), or hypertension, which could be exacerbated by cardiac stimulatory effects of these drugs; and renal or hepatic dysfunction, which could interfere with the metabolism and excretion of the drug.

Pentazocine must be administered cautiously to patients with known heart disease because the drug may cause cardiac

stimulation, including arrhythmias, hypertension, and increased myocardial oxygen consumption, which could lead to angina, MI, or heart failure.

There are no adequate studies regarding their effects during pregnancy. They should be used during pregnancy only if the benefit to the mother clearly outweighs the risk to the fetus because of potential adverse effects on the neonate, including respiratory depression. They are used to relieve pain during labor and delivery, which provides a short-term exposure to the fetus. They are known to enter breast milk and should be used with caution during lactation because of the potential for adverse effects on the baby.

Adverse Effects

The most frequently seen adverse effects associated with narcotic agonists-antagonists relate to their effects on various opioid receptors. Respiratory depression with apnea and suppression of the cough reflex is associated with the respiratory center depression. Nausea, vomiting, constipation, and biliary spasm may occur as a result of CTZ stimulation and the negative effects on GI motility. Light-headedness, dizziness, psychoses, anxiety, fear, hallucinations, and impaired mental processes may occur as a result of the activation of CNS opioid receptors in the cerebrum, limbic system, and hypothalamus. GU effects, including ureteral spasm, urinary retention, hesitancy, and loss of libido, may be related to direct receptor stimulation or to CNS activation of sympathetic pathways. Although sweating and dependence, both physical and psychological, are possible, their occurrence is considered less likely than with narcotic agonists.

Clinically Important Drug-Drug Interactions

When narcotic agonists-antagonists, like narcotic agonists, are given with barbiturate general anesthetics, the likelihood of respiratory depression, hypotension, and sedation or coma increases. If this combination cannot be avoided, patients should be monitored closely and appropriate supportive measures taken.

Use of narcotic agonists-antagonists in patients who have previously received any narcotic puts these patients at risk for increased adverse effects, including respiratory depression. When such a sequence of drugs is used, patients require support and monitoring.

Pentazocine has been abused in combination with tripeleptamine (“Ts and Blues”) because of the hallucinogenic, euphoric effect of the two drugs, with potentially fatal complications.

Prototype Summary: Pentazocine

Indications: Relief of moderate to severe pain; preanesthetic medication and a supplement to surgical anesthesia.

Actions: An agonist at specific opioid receptors in the CNS, producing analgesia and sedation; an agonist at sigma opioid

receptors, causing dysphoria and hallucinations; acts at mu-receptors to antagonize the analgesia and euphoria.

Pharmacokinetics:

Route	Onset	Peak	Duration
PO, IM, SC	15–30 min	1–3 h	3 h
IV	2–3 min	15 min	3 h

$T_{1/2}$: 2 to 3 hours; metabolized in the liver, excreted in the urine and bile.

Adverse effects: Light-headedness, dizziness, sedation, euphoria, nausea, vomiting, constipation, tachycardia, palpitations, sweating, ureteral spasm, physical dependence.

Nursing Considerations for Patients Receiving Narcotic Agonists and Narcotic Agonists-Antagonists

Assessment: History and Examination

- Assess for contraindications or cautions: any known allergies to these drugs or to sulfites if using nalbuphine to avoid hypersensitivity reactions; respiratory dysfunction, which may be exacerbated by the respiratory depression caused by these drugs; MI or CAD, which could be exacerbated by the effects of these drugs; renal or hepatic dysfunction, which might interfere with drug metabolism or excretion; current status of pregnancy and lactation, which require cautious use of the drugs; history of heart disease if administering pentazocine to reduce the risk of potential cardiac stimulation; diarrhea caused by toxic poisons because depression of GI activity could lead to increased absorption and toxicity; and after biliary surgery or surgical anastomoses because of the adverse effects associated with slowed GI activity due to narcotics.
- Perform a pain assessment with the patient to establish baseline and evaluate the effectiveness of drug therapy.
- Perform a physical assessment to establish baseline status before beginning therapy, determine drug effectiveness, and evaluate for any potential adverse effects.
- Assess orientation, affect, reflexes, and pupil size to evaluate any CNS effects; monitor respiratory rate and auscultate lungs for adventitious sounds to evaluate respiratory effects.
- Monitor pulse, blood pressure, and cardiac output to evaluate for cardiac effects.
- Palpate abdomen for distention and auscultate bowel sounds to monitor for GI effects; assess urine output and palpate for bladder distention to evaluate for GU effects.
- Monitor the results of laboratory tests such as liver and renal function tests to determine the need for possible dose adjustment and identify toxic drug effects; obtain an electrocardiogram (ECG) to evaluate for possible cardiac stimulation and arrhythmias secondary to pentazocine administration.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Disturbed Sensory Perception (Visual, Auditory, Kinesthetic) related to CNS effects
- Constipation related to GI effects
- Impaired Gas Exchange related to respiratory depression
- Risk for injury related to CNS effects of the drug
- Deficient Knowledge related to drug therapy

Implementation With Rationale

- Perform baseline and periodic pain assessments with the patient to monitor drug effectiveness and provide appropriate changes in pain management protocol as needed.
- Have a narcotic antagonist and equipment for assisted ventilation readily available when administering the drug IV to provide patient support in case of severe reaction.
- Monitor injection sites for irritation and extravasation to provide appropriate supportive care if needed.
- Monitor timing of analgesic doses. Prompt administration may provide a more acceptable level of analgesia and lead to quicker resolution of the pain.
- Use extreme caution when injecting these drugs into any body area that is chilled or has poor perfusion or shock because absorption may be delayed, and after repeated doses an excessive amount is absorbed all at once.
- Use additional measures to relieve pain (e.g., back rubs, stress reduction, hot packs, ice packs) to increase the effectiveness of the narcotic being given and reduce pain.
- Monitor respiratory status before beginning therapy and periodically during therapy to monitor for potential respiratory depression.
- Institute comfort and safety measures, such as side rails and assistance with ambulation, to ensure patient safety; bowel program as needed to treat constipation; environmental controls to decrease stimulation; and small, frequent meals to relieve GI distress if GI upset is severe.
- Reassure patients that the risk of addiction is minimal. Most patients who receive these drugs for medical reasons do not develop dependency syndromes.
- Offer support and encouragement to help the patient cope with the drug regimen.
- Provide thorough patient teaching, including drug name, prescribed dose, and schedule of administration; measures for avoidance of adverse effects; warning signs that may indicate possible problems; safety measures such as avoiding driving, getting assistance with ambulation, avoiding making important decisions or signing important papers; and the need for monitoring and evaluation to enhance patient knowledge about drug therapy and to promote compliance.

Evaluation

- Monitor patient response to the drug (relief of pain, sedation).
- Monitor for adverse effects (CNS changes, GI depression, respiratory depression, arrhythmias, hypertension).
- Evaluate the effectiveness of the teaching plan (the patient can give the drug name and dosage and describe possible adverse effects to watch for, specific measures to prevent them, and warning signs to report).
- Monitor the effectiveness of comfort measures and compliance with the regimen.

Narcotic Antagonists

The **narcotic antagonists** (Table 26.1) are drugs that bind strongly to opioid receptors but do not activate them. They block the effects of the opioid receptors and are often used to block the effects of too many opioids in the system. The narcotic antagonists in use include nalmeferene (*Revex*), naloxone (*Narcan*), and naltrexone (*ReVia*).

Therapeutic Actions and Indications

The narcotic antagonists block opioid receptors and reverse the effects of opioids, including respiratory depression, sedation, psychomimetic effects, and hypotension.

These agents are indicated for reversal of the adverse effects of narcotic use, including respiratory depression and sedation, and for treatment of narcotic overdose. (See Table 26.1 for usual indications for each narcotic antagonist agent.) The narcotic antagonists do not have an appreciable effect in most people, but individuals who are addicted to narcotics experience the signs and symptoms of withdrawal when receiving these drugs rapidly.

Pharmacokinetics

Narcotic antagonists may be administered parenterally (SQ, IM, or IV) or orally. These drugs are well absorbed after injection and are widely distributed in the body. They undergo hepatic metabolism and are excreted primarily in the urine.

Contraindications and Cautions

Narcotic antagonists are contraindicated in the presence of any known allergy to any narcotic antagonist *to avoid hypersensitivity reactions*. Caution should be used in the following circumstances: during pregnancy and lactation *because of potential adverse effects on the fetus and neonate*; with narcotic addiction *because of the precipitation of a withdrawal syndrome*; and with cardiovascular (CV) disease, *which could be exacerbated by the reversal of the depressive effects of narcotics*.

Adverse Effects

The most frequently seen adverse effects associated with these drugs relate to the blocking effects of the opioid receptors. The most common effect is an acute narcotic abstinence syndrome that is characterized by nausea, vomiting, sweating, tachycardia, hypertension, tremulousness, and feelings of anxiety. A naloxone challenge should be administered before giving naltrexone to help to avoid acute reactions.

CNS excitement and reversal of analgesia are especially common after surgery. Cardiovascular (CV) effects related to the reversal of the opioid depression can include tachycardia, blood pressure changes, dysrhythmias, and pulmonary edema.

Drug-Drug Interactions

To reverse the effects of buprenorphine, butorphanol, nalbuphine, pentazocine, or propoxyphene, larger doses of narcotic antagonists may be needed.

Prototype Summary: Naloxone

Indications: Complete or partial reversal of narcotic depression; diagnosis of suspected opioid overdose.

Actions: Pure narcotic antagonist; reverses the effects of the opioids, including respiratory depression, sedation, and hypotension.

Pharmacokinetics:

Route	Peak	Onset	Duration
IV	Unknown	2 min	4–6 h
IM, SQ	Unknown	3–5 min	4–6 h

$T_{1/2}$: 30 to 81 minutes; metabolized in the liver, excreted in the urine.

Adverse effects: Acute narcotic abstinence syndrome (nausea, vomiting, sweating, tachycardia, fall in blood pressure), hypotension, hypertension, pulmonary edema.

Nursing Considerations for Patients Receiving Narcotic Antagonists

Assessment: History and Examination

- Assess *for contraindications or cautions*: any known allergies to these drugs *to avoid hypersensitivity reactions*; history of narcotic addiction, *which may lead to narcotic abstinence syndrome*; history of MI or CAD, *which may be exacerbated by the reversal of opioid depression*; and current status of pregnancy and lactation, *which require cautious use of these drugs*.
- Perform a physical assessment to establish *baseline status before beginning therapy and for any potential adverse effects*.

- Assess the patient's neurological status, including level of orientation, affect, reflexes, and pupil size, *to evaluate CNS effects*; monitor respiratory rate and auscultate lungs for adventitious sounds *to evaluate respiratory status*.
- Monitor vital signs, including pulse and blood pressure, *to identify changes and risks to the CV system*.
- Obtain an ECG as appropriate *to evaluate for cardiac effects*.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to withdrawal and CV effects
- Decreased Cardiac Output related to CV effects
- Risk for injury related to CNS effects
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Maintain open airway and provide artificial ventilation and cardiac massage as needed *to support the patient*. Administer vasopressors as needed *to manage narcotic overdose*.
- Administer naloxone challenge before giving naltrexone *because of the serious risk of acute withdrawal*.
- Provide continuous monitoring of the patient, *adjusting the dose as needed, during treatment of acute overdose*.
- Provide comfort and safety measures *to help the patient cope with the withdrawal syndrome*.
- Ensure that patients receiving naltrexone have been narcotic free for 7 to 10 days *to prevent severe withdrawal syndrome*. Check urine opioid levels if there is any question.
- If the patient is receiving naltrexone as part of a comprehensive narcotic or alcohol withdrawal program, advise the patient to wear or carry a MedicAlert warning *so that medical personnel know how to treat the patient in an emergency*.
- Institute comfort and safety measures, such as side rails and assistance with ambulation, *to ensure patient safety*; institute bowel program as needed *for treatment of constipation*; use environmental controls *to decrease stimulation*; and provide, small frequent meals *to relieve GI irritation if GI upset is severe*.
- Offer support and encouragement *to help the patient cope with the effects of drug regimen*.
- Provide thorough patient teaching, including drug name and prescribed dosage; measures to avoid adverse effects; warning signs to report immediately that may indicate possible problems; safety measures such as avoiding driving, avoiding making important decisions, and having a responsible person available for assistance; and the importance of continued monitoring and evaluation *to enhance patient knowledge about drug therapy and to promote compliance*.

Evaluation

- Monitor patient response to the drug (reversal of opioid effects, treatment of alcohol dependence).
- Monitor for adverse effects (CV changes, arrhythmias, hypertension).
- Evaluate the effectiveness of the teaching plan (patient can give the drug name and dosage and describe possible adverse effects to watch for, specific measures to prevent them, and warning signs to report).
- Monitor the effectiveness of comfort measures and compliance with the regimen.

KEY POINTS

- ▶ Narcotic agonists react with opioid receptor sites to stimulate their activity.
- ▶ Narcotic agonists-antagonists react with some opioid receptor sites to stimulate activity and block other opioid receptor sites.
- ▶ Narcotic antagonists are used to treat narcotic overdose or to reverse unacceptable adverse effects.

MIGRAINE HEADACHES

The term **migraine headache** is used to describe several different syndromes, all of which include severe, throbbing headaches on one side of the head. This pain can be so severe that it can cause widespread disturbances, affecting GI and CNS function, including mood and personality changes.

Migraine headaches should be distinguished from cluster headaches and tension headaches (Box 26.5). Cluster headaches usually begin during sleep and involve sharp, steady eye pain that lasts 15 to 90 minutes, with sweating, flushing, tearing, and nasal congestion. Tension headaches,

FOCUS ON BOX 26.5 Gender Considerations

Headache Distribution

Headaches are distributed in the general population in a definite gender-related pattern. For example:

- Migraine headaches are three times more likely to occur in women than men.
- Cluster headaches are more likely to occur in men than in women.
- Tension headaches are more likely to occur in women than in men.

There is some speculation that the female predisposition to migraine headaches may be related to the vascular sensitivity to hormones. Some women can directly plot migraine occurrence to periods of fluctuations in their menstrual cycle. The introduction of the triptan class of antimigraine drugs has been beneficial for many of these women.

which usually occur at times of stress, feel like a dull band of pain around the entire head and last from 30 minutes to 1 week. They are accompanied by anorexia, fatigue, and a mild intolerance to light or sound.

Migraines generally are classified as common or classic. Common migraines, which occur without an aura, cause severe, unilateral, pulsating pain that is frequently accompanied by nausea, vomiting, and sensitivity to light and sound. Such migraine headaches are often aggravated by physical activity. Classic migraines are usually preceded by an aura—a sensation involving sensory or motor disturbances—that usually occurs about 1/2 hour before the pain begins. The pain and adverse effects are the same as those of the common migraine.

It is believed that the underlying cause of migraine headaches is arterial dilation. Headaches accompanied by an aura are associated with hypoperfusion of the brain during the aura stage, followed by reflex arterial dilation and hyperperfusion. The underlying cause and continued state of arterial dilation are not clearly understood, but they may be related to the release of bradykinins, serotonin, or a response to other hormones and chemicals.

ANTIMIGRAINE AGENTS

For many years, the one standard treatment for migraine headaches was acute analgesia, often involving a narcotic, together with control of lighting and sound and the use of **ergot derivatives**. In the late 1990s, a new class of drugs, the **triptans**, was found to be extremely effective in treating migraine headaches without the adverse effects associated with ergot derivative use. Because these agents are associated with many systemic adverse effects, their usefulness is limited

in some patients (Box 26.6). Table 26.2 includes additional information about each class of antimigraine agents.

Ergot Derivatives

The ergot derivatives cause constriction of cranial blood vessels and decrease the pulsation of cranial arteries. As a result, they reduce the hyperperfusion of the basilar artery vascular bed.

Available ergot derivatives include dihydroergotamine (*Migranal*, *D.H.E. 45*) and ergotamine (generic).

Therapeutic Actions and Indications

The ergot derivatives block alpha-adrenergic and serotonin-receptor sites in the brain to cause a constriction of cranial vessels, a decrease in cranial artery pulsation, and a decrease in the hyperperfusion of the basilar artery bed (see Figure 26.2). These drugs are indicated for the prevention or abortion of migraine or vascular headaches. Ergotamine, the prototype drug in this class, was the mainstay of migraine headache treatment before the development of triptans. (See Table 26.2 for usual indications for each drug.) In 2003, dihydroergotamine in the parenteral form was also approved for the treatment of cluster headaches.

Pharmacokinetics

The ergot derivatives are rapidly absorbed from many routes, with an onset of action ranging from 15 to 30 minutes. They are metabolized in the liver and primarily excreted in the bile.

BOX 26.6

Drug Therapy Across the Lifespan

Antimigraine Agents

CHILDREN

None of the drugs used to treat migraines are recommended for use in children. The ergot derivatives can have many adverse effects in children, and there is not enough clinical experience with triptans to recommend them for use in children.

ADULTS

Adults requesting treatment for migraine headaches should be carefully evaluated before one of the antimigraine drugs is used to ensure that the headache being treated is of the type that can benefit from these drugs.

The ergots and the triptans are contraindicated during pregnancy because of the potential for adverse effects in the mother and fetus. Women of childbearing age should be advised to use contraception while they are taking these

drugs. Women who are nursing should be encouraged to find another method of feeding the baby because of the potential for adverse drug effects on the baby.

OLDER ADULTS

Older adults are more likely to have chronic diseases such as cardiovascular disease or renal or hepatic impairment that would be exacerbated by the antimigraine drugs. They should be used with extreme caution in older adults. The older adult should be encouraged to take the least amount of the drug possible and should be monitored closely for any sign of chest pain, MI, or acute vascular changes. Safety measures are extremely important with the older adult. If the patient is in an institutional setting, side rails, assistance with moving, and careful monitoring should be used.

TABLE 26.2 DRUGS IN FOCUS Antimigraine Agents

Drug Name	Dosage/Route	Usual Indications
Ergot Derivatives		
dihydroergotamine (Migranal, D.H.E. 45)	One spray (0.5 mg) in each nostril, may repeat in 15 min for a total of four sprays or 1 mg IM at first sign of headache, repeat in 1 h for a total of 3 mg or 2 mg IV, do not exceed 6 mg/wk	Rapid treatment of acute attacks of migraines in adults
 ergotamine (generic)	One tablet sublingually at the first sign of headache, repeat at 30-min intervals for a total of three tablets, or one inhalation at first sign of headache, repeat in 5 min to a total of six inhalations per day	Prevention and abortion of migraine attacks in adults
Triptans		
almotriptan (Axert)	6.25–12.5 mg PO at onset of aura or symptoms	Treatment of acute migraines in adults
eletriptan (Relpax)	20–40 mg PO; may repeat in 2 h if needed; do not exceed 80 mg/d	Treatment of acute migraines in adults
frovatriptan (Frova)	2.5 mg PO as a single dose at first sign of headache; may repeat in 2 h; do not exceed three doses in 24 h	Treatment of acute migraines (with or without aura) in adults
naratriptan (Amerge)	1–2.5 mg PO with fluid; may repeat in 4 h if needed	Treatment of acute migraines in adults
rizatriptan (Maxalt, Maxalt-MLT)	5–10 mg PO; may repeat in 2 h; do not exceed 30 mg/d	Treatment of acute migraines in adults; orally disintegrating tablet may be useful if there is difficulty swallowing
 sumatriptan (Imitrex)	50–100 mg PO at first sign of headache, may repeat in 2 h; by nasal spray in one nostril, may repeat in 2 h; do not exceed 40 mg/d	Treatment of acute migraines, cluster headaches in adults
zolmitriptan (Zomig, Zomig-ZMT)	2.5 mg PO; may repeat in 2 h; do not exceed 10 mg/d	Treatment of acute migraines in adults

Dihydroergotamine is available as a nasal spray or for IM or IV administration. This agent is the drug of choice if the oral route of administration is not possible.

Ergotamine is administered sublingually for rapid absorption. *Cafergot*, the very popular oral form, combines ergotamine with caffeine to increase its absorption from the GI tract.

Contraindications and Cautions

Ergot derivatives are contraindicated in the following circumstances: presence of allergy to ergot preparations *to avoid hypersensitivity reactions*; CAD, hypertension, or peripheral vascular disease, *which could be exacerbated by the CV effects of these drugs*; impaired liver function, *which could alter the metabolism and excretion of these drugs*; and pregnancy or lactation *because of the potential for adverse effects on the fetus and neonate*. Ergotism (vomiting, diarrhea, seizures) has been reported in affected infants.

Caution should be used in two instances: with pruritus, *which could become worse with drug-induced vascular constriction*, and with malnutrition *because ergot derivatives stimulate the CTZ and can cause severe GI reactions, possibly worsening malnutrition*.

Adverse Effects

The adverse effects of ergot derivatives can be related to the drug-induced vascular constriction. CNS effects include numbness, tingling of extremities, and muscle pain; CV effects such as pulselessness, weakness, chest pain, arrhythmias, localized edema and itching, and MI may also occur. In addition, the direct stimulation of the CTZ can cause GI upset, nausea, vomiting, and diarrhea. Ergotism, a syndrome associated with the use of these drugs, causes nausea, vomiting, severe thirst, hypoperfusion, chest pain, blood pressure changes, confusion, drug dependency (with prolonged use), and a drug withdrawal syndrome.

Clinically Important Drug–Drug Interactions

If these drugs are combined with beta-blockers, the risk of peripheral ischemia and gangrene is increased. Such combinations should be avoided.

Prototype Summary: Ergotamine

Indications: Prevention or abortion of vascular headaches.

Actions: Constricts cranial blood vessels, decreases pulsation of cranial arteries, and decreases hyperperfusion of the basilar artery vascular bed; mechanism of action is not understood.

Pharmacokinetics:

Route	Onset	Peak
Sublingual	Rapid	0.5–3 h

$T_{1/2}$: 2.7 hours, then 21 hours; metabolized in the liver, excreted in the feces.

Adverse effects: Numbness, tingling in the fingers and toes, muscle pain in the extremities, pulselessness or weakness in the legs, precordial distress, tachycardia, bradycardia, ergotism (nausea, vomiting, diarrhea, severe thirst, hypoperfusion, chest pain, confusion).

Triptans

The **triptans** are a relatively new class of drugs that cause cranial vascular constriction and relief of migraine headache pain in many patients. These drugs are not associated with the vascular and GI effects of the ergot derivatives. The triptan of choice for a particular patient depends on personal experience and other preexisting medical conditions. A patient may have a poor response to one triptan and respond well to another (Box 26.5).

Available triptans include almotriptan (*Axert*), eletriptan (*Relpax*), frovatriptan (*Frova*), naratriptan (*Amerge*), rizatriptan (*Maxalt*, *Maxalt-MLT*), sumatriptan (*Imitrex*), and zolmitriptan (*Zomig*, *Zomig-ZMT*).

Therapeutic Actions and Indications

The triptans bind to selective serotonin receptor sites to cause vasoconstriction of cranial vessels, relieving the signs and symptoms of migraine headache (see Figure 26.2). They are indicated for the treatment of acute migraine and are not used for prevention of migraines. (See Table 26.2 for usual indications for each of the triptans.)

Sumatriptan, the first drug of this class, is used for the treatment of acute migraine attacks and for the treatment of cluster headaches in adults. It can be given orally, subcutaneously, or by nasal spray.

Naratriptan, rizatriptan, zolmitriptan, and eletriptan (approved in 2003) are used orally only for the treatment of

acute migraines. Rizatriptan and zolmitriptan are also available as a fast-dissolving tablets.

Pharmacokinetics

The triptans are rapidly absorbed from many sites; they are metabolized in the liver (sumatriptan by monoamine oxidase) and are primarily excreted in the urine. They cross the placenta and have been shown to be toxic to the fetus in animal studies. They also enter breast milk. The safety and efficacy of use in children have not been established.

Contraindications and Cautions

Triptans are contraindicated with any of the following conditions: allergy to any triptan *to avoid hypersensitivity reactions*; pregnancy *because of the possibility of severe adverse effects on the fetus*; and active CAD, *which could be exacerbated by the vessel-constricting effects of these drugs*. These drugs should be used with caution in elderly patients *because of the possibility of underlying vascular disease*; in patients with risk factors for CAD; in lactating women *because of the possibility of adverse effects on the infant*; and in patients with renal or hepatic dysfunction, *which could alter the metabolism and excretion of the drug*. Rizatriptan seems to have more angina-related effects, and it is not recommended for patients with a history of CAD, *which could be exacerbated by its cardiac effects*.

Adverse Effects

The adverse effects associated with the triptans are related to the vasoconstrictive effects of the drugs. CNS effects may include numbness, tingling, burning sensation, feelings of coldness or strangeness, dizziness, weakness, myalgia, and vertigo. GI effects such as dysphagia and abdominal discomfort may occur. CV effects can be severe and include blood pressure alterations and tightness or pressure in the chest. Almotriptan is reported to have fewer side effects than the other triptans, and it is also thought that the longer half-life of this drug will prevent the rebound headaches that may be seen with other triptans.

Clinically Important Drug–Drug Interactions

Combining triptans with ergot-containing drugs results in a risk of prolonged vasoactive reactions.

There is a risk of severe adverse effects if these drugs are used within 2 weeks after discontinuation of a monoamine oxidase inhibitor (MAOI) *because of the increased vasoconstrictive effects that occur*. If triptans are to be given, it is imperative that the patient has not received an MAOI in more than 2 weeks.

P Prototype Summary: *Sumatriptan*

Indications: Treatment of acute migraine; treatment of cluster headaches (SC route).

Actions: Binds to serotonin receptors to cause vasoconstrictive effects on cranial blood vessels.

Pharmacokinetics:

Route	Onset	Peak	Duration
Nasal spray	Varies	5–20 min	Unknown
Oral	1–1.5 hr	2–4 h	Up to 24 h
SQ	Rapid	1–5 h	Up to 24 h

$T_{1/2}$: 115 minutes; metabolized in the liver, excreted in the urine.

Adverse effects: Dizziness, vertigo, weakness, myalgia, blood pressure alterations, tightness or pressure in the chest, injection-site discomfort, tingling, burning sensations, numbness.

Nursing Considerations for Patients Receiving Antimigraine Agents

Assessment: History and Examination

- Assess for contraindications or cautions: any known allergies to any components of the drugs *to avoid hypersensitivity reactions*; history of MI, CAD, or hypertension, *which may be exacerbated by the drug*; hepatic or renal dysfunction, *which could alter the metabolism and excretion of the drug*; pruritus or malnutrition, *which could be exacerbated by ergot derivatives*; and current status of pregnancy and lactation, *which would be cautions to the use of these drugs*.
- Perform a physical assessment to establish *baseline status before beginning therapy, determine drug effectiveness, and evaluate for any potential adverse effects*.
- Assess the patient's neurological status, including level of orientation, affect, and reflexes, *to evaluate CNS effects of the drugs*.
- Monitor for complaints of extremity numbness and tingling *to identify effects on vascular constriction*.
- Inspect the skin for localized edema, itching, or breakdown with ergot derivatives *to evaluate potential dermatological effects*.
- Assess vital signs, including pulse rate and blood pressure; obtain an ECG as appropriate *to evaluate cardiac status for changes*.
- Monitor the results of laboratory tests, including liver and renal function tests, *to determine the need for dose adjustment and identify possible toxic effects*.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to CV and vasoconstrictive effects
- Decreased Cardiac Output related to CV effects

- Disturbed Sensory Perception (Visual, Auditory, Kinesthetic, and Tactile) related to CNS effects
- Risk for injury related to changes in peripheral sensation, CNS effects
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Administer the drug to relieve acute migraines; *these drugs are not used for prevention*.
- Administer at the first sign of a headache and do not wait until it is severe, *to improve therapeutic effectiveness*.
- Arrange for safety precautions if CNS or visual changes occur *to prevent patient injury*.
- Provide comfort and safety measures, such as environmental controls and stress reduction, *for the relief of headache*. Provide additional pain relief as needed.
- Monitor the blood pressure of any patient with a history of CAD, and discontinue the drug if any sign of angina or prolonged hypertension occurs, *to prevent severe vascular effects*.
- Offer support and encouragement *to help the patient cope with the disorder and associated drug regimen*.
- Provide thorough patient teaching, including drug name, prescribed dose and schedule for administration; measures to avoid adverse effects; warning signs that may indicate possible problems; signs of ergotism if taking ergot derivatives; safety measures such as avoiding driving and avoiding overdose; and importance of follow-up monitoring and evaluation *to enhance patient knowledge about drug therapy and to promote compliance*.

Evaluation

- Monitor patient response to the drug (relief of acute migraine headaches).
- Monitor for adverse effects (CV changes, arrhythmias, hypertension, CNS changes).
- Evaluate the effectiveness of the teaching plan (patient can give the drug name and dosage and describe possible adverse effects to watch for, specific measures to prevent them, and warning signs to report).
- Monitor the effectiveness of comfort measures and compliance with the regimen.

KEY POINTS

- ▶ Migraine headaches are severe, throbbing headaches on one side of the head that may be associated with an aura or warning syndrome. These headaches are thought to be caused by arterial dilation and hyperperfusion of the brain vessels.
- ▶ Treatment of migraines may involve either ergot derivatives or triptans. Ergot derivatives cause vasoconstriction and are associated with sometimes severe systemic vasoconstrictive effects, whereas triptans, a newer class of selective serotonin receptor blockers, cause CNS

vasoconstriction but are not associated with as many adverse systemic effects.

CHAPTER SUMMARY

- Pain occurs any time that tissue is injured and various chemicals are released. The pain impulses are carried to the spinal cord by small-diameter A-delta and C fibers, which form synapses with interneurons in the dorsal horn of the spinal cord.
- Opioid receptors found throughout various tissues in the body react with endogenous endorphins and enkephalins to modulate the transmission of pain impulses.
- Narcotics, derived from the opium plant, react with opioid receptors to relieve pain. In addition, they lead to constipation, respiratory depression, sedation, and suppression of the cough reflex; they also stimulate feelings of well-being or euphoria.
- Because narcotics of all kinds are associated with the development of physical dependency, they are controlled substances.
- The effectiveness and adverse effects associated with specific narcotics are associated with their particular affinity for various types of opioid receptors.
- Narcotic agonists react with opioid receptor sites to stimulate their activity.
- Narcotic agonists-antagonists react with some opioid receptor sites to stimulate activity and block other opioid receptor sites. These drugs are not as addictive as pure narcotic agonists.
- Narcotic antagonists, which work to reverse the effects of narcotics, are used to treat narcotic overdose or to reverse unacceptable adverse effects.

- Migraine headaches are severe, throbbing headaches on one side of the head that may be associated with an aura or warning syndrome. These headaches are thought to be caused by arterial dilation and hyperperfusion of the brain vessels.
- Treatment of migraines may involve either ergot derivatives or triptans. Ergot derivatives cause vasoconstriction and are associated with sometimes severe systemic vasoconstrictive effects, whereas triptans, a newer class of selective serotonin receptor blockers, cause CNS vasoconstriction but are not associated with as many adverse systemic effects.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-Rom in the front of the book.

MULTIPLE CHOICE

Select the best answer to the following.

1. According to the gate control theory, pain
 - a. is caused by gates in the CNS.
 - b. can be blocked or intensified by gates in the CNS.
 - c. is caused by gates in peripheral nerve sensors.
 - d. cannot be affected by learned experiences.
2. Opioid receptors are found throughout the body
 - a. only in people who have become addicted to opiates.
 - b. in increasing numbers with chronic pain conditions.
 - c. to incorporate pain perception and blocking.
 - d. to initiate the release of endorphins.
3. Most narcotics are controlled substances because they
 - a. are very expensive.
 - b. can cause respiratory depression.
 - c. can be addictive.
 - d. can be used only in a hospital setting.

4. Injecting a narcotic into an area of the body that is chilled can be dangerous because
 - a. an abscess will form.
 - b. the injection will be very painful.
 - c. an excessive amount may be absorbed all at once.
 - d. narcotics are inactivated in cold temperatures.
5. Proper administration of an ordered narcotic
 - a. can lead to addiction.
 - b. should be done promptly to prevent increased pain and the need for larger doses.
 - c. would include holding the drug as long as possible until the patient really needs it.
 - d. should rely on the patient's request for medication.
6. Migraine headaches
 - a. occur during sleep and involve sweating and eye pain.
 - b. occur with stress and feel like a dull band around the entire head.
 - c. often occur when drinking coffee.
 - d. are throbbing headaches on one side of the head.
7. The triptans are a class of drugs that bind to selective serotonin receptor sites and cause
 - a. cranial vascular dilation.
 - b. cranial vascular constriction.
 - c. clinical depression
 - d. nausea and vomiting.
8. The only triptan that has been approved for use in treating cluster headaches as well as migraines is
 - a. naratriptan.
 - b. rizatriptan.
 - c. sumatriptan.
 - d. zolmitriptan.

MULTIPLE RESPONSE

Select all that apply.

1. Narcotics are drugs that react with opioid receptors throughout the body. Which of the following would the nurse expect to find when assessing a patient who was taking a narcotic?
 - a. Hypnosis
 - b. Sedation
 - c. Analgesia
 - d. Euphoria
 - e. Orthostatic hypotension
 - f. Increased salivation
2. The nurse would expect to administer a narcotic as the analgesic of choice for which patients?
 - a. A patient with severe postoperative pain
 - b. A patient with severe chronic obstructive pulmonary disease and difficulty breathing
 - c. A patient with severe, chronic pain
 - d. A patient with ulcerative colitis
 - e. A patient with recent biliary surgery
 - f. A cancer patient with severe bone pain

General and Local Anesthetic Agents

27

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Describe the concept of balanced anesthesia.
2. Describe the actions and uses of local anesthesia.
3. Describe the therapeutic actions, indications, pharmacokinetics, contraindications, most common adverse reactions, and important drug–drug interactions associated with general and local anesthetics.
4. Outline the preoperative and postoperative needs of a patient receiving general or local anesthesia.
5. Compare and contrast the prototype drugs thiopental, midazolam, nitrous oxide, halothane, and lidocaine with other drugs in their respective classes.
6. Outline the nursing considerations, including important teaching points, for patients receiving general and local anesthetics.

Glossary of Key Terms

amnesia: loss of memory of an event or procedure

analgesia: loss of pain sensation

anesthetic: drug used to cause complete or partial loss of sensation

balanced anesthesia: use of several different types of drugs to achieve the quickest, most effective anesthesia with the fewest adverse effects

general anesthesia: use of drugs to induce a loss of consciousness, amnesia, analgesia, and loss of reflexes to allow performance of painful surgical procedures

induction: time from the beginning of anesthesia until achievement of surgical anesthesia

local anesthesia: use of powerful nerve blockers that prevents depolarization of nerve membranes, blocking the transmission of pain stimuli and, in some cases, motor activity

plasma esterase: enzyme found in plasma that immediately breaks down ester-type local anesthetics

unconsciousness: loss of awareness of one's surroundings

volatile liquid: liquid that is unstable at room temperature and releases vapors; used as an inhaled general anesthetic, usually in the form of a halogenated hydrocarbon

GENERAL ANESTHETIC AGENTS

Barbiturate Anesthetics

methohexital
thiopental

Nonbarbiturate General Anesthetics

droperidol
etomidate
ketamine

midazolam
propofol

Anesthetic Gases

cyclopropane
ethylene

nitrous oxide

Volatile Liquids

desflurane
enflurane

halothane

isoflurane
sevoflurane

LOCAL ANESTHETIC AGENTS

Esters

benzocaine
chloroprocaine
procaine
tetracaine

Amides

bupivacaine
dibucaine
levobupivacaine

lidocaine
mepivacaine
prilocaine
ropivacaine

Other

pramoxine

Anesthetics are drugs that are used to cause complete or partial loss of sensation. The anesthetics can be subdivided into general and local anesthetics, depending on their site of action. General anesthetics are central nervous system (CNS) depressants used to produce loss of pain sensation and consciousness. Local anesthetics are drugs used to cause loss of pain sensation and feeling in a designated area of the body without the systemic effects associated with severe CNS depression. This chapter discusses various general and local anesthetics. Box 27.1 highlights information about using anesthetics with various age groups.

GENERAL ANESTHESIA

General anesthesia involves the administration of a combination of several different general anesthetic agents to achieve the following goals: **analgesia**, or loss of pain perception;

unconsciousness, or loss of awareness of one's surroundings; and **amnesia**, or inability to recall what took place. Ideally, the drugs are combined to achieve the best effects with the fewest adverse effects. In addition, general anesthesia also blocks the body reflexes. Blockage of autonomic reflexes prevents involuntary reflex response to body injury that might compromise a patient's cardiac, respiratory, gastrointestinal (GI), and immune status. Blockage of muscle reflexes prevents jerking movements that might interfere with the success of the surgical procedure.

Risk Factors Associated With General Anesthesia

Widespread CNS depression, which is not without risks, occurs with general anesthesia. In addition, all other body systems are affected. Because of the wide systemic effects, patients must

FOCUS ON BOX 27.1 Drug Therapy Across the Lifespan

Anesthetic Agents

CHILDREN

Children are at greater risk for complications after anesthesia—laryngospasm, bronchospasm, aspiration, and even death. They require very careful monitoring and support, and the anesthetist needs to be very skilled at calculating dosage and balance during the procedure. Propofol is widely used for diagnostic tests and short procedures in children older than 3 years of age because of its rapid onset and metabolism and generally smooth recovery. Halothane is widely used for children, especially those with respiratory dysfunction, because it tends to dilate bronchi. It increases ICP and should not be given to children with increased ICP. Sevoflurane has a minimal impact on intracranial pressure and allows a very rapid induction and recovery with minimal sympathetic reaction. It is still quite expensive, however, which may limit its use. The dosage of anesthetics may need to be higher in children, and that factor will be considered by the anesthetist.

Nursing care after general anesthesia should include support and reassurance; assessment of the child for any skin breakdown related to immobility, and safety precautions until full recovery has occurred.

Local anesthetics are used in children in much the same way that they are used in adults.

Bupivacaine, levobupivacaine, and tetracaine do not have established doses for children younger than 12 years of age. Benzocaine should not be used in children younger than 1 year of age.

When topically applying a local anesthetic, it is important to remember that there is greater risk of systemic absorption and toxicity with infants.

Tight diapers can act like occlusive dressings and increase systemic absorption. Children need to be cautioned not to bite themselves when receiving dental anesthesia.

ADULTS

Adults require a considerable amount of teaching and support when receiving anesthetics, including what will happen, what they will feel, how it will feel when they recover, and the approximate time to recovery.

Adults should be monitored closely until fully recovered from general anesthetics and should be cautioned to prevent injury when receiving local anesthetics. It is important to remember to reassure and talk to adults who may be aware of their surroundings yet unable to speak.

Most of the general anesthetics are not recommended for use during pregnancy because of the potential risk to the fetus. Short-onset and local anesthetics are frequently used at delivery. Use of a regional or other local anesthetic is usually preferred if surgery is needed during pregnancy. During lactation, it is recommended that the mother wait 4 to 6 hours to feed the baby after the anesthetic is used.

OLDER ADULTS

Older patients are more likely to experience the adverse effects associated with these drugs, including central nervous system, cardiovascular, and dermatological effects. Thinner skin and the possibility of decreased perfusion to the skin makes them especially susceptible to skin breakdown during immobility. Because older patients often also have renal or hepatic impairment, they are also more likely to have toxic levels of the drug related to changes in metabolism and excretion. The older patient should have safety measures in effect, such as siderails, a call light, and assistance to ambulate; special efforts to provide skin care to prevent skin breakdown are especially important with older skin. The older patient may require longer monitoring and regular orienting and reassuring. After general anesthesia, it is very important to promote vigorous pulmonary toilet to decrease the risk of pneumonia.

be evaluated for factors that may increase their risk. These factors include the following:

- **CNS factors:** Underlying neurological disease (e.g., epilepsy, stroke, myasthenia gravis) that presents a risk for abnormal reaction to the CNS-depressing and muscle-relaxing effects of these drugs.
- **Cardiovascular factors:** Underlying vascular disease, coronary artery disease, or hypotension, which put patients at risk for severe reactions to anesthesia, such as hypotension and shock, dysrhythmias, and ischemia.
- **Respiratory factors:** Obstructive pulmonary disease (e.g., asthma, chronic obstructive pulmonary disease, bronchitis), which can complicate the delivery of gas anesthetics, as well as the intubation and mechanical ventilation that must be used in most cases of general anesthesia.
- **Renal and hepatic function:** Conditions that interfere with the metabolism and excretion of anesthetics (e.g., acute renal failure, hepatitis) and could result in prolonged anesthesia and the need for continued support during recovery. Toxic reactions to the accumulation of abnormally high levels of anesthetic agents may even occur.

Balanced Anesthesia

With the wide variety of drugs available, the therapeutic effects required need to be balanced with the potential for adverse effects. This is accomplished by **balanced anesthesia**—the combining of several drugs, each with a specific effect, to achieve analgesia, muscle relaxation, unconsciousness, and amnesia rather than using one drug. Balanced anesthesia commonly involves the following agents:

- **Preoperative medications**, which may include the use of anticholinergics that decrease secretions to facilitate intubation and prevent bradycardia associated with neural depression.
- **Sedative–hypnotics** to relax the patient, facilitate amnesia, and decrease sympathetic stimulation.
- **Antiemetics** to decrease the nausea and vomiting associated with the slowing of GI activity.

- **Antihistamines** to decrease the chance of allergic reaction and help to dry up secretions.
- **Narcotics** to aid analgesia and sedation.

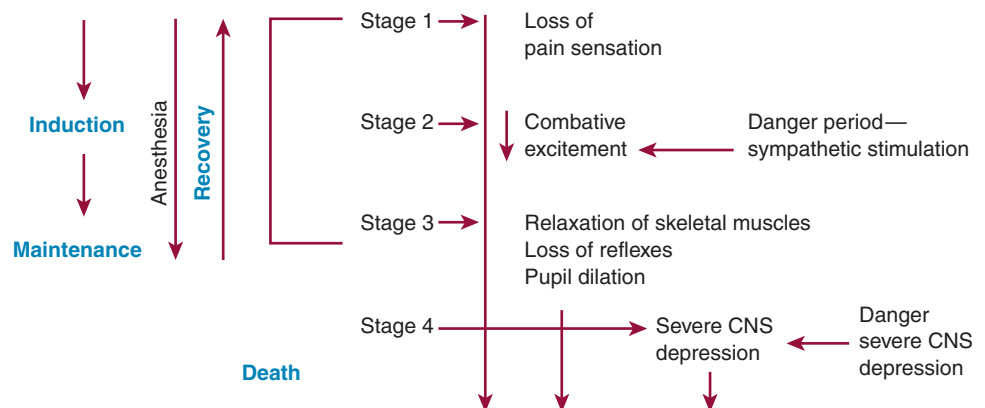

Many of these drugs are given before the general anesthetic is administered to facilitate the process. Some are continued during surgery to aid the general anesthetic, allowing therapeutic effects at lower doses. For example, patients may receive a neuromuscular junction (NMJ) blocker (Chapter 28) to stop muscle activity and a rapid-acting intravenous general anesthetic to induce anesthesia, and then a gas general anesthetic to balance the anesthetic effect during the procedure and allow for easier recovery. Careful selection of appropriate general anesthetic agents, along with monitoring and support of the patient, helps to alleviate many problems.

Administration of General Anesthesia

General anesthesia is delivered by a physician or nurse anesthetist trained in the delivery of these potent drugs along with intubation, mechanical ventilation, and full life support. During the delivery of anesthesia, the patient can go through predictable stages (Figure 27.1), referred to as the depth of anesthesia:

- Stage 1, the analgesia stage, refers to the loss of pain sensation, with the patient still conscious and able to communicate.
- Stage 2, the excitement stage, is a period of excitement and often combative behavior, with many signs of sympathetic stimulation (e.g., tachycardia, increased respirations, blood pressure changes).
- Stage 3, surgical anesthesia, involves relaxation of skeletal muscles, return of regular respirations, and progressive loss of eye reflexes and pupil dilation. Surgery can be safely performed in stage 3.
- Stage 4, medullary paralysis, is very deep CNS depression with loss of respiratory and vasomotor center stimuli, in which death can occur rapidly. If a patient reaches this level, the anesthesia has become too intense and the situation is critical.

General anesthesia administration also is divided into three phases: induction, maintenance, and recovery.

● **FIGURE 27.1** Stages of general anesthesia.

Induction

Induction is the period from the beginning of anesthesia until stage 3, or surgical anesthesia, is reached. The danger period for many patients during induction is stage 2 because of the systemic stimulation that occurs. Often a rapid-acting anesthetic is used to move quickly through this phase and into stage 3. NMJ blockers may be used during induction to facilitate intubation, which is necessary to support the patient with mechanical ventilation during anesthesia (see Chapter 28).

Maintenance

Maintenance is the period from stage 3 until the surgical procedure is complete. A slower, more predictable anesthetic, such as a gas anesthetic, may be used to maintain the anesthesia once the patient is in stage 3.

Recovery

Recovery is the period from discontinuation of the anesthetic until the patient has regained consciousness, movement, and the ability to communicate. During recovery, the patient requires continuous monitoring for any adverse effects of the drugs used and ensure support of the patient's vital functions as necessary.

KEY POINTS

- ▶ General anesthesia produces analgesia, amnesia, and unconsciousness.
- ▶ General anesthesia places the patient at risk for problems because of its extensive CNS depression and widespread effects on other body systems.
- ▶ Balanced anesthesia involves the administration of several drugs rather than a single drug to achieve analgesia, muscle relaxation, unconsciousness, and amnesia.
- ▶ Induction of anesthesia is the period ranging from administration of the anesthetic to the point of surgical anesthesia.

GENERAL ANESTHETIC AGENTS

Several different types of drugs are used as general anesthetics. These include barbiturate and nonbarbiturate anesthetics, gas anesthetics, and volatile liquids. See Table 27.1 for a listing of general anesthetic agents along with the anticipated adverse effects of these drugs.

Barbiturate Anesthetics

The barbiturate anesthetics (Table 27.1) are intravenous drugs used to induce rapid anesthesia, which is then maintained with an inhaled drug. They include methohexital (*Brevital*) and thiopental (*Pentothal*).

Therapeutic Actions and Indications

Thiopental is probably the most widely used of the intravenous anesthetics. Because it has no analgesic properties, the patient

may need additional analgesics after surgery. Like thiopental, methohexital also lacks analgesic properties, and the patient may require postoperative analgesics.

Pharmacokinetics

Thiopental has a very rapid onset of action, usually within 10 to 30 seconds, and an ultrashort recovery period of 5 to 8 minutes. Methohexital has a rapid onset of action and a recovery period that is usually 3 to 4 minutes. These drugs are lipophilic. They are dissolved and rapidly absorbed through the lipid blood–brain barrier and diffuse into the brain very rapidly.

Contraindications and Cautions

Methohexital cannot come in contact with silicone (rubber stoppers and disposable syringes often contain silicone) *because it will cause an immediate breakdown of the silicone*. As a result, it poses special problems, and special precautions must be taken. Neither drug should be used until the anesthesiologist and staff are ready and equipped for intubation and respiratory support *because of the rapid onset and because these drugs can cause respiratory depression and apnea*. These drugs should not be used during pregnancy or lactation unless the benefit clearly outweighs the potential risk to the fetus or neonate *because of the CNS depressive effects of these drugs*.

Adverse effects

The adverse effects associated with these drugs are related to the suppression of the CNS with decreased pulse, hypotension, suppressed respirations, and decreased GI activity. Nausea and vomiting after recovery are common.

Clinically Important Drug–Drug Interactions

Caution must be used when these drugs are used with any other CNS suppressants. Barbiturates can cause decreased effectiveness of theophylline, oral anticoagulants, beta-blockers, corticosteroids, hormonal contraceptives, phenylbutazones, metronidazole, quinidine, and carbamazepine. Combinations of barbiturate anesthetics and narcotics may produce apnea more commonly than occurs with other analgesics.

Prototype Summary: Thiopental

Indications: Induction of anesthesia, maintenance of anesthesia; induction of a hypnotic state.

Actions: Depresses the CNS to produce hypnosis and anesthesia without analgesia.

Pharmacokinetics:

Route	Onset	Duration
IV	1 min	20–30 min

$T_{1/2}$: 3 to 8 hours; metabolized in the liver, excreted in the urine.

Adverse effects: Emergence delirium, headache, restlessness, anxiety, cardiovascular depression, respiratory depression, apnea, salivation, hiccups, skin rashes.

TABLE 27.1 DRUGS IN FOCUS General Anesthetic Agents

Drug Name	Onset	Recovery	Analgesia	Systems Alert ^a

^aSystems alert indicates physiological systems with anticipated adverse effects to these drugs. When drugs are selected, the patient's condition and potential for serious problems with these adverse effects should be considered.

—, no effect; +, mild effect; ++, moderate effect; +++, strong effect; +++++, powerful effect

Nonbarbiturate Anesthetics

The other parenteral drugs used for intravenous administration in anesthesia are nonbarbiturates with a wide variety of effects. Such anesthetics include droperidole (*Inapsine*), etomidate (*Amidate*), ketamine (*Ketalar*), midazolam (*Versed*), and propofol (*Diprivan*). (See Table 27.1.)

Therapeutic action and indications

Midazolam is the prototype nonbarbiturate anesthetic. It is a very potent amnesiac. These drugs are thought to act in the reticular activating system (RAS) and limbic system to potentiate the effects of gamma-aminobutyric acid (GABA). Midazolam's amnesiac effects occur at doses below those

needed to cause sedation. It is widely used to produce amnesia or sedation for many diagnostic, therapeutic, and endoscopic procedures. Midazolam can also be used to induce anesthesia and to provide continuous sedation for intubated and mechanically ventilated patients. Droperidol produces marked sedation and produces a state of mental detachment. It also has antiemetic effects, reducing the incidence of nausea and vomiting in surgical and diagnostic procedures. Etomidate is used as a general anesthetic and is sometimes used to sedate patients receiving mechanical ventilation. Ketamine has been associated with a bizarre state of unconsciousness in which the patient appears to be awake but is unconscious and cannot feel pain. This drug, which causes sympathetic stimulation with increase in blood pressure and heart rate, may be helpful in situations when cardiac depression is dangerous. Propofol often is used for short procedures because it has a very rapid clearance and produces much less of a hangover effect and allows for quick recovery. It is also used to maintain patients on mechanical ventilation.

Pharmacokinetics

Midazolam has a rapid onset but does not reach peak effectiveness for 30 to 60 minutes. Droperidol has an onset of action within 3 minutes and an ultrashort recovery period. Etomidate has an onset within 1 minute and a rapid recovery period within 3 to 5 minutes. Ketamine has an onset of action within 30 seconds and a very slow recovery period (45 minutes). Propofol is a very short-acting anesthetic with a rapid onset of action of 30 to 60 seconds.

Contraindications and Cautions

Midazolam is more likely to cause nausea and vomiting than are some of the other anesthetics, and so it should be used with caution in any patient who could be compromised by vomiting. It has been associated with respiratory depression and respiratory arrest, and so life support equipment should be readily available whenever it is used. Droperidol should be used with caution in patients with renal or hepatic failure and should be used with extreme care in patients with prolonged QT intervals or who are at risk for prolonged QT intervals. Etomidate is not recommended for use in children younger than 10 years of age.

Adverse Effects

Patients receiving any general anesthetic are at risk for skin breakdown because they will not be able to move. Care must be taken to prevent decubitus ulcer formation. Patients receiving midazolam should be monitored for respiratory depression and CNS suppression. During the recovery period, droperidol may cause hypotension, chills, hallucinations, and drowsiness. It may also cause QT prolongation, which puts the patient at risk for serious cardiac arrhythmias. During the recovery period with etomidate, many patients experience myoclonic and tonic

movements, as well as nausea and vomiting. Ketamine crosses the blood–brain barrier and can cause hallucinations, dreams, and psychotic episodes. Propofol often causes local burning on injection. It can cause bradycardia, hypotension, and, in extreme cases, pulmonary edema.

Clinically Important Drug–Drug Interactions

If ketamine and halothane are used in combination, severe cardiac depression with hypotension and bradycardia may occur. If these agents must be used together, the patient should be monitored closely. Droperidol should not be used with other drugs that prolong the QT interval. If this combination is necessary, the patient should be monitored continuously. Ketamine may also potentiate the muscular blocking of NMJ blockers, and the patient may require prolonged periods of respiratory support. Midazolam is associated with increased toxicity and length of recovery when used in combination with inhaled anesthetics, other CNS depressants, narcotics, propofol, or thiopental. If any of these agents are used in combination, careful balancing of drug doses is necessary.

Prototype Summary: Midazolam

Indications: Sedation, anxiolysis, and amnesia before diagnostic, therapeutic, or endoscopic procedures; induction of anesthesia; continuous sedation of intubated patients.

Actions: Acts mainly at the limbic system and RAS; potentiates the effects of GABA; has little effect on cortical function; exact mechanism of action is not understood.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	30–60 min	12 h	2–6 h
IM	15 min	30 min	2–6 h
IV	3–5 min	<30 min	2–6 h

$T_{1/2}$: 1.8 to 6.8 hours; metabolized in the liver, excreted in the urine.

Adverse effects: Transient drowsiness, sedation, drowsiness, lethargy, apathy, fatigue, disorientation, restlessness, constipation, diarrhea, incontinence, urinary retention, bradycardia, tachycardia, phlebitis at IV injection site.

Anesthetic Gases

Like all inhaled drugs, anesthetic gases enter the bronchi and alveoli, rapidly pass into the capillary system (because gases flow from areas of higher concentration to areas of lower concentration), and are transported to the heart to be pumped throughout the body. These gases have a very high affinity for fatty tissue, and they are lipophilic, including the lipid membrane of the nerves in the CNS. The gases pass quickly into the brain and cause severe CNS depression. Once the patient is in stage 3 of anesthesia, the anesthetist regulates the amount

of gas that is delivered to ensure that it is sufficient to keep the patient unconscious but not enough to cause severe CNS depression. This is done by decreasing the concentration of the gas that is flowing into the bronchi, creating a concentration gradient that results in the movement of gas in the opposite direction—out of the tissues and back to expired air.

Anesthetic gases include cyclopropane (orange cylinder), ethylene (red cylinder), and nitrous oxide (blue cylinder). (See Table 27.1.)

Therapeutic Actions and Indications

Nitrous oxide is a very potent analgesic. However, it is the weakest of the gas anesthetics and the least toxic. It moves so quickly in and out of the body that it can actually accumulate and cause pressure in closed body compartments such as the sinuses. Because nitrous oxide is such a potent analgesic, it is used frequently for dental surgery. It does not cause muscle relaxation. Nitrous oxide is usually combined with other agents for anesthetic use.

Cyclopropane has a rapid onset of action—usually within 1 to 2 minutes—and a rapid recovery. This drug causes muscle relaxation. Ethylene is less toxic than most of the other gas anesthetics. It is not associated with bronchospasm, and there is usually less postanesthetic vomiting with this drug.

Pharmacokinetics

All of these agents have a rapid onset of action, usually within 1 to 2 minutes, and a rapid recovery period. Timing of recovery depends on the other drugs being used.

Contraindications and Cautions

Nitrous oxide and ethylene can block the reuptake of oxygen after surgery and cause hypoxia. Because of this reaction, it is always given in combination with oxygen. Susceptible patients should be monitored for signs of hypoxia, chest pain, and stroke. Cyclopropane may trigger malignant hyperthermia and should be used with caution in patients at increased risk. These drugs should not be used during pregnancy unless the benefit clearly outweighs the potential risk to the fetus. Nursing mothers should wait 4 hours before nursing a baby when they have been administered one of these drugs.

Adverse Effects

As with other general anesthetics, patients need to be monitored for skin integrity when they are not able to move for periods of time. Cyclopropane may cause pain, headache, nausea, vomiting, and delirium in the patient during the recovery phase. Ethylene can leave the patient with a headache and a very unpleasant taste in the mouth. Nitrous oxide can cause acute sinus and middle ear pain, bowel obstruction, and pneumothorax because it so rapidly moves into and accumulates in closed spaces. Because nitrous oxide inactivates vitamin B₁₂, patients

should also be monitored for low vitamin B₁₂ levels, including neurological, immune, and hematological complications.

Clinically Important Drug–Drug Interactions

Caution should be used if these drugs are combined with any other drug that causes CNS depression. If halothane and ketamine are used in combination, severe cardiac depression with hypotension and bradycardia may occur. If these agents must be used together, the patient should be monitored closely.

Prototype Summary: Nitrous Oxide

Indications: Induction and maintenance of anesthesia.

Actions: Depresses the CNS to produce anesthesia and analgesia.

Pharmacokinetics:

Route	Onset	Duration
IV	1–2 min	20 min

T_{1/2}: minutes; not metabolized, excreted in the lungs.

Adverse effects: Cardiovascular depression, respiratory depression, apnea, earache, sinus pain, vomiting, malignant hyperthermia.

Volatile Liquids

Inhaled anesthetics also can be **volatile liquids**—liquids that are unstable at room temperature and release gases. These gases are then inhaled by the patient. Therefore, volatile liquids act like gas anesthetics.

Most of the volatile liquids in use are halogenated hydrocarbons such as halothane (*Fluothane*), desflurane (*Suprane*), enflurane (*Ethrane*), isoflurane (*Forane*), and sevoflurane (*Ultane*). (See Table 27.1.)

Therapeutic Actions and Indications

Halothane is the prototype of the volatile liquids. It is usually used for maintenance of anesthesia and can be effective as an induction agent. Desflurane is widely used in outpatient surgery because of its rapid onset and quick recovery time. Isoflurane is widely used to maintain anesthesia after inductions. It can cause muscle relaxation. Sevoflurane is used in outpatient surgery as an induction agent and is rapidly cleared for quick recovery.

Pharmacokinetics

Halothane has a rapid onset of action—within 1 to 2 minutes—and rapid recovery—usually within 20 minutes. It is metabolized in the liver to toxic hydrocarbons and bromide. Desflurane, enflurane, and isoflurane have a rapid onset—also within 1 to 2 minutes—and rapid recovery—usually within 15 to 20 minutes. Sevoflurane, the newest of the volatile liquids, has a very rapid onset of action—within 30 seconds—

and a very rapid clearance—lasting only about 10 minutes. These drugs are all cleared through the lungs.

Contraindications and Cautions

Halothane should be avoided in patients with hepatic impairment *due to its hepatic metabolism, which can contribute to hepatic toxicity*. It is associated with bradycardia and hypotension, and *so it should be used with caution in any patient with cardiovascular disease*. Desflurane use should be avoided in patients with respiratory problems and in those with increased sensitivity *because of its irritation to the airways and tendency to cause respiratory depression*. In addition, it is not recommended for induction in pediatric patients *because of its irritation of the airways*. Enflurane should not be used in patients with known cardiac or respiratory disease or renal dysfunction *because it is associated with renal toxicity, cardiac arrhythmias, and respiratory depression*. Isoflurane and sevoflurane should be used with caution in patients with respiratory depression *to avoid severe respiratory depression*. All of these drugs have the potential to trigger malignant hyperthermia and should be used with caution in any patient at high risk for developing it *to avoid development of malignant hyperthermia*. Dantrolene, the preferred treatment for malignant hyperthermia, should be readily available whenever any of these drugs is used. These drugs should be avoided in pregnancy and lactation unless the benefit clearly outweighs the risk to the fetus or baby *because of the CNS depressive effects of the drugs*.

Adverse Effects

Halothane's recovery syndrome is characterized by fever, anorexia, nausea, vomiting, and eventually hepatitis, which can progress to fatal hepatic necrosis. Although this syndrome is rare, halothane is not used more frequently than every 3 weeks to reduce patient risk.

Desflurane is associated with a collection of respiratory reactions, including cough, increased secretions, and laryngospasm. Isoflurane is associated with hypotension, hypercapnia, muscle soreness, and a bad taste in the mouth, but it does not cause cardiac arrhythmias or respiratory irritation as do some other volatile liquids. Enflurane may cause renal impairment. Adverse effects of sevoflurane are thought to be minimal.

Clinically Important Drug–Drug Interactions

Caution should be used when any of these drugs is combined with other CNS suppressants.

Prototype Summary: Halothane

Indications: Induction and maintenance of general anesthesia.

Actions: Depresses the CNS, causing anesthesia; relaxes muscles; sensitizes the myocardium to the effects of norepinephrine and epinephrine.

Pharmacokinetics:

Route	Onset	Peak	Duration
Inhaled	Rapid	Rapid	End of inhalation

$T_{1/2}$: Unknown; metabolized in the liver, excreted in the urine.

Adverse effects: Transient drowsiness, sedation, lethargy, apathy, fatigue, disorientation, restlessness, constipation, diarrhea, incontinence, urinary retention, bradycardia, tachycardia, hypoxia, acidosis, apnea, arrhythmias, hepatic injury.

Nursing Considerations for Patients Receiving General Anesthetic Agents

Assessment: History and Examination

- Assess for *contraindications or cautions*: any known allergies to general anesthetics *to avoid hypersensitivity reactions*; impaired liver or kidney function, *which might interfere with drug metabolism and excretion*; myasthenia gravis or cardiac or respiratory disease, *which may be exacerbated by the depressive effects of the drug*; personal or family history of malignant hyperthermia, *which may be triggered by the use of general anesthetics*.
- Perform a physical assessment, including weighing the patient, *to determine the appropriate dosing of the drug and to establish a baseline status before beginning therapy and evaluate for any potential adverse effects*.
- Assess the patient's neurological status, including level of consciousness, affect, reflexes, and pupil size and reaction, and evaluate muscle tone and response, *to monitor CNS depression and provide appropriate support as needed*.
- Monitor vital signs, including temperature, pulse, and blood pressure, for changes, and auscultate lung and heart sounds *to monitor for adverse effects of the drugs*.
- Obtain an electrocardiogram (ECG) *to evaluate for underlying cardiac problems that may be exacerbated by the drug*.
- Assess skin color and lesions *to monitor for potential skin breakdown resulting from patient paralysis and immobility while under anesthesia*.
- Auscultate abdomen for bowel sounds *to evaluate GI motility*.
- Monitor the results of laboratory tests, including renal and liver function tests, *to determine the possible need for a reduction in dose and evaluate for possible toxicity*.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Impaired Gas Exchange related to respiratory depression.
- Impaired Skin Integrity related to immobility secondary to effects of positioning during anesthesia and immobility.
- Risk for injury related to CNS depressive effects of the drug.

- Disturbed Thought Processes and Disturbed Sensory Perception related to CNS depression.
- Deficient Knowledge regarding drug therapy.

Implementation With Rationale

- Keep in mind that the drug must be administered by trained personnel (usually an anesthesiologist) *because of the potential risks associated with its use.*
- Have emergency equipment to maintain airway and provide mechanical ventilation readily available *when patient is not able to maintain respiration because of CNS depression.*
- Monitor temperature *for prompt detection and treatment of malignant hyperthermia.* Maintain dantrolene on standby.
- Monitor pulse, respiration, blood pressure, ECG, and cardiac output continually during administration to *assess systemic response to CNS depression and provide appropriate support as needed.*
- Monitor temperature and reflexes because *dose adjustment may be needed to alleviate potential problems and to maximize overall benefit with the least toxicity.*
- Institute safety precautions, such as side rails, and monitor patient until the recovery phase is complete and the patient is conscious and able to move and communicate *to ensure patient safety.*
- Provide comfort measures *to help the patient tolerate drug effects.* Provide pain relief as appropriate, along with reassurance and support *to deal with the effects of anesthesia and loss of control, skin care and turning to prevent skin breakdown, and supportive care for conditions such as hypotension and bronchospasm.*
- Offer support and encouragement *to help the patient cope with the procedure and the drugs being used.*
- Provide preoperative patient teaching, *realizing that most patients who receive the drug will be unconscious or will be receiving teaching about a particular procedure:*
 - Information about the anesthetic (e.g., what to expect, rate of onset, time to recovery)
 - Medications that may be used preoperatively
 - Effects of the medication on the patient preoperatively
 - Measures to maintain the patient's safety preoperatively and during recovery
 - How the patient will feel during the recovery phase
 - Signs and symptoms to report during recovery and afterward

Evaluation

- Monitor patient response to the drug (analgesia, loss of consciousness).
- Monitor for adverse effects (respiratory depression, hypotension, bronchospasm, slowed GI activity, skin breakdown, malignant hyperthermia).
- Evaluate the effectiveness of the teaching plan (patient can relate anticipated effects of the drug and the recovery process).
- Monitor the effectiveness of comfort and safety measures.

KEY POINTS

- ▶ General anesthetics must be administered by physicians or nurse anesthetists trained in their administration and prepared to provide constant monitoring and life support measures to assist the patient when the CNS is depressed.
- ▶ General anesthetics include barbiturates and nonbarbiturate drugs, which are administered parenterally, and anesthetic gases and volatile liquids, which are administered through inhalation.
- ▶ Patients receiving general anesthetics must be constantly monitored because the CNS depression can cause respiratory arrest, cardiovascular reactions including hypotension, and alterations in GI activity that can lead to nausea and vomiting.

LOCAL ANESTHESIA

Local anesthesia refers to a loss of sensation in limited areas of the body. Local anesthesia can be achieved by several different methods: topical administration, infiltration, field block, nerve block, and intravenous regional anesthesia.

Topical Administration

Topical local anesthesia involves the application of a cream, lotion, ointment, or drop of a local anesthetic to traumatized skin to relieve pain. It can also involve applying these forms to the mucous membranes in the eye, nose, throat, mouth, urethra, anus, or rectum to relieve pain or to anesthetize the area to facilitate a medical procedure. Although systemic absorption is rare with topical application, it can occur if there is damage or breakdown of the tissues in the area.

Infiltration

Infiltration local anesthesia involves injecting the anesthetic directly into the tissues to be treated (e.g., sutured, drilled, cut). This injection brings the anesthetic into contact with the nerve endings in the area and prevents them from transmitting nerve impulses to the brain.

Field Block

Field block local anesthesia involves injecting the anesthetic all around the area that will be affected by the procedure or surgery. This is more intense than infiltration anesthesia because the anesthetic agent comes in contact with all of the nerve endings surrounding the area. This type of block is often used for tooth extractions.

Nerve Block

Nerve block local anesthesia involves injecting the anesthetic at some point along the nerve or nerves that run to and from the region in which the loss of pain sensation or muscle paralysis is desired. These blocks are performed not in the surgical field, but at some distance from the field. They involve a greater

area with potential for more adverse effects. Several types of nerve blocks are possible:

- Peripheral nerve block: blockage of the sensory and motor aspects of a particular nerve for relief of pain or for diagnostic purposes.
- Central nerve block: injection of anesthetic into the roots of the nerves in the spinal cord
- Epidural anesthesia: injection of the drug into the epidural space where the nerves emerge from the spinal cord.
- Caudal block: injection of anesthetic into the sacral canal, below the epidural area.
- Spinal anesthesia: injection of anesthetic into the spinal subarachnoid space.

Intravenous Regional Local Anesthesia

Intravenous regional local anesthesia involves carefully draining all of the blood from the patient's arm or leg, securing a tourniquet to prevent the anesthetic from entering the general circulation, and then injecting the anesthetic into the vein of the arm or leg. This technique is used for very specific surgical procedures.

LOCAL ANESTHETIC AGENTS

Local anesthetic agents (Table 27.2) are used primarily to prevent the patient from feeling pain for varying periods of time after the agents have been administered in the peripheral nervous system. In increasing concentrations, local anesthetics can also cause loss of the following sensations (in this sequence): temperature, touch, proprioception (position sense), and skeletal muscle tone. If these other aspects of nerve function are progressively lost, recovery occurs in the reverse order of the loss.

The local anesthetics are very powerful nerve blockers, and it is very important that their effects be limited to a particular area of the body. They should not be absorbed systemically. Systemic absorption could produce toxic effects on the nervous system and the heart (e.g., severe CNS depression, cardiac arrhythmias).

Local anesthetics are classified as esters or amides. The agent of choice depends on the method of administration, the length of time for which the area is to be anesthetized, and consideration of potential adverse effects. Esters include benzocaine (*Dermoplast, Lanacane, Ungentine*), chloroprocaine (*Nesacaine*), procaine (*Novocain*), and tetracaine (*Pontocaine*). Amides include bupivacaine (*Marcaine, Sensorcaine*), dibucaine (*Nupercainal*), levobupivacaine (*Chirocaine*), lidocaine (*Dilocaine, Solarcaine, Xylocaine, Lidoderm, Octocaine*), mepivacaine (*Carbocaine, Isocaine, Polocaine*), prilocaine (*Citanest*), and ropivacaine (*Naropin*). Pramoxine (*Tronothane, PrameGel, Itch-X, Prax*) is a local anesthetic agent that does not fit into either of these classes.

Therapeutic Actions and Indications

Local anesthetics work by causing a temporary interruption in the production and conduction of nerve impulses. They affect

the permeability of nerve membranes to sodium ions, which normally infuse into the cell in response to stimulation. By preventing the sodium ions from entering the nerve, they stop the nerve from depolarizing. A particular section of the nerve cannot be stimulated, and nerve impulses directed toward that section are lost when they reach that area.

The way in which a local anesthetic is administered helps to increase its effectiveness by delivering it directly to the area that is causing or will cause the pain, thereby decreasing systemic absorption and related toxic effects (Figure 27.2). Local anesthetics are indicated for infiltration anesthesia, peripheral nerve block, spinal anesthesia, and the relief of local pain. In 2005, the U.S. Food and Drug Administration approved a local anesthetic product that combines lidocaine and tetracaine in a dermal patch, called *Synera* (see Focus on Safe Medication Administration, under Contraindications and Cautions, for more information about this drug.)

Pharmacokinetics

The ester local anesthetics are broken down immediately in the plasma by enzymes known as **plasma esterases**. The amide local anesthetics are metabolized more slowly in the liver, and serum levels of these drugs can increase and lead to toxicity.

Contraindications and Cautions

The local anesthetics are contraindicated with any of the following conditions: history of allergy to any one of these agents or to parabens *to avoid hypersensitivity reactions*; heart block, *which could be greatly exacerbated with systemic absorption*; shock, *which could alter the local delivery and absorption of these drugs*; and decreased plasma esterases, *which could result in toxic levels of the ester-type local anesthetics*.

They should be used during pregnancy and lactation only if the benefit outweighs any potential risk to the fetus or neonate that could occur if the drug is inadvertently absorbed systemically *because of the suppressive effects on nerves*.

Safe Medication Administration

Combination Local Anesthetic

Synera, a local anesthetic product that is a combination of lidocaine and tetracaine and is available in a dermal patch, was approved for use on intact skin to provide local dermal anesthesia when doing venipunctures or inserting IV cannulae or for superficial dermatological procedures that could cause discomfort for the patient. When using it for venipunctures or inserting an IV, one patch is applied 20 to 30 minutes before the procedure. If a superficial dermatological procedure is being performed, one patch is applied to the area 30 minutes before the procedure. The patch must be removed if the patient is undergoing a magnetic resonance imaging scan to prevent burning related to the dermal patch. The site should be monitored for any local irritation.

TABLE 27.2 DRUGS IN FOCUS Local Anesthetic Agents

Drug Name	Onset	Duration	Administration	Special Considerations
Esters				
benzocaine (<i>Dermoplast</i> , <i>Lanacane</i> , <i>Ungentine</i>)	1 min	30–60 min	Skin, mucous membranes	Avoid tight bandages with skin preparation
chloroprocaine (<i>Nesacaine</i>)	6–15 min	15–75 min	Nerve block, caudal, epidural	Do not use with subarachnoid administration
procaine (<i>Novocain</i>)	2–25 min	15–75 min	Infiltration, peripheral, spinal, dental	Monitor skin condition if immobile; keep supine to avoid headache after spinal
tetracaine (<i>Pontocaine</i>)	15–30 min	2–25 h	Spinal, prolonged spinal, skin	Monitor skin condition if immobile; provide reassurance if prolonged; keep supine to avoid headache after spinal
Amides				
bupivacaine (<i>Marcaine</i> , <i>Sensorcaine</i>)	5–20 min	2–7 h	Local, epidural, dental, caudal, subarachnoid, sympathetic, retrobulbar	Do not use Bier Block—deaths have occurred
dibucaine (<i>Nupercainal</i>)	<15 min	3–4 h	Skin, mucous membranes	Monitor for local reactions
levobupivacaine (<i>Chirocaine</i>)	5–20 min	2–7 h	Regional block, OB, postop pain	Less cardiac and CNS toxicity than bupivacaine, suggests safer use in some patients
 lidocaine (<i>Dilocaine</i> , <i>Solarcaine</i> , <i>Xylocaine</i> , <i>Lidoderm</i> , <i>Octocaine</i>)	5–15 min	30–90 min	Caudal, epidural, spinal cervical, dental, skin, mucous membrane, topical patch	Short acting, preferred for short procedures; danger if absorbed systemically
mepivacaine (<i>Carbocaine</i> , <i>Isocaine</i> , <i>Polocaine</i>)	3–15 min	45–90 min	Nerve block, OB, cervical, epidural, dental, local infiltration	Caution with renal impairment
prilocaine (<i>Cilanest</i>)	1–15 min	0.5–3 h	Nerve block, dental	Advise patients not to bite themselves
ropivacaine (<i>Naropin</i>)	1–5 min	2–6 h	Nerve block, epidural, caudal	Avoid rapid infusion; offers good pain management postop and OB
Other				
pramoxine (<i>Tronothane</i> , <i>PraxeGel</i> , <i>Itch-X</i> , <i>Prax</i>)	3–5 min	<60 min	Skin, mucous membranes	Do not cover with tight bandages; protect patient from injury

Adverse Effects

The adverse effects of these drugs may be related to their local blocking of sensation (e.g., skin breakdown, self-injury, biting oneself). Loss of skin integrity is always a problem if the patient is unable to move, and care must be taken to prevent skin breakdown. Other problematic effects are associated with the route of administration and the amount of drug that is absorbed systemically. These effects are related to the blockade of nerve depolarization throughout the system. Effects that may occur include CNS effects such as headache (especially with epidural and spinal anesthesia), restlessness, anxiety, dizziness, tremors,

blurred vision, and backache; GI effects such as nausea and vomiting; cardiovascular effects such as peripheral vasodilation, myocardial depression, arrhythmias, and blood pressure changes, all of which may lead to fatal cardiac arrest; and respiratory arrest.

Clinically Important Drug–Drug Interactions

When local anesthetics and succinylcholine are given together, increased and prolonged neuromuscular blockade occurs. There is also less risk of systemic absorption and increased local effects if these drugs are combined with epinephrine.

● **FIGURE 27.2** Mechanism of action of local anesthetics. **Top.** An injury produces pain impulses (action potentials) that are conducted and transmitted in an area of the brain in which pain is perceived. **A.** Conduction of the pain impulse has been blocked by infiltration anesthetics at the site of the injury. **B.** A nerve block at some distance from the injury. Local anesthetics block the movement of sodium into the nerve and prevent nerve depolarization, stopping the transmission of the pain impulse.

Prototype Summary: Lidocaine

Indications: Infiltration anesthesia, peripheral and sympathetic nerve blocks, central nerve blocks, spinal and caudal anesthesia, topical anesthetic for skin or mucous membrane disorders.

Actions: Blocks the generation and conduction of action potentials in sensory nerves by reducing sodium permeability, reducing the height and rate of rise of the action potential, increasing the excitation threshold, and slowing the conduction velocity.

Pharmacokinetics:

Route	Onset	Peak	Duration
IM	5–10 min	5–15 min	2 h
Topical	Not generally absorbed systemically		

$T_{1/2}$: 10 minutes, then 1.5 to 3 hours; metabolized in the liver, excreted in the urine.

Adverse effects: Headache, backache, hypotension, urinary retention, urinary incontinence, pruritus, seizures; when locally applied: burning, stinging, swelling, tenderness.

Nursing Considerations for Patients Receiving Local Anesthetic Agents

Assessment: History and Examination

- Assess for *contraindications and cautions*: any known allergies to these drugs or to parabens to avoid hypersen-

sitivity reactions; impaired liver function, which could alter metabolism and clearance of the drug; low plasma esterases, which could lead to toxicity of esters; heart block, which could be exacerbated by the drug effects; shock to prevent altered local delivery and absorption; and current status of pregnancy or lactation, which are cautions to the use of the drug.

- Perform a physical assessment to establish a baseline status before beginning therapy and for any potential adverse effects.
- Inspect site for local anesthetic application to ensure integrity of the skin and to prevent inadvertent systemic absorption of the drug.
- Assess the patient's neurological status, including level of orientation, reflexes, pupil size and reaction, muscle tone and response, and sensation, to evaluate the effectiveness of the drug and monitor for potential toxic neurological effects.
- Monitor vital signs, including temperature, pulse, and blood pressure, and assess respiratory rate and auscultate lungs, for adventitious sounds to identify changes and possible systemic absorption.
- Monitor laboratory test results, such as liver function tests and plasma esterases (if appropriate), to determine possible need for dose adjustment.
- Refer to the Critical Thinking Scenario for a full discussion of nursing care for a patient who is receiving local anesthesia.

CRITICAL THINKING SCENARIO

Local Anesthesia

THE SITUATION

A.M., a 32-year-old male athlete with a history of asthma (which could indicate pulmonary dysfunction), was admitted to the hospital for an inguinal hernia repair. At the patient's request, the surgeon elected to use a local anesthetic employing spinal anesthesia. Because the extent of the repair was unknown (A.M. had undergone two previous repairs), levobupivacaine, a long-acting anesthetic, was selected. He remained alert (blood pressure 120/64 mm Hg, pulse 62 beats/min, respiration rate 10/min) and stable throughout the procedure. Two hours after the conclusion of the procedure, A.M. appeared agitated (blood pressure 154/68 mm Hg, pulse 88 beats/min, respiration rate 12/min). Although he did not complain of discomfort, he did state that he still had no feeling and had only limited movement of his legs.

CRITICAL THINKING

What safety precautions need to be taken?

What nursing interventions should be done at this point?

How could the patient be reassured? *Think about the anxiety level of the patient—an athlete who elected to have local anesthesia may have a problem with control and feel somewhat invincible. Consider the anxiety that loss of mobility and sensation in the legs may cause in a person who makes his living as an athlete.*

In addition, consider the expected duration of action of levobupivacaine and the rate of return of function.

DISCUSSION

Levobupivacaine is a long-acting anesthetic with effects that may persist for several hours. The timing of the drug's effects should be explained to A.M., and he should be monitored for a period of time to determine whether his agitated state and slightly elevated vital signs are a result of anxiety or an unanticipated reaction to the surgery or the drug. Life-support equipment should be on standby in case his condition is a toxic drug reaction or some unanticipated problem occurring after surgery.

The nurse is in the best position to perform the following interventions: explaining the effects of the drug and the anticipated recovery schedule; keeping the patient as flat as possible to decrease the headache usually associated with spinal anesthesia; encouraging the patient to turn from side to side periodically to allow skin care to be performed and to alleviate the risk of pressure sore development; and staying with the patient as much as possible to reassure him, to answer his questions, and to encourage him to talk about his feelings and reaction.

If the agitated state is caused by a stress reaction, the patient should return to normal; comfort measures, teaching, and reassurance should be provided. An elevated systolic pressure with a normal diastolic pressure often is an indication of a sympathetic stress response. An athlete is more likely than most people to suffer great anxiety and fear if his legs become numb and he is unable to move them. Teaching and comfort measures may be all that is needed to relieve the anxiety and ensure a good recovery.

NURSING CARE GUIDE FOR A.M.: LOCAL ANESTHESIA

Assessment: History and Examination

Assess for allergies to local anesthetics or to parabens, cardiac disorders, vascular problems, hepatic dysfunction; also assess for concurrent use of succinylcholine.

Focus physical examination on the following:

CV: blood pressure, pulse, peripheral perfusion, ECG

CNS: orientation, affect, reflexes, vision

Skin: color, lesions, texture, sweating

Respiratory: respiration, adventitious sounds

Laboratory tests: liver function tests, plasma esterases

Nursing Diagnoses

Disturbed Sensory Perception (Kinesthetic, Tactile) related to anesthesia

Anxiety related to drug effects

Impaired Skin Integrity related to immobility

Risk for Injury related to loss of sensation, and mobility

Deficient Knowledge regarding drug therapy

Implementation

Provide comfort and safety measures: positioning, skin care, side rails, pain medication as needed, maintain airway, antidotes on standby.

Provide support and reassurance to deal with loss of sensation and mobility.

Provide patient teaching about procedure being performed and what to expect.

Provide life support as needed.

Evaluation

Evaluate drug effects: loss of sensation, loss of movement.

Monitor for adverse effects: cardiovascular effects (blood pressure changes, arrhythmias), respiratory depression, GI upset, CNS alterations, skin breakdown, anxiety, and fear.

Monitor for drug–drug interactions as indicated for each drug.

Evaluate the effectiveness of the patient teaching program and comfort and safety measures.

Constantly monitor vital signs and muscular function and sensation as it returns.

Local Anesthesia (continued)**PATIENT TEACHING FOR A.M.**

Teaching about local anesthetics is usually incorporated into the overall teaching plan about the procedure that the patient will undergo. Things to highlight with the patient would include the following:

- Discussion of the overall procedure:
 - What it will feel like (any numbness, tingling, inability to move, pressure, pain, choking?)
 - Any anticipated discomfort
 - How long it will last
- Concerns during the procedure: Report any discomfort and ask any questions as they arise
- Discussion of the recovery:
 - How long it will take
 - Feelings to expect: tingling, numbness, pressure, itching
 - Pain that will be felt as the anesthesia wears off
 - Measures to reduce pain in the area
 - Signs and symptoms to report (e.g., pain along a nerve route, palpitations, feeling faint, disorientation)

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Disturbed Sensory Perception (Kinesthetic, Tactile) related to local anesthetic effect
- Impaired Skin Integrity related to immobility caused by actions of the drug
- Risk for Injury related to loss of sensation and mobility
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Have emergency equipment readily available *to maintain airway and provide mechanical ventilation if needed.*
- Ensure that drugs for managing hypotension, cardiac arrest, and CNS alterations are readily available *in case of severe reaction and toxicity.*
- Ensure that patients receiving spinal anesthesia or epidural anesthesia are well hydrated and remain lying down for up to 12 hours after the anesthesia *to minimize headache.*
- Establish safety precautions *to prevent injury during the time that the patient has a loss of sensation and/or mobility.*
- Provide meticulous skin care to the site of administration *to reduce the risk of breakdown.*
- Provide comfort measures *to help the patient tolerate drug effects.* Provide pain relief, as well as skin care and turning *to prevent skin breakdown,* and supportive care for hypotension *to prevent shock or serious hypoxia.*
- Offer support and encouragement *to help the patient cope with the procedure and drugs being used.*
- Provide thorough patient teaching, including anesthetic to be given, method for administration, activities involved with administering and monitoring the drug, and safety precautions.

Evaluation

- Monitor patient response to the drug (loss of feeling in designated area).

- Monitor for adverse effects (respiratory depression, blood pressure changes, arrhythmias, GI upset, skin breakdown, injury, CNS alterations).
- Evaluate the effectiveness of the teaching plan (the patient can relate the anticipated effects of the drug and the recovery process).

KEY POINTS

- ▶ Local anesthetics block the depolarization of nerve membranes, preventing the transmission of pain sensations and motor stimuli.
- ▶ Local anesthetics are administered to deliver the drug directly to the desired area and to prevent systemic absorption, which could lead to serious interruption of nerve impulses and response.
- ▶ Ester-type local anesthetics are immediately destroyed by plasma esterases. Amide local anesthetics are destroyed in the liver and have a greater risk of accumulation and systemic toxicity.

CHAPTER SUMMARY

- General anesthetics result in analgesia, amnesia, and unconsciousness; they also block muscle reflexes that could interfere with a surgical procedure or put the patient at risk for harm.
- The use of general anesthetics involves a widespread CNS depression that could be harmful, especially in patients with underlying CNS, cardiovascular, or respiratory diseases.
- Anesthesia proceeds through four predictable stages from loss of sensation to total CNS depression and death.
- Induction of anesthesia is the period of time from the beginning of anesthesia administration until the patient reaches surgical anesthesia.
- Balanced anesthesia involves giving a variety of drugs, including anticholinergics, rapid intravenous anesthetics, inhaled anesthetics, NMJ blockers, and narcotics.

- Patients receiving general anesthetics should be monitored for any adverse effects; they need reassurance and safety measures until the recovery of sensation, mobility, and ability to communicate.
- Local anesthetics block the depolarization of nerve membranes, preventing the transmission of pain sensations and motor stimuli.
- Local anesthetics are administered to deliver the drug directly to the desired area and to prevent systemic absorption, which could lead to serious interruption of nerve impulses and response.
- Ester-type local anesthetics are immediately destroyed by plasma esterases. Amide local anesthetics are destroyed in the liver and have a greater risk of accumulation and systemic toxicity.
- Nursing care of patients receiving general or local anesthetics should include safety precautions to prevent injury

and skin breakdown; support and reassurance to deal with the loss of sensation and mobility; and patient teaching regarding what to expect, to decrease stress and anxiety.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-Rom in the front of the book.

MULTIPLE CHOICE

Select the best answer to the following.

- The most dangerous period for many patients undergoing general anesthesia is during which stage?
 - Stage 1, when communication becomes difficult
 - Stage 2, when systemic stimulation occurs
 - Stage 3, when skeletal muscles relax
 - There is no real danger during general anesthesia
- Recovery after a general anesthetic refers to the period of time
 - from the beginning of the anesthesia until the patient is ready for surgery.
 - during the surgery when anesthesia is maintained at a certain level.
 - from discontinuation of the anesthetic until the patient has regained consciousness, movement, and the ability to communicate.
 - when the patient is in the most danger of CNS depression.
- While a patient is receiving a general anesthetic, he or she must be continually monitored because
 - the patient has no pain sensation.
 - generalized CNS depression affects all body functions.
 - the patient cannot move.
 - the patient cannot communicate.
- The nursing instructor determines that teaching about general anesthetics was successful when the students identify which person as being most qualified to administer general anesthetics?
 - Nursing supervisor
 - Graduate nurse
 - Trained physician
 - Surgeon
- Local anesthetics are used to block feeling in specific body areas. If given in increasing concentrations, local anesthetics can cause loss, in order, of the following:
 - Temperature sensation, touch sensation, proprioception, and skeletal muscle tone
 - Touch sensation, skeletal muscle tone, temperature sensation, and proprioception
 - Proprioception, skeletal muscle tone, touch sensation, and temperature sensation
 - Skeletal muscle tone, touch sensation, temperature sensation, and proprioception

MULTIPLE RESPONSE

Select all that apply.

- Comfort measures that are important for a patient receiving a local anesthetic would include which of the following?
 - Skin care and turning
 - Reassurance over loss of control and sensation
 - Use of antihypertensive agents
 - Use of analgesics as needed
 - Ice applied to the area involved
 - Safety precautions to prevent injury

2. A nurse would anticipate the use of general anesthetics for which of the following reasons?
- To produce analgesia
 - To produce amnesia
 - To activate the reticular activating system
 - To block muscle reflexes
 - To cause unconsciousness
 - To prevent nausea
3. Balanced anesthesia combines different classes of drugs to achieve the best effects with the fewest adverse effects. Balanced anesthesia usually involves the use of which of the following?
- Anticholinergics
 - Narcotics
 - Sedative/hypnotics
 - Adrenergic beta-blockers
 - Dantrolene
 - Neuromuscular blocking agents

Neuromuscular Junction Blocking Agents

28

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Draw and label a neuromuscular junction.
2. Describe the therapeutic actions, indications, pharmacokinetics, contraindications, most common adverse reactions, and important drug–drug interactions associated with the depolarizing and nondepolarizing neuromuscular junction blockers.
3. Discuss the use of neuromuscular junction blockers across the lifespan.
4. Compare and contrast the prototype drugs pancuronium and succinylcholine with other neuromuscular junction blockers.
5. Outline the nursing considerations, including important teaching points, for patients receiving a neuromuscular junction blocker.

Glossary of Key Terms

acetylcholine-receptor site: area on the muscle cell membrane where acetylcholine (ACh) reacts with a specific receptor site to cause stimulation of the muscle in response to nerve activity

depolarizing neuromuscular junction (NMJ) blocker: stimulation of a muscle cell, causing it to contract, with no allowance for repolarization and restimulation of the muscle; characterized by contraction and then paralysis

malignant hyperthermia: reaction to some NMJ drugs in susceptible individuals; characterized by extreme muscle rigidity, severe hyperpyrexia, acidosis, and in some cases death

neuromuscular junction (NMJ): the synapse between a nerve and a muscle cell

nondepolarizing neuromuscular junction (NMJ) blocker: no stimulation or depolarization of the muscle cell; prevents depolarization and stimulation by blocking the effects of acetylcholine

paralysis: lack of muscle function

sarcomere: functional unit of a muscle cell, composed of actin and myosin molecules arranged in layers to give the unit a striped or striated appearance

sliding filament theory: theory explaining muscle contraction as a reaction of actin and myosin molecules when they are freed to react by the inactivation of troponin after calcium is allowed to enter the cell during depolarization

NEUROMUSCULAR JUNCTION BLOCKING AGENTS

Nondepolarizing NMJs

atracurium
cisatracurium

 pancuronium
rocuronium
vecuronium

Depolarizing NMJ
 succinylcholine

Nerves communicate with muscles at a synapse called the neuromuscular junction. At this point, a nerve stimulates a muscle to contract. If the nerve is not able to communicate with the muscle cell, the muscle will not be able to contract, and paralysis will result. Certain clinical situations require that a patient not be able to move muscles, including surgery, diagnostic procedures, and mechanical ventilation. Anesthetics (discussed in Chapter 27) can prevent muscle movement by suppressing function through the central nervous system (CNS), with many systemic complications from this depression. The neuromuscular junction (NMJ)-blocking drugs are used to prevent the nerve stimulation at the muscle cell and cause paralysis of the muscle directly without total CNS depression and its many systemic effects.

THE NEUROMUSCULAR JUNCTION

The **neuromuscular junction** is the point at which a motor neuron communicates with a skeletal muscle fiber. The end result is muscular contraction. Neuromuscular junction-blocking agents affect the normal functioning of muscles by interfering with the normal processes that occur at the junction of nerve and muscle cell.

The functional unit of a muscle, called a **sarcomere**, is made up of light and dark filaments formed by actin and myosin molecules. These molecules are arranged in orderly stacks that give the sarcomere a striated or striped appearance. Normal muscle function involves the arrival of a nerve impulse at the motor nerve terminal, followed by the release of the neurotransmitter acetylcholine (ACh) into the synaptic cleft. At the **acetylcholine-receptor site** on the effector side of the synapse, the ACh interacts with the nicotinic cholinergic receptors, causing depolarization of the muscle membrane. ACh is then broken down by acetylcholinesterase (an enzyme), freeing the receptor for further stimulation. With stimulation, this depolarization allows the release of calcium ions, stored in tubules, into the cell. The calcium binds to troponin, a chemical found throughout the sarcomere. This binding of troponin releases the actin and myosin binding sites, allowing them to react with each other. The actin and myosin molecules react with each other again and again, sliding along the filament and making it shorter. This is a contraction of the muscle fiber according to the **sliding filament theory** (Figure 28.1). As the calcium is removed from the cell during repolarization of the muscle membrane, the troponin is freed and once again prevents the actin and myosin from reacting with each other. The muscle filament then relaxes or slides back to the resting position.

● **FIGURE 28.1** Sliding filament mechanism of skeletal muscle contraction. **A.** Muscle is relaxed, and there is no contact between the actin and myosin filaments. **B.** Cross-bridges form, and the actin filaments are moved closer together as the muscle fiber contracts. **C.** The cross-bridges return to their original position and attach to new sites to prepare for another pull on the actin filaments and further contraction.

A dynamic balance of excitatory and inhibitory impulses to the muscle results in muscle tone. However, if ACh cannot react with the cholinergic muscle receptor or if the muscle cells cannot repolarize to allow new stimulation and muscle contraction, muscle **paralysis**, or loss of muscle function, occurs.

KEY POINTS

- ▶ The nerves and muscles communicate at the neuromuscular junction (NMJ).
- ▶ Acetylcholine (ACh) acts as the neurotransmitter at the NMJ.
- ▶ NMJ blockers interfere with muscle function.

NEUROMUSCULAR JUNCTION-BLOCKING AGENTS

Drugs that affect the NMJ can be divided into two groups. One group, the **nondepolarizing NMJs**, includes those agents that act as antagonists to ACh at the NMJ and prevent depolarization of muscle cells. The other group, the **depolarizing NMJs**

(of which there is one drug), act as an ACh agonist at the junction, causing stimulation of the muscle cell and staying on the receptor site, preventing it from repolarizing, which results in muscle paralysis with the muscle in a constant, contracted state. Both of these types of drugs are used to cause paralysis for the performance of surgical procedures, endoscopic diagnostic procedures, or facilitation of mechanical ventilation. Table 28.1 list these drugs, their preferred uses, and potential problems. Box 28.1 highlights information about using NMJ blockers with various age groups (see also the Critical Thinking Scenario for nursing care related to an elderly patient receiving an NMJ).

Nondepolarizing Neuromuscular Junction Blockers

The first nondepolarizing NMJ blocker to be discovered was curare, a poison used on the tips of arrows or spears by hunters to paralyze their game. Animals died when their respiratory muscles became paralyzed. Because the poison was destroyed by the cooking process or by gastric acid if the meat were eaten raw, it was safe for humans. Curare was first purified for clinical use as the NMJ blocker tubocurarine, which has since been replaced with more refined drugs that can control onset and duration of effect. Nondepolarizing

TABLE 28.1 DRUGS IN FOCUS Neuromuscular Junction Blockers

Drug Name	Preferred Uses	Special Considerations
Nondepolarizing Neuromuscular Junction Blockers		
atracurium (<i>Tracrium</i>)	Mechanical ventilation; long duration of action; surgical procedures	Has no effect on pain perception or consciousness; do not use before induction of anesthesia; bradycardia is more common with this drug; reduce dose in renal failure
cisatracurium (<i>Nimbex</i>)	Intermediate action; used for surgical procedures and to facilitate intubation	No known effect on pain perception or consciousness; contains benzyl alcohol, avoid use in neonates
 pancuronium (<i>Pavulon</i>)	Surgical procedures; mechanical ventilation	Vagolytic effect, associated with increased heart rate; long-term use for mechanical ventilation, monitor for prolonged adverse effects
rocuronium (<i>Zemuron</i>)	Rapid onset; preferred for rapid intubation; short outpatient surgical procedures	No known effect on pain perception or consciousness; may be associated with pulmonary hypertension; use caution with hepatic impairment
vecuronium (<i>Norcuron</i>)	Short surgical procedures; intubation; mechanical ventilation	May contain benzyl alcohol; avoid use in neonates, can cause fatalities in premature infants; monitor with long-term use during ventilation; if response does not occur with first twitch test, discontinue, may be associated with permanent muscle damage
Depolarizing Neuromuscular Junction Blocker		
 succinylcholine (<i>Anectine, Quelicin</i>)	Surgical procedures; intubation; mechanical ventilation	May cause myalgia secondary to muscle contraction; associated with increased intraocular pressure; increased intragastric pressure, which may cause vomiting; more likely to cause malignant hyperthermia

Neuromuscular Junction (NMJ) Blocking Agents

CHILDREN

Children require very careful monitoring and support after the use of NMJ blockers. These agents are used by anesthesiologists who are skilled in their use and with full support services available.

The nondepolarizing NMJs are preferable because of the lack of muscle contraction with its resultant discomfort on recovery. Succinylcholine is usually preferred when a very short-acting, rapid-onset blocker is needed (e.g., for intubation).

ADULTS

Adults need to be monitored closely for full return of muscle function. If succinylcholine is used, they need to be told that

they will experience muscle pain and discomfort when the procedure is over.

The NMJs are used during pregnancy and lactation only if the benefit to the mother outweighs the potential risk to the fetus or neonate.

OLDER ADULTS

Because older patients often also have renal or hepatic impairment, they are more likely to have toxic levels of the drug related to changes in metabolism and excretion. The older patient should receive special efforts to provide skin care to prevent skin breakdown, which is more likely with older skin. The older patient may require longer monitoring and regular orienting and reassuring.

neuromuscular junction blockers include atracurium (*Tracrium*), cisatracurium (*Nimbex*), pancuronium (*Pavulon*), and rocuronium (*Zemuron*).

Therapeutic Actions and Indications

Nondepolarizing NMJ blockers are used when clinical situations require or desire muscle paralysis (see Table 28.1 for preferred uses). Therapeutically, nondepolarizing NMJ blockers:

- Serve as an adjunct to general anesthetics during surgery when reflex muscle movement could interfere with the surgical procedure or the delivery of gas anesthesia.
- Facilitate mechanical intubation by preventing resistance to passing of the endotracheal tube and in situations in which patients “fight” or resist the respirator.
- Facilitate various endoscopic diagnostic procedures when reflex muscle reaction could interfere with the procedure.
- Facilitate electroconvulsive therapy when intense skeletal muscle contractions as a result of electric shock could cause the patient broken bones or other injury.

Pharmacokinetics

All nondepolarizing NMJ blockers are similar in structure to ACh and compete with ACh for the muscle ACh-receptor site (Figure 28.2). As a result, they occupy the muscular cholinergic receptor site and do not allow stimulation to occur. These agents do not cause the activation of muscle cells, and consequently muscle contraction does not occur. Because they are not broken down by acetylcholinesterase, their effect is longer lasting than that of ACh. The nondepolarizing NMJ blockers are hydrophilic instead of lipophilic, so they do not readily cross the blood–brain barrier and have little effect on the ACh receptors in the brain.

Nondepolarizing NMJs are metabolized in the serum, although metabolism is dependent on the liver to produce the needed plasma cholinesterases. Most of the metabolites are excreted in the urine.

Each nondepolarizing NMJ blocker differs in terms of time of onset and duration (Figure 28.3). The drug of choice in any given situation is determined by the procedure being performed, including the estimated time involved.

Contraindications and Cautions

Nondepolarizing NMJ blockers are contraindicated in the following conditions: known allergy to any of these drugs *to prevent hypersensitivity reactions*; myasthenia gravis *because blocking of the ACh cholinergic receptors aggravates the neuromuscular disease* (which results from destruction of the ACh-receptor sites) *and increases the muscular effects* (see Chapter 32); renal or hepatic disease, *which could interfere with the metabolism or excretion of these drugs, leading to toxic effects*; and pregnancy.

Caution should be used in patients with any family or personal history of **malignant hyperthermia**, a serious adverse effect associated with these drugs that is characterized by extreme muscle rigidity, severe hyperpyrexia (fever), acidosis, and death in some cases, *because malignant hyperthermia can occur with the use of these drugs*. Caution should also be used in the following circumstances: pulmonary or cardiovascular dysfunction, *which could be exacerbated by the paralysis of the respiratory muscles and resulting changes in perfusion and respiratory function*; altered fluid and electrolyte imbalance, *which could affect membrane stability and subsequent muscular function*; some respiratory conditions *that could be made worse by the histamine release associated with some of these agents*; and lactation *because of the potential for adverse effects on the baby*.

● **FIGURE 28.2** Sites of action of the neuromuscular junction (NMJ) blockers.

Adverse Effects

The adverse effects related to the use of nondepolarizing NMJ blockers are associated with the paralysis of muscles. Profound and prolonged muscle paralysis is always possible, and patients must be supported until they are able to resume voluntary and involuntary muscle movement. When the respiratory muscles are paralyzed, depressed respiration, bronchospasm, and apnea are anticipated adverse effects. These agents are never used without an anesthesiologist or nurse anesthetist present who can provide assisted ventilatory mea-

asures and deliver oxygen under positive pressure. Intubation is an anticipated procedure with these drugs.

The histamine release associated with many of the depolarizing NMJ blockers can cause respiratory obstruction with wheezing and bronchospasm. Hypotension and cardiac arrhythmias may occur in patients who do not adapt to the drugs effectively, use the drugs for prolonged periods, have certain underlying conditions, or take certain drugs (e.g., vecuronium) that are known to affect cardiovascular receptors. Prolonged drug use may also result in gastrointestinal

● FIGURE 28.3 Onset and duration of nondepolarizing NMJ blockers.

(GI) dysfunction related to paralysis of the muscles in the GI tract; constipation, vomiting, regurgitation, and aspiration may occur. Pressure ulcers may develop because the patient loses reflex muscle movement that protects the body. Hyperkalemia may occur as a result of muscle membrane alterations.

Clinically Important Drug–Drug Interactions

Many drugs are known to react with the nondepolarizing NMJ blockers. Some drug combinations result in an increased neuromuscular effect. Halogenated hydrocarbon anesthetics such as halothane cause a membrane-stabilizing effect, which greatly enhances the paralysis induced by the nondepolarizing NMJ blockers. If these drugs are used together for a procedure, dose adjustments are necessary, and patients should be monitored closely until they recover fully. A combination of nondepolarizing NMJ blockers and aminoglycoside antibiotics (e.g., gentamicin) also leads to increased neuromuscular blockage. Patients who receive this drug combination require a lower dose of the nondepolarizing NMJ blocker and prolonged support and monitoring after the procedure.

Calcium-channel blockers may also greatly increase the paralysis caused by nondepolarizing NMJ blockers because of their effects on the calcium channels in the muscle. If this combination cannot be avoided, the dose of the nondepolarizing NMJ agent should be lowered and the patient should be monitored closely until complete recovery occurs.

If nondepolarizing NMJ blockers are combined with cholinesterase inhibitors, the effectiveness of the nondepolarizing NMJ blockers is decreased because of a buildup of ACh in the synaptic cleft.

Combination with xanthines (e.g., theophylline, aminophylline) could result in reversal of the neuromuscular blockage. Patients receiving this combination of drugs should be

monitored very closely during the procedure for the potential of early arousal and return of muscle function.

Do not mix the drug with any alkaline solutions such as barbiturates because a precipitate may form, making it inappropriate for use.

Prototype Summary: Pancuronium

Indications: As an adjunct to general anesthesia; to induce skeletal muscle relaxation; to reduce the intensity of muscle contractions in electroconvulsive therapy; to facilitate the care of patients undergoing mechanical ventilation.

Actions: Occupies the muscular cholinergic receptor site, preventing ACh from reacting with the receptor; does not cause activation of muscle cells; causes a flaccid paralysis.

Pharmacokinetics:

Route	Onset	Duration
IV	4–6 min	120–180 min

$T_{1/2}$: 89 to 161 minutes; metabolized in the tissues, excreted unchanged in the urine.

Adverse effects: Respiratory depression, apnea, bronchospasm, cardiac arrhythmias.

Depolarizing Neuromuscular Junction Blocker

There is only one agent classified as a depolarizing NMJ blocker: succinylcholine (*Anectine*, *Quelicin*).

Therapeutic Actions and Indications

Succinylcholine, a depolarizing NMJ blocker, attaches to the ACh-receptor site on the muscle cell, causing a prolonged depolarization of the muscle. This depolarization causes stimulation of the muscle and muscle contraction (seen as twitching) and then flaccid paralysis. Both effects cause muscles to stop responding to stimuli, and paralysis occurs.

Succinylcholine has a rapid onset and a short duration of action because it is broken down by cholinesterase in the plasma. Unlike endogenous ACh, however, succinylcholine is not broken down instantly. The result is a prolonged contraction of the muscle, which cannot be restimulated. Eventually a gradual repolarization occurs as continually stimulated channels in the cell membrane close. Certain ethnic groups may have a genetic predisposition for a prolongation of paralysis (Box 28.2).

Pharmacokinetics

Succinylcholine, like the nondepolarizing NMJ blockers, is metabolized in the serum, although metabolism is dependent on the liver to produce the needed plasma cholinesterases. Patients with hepatic impairment may experience prolonged

FOCUS ON
BOX 28.2 Cultural Considerations

Succinylcholine and Paralysis

Succinylcholine is broken down in the body by cholinesterase, an enzyme found in the plasma. Several conditions may cause the body to produce less of this enzyme, including cirrhosis, metabolic disorders, carcinoma, burns, dehydration, malnutrition, hyperpyrexia, thyrotoxicosis, collagen diseases, and exposure to neurotoxic insecticides. If plasma cholinesterase levels are low, the serum levels of succinylcholine remain elevated and the paralysis can last much longer than anticipated. These patients need support and ventilation for long periods after surgery.

There is also a genetic predisposition to low plasma cholinesterase levels. Patients should be asked whether they or any family member has a history of either low plasma cholinesterase levels or prolonged recovery from anesthetics. Alaskan Eskimos belong to such a genetic group, and they are especially likely to suffer prolonged paralysis and inability to breathe for several hours after succinylcholine has been used for surgery. If there is no other drug of choice for these patients, special care must be taken to monitor their response and ensure their breathing for an extended postoperative period.

effects of this drug. Onset of action is usually within 1 minute, and duration of effect is 10 to 12 minutes. Most of the metabolites are excreted in the urine. Patients with renal impairment may be at risk for increased toxicity from the drugs. Succinylcholine crosses the placenta. Effects on lactation are not known.

Contraindications and Cautions

The contraindications and cautions for succinylcholine are the same as for nondepolarizing NMJ blockers. Succinylcholine is often used during cesarean sections, but accurate timing is necessary to prevent serious effects on the fetus. In addition, succinylcholine should be used with caution in patients with fractures *because the muscle contractions it causes might lead to additional trauma*; in patients with narrow-angle glaucoma or penetrating eye injuries *because intraocular pressure increases*; and in patients with paraplegia or spinal cord injuries, *which could cause loss of potassium from the overstimulated cells and hyperkalemia*. Extreme caution is necessary in the presence of genetic or disease-related conditions causing low plasma cholinesterase levels, such as cirrhosis, metabolic disorders, carcinoma, burns, dehydration, malnutrition, hyperpyrexia, thyroid toxicosis, collagen diseases, and exposure to neurotoxic insecticides. *Low plasma cholinesterase levels may result in a very prolonged paralysis because succinylcholine is not broken down in the plasma and continues to stimulate the receptor site, leading to a need for prolonged support after use of the drug is discontinued.*

Adverse Effects

The adverse effects of succinylcholine are the same as those for nondepolarizing NMJ blockers. In addition, succinylcholine is associated with muscle pain related to the initial muscle contraction reaction. A nondepolarizing NMJ blocker may be given first to prevent some of these contractions and the associated discomfort. Aspirin also alleviates much of this pain after the procedure. Malignant hyperthermia, which may occur in susceptible patients, is a very serious condition characterized by massive muscle contraction, sharply elevated body temperature, severe acidosis, and, if uncontrolled, death. This reaction is most likely with succinylcholine, and treatment involves dantrolene (see Chapter 25) to inhibit the muscle effects of the NMJ blocker.

Clinically Important Drug–Drug Interactions

Potential drug–drug interactions for succinylcholine are the same as for the nondepolarizing NMJ blockers.

Prototype Summary: Succinylcholine

Indications: As an adjunct to general anesthesia; to facilitate endotracheal intubation; to induce skeletal muscle relaxation during surgery or mechanical ventilation.

Actions: Combines with ACh receptors at the motor endplate to produce depolarization; this inhibits neuromuscular transmission, causing a flaccid paralysis.

Pharmacokinetics:

Route	Onset	Duration
IV	30–60 sec	4–6 min

$T_{1/2}$: 2 to 3 minutes; metabolized in the tissues, excreted unchanged in the urine.

Adverse effects: Muscle pain, related to the contraction of the muscles as a first reaction; respiratory depression, apnea.

Nursing Considerations for Patients Receiving Neuromuscular Junction Blocking Agents

Assessment: History and Examination

- Assess for *contraindications or cautions*: any known allergies to these drugs *to avoid hypersensitivity reactions*; impaired liver or kidney function, *which might interfere with metabolism or excretion of the drug*; myasthenia gravis, *which may be exacerbated by the use of this drug*; impaired cardiac or respiratory function, *which may be worsened due to the drug's effect on respiratory muscles and changed in perfusion*; personal or family history of malignant hyperthermia, *which may increase the patient's risk for this condition*; fractures, *which might lead to additional trauma with administration of succinylcholine*;

narrow-angle glaucoma because an increase in intraocular pressure can occur with succinylcholine; paraplegia, which might lead to potassium imbalance with administration of succinylcholine; and current status of pregnancy or lactation.

- Perform a physical assessment to establish baseline status before beginning therapy and evaluation for any potential adverse effects.
- Assess the patient's neurological status, including level of orientation, affect, reflexes, pupil size and reactivity, and muscle tone and response, to monitor drug effects and recovery.
- Monitor respiratory rate and auscultate lung sounds for evidence of adventitious sounds to evaluate effects on respiratory muscles and monitor for adverse reactions.
- Monitor vital signs, including temperature, pulse rate, and blood pressure, to identify changes.
- Auscultate the abdomen for evidence of bowel sounds to monitor effects on GI muscles and recovery.
- Inspect the skin for color and evidence of pressure areas or breakdown, which could result when movement ceases.
- Monitor the results of laboratory tests, including liver function tests, to determine the need for possible dose adjustment and serum electrolyte levels to determine potential cautions to the use of the drugs.

Refer to the Critical Thinking Scenario for a full discussion of nursing care for an elderly patient who is receiving succinylcholine.

Nursing Diagnoses

Nursing diagnoses related to drug therapy may include the following:

- Impaired Gas Exchange related to depressed respirations
- Impaired Skin Integrity related to immobility from prolonged drug effects
- Impaired Verbal Communication related to effects on muscle activity
- Fear related to paralysis
- Risk of injury related to loss of muscle control
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Be aware that administration of the drug should be performed by trained personnel (usually an anesthesiologist) because of the potential for serious adverse effects and the need for immediate ventilatory support.
- Ensure that emergency supplies and equipment are readily available to maintain airway and provide mechanical ventilation.
- Do not mix the drug with any alkaline solutions such as barbiturates because a precipitate may form, making it inappropriate for use.
- Test patient response and recovery periodically if the drug is being given over a long period to maintain mechanical

ventilation. Discontinue the drug if response does not occur or is greatly delayed.

- Monitor patient temperature for prompt detection and treatment of malignant hyperthermia; have dantrolene readily available for treatment of malignant hyperthermia if it should occur.
- Arrange for a small dose of a nondepolarizing NMJ blocker before the use of succinylcholine to reduce the adverse effects associated with muscle contraction.
- Ensure that a cholinesterase inhibitor is readily available to overcome excessive neuromuscular blockade caused by nondepolarizing NMJ blockers.
- Have a peripheral nerve stimulator on standby to assess the degree of neuromuscular blockade, if appropriate.
- Provide comfort measures to help the patient tolerate drug effects, such as pain relief as appropriate; reassurance, support, and orientation for conscious patients unable to move or communicate; skin care and turning to prevent skin breakdown; and supportive care for emergencies such as hypotension and bronchospasm.
- Monitor patient response closely (blood pressure, temperature, pulse, respiration, reflexes) to determine effectiveness; expect dose adjustment to ensure the greatest therapeutic effect with minimal risk of toxicity.
- Provide thorough patient preoperative teaching about this drug because most patients who receive the drug will be receiving teaching about a particular procedure and will be unconscious when the drug is given. Teaching includes drug to be given, method for administration, effects of the drug (i.e., what to expect), and safety precautions.
- Offer support and encouragement to help the patient to cope with drug effects.

Evaluation

- Monitor patient response to the drug (adequate muscle paralysis).
- Monitor for adverse effects (respiratory depression, hypotension, bronchospasm, GI slowdown, skin breakdown, fear related to helplessness and inability to communicate).
- Evaluate effectiveness of the teaching plan (the patient can relate anticipated effects of the drug and the recovery process).
- Monitor the effectiveness of comfort measures and compliance with the regimen.

KEY POINTS

- ▶ Nondepolarizing NMJ blockers prevent ACh from exciting the muscle, and paralysis ensues because the muscle cannot respond.
- ▶ Depolarizing NMJ blockers cause muscle paralysis by acting like ACh. They excite (depolarize) the muscle and prevent repolarization and further stimulation. There is only one drug available in this class.

CRITICAL THINKING SCENARIO

Using Succinylcholine in an Elderly Patient

THE SITUATION

S.N., an 82-year-old white woman in very good health, has been admitted to the hospital for an exploratory laparotomy to evaluate a probable abdominal mass. On admission, health care practitioners learned that she had a history of mild hypertension that was well regulated by diuretic therapy. She received a baseline physical examination and preoperative instruction. On the morning of the surgery, it was noted that the anesthesiologist planned to give her a general anesthetic and succinylcholine to ensure muscle paralysis.

CRITICAL THINKING

What areas must be considered for S.N.? *Consider the patient's age and associated chronic problems that often occur with aging. Also consider the support that she has available and potential physical and emotional support that she might need before and after this procedure. Use of a neuromuscular junction (NMJ) blocker in the elderly presents some nursing challenges that may not be seen with younger patients.*

What particular nursing care activities should be considered with S.N.? *Because S.N. has been maintained on long-term diuretic therapy, she is at special risk for electrolyte imbalance.*

What, if any, complications could arise if S.N. has electrolyte disturbances before surgery?

DISCUSSION

Before surgery, the preoperative teaching protocol should be reviewed with the patient. S.N. should be advised that she may experience back and neck pain secondary to the muscle contractions caused by succinylcholine and throat pain after the procedure. Reassure her that this is normal and that medication will be made available to alleviate the discomfort. Review deep breathing and coughing; she may need encouragement to clear secretions from her lungs and ensure full inflation. This is usually easier to do if it is a familiar activity. S.N.'s serum electrolytes should be evaluated before surgery because potassium imbalance can cause unexpected effects with succinylcholine. Renal and hepatic function tests also should be performed to ensure that the dose of the NMJ blocker is not excessive.

During the procedure, S.N.'s cardiac and respiratory status should be monitored carefully for any potential problems; such effects are more common in people with underlying physical problems. Because of S.N.'s age and potential

circulatory problems, she should receive meticulous skin care and turning as soon as the procedure allows this kind of movement. She should be turned frequently during the recovery period, and her skin should be checked for any breakdown. Nursing personnel must remain close by the patient until she has regained muscle control and the ability to communicate. She should be evaluated for the need for pain medication and position adjustments.

S.N. will require additional teaching about her diagnosis and potential treatment. This should wait until she has regained full ability to communicate and is able to respond and participate in any discussion that may be held. At that time, she may require emotional support and encouragement. It may be necessary to contact available family or social service agencies regarding her physical and medical needs.

NURSING CARE GUIDE FOR S.N.: SUCCINYLCHOLINE

Assessment: History and Examination

Assess allergies to the drug, and assess for history of respiratory or cardiac disorders, myasthenia gravis, hepatic or renal dysfunction, fractures, and glaucoma

Concurrent use of aminoglycosides or calcium-channel blockers

Focus the physical examination on the following:

CV: Blood pressure, pulse rate, peripheral perfusion, and ECG

CNS: orientation, affect, reflexes, and vision

Skin: color, lesions, texture, and sweating

GU: urinary output and bladder tone

GI: abdominal examination

Respiratory: respirations and adventitious sounds

Nursing Diagnoses

Impaired Gas Exchange related to depressed respirations

Risk for Impaired Skin Integrity related to immobility

Deficient Knowledge regarding drug therapy

Impaired Verbal Communication due to fear related to paralysis and inability to communicate

Implementation

Provide comfort and safety measures: positioning, skin care, temperature control, pain medication as needed, maintain airway, ventilate patient, have antidotes on standby.

Provide support and reassurance to deal with paralysis and inability to communicate.

Provide patient teaching about procedure being performed and what to expect.

Assist with life support as needed.

Using Succinylcholine in an Elderly Patient (continued)**Evaluation**

Evaluate drug effects: muscle paralysis.

Monitor for adverse effects: cardiovascular effects (tachycardia, hypotension, respiratory distress, increased respiratory secretions), GI effects (constipation, nausea), skin breakdown, anxiety, fear.

Monitor for drug–drug interactions as indicated.

Evaluate the effectiveness of the patient teaching program and comfort and safety measures.

Constantly monitor vital signs and watch for return of normal muscular function.

PATIENT TEACHING FOR S.N.

- Before the surgery is performed, you will be given a drug to paralyze your muscles called a neuromuscular blocking agent. It is important that your muscles do not move at this time because it could interfere with the procedure.
- Common effects of these drugs include complete paralysis:
 - You will not be able to move or to speak while you are receiving this drug.
 - You will not be able to breathe on your own, and you will receive assistance in breathing.
 - This drug may not affect your level of consciousness, and it can be very frightening to be unable to communicate with anyone around you. Someone will be with you, will try to anticipate your needs, and will explain what is going on at all times.
 - This drug may have no effect on your pain perception. Every effort will be made to make sure that you do not experience pain.
 - You will be receiving succinylcholine; with this drug, you may experience back and throat pain related to muscle contractions that occur. You will be able to take aspirin to relieve this discomfort.
 - Recovery of your muscle function may take 2 to 3 hours, and someone will be nearby at all times until you have recovered from the paralysis.

CHAPTER SUMMARY

- The nerves communicate with muscles at a point called the neuromuscular junction (NMJ), using acetylcholine (ACh) as the neurotransmitter.
- NMJ blockers interfere with muscle function. The two groups of NMJ blockers are nondepolarizing and depolarizing agents.
- The nondepolarizing NMJs include those agents that act as antagonists to ACh at the NMJ and prevent depolarization of muscle cells. The depolarizing NMJs act as an ACh agonist at the junction, causing stimulation of the muscle cell and then preventing it from repolarizing.
- NMJ blockers are primarily used as adjuncts to general anesthesia, to facilitate endotracheal intubation, to facilitate mechanical ventilation, and to prevent injury during electroconvulsive therapy.
- Adverse effects of NMJ blockers, such as prolonged paralysis, inability to breathe, weakness, muscle pain and soreness, and effects of immobility, are related to muscle function blocking.
- Care of patients receiving NMJ blockers must include support and reassurance because communication is decreased

with paralysis; vigilant maintenance of airways and respiration; prevention of skin breakdown; and monitoring for return of function.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-Rom in the front of the book.

MULTIPLE CHOICE

Select the best answer to the following.

- Nondepolarizing NMJ blockers
 - antagonize acetylcholine to prevent depolarization of muscle cells.
 - act as agonists of acetylcholine, leading to depolarization of muscle cells.
 - prevent the repolarization of muscle cells.
 - are associated with painful muscle contractions on administration.
- Curare is used as a poison on arrow tips in some cultures. Curare
 - is a depolarizing NMJ blocker.
 - causes muscle paralysis in the brain.
 - is not affected by cooking.
 - has no clinical use today.
- Succinylcholine has a more rapid onset of action and a shorter duration of activity than the nondepolarizing NMJ blockers because it
 - does not bind well to receptor sites.
 - rapidly crosses the blood–brain barrier and is lost.
 - is broken down by acetylcholinesterase that is found in the plasma.
 - is very unstable.
- When planning the care of a patient who is to receive a NMJ blocker, the nurse would expect which of the following about the patient?
 - Transfer to an intensive care unit would be essential.
 - Intubation would be necessary to maintain respirations.
 - He would have no memory of any events.
 - No adverse effects would occur after the drug is stopped.
- Malignant hyperthermia can occur with any NMJ blocker, but it most often occurs with succinylcholine. The nurse would expect to see which drug ordered?
 - Phenobarbital
 - Pancuronium
 - Dantrolene
 - Diazepam
- Patient recovery from an NMJ blocker
 - is predictable, based on the drug given.
 - can be affected by genetic enzyme deficiency.
 - can always be ensured because of the drug half-life.
 - can be shortened by administration of oxygen.
- When preparing NMJ blockers for administration, it is important that they
 - are not mixed in with any alkaline solutions.
 - are not exposed to light.
 - are not mixed with any other drug.
 - are not mixed with heparin.

MULTIPLE RESPONSE

Select all that apply.

- The nurse would expect administration of a NMJ blocker as the drug of choice to accomplish which of the following?
 - Facilitate endotracheal intubation
 - Facilitate mechanical ventilation
 - Prevent injury during electroconvulsive therapy
 - Relieve pain during labor and delivery
 - Treat myasthenia gravis
 - Treat a patient with a history of malignant hyperthermia

Introduction to the Autonomic Nervous System

29

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Describe how the autonomic nervous system differs anatomically from the rest of the nervous system.
2. Outline a sympathetic response and the clinical manifestation of this response.
3. Describe the alpha- and beta-receptors found within the sympathetic nervous system by sites and actions that follow the stimulation of each kind of receptor.
4. Outline the events that occur with stimulation of the parasympathetic nervous system.
5. Define the terms muscarinic receptor and nicotinic receptor, giving an example of each.

Glossary of Key Terms

acetylcholinesterase: enzyme responsible for the immediate breakdown of acetylcholine when released from the nerve ending; prevents overstimulation of cholinergic receptor sites

adrenergic receptors: receptor sites on effectors that respond to norepinephrine

alpha-receptors: adrenergic receptors that are found in smooth muscles

autonomic nervous system: portion of the central and peripheral nervous systems that, with the endocrine system, functions to maintain internal homeostasis

beta-receptors: adrenergic receptors that are found in the heart, lungs, and vascular smooth muscle

cholinergic receptors: receptor sites on effectors that respond to acetylcholine

ganglia (ganglion[s]): groups of closely packed nerve cell bodies

monoamine oxidase (MAO): enzyme that breaks down norepinephrine to make it inactive

muscarinic receptors: cholinergic receptors that also respond to stimulation by muscarine

nicotinic receptors: cholinergic receptors that also respond to stimulation by nicotine

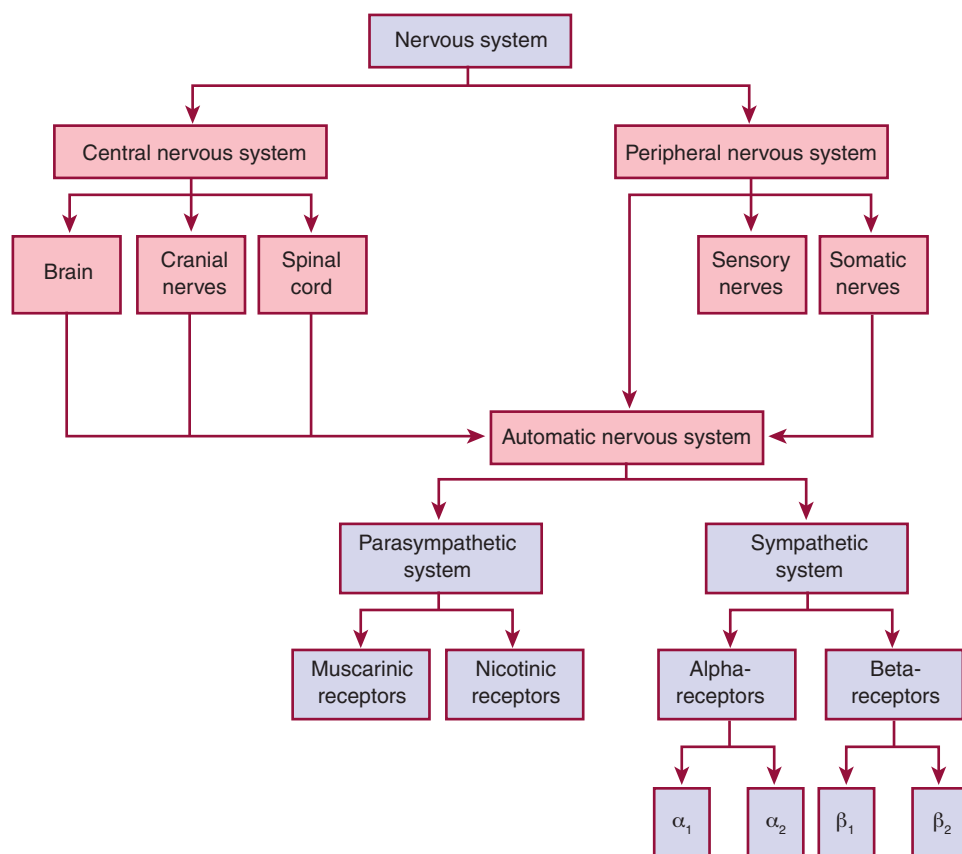

parasympathetic nervous system: “rest-and-digest” response mediator that contains central nervous system (CNS) cells from the cranium or sacral area of the spinal cord, long preganglionic axons, ganglia near or within the effector tissue, and short postganglionic axons that react with cholinergic receptors

sympathetic nervous system: “fight-or-flight” response mediator; composed of CNS cells from the thoracic or lumbar areas, short preganglionic axons, ganglia near the spinal cord, and long postganglionic axons that react with adrenergic receptors

The **autonomic nervous system** (ANS) is sometimes called the involuntary or visceral nervous system because it mostly functions with the person having little conscious awareness of its activity. Working closely with the endocrine system, the ANS helps to regulate and integrate the body’s internal functions within a relatively narrow range of normal, on a minute-to-minute basis. The ANS integrates parts of the central nervous system (CNS) and peripheral nervous system to automatically react to changes in the internal and external environments (Figure 29.1).

STRUCTURE AND FUNCTION OF THE AUTONOMIC NERVOUS SYSTEM

The main nerve centers for the ANS are located in the hypothalamus, the medulla, and the spinal cord. Nerve impulses that arise in peripheral structures are carried to these centers by afferent nerve fibers. These integrating centers in the CNS respond by sending out efferent impulses along the autonomic nerve pathways. These impulses adjust the functioning of

● FIGURE 29.1 Organization of the nervous system.

various internal organs in ways that keep the body’s internal environment constant, or homeostatic.

Nerve Impulse Transmission

Throughout the ANS, nerve impulses are carried from the CNS to the outlying organs by way of a two-neuron system. In most peripheral nervous system activities, the CNS nerve body sends an impulse directly to an effector organ or muscle. The ANS does not send impulses directly to the periphery. Instead, axons from CNS neurons end in **ganglia**, or groups of nerve bodies that are packed together, located outside of the CNS. These ganglia receive information from the preganglionic neuron that started in the CNS and relay that information along postganglionic neurons. The postganglionic neurons transmit impulses to the neuroeffector cells—muscles, glands, and organs.

Functions

The ANS works to regulate blood pressure, heart rate, respiration, body temperature, water balance, urinary excretion, and digestive functions, among other things. This system exerts minute-to-minute control of body responses, which is balanced by the two divisions of the ANS.

Divisions

The ANS is divided into two branches: the **sympathetic nervous system** and the **parasympathetic nervous system**. These two branches differ in three basic ways: (1) the location of the originating cells in the CNS, (2) the location of the nerve ganglia, and (3) the preganglionic and postganglionic neurons (Table 29.1 and Figure 29.2).

● TABLE 29.1 Comparison of the Sympathetic and Parasympathetic Nervous Systems

CHARACTERISTIC	SYMPATHETIC	PARASYMPATHETIC
CNS nerve origin	Thoracic, lumbar spinal cord	Cranium, sacral spinal cord
Preganglionic neuron	Short axon	Long axon
Preganglionic neurotransmitter	Acetylcholine	Acetylcholine
Ganglia location	Next to spinal cord	Within or near effector organs
Postganglionic neuron	Long axon	Short axon
Postganglionic neurotransmitter	Norepinephrine, epinephrine	Acetylcholine
Neurotransmitter terminator	Monoamine oxidase (MAO), catechol-O-methyltransferase (COMT)	Acetylcholinesterase
General response	Fight or flight	Rest and digest

● **FIGURE 29.2** The autonomic nervous system. The sympathetic, or thoracolumbar, division sends relatively short preganglionic fibers to the chains of paravertebral ganglia and to certain outlying ganglia. The second cell, or postganglionic cell, sends relatively long postganglionic fibers to the organs it innervates. The parasympathetic, or craniosacral, division sends long preganglionic fibers that synapse with a second nerve cell in ganglia located close to or within the organs that are then innervated by short postganglionic fibers.

THE SYMPATHETIC NERVOUS SYSTEM

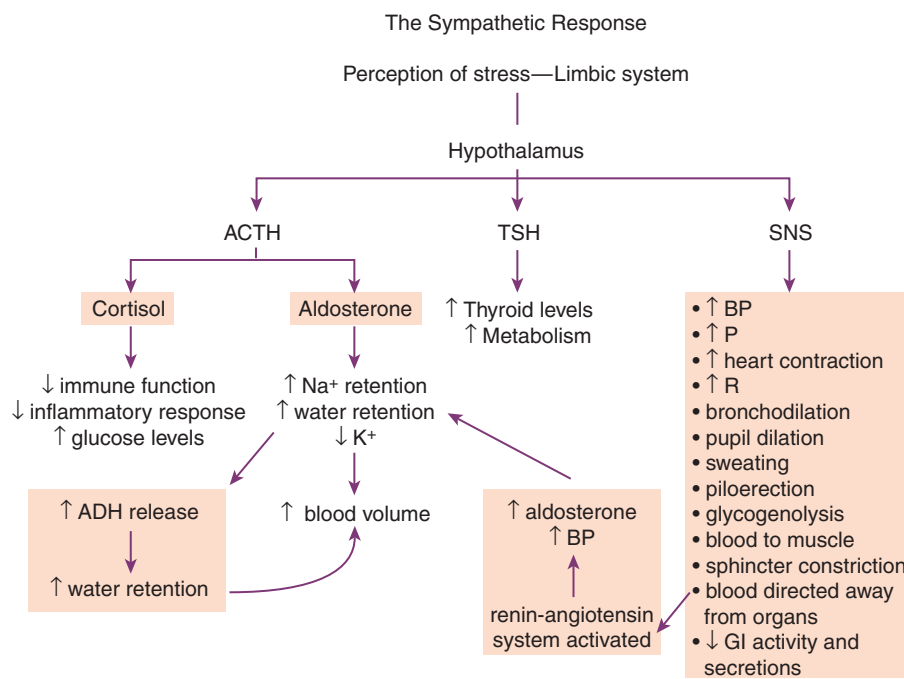

The sympathetic nervous system (SNS) is sometimes referred to as the “fight-or-flight” system, or the system responsible for preparing the body to respond to stress. Stress can be either internal, such as cell injury or death, or external, such as a perceived or learned reaction to various external situations or stimuli. For the most part, the SNS acts much like an accelerator, speeding things up for action.

Structure and Function

The SNS is also called the thoracolumbar system because the CNS cells that originate impulses for this system are located in the thoracic and lumbar sections of the spinal cord. These cells send out short preganglionic fibers that synapse or com-

municate with nerve ganglia located in chains running alongside the spinal cord. Acetylcholine is the neurotransmitter released by these preganglionic nerves. The nerve ganglia, in turn, send out long postganglionic fibers that synapse with neuroeffectors, using norepinephrine or epinephrine as the neurotransmitter. One of the sympathetic ganglia, on either side of the spinal cord, does not develop postganglionic axons but produces norepinephrine and epinephrine, which are secreted directly into the bloodstream. These ganglia have evolved into the adrenal medullae. When the SNS is stimulated, the chromaffin cells of the adrenal medullae secrete epinephrine and norepinephrine directly into the bloodstream.

When stimulated, the SNS prepares the body to flee or to turn and fight (Figure 29.3). Cardiovascular activity increases, as do blood pressure, heart rate, and blood flow to the skeletal muscles. Respiratory efficiency also increases; bronchi dilate

● **FIGURE 29.3** The “fight-or-flight” response: the sympathetic stress reaction. ACTH, adrenocorticotropic hormone; ADH, antidiuretic hormone; BP, blood pressure; GI, gastrointestinal; P, pulse; R, respiratory rate; SNS, sympathetic nervous system; TSH, thyroid-stimulating hormone.

to allow more air to enter with each breath, and the respiratory rate increases. Pupils dilate to permit more light to enter the eye, to improve vision in darkened areas (which helps a person to see in order to fight or flee). Sweating increases to dissipate heat generated by the increased metabolic activity.

Piloerection (hair standing on end) also occurs. In lower animals, this important protection mechanism makes the fur stand on end so that an attacking larger animal is often left with a mouthful of fur while the intended victim scurries away. The actual benefit to humans is not known, except that this activity helps to generate heat when the core body temperature is too low.

Stimulation of the SNS causes blood to be diverted away from the gastrointestinal (GI) tract because there is no real need to digest food during a flight-or-fight situation. Subsequently, bowel sounds decrease and digestion slows dramatically; sphincters are constricted, and bowel evacuation does not occur. Blood is also diverted away from other internal organs, including the kidneys, resulting in activation of the renin-angiotensin system (Chapter 42) and a further increase in blood pressure and blood volume as water is retained by the kidneys. Sphincters in the urinary bladder are also constricted, precluding urination.

Several other metabolic activities occur that prepare the body to fight or flee. For example, glucose is formed by glycogenolysis, to increase blood glucose levels and provide energy. The hypothalamus causes the secretion of adrenocorticotropic hormone (ACTH), leading to a release of the adrenal hormones, including cortisol, which suppresses the immune and inflammatory reactions to preserve energy that otherwise might be used by these activities. The corticosteroid hormones also block protein production, another energy-saving activity, and increase the release of glucose to provide energy. Aldosterone, also released with adrenal stimulation, retains

sodium and water and causes the excretion of potassium in the urine. The hypothalamus also causes the release of thyroid-stimulating hormone (TSH), which stimulates the production and release of thyroid hormone, which increases metabolism and the efficient use of energy. Together, all of these activities prepare the body to flee or to fight more effectively. When overstimulated, however, they can lead to system overload and a variety of disorders.

Adrenergic Response

Sympathetic postganglionic nerves that synthesize, store, and release norepinephrine are referred to as adrenergic nerves. Adrenergic nerves are also found within the CNS. The chromaffin cells of the adrenal medulla also are adrenergic because they synthesize, store, and release norepinephrine, as well as epinephrine.

Norepinephrine Synthesis and Storage

Norepinephrine belongs to a group of structurally related chemicals called catecholamines that also includes dopamine, serotonin, and epinephrine. Norepinephrine is made by the nerve cells using tyrosine, which is obtained in the diet. Dihydroxyphenylalanine (dopa) is produced by a nerve, using tyrosine from the diet and other chemicals. With the help of the enzyme dopa decarboxylase, the dopa is converted to dopamine, which in turn is converted to norepinephrine in adrenergic cells. The norepinephrine then is stored in granules or storage vesicles within the cell. These vesicles move down the nerve axon to the terminals of the axon, where they line up along the cell membrane. To be an adrenergic nerve, the nerve must contain all of the enzymes and building blocks necessary to produce norepinephrine (Figure 29.4).

● **FIGURE 29.4** Sequence of events at an adrenergic synapse. 1. Dopamine, a precursor of norepinephrine (NE), is synthesized from tyrosine in several steps. 2. Dopamine is taken into the storage vesicle and converted to NE. 3. Release of neurotransmitter by an action potential (AP) in the presynaptic nerve. 4. Diffusion of neurotransmitter across synaptic cleft. 5. Combination of neurotransmitter with receptor. The events resulting from NE's occupying of receptor sites depend on the nature of the postsynaptic cell. 6. Interaction of NE with many beta-receptors leads to increased synthesis of cyclic adenosine monophosphate (C-AMP). 7. Feedback control at α_2 -receptor leads to decreased NE release from presynaptic neuron. Deactivation of NE occurs by breakdown of NE by the enzyme COMT (A) or most important by reuptake into the presynaptic neuron (C), where it may be reused or inactivated by another enzyme, monoamine oxidase (MAO). Some of the neurotransmitter may also diffuse away from the synaptic cleft (B).

Norepinephrine Release

When the nerve is stimulated, the action potential travels down the nerve axon and arrives at the axon terminal (see Chapter 19). The action potential then depolarizes the axon membrane. This action allows calcium into the nerve, causing the membrane to contract and the storage vesicles to fuse with the cell membrane, releasing their load of norepinephrine into the synaptic gap or cleft. The norepinephrine travels across the very short gap to very specific adrenergic receptor sites on the effector cell on the other side of the synaptic gap.

Adrenergic Receptors

Adrenergic receptors can be stimulated by the neurotransmitter released from the axon in the immediate vicinity, and they can be further stimulated by circulating norepinephrine and epinephrine secreted directly into the bloodstream by the

adrenal medulla. The receptor sites that react with neurotransmitters at adrenergic sites have been classified as **alpha-receptors** and **beta-receptors**. These receptors are further classified as α_1 -, α_2 -, β_1 -, and β_2 -receptors (Table 29.2). It is thought that receptors may respond to different concentrations of norepinephrine or different ratios of norepinephrine and epinephrine. Different drugs that are known to affect the SNS may affect parts of the sympathetic response but not all of it, because they are designed to stimulate specific adrenergic receptors.

Alpha-Receptors

α_1 -receptors are found in blood vessels, in the iris, and in the urinary bladder. In blood vessels, they can cause vasoconstriction and increase peripheral resistance, thus raising blood pressure. In the iris, they cause pupil dilation. In the urinary bladder, they cause the increased closure of the internal sphincter.

Alpha₂-receptors are located on nerve membranes and act as modulators of norepinephrine release. When norepinephrine is released from a nerve ending, it crosses the synaptic cleft to react with its specific receptor site. Some of it also flows back to react with the alpha-receptor on the nerve membrane. This causes a reflex decrease in norepinephrine release. In this way, the alpha₂-receptor helps to prevent overstimulation of effector sites. These receptors are also found on the beta cells in the pancreas, where they help to moderate the insulin release stimulated by SNS activation.

Beta-Receptors

Beta₁-receptors are found in cardiac tissue, where they can stimulate increased myocardial activity and increased heart rate. They are also responsible for increased lipolysis or breakdown of fat for energy in peripheral tissues.

Beta₂-receptors are found in the smooth muscle in blood vessels, in the bronchi, in the periphery, and in uterine muscle. In blood vessels, beta₂ stimulation leads to vasodilation. Beta₂-receptors also cause dilation in the bronchi. In the periphery, they can cause increased muscle and liver breakdown of glycogen and increased release of glucagon from the alpha cells of the pancreas. Stimulation of beta₂-receptors in the uterus results in relaxed uterine smooth muscle.

Termination of Response

Once norepinephrine has been released into the synaptic cleft, stimulation of the receptor site is terminated and disposal of

any extra norepinephrine, as well as the neurotransmitter that has reacted with the receptor site, must occur. Most of the free norepinephrine molecules are taken up by the nerve terminal that released them in a process called reuptake. This neurotransmitter is then repackaged into vesicles to be released later with nerve stimulation. This is an effective recycling effort by the nerve. Enzymes are also in the area, as well as in the liver, to metabolize or biotransform any remaining norepinephrine or any norepinephrine that is absorbed into circulation. These enzymes are **monoamine oxidase (MAO)** and **catechol-*O*-methyl transferase (COMT)**.

KEY POINTS

- ◆ The autonomic nervous system (ANS), which is divided into two branches—the sympathetic nervous system (SNS) and the parasympathetic nervous system—works with the endocrine system to regulate internal functioning and maintain homeostasis.
- ◆ The SNS is responsible for the fight-or-flight response.
- ◆ The SNS is composed of CNS cells arising in the thoracic or lumbar area of the spinal cord and long postganglionic axons that react with effector cells. The neurotransmitter used by the preganglionic cells is acetylcholine (ACh); the neurotransmitter used by the postganglionic cells is norepinephrine.
- ◆ SNS adrenergic receptors are classified as alpha₁-, alpha₂-, beta₁-, or beta₂-receptors.

THE PARASYMPATHETIC NERVOUS SYSTEM

In many areas, the parasympathetic nervous system works in opposition to the SNS. This allows the autonomic system to maintain a fine control over internal homeostasis. For example, the SNS increases heart rate, whereas the parasympathetic system decreases it. Thus, the ANS can influence heart rate by increasing or decreasing sympathetic activity or by increasing or decreasing parasympathetic activity. This is very much like controlling the speed of a car by moving between the accelerator and the brake or combining the two. Whereas the SNS is associated with the stress reaction and expenditure of energy, the parasympathetic system is associated with activities that help the body to store or conserve energy, a “rest-and-digest” response (Table 29.3).

Structure and Function

The parasympathetic system is sometimes called the craniosacral system because the CNS neurons that originate parasympathetic impulses are found in the cranium (one of the most important being the vagus or tenth cranial nerve) and in the sacral area of the spinal cord (see Figure 29.1). It has long preganglionic axons that meet in ganglia located

close to or within the organ to be affected. The postganglionic axon is very short, going directly to the effector cell. The neurotransmitter used by both the preganglionic and postganglionic neurons is ACh.

Parasympathetic system stimulation results in the following actions:

- Increased motility and secretions in the GI tract to promote digestion and absorption of nutrients.
- Decreased heart rate and contractility to conserve energy and provide rest for the heart.
- Constriction of the bronchi, with increased secretions.
- Relaxation of the GI and urinary bladder sphincters, allowing evacuation of waste products.
- Pupillary constriction, which decreases the light entering the eye and decreases stimulation of the retina.

These activities are aimed at increasing digestion, absorption of nutrients, and building of essential proteins, as well as a general conservation of energy.

Cholinergic Response

Neurons that use ACh as their neurotransmitter are called cholinergic neurons. There are four basic kinds of cholinergic nerves:

TABLE 29.3 Comparing the Effects of Autonomic Stimulation

EFFECTOR SITE	SYMPATHETIC REACTION	PARASYMPATHETIC REACTION
Eye structures		
Iris radial muscle	Contraction (pupil dilates)	—
Iris sphincter muscle	—	Contraction (pupil constricts)

—, no reaction or response.

1. All preganglionic nerves in the ANS, both sympathetic and parasympathetic
2. Postganglionic nerves of the parasympathetic system and a few SNS nerves, such as those that reenter the spinal cord and cause general body reactions such as sweating
3. Motor nerves on skeletal muscles
4. Cholinergic nerves within the CNS

Acetylcholine Synthesis and Storage

ACh is an ester of acetic acid and an organic alcohol called choline. Cholinergic nerves use choline, obtained in the diet, to produce ACh. The last step in the production of the neurotransmitter involves choline acetyltransferase, an enzyme that is also produced within cholinergic nerves. Just like norepinephrine, the ACh is produced in the nerve and travels to the end of the axons, where it is packaged into vesicles. To be

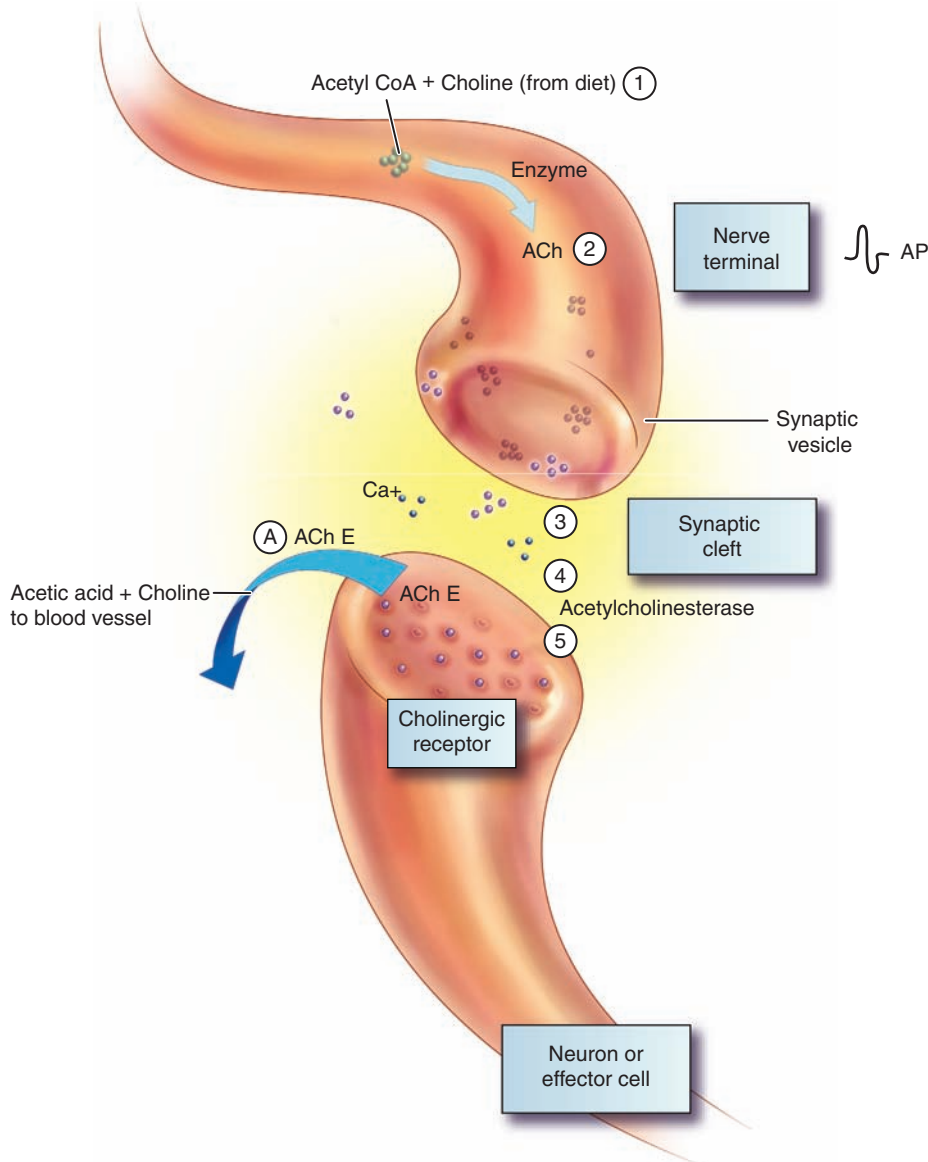

a cholinergic nerve, the nerve must contain all of the enzymes and building blocks necessary to produce ACh.

Acetylcholine Release

The vesicles full of ACh move to the nerve membrane; when an action potential reaches the nerve terminal, calcium entering the cell causes the membrane to contract and secrete the neurotransmitter into the synaptic cleft. The ACh travels across the synaptic cleft and reacts with very specific **cholinergic receptor** sites on the effector cell (Figure 29.5).

Cholinergic Receptors

Cholinergic receptors or ACh receptors are found on organs and muscles. They have been classified as **muscarinic receptors** and **nicotinic receptors**. This classification is based on very early research of the ANS that used muscarine (a plant

● **FIGURE 29.5** Sequence of events at a cholinergic synapse. 1. Synthesis of acetylcholine (ACh) from choline (a substance in the diet) and a cofactor (the enzyme is choline acetyltransferase, CoA). 2. Uptake of neurotransmitter into storage (synaptic) vesicle. 3. Release of neurotransmitter by an action potential (AP) in the presynaptic nerve. 4. Diffusion of neurotransmitter across the synaptic cleft. 5. Combination of neurotransmitter with receptor. The events resulting from ACh's occupation of receptor sites depend on the nature of the postsynaptic cell. ACh excites some cells and inhibits others. An enzyme, acetylcholinesterase (AChE), found in the tissues and on the postsynaptic cell, inactivates ACh (A). Some of the products diffuse into the circulation, but most of the choline formed is taken up and reused by the cholinergic neuron.

alkaloid from mushrooms) and nicotine (a plant alkaloid found in tobacco plants) to study the actions of the parasympathetic system.

Muscarinic Receptors

As the name implies, muscarinic receptors are receptors that can be stimulated by muscarine. They are found in visceral effector organs, such as the GI tract, bladder, and heart, in sweat glands, and in some vascular smooth muscle. Stimulation of muscarinic receptors causes pupil constriction, increased GI motility and secretions (including saliva), increased urinary bladder contraction, and a slowing of the heart rate.

Nicotinic Receptors

Nicotinic receptors are located in the CNS, the adrenal medulla, the autonomic ganglia, and the neuromuscular junction. Stimulation of nicotinic receptors causes muscle contractions, autonomic responses such as signs and symptoms of a stress reaction, and release of norepinephrine and epinephrine from the adrenal medulla.

Termination of Response

Once the effector cell has been stimulated by ACh, stimulation of the receptor site must be terminated and destruction of any ACh must occur. The destruction of ACh is carried out by the enzyme **acetylcholinesterase**. This enzyme reacts with the ACh to form a chemically inactive compound. The breakdown of the released ACh is accomplished in 1/1000 second, and the receptor is vacated, allowing the effector membrane to repolarize and be ready for the next stimulation.

KEY POINTS

- ◆ The parasympathetic system, when stimulated, acts as a rest-and-digest response. It increases the digestion, absorption, and metabolism of nutrients and slows metabolism and function to save energy.
- ◆ The parasympathetic system comprises CNS cells that arise in the cranium and sacral region of the spinal cord, long preganglionic axons that secrete ACh, ganglia located very close to or within the effector tissue, and short postganglionic axons that also secrete ACh.
- ◆ ACh is made by choline from the diet and packaged into storage vesicles to be released by the cholinergic nerve into the synaptic cleft. ACh is broken down to an inactive form almost immediately by acetylcholinesterase.
- ◆ Parasympathetic system receptors are classified as muscarinic or nicotinic, depending on what response they have to these plant alkaloids.

CHAPTER SUMMARY

- The autonomic nervous system (ANS) works with the endocrine system to regulate internal functioning and maintain homeostasis.

- The two branches of the ANS, the sympathetic nervous system (SNS) and the parasympathetic nervous system, work in opposition to maintain minute-to-minute regulation of the internal environment and to allow rapid response to stress situations.
- The SNS, when stimulated, is responsible for the fight-or-flight response. It prepares the body for immediate reaction to stressors by increasing metabolism, diverting blood to big muscles, and increasing cardiac and respiratory function.
- The parasympathetic system, when stimulated, acts as a rest-and-digest response. It increases the digestion, absorption, and metabolism of nutrients and slows metabolism and function to save energy.
- The SNS is composed of CNS cells arising in the thoracic or lumbar area of the spinal cord, short preganglionic axons, ganglia located near the spinal cord, and long postganglionic axons that react with effector cells. The neurotransmitter used by the preganglionic cells is acetylcholine (ACh); the neurotransmitter used by the postganglionic cells is norepinephrine.
- One SNS ganglion on either side of the spinal cord does not develop postganglionic axons but instead secretes norepinephrine directly into the bloodstream to travel throughout the body to react with adrenergic receptor sites. These ganglia evolve into the adrenal medulla.
- SNS adrenergic receptors are classified as being α_1 -, α_2 -, β_1 -, or β_2 -receptors based on the effectors that they stimulate.
- ACh is made by choline from the diet and packaged into storage vesicles to be released by the cholinergic nerve into the synaptic cleft. ACh is broken down to an inactive form almost immediately by acetylcholinesterase.
- The parasympathetic system comprises CNS cells that arise in the cranium and sacral region of the spinal cord, long preganglionic axons that secrete ACh, ganglia located very close to or within the effector tissue, and short postganglionic axons that also secrete ACh.
- Norepinephrine is made by adrenergic nerves using tyrosine from the diet. It is packaged in storage vesicles that align on the axon membrane and is secreted into the synaptic cleft when the nerve is stimulated. It reacts with specific receptor sites and is then broken down by MAO or COMT to relax the receptor site and recycle the building blocks of norepinephrine.
- Parasympathetic system receptors are classified as muscarinic or nicotinic, depending on what response they have to these plant alkaloids.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-Rom in the front of the book.

MULTIPLE CHOICE

Select the best answer to the following.

- When describing the functions of the autonomic nervous system, which of the following would the instructor include?
 - Maintenance of balance and posture
 - Maintenance of the special senses
 - Regulation of integrated internal body functions
 - Coordination of peripheral and central nerve pathways
- The autonomic nervous system differs from other systems in the CNS in that it
 - uses only peripheral pathways.
 - affects organs and muscles via a two-neuron system.
 - uses a unique one-neuron system.
 - bypasses the CNS in all of its actions.
- If you suspect that a person is very stressed and is experiencing a sympathetic stress reaction, you would expect to find
 - increased bowel sounds and urinary output.
 - constricted pupils and warm, flushed skin.
 - slow heart rate and decreased systolic blood pressure.
 - dilated pupils and elevated systolic blood pressure.
- The nurse determines that the beta₂-receptors in the sympathetic nervous system have been stimulated by which finding?
 - Increased heart rate
 - Increased myocardial contraction
 - Bronchial dilation
 - Uterine contraction
- Once a postganglionic receptor site has been stimulated, the neurotransmitter must be broken down immediately. The sympathetic system breaks down postganglionic neurotransmitters by using
 - liver enzymes and acetylcholinesterase.
 - acetylcholinesterase and MAO.
 - COMT and liver enzymes.
 - MAO and COMT.
- The parasympathetic nervous system, in most situations, opposes the actions of the sympathetic nervous system, allowing the autonomic nervous system to
 - generally have no effect.
 - maintain a fine control over internal homeostasis.
 - promote digestion.
 - respond to stress most effectively.
- Cholinergic neurons, those using acetylcholine as their neurotransmitter, would be least likely found in
 - motor nerves on skeletal muscles.
 - preganglionic nerves in the sympathetic and parasympathetic systems.
 - postganglionic nerves in the parasympathetic system.
 - the adrenal medulla.
- Stimulation of the parasympathetic nervous system would cause
 - slower heart rate and increased GI secretions.
 - faster heart rate and urinary retention.
 - vasoconstriction and bronchial dilation.
 - pupil dilation and muscle paralysis.

MULTIPLE RESPONSE

Select all that apply.

- The sympathetic nervous system
 - is called the thoracolumbar system.
 - is called the fight-or-flight system.
 - is called the craniosacral system.
 - uses acetylcholine as its sole neurotransmitter.
 - uses epinephrine as its sole neurotransmitter.
 - is active during a stress reaction.
- The sympathetic system uses catecholamines at the postganglionic receptors. Which of the following are considered to be catecholamines?
 - Dopamine
 - Norepinephrine
 - Acetylcholine
 - Epinephrine
 - Monoamine oxidase
 - Serotonin

Adrenergic Agonists

30

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Describe two ways that sympathomimetic drugs act to produce effects at adrenergic receptors.
2. Describe the therapeutic actions, indications, pharmacokinetics, contraindications, most common adverse reactions, and important drug–drug interactions associated with adrenergic agonists.
3. Discuss the use of adrenergic agents across the lifespan.
4. Compare and contrast the prototype drugs dopamine, phenylephrine, and isoproterenol with other adrenergic agonists.
5. Outline the nursing considerations, including important teaching points, for patients receiving an adrenergic agent.

Glossary of Key Terms

adrenergic agonist: a drug that stimulates the adrenergic receptors of the sympathetic nervous system, either directly (by reacting with receptor sites) or indirectly (by increasing norepinephrine levels)

alpha-agonist: specifically stimulating to the alpha-receptors within the sympathetic nervous system, causing body responses seen when the alpha-receptors are stimulated

beta-agonist: specifically stimulating to the beta-receptors within the sympathetic nervous system, causing body responses seen when the beta-receptors are stimulated

glycogenolysis: breakdown of stored glucose to increase the blood glucose levels

sympathomimetic: drug that mimics the sympathetic nervous system (SNS) with the signs and symptoms seen when the SNS is stimulated

ALPHA- AND BETA-ADRENERGIC AGONISTS

P dobutamine
dopamine
ephedrine
epinephrine
metaraminol
norepinephrine

ALPHA-SPECIFIC ADRENERGIC AGONISTS

P clonidine (alpha₂-specific)
midodrine
phenylephrine

BETA-SPECIFIC ADRENERGIC AGONISTS (Also See Beta-Adrenergic Agonists in Chapter 55)

P albuterol
bitolterol
isoetharine
isoproterenol

levalbuterol
metaproterenol
pirbuterol
salmeterol
terbutaline

An **adrenergic agonist** is also called a **sympathomimetic** drug because it mimics the effects of the sympathetic nervous system (SNS). The therapeutic and adverse effects associated with these drugs are related to their stimulation of adrenergic receptor sites. That stimulation can be either direct, by occupation of the adrenergic receptor, or indirect, by modulation of the release of neurotransmitters from the axon. Some

drugs act in both ways. Adrenergic agonists also can affect both the alpha- and beta-receptors, or they can act at specific receptor sites.

The use of adrenergic agonists varies from ophthalmic preparations for dilating pupils to systemic preparations used to support individuals experiencing shock. They are used in patients of all ages (Box 30.1).

BOX 30.1

Drug Therapy Across the Lifespan

Adrenergic Agonists

CHILDREN

Children are at greater risk for complications associated with the use of adrenergic agonists, including tachycardia, hypertension, tachypnea, and gastrointestinal complications. The dosage for these agents needs to be calculated from the child's body weight and age. It is good practice to have a second person check the dosage calculation before administering the drug to avoid potential toxic effects. Children should be carefully monitored and supported during the use of these drugs.

Phenylephrine is often found in over-the-counter (OTC) allergy and cold preparations, and parents need to be instructed to be very careful with the use of these drugs—they should check the labels for ingredients, monitor the recommended dose, and avoid combining drugs that contain similar ingredients.

ADULTS

Adults being treated with adrenergic agonists for shock or shock-like states require constant monitoring and dosage adjustments based on their response. Patients who may be at increased risk for cardiac complications should be monitored very closely and started on a lower dose. Adults using

these agents for glaucoma or for seasonal rhinitis need to be cautioned about the use of OTC drugs and alternative therapies that might increase the drug effects and cause serious adverse effects.

Many of these drugs are used in emergency situations and may be used during pregnancy and lactation. In general, there are no adequate studies about their effects during pregnancy and lactation, and in those situations, they should be used only if the benefit to the mother is greater than the risk to the fetus or neonate.

OLDER ADULTS

Older patients are more likely to experience the adverse effects associated with these drugs—central nervous system, cardiovascular, gastrointestinal, and respiratory. Because older patients often have renal or hepatic impairment, they are also more likely to have toxic levels of the drug related to changes in metabolism and excretion. Older patients should be started on lower doses of the drugs and should be monitored very closely for potentially serious arrhythmias or blood pressure changes.

They also should be cautioned about the use of OTC drugs and complementary therapies that could increase drug effects and cause serious adverse reactions.

Safe Medication Administration

Administering Ophthalmic Medications

Some of the adrenergic agonists are applied in the eye; it is important to review the administration technique. First, wash hands thoroughly. Do not touch the dropper to the eye or to any other surfaces. Have the patient tilt his or her head back or lie down and stare upward. Gently grasp the lower eyelid and pull the eyelid away from the eyeball. Instill the prescribed number of drops into the lower conjunctival sac and then release the lid slowly (Figure 30.1). Have the patient close the eye and look downward. Apply gentle pressure to the inside corner of the eye for 3 to 5 minutes. Do not rub the eyeball, and do not rinse the dropper. If more than one type of eye-drop is being used, wait 5 minutes before administering the next one.

ALPHA- AND BETA-ADRENERGIC AGONISTS

Drugs that are generally sympathomimetic (Figure 30.2) are called **alpha-agonists** (stimulate alpha-receptors) and **beta-agonists** (stimulate beta-receptors). These agonists stimulate all of the adrenergic receptors, that is, they affect both alpha- and beta-receptors (Table 30.1). Agents that affect both alpha- and beta-receptor sites include dobutamine (*Dobutrex*), dopamine

(*Intropin*), ephedrine (generic), epinephrine (*Adrenalin*, *Sus-Phrine*), metaraminol (*Aramine*), and norepinephrine (*Levophed*). Some of these drugs are naturally occurring catecholamines.

Therapeutic Actions and Indications

The effects of the sympathomimetic drugs are mediated by the adrenergic receptors in target organs: Heart rate increases with increased myocardial contractility; bronchi dilate and

● **FIGURE 30.1** After gently exposing the lower conjunctival sac, the nurse administers an eyedrop. [From Lynn, P. (2006). *Taylor's clinical nursing skills: A nursing process approach* (2nd ed.). Philadelphia: Lippincott Williams & Wilkins, p. 244, Figure 4.]

● **FIGURE 30.2** Sympathetic nervous system and physiological effects of adrenergic stimulation. Adrenergic agonists cause stimulation of adrenergic receptors, producing physiological effects associated with sympathetic stimulation. Receptor-site-specific adrenergic agonists have more pronounced effect on particular responses.

respirations increase in rate and depth; blood vessels constrict, causing an increase in blood pressure; intraocular pressure decreases; **glycogenolysis** (breakdown of glucose stores so that the glucose can be used as energy) occurs throughout the body; pupils dilate; and sweating can increase (see Figure 30.2). These drugs generally are indicated for the treatment of hypotensive states or shock, bronchospasm, and some types of asthma. Table 30.1 discusses usual indications for each of these agents.

Dopamine, a naturally occurring catecholamine, is the sympathomimetic of choice for the treatment of shock. It stimulates the heart and blood pressure but also causes a renal and splanchnic arteriole dilation that increases blood flow to the kidney, preventing the diminished renal blood supply and possible renal shutdown that can occur with epinephrine or norepinephrine, which are also naturally occurring catecholamines that interact with both alpha- and beta-adrenergic receptors

and are used for the treatment of shock and to stimulate the body after cardiac arrest (see Table 30.1 for additional indications for epinephrine and norepinephrine).

Dobutamine, ephedrine, and metaraminol are synthetic catecholamines. Dobutamine, although it acts at both receptor sites, has a slight preference for beta₁-receptor sites. It is used in the treatment of heart failure because it can increase myocardial contractility without much change in rate and does not increase the oxygen demand of the cardiac muscle, an advantage over all of the other sympathomimetic drugs.

Ephedrine stimulates the release of norepinephrine from nerve endings and acts directly on adrenergic receptor sites. Although ephedrine was once used for situations ranging from the treatment of shock to chronic management of asthma and allergic rhinitis, its use in many areas is declining because of the availability of less toxic drugs with more predictable onset and action.

TABLE 30.1 DRUGS IN FOCUS Alpha- and Beta-Adrenergic Agonists

Drug Name	Dosage/Route	Usual Indications
dobutamine (<i>Dobutrex</i>)	2.5–10 mcg/kg/min IV with dose adjusted based on patient response	Treatment of heart failure
 dopamine (<i>Intropin</i>)	Initially 5–10 mcg/kg per minute IV with incremental increases up to 20–50 mcg/kg per minute based on patient response	Treatment of shock
ephedrine (generic)	Adult: 25–50 mg IM, SQ, or IV for acute treatment; 25–50 mg PO for asthma maintenance Pediatric: 25–100 mg/m ² IM or SQ in four to six divided doses; 3 mg/kg per day in four to six divided doses PO, SC, or IV for bronchodilation	Treatment of hypotensive episodes
epinephrine (<i>Adrenalin</i> , <i>Sus-Phrine</i>)	Adult: 0.5–1.0 mg IV for acute treatment; 0.3–0.5 mg SQ or IM for respiratory distress; may be used in a nebulizer or as topical nasal drops Pediatric: 0.005–0.01 mg/kg IV, base dose on age, weight, and response; do not repeat more than q6h; topical nasal drops for children >6 yr as needed	Treatment of shock when increased blood pressure and heart contractility are essential; to prolong effects of regional anesthetic; primary treatment for bronchospasm; as an ophthalmic agent; to produce a local vasoconstriction that prolongs the effects of local anesthetics
metaraminol (<i>Aramine</i>)	Adult: 2–10 mg SQ or IM to prevent hypotension; 15–100 mg IV in 250–500 mL sodium chloride or dextrose solution to treat hypotension Pediatric: 0.01 mg/kg IV as a single dose	Treatment of shock if norepinephrine or dopamine cannot be used; prevention of hypotension with spinal anesthesia
norepinephrine (<i>Levophed</i>)	8–12 mcg base/min IV; base rate and dose on patient response	Treatment of shock; used during cardiac arrest to get sympathetic activity

Safe Medication Administration

Ephedra, an herb that acts like ephedrine, has been in headlines in recent years because people who were using the herb to promote weight loss died suddenly. Several states have limited its sale, and the U.S. Food and Drug Administration (FDA) is studying the herb—an isomer of epinephrine—and pushing for the authority to regulate the product. The FDA has banned ephedra as a drug, but many states still allow the sale of the herb. Patients should be taught about the potential danger of this product. Any patient who is at risk for serious reactions to the stimulatory effects of a sympathomimetic—patients with narrow-angle glaucoma, dehydration, cerebral or peripheral vascular disease, cardiac disease or arrhythmias, hypertension, renal dysfunction, thyroid disease, diabetes, prostatic disorders, pregnancy, or lactation—should receive direct teaching about the dangers of this product. To review the FDA warnings in preparing your teaching protocol, go to <http://nccam.nih.gov/health/alerts/ephedra/consumeradvisory.htm>.

Many over-the-counter cold products contain ephedrine or pseudoephedrine. These products can be used to produce methamphetamine, an often-abused street drug. By law, the sale of these products is now restricted. The products are found

behind the counter at pharmacies, not on open shelves, and the amount that can be purchased at any given time is limited.

Metaraminol is very similar to norepinephrine. It is given as a single parenteral injection to prevent hypotension by increasing myocardial contractility and causing peripheral vasoconstriction. Its use is limited to situations in which dopamine or norepinephrine cannot be used.

Pharmacokinetics

These drugs are generally absorbed rapidly after injection or passage through mucous membranes. They are metabolized in the liver and excreted in the urine. When used in emergency situations, they are given intravenously (IV) to achieve rapid onset of action.

Contraindications and Cautions

The alpha- and beta-agonists are contraindicated in patients with known hypersensitivity to any component of the drug *to prevent hypersensitivity reactions*; pheochromocytoma *because the systemic overload of catecholamines could be fatal*; with tachyarrhythmias or ventricular fibrillation *because the increased heart rate and oxygen consumption usually caused by these drugs could exacerbate these conditions*; with hypovolemia, *for which fluid replacement would be the treatment*

for the associated hypotension; and with halogenated hydrocarbon general anesthetics, which sensitize the myocardium to catecholamines and could cause serious cardiac effects. Caution should be used with any kind of peripheral vascular disease (e.g., atherosclerosis, Raynaud disease, diabetic endarteritis), which could be exacerbated by systemic vasoconstriction. Because the sympathomimetic drugs stimulate the SNS, they should be used during pregnancy and lactation only if the benefits to the mother clearly outweigh any potential risks to the fetus or neonate.

Adverse Effects

The adverse effects associated with the use of alpha- and beta-adrenergic agonists may be associated with the drugs' effects on the SNS: arrhythmias, hypertension, palpitations, angina, and dyspnea related to the effects on the heart and cardiovascular (CV) system; nausea, vomiting, and constipation related to the depressant effects on the gastrointestinal (GI) tract; and headache, sweating, feelings of tension or anxiety, and piloerection related to the sympathetic stimulation. Because all of these drugs cause vasoconstriction, care must be taken to avoid extravasation of any infused drug. The vasoconstriction in the area of extravasation can lead to necrosis and cell death in that area.

Clinically Important Drug–Drug Interactions

Increased effects of tricyclic antidepressants and monoamine oxidase inhibitors (MAOIs) can occur because of the increased norepinephrine levels or increased receptor stimulation that occurs with both drugs. There is an increased risk of hypertension if alpha- and beta-adrenergic agonists are given with any other drugs that cause hypertension, including herbal therapies and OTC preparations (Box 30.2). Any adrenergic agonist will lose effectiveness if combined with any adrenergic antagonist. Monitor the patient's drug regimen for appropriate use of the drugs.

Prototype Summary: Dopamine

Indications: Correction of hemodynamic imbalances present in shock.

Actions: Acts directly and by the release of norepinephrine from sympathetic nerve terminals; mediates dilation of vessels in the renal and splanchnic beds to maintain renal perfusion while stimulating the sympathetic response.

Pharmacokinetics:

Route	Onset	Peak	Duration
IV	1–2 min	10 min	Length of infusion

$T_{1/2}$: 2 minutes; metabolized in the liver, excreted in the urine.

Adverse effects: Tachycardia, ectopic beats, anginal pain, hypotension, dyspnea, nausea, vomiting, headache.

BOX 30.2 Herbal and Alternative Therapies

Patients being treated with any adrenergic agonists who are also taking ma huang, guarana, or caffeine are at increased risk for overstimulation, including increased blood pressure, stroke, and death. Counsel patients to avoid these combinations.

Nursing Considerations for Patients Receiving Alpha- and Beta-Adrenergic Agonists

Assessment: History and Examination

Assess for contraindications or cautions: any known allergies to these drugs to avoid hypersensitivity reactions; pheochromocytoma, which could lead to fatal reactions due to systemic overload of catecholamines; tachyarrhythmias or ventricular fibrillation, which could be exacerbated by these drugs; hypovolemia, which would require fluid replacement as treatment for the associated hypotension; general anesthesia with halogenated hydrocarbon anesthetics, which could lead to serious cardiac effects; the presence of vascular disease, which could be exacerbated with the use of these drugs; and current status of pregnancy and lactation.

- Perform a physical assessment to establish baseline status before beginning therapy, and during therapy to evaluate for any potential adverse effects and to determine the effectiveness of therapy.
- Assess vital signs, especially pulse and blood pressure, to monitor for possible excess stimulation of the cardiac system; obtain an electrocardiogram (ECG) to evaluate for possible arrhythmias.
- Note respiratory rate and auscultate lungs for adventitious sounds to evaluate effects on bronchi and respirations.
- Monitor urine output to evaluate perfusion of the kidneys and therapeutic effects.
- Monitor the results of laboratory tests, such as renal and liver function tests, to determine the need for possible dose adjustment, and serum electrolyte levels to evaluate fluid loss and appropriateness of therapy.

Refer to Critical Thinking Scenario for a full discussion of nursing care for a patient who is experiencing adrenergic agonist toxicity.

Nursing Diagnoses

Nursing diagnoses related to drug therapy may include the following:

- Decreased Cardiac Output related to CV effects
- Ineffective Tissue Perfusion related to CV effects or possible extravasation
- Deficient Knowledge regarding drug therapy

CRITICAL THINKING SCENARIO

Adrenergic Agonist Toxicity

THE SITUATION

M.C. is a 26-year-old man who has recently moved to the northeastern United States from New Mexico. He has been suffering from sinusitis, runny nose, and cold-like symptoms for 2 weeks. He appears at an outpatient clinic with complaints of headache, “jitters,” inability to sleep, loss of appetite, and a feeling of impending doom. He states that he feels “on edge” and has not been productive in his job as a watch repairman and jewelry maker. According to his history, M.C. has been treated with several different drugs for nocturnal enuresis, a persisting childhood problem. Only ephedrine, which he has been taking for 2 years, has been successful (an off-label use of the drug). He has no other significant health problems. He denies any side effects from the use of ephedrine but does admit to self-medicating his nagging cold with over-the-counter (OTC) preparations—a nasal spray used four times a day and a combination decongestant–pain reliever. A physical examination reveals a pulse of 104 beats/min, blood pressure 154/86 mm Hg, and respiration 16/min. The patient appears flushed and slightly diaphoretic.

CRITICAL THINKING

What are the important nursing implications for M.C.?

Think about the problems that confront a patient in a new area seeking health care for the first time.

What could be causing the problems that M.C. presents with? *The diagnosis of ephedrine overdose was eventually made based on the patient history of OTC drug use and the presenting signs and symptoms.*

Keeping in mind that this diagnosis means that M.C. has an overstimulated sympathetic stress reaction, what other physical problems can be anticipated? *Overwhelming feelings of anxiety and stress are influencing M.C.’s response to work and health care.*

Given this fact, how may the nurse best deal with explaining the problem and how it could have happened—without making the patient feel uninformed or that the practice of his former health care provider is being questioned?

What treatment should be planned and what teaching points should be covered for M.C.?

DISCUSSION

The first step in caring for M.C. is establishing a trusting relationship to help alleviate some of the anxiety he is feeling. Being in a new state and seeking health care in a new setting can be very stressful for patients under normal circumstances. In M.C.’s case, the sympathomimetic effects of the drugs

that he has been taking make him feel even more anxious and jittery.

A careful patient history will help to determine whether there are any underlying medical problems that could be exacerbated by these drug effects. A review of M.C.’s nocturnal enuresis and the treatments that have been tried will enhance understanding of his former health care and suggest possible implications for further study. This questioning will also reassure M.C. that he is an important member of the health team and that the information he has to offer is valued.

A careful review of the OTC drugs that M.C. has been using will be informative for the patient, as well as for the health care providers, who have not actually checked OTC drugs for those specific ingredients, but combining them to ease signs and symptoms often results in toxic levels and symptoms of overdose. Many of these preparations contain sympathomimetics, such as phenylephrine, which will have additive effects to the ephedrine. M.C. will need a full teaching program about the effects of his ephedrine and which OTC drugs to avoid. The treatment for his current problems involves withdrawal of the OTC drugs; when these drug levels fall, the signs and symptoms will disappear. M.C. may also wish to avoid nicotine and caffeine because these stimulants could increase his “jitters.”

To build trust and ensure that the underlying cause of the problem was drug toxicity, M.C. should receive written patient instructions that highlight warning signs to report, including chest pain, palpitations, and difficulty voiding. He also should be given the health care provider’s telephone number with instructions to call the next day and report on his health status. Finally, specimens of nasal discharge should be cultured and antibiotic treatment prescribed, if appropriate.

NURSING CARE GUIDE FOR M.C.: ADRENERGIC AGONIST TOXICITY

Assessment: History and Examination

Assess the patient’s history of drug allergies, cardiovascular dysfunction, pheochromocytoma, narrow-angle glaucoma, prostatic hypertrophy, thyroid disease, or diabetes, as well as concurrent use of MAOIs, tricyclic antidepressants, reserpine, ephedrine, or urinary alkalinizers.

Focus the physical examination on the following:

CV: Blood pressure, pulse rate, peripheral perfusion, and ECG

CNS: orientation, affect, reflexes, peripheral sensation, and vision

Adrenergic Agonist Toxicity (continued)

Skin: color and temperature
 GI: abdominal examination
 GU: urine output, bladder percussion, and prostate palpation
 Respiratory: respiratory rate and adventitious sounds

Nursing Diagnoses

Decreased Cardiac Output related to CV effects
 Acute Pain related to CV and systemic effects
 Impaired Tissue Perfusion related to CV effects
 Deficient Knowledge regarding drug therapy

Implementation

Ensure safe and appropriate administration of the drug.
 Provide comfort and safety measures: temperature and lighting control (patient may have pupil dilation secondary to sympathetic effects), mouth care, and skin care.
 Monitor blood pressure, pulse rate, and respiratory status throughout drug therapy.
 Provide support and reassurance to deal with drug therapy and drug effects.
 Provide patient teaching about drug name, dosage, side effects, precautions, and warning signs to report.

Evaluation

Evaluate drug effects: relief of enuresis.
 Monitor for adverse effects: CV effects, dizziness, confusion, headache, rash, difficulty voiding, sweating, flushing, and pupillary dilation.
 Monitor for drug–drug interactions as indicated.
 Evaluate the effectiveness of the patient teaching program and comfort and safety measures.

PATIENT TEACHING FOR M.C.

- The drug that you have been taking is ephedrine. It is called an adrenergic agonist (or a sympathomimetic drug). Ephedrine acts by mimicking the effects of the sympathetic nervous system, which is the part of your nervous system that is responsible for your response to fear or dan-

ger (this is called the “fight-or-flight” response). Because this drug triggers many effects in the body, you may experience some undesired adverse effects. It is crucial to discuss the effect of the drug with your health care provider and to try to make the effect as tolerable as possible.

- If the drug is in a solution, check it before each use. If the solution is pink, brown, or black, discard it.
- If you have diagnosed prostate problems, it might help to void before taking each dose of the drug.
- Some of the following adverse effects may occur:
 - *Restlessness or shaking*: If these occur, avoid driving, operating machinery, or performing delicate tasks.
 - *Flushing or sweating*: Avoid warm temperatures and heavy clothing; frequent washing with cool water may help.
 - *Heart palpitations*: If you feel that your heart is beating too fast or skipping beats, sit down for awhile and rest. If the feeling becomes too uncomfortable, notify your health care provider.
 - *Sensitivity to light*: Avoid glaring lights or wear sunglasses if you are in bright light. Be careful when moving between extremes of light because your vision may not adjust quickly.
- Report any of the following to your health care provider: *difficulty voiding, chest pain, difficulty breathing, dizziness, headache, or changes in vision.*
- Do not stop taking this drug suddenly; make sure that you have enough of your prescription. This drug dose should be reduced gradually over 2 to 4 days when you are instructed to discontinue it by your health care provider.
- Avoid over-the-counter medications, including cold and allergy remedies and diet pills. If you feel that you need one of these, check with your health care provider first.
- Tell any health care provider who takes care of you that you are taking this drug.
- Keep this drug and all medications out of the reach of children. Do not share this drug with other people.

Implementation With Rationale

- Use extreme caution in calculating and preparing doses of these drugs *because even small errors could have serious effects*. Always dilute a parenteral drug before use if it is not prediluted *to prevent tissue irritation on injection*.
- Use proper, aseptic technique when administering ophthalmic or nasal agents *to prevent infection and assure the therapeutic effectiveness of the drug*.
- Monitor patients receiving the drug ophthalmically or nasally for all of the systemic effects associated with parenteral administration *to prevent potentially serious adverse effects if the drug is absorbed systemically*.

- Monitor patient response closely (blood pressure, ECG, urine output, cardiac output) and adjust dose accordingly *to ensure the most benefit with the least amount of toxicity*.
- Maintain phentolamine on standby *in case extravasation occurs*; infiltration of the site with 10 mL of saline containing 5 to 10 mg of phentolamine is usually effective in saving the area.
- Offer support and encouragement *to deal with the drug regimen*.
- Provide comfort measures to help the patient cope with sympathomimetic effects of the drug; Monitor light

exposure to prevent sensitivity to light caused by pupil dilation, encourage voiding before giving the drug to alleviate urinary retention caused by sphincter contraction, monitor bowel function and provide assistance as needed to deal with GI suppression, and offer support and relaxation measures to deal with feelings of tension and anxiety.

- Provide the following patient teaching to patients using these drugs orally or ophthalmically. Most of these drugs are given in emergency situations and teaching will be based on the patient's condition and awareness.

Teaching includes:

- Drug name, prescribed dosage, and schedule for administration
- Rationale for the drug
- Proper technique for administration
- Measures to prevent or avoid adverse effects
- Need to check with prescriber before taking any over-the-counter medication
- Warning signs that might indicate a problem
- Importance of avoiding intake of caffeine-containing products
- Need for follow-up monitoring and evaluation

Evaluation

- Monitor the patient response to the drug (improvement in blood pressure, ocular pressure, bronchial airflow).
- Monitor for adverse effects (cardiovascular changes, decreased urine output, headache, GI upset).
- Monitor the effectiveness of comfort measures and compliance with the regimen.
- Evaluate the effectiveness of the teaching plan (patient can name the drug, dosage, adverse effects to watch for, and specific measures to avoid them).

KEY POINTS

- ▶ Adrenergic agonists (sympathomimetics) stimulate the adrenergic receptors in the SNS.
- ▶ Alpha- and beta-adrenergic agonists stimulate all of the adrenergic receptors in the SNS. They induce a fight-or-flight response and are frequently used to treat shock.

ALPHA-SPECIFIC ADRENERGIC AGONISTS

Alpha-specific adrenergic agonists (Table 30.2), or alpha-agonists, are drugs that bind primarily to alpha-receptors rather than to beta-receptors. Three drugs belong to this class: clonidine (*Catapres*), midodrine (*ProAmantine*), and phenylephrine (*Neo-Synephrine*, *Allerest*, *AK-Dilate*, and others).

Therapeutic Actions and Indications

Therapeutic effects of the alpha-specific adrenergic agonists result from the stimulation of alpha-receptors within the SNS (see Figure 30.2). The uses are varied, depending on the specific drug and the route of administration (Table 30.2).

Phenylephrine, a potent vasoconstrictor and alpha₁-agonist with little or no effect on the heart or bronchi, is used in many combination cold and allergy products. Parenterally it is used to treat shock or shock-like states, to overcome paroxysmal supraventricular tachycardia, to prolong local anesthesia, and to maintain blood pressure during spinal anesthesia. Topically it is used to treat allergic rhinitis and to relieve the symptoms of otitis media. Ophthalmically it is used to dilate the pupils for eye examination, before surgery, or to relieve elevated eye pressure associated with glaucoma. Phenylephrine is found in many cold and allergy products because it is so effective in constricting topical vessels and decreasing the swelling, signs, and symptoms of rhinitis.

Midodrine is an oral drug that is used to treat orthostatic hypotension in patients who do not respond to traditional therapy. It activates alpha₁-adrenergic receptors, leading to peripheral vasoconstriction and an increase in vascular tone and blood pressure. This effect can cause a serious supine hypertension. Patients need to be monitored in the standing, sitting, and supine positions to determine whether this will be a problem.

Clonidine specifically stimulates central nervous system (CNS) alpha₂-receptors. This leads to decreased sympathetic outflow from the CNS because the alpha₂-receptors moderate the release of norepinephrine from the nerve axon. Clonidine is available in oral and transdermal forms for use to control

TABLE 30.2 DRUGS IN FOCUS Alpha-Specific Adrenergic Agonists

Drug Name	Dosage/Route	Usual Indications
clonidine (<i>Catapres</i>)	0.1 mg PO b.i.d. initially up to a maximum 2.4 mg/d if needed; transdermal system may increase from 0.1 to 0.3 mg/d	Treatment of essential hypertension; chronic pain; to ease opiate withdrawal; used only for adults
midodrine (<i>ProAmantine</i>)	10 mg PO t.i.d. during daytime hours when patient is upright	Treatment of orthostatic hypotension
 phenylephrine (<i>Neo-Synephrine</i>)	1–10 mg SQ or IV or 0.1–0.5 mg IV as a starting dose; 0.5 mg IV by rapid injection to convert tachycardias; 1–2 gtt in affected eye(s) for glaucoma	Cold and allergies; shock and shock-like states; supraventricular tachycardias; glaucoma; allergic rhinitis; otitis media

hypertension and as an injection for epidural infusion to control pain in cancer patients. Because of its centrally acting effects, clonidine is associated with many more CNS effects (bad dreams, sedation, drowsiness, fatigue, headache) than other sympathomimetics. It can also cause extreme hypotension, heart failure, and bradycardia due to its decreased effects of the sympathetic outflow from the CNS.

Pharmacokinetics

These drugs are generally well absorbed from all routes of administration and reach peak levels in a short period—20 to 45 minutes. They are widely distributed in the body, metabolized in the liver, and primarily excreted in the urine. The transdermal form of clonidine is slow release and has a 7-day duration of effects, so it only needs to be replaced once a week. Phenylephrine can be given intramuscularly (IM), subcutaneously (SQ), IV, orally, and as a nasal or an ophthalmic solution.

Contraindications and Cautions

The alpha-specific adrenergic agonists are contraindicated in the presence of allergy to the specific drug *to avoid hypersensitivity reactions*; severe hypertension or tachycardia *because of possible additive effects*; and narrow-angle glaucoma, *which could be exacerbated by arterial constriction*. There are no adequate studies about use during pregnancy and lactation, so use should be reserved for situations in which the benefit to the mother outweighs any potential risk to the fetus or neonate.

They should be used with caution in the presence of cardiovascular disease or vasomotor spasm *because these conditions could be aggravated by the vascular effects of the drug*; thyrotoxicosis or diabetes *because of the thyroid-stimulating and glucose-elevating effects of sympathetic stimulation*; or renal or hepatic impairment, *which could interfere with metabolism and excretion of the drug*.

Adverse Effects

Patients receiving these drugs often experience adverse effects that are extensions of the therapeutic effects or other sympathetic stimulatory reactions. CNS effects include feelings of anxiety, restlessness, depression, fatigue, strange dreams, and personality changes. Blurred vision and sensitivity to light may occur because of the pupil dilation that occurs when the sympathetic system is stimulated. Cardiovascular effects can include arrhythmias, ECG changes, blood pressure changes, and peripheral vascular problems. Nausea, vomiting, and anorexia can occur, related to the depressant effects of the SNS on the GI tract. Genitourinary effects can include decreased urinary output, difficulty urinating, dysuria, and changes in sexual function related to the sympathetic stimulation of these systems. These drugs should not be stopped suddenly; adrenergic receptors will be very sensitive to catecholamines, and

sudden withdrawal can lead to tachycardia, hypertension, arrhythmias, flushing, and even death. Avoid these effects by tapering the drug over 2 to 4 days when it is being discontinued. As with other sympathomimetics, if phenylephrine is given IV, care should be taken to avoid extravasation. The vasoconstricting effects of the drug can lead to necrosis and cell death in the area of extravasation.

Clinically Important Drug–Drug Interactions

Phenylephrine combined with MAOIs can cause severe hypertension, headache, and hyperpyrexia; this combination should be avoided. Increased sympathomimetic effects occur when phenylephrine is combined with tricyclic antidepressants (TCAs); if this combination must be used, the patient should be monitored very closely.

Clonidine has a decreased antihypertensive effect if taken with TCAs, and a paradoxical hypertension occurs if it is combined with propranolol. If these combinations are used, the patient response should be monitored closely and dose adjustment made as needed.

Midodrine can precipitate increased drug effects of digoxin, beta-blockers, and many antipsychotics. Such combinations should be avoided.

Any adrenergic agonist will lose effectiveness if combined with any adrenergic antagonist. Monitor the patient's drug regimen for appropriate use of the drugs.

Prototype Summary: Phenylephrine

Indications: Treatment of vascular failure in shock or drug-induced hypotension; to overcome paroxysmal supraventricular tachycardia; to prolong spinal anesthesia; as a vasoconstrictor in regional anesthesia; to maintain blood pressure during anesthesia; topically for symptomatic relief of nasal congestion and as adjunctive therapy in middle ear infections; ophthalmically to dilate pupils and as a decongestant to provide temporary relief of eye irritation.

Actions: Powerful postsynaptic alpha-adrenergic receptor stimulant causing vasoconstriction and raising systolic and diastolic blood pressure with little effect on the beta-receptors in the heart.

Pharmacokinetics:

Route	Onset	Duration
IV	Immediate	15–20 min
IM, SQ	10–15 min	30–120 min
Topically	Very little systemic absorption occurs	

$T_{1/2}$: 47 to 100 hours; metabolized in the tissues and liver; excreted in urine and bile.

Adverse effects: Fear, anxiety, restlessness, headache, nausea, decreased urine formation, pallor.

● Nursing Considerations for Patients Receiving Alpha-Specific Adrenergic Agonists

Assessment: History and Examination

- Assess for contraindications or cautions: any known allergies to the drug *to avoid hypersensitivity reactions*; presence of any cardiovascular diseases, *which could be exacerbated by the vascular effects of these drugs*; thyrotoxicosis or diabetes, *which would lead to an increase in thyroid stimulation or glucose elevation*; chronic renal failure, *which could be exacerbated by drug use*; renal or hepatic impairment, *which could interfere with drug excretion or metabolism*; and current status of pregnancy and lactation.
- Perform a physical assessment to establish *baseline status before beginning therapy to determine effectiveness and during therapy to evaluate for any potential adverse effects*.
- Assess level of orientation, affect, reflexes, and vision *to monitor for CNS changes related to drug therapy*.
- Monitor blood pressure and pulse, assess peripheral perfusion, and obtain ECG, if indicated, *to determine drug effectiveness and evaluate for adverse cardiovascular effects*.
- Assess urinary output *to evaluate renal function and monitor for adverse effects of the drug*.
- Evaluate patient for nausea and constipation *to assess adverse effects of the drug and establish appropriate interventions*.
- Monitor laboratory test results, such as renal and liver function tests, *to determine drug effects on renal and hepatic systems*.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Disturbed Sensory Perception (Visual, Kinesthetic, Tactile) related to CNS effects
- Discomfort related to GI and GU effects of the drug and pupil dilation causing sensitivity to light
- Risk for Injury related to CNS or CV effects of the drug and potential for extravasation
- Decreased Cardiac Output related to blood pressure changes, arrhythmias, or vasoconstriction
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Do not discontinue the drug abruptly *because sudden withdrawal can result in rebound hypertension, arrhythmias, flushing, and even hypertensive encephalopathy and death*; taper drug over 2 to 4 days.
- Do not discontinue the drug before surgery; mark the patient's chart and monitor blood pressure carefully during

surgery. *Sympathetic stimulation may alter the normal response to anesthesia, as well as recovery from anesthesia.*

- Monitor blood pressure, orthostatic blood pressure, pulse, rhythm, and cardiac output regularly, even with ophthalmic preparations, *to adjust dose or discontinue the drug if cardiovascular effects are severe*.
- When giving phenylephrine intravenously, ensure that an alpha-blocking agent is readily available to counteract the effects *in case severe reaction occurs*; infiltrate any area of extravasation with phentolamine within 12 hours after extravasation *to preserve tissue*.
- Arrange for supportive care and comfort measures, including rest and environmental control, *to decrease CNS irritation*; analgesics for headache *to relieve discomfort*; safety measures, such as use of side rails and assistance with ambulation if CNS effects occur, *to protect the patient from injury*; and protective measures *if CNS effects are severe*.
- Provide thorough patient teaching about drug name, dose and schedule for administration; technique for administration if appropriate; measures to prevent potential adverse effects such as voiding before taking the drug and use of bowel training activities if constipation is a problem; safety measures such as avoiding driving and operating dangerous machinery if CNS effects occur and getting up and down slowly if orthostatic hypotension is an issue; warning signs of problems; and importance of monitoring and follow-up.

Evaluation

- Monitor patient response to the drug (improvement in condition being treated).
- Monitor for adverse effects (GI upset, CNS and cardiovascular changes).
- Monitor the effectiveness of comfort measures and compliance with the regimen.
- Evaluate the effectiveness of the teaching plan (patient can name drug, dosage, adverse effects to watch for, and specific measures to avoid them).

KEY POINTS

- ▶ Alpha-specific adrenergic agonists, such as phenylephrine, midodrine, and clonidine, stimulate only the alpha-receptors within the SNS. Clonidine specifically stimulates alpha₂-receptors and is used to treat hypertension because its action blocks the release of norepinephrine from nerve axons.
- ▶ Care must be taken to prevent extravasation when used IV; the vasoconstrictive properties of the drug can cause necrosis and cell death in the area of extravasation.
- ▶ These drugs should be tapered over 2 to 4 days when discontinued because the adrenergic receptors will be very sensitive, and rebound hypertension, tachycardia, arrhythmias, and even death can occur.

BETA-SPECIFIC ADRENERGIC AGONISTS

Most of the drugs that belong to the class of beta-specific adrenergic agonists (Table 30.3), or beta-agonists, are beta₂-specific agonists and are used to manage and treat bronchial spasm, asthma, and other obstructive pulmonary conditions. These drugs, including albuterol (*Proventil*), bitolterol (*Tornalate*), isoetharine (generic), levalbuterol (*Xopenex*), metaproterenol (*Alupent*), pirbuterol (*Maxair*), salmeterol (*Serevent*), and terbutaline (*Brethaire*), are discussed at length in Chapter 55, which deals with drugs used to treat obstructive pulmonary diseases. This chapter specifically addresses isoproterenol (*Isuprel*), which is used as a sympathomimetic for its overall stimulatory properties.

Therapeutic Actions and Indications

Therapeutic effects of isoproterenol are related to its stimulation of all beta-adrenergic receptors. Desired effects of the drug

include increased heart rate, conductivity, and contractility; bronchodilation; increased blood flow to skeletal muscles and splanchnic beds; and relaxation of the uterus. Its use has decreased over the years as more specific drugs with less toxicity have been developed to treat the cardiac problems isoproterenol was developed to treat. Some research has shown that isoproterenol exerts a “coronary steal” effect, diverting blood away from injured or hypoxic areas of the heart muscle, an effect that can increase the size and extent of an evolving myocardial infarction, further decreasing its usefulness in the clinical setting. There are some emergency situations, however, that respond well to isoproterenol. See Table 30.3 for usual indications.

Pharmacokinetics

Isoproterenol is rapidly distributed after injection; it is metabolized in the liver and excreted in the urine. The half-life is relatively short—less than 1 hour.

TABLE 30.3 DRUGS IN FOCUS Beta-Specific Adrenergic Agonists

Drug Name	Dosage/Route	Usual Indications
albuterol (<i>Proventil</i> , <i>Ventolin</i>)	Adult: 2–4 mg t.i.d.–q.i.d. PO, or 1–2 inhalations every 4–6 h Pediatric: 2 mg t.i.d.–q.i.d. PO, or 1.25–2.5 mg b.i.d. by inhalation	Treatment and prevention of bronchospasm; treatment of acute bronchospasm and exercise-induced bronchospasm when used by inhalation
bitolterol (<i>Tornalate</i>)	1.5–3.5 mg over 10 × 15 min by continuous nebulization; not recommended <12 yr of age	Treatment of bronchial asthma and reversible bronchospasm
isoetharine (generic)	Adult: four inhalations every 4 h	Treatment and prevention of bronchial asthma and reversible bronchospasm
 isoproterenol (<i>Isuprel</i>)	Adult: IV injection, 0.02–0.06 mg; IV infusion, 5 mcg/min; 0.2 mg IM or SQ Pediatric: 0.1–1.0 mcg/kg/min IV has been used	Treatment of shock, cardiac arrest, and certain ventricular arrhythmias; treatment of heart block in transplanted hearts; prevention of bronchospasm during anesthesia
levalbuterol (<i>Xopenex</i>)	Adult and children ≥12 yr: 0.63 mg t.i.d. by nebulization 6–11 yr: 0.31 mg t.i.d. by nebulization ≥4 yr: two inhalations every 4–6 h	Treatment and prevention of bronchial asthma and reversible bronchospasm in patients ≥4 yr
metaproterenol (<i>Alupent</i>)	Adult and children ≥12 yr: 2–3 inhalations every 3–4 h; 2.5 mL by nebulization; 20 mg PO t.i.d.–q.i.d. Children 6–9 yr: 10 mg PO t.i.d.–q.i.d.; 0.1–0.2 mL in saline by nebulization	Treatment of bronchial asthma and reversible bronchospasm; by inhalation, treatment of acute asthma attacks in children ≥6 yr
pirbuterol (<i>Maxair Autohaler</i>)	Adults and children ≥12 yr: 2 inhalations (0.4 mg); do not exceed maximum daily dose of 12 inhalations	Treatment and prevention of bronchial asthma and reversible bronchospasm
salmeterol (<i>Serevent Diskus</i>)	Adults and children ≥12 yr: 1 inhalation b.i.d.; 30 min before exercise with exercise-induced bronchospasm	Treatment and prevention of bronchial asthma and reversible bronchospasm, including exercise-induced bronchospasm (patients ≥4 yr)
terbutaline (<i>Brethine</i>)	Adults and children >15 yr: 5 mg PO t.i.d.; 0.25 mg SQ, may be repeated in 15 min to a maximum of 0.5 mg/4 h Children 12–15 yr: 2.5 mg PO t.i.d.	Treatment and prevention of bronchial asthma and reversible bronchospasm

Contraindications and Cautions

Isoproterenol is contraindicated in the presence of allergy to the drug or any components of the drug *to avert hypersensitivity reactions*; with pulmonary hypertension, *which could be exacerbated by the effects of the drug*; during anesthesia with halogenated hydrocarbons, *which sensitize the myocardium to catecholamines and could cause a severe reaction*; with eclampsia, uterine hemorrhage, and intrauterine death, *which could be complicated by uterine relaxation or increased blood pressure*; and during pregnancy and lactation *because of potential effects on the fetus or neonate*. Caution should be used with diabetes, thyroid disease, vasomotor problems, degenerative heart disease, or history of stroke, *all of which could be exacerbated by the sympathomimetic effects of the drug*, and with severe renal impairment, *which could alter the excretion of the drug*.

Adverse Effects

Patients receiving isoproterenol often experience adverse effects related to the stimulation of sympathetic adrenergic receptors. CNS effects include restlessness, anxiety, fear, tremor, fatigue, and headache. Cardiovascular effects can include tachycardia, angina, myocardial infarction, and palpitations. Pulmonary effects can be severe, ranging from difficulty breathing, coughing, and bronchospasm to severe pulmonary edema. GI upset, nausea, vomiting, and anorexia can occur as a result of the slowing of the GI tract with SNS stimulation. Other anticipated effects can include sweating, pupil dilation, rash, and muscle cramps.

Clinically Important Drug–Drug Interactions

Increased sympathomimetic effects can be expected if this drug is taken with other sympathomimetic drugs. Decreased therapeutic effects can occur if this drug is combined with beta-adrenergic blockers.

Prototype Summary: Isoproterenol

Indications: Management of bronchospasm during anesthesia; vasopressor during shock; adjunct in the management of cardiac standstill and arrest, as well as serious ventricular arrhythmias that require increased inotropic action.

Actions: Acts on beta-adrenergic receptors to produce increased heart rate, positive inotropic effect, bronchodilation, and vasodilation.

Pharmacokinetics:

Route	Onset	Duration
IV	Immediate	1–2 min

$T_{1/2}$: Unknown; metabolized in the tissues.

Adverse effects: Restlessness, apprehension, anxiety, fear, cardiac arrhythmias, tachycardia, nausea, vomiting, heartburn, respiratory difficulties, coughing, pulmonary edema, sweating, pallor.

Nursing Considerations for Patients Receiving Beta-Specific Adrenergic Agonists

Assessment: History and Examination

- Assess for contraindications or cautions: any known allergies to any drug or any components of the drug *to avoid possible hypersensitivity reactions*; pulmonary hypertension, *which could be exacerbated by the effects of the drug*; anesthesia with halogenated hydrocarbons, *which sensitize the myocardium to catecholamines and could cause severe reaction*; eclampsia, uterine hemorrhage, and intrauterine death, *which could be complicated by uterine relaxation or increased blood pressure*; diabetes, thyroid disease, vasomotor problems, degenerative heart disease, or history of stroke, *all of which could be exacerbated by the sympathomimetic effects of the drugs*; severe renal impairment, *which could interfere with the excretion of the drug*; and current status of pregnancy and lactation.
- Perform a physical assessment to establish a *baseline before beginning therapy and during therapy to determine the drug's effectiveness and identify any potential adverse effects*.
- Assess cardiovascular status, including pulse rate and blood pressure, *to evaluate for any cardiovascular effects associated with SNS stimulation*; obtain an ECG *to evaluate for changes indicating excessive SNS stimulation*.
- Assess respiratory status and listen for adventitious sounds *to monitor drug effects and assess for any adverse effects*.
- Monitor urine output *to evaluate renal function and kidney perfusion*.
- Monitor laboratory test results, including thyroid function tests, blood glucose levels, and renal function, *to monitor drug effects and potential adverse effects*.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to CV and systemic effects
- Decreased Cardiac Output related to CV effects
- Ineffective Tissue Perfusion related to CV effects
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Monitor pulse and blood pressure carefully during administration *to arrange to discontinue the drug at any sign of toxicity*.
- Ensure that a beta-adrenergic blocker is readily available when giving parenteral isoproterenol *in case severe reaction occurs*.

- Use minimal doses of isoproterenol needed to achieve desired effects *to prevent adverse effects and maintain patient safety*.
- Arrange for supportive care and comfort measures, including rest and environmental control, *to relieve CNS effects*; provide analgesics for headache and safety measures if CNS effects occur *to provide comfort and prevent injury*; and avoid overhydration *to prevent pulmonary edema*.
- Provide thorough patient teaching, including drug name, dosage, and frequency of administration; rationale for administration; monitoring required; anticipated adverse effects, measures to reduce these, and warning signs of problems to report immediately.

Evaluation

- Monitor patient response to the drug (improvement in condition being treated, stabilization of blood pressure, prevention of preterm labor, cardiac stimulation).
- Monitor for adverse effects (GI upset, CNS changes, respiratory problems).
- Evaluate the effectiveness of the teaching plan (patient can name drug, dosage, adverse effects to watch for, and specific measures to reduce them).
- Monitor the effectiveness of comfort measures and compliance with the regimen.

KEY POINTS

- ▶ Most of the beta₂-specific adrenergic agonists are used to manage and treat asthma, bronchospasm, and other obstructive pulmonary diseases.
- ▶ Isoproterenol, a nonspecific beta-specific adrenergic agent, is used for its sympathomimetic effects to treat shock, cardiac standstill, and certain arrhythmias when used systemically; it is especially effective in the treatment of heart block in transplanted hearts.
- ▶ Because of its many adverse effects, isoproterenol is reserved for use in emergency situations that do not respond to other, safer therapies.

CHAPTER SUMMARY

- Adrenergic agonists, also called sympathomimetics, are drugs that mimic the effects of the SNS and are used to stimulate the adrenergic receptors within the SNS. The adverse effects associated with these drugs are usually also a result of sympathetic stimulation.
- Adrenergic agonists include alpha- and beta-adrenergic agonists, which stimulate both types of adrenergic receptors in the SNS, and alpha-specific and beta-specific adrenergic agonists, which stimulate only alpha- or only beta-receptors, respectively.
- Alpha-specific adrenergic agonists, such as phenylephrine, midodrine, and clonidine, stimulate only the alpha-receptors within the SNS. Clonidine specifically stimulates alpha₂-receptors and is used to treat hypertension because its action blocks the release of norepinephrine from nerve axons.
- Many of the beta₂-specific adrenergic agonists are used to manage and treat asthma, bronchospasm, and other obstructive pulmonary diseases.
- Isoproterenol, a nonspecific beta-specific adrenergic, is used to treat shock, cardiac standstill, and certain arrhythmias when used systemically; it is especially effective in the treatment of heart block in transplanted hearts.

CHECK YOUR UNDERSTANDING

Answers to the questions in this chapter can be found in Answers to Check Your Understanding Questions on the CD-Rom in the front of the book.

MULTIPLE CHOICE

Select the best answer to the following.

- The instructor determines that teaching about adrenergic drugs has been successful when the class identifies the drugs as also being called
 - sympatholytic agents.
 - cholinergic agents.
 - sympathomimetic agents.
 - anticholinergic agents.
- The adrenergic agent of choice for treating the signs and symptoms of allergic rhinitis is
 - norepinephrine.
 - phenylephrine.
 - dobutamine.
 - dopamine.
- An adrenergic agent being used to treat shock infiltrates into the tissue with intravenous administration. Which action by the nurse would be most appropriate?
 - Watch the area for any signs of necrosis and report it to the physician.
 - Notify the physician and decrease the rate of infusion.
 - Remove the IV and prepare phentolamine for administration to the area.
 - Apply ice and elevate the arm.
- Phenylephrine, an alpha-specific agonist, is found in many cold and allergy preparations. The nurse instructs the patient to be alert for which adverse effects?
 - Urinary retention and pupil constriction
 - Hypotension and slow heart rate
 - Personality changes and increased appetite
 - Cardiac arrhythmias and difficulty urinating
- Adverse effects associated with adrenergic agonists are related to the generalized stimulation of the sympathetic nervous system and could include
 - slowed heart rate.
 - constriction of the pupils.
 - hypertension.
 - increased GI secretions.
- A patient has elected to take an over-the-counter cold preparation that contains phenylephrine. The nurse would advise the patient not to take that drug if the patient has
 - thyroid or cardiovascular disease.
 - a cough and runny nose.
 - chronic obstructive pulmonary disease.
 - hypotension.

MULTIPLE RESPONSE

Select all that apply.

- Isoproterenol is a nonspecific beta-agonist. The nurse might expect to administer this drug for which of the following conditions?
 - Preterm labor
 - Bronchospasm
 - Cardiac standstill
 - Shock
 - Heart block in transplanted hearts
 - Heart failure
- A nurse would question the order for an adrenergic agonist for a patient who is also receiving which of the following:
 - Anticholinergic drugs
 - Halogenated hydrocarbon anesthetics
 - Beta-blockers
 - Benzodiazepines
 - MAO inhibitors
 - Tricyclic antidepressants

Adrenergic Blocking Antagonists

31

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Describe the effects of adrenergic blocking agents on adrenergic receptors, correlating these effects with their clinical effects.
2. Describe the therapeutic actions, indications, pharmacokinetics, contraindications and cautions, most common adverse reactions, and important drug–drug interactions associated with adrenergic blocking agents.
3. Discuss the use of adrenergic blocking agents across the lifespan.
4. Compare and contrast the prototype drugs labetalol, phentolamine, doxazosin, propranolol, and atenolol with other adrenergic blocking agents.
5. Outline the nursing considerations, including important teaching points, for patients receiving an adrenergic blocking agent.

GLOSSARY OF KEY TERMS

adrenergic-receptor-site specificity: a drug's affinity for only adrenergic receptor sites; certain drugs may have specific affinity for only alpha- or only beta-adrenergic receptor sites

alpha₁-selective adrenergic blocking agents: drugs that block the postsynaptic alpha₁-receptor sites, causing a decrease in vascular tone and a vasodilation that leads to a fall in blood pressure; these drugs do not block the presynaptic alpha₂-receptor sites, and therefore the reflex tachycardia that accompanies a fall in blood pressure does not occur

beta-adrenergic blocking agents: drugs that, at therapeutic levels, selectively block the beta-receptors of the sympathetic nervous system

beta₁-selective adrenergic blocking agents: drugs that, at therapeutic levels, specifically block the beta₁-receptors in the sympathetic nervous system while not blocking the beta₂-receptors and resultant effects on the respiratory system

bronchodilation: relaxation of the muscles in the bronchi, resulting in a widening of the bronchi; an effect of sympathetic stimulation

pheochromocytoma: a tumor of the chromaffin cells of the adrenal medulla that periodically releases large amounts of norepinephrine and epinephrine into the system with resultant severe hypertension and tachycardia

sympatholytic: a drug that lyses, or blocks, the effects of the sympathetic nervous system

NONSELECTIVE ADRENERGIC BLOCKING AGENTS

amiodarone
carvedilol
labetalol

NONSELECTIVE ALPHA-ADRENERGIC BLOCKING AGENTS

phentolamine

ALPHA₁-SELECTIVE ADRENERGIC BLOCKING AGENTS

alfuzosin
doxazosin
prazosin
tamsulosin
terazosin

NONSELECTIVE BETA-ADRENERGIC BLOCKING AGENTS

carteolol
nadolol
nebivolol
penbutolol
pindolol
propranolol
sotalol
timolol

BETA₁-SELECTIVE ADRENERGIC BLOCKING AGENTS

acebutolol
atenolol
betaxolol
bisoprolol
esmolol
metoprolol

Adrenergic blocking agents are also called **sympatholytic** drugs because they lyse, or block, the effects of the sympathetic nervous system (SNS). The therapeutic and adverse effects associated with these drugs are related to their **adrenergic-receptor-site specificity**, that is, the ability to react with specific adrenergic receptor sites without activating them, thus preventing the typical manifestations of SNS activation. By occupying the adrenergic receptor site, they prevent norepinephrine released from the nerve terminal or from the adrenal medulla from activating the receptor, thus blocking the SNS effects.

The adrenergic blockers have varying degrees of specificity for the adrenergic receptor sites. For example, some can interact with both alpha- and beta-receptors. Some are specific to alpha-receptors, with some being even more specific to just alpha₁-receptors. Other adrenergic blockers interact with both beta₁- and beta₂-receptors, whereas others interact with just either beta₁- or beta₂-receptors. This specificity allows the clinician to select a drug that will have the desired therapeutic effects without the undesired effects that occur when the entire SNS is blocked. In general, however, the specificity of adrenergic blocking agents depends on the concentration of drug in the body. Most specificity is lost with higher serum drug levels (Figure 31.1).

The effects of the adrenergic blocking agents vary with the age of the patient (Box 31.1). Various alternative and herbal remedies also can affect these drugs (Box 31.2).

NONSELECTIVE ADRENERGIC BLOCKING AGENTS

Drugs that block both alpha- and beta-adrenergic receptors are primarily used to treat cardiac-related condition. These drugs include amiodarone (*Cordarone*), carvedilol (*Coreg*), and labetalol (*Normodyne, Trandate*) (see Table 31.1).

Therapeutic Actions and Indications

Adrenergic blocking agents competitively block the effects of norepinephrine at alpha- and beta-receptors throughout the SNS. Subsequently, this results in lower blood pressure, slower pulse rate, and increased renal perfusion with decreased renin levels. Most of these drugs are indicated to treat essential hypertension, alone or in combination with diuretics.

Labetalol is a newer drug that is used intravenously (IV) and orally to treat hypertension. It also can be used with diuretics and has been used to treat hypertension associated with **pheochromocytoma** (tumor of the chromaffin cells of the adrenal medulla, which periodically releases large amounts of norepinephrine and epinephrine into the system) and clonidine withdrawal. Amiodarone, which is available in oral and IV forms, is saved for serious emergencies and only used as an antiarrhythmic (see Chapter 45). Carvedilol is only available orally and is used to treat hypertension, as well as heart failure and left ventricular dysfunction after myocardial

● **FIGURE 31.1** Site of action of adrenergic receptors and resultant physiological responses. These responses are blocked by adrenergic blockers.

FOCUS
BOX 31.1

Drug Therapy Across the Lifespan

Adrenergic Blocking Agents

CHILDREN

Children are at greater risk for complications associated with the use of adrenergic blocking agents, including bradycardia, difficulty breathing, and changes in glucose metabolism. The safety and efficacy for use of these drugs has not been established for children younger than 18 years of age. If one of these drugs is used, the dose for these agents needs to be calculated from the child's body weight and age. It is good practice to have a second person check the dose calculation before administering the drug to avoid potential toxic effects. Three adrenergic blocking agents have established pediatric doses, and they might be the drugs to consider when one is needed: prazosin is used to treat hypertension, and phenolamine, which is used during surgery for pheochromocytoma. Children should be carefully monitored and supported when these drugs are given.

ADULTS

Adults being treated with adrenergic blocking agents should be cautioned about the many adverse effects associated with the drugs. Patients with diabetes need to be reeducated about ways to monitor themselves for hyperglycemia and hypoglycemia because the sympathetic reaction (sweating, feeling tense, increased heart rate, rapid breathing) usually alerts patients that there is a problem with their glucose levels. Patients with severe thyroid disease are also at high risk for serious adverse effects when taking these drugs, and if one of them is needed, the patient should be monitored very closely. Propranolol and metoprolol are associated with

more central nervous system (CNS) adverse effects than other adrenergic blockers, and patients who have CNS complications already or who develop CNS problems while taking an adrenergic blocker might do better with a different agent.

In general, there are no adequate studies about the effects of adrenergic blockers during pregnancy and lactation, and they should be used only in those situations in which the benefit to the mother is greater than the risk to the fetus or neonate. Adrenergic blockers can affect labor, and babies born to mothers taking these drugs may exhibit adverse cardiovascular, respiratory, and CNS effects. Many of these drugs were teratogenic in animal studies. Because of a similar risk of adverse reactions on the baby, nursing mothers should find another way to feed the baby if an adrenergic blocking drug is needed.

OLDER ADULTS

Older patients are more likely to experience the adverse effects associated with these drugs—CNS, cardiovascular, GI, and respiratory effects. Because older patients often also have renal or hepatic impairment, they are more likely to have toxic levels of the drug related to changes in metabolism and excretion. The older patient should be started on lower doses of the drugs and should be monitored very closely for potentially serious arrhythmias or blood pressure changes. Bisoprolol is often a drug of choice for older patients who require an adrenergic blocker for hypertension because it is not associated with as many problems in the elderly and regular dosing profiles can be used.

FOCUS
BOX 31.2

Herbal and Alternative Therapies

Patients who use alternative therapies as part of their daily regimen should be cautioned about potential increased adrenergic blocking effects if the following alternative therapies are combined with adrenergic blocking agents:

- *Ginseng, sage*—increased antihypertensive effects (risk of hypotension and increased central nervous system effects)
- *Xuan shen, nightshade*—slow heart rate (risk of severe bradycardia and reflex arrhythmias)
- *Celery, coriander, Di huang, fenugreek, goldenseal, Java plum, xuan seng*—lower blood glucose (increased risk of severe hypoglycemia)
- *Saw palmetto*—increased urinary tract complications

Patients who are prescribed an adrenergic blocking drug should be cautioned about the use of herbs, teas, and alternative medicines. If a patient feels that one of these agents is needed, the health care provider should be consulted and appropriate precautions should be taken to ensure that the patient is able to achieve the most therapeutic effects with the least adverse effects while taking the drug.

infarction (MI). Table 31.1 shows usual indications for each of these agents.

Pharmacokinetics

These drugs are well absorbed when given orally and are distributed throughout the body when given IV or orally. They are metabolized in the liver and excreted in feces and urine. The half-life varies with the particular drug and preparation.

Contraindications and Cautions

The nonselective adrenergic blocking agents are contraindicated in patients with known hypersensitivity to any component of the drug *to avoid potentially serious hypersensitivity reactions*; with bradycardia or heart blocks, *which could be worsened by the slowed heart rate and conduction*; with asthma, *which could be exacerbated by the loss of norepinephrine's effect of bronchodilation*; with shock or heart failure (HF), *which could become worse with the loss of the sympathetic reaction*; and who are lactating *because of the potential adverse effects on neonate*.

TABLE 31.1 DRUGS IN FOCUS Nonselective Adrenergic Blocking Agents

Drug Name	Dosage/Route	Usual Indications
amiodarone (<i>Cordarone</i>)	800–1600 mg/d PO, reduce to 400 mg/d for maintenance; 1000 mg IV over 24 h; for maintenance 540 mg IV over 18 h	Treatment of life-threatening ventricular arrhythmias
carvedilol (<i>Coreg</i>)	6.25–12.5 mg PO b.i.d. for hypertension; 3.125–6.25 mg PO b.i.d. for heart failure	Treatment of hypertension and heart failure in adults, alone or as part of combination therapy
 labetalol (<i>Normodyne</i> , <i>Trandate</i>)	100 mg PO b.i.d. initially, maintenance 200–400 mg PO b.i.d.; 20 mg IV, slowly with additional doses given at 10-min intervals to a maximum dose of 300 mg for severe hypertension	Treatment of hypertension, hypertension associated with pheochromocytoma, and clonidine withdrawal

These drugs should be used with caution in patients with diabetes *because the disorder could be aggravated by the blocked sympathetic response and because the usual signs and symptoms of hypoglycemia and hyperglycemia are masked with the SNS blockade*. Caution also should be used in patients with bronchospasm, *which could progress to respiratory distress due to the loss of norepinephrine's bronchodilating actions*; and in pregnancy *because there are no well-defined studies to evaluate the potential risk to the fetus*. The drugs should only be used if the benefit to the mother clearly outweighs the potential risk to the fetus.

Adverse Effects

The adverse effects associated with the use of nonselective adrenergic blocking agents are usually associated with the drug's effects on the SNS. These effects can include dizziness, paresthesias, insomnia, depression, fatigue, and vertigo, *which are related to the blocking of norepinephrine's effect in the central nervous system (CNS)*. Nausea, vomiting, diarrhea, anorexia, and flatulence are *associated with the loss of the balancing sympathetic effect on the gastrointestinal (GI) tract and increased parasympathetic dominance*. Cardiac arrhythmias, hypotension, HF, pulmonary edema, and cerebrovascular accident, or stroke, are *related to the lack of stimulatory effects and loss of vascular tone in the cardiovascular (CV) system*. Bronchospasm, cough, rhinitis, and bronchial obstruction are *related to loss of bronchodilation of the respiratory tract and vasodilation of mucous membrane vessels*. Other effects reported include decreased exercise tolerance, hypoglycemia, and rash *related to the sympathetic blocking effects*. Abruptly stopping these drugs after long-term therapy can result in MI, stroke, and arrhythmias *related to an increased hypersensitivity to catecholamines that develops when the receptor sites have been blocked*. Carvedilol has been associated with hepatic failure *related to its effects on the liver*.

Clinically Important Drug–Drug Interactions

There is increased risk of excessive hypotension if any of these drugs is combined with volatile liquid general anesthetics such

as enflurane, halothane, or isoflurane. The effectiveness of diabetic agents is increased, leading to hypoglycemia when such agents are used with these drugs; patients should be monitored closely and dose adjustments made as needed. In addition, carvedilol has been associated with potentially dangerous conduction system disturbances when combined with verapamil or diltiazem; if this combination is used, the patient requires continuous monitoring.

Prototype Summary: Labetalol

Indications: Hypertension, alone or in combination with other drugs; off-label uses—control of blood pressure in pheochromocytoma, clonidine-withdrawal hypertension.

Actions: Competitively blocks alpha- and beta-receptor sites in the SNS, leading to lower blood pressure without reflex tachycardia and decreased renin levels.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	Varies	1–2 h	8–12 h
IV	Immediate	5 min	5.5 h

$T_{1/2}$: 6 to 8 hours, with hepatic metabolism and excretion in the urine.

Adverse effects: Dizziness, vertigo, fatigue, gastric pain, flatulence, impotence, bronchospasm, dyspnea, cough, decreased exercise tolerance.

Nursing Considerations for Patients Receiving Nonselective Adrenergic Blocking Agents

Assessment: History and Examination

- Assess for contraindications or cautions: any known allergies to these *to avoid hypersensitivity reactions*; presence of bradycardia or heart blocks, *which could be worsened by the slowing of heart rate and conduction*; asthma or bronchospasm, *which could be exacerbated by the loss*

- of the bronchodilation effect of norepinephrine; shock or HF, which could worsen with the loss of the sympathetic reaction; diabetes, which could be aggravated by the blocking of the sympathetic response and the masking of the usual signs and symptoms of hypoglycemia and hyperglycemia; and pregnancy or lactation status because of the potential adverse effects on the fetus or neonate.
- Perform a physical assessment to establish baseline data for determining the effectiveness of the drug and the occurrence of any adverse effects associated with drug therapy; assess the level of orientation and for any complaints of dizziness, paresthesias, or vertigo.
 - Monitor vital signs and assess cardiovascular status, including pulse, blood pressure, and cardiac output, to evaluate for possible cardiac effects; obtain an electrocardiogram (ECG) as ordered to assess for possible irregularities in rate or rhythm; assess respiratory rate and auscultate lungs to determine the presence of any adventitious sounds; observe for ease of breathing, and report any signs and symptoms of bronchospasm or respiratory distress; and monitor GI activity to determine the need for interventions to deal with increased activity.
 - Monitor the results of laboratory tests such as renal and liver function studies and electrolyte levels to determine the need for possible dose adjustment; monitor blood glucose levels to evaluate for hyper- or hypoglycemia

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Decreased Cardiac Output related to CV effects
- Ineffective Airway Clearance related to lack of bronchodilating effects
- Risk for Injury related to CNS effects
- Diarrhea related to increased parasympathetic activity
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Do not discontinue abruptly after chronic therapy because hypersensitivity to catecholamines may develop and the patient could have a severe reaction; taper drug slowly over 2 weeks, monitoring the patient.
- Consult with the physician about withdrawing the drug before surgery because withdrawal is controversial; effects on the sympathetic system after surgery can cause problems.
- Encourage the patient to adopt lifestyle changes, including diet, exercise, smoking cessation, and stress reduction, to aid in lowering blood pressure.
- Assess heart rate for changes that might suggest arrhythmias. Obtain blood pressure in various positions to assess for orthostatic hypotension.
- Institute safety precautions especially if the patient complains of dizziness, fatigue, or vertigo or if orthostatic hypotension occurs to prevent injury to the patient.

- Monitor GI function and need for increased access to bathroom facilities and need for increased fluid intake related to diarrhea.
- Monitor for any sign of liver failure to arrange to discontinue the drug if this occurs (this effect is more likely to happen with carvedilol).
- Offer support and encouragement to help the patient deal with the drug regimen.
- Provide thorough patient teaching, including drug name, dosage, and schedule for administration; measures to prevent adverse effects and warning signs of problems; the need to avoid herbal or alternative therapies unless allowed by the prescriber; and safety measures, such as changing position slowly and avoiding driving or operating hazardous machinery; and the need for monitoring and evaluation to enhance patient knowledge about drug therapy and to promote compliance.

Evaluation

- Monitor patient response to the drug (improvement in blood pressure and HF).
- Monitor for adverse effects (CV changes, headache, GI upset, bronchospasm, liver failure).
- Evaluate the effectiveness of the teaching plan (patient can name drug, dosage, adverse effects to watch for, specific measures to avoid adverse effects).
- Monitor the effectiveness of comfort measures and compliance with the regimen.

KEY POINTS

- ▶ Adrenergic blocking agents block the effects of the sympathetic nervous system (SNS).
- ▶ The nonselective adrenergic blocking agents block all receptors, that is, both alpha- and beta-receptors. Selective adrenergic blocking agents have specific affinity for alpha- or beta-receptors or for specific α_{1-} , β_{1-} , or β_{2-} -receptor sites.
- ▶ Blocking all of the receptor sites within the SNS results in a lowering of blood pressure.

NONSELECTIVE ALPHA-ADRENERGIC BLOCKING AGENTS

Some adrenergic blocking agents have a specific affinity for alpha-receptor sites. Their use is somewhat limited because of the development of even more specific and safer drugs. Only one of these drugs, phentolamine (*Regitine*), is still used (Table 31.2).

Therapeutic Actions and Indications

Phentolamine blocks the postsynaptic α_{1-} -adrenergic receptors, decreasing sympathetic tone in the vasculature and causing vasodilation, which leads to a lowering of blood pressure.

TABLE 31.2 DRUGS IN FOCUS Nonselective Alpha-Adrenergic Blocking Agent

Drug Name	Dosage/Route	Usual Indications
 phentolamine (Regitine)	Adult: 5 mg IV or IM 1–2 h before surgery; 5–10 mg in 10 mL of saline injected into area of extravasation within 12 h after extravasation Pediatric: 1 mg IM or IV 1–2 h before surgery; treat extravasation as in the adult	Prevention of cell death and tissue sloughing after extravasation of intravenous norepinephrine or dopamine, and severe hypertension reactions caused by manipulation of the pheochromocytoma before and during surgery; diagnosis of pheochromocytoma

It also blocks presynaptic α_2 -receptors, preventing the feedback control of norepinephrine release. The result is an increase in reflex tachycardia that occurs when blood pressure is lowered. Phentolamine is most frequently used to prevent cell death and tissue sloughing after extravasation of intravenous norepinephrine or dopamine, causing a local vasodilation and a return of blood flow to the area. Table 31.2 shows usual indications for each of these agents.

Pharmacokinetics

Phentolamine is rapidly absorbed after intravenous or intramuscular injection and is excreted in the urine. There are few data on its metabolism and distribution.

Contraindications and Cautions

Phentolamine is contraindicated in the presence of allergy to this or similar drugs and in the presence of coronary artery disease or MI *because of the potential exacerbation of these conditions*; it should be used cautiously in pregnancy or lactation *because of the potential adverse effects on the fetus or neonate*.

Adverse Effects

Patients receiving phentolamine often experience extensions of the therapeutic effects, including hypotension, orthostatic hypotension, angina, MI, cerebrovascular accident, flushing, tachycardia, and arrhythmia—all of which are related to vasodilation and decreased blood pressure. Headache, weakness, and dizziness often occur *in response to hypotension*. Nausea, vomiting, and diarrhea may also occur.

Clinically Important Drug–Drug Interactions

Ephedrine and epinephrine may have decreased hypertensive and vasoconstrictive effects if they are taken concomitantly with phentolamine because these agents work in opposing ways in the body. Increased hypotension may occur if this drug is combined with alcohol, which is also a vasodilator.

Prototype Summary: Phentolamine

Indications: Prevention or control of hypertensive episodes associated with pheochromocytoma; test for diagnosis of pheochromocytoma; prevention and treatment of dermal necrosis and sloughing associated with IV extravasation of norepinephrine or dopamine.

Actions: Competitively blocks postsynaptic α_1 - and presynaptic α_2 -receptors, causing a vasodilation and lowering of blood pressure, accompanied by increased reflex tachycardia.

Pharmacokinetics:

Route	Onset	Peak	Duration
Intramuscular	Rapid	20 min	30–45 min
IV	Immediate	2 min	15–30 min

$T_{1/2}$: Metabolism and excretion are unknown.

Adverse effects: Acute and prolonged hypotensive episodes, MI, tachycardia, arrhythmias, nausea, flushing.

Nursing Considerations for Patients Receiving Nonselective Alpha-Adrenergic Blocking Agents

Assessment: History and Examination

- Assess for contraindications or cautions: any known allergies to these drugs *to avoid hypersensitivity reactions*; presence of any cardiovascular diseases, *which may be exacerbated by the use of this drug*; and current status of pregnancy or lactation *because of the potential for adverse effects to the fetus or neonate*.
- Perform a physical assessment *to establish baseline data for determining the effectiveness of the drug and occurrence of any adverse effects*.
- Assess orientation, affect, and reflexes *to monitor for CNS changes related to drug therapy*; monitor cardiovascular status, including pulse, blood pressure, peripheral perfusion, and cardiac output, *to determine changes in function*, and urine output, *which will reflect perfusion of the kidney as another assessment of cardiac function*.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Risk for Injury related to CNS and CV effects of the drug
- Decreased Cardiac Output related to blood pressure changes, arrhythmias, and vasodilation
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Monitor heart rate and blood pressure closely and frequency for changes *to anticipate the need to discontinue the drug if adverse reactions are severe*; provide supportive management if needed.
- Inject phentolamine directly into the area of extravasation of epinephrine or dopamine *to prevent local cell death*.
- Arrange for supportive care and comfort measures, such as rest, environmental control, and other measures, *to decrease CNS irritation*; provide headache medication *to alleviate patient discomfort*.
- Institute safety measures *to prevent injury* if the patient experiences weakness, dizziness or orthostatic hypotension.
- Provide thorough patient teaching, including drug name, dosage, and schedule for administration; potential adverse effects and measures to prevent them; and warning signs of problems, *to enhance patient knowledge about drug therapy and to promote compliance*.
- Offer support and encouragement *to help the patient deal with the need for the drug*.

Evaluation

- Monitor patient response to the drug (improvement in signs and symptoms of pheochromocytoma, improvement in tissue condition after extravasation).
- Monitor for adverse effects (orthostatic hypotension, arrhythmias, CNS effects such as headache or dizziness)

- Evaluate the effectiveness of the teaching plan (patient can name drug, dosage, adverse effects to watch for, and specific measures to avoid them).
- Monitor the effectiveness of support measures.

KEY POINTS

- ◆ Nonselective alpha-adrenergic blocking agents are used to treat pheochromocytoma, a tumor of the adrenal medulla. A reflex tachycardia commonly occurs when the blood pressure falls.
- ◆ Phentolamine is a nonselective alpha-adrenergic blocker used most commonly for the prevention and treatment of dermal necrosis and sloughing associated with IV extravasation of norepinephrine or dopamine.

ALPHA₁-SELECTIVE ADRENERGIC BLOCKING AGENTS

Alpha₁-selective adrenergic blocking agents are drugs that have a specific affinity for alpha₁-receptors. These drugs include alfuzosin (*Uroxatral*), doxazosin (*Cardura*), prazosin (*Minipress*), tamsulosin (*Flomax*), and terazosin (*Hytrin*) (see Table 31.3).

Therapeutic Actions and Indications

The therapeutic effects of the alpha₁-selective adrenergic blocking agents come from their ability to block the postsynaptic alpha₁-receptor sites. This causes a decrease in vascular tone and vasodilation, which leads to a fall in blood pressure. Because these drugs do not block the presynaptic alpha₂-receptor sites, the reflex tachycardia that accompanies a fall in blood pressure does not occur. They also block smooth muscle receptors in the prostate, prostatic capsule, prostatic urethra,

TABLE 31.3 DRUGS IN FOCUS Alpha₁-Selective Adrenergic Blocking Agents

Drug Name	Dosage/Route	Usual Indications
alfuzosin (<i>Uroxatral</i>)	10 mg/d PO	Treatment of benign prostatic hyperplasia (BPH)
 doxazosin (<i>Cardura</i>)	1 mg/d PO up to 16 mg/d PO for hypertension; 1–8 mg/d PO for BPH	Treatment of hypertension and BPH
prazosin (<i>Minipress</i>)	Adult: 1 mg PO b.i.d. to t.i.d. with maintenance at 6–15 mg/d PO in divided doses Pediatric: 0.5–7 mg PO t.i.d.	Treatment of hypertension alone or in combination with other drugs
tamsulosin (<i>Flomax</i>)	0.4–0.8 mg/day PO 30 min after the same meal each day	Treatment of BPH
terazosin (<i>Hytrin</i>)	1–5 mg/d PO, preferably at bedtime for hypertension; 10 mg/d PO for BPH	Treatment of hypertension and BPH

and urinary bladder neck, which leads to a relaxation of the bladder and prostate and improved flow of urine in male patients. These drugs are available in oral form and can be used to treat benign prostatic hypertrophy (BPH) (see Chapter 52 for further discussion on BPH) and hypertension. The drugs may be used alone or as part of a combination therapy. Table 31.3 shows usual indications for each of these agents.

Pharmacokinetics

The α_1 -selective adrenergic blocking agents are well absorbed after oral administration and undergo extensive hepatic metabolism. They are excreted in the urine.

Contraindications and Cautions

The α_1 -selective adrenergic blocking agents are contraindicated in the presence of allergy to any of these drugs *to avoid hypersensitivity reactions* and also with lactation *because the drugs cross into breast milk and could have adverse effects on the neonate*. They should be used cautiously in the presence of HF or renal failure *because their blood pressure–lowering effects could exacerbate these conditions* and with hepatic impairment, *which could alter the metabolism of these drugs*. Caution also should be used during pregnancy *because of the potential for adverse effects on the fetus*.

Adverse Effects

The adverse effects associated with the use of these drugs *are usually related to their effects of SNS blockage*. CNS effects include headache, dizziness, weakness, fatigue, drowsiness, and depression. Nausea, vomiting, abdominal pain, and diarrhea may occur *as a result of direct effects on the GI tract and sympathetic blocking*. Anticipated cardiovascular effects include arrhythmias, hypotension, edema, HF, and angina. The vasodilation caused by these drugs can also cause flushing, rhinitis, reddened eyes, nasal congestion, and priapism.

Clinically Important Drug–Drug Interactions

Increased hypotensive effects may occur if these drugs are combined with any other vasodilating or antihypertensive drugs, such as nitrates, calcium-channel blockers, and angiotensin-converting-enzyme (ACE) inhibitors.

Prototype Summary: Doxazosin

Indications: Treatment of mild to moderate hypertension as monotherapy or in combination with other antihypertensives; treatment of BPH.

Actions: Reduces total peripheral resistance through α blockade; does not affect heart rate or cardiac output; increases high-density lipoproteins while lowering total cholesterol levels.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	Varies	2–3 h	Not known

$T_{1/2}$: 22 hours, with hepatic metabolism and excretion in the bile, feces, and urine.

Adverse effects: Headache, fatigue, dizziness, postural dizziness, vertigo, tachycardia, edema, nausea, dyspepsia, diarrhea, sexual dysfunction.

Nursing Considerations for Patients Receiving α_1 -Selective Adrenergic Blocking Agents

Assessment: History and Examination

- Assess for contraindications or cautions: any known allergies to either drug *to avoid hypersensitivity reactions*; HF or renal failure, *which could be exacerbated by drug use*; hepatic dysfunction, *which could alter the drug's metabolism*; and current status of pregnancy or lactation *because of unknown or adverse effects to the fetus or neonate*.
- Perform a physical assessment *to establish baseline data for determining the effectiveness of drug therapy and the occurrence of any adverse effects*.
- Monitor the level of orientation, affect, and reflexes *to monitor for CNS changes related to drug therapy*.
- Monitor vital signs and assess cardiovascular status, including pulse, blood pressure, peripheral perfusion, and cardiac output, *to evaluate for possible cardiac effects*; obtain an ECG as ordered *to assess for possible irregularities in rate or rhythm*.
- Assess renal function, including urinary output, *to evaluate effects on the renal system and assess BPH and its effects on urinary output*.
- Monitor renal and hepatic function tests *to evaluate potential need for dose adjustment*.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to headache, GI upset, flushing, nasal congestion
- Risk for Injury related to CNS or CV effects of the drug
- Decreased Cardiac Output related to blood pressure changes, arrhythmias, vasodilation
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Monitor blood pressure, pulse, rhythm, and cardiac output regularly *to evaluate for changes that may indicate a need to adjust dose or discontinue the drug if cardiovascular effects are severe*.

- Establish safety precautions if CNS effects or orthostatic hypotension occurs *to prevent patient injury*.
- Arrange for small, frequent meals if GI upset is severe *to relieve discomfort and maintain nutrition*.
- Arrange for supportive care and comfort measures (rest, environmental control, other measures) *to decrease CNS effects*; provide headache medication *to alleviate patient discomfort*; arrange safety measures if CNS effects occur *to prevent patient injury*.
- Offer support and encouragement *to help the patient deal with the drug regimen*.
- Provide thorough patient teaching, including drug name, dosage, and administration; measures to prevent adverse effects and warning signs to report to prescriber; safety measures such as changing positions slowly and avoiding driving or operating hazardous machinery, and dietary measures in conjunction with drug therapy to promote blood pressure control or alleviate GI upset *to enhance patient knowledge about drug therapy and to promote compliance*.
- Offer support and encouragement *to help the patient deal with the drug regimen*.

Evaluation

- Monitor patient response to the drug (lowering of blood pressure).
- Monitor for adverse effects (GI upset, CNS or cardiovascular changes).
- Evaluate effectiveness of the teaching plan (patient can name drug, dosage, adverse effects to watch for, and specific measures to avoid them).
- Monitor the effectiveness of comfort measures and compliance with the regimen.

KEY POINTS

- ▶ Alpha₁-selective adrenergic blocking agents decrease blood pressure by blocking the postsynaptic alpha₁-receptor sites, decreasing vascular tone, and promoting vasodilation.
- ▶ Alpha₁-selective adrenergic blocking agents are used to treat hypertension and are often used to treat BPH because of their relaxing effects on the bladder and prostate.

NONSELECTIVE BETA-ADRENERGIC BLOCKING AGENTS

The **beta-adrenergic blocking agents** (Table 31.4) are used to treat cardiovascular problems (hypertension, angina, migraine headaches) and to prevent reinfarction after MI. These drugs are widely used and include carteolol (*Cartrol*), nadolol (*Corgard*), nebivolol (*Bystolic*), penbutolol (*Levator*), pindolol (*Visken*), propranolol (*Inderal*), sotalol (*Betapace*, *Betapace AF*), and timolol (*Blocadren*, *Timoptic*). The prototype drug, propranolol, was, in fact, the most prescribed drug in the United States in the 1980s.

Therapeutic Actions and Indications

The therapeutic effects of these drugs are related to their competitive blocking of the beta-adrenergic receptors in the SNS. The blockade of the beta-receptors in the heart and in the juxtaglomerular apparatus of the nephron accounts for the majority of the therapeutic benefit. Decreased heart rate, contractility, and excitability, as well as a membrane-stabilizing effect, lead to a decrease in arrhythmias, a decreased cardiac workload, and decreased oxygen consumption. The juxtaglomerular cells are not stimulated to release renin, which further decreases the blood pressure. These effects are useful in treating hypertension and chronic angina and can help to prevent reinfarction after an MI by decreasing cardiac workload and oxygen consumption. Sotalol is used exclusively for treating life-threatening ventricular arrhythmias and to maintain sinus rhythm in patients with atrial flutter or atrial fibrillation (see Chapter 45).

Propranolol is very effective in blocking all of the beta-receptors in the SNS and was one of the first drugs of the class (see Table 31.4 for usual indications). Since the introduction of propranolol, newer and more selective drugs have become available that are not associated with some of the adverse effects seen with total blockade of the SNS beta-receptors. Nebivolol is the newest adrenergic blocker available and is not associated with the variety of adverse effects seen with propranolol use. Timolol has several recommended uses, which are listed in Table 31.4; timolol and carteolol are available as an ophthalmic form of the drug for reduction of intraocular pressure in patients with open-angle glaucoma. When this drug is used topically, eye muscle relaxation occurs. In addition, because it is applied topically, it is usually not absorbed systemically from this route.

Pharmacokinetics

These drugs are absorbed from the GI tract after oral administration and undergo hepatic metabolism. Food has been found to increase the bioavailability of propranolol, although this effect was not found with other beta-adrenergic blocking agents. Absorption of sotalol is decreased by the presence of food. Propranolol also crosses the blood–brain barrier, but carteolol, nadolol, and sotalol do not, making them a better choice if CNS effects occur with propranolol. These drugs are all excreted in the urine.

Contraindications and Cautions

Nonselective beta-adrenergic blocking agents are contraindicated in the presence of allergy to any of these drugs or any components of the drug being used *to avoid hypersensitivity reactions*; with bradycardia or heart blocks, shock, or HF, *which could be exacerbated by the cardiac-suppressing effects of these drugs*; with bronchospasm, chronic obstructive pulmonary disease (COPD), or acute asthma, *which could worsen due to the blocking of the sympathetic bronchodilation*; with pregnancy *because teratogenic effects have occurred in animal*

TABLE 31.4 DRUGS IN FOCUS Nonselective Beta-Adrenergic Blocking Agents

Drug Name	Dosage/Route	Usual Indications
carteolol (<i>Cartrol</i>)	Initially 2.5 mg/d PO, titrate to 5–10 mg/d PO based on patient response; reduce dose with renal impairment	Treatment of hypertension in adults, alone or as part of combination therapy
nebivolol (<i>Bystolic</i>)	Initially 5 mg/d PO, increase at 2-wk intervals based on patient response; maximum dose 40 mg/d	Treatment of hypertension, alone or as part of combination therapy in adults
nadolol (<i>Corgard</i>)	Angina: 40–80 mg/d PO Hypertension: 40–80 mg/d PO, up to 320 mg/d may be needed; reduce dose in renal impairment	Treatment of hypertension, management of chronic angina in adults; drug of choice in an angina patient who is also hypertensive
penbutolol (<i>Levator</i>)	Initially 20 mg/d PO, titrate up to 40–80 mg/d PO based on patient response	Treatment of hypertension in adults
pindolol (<i>Visken</i>)	Initially 5 mg PO b.i.d., to a maximum of 60 mg/d PO	Treatment of hypertension in adults
 propranolol (<i>Inderal</i>)	Dose varies widely based on indication; check drug guide for specific information	Treatment of hypertension, angina, idiopathic hypertrophic subaortic stenosis (IHSS)–induced palpitations, angina and syncope, certain cardiac arrhythmias induced by catecholamines or digoxin, pheochromocytoma; prevention of reinfarction after myocardial infarction; prophylaxis for migraine headache (which may be caused by vasodilation and is relieved by vasoconstriction, although the exact action is not clearly understood); prevention of stage fright (which is a sympathetic stress reaction to a particular situation); and treatment of essential tremors
sotalol (<i>Betapace</i> , <i>Betapace AF</i>)	<i>Betapace</i> : 80 mg PO b.i.d., up to 320 mg PO b.i.d. may be needed <i>Betapace AF</i> : 80 mg/d PO based on QT interval and patient response, up to 120 mg b.i.d. may be needed Reduce dose of both with renal impairment	Treatment of potentially life-threatening ventricular arrhythmias (<i>Betapace</i>); maintenance of normal sinus rhythm in patients with atrial fibrillation/flutter (<i>Betapace AF</i>)
timolol (<i>Blocadren</i> , <i>Timoptic</i>)	10 mg PO b.i.d., increases based on patient response; 1–2 drops (gtt) in affected eye(s) for glaucoma	Treatment of hypertension; prevention of reinfarction after myocardial infarction; prophylaxis for migraine; in ophthalmic form, reduction of intraocular pressure in open-angle glaucoma

studies with all of these drugs except sotalol and because neonatal apnea, bradycardia, and hypoglycemia could occur; and with lactation because of the potential effects on the neonate, which could include slowed heart rate, hypotension, and hypoglycemia. The safety and efficacy for use of these drugs in children have not been established.

These drugs should be used cautiously in patients with diabetes and hypoglycemia because of the blocking of the normal signs and symptoms of hypoglycemia and hyperglycemia; with thyrotoxicosis because of the adrenergic blocking effects on the thyroid gland; or with renal or hepatic dysfunction, which could interfere with the excretion and metabolism of these drugs.

Adverse Effects

Patients receiving these drugs often experience adverse effects related to blockage of beta-receptors in the SNS. CNS effects

include headache, fatigue, dizziness, depression, paresthesias, sleep disturbances, memory loss, and disorientation. Cardiovascular effects can include bradycardia, heart block, HF, hypotension, and peripheral vascular insufficiency. Pulmonary effects can range from difficulty breathing, coughing, and bronchospasm to severe pulmonary edema and bronchial obstruction. GI upset, nausea, vomiting, diarrhea, gastric pain, and even colitis can occur as a result of unchecked parasympathetic activity and the blocking of the sympathetic receptors. Genitourinary effects can include decreased libido, impotence, dysuria, and Peyronie disease. Other effects that can occur include decreased exercise tolerance (patients often report that their “get up and go” is gone), hypoglycemia or hyperglycemia, and liver changes. If these drugs are stopped abruptly after long-term use, there is a risk of angina, MI, hypertension, and stroke because the receptor sites become hypersensitive to catecholamines after being blocked by the drugs.

Clinically Important Drug–Drug Interactions

A paradoxical hypertension occurs when beta-blockers are given with clonidine, and an increased rebound hypertension with clonidine withdrawal may also occur. It is best to avoid this combination.

A decreased antihypertensive effect occurs when beta-blockers are given with nonsteroidal anti-inflammatory drugs (NSAIDs); if this combination is used, the patient should be monitored closely and dose adjustment should be made to achieve the desired control of blood pressure.

An initial hypertensive episode followed by bradycardia may occur if these drugs are given with epinephrine. Peripheral ischemia may occur if the beta-blockers are taken in combination with ergot alkaloids.

When these drugs are given with insulin or other antidiabetic agents, there is a potential for change in blood glucose levels. The patient will not display the usual signs and symptoms of hypoglycemia or hyperglycemia, which are caused by activation of the SNS. Because these effects are blocked, the patient will need new indications to alert him or her to potential problems. If this combination is used, the patient should monitor blood glucose levels frequently throughout the day and should be alert to new manifestations indicating glucose imbalance.

Prototype Summary: *Propranolol*

Indications: Treatment of hypertension, angina pectoris, idiopathic hypertrophic subaortic stenosis (IHSS), supraventricular tachycardia, tremor; prevention of reinfarction after MI; adjunctive therapy in pheochromocytoma; prophylaxis of migraine headache; management of situational anxiety.

Actions: Competitively blocks beta-adrenergic receptors in the heart and juxtaglomerular apparatus; reduces vascular tone in the CNS.

Pharmacokinetics:

Route	Onset	Peak	Duration
Oral	20–30 min	60–90 min	6–12 h
IV	Immediate	1 min	4–6 h

$T_{1/2}$: 3 to 5 hours with hepatic metabolism and excretion in the urine.

Adverse effects: Allergic reaction, bradycardia, HF, cardiac arrhythmias, cerebrovascular accident, pulmonary edema, gastric pain, flatulence, impotence, decreased exercise tolerance, bronchospasm.

Nursing Considerations for Patients Receiving Nonselective Beta-Adrenergic Blocking Agents

Assessment: History and Examination

- Assess for contraindications or cautions: known allergy to any drug or to any components of the drug to avoid hypersensitivity reactions; bradycardia or heart blocks,

shock, or HF, which could be exacerbated by the cardiac-suppressing effects of these drugs; bronchospasm, COPD, or acute asthma, which could worsen with blocking of the sympathetic bronchodilation; diabetes or hypoglycemia, which could lead to altered blood glucose levels; thyrotoxicosis because of adrenergic blocking effects on the thyroid gland; renal or hepatic dysfunction, which could interfere with the excretion or metabolism of these drugs; and status of pregnancy and lactation because of the potential effects on the fetus or neonate.

- Perform a physical assessment to establish baseline data for determining the effectiveness of the drug and the occurrence of any adverse effects.
- Assess level of orientation and sensory function to evaluate for possible CNS effects.
- Monitor cardiopulmonary status, including pulse, blood pressure, and respiratory rate; auscultate lungs for adventitious breath sounds; obtain an ECG as ordered to evaluate for changes in heart rate or rhythm; check color, sensation, and capillary refill of extremities to evaluate for possible peripheral vascular insufficiency.
- Assess abdomen, including auscultating bowel sounds, to monitor for GI effects.
- Monitor the results of laboratory tests, such as electrolyte levels, to monitor for risks for arrhythmias, adrenal and hepatic function studies, to determine the need for possible dose adjustment.

Refer to the Critical Thinking Scenario for a full discussion of nursing care for a patient who is receiving beta-adrenergic blocking agents.

Nursing Diagnoses

Nursing diagnoses related to drug therapy might include the following:

- Acute Pain related to CNS, GI, and systemic effects
- Decreased Cardiac Output related to CV effects
- Ineffective Tissue Perfusion related to CV effects
- Risk for injury related to CNS effects
- Risk for Activity Intolerance related to suppression of the sympathetic system
- Deficient Knowledge regarding drug therapy

Implementation With Rationale

- Do not stop these drugs abruptly after chronic therapy, but taper gradually over 2 weeks because long-term use of these drugs can sensitize the myocardium to catecholamines, and severe reactions could occur.
- Continuously monitor any patient receiving an intravenous form of these drugs to avert serious complications caused by rapid sympathetic blockade.
- Monitor blood pressure, pulse, rhythm, and cardiac output regularly to evaluate drug effectiveness and to monitor for changes that may indicate a need to adjust dose or discontinue the drug if cardiovascular effects are severe.

CRITICAL THINKING SCENARIO

Nonselective Beta-Blockers (Propranolol)

THE SITUATION

M.R., a 59-year-old man, has been seen several times complaining of tremor in his hands that eventually made it very difficult for him to work as a computer programmer. A diagnosis of essential tremor was made, and he was prescribed propranolol (*Inderal*) 40 mg twice daily. M.R. had good effects with the drug and had no further problems until the following June, when acute respiratory distress developed while he was picnicking in a state park with his family. On the way to the emergency room, he suffered an apparent respiratory arrest. He was admitted to the hospital and placed in the respiratory intensive care unit. It was found that M.R. had a history of hay fever and allergic rhinitis during the pollen season but had never experienced such a severe reaction.

CRITICAL THINKING

Why did M.R. have such a severe reaction? What appropriate measures should be taken to ensure that M.R. recovers fully and does not reexperience this event?

What sort of support will M.R. and his family need after going through such a frightening experience? Think about the children who may have witnessed the respiratory arrest and how they should be reassured, depending on their ages. *Think about the support M.R.'s wife may need and the fear that may now be associated with M.R.'s condition. M.R. has been taking propranolol for several months and needs to decide whether he should continue the drug with modifications to his lifestyle or the addition of other drugs to deal with his respiratory issues.*

What kind of teaching program will need to be developed to help M.R. deal with this drug, and its potential adverse effects?

DISCUSSION

Propranolol, a nonselective beta-blocker, was prescribed to decrease the tremor he was experiencing. The exact action of this drug to decrease the tremor is thought to be related to its membrane-stabilizing properties. The desired therapeutic effect is the reduction of the tremor, but all of the beta-blocking effects will occur and need to be monitored. He did well on the drug until pollen season arrived. That is because propranolol, a nonselective beta-blocker, prevented the compensatory bronchodilation that occurs when the sympathetic nervous system is stimulated. When the pollen reacted with M.R.'s airways, causing them to swell and become narrower, his swollen bronchial tubes were unable to allow air to flow through them. The result was bronchial constriction and respiratory distress that, in M.R.'s case, progressed to a respiratory arrest. Before he began taking propranolol, M.R. probably had been effec-

tively compensating for the swelling of the bronchi through bronchodilation and had never experienced such a reaction. There are few other drugs for treating essential tremor. M.R. and his health care providers will need to decide whether the benefit that the drug has brought to him is worth the potential for adverse effects. They might be able to suggest additional drugs to deal with the seasonal allergic reactions to make the use of the propranolol safer for this patient.
