Table of Contents

Preface	xxi
----------------------	-----

Volume I

Section 1 Fundamental Concepts and Theories

This section serves as a foundation for this exhaustive reference tool by addressing underlying principles and provides in-depth coverage of conceptual architecture frameworks essential to the understanding of Public Health and Welfare. Chapters found within these pages provide an excellent framework in which to position Public Health and Welfare within the field of information science and technology. Insight regarding the critical incorporation of global measures into Public Health and Welfare is addressed, and examinations to specific discussions on methodology. With 13 chapters comprising this foundational section, the reader can learn and chose from a compendium of expert research on the elemental theories underscoring the Public Health and Welfare discipline.

Chapter 1

The Fundamentals of Health Literacy	1
<i>Kijpokin Kasemsap, Suan Sunandha Rajabhat University, Thailand</i>	

Chapter 2

The Information Paradox: Researching Health Service Information Systems Development	22
<i>Said Shahtahmasebi, The Good Life Research Centre Trust, New Zealand & University of Kentucky, USA</i>	

Chapter 3

Health in MENA: Policies for Inclusive Development.....	38
<i>Randa Alami, University of London, UK</i>	

Chapter 4

Innovation in the Health System: Evidences from Brazilian Local Production and Innovation Systems	64
<i>Marcelo Pessoa de Matos, Federal University of Rio de Janeiro, Brazil</i>	
<i>Maria Clara Couto Soares, Federal University of Rio de Janeiro, Brazil</i>	
<i>José Eduardo Cassiolato, Federal University of Rio de Janeiro, Brazil</i>	
<i>Julia Queiroz, Fundo Brasileiro para a Biodiversidade, Brazil</i>	

Chapter 5

Infectious Diseases and Climate Vulnerability in Morocco: Governance and Adaptation Options 91

Mohamed Behnassi, Ibn Zohr University of Agadir, Morocco

Kholoud Kahime, Cadi Ayyad University of Marrakesh, Morocco

*Samia Boussaa, Higher Institute of Nursing Professions and Health Techniques of
Marrakesh, Morocco*

Ali Boumezzough, Cadi Ayyad University of Marrakesh, Morocco

Mohammed Messouli, Cadi Ayyad University of Marrakesh, Morocco

Chapter 6

Nurses, Healthcare, and Environmental Pollution and Solutions: Breaking the Cycle of Harm..... 110

A. Elaine McKeown, Independent Researcher, USA

Chapter 7

Health Policy Implementation and Its Barriers: The Case Study of US Health System 134

Augustine Nduka Eneanya, University of Lagos, Nigeria

Chapter 8

Antimicrobial Consumption and Multidrug Resistant Organisms in Intensive Care Units: Lessons
from Saudi Arabia..... 151

Fouad Farouk Jabri, Alfaisal University, Saudi Arabia

Chapter 9

Genomics Applications in Public Health..... 183

E. William Ebomoyi, Chicago State University, USA

Chapter 10

Modeling Energy Portfolio Scoring: A Simulation Framework 203

Rafael Diaz, Old Dominion University, USA

Joshua Behr, Old Dominion University, USA

Rafael Landaeta, Old Dominion University, USA

Francesco Longo, University of Calabria, Italy

Letizia Nicoletti, University of Calabria, Italy

Chapter 11

A Framework to Analyze Variation of the Satisfaction of Patients for Outpatient Needs: A Case of
West Bengal, India 227

Arnab Jana, Indian Institute of Technology Bombay, India

Noboru Harata, The University of Tokyo, Japan

Chapter 12

Promoting Health Literacy in Global Health Care 242

Kijpokin Kasemsap, Suan Sunandha Rajabhat University, Thailand

Chapter 13

Accountability and Public Reporting: Publication of Performance to Improve Quality	264
--	-----

Maria Tanzariello, Università Cattolica del Sacro Cuore, Rome, Italy

Sabina Bucci, Università Cattolica del Sacro Cuore, Rome, Italy

Walter Ricciardi, Università Cattolica del Sacro Cuore, Rome, Italy

Antonio Giulio de Belvis, Università Cattolica del Sacro Cuore, Rome, Italy

Section 2

Tools and Technologies

This section presents an extensive coverage of various tools and technologies available in the field of Public Health and Welfare that practitioners and academicians alike can utilize to develop different techniques. These chapters enlighten readers about fundamental research on the many tools facilitating the burgeoning field of Public Health and Welfare. It is through these rigorously researched chapters that the reader is provided with countless examples of the up-and-coming tools and technologies emerging from the field of Public Health and Welfare. With 13 chapters, this section offers a broad treatment of some of the many tools and technologies within the Public Health and Welfare field.

Chapter 14

The Role of Management Accounting Systems in Public Hospitals and the Construction of	
---	--

Budgets: A Literature Review	289
------------------------------------	-----

Carla Marina Pereira de Campos, University of Aveiro, Portugal

Lúcia Lima Rodrigues, University of Minho, Portugal

Susana Margarida Faustino Jorge, University of Coimbra, Portugal

Chapter 15

Laboratory Information Management Systems: Role in Veterinary Activities	313
--	-----

Patrizia Colangeli, Istituto Zooprofilattico Sperimentale dell'Abruzzo e del Molise "G. Caporale", Italy

Fabrizio De Massis, Istituto Zooprofilattico Sperimentale dell'Abruzzo e del Molise "G. Caporale", Italy

Francesca Cito, Istituto Zooprofilattico Sperimentale dell'Abruzzo e del Molise "G. Caporale", Italy

Maria Teresa Mercante, Istituto Zooprofilattico Sperimentale dell'Abruzzo e del Molise "G. Caporale", Italy

Lucilla Ricci, Istituto Zooprofilattico Sperimentale dell'Abruzzo e del Molise "G. Caporale", Italy

Chapter 16

Developing SMS Health Messages for Pregnant Indigenous Australians Using Persuasive	
---	--

Technology	327
------------------	-----

Reece George, University of Newcastle, Australia

Chapter 17

Health Information Technology and Quality Management	354
--	-----

T. Ray Ruffin, University of Phoenix, USA & Colorado Technical University, USA & University of Mount Olive, USA & Wake Technical Community College, USA

Chapter 18

Twitter and Its Role in Health Information Dissemination: Analysis of the Micro-Blog Posts of Health-Related Organisations 372

Dan Dumbrell, The University of Sydney, Australia

Robert Steele, The University of Sydney, Australia

Chapter 19

Health Information Technology and Change 389

T. Ray Ruffin, University of Phoenix, USA & Colorado Technical University, USA &

University of Mount Olive, USA & Wake Technical Community College, USA

Chapter 20

On Piloting Web-Based Rabies Surveillance System for Humans and Animals: Web-Based Rabies Surveillance System 418

Maulilio J. Kipanyula, Sokoine University of Agriculture, Tanzania

Camilius Sanga, Sokoine University of Agriculture, Tanzania

Anna M. Geofrey, Sokoine University of Agriculture, Tanzania

Kadeghe G. Fue, Sokoine University of Agriculture, Tanzania

Chapter 21

Social Media and Alcohol Use: Adverse Impact of Facebook and Twitter on College Students 437

Gulzar H. Shah, Jiann-Ping Hsu College of Public Health, USA

Moya L. Alfonso, Jiann-Ping Hsu College of Public Health, USA

Nina Jolani, National Association of County and City Health Officials (NACCHO), USA

Chapter 22

The Philippine Health Care Delivery System and Health Expenditure 457

Abdulkadir Işık, Namık Kemal University, Turkey

Abdulhamid Mauyag Gunda, Namık Kemal University, Turkey

Birol Topçu, Namık Kemal University, Turkey

Chapter 23

Socio-Technical Systems on the Move: Some Insights for Policy Activity 471

Sylvie Occelli, Istituto di Ricerche Economico Sociali del Piemonte (IRES), Italy

Volume II

Chapter 24

Online Spatial HIV/AIDS Surveillance and Monitoring System for Nigeria 495

Peter Adebayo Idowu, Obafemi Awolowo University, Nigeria

Chapter 25

Early Warning System and Adaptation Advice to Reduce Human Health Consequences of Extreme Weather Conditions and Air Pollution 527

Dragan Bogdanović, State University of Novi Pazar, Serbia

Konstansa Lazarević, State University of Novi Pazar, Serbia

Chapter 26

Identification of Associations between Clinical Signs and Hosts to Monitor the Web for Detection of Animal Disease Outbreaks 565

Elena Arsevska, French Agricultural Research and International Cooperation Organization (CIRAD), France

Mathieu Roche, French Agricultural Research and International Cooperation Organization (CIRAD), France

Pascal Hendrikx, French Agency for Food, Environmental and Occupational Safety (ANSES), France

David Chavernac, French Agricultural Research and International Cooperation Organization (CIRAD), France

Sylvain Falala, French National Institute for Agricultural Research (INRA), France

Renaud Lancelot, French Agricultural Research and International Cooperation Organization (CIRAD), France

Barbara Dufour, Université Paris Est, France

Section 3

Utilization and Applications

This section discusses a variety of applications and opportunities available that can be considered by practitioners in developing viable and effective Public Health and Welfare programs and processes. This section includes 12 chapters that review topics from case studies to best practices and ongoing research. Further chapters discuss Public Health and Welfare in a variety of settings. Contributions included in this section provide excellent coverage of today's IT community and how research into Public Health and Welfare is impacting the social fabric of our present-day global village.

Chapter 27

An Investigation of the Application of New Media and Its Impact on Taiwan Health Communication 588

Rose Hung, Shih Hsin University, Taiwan

Pi-Fang Hsu, Shih Hsin University, Taiwan

Chia-Wen Tsai, Ming Chuan University, Taiwan

Chapter 28

Extending Care Outside of the Hospital Walls: A Case of Value Creation through Synchronous Video Communication for Knowledge Exchange in Community Health Network 603

Jiban Khuntia, University of Colorado, USA

Mohan Tanniru, Oakland University, USA

John Zervos, Henry Ford Health System, USA

Chapter 29

The Analysis of Health Care Expenses of Turkey between 1990-2012 621

Hayriye Işık, Namık Kemal University, Turkey

Yaşar Akdağ, Hakkari University, Turkey

Chapter 30

The Greenhouse Gas Emissions of Various Dietary Practices and Intervention Possibilities to Reduce This Impact 636

Celia Green, Australian National University, Australia

Andrew Joyce, Swinburne University of Technology, Australia

Jonathan Hallett, Curtin University, Australia

Toni Hannelly, Curtin University, Australia

Gemma Carey, Australian National University, Australia

Chapter 31

An Evaluation of Partnership for Productive Development in Brazil's Healthcare: Measuring the Knowledge Translation from Implementation to the Impact 662

Jorge Lima Magalhães, Oswaldo Cruz Foundation (FIOCRUZ), Brazil

Zulmira Hartz, Universidade Nova de Lisboa (UNL), Portugal

Adelaide M. S. Antunes, National Institute for Industrial Property (INPI), Brazil &

University of Rio de Janeiro (UFRJ), Brazil

Chapter 32

Successful Integration of Knowledge for Innovation: A Case Study of Opportunities for Product Development Partnerships in Brazil 682

J. L. Magalhaes, Ministry of Health, Brazil

R. Cartaxo, Federal University of Rio de Janeiro (UFRJ), Brazil

Adelaide M. S. Antunes, National Institute for Industrial Property (INPI), Brazil &

University of Rio de Janeiro (UFRJ), Brazil

Chapter 33

Environmental Cost Studies and Their Application in Environmental Protection Planning for Electricity Production 701

Željko Tomšić, University of Zagreb, Croatia

Chapter 34

Doing Together: Co-Designing the Socio-Materiality of Services in Public Sector 740

Juha Koivisto, National Institute for Health and Welfare, Finland

Pasi Pohjola, National Institute for Health and Welfare, Finland

Chapter 35

Culture of Learning Cities: Connecting Leisure and Health for Lifelong Learning Communities 755

Ebbin Dotson, University of Illinois at Chicago, USA

Dan K. Hibbler, DePaul University, USA

Leodis Scott, Columbia University, USA

Chapter 36

Hunting HIV-Positive Women in Greece as Parasites 779

Pitsou Anastasia, The Aristotle University of Thessaloniki, Greece

Chapter 37

- Health Impact of Water-Related Diseases in Developing Countries on Account of Climate Change: A Systematic Review – A Study in Regard to South Asian Countries..... 789
Sukanya Das, TERI University, India

Chapter 38

- A Study on Adoption of Employee Welfare Schemes in Industrial and Service Organisations: In Contrast with Public and Private Sectors..... 809
Chandra Sekhar Patro, GVP College of Engineering (Autonomous), India

Section 4

Organizational and Social Implications

This section includes a wide range of research pertaining to the social and behavioral impact of Public Health and Welfare and contemporary coverage related to the corporate and managerial utilization of information sharing technologies and applications. Chapters in this section critically analyze and discuss trends in Public Health and Welfare. Also investigating a concern within the field of Public Health and Welfare is research which discusses the effect of user behavior. With 11 chapters, the discussions presented in this section offer research into the integration of global Public Health and Welfare as well as implementation of ethical and workflow considerations for all organizations.

Chapter 39

- Fostering Global Citizenship in Higher Education: Development of an International Course in Global Health..... 826
Lee Stoner, Massey University, New Zealand
Lane Perry, Western Carolina University, USA
Daniel Wadsworth, Massey University, New Zealand
Mikell Gleason, University of Georgia, USA
Michael A. Tarrant, University of Georgia, USA
Rachel Page, Massey University, New Zealand
Krystina R. Stoner, University of Georgia, USA

Chapter 40

- Community Development and Faith-Based Organizations: Lessons for Global Health 848
Stephanie Wrightman, Catholic Mission Australia, Australia

Chapter 41

- The Role of Average Health Status: Health Inequalities Matrix for Assessing Impacts on Population Health in Health in All Policies..... 884
Jordan Panayotov, Independent Centre for Analysis and Research of Economies (ICARE), Australia

Chapter 42

- Spatial Aspects of Mortality Rates and Neighborhood Environmental Characteristics in Seoul Mega City Region, South Korea 900
Yoohyung Joo, Seoul National University, South Korea
Hee Yeon Lee, Seoul National University, South Korea

Chapter 43

Stakeholders Engagement and Agenda Setting in a Developing Context: The Case of the Bangladesh Health Policy 925

Golam Rabbani, Rajshahi University, Bangladesh

Chapter 44

Response to School Violence..... 941

Roger Neal McIntyre Jr., Valdosta State University, USA

Lorna L. Alvarez-Rivera, Valdosta State University, USA

T. Chris Owens, Independent Researcher, USA

Chapter 45

The Role of Online Health Education Communities in Wellness and Recovery 964

Kathleen P. King, University of Central Florida, USA

Julie A. Leos, University of South Florida, USA

Lu Norstrand, University of South Florida, USA

Volume III

Chapter 46

Phenomenology, Epigenome and Epigenetic Influence on the Growth and Development of School-Age Children..... 999

E. William Ebomoyi, Chicago State University, USA

Chapter 47

Employee Welfare Measures in Public and Private Sectors: A Comparative Analysis 1026

Chandra Sekhar Patro, Gayatri Vidya Parishad College of Engineering (Autonomous), India

Chapter 48

Organizational Leadership and Health Care Reform 1043

T. Ray Ruffin, University of Phoenix, USA & Colorado Technical University, USA &

University of Mount Olive, USA & Wake Technical Community College, USA

Joyce Marie Hawkins, Wake Technical Community College, USA

When the System Fails: Challenges of Child Trauma on Adoptive Families' Social and Emotional System..... 1064

Jacqueline Y. Ford, Walden University, USA

Section 5

Critical Issues and Challenges

This section contains 10 chapters, giving a wide variety of perspectives on Public Health and Welfare and its implications. Within the chapters, the reader is presented with an in-depth analysis of the most current and relevant issues within this growing field of study. Crucial questions are addressed and alternatives offered along with theoretical approaches discussed.

Chapter 50

- The Crisis of Public Health as a Media Event: Between Media Frames and Public Assessments 1091
Valentina Marinescu, University of Bucharest, Romania

Chapter 51

- Exacerbating Health Risks in India due to Climate Change: Rethinking Approach to Health Service Provision 1102
Joyashree Roy, Jadavpur University, India
Duke Ghosh, Global Change Research, India
Kuheli Mukhopadhyay, Jadavpur University, India & West Bengal State University, India
Anupa Ghosh, The Bhawanipur Education Society College, India

Chapter 52

- Climate Change Effects on Human Health with a Particular Focus on Vector-Borne Diseases and Malaria in Africa: A Case Study from Kano State, Nigeria Investigating Perceptions about Links between Malaria Epidemics, Weather Variables, and Climate Change 1128
Salisu Lawal Halliru, Federal College of Education Kano, Nigeria

Chapter 53

- The Idea of Human Rights in Conditions of Hospital Treatment 1147
Bogusław Sygit, University of Łódź, Poland
Damian Wąsik, Nicolaus Copernicus University in Torun, Poland

Chapter 54

- What Drives the Adoption of Social Media Applications by the Public Sector? Evidence from Local Health Departments 1166
Liang Ma, Renmin University of China, China & Nanyang Technological University, Singapore

Chapter 55

- Are Climate Change Adaptation Policies a Game Changer? A Case Study of Perspectives from Public Health Officials in Ontario, Canada 1186
Chris G. Buse, University of Northern British Columbia, Canada

Chapter 56

- A Systems Approach for Sustainably Reducing Childhood Diarrheal Deaths in Developing Countries 1208
Monica Gray, The Lincoln University, USA

Chapter 57

- A Systematic Approach towards the Typology of Functions of National Health System: Provision of Functional Model of National Health System 1228
Mostafa Zamanian, University of Tehran, Iran
Zohreh Karimmian, University of Tehran, Iran

Chapter 58

Rough Fuzzy Set Theory and Neighbourhood Approximation Based Modelling for Spatial Epidemiology 1257

Balakrushna Tripathy, VIT University, India

Sharmila Banu K., VIT University, India

Chapter 59

Toward an Informed-Patient Approach to E-Health Services..... 1269

Keren Mazuz, Hadassah Academic College, Israel

Seema Biswas, Medical School for International Health, Israel

Rui Amaral Mendes, Case Western Reserve University, USA

Section 6

Emerging Trends

This section highlights research potential within the field of Public Health and Welfare while exploring uncharted areas of study for the advancement of the discipline. Introducing this section are chapters that set the stage for future research directions and topical suggestions for continued debate, centering on the new venues and forums for discussion. A pair of chapters on space-time makes up the middle of the section of the final 12 chapters, and the book concludes with a look ahead into the future of the Public Health and Welfare field. In all, this text will serve as a vital resource to practitioners and academics interested in the best practices and applications of the burgeoning field of Public Health and Welfare.

Chapter 60

Health Policy Implementation: Moving Beyond Its Barriers in United States..... 1284

Khadijeh Rouzbehani, University of Tehran, Iran

Chapter 61

Public Hospitals in China: The Next Priority for Meaningful Health Care Reform..... 1296

Donghai Wei, Guangzhou Medical University, China

Louis Rubino, California State University, Northridge, USA

Chapter 62

A Follow up to Semi-Automatic Systems for Exchanging Health Information: Looking for a New Information System at Fixed E-Healthcare Points for Citizens in Greece..... 1316

Dimitrios Emmanouil, University of Athens, Greece

Antonia Mourtzikou, University of Athens, Greece

Chapter 63

The Future of Antibiotics and Meat..... 1335

Talia Raphaely, Curtin University, Australia

Dora Marinova, Curtin University, Australia

Mira Marinova, Notre Dame University, Australia

Chapter 64

Towards European Modern Societies with Health Systems That Are Able to Add More Years to Life, But Also to Add More Life to Years 1358

Androutsou Lorena, University of Thessaly, Greece

Androutsou Foulvia, University of Crete, Greece

Chapter 65

Improving the Effects of Global Health Initiatives through FOMENT: An Enhancement to the Diffusion Process 1379

Muhiuddin Haider, University of Maryland, USA

Theofani Makrinos, Independent Public Health Consultant, USA

Madhurima Sarkar, Nationwide Children's Hospital, USA

Chapter 66

The States as Generators of Incremental Change in American Health Care Policy: 1935 to 1965 1398

Robert A. Peters, Western Michigan University, USA

Minerva Cruz, Western Michigan University, USA

Chapter 67

Change through Experience: How Experiential Play and Emotional Engagement Drive Health Game Success 1421

Georges Elias Khalil, University at Buffalo, The State University of New York, USA & The University of Texas, M. D. Anderson Cancer Center, USA

Chapter 68

Emerging Role of Technology in Health Education for Youth..... 1447

Amir Manzoor, Bahria University, Pakistan

Chapter 69

Clinical Communication in the Aspect of Development of New Technologies and E-Health in the Doctor-Patient Relationship..... 1465

Aleksandra Rosiek-Kryszewska, Nicolaus Copernicus University in Toruń, Poland

Łukasz Leksowski, Nicolaus Copernicus University in Toruń, Poland

Anna Rosiek, Nicolaus Copernicus University in Toruń, Poland

Krzysztof Leksowski, Nicolaus Copernicus University in Toruń, Poland & Military Clinical Hospital No. 10, Poland

Preface

The constantly changing landscape of Public Health and Welfare makes it challenging for experts and practitioners to stay informed of the field's most up-to-date research. That is why Information Science Reference is pleased to offer this three-volume reference collection that will empower students, researchers, and academicians with a strong understanding of critical issues within Public Health and Welfare by providing both broad and detailed perspectives on cutting-edge theories and developments. This reference is designed to act as a single reference source on conceptual, methodological, technical, and managerial issues, as well as provide insight into emerging trends and future opportunities within the discipline.

Public Health and Welfare: Concepts, Methodologies, Tools and Applications is organized into six distinct sections that provide comprehensive coverage of important topics. The sections are:

1. Fundamental Concepts and Theories;
2. Tools and Technologies;
3. Utilization and Applications;
4. Organizational and Social Implications;
5. Critical Issues and Challenges; and
6. Emerging Trends.

The following paragraphs provide a summary of what to expect from this invaluable reference tool.

Section 1, "Fundamental Concepts and Theories," serves as a foundation for this extensive reference tool by addressing crucial theories essential to the understanding of Public Health and Welfare. Introducing the book is *The Fundamentals of Health Literacy* by Kijpokin Kasemsap; a great foundation laying the groundwork for the basic concepts and theories that will be discussed throughout the rest of the book. The section also presents in-depth coverage of the conceptual design and architecture of Public Health and Welfare. Section 1 concludes, and leads into the following portion of the book with a nice segue chapter, *Accountability and Public Reporting: Publication of Performance to Improve Quality* by Maria Tanzariello, Sabina Bucci, Walter Ricciardi, and Antonio Giulio de Belvis.

Section 2, "Tools and Technologies," presents extensive coverage of the various tools and technologies used in the implementation of Public Health and Welfare. Section 3 begins where Section 2 left off, though this section describes more concrete tools at place in the modeling, planning, and applications of Public Health and Welfare. The first chapter, *The Role of Management Accounting Systems in Public Hospitals and the Construction of Budgets: A Literature Review* by Carla Marina Pereira de Campos, Lúcia Lima Rodrigues, and Susana Margarida Faustino Jorge, lays a framework for the types of works that

can be found in this section. The section concludes with *Identification of Associations between Clinical Signs and Hosts to Monitor the Web for Detection of Animal Disease Outbreaks* by Elena Arsevska *et al.* Where Section 2 described specific tools and technologies at the disposal of practitioners, Section 3 describes the use and applications of the tools and frameworks discussed in previous sections.

Section 3, “Utilization and Applications,” describes how the broad range of Public Health and Welfare efforts has been utilized and offers insight on and important lessons for their applications and impact. The first chapter in the section is titled *An Investigation of the Application of New Media and Its Impact on Taiwan Health Communication* written by Rose Hung, Pi-Fang Hsu, and Chia-Wen Tsai. This section includes the widest range of topics because it describes case studies, research, methodologies, frameworks, architectures, theory, analysis, and guides for implementation. The breadth of topics covered in the chapter is also reflected in the diversity of its authors, from countries all over the globe. The section concludes with *A Study on Adoption of Employee Welfare Schemes in Industrial and Service Organisations: In Contrast with Public and Private Sectors* by Chandra Sekhar Patro, a great transition chapter into the next section.

Section 4, “Organizational and Social Implications,” includes chapters discussing the organizational and social impact of Public Health and Welfare. The section opens with *Fostering Global Citizenship in Higher Education: Development of an International Course in Global Health* by Lee Stoner *et al.* This section focuses exclusively on how these technologies affect human lives, either through the way they interact with each other, or through how they affect behavioral/workplace situations. It also presents focused coverage of Public Health and Welfare in a managerial perspective. This section serves as a vital resource for developers who want to utilize the latest research to bolster the capabilities and functionalities of their processes. The section concludes with *When the System Fails: Challenges of Child Trauma on Adoptive Families’ Social and Emotional System* by Jacqueline Y. Ford.

Section 5, “Critical Issues and Challenges,” presents coverage of academic and research perspectives on Public Health and Welfare tools and applications. The section begins with *The Crisis of Public Health as a Media Event: Between Media Frames and Public Assessments* by Valentina Marinescu. Chapters in this section will look into theoretical approaches and offer alternatives to crucial questions on the subject of Public Health and Welfare. The section concludes with *Toward an Informed-Patient Approach to E-Health Services* by Keren Mazuz, Seema Biswas, and Rui Amaral Mendes.

Section 6, “Emerging Trends,” highlights areas for future research within the field of Public Health and Welfare, opening with *Health Policy Implementation: Moving Beyond Its Barriers in United States* by Khadijeh Rouzbehani. This section contains chapters that look at what might happen in the coming years that can extend the already staggering amount of applications for Public Health and Welfare. The final chapter of the book looks at an emerging field within Public Health and Welfare, in the excellent contribution, *The Future of Healthcare: Political Participation of Nursing and Public Health Students* by Christine Vandenhouten *et al.*

Although the primary organization of the contents in this multi-volume work is based on its six sections, offering a progression of coverage of the important concepts, methodologies, technologies, applications, social issues, and emerging trends, the reader can also identify specific contents by utilizing the extensive indexing system listed at the end of each volume. As a comprehensive collection of research on the latest findings related to using technology to providing various services, *Public Health and Welfare: Concepts, Methodologies, Tools and Applications*, provides researchers, administrators

Preface

and all audiences with a complete understanding of the development of applications and concepts in Public Health and Welfare. Given the vast number of issues concerning usage, failure, success, policies, strategies, and applications of Public Health and Welfare in countries around the world, *Public Health and Welfare: Concepts, Methodologies, Tools and Applications* addresses the demand for a resource that encompasses the most pertinent research in technologies being employed to globally bolster the knowledge and applications of Public Health and Welfare.

Section 1

Fundamental Concepts and Theories

This section serves as a foundation for this exhaustive reference tool by addressing underlying principles and provides in-depth coverage of conceptual architecture frameworks essential to the understanding of Public Health and Welfare. Chapters found within these pages provide an excellent framework in which to position Public Health and Welfare within the field of information science and technology. Insight regarding the critical incorporation of global measures into Public Health and Welfare is addressed, and examinations to specific discussions on methodology. With 13 chapters comprising this foundational section, the reader can learn and chose from a compendium of expert research on the elemental theories underscoring the Public Health and Welfare discipline.

Chapter 1

The Fundamentals of Health Literacy

Kijpokin Kasemsap

Suan Sunandha Rajabhat University, Thailand

ABSTRACT

This chapter describes the overview of health literacy; the characteristics of functional health literacy, interactive health literacy, and critical health literacy; and the significance of health literacy in global health care. Health literacy is about how patients understand health information about health and health care, and how they apply that health information to their daily lives, utilize it to make health-related decisions, and act on it. Being able to understand health information and make decisions from that information is vital to patients' well-being. Health literacy can help patients prevent their health problems and protect their health, as well as better manage those problems and unexpected situations that happen. Patients with good health literacy make effective health decisions because they can find, understand, and evaluate the health information in global health care.

INTRODUCTION

Health literacy is established as a central concept in health communication and education (Dubowicz & Schulz, 2013). The concept of health literacy includes not only the ability of individuals to read and understand health care information, but also the ability to function within the health care system (Torres & Nichols, 2014). Health literacy is the degree to which individuals can obtain, process, understand, and communicate about health-related information needed to make health decisions (Berkman, Davis, & McCormack, 2010). Health literacy comprises skills in obtaining, understanding, and acting on information about health issues in ways that promote and maintain health (Mårtensson & Hensing, 2012).

Health literacy is the mechanism by which individuals obtain and utilize health information to make health decisions about individual treatments in the home, access care in the community, promote patient-health care provider interactions, structure self-care, and navigate health care programs both locally and nationally (Westlake, Sethares, & Davidson, 2013). Distributed health literacy is a potential resource for managing individual's health, thus communicating with health professionals and making health deci-

DOI: 10.4018/978-1-5225-1674-3.ch001

sions (Edwards, Wood, Davies, & Edwards, 2015). Low health literacy is a burden to individuals and to health care-related society (Carollo, 2015).

Health information is created, updated, and exchanged by people, and electronic communication networks can distribute the health information to provide easy access to users (Yim, Khuntia, & Argyris, 2015). Health literacy provides the skills to effectively utilize the health information (Londono & Schulz, 2015). The effectiveness of health information largely depends on people's ability to understand and utilize information (Meppelink & Bol, 2015). Providing explicit health information to people with limited health literacy is necessary to reduce these health-related difficulties (Meppelink & Bol, 2015).

This chapter aims to bridge the gap in the literature on the thorough literature consolidation of health literacy. The extensive literature of health literacy provides a contribution to practitioners and researchers by describing theory and applications of health literacy in order to promote the health care literacy in global health care.

BACKGROUND

The term literacy is globally used and it is often used to separate a technical understanding of reading and writing on one hand, and a wider understanding of communication on the other hand (Lundvall, 2015). Health literacy has been prioritized in public health and rigorously studied since the 1990s (Leung, Cheung, & Chi, 2015). Public health is concerned with protecting the health of populations which can be as small as a local neighborhood or as large as an entire country (Raghupathi & Raghupathi, 2013). Early research on health literacy focused on health outcomes among individuals with low health literacy (Leung et al., 2015). As health care moves toward greater choice, with shared responsibility and decision making between doctors and patients, a wide variety of resources and skills are needed by individuals if they are to be active participants in their health (Manning & Dickens, 2006).

Early definitions focused on the ability to apply reading, writing, and numeracy skills to the health-related materials, such as prescriptions, appointment cards, and medicine labels (Parker, Baker, Williams, & Nurss, 1995), while later conceptualizations encompassed a range of skills, including social and communication skills that enable people to obtain, understand, and use the health information in ways that enhance health, well-being, and engagement in the medical decision making (Nutbeam, 2000). Health literacy has been conceptualized in various ways (Nielsen-Bohlman, Panzer, & Kindig, 2004), and its scope have been widened during the last decade (Estacio, 2013). Health literacy has become a topic of significant interest among health and medical researchers during the past two decades, particularly in regard to its explanatory role in health disparities (Reeve & Basalik, 2014).

Health illiteracy is a societal issue that, if successfully addressed, may help reduce health disparities (Brown, Teufel, & Birch, 2007). Health literacy, or the degree to which individuals have the capacity to obtain, communicate, process, and understand basic health information and services needed to make suitable health decisions, is an important predictor of health outcomes (Kaphingst, Goodman, MacMillan, Carpenter, & Griffey, 2014). Inadequate health literacy has been linked to increased health disparities, unsuccessful self-care, poor health outcomes, poor use of health care services, and among elderly persons, poor overall health status, and high mortality rates (Berkman, Sheridan, Donahue, Halpern, & Crotty, 2011).

Health literacy is recognized as an essential factor in optimizing health (Carollo, 2015). Malloy-Weir et al. (2015) indicated that ethical arguments for enabling people to participate in decision making

about their treatment are widely accepted. More recent definitions of health literacy include the ability to apply these skills in various settings and across the life span (Rootman & Gordon-El-Bihbety, 2008). Lower educational attainment is associated with suboptimal health literacy (Sentell, Braun, Davis, & Davis, 2013); however, those who have higher educational attainment may still have low health literacy (Institute of Medicine, 2004). Limited health literacy has been linked with higher incidence of chronic illness, poorer self-reported health, lower utilization of preventive health services, higher rates of hospitalization, and higher health care costs (Weiss & Palmer, 2004).

PERSPECTIVES ON HEALTH LITERACY IN GLOBAL HEALTH CARE

This section explains the overview of health literacy; the characteristics of functional health literacy, interactive health literacy, and critical health literacy; and the significance of health literacy in global health care.

Overview of Health Literacy

Health care is experiencing an exponential growth in the scientific understanding of diagnostic, diseases, and care pathways (Akaichi & Mhadhbi, 2016). Over the last decades, health care policies in many countries have shifted from a supply to a demand or consumer driven organization of health care services (Rademakers, Nijman, Brabers, de Jong, & Hendriks, 2014). Health care sector is a growing field and health conscience has been a major concern for everyone (Sankaranarayanan & Ganesan, 2016). Advances in medical technologies and medical services require adequate health literacy from patients in order to improve quality of life (Tung et al., 2014). Health information should be accessible everywhere and at any time to help with clinical decision and be available for clinical studies (Peixoto, Domingues, & Fernandes, 2016).

Health literacy has been conceptualized to explain how health information facilitates the maintenance of health (Freeman, 2015) regarding medical and public health contexts (Nutbeam, 2000). Knowledge-intensive industries regularly seek to improve positive relationships between forms of human capital and modes of competency (Kasemsap, 2016a). Health literacy is the range of skills and competencies that people develop to seek out, comprehend, evaluate, and utilize health information and concepts to make informed choices, reduce health risks, and increase quality of life (Nielsen-Bohlman et al., 2004). Both providing patients with health information and involving them in health decisions are the major components of patient-centered health care (Coulter, 2002). Active involvement in modern health care is unlikely to be achieved if patients have suboptimal health literacy (Jordan et al., 2013). Research linking health literacy to health knowledge, health behaviors, health outcomes, health disparity, and health status is prevalent across the globe (Mancuso, 2009).

Appropriate health information provision regarding diagnosis, treatment, long-term effects, and health care services can result in informed decision making, improved treatment adherence, lower levels of distress, and higher satisfaction with care (Mallinger, Griggs, & Shields, 2005). There is a growing recognition that inadequate health literacy contributes to health inequalities as it is more prevalent among lower socioeconomic groups, ethnic minorities, the elderly and those with long-term conditions or disabilities (Sihota & Lennard, 2004). Health literacy researches among adolescents are the developing fields and have established the independent associations among lower health literacy levels, poorer

understanding of preventive care information, among limited access to preventive care services (Shone, King, Doane, Wilson, & Wolf, 2011).

To become health literate, individuals need to mobilize their family, school, social, cultural, and professional assets, gathered over time through contact with knowledge, attitudes, and health behaviors (Zanchetta, Perreault, Kaszap, & Viens, 2007). Therefore, individuals need to be skilled in interpreting the health-related world, accessing knowledge (Barton & Hamilton, 1999), and communicating health messages (Institute of Medicine of the National Academies, 2004). It has a strong influence on communication in medical settings and consequences for the patients' health outcomes (Andrus & Roth, 2002). The necessity of the concept of health literacy as a link between communication and better health outcomes is demonstrated in the fact that low health literacy levels are a better predictor of an individual's health than the classical socio-demographic variables of age, income education, employment status, and race.

Many studies about health literacy measures (Ishikawa, Takeuchi, & Yano, 2008) focus on evaluating health information-related reading, comprehension, and numeracy skills (Jordan, Osborne, & Buchbinder, 2011). There is a growing consensus that health literacy encompasses a broader range of attributes other than only literacy skills, such as abilities to interact within broader social and environmental contexts (Lee, Arozullah, & Cho, 2004). Results from the available health literacy measures have shown that people with suboptimal health literacy have difficulty understanding health information (Schillinger, Bindman, Wang, Stewart, & Piette, 2004), poorer knowledge of their condition (Gazmararian, Williams, Peel, & Baker, 2003), and lower utilization of preventive health services (Guerra, Krumholz, & Shea, 2005).

Measuring health literacy is likely to be a particular challenge as it is an emerging and evolving construct (Nutbeam, 2008). Assessment of health literacy has yet to become the clearly established aspect of clinical practice or population-level health needs assessment (Chinn & McCarthy, 2013). A comprehensive model of health literacy was proposed by Schulz and Nakamoto (Rubinelli, Schulz, & Nakamoto, 2009). To emphasize the patient centeredness and component of health literacy concept, Schulz and Nakamoto added judgment skills to the concept, retaining the other components of functional health literacy, declarative knowledge, and procedural knowledge (Schulz & Nakamoto, 2013). Attention to judgment skills is driven by the idea that a patient, in new situations regarding the disease, needs to make autonomous decisions based on knowledge, personal competence, and practical intelligence in general (Dubowicz & Schulz, 2013).

Training in clear health communication improves resident knowledge, attitudes, and skills regarding health literacy (Green, Gonzaga, Cohen, & Spagnoletti, 2014). Researchers investigated how health literacy related to the individual's knowledge and motivation (Paasche-Orlow & Wolf, 2007) and whether health literacy is viewed as a set of health care skills as proposed by the Institute of Medicine (Nielsen-Bohlman et al., 2004). Tsai et al. (2014) indicated that health-related programs that are literacy sensitive and culturally appropriate are needed to teach and encourage individual's health-promoting behaviors. Knowledge and motivation are recognized as the important factors contributing to the development of health literacy (Leung et al., 2015).

The widespread low health literacy affects health and health service delivery (Canadian Council on Learning, 2008). For these reasons, health literacy needs to be extensively introduced and further developed in nursing education curricula (Zanchetta et al., 2013). Regarding nursing education, analyzing students' performance and self-criticism of their roles in promoting health literacy can inform nursing education in a social environment that expects new graduates to be health promoters (Zanchetta et al., 2013). Nurses play a key role in providing health care information to individuals in a wide variety of

The Fundamentals of Health Literacy

health care settings; therefore, it is crucial that nurses are prepared to experience the challenges of working with patients who may have the limited literacy skills (Torres & Nichols, 2014).

The concept of health literacy is widely utilized for measuring the patients' abilities to obtain, process, and communicate information about their health condition, and lately major work in defining and theory-building has been done (Speros, 2005). Patient teaching and engagement are core nursing responsibilities (Sofaer & Schumann, 2013). However, if patients do not understand what nurses have taught them, effective communication has not taken place (Parker & Gazmararian, 2003). The socio-epidemiological relevance of health literacy as a social determinant of health (Raphael, 2009) requires nurses to update their professional knowledge, innovate within their scope of practice and generate new knowledge in the area of promotion of health literacy (Rootman, 2004). Nurses are in the privileged position of being able follow up clients' learning related to health literacy (Zanchetta et al., 2007).

The average American adult reads at the 8th grade level while most written health information materials, including medication guides, are written at the 12th grade level (Chen, Noureldin, & Plake, 2013). To assist students with health literacy-sensitive communication, pharmacy schools should incorporate educational activities addressing health literacy competencies (Chen et al., 2013). Despite the opportunity for pharmacists to reduce the health literacy demands placed on patients, there are many obstacles to making such improvements in retail pharmacies, such as the hectic pace of pharmacies, high prescription volumes, low profit margins limiting pharmacy resources for the improvement activities, a workflow designed to dispense medications, and physical layouts limiting communication between pharmacists and patients (Shoemaker, Staub-DeLong, Wasserman, & Spranca, 2013).

Limited health literacy is associated with increased use of emergency care services, elevated risks for several chronic diseases and overall mortality, and poorer utilization of preventive health services, such as cancer screening (Bennett, Chen, Soroui, & White, 2009). Factors contributing to the decrease in cancer mortality rates include increases in cancer screening rates, appropriate abnormal screening test follow-up, and treatment advances (Oldach & Katz, 2014). Regarding health literacy, the provision of appropriate information is one of the most important aspects of the support for cancer survivors (Verkisen et al., 2014). Limited health literacy skills may explain the overall low uptake of screening and social inequalities in screening, and they may inhibit the individuals' capacity to understand, and subsequently engage with the written screening information (von Wagner, Semmler, Good, & Wardle, 2009).

Characteristics of Functional Health Literacy, Interactive Health Literacy, and Critical Health Literacy

Nutbeam (2000) emphasized the significance of obtaining health literacy at the functional, interactive, and critical levels. Functional health literacy is concerned with the use of general literacy skills (e.g., reading and writing) to clearly understand the basic health messages (Velardo, 2015). Toci et al. (2014) indicate that functional health literacy is related to individual characteristics, ill health, and disease knowledge. Functional health literacy has been shown to be linked with the demographic and socioeconomic characteristics of individuals (von Wagner, Knight, Steptoe, & Wardle, 2007).

Many studies have reported the significant associations of functional health literacy with age (Jovic-Vranes, Bjegovic-Mikanovic, & Marinkovic, 2009), education (Artinian, Lange, Templin, Stallwood, & Hermann, 2003), and income (von Wagner et al., 2007). The limited or marginal functional health literacy has been linked with worse or less favorable health outcomes or disease knowledge (DeWalt, Berkman, Sheridan, Lohr, & Pignone, 2004). Nakagami et al. (2014) stated that both inadequate and

marginal functional health literacy are associated with older age, lower income, lower educational attainment, and poor health knowledge. People with limited functional health literacy are significantly less likely to perceive the lifestyle factors as cancer risks (Adams et al., 2013).

Interactive health literacy focuses on the ability to understand and utilize the information for prevention and self-management. The terms interactive health literacy and communicative health literacy have both been used in literature to refer to the skills that can be used to actively participate in everyday situations, extract health information, and derive meaning from the different patterns of health communication, and apply this perspective to the changing health care circumstances (Chinn, 2011). The increasing amounts of attention are being paid to the interactive and critical health literacy (Sykes, Wills, Rowlands, & Popple, 2013). van der Heide et al. (2015) indicated that interactive health literacy is associated with patients' perceived ability to organize care, interact with the health care providers and perform self-care, whereas only functional health literacy is associated with a number of general practitioner visits.

Most studies on health literacy have focused on functional health literacy, which reflects the basic skills in reading and writing (Chinn, 2011). Age has been found to be a significant inverse predictor of health literacy, both in general populations (Paasche-Orlow, Parker, Gazmararian, Nielsen-Bohlman, & Rudd, 2005) and among older individuals (Benson & Forman, 2002). Regarding cognitive ability perspectives, individuals with inadequate health literacy have lower verbal ability for oral expression and verbal communication; lower mental processing ability for speed and efficiency of thought, comprehension of text and numerical information; poorer memory ability for recalling spoken instructions; lower perceptual speed ability for performance of electronic health searches; and poorer executive function ability for critical thinking, weighing options, and making decisions and inferences (Wilson & Wolf, 2009).

Reading and numeracy are recognized as the fundamental cognitive abilities necessary for navigating and understanding the health care system (Wolf et al., 2009). Because poor cognitive function may undermine health literacy, efforts to target older adults on improving health literacy should consider cognitive function as a risk factor (Nguyen et al., 2013). Overall cognitive ability and education are positively related to health literacy (Yost, DeWalt, Lindquist, & Hahn, 2013). Cognitive status has been shown to be a significant predictor of health literacy among older adults (Federman, Sano, Wolf, Siu, & Halm, 2009).

Critical literacy refers to more advanced cognitive skills that allow individuals to extract information, derive meaning from the different patterns of communication, and utilize this information (Nutbeam, 2000). Critical health literacy is the cognitive and social skills needed to critically assess the applicability of health information to personal situations or its reliability, such as information about the performance of health care providers (Chinn, 2011). Heijmans et al. (2015) indicated that communicative and critical health literacy play a role in successful self-management of chronic disease but the impact differs by the health-related context.

Significance of Health Literacy in Global Health Care

Addressing health literacy as a theory of behavior change can generate the positive gains in individual, health care community, and global health care (Pleasant, 2011). Rehabilitating a debilitated health care system is essential to public, social, and economic health (Ridpath, Larson, & Greene, 2012). Health literacy is a multidimensional construct that bridges basic literacy skills and various health and illness contexts (Yamashita & Kart, 2011). Studies of adults have shown an association between low health

The Fundamentals of Health Literacy

literacy and worse health outcomes, decreased use of preventive services, and poor self-reported health status (Bennett et al., 2009).

Low literacy is an unrecognized barrier to the effective self-health management (Reyes, 2010). Fransen et al. (2014) stated that inadequate health literacy is regarded as a common barrier in patient and public health education. Inadequate health literacy is associated with the inadequate understanding of written information and the poor communication with health care professionals (Davis & Wolf, 2004). Recent studies in health literacy among adolescents, link literacy rates with health behaviors and outcomes including online health information seeking, over-the-counter (OTC) medication use, and obesity (Sharif & Blank, 2010).

In comparison with individuals with adequate health literacy, those with inadequate health literacy have less knowledge of diseases and treatments, often lack the skills to negotiate health care system, exhibit suboptimal self-management, and have worse health outcomes (Gazmararian et al., 2003). Differences in health literacy levels by race and education are broadly hypothesized to contribute to health disparities (Howard, Sentell, & Gazmararian, 2006). The observed relations between health literacy and important indicators of health status have led investigators to develop the effective health interventions to improve health literacy (Sheridan et al., 2011) in the anticipation that they may be effective in improving patient health and address ethnicity-related health disparities (Waldrop-Valverde et al., 2010). Health disparities on the basis of geographic location, social economic factors, and education levels are well documented (Murimi & Harpel, 2010). Limited health literacy may also partially explain racial disparities in outcomes (Saha, 2006).

Low health literacy is recognized as a burden to the individual, thus influencing the access to health services, limiting the understanding of health information, and impacting the quality of health-related decisions (Baker et al., 2007). Low health literacy has been associated with inappropriate use of emergency services, higher rates of hospitalization, and increased health care costs (Koskan, Friedman, & Messias, 2010). Individuals with limited health literacy have overall poorer physical function, less knowledge about managing their chronic health conditions, and participate less in the health care decision-making process (DeWalt, Boone, & Pignone, 2007).

Patients with limited health literacy are reported to have less interest in shared health decision making (Levinson, Kao, Kuby, & Thisted, 2005) which has implications for treatment adherence and health outcomes (Eckman et al., 2012). Health care providers have difficulty detecting patients with limited health literacy (Wittich, Mangan, Grad, Wang, & Gerald, 2007). Patients with limited health literacy are less likely to ask questions (Katz, Jacobson, Veledar, & Kripalani, 2007), seek information from print resources (Koo, Krass, & Aslani, 2006), remember the verbally communicated medication instructions (McCarthy et al., 2012), toward contributing to patients' inability to effectively utilize information. Speaking and listening skills are considered more important than reading and numeracy in patient self-advocacy within the health care system (Martin et al., 2011). Verbal exchange skills are key to patient understanding and use of health information that impact health outcomes (Finan, 2002). Swavely et al. (2014) indicated that low health literacy is more prevalent in persons with limited education, members of ethnic minorities, and those who speak English as a second language, and is associated with multiple adverse diabetes-related health outcomes.

Beyond having poorer health outcomes than their adequate health literacy counterpart (Bostock & Steptoe, 2012), patients with suboptimal health literacy show poorer ability to understand medical instructions and medication labels, and to properly take their medications (Berkman et al., 2011). Patients with low health literacy contribute to the increase in health care expenditure through the less frequent

use of preventive health services, the poorly managed chronic illness, and the greater use of emergency department services (Larsen & Lubkin, 2009).

Patients with limited health literacy may have difficulty locating providers and services, understanding written medical information, communicating with health care providers, and implementing self-care instructions (Green et al., 2014) and tend to ask the fewer questions of clinicians because of fear and embarrassment associated with this condition (Aboumatar, Carson, Beach, Roter, & Cooper, 2013). This translates into an array of adverse outcomes, including increased hospitalizations (Baker, Parker, Williams, & Clark, 1998), decreased preventive health care (White, Chen, & Atchison, 2008), poorer overall health status (Cho, Lee, Arozullah, & Crittenden, 2008), and higher mortality rates (Baker, Wolf, Feinglass, & Thompson, 2008).

Health literacy has established the links between literacy skills and health outcomes and is considered as an important strategy for improving the health of disadvantaged populations and addressing social inequality (Flecha, García, & Rudd, 2011). Low health literacy negatively affects a woman's health knowledge, preventive behavior, ability to navigate the health care system, and ability to care for her children (Shieh & Halstead, 2009). In pregnancy, woman's health status and her understanding of health information may directly affect the maternal-fetal health (Lupattelli, Picinardi, Einarson, & Nordeng, 2014). Previous research among pregnant subjects with pregestational diabetes has shown that low health literacy is positively associated with unplanned pregnancies, no use of folic acid prior or during pregnancy, and later presentation for prenatal care (Endres, Sharp, Haney, & Dooley, 2004).

FUTURE RESEARCH DIRECTIONS

The classification of the extensive literature in the domains of health literacy will provide the potential opportunities for future research. Patient safety issues are the avoidable errors in health care that can cause harm to patients. Harm in this context means injury, suffering, disability or death. The effective communities of practice (CoPs) facilitate the social interactions and encourage the members' willingness to share knowledge and ideas in the workplace (Kasemsap, 2016b). Social media tools are open to anyone, whereas reaching the traditional media often requires a lot of money and a good network of media industry contacts (Kasemsap, 2016c). Total quality management (TQM) practices in quality performance has the potential to improve organizational performance (Kasemsap, 2015). Encouraging both health literacy and patient safety improvement through CoPs, social media, and TQM practices in modern health care will be the essential issue for future research direction.

CONCLUSION

This chapter highlighted the overview of health literacy; the characteristics of functional health literacy, interactive health literacy, and critical health literacy; and the significance of health literacy in global health care. Health literacy is about how patients understand health information about health and health care, and how they apply that health information to their daily lives, utilize it to make health-related decisions, and act on it. Health literacy is important because it affects an individual's ability to manage personal health: to navigate the health care system, share health history with health care providers, engage in self-care and manage chronic disease, and understand concepts, such as probability and risk.

Being able to understand health information and make sound health decisions from that information is vital to patients' well-being in health care settings.

Health literacy can help patients prevent their health problems and protect their health, as well as better manage those problems and unexpected situations that happen. Patients with good health literacy make effective health decisions because they can find, understand, and evaluate the health information in global health care. Low health literacy is linked to higher rates of hospitalization and use of emergency services, and less frequent use of preventive services in health care settings, and is linked to health disparities regarding population-specific differences in the presence of disease, health outcomes, or access to health care.

KEY TERMS AND DEFINITIONS

Communication: The two-way process of reaching mutual understanding, in which participant not only exchange information, news, ideas, and feelings, but also create and share meaning.

Health Care: The act of taking the preventative or necessary medical procedures to improve a person's well-being.

Information: The data that is organized for a specific purpose and presented within a context that gives it meaning and relevance.

Knowledge: The understanding of a circumstance gained through experience.

Literacy: The ability to read and write.

Patient: A person who is receiving medical care, or who is cared for by a particular doctor or dentist when necessary.

Skill: The ability acquired through the deliberate, systematic, and sustained effort to smoothly and adaptively execute the complex activities.

Understanding: The knowledge about a situation or about how something works.

Chapter 2

The Information Paradox: Researching Health Service Information Systems Development

Said Shahtahmasebi

The Good Life Research Centre Trust, New Zealand & University of Kentucky, USA

ABSTRACT

This paper is based on a 2008 chapter (Shahtahmasebi, 2008) exploring the availability of information for public health policy purposes which argued its ineffectiveness to add insight and inform the process of policy development. Processes are dynamic by nature which politicians and professionals often neglect in addressing public health issues. The Chapter argued that whilst information is a major currency within health systems a lack of understanding of what constitutes information has disguised available data as small change. Since 2008, against a backdrop of reorganisations, restructuring, buzzwords, and coupled with the rapid advancement in technology the issues remain the same but are somewhat more complicated due to the feedback effect of dynamic processes. For example, a curious persistence of various governments with electronic health records has done nothing to address the gap in “information” or incompatibility in the information systems developed and managed by various care agencies. Furthermore, changing information to “intelligence” (e.g. Public Health Intelligence Units) or “observatories” to carry out similar tasks of reporting health outcomes using the same routine data will not solve the problem. This paper proposes a re-evaluation of the author’s focus on informatics and suggests a move away from a technological “solution” based approach to a human behaviour-led approach that utilises the full potential of technologies to address important issues. To this end, this paper proposes a conceptual model to improve access, over and above clinical data, to health data.

INTRODUCTION

Data is the main currency within any organisation, especially within health services around the world. However, currency gains value when it informs the process of policy and service development that is appropriate, efficient, effective, and value for money.

For the purpose of administration, health services routinely collect monitoring and clinical data. Such data helps to forecast and plan population-based interventions, e.g. secondary care services that may be

DOI: 10.4018/978-1-5225-1674-3.ch002

required such as the number of hospital beds, number of operations, number of health professionals, for the following financial year. In other words, this data refers to morbidity and mortality after the event, to add insight into the process of morbidity or disease development decision makers often rely on funded projects and research studies.

Until recently data collection was paper-based and as such the method was designed to suit the medium on which data were recorded. Rapid advancement in technology substantially improved the collection and access to digitised data with a much increased capacity for data storage. Information technology (IT) opened up whole new horizons to be creative with data and enhance its value as a currency.

However, practice suggests that creativity may only be limited to the technology. For example, Pagliari (Pagliari *et al.*, 2007) explains that “HealthSpace (www.healthspace.nhs.uk/) is a secure online personal health organiser available to all patients in England. The system was initially launched in 2003 to store health notes generated by patients.” The system collects and stores administrative and clinical data selection and booking of hospital appointments; storage and charting of health indicators such as blood pressure, peak flow, or weight; a calendar with the option to generate email reminders; a database of NHS contacts; and links to online health information (Pagliari *et al.*, 2007). The system provides patients with access to their NHS Summary Care Record—a snapshot of the general practice record documenting allergies, adverse reactions, and drug treatment (Pagliari *et al.*, 2007). “Although HealthSpace will not provide access to detailed care records, clinicians can add data to the summary record with the patient’s agreement. Other features under consideration include allowing patients to enter their needs or preferences, such as for wheelchair access or translators; greater use of text and email alerting; and enhanced tools for patients with chronic disease. The link with NHSDirect Online (www.nhsdirect.nhs.uk) also offers possibilities for integrating electronic consulting and education in the future. Although HealthSpace promises a national solution to electronic personal health records, it will be some time before its full potential is realised.” (Pagliari *et al.*, 2007).

It seems that despite the level of advancement in IT and database technology and after allocating billions of dollars, creativity has been limited mainly to digitising the paper format. The heavy emphasis on intervention and clinical data has removed all concerns for converting data into valuable information to gain insight into the process of disease development (Shahtahmasebi, 2008). For example, the creation of electronic health records is testimony to the narrow and unwise focus of governments and health services decision makers; why spend billions of dollars to recreate what is already available? Furthermore, given the emphasis of the strategy on access to clinical/administrative data (Boonstra *et al.*, 2014; Garrety *et al.*, 2014; Soumerai & Avery, 2010; Waterson, 2014) for governments to go ahead with e-records is like reinventing the wheel!

It is claimed that the technology will lead to enhanced health maintenance and self-care, participation in decision making, better health and quality of life, improved quality of care including patients’ safety, and lower costs (Pagliari *et al.*, 2007). The main problem is that such statements are often made without any supportive evidence. It is plausible that the high level of technology integration is based on presumed benefits. It is not surprising that a technology solution based approach will be of limited application (Boonstra *et al.*, 2014; Buntin *et al.*, 2011; Coiera, 2011; Garrety *et al.*, 2014; Trisha Greenhalgh *et al.*, 2010a; Kellermann & Jones, 2013; Kidd, 2008; Waterson, 2014).

Even without access to millions of dollars, the questions of design should have considered other issues besides reproducing clinical data that is already available on a different platform. The design should have included the role of other actors such as the public, researchers, other disciplines, information and

communication technology (see (Shahtahmasebi & Liddell, 2011; Shahtahmasebi & Millar, 2013)). For example, an appropriate question may be “what database design can assist to enhance the value of data, i.e. convert it into useful information?” Such a question would have opened up the scope of the discussion and widened the focus to understand health before designing a limited database for clinical use. Ironically, a complex and expensive medium for an informatics system does not necessarily equate to a commensurate improved quality in information – information is as good as the data input into the system, e.g. the onus is on the health practitioners to record patients’ data (Garrety et al., 2014; Walsh, 2004). Most health informatics systems collect minimum clinical/administrative patients’ data, yet, governments around the world e.g. USA, Australia, New Zealand are pumping billions of dollars into the medium for storage rather than the needed information.

The motivation for a narrow focus may have been due to lack of a unified health information strategy and various governments submitting to the market forces giving rise to many different information systems which are incompatible with each other. Indeed, this question was raised in the meeting of the steering group on the ‘Health of the Nation’s targets on Mental Health’ and was adopted as one of the main guidelines on data collection ((Yorkshire Regional Health Authority, 1993), pp12). The guideline prescribed that the health service commissioners should develop a *unified* database by 1994 with particular reference to suicide. Despite the advancement in technology since 1994, two decades on, no such thinking has been developed into an information strategy (Shahtahmasebi, 2008; Shahtahmasebi & Liddell, 2011; Shahtahmasebi & Millar, 2013).

As with any decision making process, a major problem with IT in the health services is a lack of evidence. Improvement in health and administrative outcomes are often presumed and projected improvements are based on a misinterpretation of the capability of technology. In other words, technology can improve health care delivery because technology can offer tera bytes of storage in the form of a small computer disc and provide access to them within a fraction of a second from anywhere in the world, and perform millions of calculations per second. However, some studies suggest that there is a large gap between the perceived and empirically demonstrated benefits of e-health technologies e.g. see (Black *et al.*, 2011; Kellermann & Jones, 2013). Statements such as “if problems are addressed effectively then electronic records may improve...” (Pagliari et al., 2007) suggests major issues with the perceived application of technology to deliver appropriate and relevant information to stakeholders.

On the other hand, addressing the issues of designing a database will involve consideration of the dynamics of knowledge. As health care systems have become more complex in order to respond to all the health needs of the population, cracks in the system were identified and were attributed to resources distribution with rising demand, which in turn attributed to inequalities in health. The fable of the physician on the river bank may describe the problem more clearly, retold by (McKinlay, 1975), though attributed by him to Irving Zola:

“you know”, he said, “sometimes it feels like this. There I am standing by the shore of a swiftly flowing river and I hear the cry of a drowning man. So I jump into the river, put my arms around him, pull him to the shore and apply artificial respiration. Just when he begins to breathe, there is another cry for help. So I jump into the river, reach him, pull him to shore, apply artificial respiration, and then just as he begins to breathe, another cry for help. So back in the river again, reaching, pulling, applying, breathing and then another yell. Again and again, without end, goes the sequence. You know, I am so busy jumping in, pulling them to shore, applying artificial respiration, that I have no time to see who the hell is upstream pushing them all in.”

The Information Paradox

Thunhurst ((Thunhurst, 1982)) argued that we have spent too long measuring the flow of the river, the size of the fishing nets and the rate at which people are brought to shore. Health statisticians and health professionals need to refocus, Thunhurst further argues investigating the largely unmapped terrain upstream, particularly in solving the problem of differential class experiences of health.

In an earlier paper, Shahtahmasebi ((Shahtahmasebi, 2006)) argued that health services still rely heavily on downstream activities, thus health informatics are based on an illness having occurred. In other words, health informatics systems do not provide access to information prior to illness. The information is often gathered from ad hoc cross-sectional sample surveys which are then unwisely generalised about the population.

The principle of collecting information on morbidity and mortality as and when they present themselves in order to cater for the health needs of the population will lead to a reactive health care system. In other words, the health care system is reacting to cries of help from people in need of being saved but only reaches some of them and not all.

There is no doubt that mortality and morbidity data are essential to help with the planning and distribution of resources to deliver health care. However, without interrogating the data and asking the question “why”, health care systems remains ignorant of disease development and in particular how they could be more effective in preventing an outcome.

Today’s health care systems are far too big and complex, and governments around the world spend huge sums of money maintaining these systems. In the short term, maintaining is often all that can be done. Research and Development (R&D) funding and evidence-based decision making is often restricted to RCTs of specific treatments or to bring about a change in providing/withdrawing care. In other words, limitations and pitfalls of evidence-based medicine (Friedman & Richter, 2004; Kelly *et al.*, 2015; Timmermans & Mauck, 2005) is really a method of limiting services in the face of maintaining complex health care systems with limited resources and no knowledge of the upstream.

To illustrate this, consider the leading causes of death and mortality over the last few decades, such as heart disease, cancers, and suicide. Despite decades of rapid advancements in medical technology and investing billions of dollars to prevent them, these same diseases are still the leading reasons for mortality and morbidity. For example, transplant technology may add years to the life of a patient, but it doesn’t provide insight as to why and how disease was developed in the first place, and more importantly, someone else has to die in order for another patient to live longer.

Government agencies’ funding of poor research leading to ambiguities is, in part, responsible for focusing on the downstream in order to maintain a reactive health care system. Suicide prevention is a good example of a reactive system. Despite a growing body of work criticising lack of insight into suicide (Cutcliffe, 2003; De Leo, 2002; Institute of Medicine, 2002; Shahtahmasebi, 2003; Shahtahmasebi, 2005a; Shahtahmasebi, 2013), and discrediting psychological autopsies (Hjelmeland *et al.*, 2012; Shahtahmasebi, 2005a; Shahtahmasebi, 2013), and the fact that between two-thirds and three-quarters of all suicide cases do not come into contact with psychiatric services, decision makers insist on a policy of intervention in order to prevent suicide.

The suicide (or the information) paradox is that instead of finding a way of utilising the available data (e.g. from health services, education, social, justice) to explore suicide prevention, vast amount of money and resources are instead allocated to support poor research and information systems.

In the absence of information arising from relevant data a culture of short-termism has developed in which health services thrive on buzz words and phrases (Shahtahmasebi, 2008). Each buzz word symbolises a new strategy in the hope that it will last longer than the preceding ones. Of note are buzz words

such as “restructuring”, “streamlining”, “evidence-based” decision making, “intelligence” units, “public health observatories”, “targeting care”, “needs assessment”, and so on. If any one of these strategies worked well then the buzz words will no longer be needed. All these strategies have accomplished is to perform the same tasks as before but under a new name (Shahtahmasebi, 2008).

INNOVATIVE APPROACH

Informatics is essentially the collection and management of data in order to inform. There are two main aspects to informatics: information, and technology. An informatics system is effective only when it informs and adds insight about a process. Technology merely expedites the process and will have little impact on the quality and appropriateness of data. Information depends on the relevance and quality of data, appropriateness of analytical methodology, and interpretation. However, rapid advancements in ICT has led to sophisticated informatics systems, but such complexities have not led to commensurate progress in gaining insight from them – ICT is employed ineffectively to reproduce and report the same data, namely, routine morbidity and mortality data. To remedy the situation we must refocus our emphasis from what technology can do for our current data administration to how technology can be utilised to inform our processes.

The link between various processes and health is well documented and acknowledged, e.g. health outcomes have been linked to other social, educational and economic outcomes (Butterworth *et al.*, 2009; Holstein *et al.*, 2009; Shahtahmasebi, 2004, 2006; Shahtahmasebi *et al.*, 1992; Wagstaff, 2002). These relationships are often acknowledged but in the context of government policy the approach is disjointed and lacks continuity in developing government strategies for health and social care services. For example, the UK government acknowledged the link between socio-economic factors, e.g. employment status, and health outcomes in the UK’s mental health strategy (Department of Health, 2011), yet, there is no promise of a coherent information action policy. The main issue is how the policy statement of a causal relationship between poverty and mental health outcomes will be translated into relevant and appropriate policy actions? The public, social and political sectors responsible for policy development, implementation and monitoring social, educational and economic outcomes have their own information systems that are likely to be incompatible with each other. Unfortunately, when a tragedy occurs, the first outcome of a review is often for the various agencies to share information (e.g. see (ComputerWorldUK, 2010; NZHerald, 2015)). An effective informatics system should make the information readily accessible to all health professionals and decision makers. In other words, for health informatics to effectively inform health care planning and delivery, it should be able to communicate with the other sectors over and above multi-disciplinary research activities.

Although technology is sufficiently advanced to create a unified database most of the effort in translating access to information have concentrated on access to clinical information. For example, the recommendation and development of e-records by various governments such as the UK, Australia, USA, New Zealand and Canada will ultimately lead to e-health (Whetton, 2005), which may encourage a move towards self-treatment ((Stevenson *et al.*, 2003), also see <http://computerworld.co.nz/news.nsf/management/health-it-board-drafts-e-health-plan>; or, <http://www.who.int/goe/ehir/2010/24-august-2010/en/index.html>).

The main issue here is that, in terms of information, we may have improved access to numbers, rates and ratios of morbidity, mortality and possibly other events such as administration of a treatment e.g.

The Information Paradox

type of medication, surgery, but we do not have any ideas or information about the competing forces in society (as shown in Figure 1) on health-related behaviour. As an example, consider smoking behaviour and suicide. Smoking is considered a major cause of morbidity and mortality yet, despite the restriction placed on the sale (including advertising) of tobacco, taxation regime and prohibition of smoking in public places, people continue to smoke. It seems that the single message of “smoking kills” on its own is not sufficient, which may be a feedback effect of an advancing medical technology e.g. the expectation that the cure for heart disease and cancers, in particular lung cancer, is not too far away. Other competing forces include the tobacco industry and the media’s portrayal of smoking constantly exposing the public to smoking often disguised as “a fact of life”, “art”, “entertainment”, and public interest (for a discussion of such issues see (Shahtahmasebi, 2007)).

As mentioned above, technological advancements to improve data access has not led to commensurate improvements in data. For example, data held in health informatics system on suicide does not contain additional information over and above number of deaths and hospitalisation which can make health care planning a hit and miss process (Shahtahmasebi, 2013; Shahtahmasebi, 2014). Any “hits” may be the temporary feedback effect coinciding with the effects of other competing forces. To illustrate, consider the suicide report issued by Doncaster PHUI on their web page (Doncaster PHUI, 2003). Once again the same data (i.e. rates and ratios by sex, age and groups) are presented graphically and a description of

Figure 1. An example of a conceptual model of smoking (Shahtahmasebi, 2006)

the graphs (highs and lows) is given. This report, however, takes an extra step of looking into the claim that a pain killer (co-proxamol) had been a common method of committing suicide. Therefore, in 1998 attempts were made by the Doncaster Health Authority to reduce access to this drug. The report presents a graph of superimposing the rate of prescriptions of co-proxamol on the number of suicides using co-proxamol and makes a tantalizing projection that such a policy may have had a significant effect on reducing suicide ((Doncaster PHUI, 2003), page 8). The report does not take into account the fact that there were the same number of suicides in 1995, 1996 and 1997, when the prescription of co-proxamol was at its highest, as that in 1999 and 2001 after the reduction in prescribing co-proxamol. By the same token, a policy of removing access to a method of suicide may have had an effect on suicides using that method but there is evidence to suggest that suicide victims do switch to more violent methods to ensure successful completion (e.g. see (Shahtahmasebi, 2005a, 2005b)). To conceptualise suicide prevention, in Figure 1 smoking is replaced by suicide.

Neither health and social outcomes nor resources are static. Health informatics that is too focused on clinical outcomes will, on average, only serve a particular group, namely, some of those who happen to fall ill. This approach has prevented us exploring 'upstream' and has made sure the progress remains 'downstream'. For example, as a result of clinical successes in making organ transplantation fairly routine, social expectations have changed accordingly; the public are expected to automatically become donors. On the other hand, those in need of a transplant may be praying for a donor which is ironic as it means someone else must die for a transplant organ to become available. The feedback effect leads to a perpetual cycle of more intervention e.g. cloning designer organs for transplantation.

Clearly, it is not possible for one service provider to design and collect information on a massive scale as conceptualised in Figure 1. Certainly, I am not proposing that health services around the world develop complex IT systems. What I am proposing is that the authorities go beyond their buzzwords invented to gloss over the reinvention of the wheel such as "intelligence" units, observatories, neighbourhood building block, 'Health of the Nation Targets' and so on. In other words, if we do not put meanings into each buzzword the buzzword is a lost opportunity. For example, in the early '90s when the UK Government announced targets on mortality and morbidity rates in its 'Health of the Nation Targets' strategy (Department of Health, 1992), health authorities and districts in England and Wales translated the strategy as a target setting exercise and converted national targets into local targets! Thus an opportunity was lost to explore 'upstream' and develop prevention plans that reduce the need for intervention and thus holistically achieve national or local targets. As it was, most of the discussion around achieving targets was focused on administration and possible interventions.

We need to understand that we need information *not* only to calculate targets on mortality/morbidity rates, budgets and costing of services for intervention, but in order to develop sustainable and effective services we need to gain an insight into disease development. We need information from other processes. Theoretically, given the advancement in ICT, this is not impossible or difficult to achieve.

In order to refocus on what constitutes appropriate data we need to re-evaluate our view of routine data. In the UK the NHS and other agencies routinely collect information in various formats e.g. from qualitative and textual reports such as health visitors' records to minimum data sets and hospital records. From these records it should be possible to gain factual and objective information on the population from birth to death. Apart from the quantitative hospital records and mortality data, almost no other NHS records have been utilised (see (Shahtahmasebi, 1997)). It is plausible that until recently there were technical issues with utilising such records. However, the technology is now available, e.g. powerful palmtops with cell phone technology and networking capability.

It must be first recognized and acknowledged that appropriate information is necessary for any sustainable policy development. One of the features of the conceptualisation in Figure 1 is an understanding that data from various processes is essential. It can then be conceptualised that in order for the model to work data must be allowed to flow between processes. This means the depoliticising and sharing of data. Most countries now have IT systems for the monitoring of health, social, education and economic outcomes. A unified database could be in the form of a *virtual* warehouse, acting as a buffer or filter, providing access to *more* data collected at various stages of life.

Assuming that the technology can be utilised to accommodate privacy and confidentiality requirements, there are two immediate benefits for clinical practice and research. The virtual warehousing can be used to generate aggregate and anonymous multi-level population based data for research, be it a pilot or feasibility study, in order to explore and assess a broad issue or test developed hypotheses using appropriate modelling methodologies.

The second advantage is that individuals can be given an access key (such as National Insurance Number) to access all information held on them. This facility can be extended to provide further information in the form of responding to online voluntary update forms. Perhaps the greatest gain will be in the clinical practice where health care professionals are able to access primary care records (GPs, public health nurses, health visitors, etc) as well as hospitals, and socio-economic and education parameters. However, access to all records may not be appropriate for every health/social professional, and access to all information may be provided by the individual. On the other hand, an ability to have an objective life events history complemented by the patient's own recounting will be an important tool in predicting and preventing or modifying health-related behaviour, e.g. suicide and self-harm, obesity and smoking.

CONCEPTUALISING A UNIFIED DATABASE

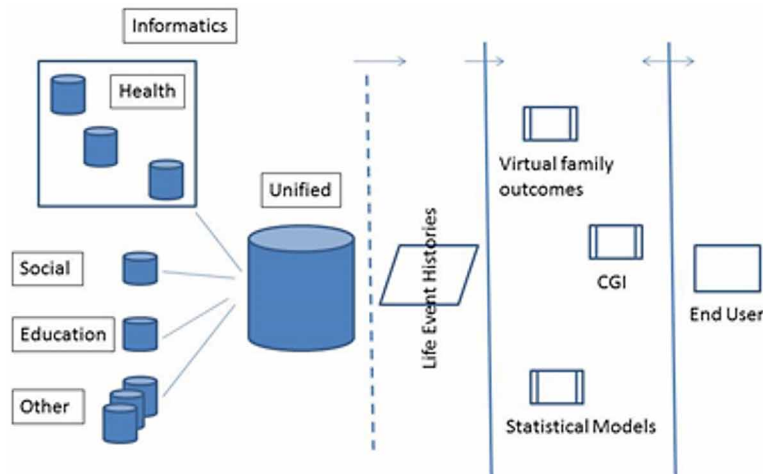

Table 1 provides an example of routinely collected data that, when complete, can provide upstream data. Together, the data collection systems have the potential to provide life event histories for any individual. The major issue here is that these data collection systems are not linked and do not communicate with each other. It is possible that data collection systems are often purpose-built and designed independently. Nevertheless, most data systems will have a common unique individual identifier(s) that can be used to link data systems together. In an ideal world databases would have been part of the same design and by default would have been linked so that upstream data may inform the planning of downstream activities (clinical interventions). Whilst, we do not live in an ideal world, given the vast advancement in hardware and software technology, we can conceptualise a unified database that is populated with data from different sources.

As shown in Figure 2, a virtual mega database could be conceptualised to provide access to life history events including health, morbidity (hospital records) and mortality records for professional practice, and, anonymised and aggregated life histories for research. We do not propose to re-invent the wheel by insisting on another physical database such as e-records. The unified database could be a set of communication software protocols acting as secure gateways to other databases, or, it can be a virtual database which is populated from other databases via communications software protocol. As suggested earlier, health and social outcome data and life event histories are already available from different sources and in different formats. The technical issues in this scenario will relate to the architectural design of the database (or interface) and thus populating it with anonymised life history records.

Table 1. An example of available data systems and routinely collected data

Data exist because of incidents of ill health		Data exists because of reporting checks and monitoring	
Ill-health data systems	Data Items	"Qualitative" Health data systems	Data Items
Patients records	e.g. unique identifier, personal details, diagnosis, treatment, referrals, ...	Midwifery records	e.g. unique identifier, personal details, baby's nutrition, weight, height, problems and issues,...
Hospital records	e.g. unique identifier, personal details, diagnosis, treatment, hospital identifier, specialists, referrals, ...	Nursing records	e.g. unique identifier, personal details, nutrition, weight, prenatal and postnatal monitors, problems and issues,...
GP records	e.g. unique identifier, personal details, diagnosis, treatment, referrals, ...	Monitoring records	e.g. Screening records (e.g. breast and cervical), routine check-ups (e.g. heart),...
Mortality records	e.g. unique identifier, personal details, cause(s) of death,...	Other records	e.g. Education records, Justice/police records, social and employment records,...

Figure 2. A conceptual model of a unified (health) informatics

Of course the records will have to be linked perhaps via a unique identifier code such as a National Insurance number or social security number. It is possible to conceptualise a unified database in terms of access to anonymised life histories which are linked by a unique identifier. The basic structure of a unified database will be a 'hub' that is enabled to communicate with other available databases and run queries on them. The hub will be software interfaced to perform basic as well as complex time series

statistical modelling. In both scenarios, the ability to communicate in real time will need to be considered in order to help health care professionals make informed decisions.

In addition, the ability to communicate in real time will address the criticism of various health, social and justice agencies for repeatedly failing to share information, which will be a major benefit of a unified database. For example, often a lack of communication and sharing of information between different agencies is blamed for failing to prevent a tragedy such as death due to suicide or child abuse. Because, operationalising an appropriately designed unified database, any concerns raised by a care service provider (e.g. hospital) will be immediately flagged and seen by another (e.g. social services, police).

Obviously, there are many issues that are relevant for the design and architecture of a database, such as ethics (privacy and confidentiality), resources, stakeholders and access, will need to be identified and resolved. Clearly, issues necessary for creating a unified database such as design, ethics and so on are large scale research projects in their own right.

POLITICS OF INFORMATION

Although, society responds well to technological gadgets and is enthusiastic about technology, its application in public administration is resource intensive, politicised and is challenged with legal and ethical issues including privacy and confidentiality. In the UK, during 1993-4, a proposal for the analysis of hospital records to utilise the added data item 'social class' did not proceed because the data item 'social class' had not been populated with relevant values. The high missing values is not surprising as an exploratory analysis of such records suggested that professionals, on average, reported statutory minimum clinical data requirement. In an evaluation study of the English e-records system (T. Greenhalgh *et al.*, 2010b) a lack of compliance with reporting on all the data items, ethical considerations, skills gap, experience and knowledge of the systems in use, shortage of resources, immediate and free access to an informatics station, are some of the issues raised as barriers for the full utilisation of the e-records.

The shift towards a technology-based culture may reinforce barriers to the utilisation of new informatics systems. For example, at the Health Informatics New Zealand (HINZ) Conference in 2010, speakers and delegates commonly described the available technologies such as smart pens, smart pads, e-health and mobile technology as solutions. In other words, we can now define, or, perhaps create a problem/market for which there exists a 'solution' in the form of a device. By the same token, the fact that we have lots of 'solutions' suggests that, as mentioned earlier, the technology is no longer an issue but its applications are.

However, most 'solutions' appear to address clinical administration e.g. improved and fast access to patients' records, reduction in human error, and accounting. Given the extent of the technological advancement in hardware and software we ought to have, at some point, asked ourselves why stop with 'solutions' for administrative aspects of health care while there are questions that can be investigated? In other words, technological solutions must be human behaviour-led (evidence-based) and not the other way round. This approach can also assist to overcome some of the barriers in the full utilisation of technology.

On the other hand, under a human behaviour-led approach barriers can be conceptualised as opportunities in developing more socially acceptable 'solutions', see Figure 2. In other words, the inclusion of human and social parameters in the process of developing technology and informatics systems at the concept stage will enhance the decision making process and its outcomes, see Figure 3. Indeed,

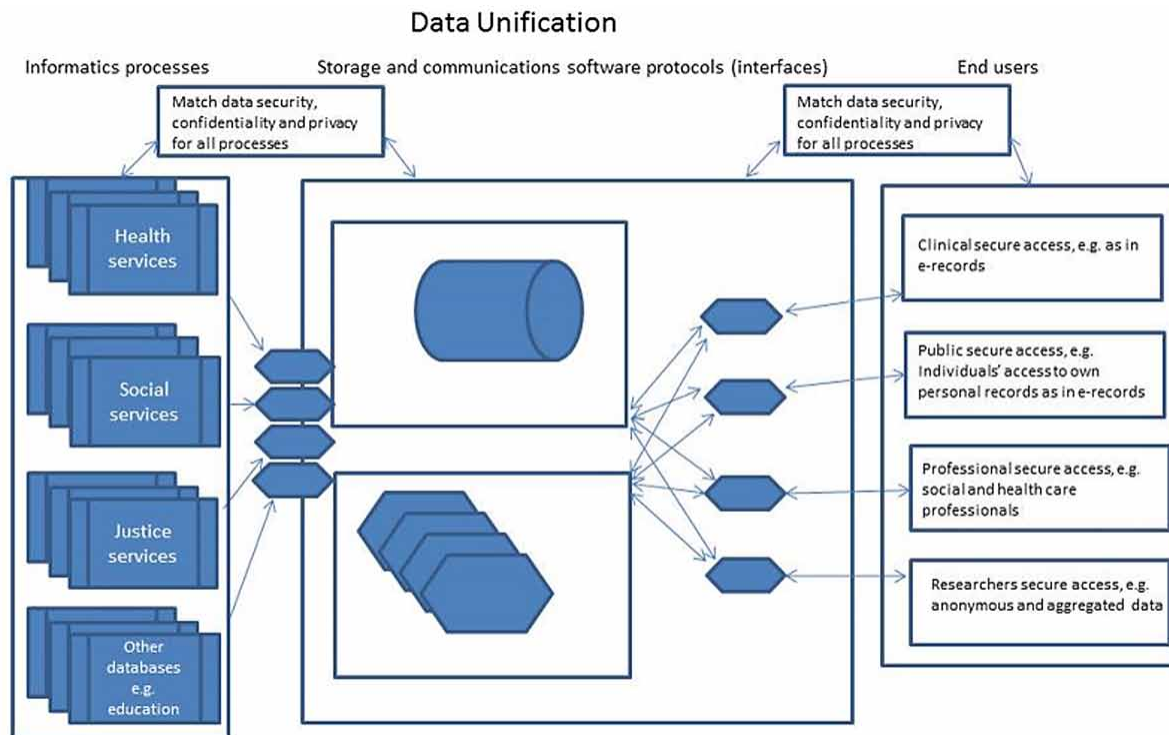

conceptualisation considers barriers as part of the solution by assuming they are processes in their own right, and, processes are dynamic by nature. Thus barriers become multi-disciplinary research projects to inform the process of defining a unified database and its functions.

CONCLUSION

Ironically, the problems and issues discussed in this paper, including failing to prevent tragedies because different care agencies fail to communicate, were supposed to be resolved through major IT strategies both at government and agency level. The various strategies may have actually contributed to more complexities while addressing the digitisation of data. Due to market forces health care providers may have opted for the IT systems that met their IT strategy for their budget, e.g. value for money. A unified IT strategy approach would have been far better so that all care agencies are invited to subscribe to the same purpose-built and designed data collection system. This approach would have reduced variability and facilitated communication between systems.

However, as part of an IT strategy, some care agencies attempt to improve access to information. For example, with some systems mortality or morbidity (hospital records) data and appropriate population files can be queried through the organisation's network. This solution can only provide a snapshot of past mortality and morbidity in the context of a population. There is still no sign of a unified database,

Figure 3. Conceptualising the informatics processes

despite health outcomes being linked to variations in social, economic and environmental circumstance (Butterworth et al., 2009; Holstein et al., 2009; Shahtahmasebi, 2004, 2006; Shahtahmasebi et al., 1992; Wagstaff, 2002), and the cumbersome methods of combining hospital data with data from other sources.

Although meeting the challenges of utilising different datasets can be exciting and satisfying, the question arises yet again: why is health data from the same organisation administered and stored in different sources, some of which are incompatible with each other? Indeed, this was raised in the meeting of the steering group on the 'Health of the Nation's targets on Mental Health', former Yorkshire Regional Health Authority (UK), and was adopted as one of the main guidelines on data collection ((Yorkshire Regional Health Authority, 1993), pp12). The guideline prescribed that health service commissioners develop a unified database by 1994 with particular reference to suicide prevention.

Although it is apparent that routinely collected data such as mortality and hospital records may be readily accessible, it is more difficult to access primary care data such as GPs and nursing and social care records. Nevertheless, data is routinely collected by the various care organisations and their internal departments but the various data or information systems do not communicate with each other in terms of the flow and sharing of data. Whether the blocking issues are political so that each department is viewed as a separate entity to perform a certain task, or incompatible technologies, or a combination of processes, it is, nevertheless, possible using the current information technology to create a multidimensional flow of information. An important implication is access to additional data/information from publicly funded projects (e.g. medical and health research councils, government departments, research and development). These projects may be linked to the virtual warehouse in a multi-way flow of information, to some extent, to fill the current and future gaps in data and research. The concept of a holistic approach to inform the process of policy formation is the subject of a proposal currently being developed by the author. Therefore, it is difficult to prejudge the outcomes in terms of strength and weaknesses. However, the idea of a holistic approach is to create a flexible policy that can respond to the short-term needs and is sustainable to respond to future needs. The limitation or weaknesses associated with such an ideal 'framework' are the complexities associated with human behaviour (e.g. Politics, conflict and politics e.g. see (Irestig & Timpka, 2007)), methodology (e.g. see (Pilemalm & Timpka, 2007)) and costs. On the other hand, assessments of a flexible policy, at least theoretically, could lead to the projection that sustainable policies may be more economical over time as the need for short-term expenditure will be greatly reduced.

The intention of this paper is to highlight the shift away from evidence that has coincided with technological advancements in the light of a heavy emphasis on "evidence-based" decision making. Of course, it is good to know that one can find data at a touch of a button and through fast access to the internet, but this feeling would soon change to frustration when data is insufficient, irrelevant and inappropriate. On the other hand there are a number of specialty longitudinal databases such as the longitudinal census and FACS (the Department of Work and Pension's Families and Children Study). As discussed in this chapter, analytical methodologies are equally as important as the research methodology to translate data into information (e.g. see (Emerson *et al.*, 2008)). Although, the creation of longitudinal databases is a step in the right direction, given the technological advances to date, the political will towards a unified database is still well out of sight.

Chapter 3

Health in MENA: Policies for Inclusive Development

Randa Alami
University of London, UK

ABSTRACT

This chapter argues that health is an essential pillar of growth, and that ensuring Universal Health Coverage is a key pre-requisite for equitable and inclusive development. MENA health systems are far from meeting this challenge, because of clear developmental failures and lack of political will, not to mention wars. At present, MENA health systems are fragmented, inefficient, and deficient, delivering often mediocre, urban centered, tertiary care. They exclude large swathes of the population, particularly the poor, resulting in persistent disparities and inequities. Because of privatization, the neglect of public health, and defective social protection, MENA citizens shoulder some of the highest financial burdens amongst developing regions, which worsen and deepen poverty. To meet its health challenges and achieve inclusive development, governments need to revamp their public health sectors, and play a more central role in protecting the poor and vulnerable. MENA must invest in health, equity and development.

BACKGROUND AND INTRODUCTION

Mainstream macroeconomic views of Middle East and North Africa (MENA)¹ continue to depict the region as benefitting from significant historical improvements in health and education delivered by its old social contract, though concerns may be voiced about inequalities of outcomes or about the quality of public goods and services.² However welcome, achievements in health outcomes (e.g. life expectancy) are not exclusive to MENA: they are displayed by most middle income countries. Since the 2001 report on *Macroeconomics and Health*, it has been shown that national health indicators in these countries cannot be used to draw any firm conclusions about health or of health systems.

In MENA's case, such limited macro-level analysis focused on a few "visible" outcomes is incompatible with three bodies of evidence. Firstly, the upheavals associated with the Arab Spring exposed with widespread dissatisfaction with the status quo and many structural problems, including pervasive inequalities and deficient social protection mechanisms. In this context, Alami and Karshenas (2012)

DOI: 10.4018/978-1-5225-1674-3.ch003

argue that: the region suffers serious deficiencies in health; public resources allocated to the sector were typically below international norms; and many people were being left behind because of waning government commitments. Earlier, Salehi-Isfahani (2010) and El-Laithy (2011) noted an increasing shift from the principle of universality to the ability to pay. Secondly, since the late 2000s, a spate of sectoral studies, typically based on household surveys, noted deficiencies and inequities in access to and delivery of healthcare. Thirdly, World Health Organisation (WHO) country and regional reports³ point to systemic problems if not widespread crises.

Arguably, the question is not whether health outcomes improved historically, but why there are still so many failings, and why do improvements continue to elude many people. The aforementioned macro-approach recognises there has been non-inclusive growth in the region, but is unable to relate it to these problems, and has little to say about unmet needs or relevant public policy. That would require looking at health in a more meaningful way that would, *inter-alia*, reflect its centrality to both development and social justice. Using this perspective, this chapter proposes a more relevant diagnosis whose policy recommendations are compatible with sectoral evidence. It shows that MENA health systems face a double whammy of not coping with current needs or with the looming epidemiological transition to Non-Communicable Diseases (NCDs). It echoes the sectoral call for action, arguing that MENA countries need to reverse the neglect of public health sectors, address the structural deficiencies that underpin the observed inequities, and work towards Universal Health Coverage (UHC). The latter also means addressing other aspects of public policy, particularly extending social protection to the poor and vulnerable.

To demonstrate its case, the chapter proceeds as follows. Firstly, in the next section, it traces the rising importance of health equity and of UHC. UHC aims to provide to key promotive, preventive, curative, and rehabilitative health interventions for all, at an affordable price (OECD, 2013; Stuckler *et al.*, 2010). It then demonstrates the considerable convergence between UHC and an inclusive growth (IG) strategy, the former becoming a barometer for success in health policies. The third section applies these approaches to MENA. It shows the deficiencies in health outcomes and systems, and traces the retreat of public health spending in the region. The fourth section outlines the financial burden of healthcare and consequences of ill health in MENA. A key result here is that Out of Pocket spending (OOP) on health in MENA is perhaps the worst amongst middle income countries. The fifth section categorises these deficiencies and placing them in an international context, while section six outlines the political economy that led to this neglect, and derives policy suggestions. The last section concludes, stressing the need to go beyond health targets, and the need to put back development, equity, and inclusiveness into political priorities.

HEALTH, EQUITY, AND DEVELOPMENT

All Roads Lead To Universal Health Coverage

Until recently, mainstream economics tended to view health and health improvements as a by-product or natural consequence of income growth. This approach to health was strengthened by the dominance in the 1980s and 1990s of the Washington Consensus (WC), which tended to belittle the importance of public health interventions and of the public sector in healthcare. In that framework, health was at best an item of public expenditure that merits ring-fencing. Improving the financing of healthcare systems

and catering for unmet needs were to be done by championing the private sector, and by improving efficiency and cost recovery.

This narrow treatment of health was not uncontested. Amartya Sen's work, rooted in his capabilities approach, had a seminal influence in restoring the importance of health for both individual and national development, and in highlighting its direct relation to poverty.⁴ Furthermore, Anand and Ravallion (1993) show that far from being a by-product of growth, two thirds of the achievements in well-being (life expectancy) could be distinctly attributed to public spending on health, whereas the rest came from poverty-reducing income growth. Sen (2004) went on to add that health achievements need to be related to: resource allocation; fairness in process and access; the way social arrangements undermine or support health equity and the health of the deprived.

At the same time, a large body of literature was arguing that the importance of health and health investments for growth were grossly underestimated, this being captured by the 2001 report on *Macroeconomics and Health*. The Report further noted that despite life expectancy in middle income countries reaching over 70 years, these still faced significant health challenges. The key issue for them was to build well-structured systems that reached the poor, and UHC is the best strategy to do so. A UHC strategy is centred around three policy axes:⁵ to cater for unmet healthcare needs and manage disease burdens by relying on good quality public healthcare, including primary; to work on pooled schemes to deal with the associated financial burdens.

Conversely, compelling evidence was emerging about the presence of “medical poverty traps”,⁶ whereby health spending, particularly in emergencies, pushes people to fall into or stay in poverty. This helped to raise the alarm about the burden of healthcare costs, and spearheaded a large body of WHO-led investigations into OOP.⁷ At the same time, the WC was beginning to acknowledge the importance of equity in economic growth.⁸ As argued by Elgazzar *et al.* (2010), both streams contributed to the proliferation of research into health inequity.

All these arguments pushed the policy pendulum in favour of equity-oriented health sector reforms and of strengthening public health. The WC-inspired budgetary cuts and retreat of public health sectors began to be reversed with the launch of the Millennium Development Goals (MDGs) in 2000. With four main goals dedicated to health,⁹ the MDG process did much to commit national and international resources for health. Together with the Sachs report, they helped to establish an international consensus on UHC, leading to the adoption of a UN resolution in December 2012.¹⁰ The World Bank has now added its institutional weight behind this campaign “...to achieve universal health coverage, with the aim of providing quality, affordable health care to everyone—ultimately improving health outcomes, reducing financial risks associated with ill health, and increasing equity”.¹¹

Health, Inclusive Growth and Development

Just as our understanding of health has evolved towards integrating the consequences of ill health and the determinants for health inequities, Inclusive Growth (IG) has also grown in response to persistent developmental failures and/or socio-economic exclusion in spite of income growth. IG shares the same intellectual drivers as those in the debate on equity and health, and is now a vast field that covers a multitude of conceptual approaches. These differ in their emphasis on: achieving income growth while reducing inequality, improving social opportunities, ensuring equality of access, and protecting the vulnerable. A fairly representative definition of IG is: it is growth that grants equal access to income growth, reduces disparities, and involves “disadvantaged-reducing improvements in non-income dimen-

sions of well-being” (Klasen, 2010, p. 3). IG frameworks also typically require the poor to be the main, but not the only, beneficiaries of growth, and that growth improves income poverty (OECD, 2013). In both senses, IG is about inclusive development.

The IG literature is also clear about the importance of public policy. It places particular emphasis on investments in public services to support human capabilities, and on the mitigation of risks via social protection. However, there are substantive differences in the literature about the role assigned to actors (state vs. market forces), and in policy recommendations. Thus, protecting the vulnerable means targeting and social safety *nets* in Post Washington Consensus (WC) analysis, but means universality and social protection *floor* for UN agencies.

As health is crucial aspect of equity, development, and growth, health enters IG frameworks in three major ways:

- In its own right;
- As a pillar of equitable growth (both at the micro and macro levels); and
- As key to the ability to participate in the economy.

Health also matters for IG because it matters for poverty reduction, since poor health can compromise the acquisition of both human capital and income, thereby perpetuating poverty. In that sense, IG is echoing Sen’s work, re-emphasising the need to improve income and well-being simultaneously. Arguably, IG is converging towards the aforementioned consensus on an equity-oriented view of health.

These considerations suggest that there are three key policy components to an IG strategy: improving health outcomes for all, reducing inequities in the use of and access to health services, and reducing the financial barriers to and financial consequences of healthcare. Therefore, success in and attention to these policy areas become important barometers of inclusive developmental strategies. The most direct expression of health dimension of IG is that of the OECD (2013): growth is inclusive to the extent that it leads to better health statuses *and* declining inequities in access to health services. In OECD (2011), monitoring the inclusiveness of health involves a wide range of indicators, such as cancer screening, waiting time for elective operations, etc.

The fact that health and health equity remain important for participatory growth and social justice in rich industrial countries, suggests even more pressing importance for developing countries (DCs). Applying this approach here implies going beyond national indicators, and tests the inclusiveness of growth by asking the following questions:

- A. Has growth led to better health outcomes for all?
- B. Have the provision, delivery, and access to healthcare improved?
- C. What has been the impact on the poor and on poverty reduction?

Despite strong conceptual foundations, in practice, the success of IG in incorporating health has been mixed. Monitoring outcomes, access, and provision, is weakened by an often mechanical use of key indicators. Despite facilitating cross-country comparison, these indicators, like MDGs, are plagued by problems of relevance (e.g., monitoring malaria where diabetes is more important) and by their inability to pick up problems of quality and equity. Hence, it is not just the number of doctors that matters, but also their distribution and quality of their training and of the treatment they offer. All these are considerations that are being actively discussed, including by MENA, in the context of Post-2015 Development Agenda.

For example, a recent study of MENA (FEMISE 2014), builds on the methodology of the Human Development Index and on the Asian Development Bank's work on IG. It presents an IG index, which is the geometric mean of standardised values of different indicators grouped into seven pillars, one of which being health. The health index is based on indicators of: public health expenditure in GDP, life expectancy, child mortality, tuberculosis (TB) rates. This analysis picked up low levels of funding for public health in Morocco and Egypt, and the poor performance of Yemen. However, most countries have similar levels of life expectancy, and have overcome TB and other communicable diseases, resulting in similar scores. Similarly, the IG index includes indicators for water and sanitation, both crucial for health and human development. But these indicators have severe limitations, ignore problems of cost and quality.¹² Therefore, these indicators and the IG index paint an overoptimistic picture of health and of the inclusiveness of growth in MENA.

More successful results have been obtained by research using disaggregated and survey data, or indicators of spatial distribution of health services, or of the use of services by income quintiles. Such information is more useful for gauging the inclusiveness of an IG process, potentially leading to more relevant policy directions. For example, a stylized fact in DCs is that maternal and infant mortality rates can be 3-10 times higher for poorer women, especially in remote areas. Policies to reduce these rates are different from the ones based on an average figure influenced by the outcomes of the rich quintiles. An example is the study by Tandon and Zhuang (2006). It uses spatial data from both Chinese micro surveys and data from WHO surveys to highlight inequalities in health outcomes across China, arguing that while large income gains have resulted in significant improvements in health outcomes, inequalities undermine the inclusiveness of China's growth, and therefore need to be addressed directly.¹³

Finally, though many IG frameworks analyse social protection, they rarely consider health protection. Likewise, the literature has typically overlooked the financial burden of healthcare and its impact on poverty. However, this dimension can be easily incorporated by looking at OOP, and the proportion of households who fall into poverty, or for whom health outlays have "catastrophic" consequences. Healthcare payments are considered "catastrophic" for households if they take up on average 10% or more of their total expenditure (the international range being between 5-25%) (Elgazzar *et al.*, 2010). Examining OOP and the nature of catastrophic health expenditure (CHE) allows us to detect the impoverishing and disqualifying effects of health spending, as well as any deterrent effect on utilisation (Abu-Zaineh *et al.*, 2013).

Implications for Analysis

So far, this chapter argued that an IG strategy is relevant for MENA because it can help to address key problems MENA faces, namely the needs to: improve health outcomes for all; reduce inequalities in the use of and access to health services; and reduce financial barriers to and consequences of healthcare spending, particularly for the poor. Therefore, it extends existing studies in a number of ways.

Firstly, it goes beyond health outcomes, and uses a disaggregated level of analysis and more relevant set of diagnostics. Secondly, it does so in the context of the WHO framework whereby *outcomes* (health statuses, equity, public satisfaction) are the results of systems of *delivery* (proxied by access and quality indicators), these themselves reflecting the underlying *structural aspects* (financing and infrastructure) (Stuckler *et al.*, 2010). Thirdly, it complements the sectorial assessment with a look at the financial burden of healthcare and the availability of social protection. Lastly, it adopts a thematic emphasis on equity in health, which also means putting overall policy direction in the context of progress towards UHC.

HEALTHCARE IN MENA: STRUCTURE AND FINANCING

Statuses and Outcomes

From the standpoint of the 1960s or even later, there have been improvements in national health outcomes in MENA. The region has eliminated many major communicable “Type I” diseases and epidemics, except perhaps in Yemen, Iraq and now Syria, where some major diseases have reappeared.¹⁴ In most MENA, life expectancy has been over 70 years since mid-2000s. These indicators place most of these countries in the UNDP’s category of medium human development. However, closer scrutiny reveals serious and persistent problems

Firstly, progress has tended to stall or slowdown in recent years. The region’s average maternal mortality rate may be better than Africa, but is only at par with Latin America, and most countries are behind Turkey, China, or Sri Lanka (see Table 1). Secondly, there continues to be clear differentiation of outcomes by income levels: indicators are twice to four times worse for poorer income quintiles than for richer ones. This trend is also confirmed by surveys and occasional studies,¹⁵ which also document the widespread persistence of regional disparities. In most countries, poorer and rural women and children display health outcomes that were reached by top income quintiles ten years ago, *clearly not an inclusive process*.

Table 1. Arab countries: Basic health indicators, 1990-2013

	Life expectancy (years)			Maternal Mortality Ratio			Mortality rate, under-5 (per 1,000 live births)		
	1990	2000	2012	1990	2000	2013	1990	2000	2012
Algeria	59.6	70.0	70.9	220	120	89	67.6	34.7	20

In particular, Algeria boasts that its maternal mortality ratio (MMR) of 97-100 per 10,000 in 2010 is above African averages.¹⁶ Yet it is only at par with poorer Morocco and worse than Syria's. This ratio is also high given that most births in Algeria are said to be attended by skilled staff, raising serious questions about the quality of care. As clear from any field visits, the under-provision and poor quality of maternal health care is a major deficiency of the Algerian health sector. According to IPED (2012) and the latest WHO report, this situation has been going on despite a major inquiry into the problem in 1999.

Similarly, improvements in Tunisia's maternal health outcomes are unevenly distributed. In 2002-2006, the rates for unassisted deliveries stood at 5.4 nationally, 11 in rural areas, and a high of 22-29 in the underdeveloped areas. The corresponding levels in 1994 were respectively at 15.8, 30.6, and 34 (Boutayeb & Helmert, 2011). Similarly, in Morocco, in 2010, the national, urban, and rural MMRs stood at 112, 73 and 148 respectively, while medically assisted deliveries *in urban and rural areas stood at 94% and 57%* (Haut Commissariat du Plan, 2013). Yet the latter had seen an improvement from 18.75 to 45% in five years thanks to the provision of lodging and infrastructure to personnel in disadvantaged regions (Elgazzar *et al.*, 2010).

Survey data confirm a similar pattern of uneven and unequal outcomes in child health (see Table 2). The proportions of underweight children are relatively low in MENA, but child stunting remains a significant problem in Egypt, Morocco, Syria, and Yemen. Furthermore, outcomes are mostly worse amongst poor quintiles: children in poorest quintiles in North Africa are 3 to 5 times more likely to die (Boutayeb & Helmert, 2011, pp.7-9). Similarly, Assaad *et al.* (2012) highlight inequalities in outcomes and opportunities in child health in Egypt, Jordan, Tunisian and Turkey. They find that total inequality and inequality in opportunities only clearly improved in Turkey, the country with the lowest health differentials amongst children.

Table 2. Health indicators by income groups in Arab countries

		Births attended by skilled health personnel (%)		Urban Under-five mortality rate (%)			Underweight prevalence in children under 5 (%)	
		Poorest 20%	Richest 20%	Poorest 20%	Richest 20%	National	Poorest 20%	Richest 20%

Clearly then, MENA has *not* continued to improve basic health interventions, nor has it been improving their quality or extending them to all the population. Further, the lingering focus on vaccinations and indicators of Type I diseases means that MENA systems are not responding to the epidemiological transition to NCDs (cardio-vascular and mental diseases, etc.).

Provisions and Structures

Human and Physical Infrastructures

MENA health infrastructures can be described as biased towards tertiary care and large hospitals (Femise, 2009; El-Laithy, 2011; Kronfol, 2012a, 2012b), with services and workforces concentrated in urban areas and amongst richer income quintiles. As shown in Table 3, in terms of hospital beds, except for Yemen and Iraq, the number of beds in most countries is in the range of 1.4-2.4 beds per 1,000 displayed by middle income countries, but below the rates for China, Sri Lanka, or Brazil. The national bed/population of 3.6 in Lebanon has a highly skewed distribution: bed capacity is concentrated around Beirut, where the ratio is 7 (Salti *et al.*, 2010). In Morocco in 2005, the ratios of private practice per population

Table 3. Key health infrastructure indicators per population

	Bed/1000 people (1)	Physicians (2)	Primary Health Care units or centres (3)

Egypt (2005); Libya (2011)

were 1 per 3,057, and 1 per 59,561 in urban and rural areas respectively (IPEMED, 2012). Access to facilities is further fragmented according to status. For example, in Lebanon, most beds are available only to private or insured users. In Jordan, *19 percent of bed capacity is reserved for the military and their families* (Ajlouni, 2011).¹⁷

The regional literature and country reports leave little doubt about another feature of health systems in MENA:¹⁸ the private sector has become a key provider of health infrastructures and services, even in public-led systems like Jordan or Tunisia. In Tunisia, in 20 years only 3,000 public beds were added, allowing the private sector to expand its share to 12.5% in 2008. Further, modern diagnostic equipment are concentrated or only available in private facilities (IPEMED, 2012; Abu-Zaineh *et al.*, 2013). In Jordan, private hospitals account for about a third of bed capacity, but the occupancy rate is low (below 50%). Similarly, WHO data show that except in Iran, the availability of generic medicine is distinctly higher in the private sector at 70%-98%, vs 28%-64% in the public sector.¹⁹

In terms of health workforce, Table 3 shows that only three countries have more than 20 physicians per 10,000 people. Yemen only had 2 physicians and 7 nurses/10,000. Yemen, Morocco and Iraq are among 57 countries indicated by the WHO as facing a critical shortage of workforce.²⁰ In Algeria, the 2008 ratio of the health workforce of 2.4 per 1000 is a cut over the 1999 level of 3.4, with shortages noted in specialists, surgeons, and pharmacists (IPEMED, 2012). Jordan also had a low ratio of nurses in the private sector, mainly due to the poor salaries (Ajlouni, 2011). Similarly, country studies show health staff are concentrated around urban centres and richer regions, in line with the concentration in the infrastructure. Hence, most Jordanian Ministry of Health personnel were in hospitals (6% in primary health centres), and physicians were mostly urban based (90%) and in the private sector (28%) (Ajlouni, 2011).

Most countries have a basic, though typically thin, network of primary health care centres, with a typical ratio of 1-2 per 10,000 people. Turkey, Jordan and Egypt did better than the rest, but substantive physical barriers remain in most countries. This is particularly true of Yemen, Morocco, and Syria, where most people have to travel more than 5 km to reach basic health care (El-Laithy, 2011). These centres also suffer from a number of problems affecting their role in health provision, such as insufficient resources, dilapidated facilities, or short opening hours. In Tunisia, 45% of primary care centres opened 1 day a week (WHO Country Brief 2006). In Lebanon, only 120 of the 800 primary health care centres are public (WHO Country Brief, 2010). *An important consequence of the weakness of primary care is that users are forced onto the more expensive secondary and tertiary sectors.*

Systemic Problems

Regional and country studies also document of a host of systemic challenges that undermine the operation and performance of health systems, with negative effects on accessibility and ability to satisfy needs. The first category of issues are: the *quality* and *safety* of the facilities, medication and treatment; ways of monitoring them; ensuring continuous improvements, etc.²¹ It also seems there is a lack of effective regulation or of strong regulatory authorities, which would monitor or control quality and safety standards.²² Under-resourcing have been a key reason for the poor quality of public systems, which are now synonymous with bad quality and long queues (Salehi-Isfahani, 2010).

A second category of problems highlighted by the literature are pervasive inefficiencies in the use of available resources (be it unused private bed capacity in Jordan, high nursing staff levels in Libya, idle high-tech equipment in Lebanon) and in procurement systems. The third and related problem is that of the lack of coordination between providers and between various levels of health care, *and between*

*financing schemes.*²³ Furthermore, poor governance and poor administrative capacities hamper the interface between private and public.

A fourth set of problem is: poor data collection, underdeveloped information systems, and poor management of these, with little ability to track patients, patient needs, or utilization. Examples are: the lack of systematic or coherent recording of deaths in Jordan; the reliance of Tunisia's FMAP system on *manual* recording and different data systems that do not monitor quality or cost; the need for digitization in Libya. Another common recommendation has been the desperate need for more: evidence based research; systematic and comprehensive data collection; actuarial and feasibility studies; and performance assessments and utilisation analyses.²⁴ Evidence-based research is also crucial for improving sectoral performance, guiding policy, and moving towards UHC. Indeed, cases of successful progress towards UHC were supported by accurate actuarial information, and by developing appropriate administrative capacity.²⁵

The Demise of Public Health Spending in MENA

The levels and allocations of government spending on health around the world vary significantly, requiring caution in interpretation (WHO, 2011). There are large and small “allocators”: Thailand managed to extend UHC at relatively low per capita levels, while Korea provides good healthcare with 4% of GDP. Nonetheless, in so far as extending and improving medical services in DCs require investments, government allocations to health are expected to rise, with a similar trend noted in developed countries albeit for different reasons. Conversely, the general tendency of health spending in DCs to fall in the 1990s, was seen as setback that undermined progress, with a reversal required to support the MDGs in the 2000s.

With this caveat in mind, this section argues that trends in MENA health spending, be it in terms of the size of the economies or government allocations, point towards a neglect of health, or at best a recovery from low levels. Salehi-Isfahani (2010), El-Laithy (2011), Karshenas and Alami (2012) all agree that public health systems have had to cater for larger populations and expanding health needs on the back of limited, if not shrinking, resources. Additionally, the latter show that, with a few exceptions, public and total health spending as share of 2005-2010 GDP in MENA were *below* international norms, often below the 2.7% for Sub-Saharan Africa. In FEMISE (2014), the average share of health spending in GDP for the Arab World²⁶ was *the lowest of all regions between 2000 and 2010*.

Table 4 below confirms these trends. Firstly, government health expenditure (GHE) accounted for less than half of Total Health Expenditure (THE) in: Egypt, Iran, Lebanon, Syria, Yemen, and Morocco. Secondly, rises in all three indicators are only registered in Iraq and Morocco; levels fell in at least five countries, stagnating in Algeria and Tunisia. The expansion in the share of government health spending in Jordan is countered by a fall from 4.1 to 3.2 of GDP between 2006 and 2010 (ESCWA 2012).

Similar trends are found on a per capita basis. On a global level, there has been a tendency for health spending to fall in the 1990s due to fiscal retrenchment, and to recover as of the early 2000s. As illustrated in Figure 1 below, in constant US\$ terms, MENA levels recovered later, and mainly in Algeria, Iraq and Libya. WHO data for 2011 show that the East Mediterranean region had the *lowest regional levels* of CGHE in GE and in THE in GDP. Similarly, on a PPP basis, Table 5 shows that the average per capita health spending in the East Mediterranean was close to low income countries, and about half of the average for middle income countries. The regional median of US\$114-115 was below the \$146 in Sub-Saharan Africa. The region also had the slowest growth. Likewise, in constant 2005 US\$ terms,

Table 4. Out-of-pocket health expenditure (% of total expenditure on health)

in 2011, per capita GHE in Egypt, Syria, Morocco, and Yemen were below the US\$62 needed to reach MDGs (WHO 2010).

Finally, Figure 2 puts the regional average in an international context. Clearly, it lags behind Latin America and Turkey. It was ahead of India, but progress has been slower than Thailand, where levels in constant terms almost tripled. In other words, aggregates for government health spending are below levels displayed by reforming countries embracing UHC, which witnessed expanding government outlays on health, improving outcomes, and falling OOP. *In MENA, only Turkey has managed to achieve this result*; Yemen, on the other hand, recorded the largest drop in GHE and largest rise in OOP.

FINANCIAL BARRIERS TO HEALTH CARE

Deficient Provision of Health Protection

Health protection in MENA is characterized by the restriction of public health insurance to public sector or government employees, and the dearth of both private and social health insurance. In 2011, at 6% and 4% of total health financing, social health insurance and private plans in the Arab world were

Figure 2. Government Health Expenditure per capita: Arab countries vs others, 1995-2010

amongst the lowest in all developing regions, and compared with 38% and 18% in the Non-Arab world. OOP for the two regions stood at 32% and 18% respectively,²⁷ with OOP only worse in South Asia. Consequently, the region faces a substantive challenge of extending and revamping existing financial protection or risk-pooling mechanisms.

Though many countries claim to provide healthcare to all citizens, this remains a distant promise in practice. Indeed, public health insurance is *only* available on a *contributory basis*, and tends to be restricted to civil servants and the military. This means that *de facto*, only 30%-40% of the population are covered by public health insurance. The proportion of uninsured population ranges from a *de jure* rate of 15% in Algeria and Tunisia, to 80% in Yemen. Private health insurance is restricted to the rich, urban based population, and is only significant in Lebanon and Jordan. In Lebanon, the insurance coverage is 48%, ranging from 18% to 70% between the bottom and top income quintiles (Salti *et al.*, 2010).

Furthermore, public healthcare and the insurance that come with it are not one unit: they tend to be delivered by a multitude of public funds and agencies, many of which are dedicated to particular categories or segments of public sector and government employees.²⁸ Such fragmentation leads to considerable inefficiencies and distortions, such as the existence of parallel forms of covers, or bureaucratic limitations on access and on refunds.

The region has witnessed recent initiatives to extend coverage to the uninsured, and/or overcome the fragmentation. Perhaps the most comprehensive initiative has been that launched by Tunisia in 2007-2008, when Tunisia merged its two formal medical insurance systems, unified its mandatory schemes, and started defining the basket of services covered (ISSA, 17/12/2008). This provided progress on *de jure* basis: *de facto* population coverage remained at some 31% with little access to the uninsured (Elgazzar *et al.*, 2010). Arfa and Elgazzar (2013) show the FMAP program targeting the poor (now believed to be 15 percent of the population) only reached 40%, while health cards for the needy had are severe limitations, because of the prevalence of co-payments and the reluctance of providers to provide free care. Consequently, at 68%, OOP amongst poor Tunisians is higher than for the richer, not to mention the significant dissatisfaction at “worsening” delivery.

A more patchy record exists elsewhere. In Syria where only 20.5% of the population have social protection, Sen and El-Faisal (2011) report that the social health insurance pilot scheme introduced in 2008 suffered from poor administration and poor data, and required contribution. Similarly, the Lebanese government has attempted to offer free hospitalisation to the poor uninsured, but this is hardly known or believed in practice (Kronfol, 2012a), particularly that there are so few public hospitals. Egypt and Morocco began piloting health card systems in the last few years. While the Egyptian scheme remained limited to Suez, Morocco made health insurance mandatory as of 2005, and over 2012-2014, it rolled out the RAMED health cards system, aiming to reach 8 million needy Moroccans. No evaluations or monitoring reports are publicly available.

Review of OOP

As previously mentioned, OOP is a good indicator of the financial burden of healthcare, with high levels pointing to inequities in the provision and accessibility of healthcare. By definition, it is high wherever government spending and pre-paid health insurance plans are low: even amongst OECD countries, higher shares of public spending on health are associated with lower OOP (OECD, 2011). By the same token, OOP is lower (under 20% of THE) where there is UHC, which entails good public health provision and significant use of social health insurance. Furthermore, countries with 2 percent or less poverty tend to have OOP levels of less than 15 percent (*World Social Security Report, 2010/11*). Therefore high OOP contributes significantly to poverty.

Figures 3 and 4 depict the situation for MENA. Figure 3 shows that OOPs tend to be 30% or less where government health spending is above 3% of GDP. Figure 4 indicates that households paid for about a quarter of THE where GHE reached at least two thirds of total health spending. Clearly, MENA households shouldered most of the burden of healthcare, with Egypt, Morocco, Syria, Yemen and Iran displaying ratios of 50% or more for quite some time. Moreover, most countries saw stagnating or worsening OOPs. Only Libya and Turkey almost halved of their OOP by doubling their GHE.

Figure 3. OOP vs Government Health Expenditure in GDP, 1995

Figure 4. OOP and Government Health Expenditure, 2011

Table 5 not only shows a lack of progress over time, but document a remarkable fact: *MENA countries display some of the highest OOP levels in the world*, a point previously noted by Karshenas and Alami (2012) and ESCWA (2012). The 2010 regional average of 42.4% was higher than the 31.8% displayed by Sub-Saharan Africa. It also clearly exceeded the 33.3% and 36.4% displayed by upper middle and middle income countries respectively. MENA had also maintained this ranking for the last decade. While levels in middle income countries clearly fell from the 2000-2002 levels of 41-45%, MENA did not progress.

There are only a handful of studies on OOP in MENA, two of which (Elgazzar *et al.*, 2010; Abu Zaineh *et al.*, 2013), are of seminal importance. The former covers six MENA countries, and the latter looks at Tunisia. Elgazzar find that CHE in MENA affect between 7-13% of households, and that 10-35% of households *forgo* healthcare because of these costs. Abu-Zaineh finds that 12% of Tunisian households were exposed to CHE at the threshold of 10% of total expenditure, this proportion rising to 49% of households at the threshold of 10% of total non-food expenditure. Furthermore, *poorer quintiles are four times more likely* to suffer CHE, with the overshoot over the threshold being higher amongst them. Zouari and Ayadi (2014) find a mild improvement in the proportion of households suffering CHE in Tunisia between 2005 and 2010 (from 19.5% to 17.1% at the 10% threshold). Rashad (2014) finds that 20% of the population in Egypt is vulnerable to CHE at the 10% threshold, but reports a mild impact in Jordan and Palestine. Abu Zaineh finds that the percentage of Tunisian households exposed to CHE is triple the levels in Malaysia or Thailand, but slightly lower than those in India or Bangladesh.

All studies document serious worsening of poverty levels and headcounts as a result. In Elgazzar *et al.* (2010), *headcount poverty increased by 5-14% post-healthcare payments, with 23% more people pushed below the poverty line when accounting for healthcare.*²⁹ In Yemen, the poorest households display lower OOP because they forgo healthcare altogether. In Tunisia, poverty rises between 13%-17%, from 3.69% to 4.35% using the World Bank poverty line of \$1.08, and 12.3% to 13.8% using the WHO approach (Abu-Zaineh *et al.*, 2013; Zaouri & Ayadi, 2014). Rashad reports that an additional 4%

of the Egyptian population is pushed below the \$2 poverty line due to CHE. The increase in poverty headcounts in MENA are slightly above the rises in poverty headcounts in Asia when the US\$2 poverty line is used, but comparable to the 14% increase at the \$1.08 poverty line (van Doorslater *et al.*, 2006).

Clearly then, poverty in MENA is much higher (typically 10% or more) and deeper than is believed if healthcare spending is taken into account. However, although CHE may deepen poverty, what is also clear particularly in Tunisia and Lebanon, is that paying for healthcare have significant impoverishing effects for the non-poor, with OOP making significant impacts on the discretionary non-food budgets of large proportions of non-poor households. In other words, OOPs are a cause of both poverty and vulnerability.

Three studies (Salti *et al.*, 2010; Elgazzar *et al.*, 2010; Abu-Zaineh *et al.*, 2013) also find that the worst impacts of OOP and CHE tend to be found amongst uninsured households. However, OOP or even CHE may be observed where there is social protection because of: extensive use of co-payment; the poor provision or availability of public services or medication, typically restricted benefit package (e.g. cover for hospitalisation but not medication, or for cancer diagnostics but not treatment).

Though limited, information on the main components of OOP that can be extracted from the literature indicates the following. In Iran, the largest component is inpatient care. In Yemen and Tunisia, the three largest categories are medication and pharmaceuticals, exceptional medical care, visits to physicians. Zaouri and Ayadi (2014) and Abu-Zaineh *et al.* (2013) show that co-payments, caps on expenditure, exemptions, all contribute to high OOP, despite the Tunisia system being publicly led and offering free services to the poor.

In light of the previous sections, which showed deficiencies in the quality, quantity, and coverage of the health infrastructure, in light of the limited social protection, and in light of the regional literature presented thus far, OOP is a burden for most MENA citizens, not just the poor. They are symptomatic of systemic problems due to the way MENA health systems have evolved, i.e. below what they could be for the middle income status. Therefore, OOP in MENA is arguably exceptionally high in MENA because of the following factors:

1. The deterioration in the quality and availability of public health, with GHE falling, stagnating or failing to respond to needs in most countries.
2. The creeping explicit and implicit privatisation of services and infrastructure, with the private sector becoming a dominant supplier in many countries.
3. The neglect of primary health care, forcing people to use specialists, secondary or tertiary care.
4. The shift to cost-sharing and fee recovery, resulting in forgone healthcare for the poor, and high OOP for those who can buy it.
5. The inability of MENA health systems to respond to the epidemiological transition to NCDs,³⁰ resulting in big gaps in both services and social protection available.

MENA SYSTEMS IN A COMPARATIVE CONTEXT

To sum up, in terms of outcomes, MENA has not done badly, though progress has stalled recently and is less impressive when compared to many of its peers. Furthermore these outcomes are characterised by serious inequities in terms of gender, location, or income. Inequities are also found in the provision and delivery of healthcare, be it in terms of quality, access, or financial burden. As captured by OOP, the financial burden of healthcare in MENA is high for its income category, and is made worse by limited

social protection. Using the WHO's three dimensions of UHC (who, what and how much is covered in terms of healthcare)³¹, MENA insures or covers less than half of its population, only for basic health issues, and with important exclusions.

As argued throughout this paper, UHC is particularly relevant for Arab health sectors, because it seeks both to improve health outcomes for all, and to reduce inequities in access and use of healthcare. Furthermore, a number of policy directions have been developed from international experiences of achieving UHC, and these provide benchmarks against which regional performance can be assessed. The exercise results in the following policy suggestions.

Firstly, more government resources need to be mobilised. Countries need to spend at least US\$65 per capita by 2015, and it is difficult to achieve UHC by spending less than 4-5% of GDP on health. This is particularly relevant for Egypt, Syria, Morocco, and Yemen. Similarly, the share of CGHE needs to increase, or at least be preserved. After all, the WHO Africa region has suggested a voluntary target of 15% of government spending. Secondly, OOP levels need to be halved in most countries, particularly amongst vulnerable groups. This means improving on who is covered, and on the proportion of costs included. Thirdly, financial and physical barriers must be reduced by a combination of supply and demand interventions (Elgazzar *et al.*, 2010).

The feasibility of these strategies has already been demonstrated worldwide and in Turkey, which followed a UHC-oriented strategy to eliminate the same challenges now facing MENA. According to Atun *et al.* (2013), Turkish health reforms, which spanned over a decade, adopted UHC and the right to healthcare as an integral part of citizenship, and gradually filled the gaps in provisions and outreach. For example, the tenfold increase in the number of beds (including the use of spare capacity in the private sector), allowed Turkey to offer free emergency healthcare as of 2008. It improved the access of the poorest deciles through both contributory and non-contributory schemes. Likewise, the number of poor people covered rose from 2.4 to 10.2 million, and maternal health indicators improved dramatically. This expansion was built on a rise of CGHE/THE from under 10% in 2000 to 13.8% in 2011, with THE/GDP rising from 2.7% to 6.1% between 1990 and 2008.

The UHC framework is also at the root of the classification used by the *World Social Security Report 2010/2011* to classify the levels of vulnerability of populations in DCs. Most middle income countries, particularly those which made significant progress towards UHC, have a low level of vulnerability. On average this means less than 17% of the population with no coverage, and only a 14.7% deficit in health staff.³² In terms of financial burden, countries with low vulnerability tend to have OOP of 38.5% or less, with financial barriers affecting 19.3% or less of the population.³³ In countries with medium levels of vulnerability, these ratios are 30.8%, 27.3%, 41.7%, and 39.7% respectively. Significantly, low levels of vulnerability are characteristic of countries where public resources GHE account for at least 60% of THE.

The MENA regional profile places *most countries in the medium to high levels of vulnerability*. It also seems there are two regional sub-grouping. The first group consists of Turkey, Algeria, Jordan, and Tunisia, which have less severe problems. Turkey is the best performer, displaying indicators associated with low vulnerability. The second group, to which Iraq and Libya can probably be added, can be classified as displaying high vulnerability, due low health coverage, high OOP, and major deficiencies in provision.

In terms of social protection, the regional average is almost 49%. On the one hand, we have Tunisia, Algeria, and Jordan, where the *de jure* gap in coverage is 20% or less. On the other hand, in Yemen and Morocco, the majority of the population are not covered, to which crippling deficit in health personnel can be added. Financial barriers are significant and above 20% in all but Jordan, Iran, Tunisia and Lebanon.

However, the scores reveal a number of problems and suffer from inconsistencies. For example, Algeria is said to have an OOP of 21% but financial barriers affect nearly 30% of the population. Conversely, Tunisia has high OOP levels that do not gel with the estimated *de jure* level of coverage. Indicators report no deficit in personnel in Lebanon or Egypt, though these suffer significant bottlenecks and uneven geographical distribution.

Furthermore, even among the star performers in MENA, the dominance of government spending provision in healthcare is yet to be translated into low vulnerability and low OOP, a result only achieved by Turkey. For the rest of MENA, huge barriers remain in terms of protection, finance, staffing, and physical resource. These countries are unlikely to be able to close the deficits without scaling up government health spending.

POLICY IMPLICATIONS

Sectoral evidence presented thus far leaves little doubt that MENA countries face massive policy challenges in moving towards good quality, accessible and affordable healthcare for all, these being key policy goals in IG and UHC frameworks. While the large gaps in provisions in Morocco and Yemen are not unusual amongst poorer countries, many such countries have done better, and even embarked on major reforms. MENA is also similar to other developing regions in that public health provisions clearly suffered from budgetary pressures and economic crises in the 1990s. However, whilst there was a clear reversal of this trend elsewhere, MENA has yet to see a reversal of fortunes, with many health sectors stagnating despite strong economic growth in 2004-2009.

As documented by the literature on the MDGs and UHC, health sectors in DCs were also undermined by the political economy of neo-liberal frameworks of the WC, which prioritised cost recovery and financial goals over clinical soundness and equity.³⁴ The regional literature³⁵ establishes a similar situation in MENA. For example, Sen and Al Faisal (2011) show that EU's privatisation-driven modernisation program had negative effects the Syrian public health sector, and was designed with little consideration for equity. In Tunisia, the shortages of medications and public services and creeping privatisation have been hidden behind stable shares of health spending in the economy.

But the crises in MENA sectors are not just about insufficient resources. The demise of public health in MENA is also reflected in a deterioration of performance and status. According to Jabbour (2013), who summarises the findings of the regional public health alliance, public health in the region is weak “in institutional capacity and human resources, undermining its leadership potential”. This is a very serious situation, since public health sectors are the very vehicle that is required to deliver equitable health for all. In their current state, MENA health sectors have continued to deliver inequities in access, delivery, and outcomes, as a clearly documented in the first section of this chapter. Governments have been happy to roll on health policies that were not just out of synch with their population needs, but also led to substantive financial burdens, despite protests from sectoral specialists who have been championing UHC for some time.

As Kronfol (2012b) and Jabbour (2013) argued, it seems that what has made the situation worse in MENA has been the lack of political commitment, which have amplified the negative effects of insufficient resources. This political neglect has arguably been two-pronged: a lack of “political visibility”

or “political clout” for health ministries and agencies (Arfa and Elgazzar, 2013); a neglect of equity dimensions of economic policies and lack of serious anti-poverty policies. Most analysts now agree that poverty and equity would not have made it to the policy agenda where it not for the protests of the Arab Spring. Likewise, the fact that some many rural areas in MENA continue to be deprived of good health services is indicative of failing rural development and poverty reduction strategies.

The lack of political commitment is more glaring when MENA’s piecemeal initiatives are compared to the multi-year, cross-party, national political commitment and holistic reforms elsewhere. Brazil initially committed to UHC in 1990, and went on to scale up and improve its Family Health Care primary health system since 1996. Its Bolsa Familia program emerged from reforming, in 2003, four assistance programs; a key element in this was the construction by a common information and registry system. Thailand committed to address domestic social problems and extend healthcare to all the population in 2001. South Korea constructed its public health system over a period of 12 years as of the 1980s (van Ginneken 2003). Similarly, political factors (such as democratic transitions or commitment of major parties or trade unions), were found to be statistically significant determinants in cases of UHC adoption (Stuckler *et al.*, 2010).

While in MENA, economists are still trying to demonstrate the feasibility of extending basic healthcare to all³⁶ (i.e. really paying for basic services for the poor), Latin America has been earmarking significant resources to health transfers in kind, which come on top of other transfers. According to Lustig *et al.* (2013), these transfers ranged between 2.6% and 4.7% of GDP and were almost equally split between a contributory and non-contributory basis. The study showed that these transfers had a tangible redistributive role in those countries, with social spending achieved significant reduction in GINI coefficients and poverty levels. In this sense too, MENA is far from mobilising tax revenues and far from being having fiscal policies with a redistributive potential.

CONCLUSION: TIME FOR ACTION

Since the MDG process, there has been a push towards a holistic approach to dealing with development failures, i.e. towards an inclusive development process that prioritizes equity and gives attention to non-income aspects of well-being. This set the scene for the current global consensus on UHC, which has helped restore the centrality of health and of health equity to growth, development, and social justice. In working towards affordable healthcare for all, UHC established the need to go beyond national health outcomes to look at the building blocks of health systems, which determine fairness in access and delivery, and shape the financial risks associated with ill-health. Ensuring good health for all is in turn a pillar of an IG process, and crucial for achieving poverty reduction.

These frameworks imply particular benchmarks for success, and their applications in developing regions have produced a number of policy directions that need to be followed to achieve UHC within an IG process. The former include the elimination of inequities in provision, utilisation, and outcomes, while the latter typically require well-supported public health systems that receive a minimum of public resources.

In the MENA region, sectoral specialists have enthusiastically embraced UHC as a framework that could deliver solutions to the problems besieging regional health systems. MENA systems are far from

ensuring good health for all, and are characterised by a focus on often mediocre tertiary care centred on large urban centres. They are still described as mismanaged, inefficient, and fragmented (between levels of care, civilian/military, insured/uninsured). Severe disparities and inequities remain, and large swathes of the population, particularly poor mothers, are barely achieving what rich quintiles achieved ten years ago: they are unlikely to do so if current policies continue.

Underpinning this situation has been a policy of tangible neglect of public sectors, be it in terms of financing, equipment, or staff. MENA public health systems suffer from systemic problems in terms of management, institutional capacity, and regulatory abilities. Even amongst star performers, there are major deficiencies in the organisation, collection, and use of information, data and evidence. Considerable efforts are also needed throughout the region in terms of improving the standards, quality, and safety of care, medication, and facilities.

In most MENA, public health spending and budgetary allocations have been below the norm of middle income countries, and certainly below the reported needs of their population. There has been a pervasive, though often implicit, privatisation, with a clear shift to the ability to pay. The poor state of public facilities and services, *de facto* privatisation, and deficiencies in social protection, have all contributed to the fact that OOP in MENA is the highest amongst their middle income peers. Far from being eased by a golden social contract, poverty and vulnerability in the region are considerably worsened by the financial burden of healthcare.

Politicians and macro-economists have largely ignored this reality, the former largely because of their focus on the preservation of power and use of force, and the latter largely because of a narrow focus on income growth, and because of the false reassurance of few health indicators. In doing so, they have contributed to policies that have undermined the vehicle that can deliver good healthcare for all, namely the public health sector. This vehicle has to be revamped just to cope with current needs, and would have to be scaled up in order to respond to the epidemiological transition to NCDs.

However, revamping health sectors is not just about financing requirements, but rather it is about having a developmental strategy and a political will. At the heart of the health challenges facing MENA are clear developmental failures in terms of rural development, poverty reduction, and social protection, all of which require serious departures from current practices. Thus, it is easy to recommend an increase in health personnel, but deploying and retaining them in rural areas is more complex. Furthermore, improving health outcomes for the poor also means improving living conditions, access to water, etc. Likewise, it is easy to issue free medical cards to the poor. But as the Tunisian case shows, public provision is often neither free nor available. Finally, improving social protection is a complex institutional and fiscal challenge, but without it, shortages in coverage will not take care of themselves, and vulnerability levels will remain high.

Lastly, regional political systems have continuously provided short-termist, piecemeal policy suggestions, and only paid lip service to the UHC agenda. What it needed is the political will to tackle the political exclusions that led to regional, income, and health inequities in the first place. Such political will come from a commitment to prioritising development and social justice in the political agenda, paving the way to dealing with them within a holistic road map. Alas, the Arab Spring may have created a political opportunity for social justice, but at present, such needs are being pushed aside by more instability, emergencies, sectarianism, and tribalism.

KEY TERMS AND DEFINITIONS

Catastrophic Health Payments: Health payments are said to be “catastrophic” when they exceed a certain threshold. This can be calculated either out of the total budget, or net of food spending, which some see as a closer reflection of the ability to pay.

Inclusive Growth: Growth is inclusive to the extent that it that grants equal access to income growth, reduces disparities and inequities, and improves non-income dimensions of well- being for all. Inclusive development can be thought of as the same process but in a developmental context, where major challenges such as poverty or depravation prevail.

Millennium Development Goals: These are eight international developmental goals endorsed at the 2000 Millennium Summit with a target date of 2015. These goals are: eradicating extreme poverty and hunger; achieving universal primary education; empowering women and improving gender equality;

improving maternal health; combating major killer diseases (e.g. HIV/AIDS); ensuring environmental sustainability; working in a genuine global partnership for development.

Non-Communicable Diseases: These are chronic diseases and/or diseases that are not passed on from person to person, but which are important causes of morbidity and ill health. The main categories are cardio-vascular diseases, cancer, diabetes, mental illnesses.

Out of Pocket Expenditure: Any health related expenditure paid by individuals or households that are not covered by insurance, government, or other sources.

Social Protection Floor: Refers to the minimum set of interventions provided by a social protection system. Ideally it guarantees access to healthcare and basic income to children, older persons, and others who are unable to earn that income.

Universal Health Coverage: UHC is about providing key promotive, preventive, curative, and rehabilitative health interventions for all, at an affordable price.

ENDNOTES

- ¹ In this chapter, Arab Countries and Arab World refer to: Lebanon, Syria, Jordan, Iraq, Yemen, Egypt, Libya, Tunisia, Algeria, and Morocco. MENA refers to these countries plus Turkey and Iran. The latter two are mainly used as comparators, with Turkey having made the most progress.

ABSTRACT

This chapter discusses the main findings of five empirical studies focusing on local health innovation systems in Brazil. It focuses on the articulation of service and manufacturing segments within the Health complex and the other organizations that constitute a Local Innovation and Production System (LIPS) and discusses the learning, capacity building and innovation processes and their effective and potential impact on the local territory. The findings suggest that the types and intensity of interactions are closely related to the characteristics of what can be called a local cognitive territory. The directions of capacity building and scientific and technological evolution are directly influenced by conflicts among individuals and groups. The influence of these power relations, which are often associated with diverging private and public (collective) interests, highlights the importance of the institutional and policy dimensions for mediation and for promoting an evolution of the system that favors social inclusion and efficiency.

INTRODUCTION

Health and, specifically, the service and manufacturing segments of the health complex are of central importance for development at the national, regional and local level. This importance is related to two general vectors of development: on one side health figure as a structuring factor of the Welfare State (life quality and citizenship), and on the other side it is a major driver of economic growth, given the mass consumption characteristic of health products and services, as well as its potential for job creation, investment and innovation.

DOI: 10.4018/978-1-5225-1674-3.ch004

This is especially relevant in the case of Brazil where the 1988 constitution guaranteed universal and integral access to health treatment for the entire population. Given its almost 200 million inhabitants, it constitutes the biggest universal and integral public health system in the world. Thus, the analysis of health from a development perspective cannot be exclusively subordinated to the logic of industry competitiveness. Both from an analytical point of view and from a normative one, the health system must be understood from a dual perspective that encompasses economic competitiveness and its dimensions as a public and social essential service. This involves criteria of availability, access and quality. The state plays a fundamental role, not only for introducing active policies aimed at strengthening the technological production base, as well as for ensuring the convergence with social objectives.

Reducing interregional and intraregional inequalities figure as one of the main goals of the Brazilian development policy. The trend towards concentration of the manufacturing activities within the health industry that occurs on the international sphere is reproduced within the country. Thus, recognizing and mobilizing the productive, scientific and technological potential related to health in different states, counties and micro-regions of the country is a key goal.

A territorial approach to the health production and innovation system allows using the capillarity health services have to stimulate the territorial diffusion of productive and innovative activities and to articulate the economic and social dimensions of development. If, on the one hand, health services are relatively evenly spread across the territory, the same is not true for the manufacturing segments, nor to the process of generation and dissemination of knowledge and innovation. Recognizing the territorially and socially rooted dimension of learning process and the generation of innovations, health offers a potential to make transformations that are relevant and related to the needs and opportunities of each local territory.

Thus, the focus of this chapter is to discuss the empirical evidences related to the processes of learning and innovation in healthcare production/service provision activities in a local territorial dimension. The empirical findings come from the research project “Health and Innovation: Territorialization of the Health Economic-Industrial Complex” where five different cases were analyzed.

These studies were based on the analytical and methodological framework of Local Innovation and Production Systems (LIPSs), which emphasizes a systemic perspective for the analysis of social processes in a specific territory. The cases cover five different states of the country, offering a broad and diversified set. The findings from these studies converge to form a complex mosaic of issues that are of central relevance for the territorialization of the health system. Therefore, we focus on those aspects that represent general implications that may help to advance on federal and state policies for health system on a territorial sphere.

The text is structured in five sections. The first one discusses the conceptual framework for the analysis of health production and innovation systems. The second section offers a concise overview of the five cases. The next section discusses the findings related to the learning and innovation processes. The fourth section focuses on the institutional dimension that influences the development of these local cases. Finally, the conclusion addresses some policy implications.

HEALTH INNOVATION SYSTEMS

The Brazilian industrial policy directed to the health industry has been carried out in the last decade under the header of the Health Economic-Industrial Complex – HEIC. It encompasses both manufactur-

ing industries (the chemical and biotechnology industry and the mechanics, electronics and materials industry) as well as service providers (hospitals, clinics, diagnostic and treatment) that are consumers of the products manufactured in the first group and at the same time articulate the consumption of these industrial products by the population. Figure 1 shows the structure of the HEIC and the three production subsystems that compose it.

From the Systems of Innovation perspective we consider that the HEIC comprises a central part of the National Health Innovation System (Gadelha, 2010). Thus, beyond the production and innovation subsystem, the health innovation system also includes the subsystem of organizations dedicated to education, science and technology, the subsystem of demand (users/beneficiaries), the subsystem of promotion, regulation and support, as well as the broader social, cultural and institutional environment (Cassiolato & Lastres 2008). For analyzing this systemic dimension of health on a concrete territorial dimension we use the analytical and methodological framework of Local Innovation and Production Systems (LIPSs), developed by the Brazilian research network RedeSist for analyzing production, learning and innovation and their impact on competitiveness and sustained development (Cassiolato et al. 2003). This framework is based on the broader framework of innovation systems (Freeman 1987; Lundvall 1992; Nelson 1993), focusing on the local sphere of production and innovation, but also considering its insertion within the broader national and international contexts. (Lastres et al, 2003).

In the case of the health sector, the service segment within the production and innovation subsystem is primarily responsible for the mobilization and coordination of the manufacturing segments of the HEIC, given its strong impact on the demand for products. In addition, the services subsystem not only uses the innovations generated in the manufacturing sectors, but also has the capacity to endogenously innovate and drive innovative efforts in others segments. Thus, we find intense (nonlinear) interactive relations of the services subsystem with suppliers and customers (Gadelha, 2010). In addition to these dynamic elements, from a social perspective, we find that the service segments generate the most relevant impacts in terms of jobs and income generation. Thus, it conforms a strategic locus for systemic innovation processes, becoming the core of the health LIPS.

Figure 1. The Health Economic Industrial Complex – HEIC
Source: Gadelha, 2010

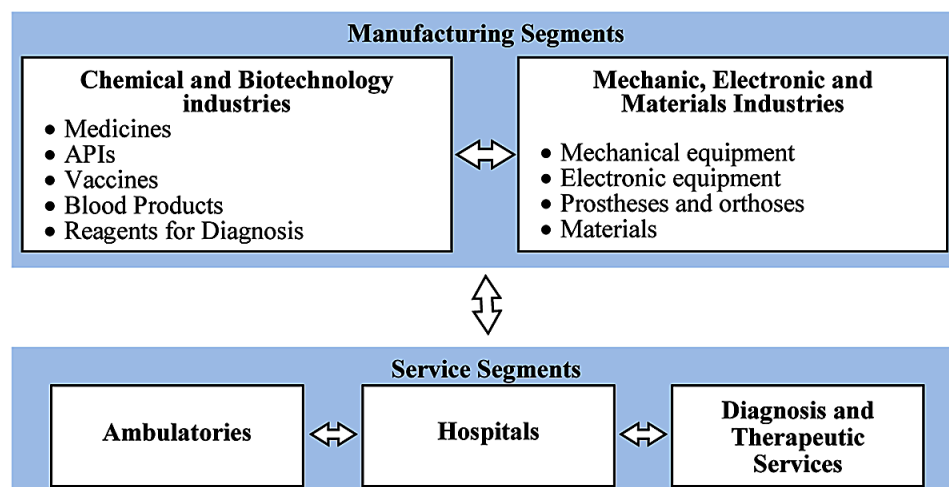

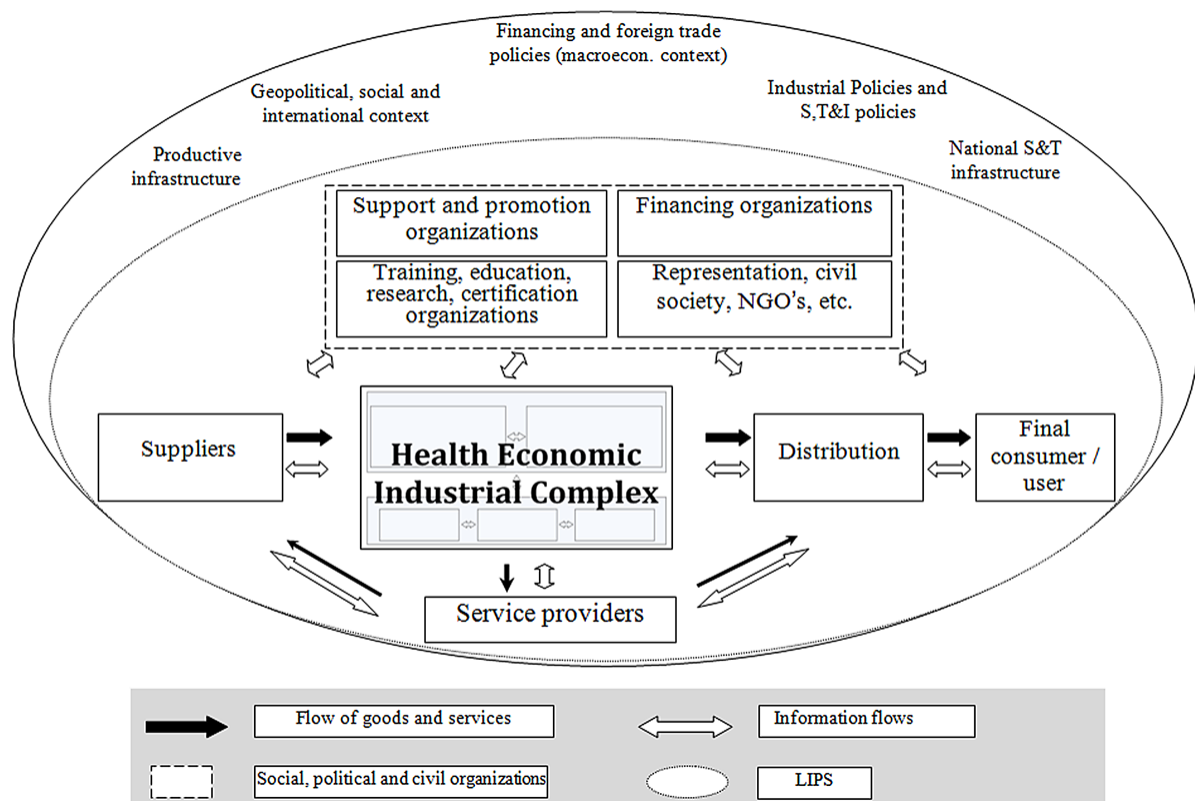

Figure 2 shows the schematic structure of a LIPS, which has in its centre the production activities of the different manufacturing segments and services related to health.

As we know, this systemic perspective of health is relatively new, since most studies have focused on specific sectors (such as biotechnology and pharmaceutical industries, for example). Thus, it is a challenge to consider innovation, production and health services within a systemic perspective. The challenge is even bigger if we consider this within a specific local dimension, which indeed is fundamental for closing the “gap” between social policies and industrial and innovation policies.

The analytical and methodological framework of LIPSs has also been recently used in research efforts in the scope of a Globelics network project entitled “RISSI-Research on Innovation Systems and Social Inclusion”. This framework involves empirical studies, using specific questionnaires and interview guides that explore issues related to the structure and dynamics of firms, the processes of interactive learning, cooperation and innovation in the territory and the articulation with the training, scientific and technological subsystem, the social dimension and the broader institutional set-up. It also encompasses analytical guidelines for answering the main issues related to the LIPS research agenda. For the study of the health system many adaptations and modifications had to be made both in relation to the field research tools and to the guidelines for analysis. This derives from the specific characteristics of the health system and its different segments. Especially, when considering the service segments as central drivers and coordinators of production, knowledge generation and innovation activities, the recent literature on

Figure 2. A local innovation and production system with the HEIC in its centre

Source: Own elaboration, based on Matos et al. (2012)

‘service innovation’ (Sundbo & Gallouj 2000; Hipp & Grupp 2005; Miles 2008) and on innovation in health segments (Barbosa 2009; Engel 2008; Cunningham 2005; Consoli et al. 2005) offered important insights. Since the study takes inclusive development as a main normative reference, the recent literature on inclusion/exclusion, empowerment and capabilities (Sen 1999; Joseph et al. 2010, Sutz 2010, Soares & Cassiolato 2008, Soares et al. 2014) also constituted a central reference¹.

Since the health system constitutes a very ample and diversified field, each empirical study opted for focusing on specific subsets of this system. This led, for example, to the choice to focus on the different actors and processes that relate to a specific field of illness. Furthermore, the studies focused on a specific urban area or a broader territorial dimension, on specific core institutions or adopting a more horizontal approach. But in all cases the same key aspects of interactive learning and innovation, the articulation with the broader production base and the social-cultural dimension of the territory were analyzed. In this paper we discuss the main findings from a qualitative and appreciative perspective.

RESEARCH METHODOLOGY

The research methodology of LIPS is based on field research with specific questionnaires and interview guides and qualitative and semi-quantitative analysis of the results.

The LIPS methodology emphasizes the importance of gathering original primary data for understanding local processes of systemic innovation, learning and capacity building. Secondary information, available from data gathering official agencies do not suffice. So there is a need to collect information directly from local actors, combining the secondary information that may be available with this primary information.

The questionnaire is directed to the productive actors/agents who are at the core of the local system. These actors can be formal enterprises, informal ones or individuals. The set of productive agents and other organizations to which this questionnaire and the interview guides would be applied should be defined in advance, based on the previous characterization of the LIPS and the identification of the relevant segments and actors.

The questionnaire is structured in five blocks of questions. The first aims to characterize the productive organization, with questions about segments, products, origin and structure of the capital, and characteristics of the employees. The second block poses questions about the economic performance of the enterprise/organization, such as turnover, sales and markets attended, as well as factors considered to be important for the competitive capacity of the enterprise. The third block poses the central questions for the analysis, investigating the innovative efforts and the social and economic performance of the enterprise, the activities of learning and cooperation with diverse agents and the impact of these interactive processes on the capabilities of the enterprise. The forth block investigates aspects related to the competitive advantages associates to the local environment, the articulation to the local productive structure, and the patterns of governance. The fifth block evaluates the existing and potential support and promotion policies.

The field research tools also encompass three different interview guides. The first is directed to organizations with functions of education, training and research such as technical schools, universities, technological centers and social organizations. The main questions include not only issues about the research lines and the characteristics of the courses that are offered, but also matters such as the interaction between scientific and traditional/local knowledge, information and knowledge flows, and the main agents with which those organizations interact. The second interview guide is directed to organizations

with representation functions such as associations and unions, as well as relevant social organizations. It evaluates their action in relation to the productive agents, other organizations and the public sphere, considering their role in the intermediation and coordination of the diverse policy actions. We highlight the questions related to the efforts of the organizations for the technological capacity building of the associated productive organizations, to the main potentialities and difficulties of the productive sphere including working conditions and the circumstances for participation and social inclusion, and the possible implications for future policy actions. The third interview guide is directed to public and private organizations (including international cooperation) with promotion and policy functions. It includes questions related to their action in relation to professional training, technical consultancy, credit lines, fiscal incentives, scholarships, as well as for the strengthening of social organization and management, provision of basic infrastructure and other forms of social improvement. It also includes their perception on the contribution of the LIPS to the improvement of the social conditions in the territory. These questions help to identify the main policy actions, their objectives and targets, the organizations that are involved and their function, the tools and the methodology for evaluation, the origin of resources and the lessons that can be extracted from the present stage of those programs.

Many questions of the interview guides are complementary to questions of the questionnaire, focusing on the same issues on to different perspectives. The combination of these different perspectives allows identifying with more detail the positive and negative points of actions, projects and policies. This helps to propose targeted policy actions that may have a greater chance of being successful and contribute to the development of the LIPS and territory in which it is inserted.

THE FIVE HEALTH LIPSs

The following five empirical studies of health Local Innovation and Production Systems were carried out during the year of 2012 in different parts of Brazil²:

The study of Bahia focused on health activities related to cancer treatment in this northeastern state. On the one hand, the tumors are responsible for a significant proportion of deaths in the state (nearly 14% in 2010) and, with the aging of population an increase of this percentage can be expected. On the other hand, treatment of neoplasm is intensive in high-cost technologies, involving high-level spending of the state, which becomes even more relevant when considering the growing incidence of the disease. Specifically, the study focuses on breast cancer and the institutional setup related to the access of the population to treatment in the public health system (Ferreira Júnior 2012).

The study in the State of Espírito Santo focused on the institutional setup for public health provision in the metropolitan area of Vitoria. The study chose as focal point the Evangelical Hospital in the municipality of Vila Velha. This hospital is especially relevant since it provides reference services in various specialties (cardiac surgery, bariatric surgery, neurosurgery, vascular surgery, ophthalmology, renal transplantation, transplant corneas, bone transplantation and oncology) and has been granted certifications for its high level of service and patient safety. This hospital was also the first charity hospital in the state to receive a high level of accreditation by the National Accreditation Organization (ONA), a title given only to health institutions that stand out with a high level of quality of care and patient safety. Thus, the interest is on how such an outstanding institution deals with complex problems of health service provision in varied fields within a big metropolitan area (Villaschi 2012).

In the case of the State of Minas Gerais, the study focused on the treatment of cardiovascular diseases in the Triângulo Mineiro region. Cardiovascular diseases are the leading cause of mortality in the region. The focus of research was on high-complexity care carried out within the public health system, since treatments in this area are situated on the frontier of scientific and technological knowledge. The field research took as a reference the participation of university hospitals in the health system in the region, especially the Clinical Hospital of the Federal University of Uberlândia and the Clinical Hospital of the Federal University of Triângulo Mineiro (Uberaba), because both have broad regional coverage, offer services of high complexity and its functions go beyond the typical university hospitals. At the same time, they encompass high level treatment together with education and research tasks, and constitute almost the only access point for public health services in ambulatory and emergency in the region (Botelho 2012).

In the case of the state of Paraíba, the analysis focused on the LIPS of João Pessoa. This study articulated the systems of innovation framework with theoretical and methodological propositions of Cavalcanti Filho (2011), which focused on 12 dimensions that characterize the existence of a Production System. Those can be grouped into three subsystems: Cultural (Population, History and Territory), Political (Power, Property and Labour) and Economic (Investment, Consumption, Production, Marketing, Finance and Innovation), trying to analyze the LIPSs from the dimensions described. From this analysis, the study investigated the 'economic functions' that characterize the system and its bonds with other LIPSs and the broader productive system (formed mostly by pharmaceutical companies and firms specialized in the production of electronic equipment for hospitals, clinics and laboratories). Cardiovascular diseases were taken as reference for the development of research, given the large percentage of deaths caused by this disease in the city of João Pessoa (Cavalcanti Filho 2012).

Finally, the study in the state of Rio Grande do Sul focused on the health LIPS in the metropolitan region of Porto Alegre linked to cardiovascular and oncological treatments. This metropolitan area encompasses a large share of the state health care services, as well as relevant number of manufacturing activities within the HEIC in the fields of chemistry and biotechnology, mechanics, electronics and materials. The same is true for the structure of education and research in the state. The focus on cardiovascular and oncological treatment was due to the prevalence of these diseases in the epidemiological profile of the region. The choice was to focus on teaching and research hospitals of Porto Alegre, which are those that offer services of high complexity and allow examining the interplay between education, knowledge generation and their impact on the services provided (Tatsch 2012).

LEARNING, CAPACITY BUILDING AND INNOVATION IN HEALTH LIPSs

Empirical evidences highlight the varied processes of knowledge generation, diffusion and socialization on the part of companies, organizations and individuals in Local Innovation and Production Systems. This is particularly relevant in the case of tacit knowledge, which is implicit and embedded in individuals, organizations and even regions. Learning is fundamental for the transmission of knowledge and the expansion of productive and innovative capacities of companies and other organizations. Training activities are essential for enabling the introduction of new products, processes, methods and organizational formats (Lundvall & Johnson, 1994). In the sphere of private firm, these processes are crucial for ensuring their sustained competitiveness. In the sphere of public essential services there is an additional dimension related to ensuring universal access and quality to health services and products.

Our focus on the research of health related activities with emphasis on its public service dimension aims to contribute to innovation system research in issues that are still little explored even though they are key for knowledge generation and innovation. Recent research on innovation in services explain the importance of considering the characteristics of each segment to understand: (i) the ways of articulation among actors (ii) the channels and processes through which information is transmitted, (iii) how the logic of the services provided and the types of critical knowledge (and technical base) influence the features and direction of learning and innovation. These factors are even more specific in the case of innovation systems rooted in local territorial bases. In the following section we explore the qualitative results of the five empirical studies which might help us to advance in the understanding of these issues.

The Cognitive Territory within the Health LIPSs

A key concept for understanding the interactive processes of knowledge generation, dissemination and use in a LIPS is that of the 'Cognitive Territory'. This consists of the set of actors that are part of a LIPS, their knowledge, the interaction channels and the ways in which information circulates. Therefore, identifying the actors and their modes of interaction contributes to understand the characteristics of a specific cognitive territory. Each of the five LIPSs has a specific structure with regard to the agents that constitute the institutional framework and the socio-cultural dimension. This translates into specific patterns of learning, generation and diffusion of innovations and building of capacities.

In all studies we found what can be characterized as different levels of fragmentation of these cognitive territories. Be it because of the absence of agents that constitute specific links of a complex system or because of the way processes are organized. Such logics are conditioned by the institutional framework, by economic conditions and power relations that are established between different actors.

Although each case is very specific, some of the features that conform the cognitive territories and the processes of capabilities generation and innovations stand out in all studies as important aspects for discussing the potential for promoting health systems in a territorial dimension.

The Subsystem of Education, Science and Technology

According to the categorization proposed by Cassiolato and Lastres (2008) we can characterize the subsystem of Education, Science and Technology as the set of organizations that are connected to the production sphere and are centered on research, education, certification, metrology etc. These organizations play an important role in the processes of generation and dissemination of knowledge, because they are the locus where new people are trained and where the bulk of research efforts are developed, especially basic and applied research, but also the search for practical solution for specific problems/challenges. Although situated in quite disparate contexts, in all five LIPSs there is a diverse and relevant training, education and research base.

In the case of Minas Gerais, we find that this state has a strong knowledge base in S&T in the field of health, with internationally recognized academic research. Especially important are the Federal University of Minas Gerais - UFMG, Fiocruz Minas - Research Center René Rachou and Ezequiel Dias Foundation (FUNED). However, these organizations are located in the state capital, while the empirical study focused on the LIPS in the region of the Triângulo Mineiro. In this region there are two federal universities, university hospitals and research institutions linked to the areas of health. One challenge highlighted in the study is precisely to promote greater interaction between the local base of S&T and that

in a broader dimension, particularly in relation to the participation in major research programs, training and use of the infrastructure. Further, linked to Higher Education Institutions (HEIs), we find a multitude of research groups, which develop research in different areas related to medicine and biosciences.

The case of Rio Grande do Sul is outstanding for its ample and prestigious S&T infrastructure. In this state 58 higher education institutions (HEIs) offer courses in healthcare area. Particularly important is the Federal University of Rio Grande do Sul (UFRGS). Other institutions situated in the LIPS territory are the Federal University of Health Sciences of Porto Alegre (FUFCSPA), the Pontifical Catholic University of Rio Grande do Sul (PUCRS), the Cardiology Institute of RS - University Foundation of Cardiology (IC-FUC) and the State Foundation for the Production and Health Research (FEPPS).

The research conducted by these organizations is largely linked to the testing of new drugs, i.e., participation in international protocols for testing. On one hand, such involvement leads to many benefits - related to new scientific knowledge and the possibility of treating people who are in need - on the other hand, the primary focus in this type of research leaves little space for specific research that is closer related to the characteristics of the specific territory, such as its epidemiological profile.

Both studies mentioned above highlight the importance of research activities carried out by research groups linked to HEIs. Specifically in the fields of cardiology and oncology there are 43 groups. In both studies we find their important contribution for advancing in areas of basic and applied research and for enabling the creation of technology-based companies. On the other hand, the studies also highlight the obstacles for a greater coordination of these groups with the various organizations of the local health system. Noteworthy is the fact that the areas of research are very specific, so that it is very rare to find other organizations and research groups developing related research activities. In the main, there is a great but rather unexplored potential for articulating the research efforts with the specific challenges/demands of public health in those territories. Although mostly supported by public funds, through research grants and use of the infrastructure of public institutions, research efforts show to be linked rather to the outside (national and international scientific community) than to the territory. This constitutes a first dimension of fragmentation of local cognitive territory where changes in incentive structures may be necessary.

In the case of Paraíba there are 85 university courses related to health, of which 49.4% are located in the capital João Pessoa. The largest university hospital in the state is also linked to a public university (UEPB). In terms of research efforts, there are some laboratories and several research lines related to the College of Santa Emilia Rodat (FASER) and the Colleges of Nursing and Medicine Nova Esperança. The FASER also establishes partnerships with clinical laboratories of João Pessoa, the Federal University of Paraíba, the Federal University of Pernambuco and the Integrated Faculty of Patos. However, the authors of the study stressed the low innovativeness within the LIPSs and found this to be directly related to the low density in terms of research and development that is undertaken. In the case of Espírito Santo, higher education is mainly related to the Federal University of Espírito Santo (12 courses) although there are other important higher education institutions, which are spread throughout the state. Private Institutions of Higher Education offer 48 courses related to health.

In these two cases we find a relatively smaller contribution of these organizations in the field of research. But even in these cases, as in all studies, educational institutions play a key role for the formation of human resources. Training is the most important link of this subsystem to the production and service activities. All studies highlight education and training at a technical level, undergraduate and graduate level as a decisive factor for the functioning of the health systems of those states and localities. The great demand for professionals is supplied by continuous training of professionals in these institutions.

On the other hand, several studies point to challenges related to this education structure. Firstly, they highlight the mismatch between the type of education privileged and the needs arising from the public health system. There is a great demand (and consequently greater number of vacancies) in areas related to the formation of specialists at the expense of training of general practitioners. Specialists comparatively earn higher salaries besides finding higher profitability when working as liberal professionals in private offices or clinics. But considering the health system as a whole, it has a relatively greater demand for general practitioners, especially in relation to preventive health care and low and medium complexity activities.

Secondly, some of the studies highlight the lagging quality of training offered by some organizations, which may impact directly on the quality of health services provided. This aspect is particularly emphasized in the study of Espírito Santo. The formation of professionals (middle and upper levels) is quite heterogeneous. There are, for example, frequent complaints about the nursing staff. The quality of higher education presents also various levels (both between areas and intra-areas). In medical training, for example, there are important differences in training offered by the more traditional schools and those that were created in the last ten years (mostly private).

Thirdly, the results of the case studies point to a broader discussion related to the structure of education in the area of health. This issue is especially prominent in the study on the LIPS in Paraiba. This study draws attention to external forces which act on the local activities. This influence is exerted mostly by manufacturers of drugs and medical equipment, both from other parts of the country and from abroad. Noteworthy is the inductive role that these organizations have in shaping the ‘business model’ of health service. Specifically with regard to training, this translates into a specific formative profile of the physicians, since these organizations are major funders of research in medical areas. In many cases, more attention is directed to areas that offer higher profitability and others are neglected despite their potential impact on a greater share of the population, but with a low income profile.

Finally, the study in Paraiba also highlights the influence of power relations, related to the dominance of a local elite on the training facilities and the provision of health services. This translates, for example, into a low inclination to expand the number of vacancies in higher education in the medical field, although there is wide demand for qualified personnel in the region. The relative scarcity of these professionals favors a ‘business model’ in which the established medical body “divides” its attention between the public health system and the private practice, the later being responsible for a higher share of their income.

In all this cases we find a fundamental conflict between the public (socially inclusive) and private (profit and notoriety oriented) logic. All the aspects discussed are significant challenges for the consolidation of educational projects focused on a public logic for the offering of universal free health services. This translates into a training profile that does not favor the convergence between the supply of health services (in terms of training, availability of health professionals and access and quality) and demand (in terms of the needs of the population which depends on the public health system). Such issues deserve special attention in the section that discusses the policy implications.

The Hospital – University Relation

We now focus on those actors that constitute the core of the LIPS according to this conceptual framework: the organizations providing health services. The studies focused especially on the major hospitals as reference centers for medium and high complexity treatment. The methodological choice of placing

such organizations as central actors proved to be correct, since all studies stressed their important role as a place of convergence, mobilization and transformation of capacities.

Especially rich is the articulation of these organizations with the subsystem composed by training, education and research organizations. This relationship is particularly nurtured in the case of LIPSs where university hospitals are key actors. As mentioned before, the LIPS in Minas Gerais has two university hospitals as central health service providers. Especially with regard to high complexity treatment related to cardiovascular diseases, these organizations are core references. The association between the activities of medical practice, teaching and research sets these hospitals as privileged loci for the generation and expansion of scientific and technological capabilities and training of personnel.

However, the studies also highlight issues that prevent such privileged spaces for capacity building to materialize all their potential. A central aspect is the fact that most services provided by the university hospitals are characterized as emergency procedures. This implies enormous limitations to schedule appointments and planning activities related to research and training.

The study of the LIPS in Rio Grande do Sul also sets the teaching hospitals as key actors. Especially important are the residency programs for more than thousand students each year, as well as undergraduate and postgraduate formation and scientific and technological research. The Santa Casa de Misericórdia de Porto Alegre for example has an agreement with more than 13 higher education institutions (HEIs), developing several residency programs. In the case of the LIPS in Paraíba, the most complex example of cooperation for innovative learning involves the federal university UFPB and the Lauro Wanderley University Hospital, which operates exclusively for the public health system. This organization provides an ample residency program and makes available equipments used for medical research undertaken by the university.

Both studies give special attention to a central figure of great importance: the professionals who work both in practice and in medical research and teaching. These professionals are important bridges between the structure of health services provision (notably hospitals), on one side, and universities and other scientific and technological organizations, on the other side. Thus, they play a special role in relation to the following aspects: (i) the application of scientific knowledge (and eventually the knowledge related to new technologies) to medical practice, incorporating it into medical procedures and allowing therapeutic application; (ii) the application of knowledge generated in practice in teaching and research activity; (iii) structuring of residency programs, and (iv) the conduct of research that depends both on laboratory infrastructure and testing activities with patients.

The study of the LIPS in Bahia highlights the importance of different internal and external knowledge sources for healthcare organizations. With regard to internal sources, the body of professionals is key, since the bulk of learning is linked to the interaction of qualified staff in everyday procedures (learning-by-doing and learning-by-using). This learning is even more relevant in the case of doctors and nurses who besides working in oncology units are also teachers in local universities. With regard to external sources of learning, health service organizations highlight the importance of universities within the LIPS, as well as professional training organizations and partnerships with research institutes. Universities, especially public ones that offer courses in health areas, are important pillars for learning. Research institutes, in turn, serve as a benchmark for healthcare facilities, providing new protocols and space for the evaluation of treating techniques.

However, the studies also stress factors that limited the potential benefits related to this interaction between the service provision and the knowledge base. The most common picture is that of teacher-researcher which exerts a limited role as a doctor in the hospital and develops research that is rather un-

related to assistance activities. All studies find that there is, with varying intensity, a low commitment of these professionals to practice in hospitals. In many cases doctors use their activity in the public hospital and the university as showcases to promote their activities in private practice, the latter being the most important source of income. The absence of regimes of exclusive dedication favors this type of allocation of time, so that the contribution of these professionals for the generation and dissemination of knowledge in the public health system tends to be relatively less significant.

Manufacturing Segments of the Health System

Manufacturing segments of the Health Economic-Industrial Complex are other important potential links in the cognitive territory of the LIPS. These companies play an important role in the generation and dissemination of knowledge, especially in relation to the development and market introduction of new drugs, equipment, techniques and prostheses. The interaction of companies with potential users of innovations – organizations of the health service segment or final consumers – spurs their continued learning, improving and creating new products.

But this dimension is where we find the greatest heterogeneity among the five cases which were analyzed. While the structure of the national public health system favors the relatively widespread presence of organizations from service segments in the territory (given the need for direct interaction with the user / beneficiary), the same does not apply to manufacturing segments. In this case, economic factors are those that almost exclusively influence the existence and location of firms. In many cases, the actual requirements of scale and agglomeration economies favor the existence of few companies in a particular segment and their concentration in few regions. Factors related to the sphere of the National Innovation System help to explain the existence or not and the importance of different industries in the country.

In the case of the LIPSs in the Triângulo Mineiro in Minas Gerais we find some companies from different manufacturing segments of the HEIC. Five companies operate in the area of human health, three of which are startups that are still at the stage of prototyping and testing of its products. These companies were spinoffs linked to research centers at the Federal University of Uberlândia and Incubation Center for Entrepreneurial Activities of Uberlândia (CIAEM). This incubator offers technical consulting service and strategic planning, in addition to physical infrastructure for the construction of laboratories. Although this is a small set of firms we find very relevant interactive relations with other actors. An agreement with the Federal University of Uberlândia enables the utilization of the Laboratory of Biochemistry and Molecular Biology to develop methods, consulting and diagnosis activities related to molecular biomarkers in the areas of human / animal health, athletic performance and oral health. Many equipments required for the development of research on the part of these companies were incorporated into the laboratory occupied by researchers in universities. Companies have access to the university's databases of genetic material and offer access to their databases for university research.

As detailed beneath, these companies have a significant innovative performance with the introduction of products which are new even for the world market. Thus, these companies highlight the university and its laboratories as their primary cooperation partner. Cooperative relations occur both through formal channels such as covenants and doctoral programs and informal channels offered by the academic environment. Not surprisingly, the companies cite as main driver and facilitator for their innovative efforts the articulation with the Federal University of Uberlândia and Research Institutes.

The LIPS in the Metropolitan Region of Porto Alegre, Rio Grande do Sul, has a far wider industrial base. Companies operate in different segments of mechanics, electronics and materials and chemistry

and biotechnology. The products manufactured are diverse: food supplements; the homeopathic, herbal and, less frequently, allopathic medicines; radiopharmaceuticals; vaccines and antibodies; equipment for cardiovascular and general surgery; laboratory equipment; orthopedic devices; dental and optical products and general hospital consumables. However, unlike what happens in the case of Minas Gerais, in this case there is not a close articulation with universities and research institutes. Among the information sources for learning companies highlight the institutions for testing and certifications and public agencies, including regulation agencies. Customers (especially health service organizations that use the products) and companies related to distribution and sale activities are also relatively important. This structure of interaction is directly related to the profile of these companies – well established and operating in a broad market. Thus, instances that relate to quality, compliance and certification of their products are more relevant. Likewise, this study confirms the central importance of organizations providing health services as users of the products developed by companies, providing important information about their use, potential for improvement and demand for new solutions. On the other hand, this study demonstrates the low articulation and limited information flow between different industrial segments of the HEIC and between these and other directly or indirectly related segments. This constitutes a major dimension in which the cognitive territory could be better articulated, promoting more systemic relations and expanding the potential of knowledge generation.

The other three studies emphasize the other side of the coin, related to an almost absolute absence of companies in the manufacturing segments of the HEIC. As noted above, many of the economic factors help to explain why one cannot expect to build up “complete” system in all localities, even in the case of state capitals. However, the case of Minas Gerais discussed above, exemplifies how, departing from research activities in higher education institutions and counting with incentive funds, an initial industrial structure may be viable, which can cooperate with the search for solutions related to the specific challenges of public health in a given territory. To the extent that there is no presence of these kinds of firms in the three LIPSs, many opportunities are lost to generate and disseminate knowledge endogenously. At the same time, these studies stress that this enhances the power of big enterprises from outside to influence productive and scientific and technological choices. These firms end up directly influencing the direction of technological change via incorporation of equipment, medications, procedures, etc. This is discussed in more detail below. If, in the future, new public policies are to succeed in internalizing some of the industrial production segments in the LIPS, especially those that do not rely on very large economies of scale, local actors of the service segments would be able to influence the innovation and production process of their suppliers. As vastly shown in the literature ‘user-producer’ interactions are essential for innovation and for determining the direction of technological change (Lundvall 1985). When it comes to the needs of health systems in specific territories, many solutions may have to emerge locally.

Summing Up

Even with different characteristics and with greater or lesser relevance (and presence) of different actors that compose the nodes of the cognitive territory, all studies highlight the positive impacts derived from interactive learning processes.

From the point of view of manufacturing enterprises, the studies of Rio Grande do Sul and Minas Gerais stress: (i) an improved capacity to develop new products and processes, (ii) an improvement on the quality of products and services (iii) new business opportunities, (iv) greater ability to comply with

Innovation in the Health System

the requirements of regulatory agencies, and (v) implementation of improvements in infrastructure, equipment and materials.

From the point of view of health services organizations (notably hospitals), the studies points to a significant impact of these interactive processes related to: (i) training and improvements in service provision; (ii) partnership with research institutes and advances in the quality of products and services; (iii) the ability to introduce organizational innovations. As will be discussed in the next section, the impact of learning and cooperation processes related to organizational innovations is particularly relevant for the local sphere of health innovation systems.

Innovation in the Health LIPs

The bulk of innovation literature stresses the ability to innovate as a fundamental aspect for the competitiveness of organizations, regions and countries. Competitiveness is defined as the ability to formulate and implement competitive strategies that allow an organization or set of organizations to expand or maintain a sustainable position in the market. The strategic objective of seeking competitive advantages, which provide greater market power, induces economic agents to make efforts for the introduction of new products and processes as well as organizational innovations (Nelson and Winter 1982; Freeman 1987; Dosi 1988; Nelson 1993). Such formulations are closer related to the reality of private companies. Considering innovation in the areas of public services and especially highlighting its social development dimension necessarily implies the need to broaden the understanding of the role of innovation, driving forces and mechanisms through which these are enabled and put into practice. The five empirical studies present a range of evidences for innovation on this broader perspective and discuss the obstacles and limitations for these processes.

Innovations in the Manufacturing Segments

In those two LIPs where we find some firms of the manufacturing segments, there are also relevant innovations being undertaken. In the case of Rio Grande do Sul, 25 out of 29 companies that were interviewed introduced product innovation (86.2%), 9 introduced process innovations (31.0%) and 6 organizational innovations (20.7%). Both in the case of product innovation and in the case of process, the firms adopt a strategic stance as a close follower, observing the leaders (Freeman and Soete 1997). Thus, most product innovations (75.9%) and process innovations (27, 6%) were new only for the company, but already existing in the market.

In the case of Minas Gerais the close articulation of companies with the university environment contributes to a high rate of innovation. Only one of the companies did not introduce relevant innovations. On the other hand, all other cite innovations that can be considered new not only for the company but for the market. These involve: kits for diagnosis of allergies through blood test; software for diagnostic in audiology; molecular test for the detection of HPV; molecular test for the detection of prostate cancer; molecular test for the detection of predisposition to hypertension; kit for determination of Salivary total protein concentration; kit for the diagnosis of salivary alpha amylase; process for assessment of salivary alpha-amylase, and process for evaluating the total salivary protein. As noted above, although the innovative activity of these companies is significant, impacts specifically related to health issues in the region are very limited. These are very specific innovations mostly derived from the specialized

competences and research interests of the companies' owners. Taking up the perspective of a LIPS as a privileged sphere for the generation and use of innovative solutions, the main challenge is how to induce the existing innovative capacity of these companies to products and processes related to the pressing needs of the public health system.

Innovations in the Service Segments

Secondly, we highlight the diverse array of innovations that are developed and implemented by hospitals and other organizations providing health services.

In all five studies the innovations were mainly related to processes and organizational methods. An interesting organizational model is related to private policlinics, where the concentration of specialists and diagnostic services cheapens the consultation and testing. This model constitutes an alternative especially for those who do not have private Health Insurance Plans and want or need to find faster solutions for their complaints. The longer the waiting is in the hall of public health organizations, the more this alternative business model prospers. In many cases, people use this cheap private option for acquiring the diagnostic which is a precondition for the subsequent treatment, which is costly and will be done in the public system. The main inducing factors for innovations are: (i) the improvement and efficiency of care and increased quality control over services; (ii) the high demand for treatment and tests; and (iii) the very technological advancement.

The case of Rio Grande do Sul also highlights the importance of organizational innovations in the public organizations. Changes in ways services are provided, organizing processes of care, diagnosis, hospitalization, etc., are critical to the efficient functioning of the hospitals. Regardless whether in the public or philanthropic organizations we can observe, over the last few years, a clear process of professionalization of management. Major impacts are related to the quality of services and efficiency, in terms, for example, of the occupancy rate, treatment time, etc. These efficiency gains related to management can generate positive outcomes for patients and also for the public health system with potential cost reductions. The Hospital das Clínicas de Porto Alegre, for example, is a reference in terms of management, being the benchmark for the National Recovery Program of University Hospitals (REHUF) of the Ministry of Education. The Hospital takes part of this program since 2009, helping to transfer its management model to other University Hospitals.

In Espírito Santo, the study found innovative activities in all levels and nodes of the health system. But they are rather incremental and limited to the adoption of organizational procedures and embodied technologies. In most cases they are focused on enabling the access of larger portions of the population to health services, in all levels of treatment complexity. The same situation occurs in the LIPS of Bahia. Despite the presence of a relatively well established system for the treatment of cancer, the service units, although in partnership with universities and research institutes in the region, do not innovate much internally, limiting themselves to the incorporation of embodied technologies.

The cases of Espírito Santo and Bahia highlight that most innovations in health service organizations occur through the adoption of 'closed packages'. This characteristic is directly related to the subordination of innovation to an economic logic. Big companies from outside the LIPS exert strong influence on the service organizations, inducing the adoption of drugs and medical equipment. This is perceived as a good substitute for own innovation efforts, since it apparently doesn't involve any considerable risk. Examples are:

Innovation in the Health System

- The acquisition of machinery, equipment drugs etc. without any closer interaction between innovative vendors and local users, thus without any adaptation. Technological standard is exogenously determined and meets the requirements of the broader production system but not necessarily the local needs;
- The incorporation of new products to meet the changes in the consumption pattern that are determined external to the LIPS, without considering local consumers/users as a main source of information and without any connection with local research and development initiatives, i.e., the local knowledge base;
- New operational procedures and analysis techniques, diagnosis and treatments, that are not flexible to be adapted to the organizational particularities of the hospital.

Thus, these big players affect the technological and innovative pattern, influencing the profile of health care provision. In this case the ‘direction’ of the innovation process is exogenously determined. This pattern is strengthened in so far as local physicians receive considerable incentives for prescribing medicaments and treatments that fit into this model. This approach often implies the demand for technologies that have not yet been fully tested in the country and cannot guaranty safety and ensure effectiveness of treatments. In this perspective, the strengthening of the regulatory framework, as discussed beneath, is paramount.

As said before, the health service providers, especially big hospitals, may exert a central role within a health innovation system, mobilizing competences and directing innovative efforts. In part, the empirical findings suggest they do. But we also find this potential to be limited by different aspects. First of all, it is important to recognize a hospital as one of the most complex types of organizations. This translates into two characteristics. First, in order to efficiently manage this complex structure, most innovative efforts are directed to organizational efficiency. Decisions concerning organizational modes are restricted to a rather small group of agents. An interesting element related to organizational innovations in all cases is that they are mostly directed to grant access, given that the potential and effective demand is much bigger than the service provision capacity³. Thus, efforts are directed in this sphere instead of taking as focal points the quality of services and preventive accompaniment after treatments.

Second, in the case of innovations related to products and processes, two main elements of complexity arise: the need to coordinate diversified teams, which do not have innovation as their main objective and the organizational rigidities for enabling articulations with external actors, such as firms in specific niches of manufacturing segments. On the one side, this may favor the adoption of “closed packages”, as discussed above. On the other side this may limit the potential for mobilizing and boosting local processes. Organizational and institutional barriers are even greater in the case of public organizations which are subject to a complex set of regulations and bureaucratic procedures. These elements will be discussed in more detail beneath.

THE INSTITUTIONAL DIMENSION IN THE HEALTH SYSTEM

Through explicit and implicit policies, the state has an influence in the case of health hardly found in other production systems. This influence is related to (i) the purchase of goods and services, (ii) the allocation of funds to the service provision infrastructure, (iii) investments and incentives directed to

industry and health care networks, as well as (iv) a wide range of regulatory activities that delimit the strategies of economic agents.

The compliance of policies from the federal government level in the territory is strongly mediated by state and municipal institutions, since the public health system is organized in a tripartite structure. According to legislation there are specific responsibilities for each of the three government spheres. Thus, the institutional arrangement of the public health system is based on a number of instances of agreement, involving different institutions and various segments of society.

Social, territorial and political divergent interests are involved that may lead to conflicts, such as disputes concerning priorities for the allocation of the public budget. Thus it is not possible to understand the learning, competence building and innovation processes in the local sphere without understanding the institutional environment that conditions these processes.

Power Structures and the Institutional Framework

The study on the LIPS in the State of Paraíba centers its discussion on some aspects which are relevant in all five cases. This study discusses the influence of the local political structure on the dynamics of the LIPS. The local elite is directly related to the origin and evolution of the health service system in the state. Owning most hospitals, clinics and laboratories, besides belonging to the staff of public hospitals and universities, the local elite consolidates a specific health services ‘business model’. As mentioned before, this model, influenced by large multinational corporations in the fields of drugs and equipment, set the technological standard, the profile of services and the organization of the LIPS in the territory. Besides the economic sphere, this elite exerts strong influence on the political dimension at the state level, capturing regulators, influencing the profile of education and training (favoring a relative scarcity of skilled personnel), among others. This has the effect of selective mechanism within the LIPS, restricting or enabling forms of articulation between finance, innovation, marketing and production. Thus, the case of Paraíba clearly shows how the evolution of the health LIPS in a direction that favors a public service logic, is inextricably hinged by local political and institutional structures.

It is important to underline that national strategic policies can reinforce or counteract local political-institutional dynamics that are less virtuous. Funding policies by federal agencies, such as BNDES, federal programs aimed at democratizing access to higher education, such as REUNE, among others, may contribute to the progressive disruption of the links that favor a ‘feedback circuit of power’ of the local elite. This shows that S&T policy, innovation policy and industrial policies are not neutral even if horizontally shaped. They favor specific technological trajectories and specific business models. Thus, the challenge is not only to expand investments in the health system but to orient those investments in a direction that is consistent with the constitutional assignment of a universal and integral health system. Some changes are in place, as discussed in the next section.

Regulation and Public Procurement

The state possesses important means for influencing the dynamics within the health system at the local sphere, favoring specific patterns of learning and innovative efforts and fomenting the local productive structure. These can help to diminish the influence and dependence on external actors and provide a more efficient use of public resources.

First, we emphasize that, to a large extent, the introduction of technological innovations is conditioned by national regulatory instances. The regulation of the incorporation of new technologies is a central element in modern systems of health care. It is decisive for the reduction of possible negative effects, for maintaining some control over their impact on costs, and for evaluating ethical and social aspects that may be involved.

In Brazil, the Ministry of Health has the incumbency for deciding about the adoption of technologies in the health system. Only recently a more coherent institutional setup has been created for dealing with this delicate issue. In 2011 the National Commission for the Incorporation of Technologies in the public health system (CONITEC) and the Department of Management and Incorporation of Technology in Health – DEGITS have been created.

CONITEC advises the Ministry of Health in issues related to the incorporation, exclusion or modification of new drugs, and procedures, as well as the alteration of clinical protocols or therapy guidelines. This technical advice takes into account issues such as efficiency, accuracy, effectiveness and safety of the technology, in addition to considering cost-benefit aspects in comparison to existing technologies.

The study of the LIPS in Bahia highlights the importance of therapeutic guidelines, clinical protocols and technologies to be incorporated into cancer care under CONITEC. The high costs for cancer treatment reflect the fact that this is one of the services that incorporate most technologies, both from the pharmaceutical/biotech industry and from the equipment industry. Such technologies are produced by large multinationals whose main competitive strategy is product differentiation.

A second important dimension that directly influences the dynamic processes in the health LIPSs is public procurement at the federal, state and local administrative level. Procurement linked to the supply of goods and services for the Health System represent a broad, dynamic and constantly growing market. In 2007 public spending on health reached 3.7% of GDP. This is a rather small number if compared with other countries with universal and integral health systems. Thus the growing tendency of this spending stresses the potential for setting a powerful policy instrument aimed at the development of productive and innovative capacity in the country.

Linking the industrial development to government procurement is, in this sense, strategic for the dynamics of the productive structure related to health in the territory. Only with the purchase of medicines, the federal government, state and municipalities spend more than US\$ 6 billion in 2012, according to data from the Ministry of Health. Data for spending with other medical products are less accurate but the Ministry of Health estimates that in 2007 spending totaled more than US\$ 2 billion. Nevertheless, and especially in view of the restrictions brought about by the legislation governing public procurement, this instrument has been used in an extremely limited way in the country.

The legislation governing the acquisitions of public hospitals (bidding system) implies that the supply of certain items may be undertaken by companies located outside of the LIPS, even in situations where firms with similar capabilities are present in the local sphere. This type of mechanism favors only price, regardless of product quality, customer follow up, or strengthening of local production ties. In some situations, purchases are realized via federal auctions, as in the case of the Central Hospital of Porto Alegre, in other cases auctions are conducted by the hospital itself, both having price as the only relevant attribute.

However, in 2010, the government approved the Law 12,349, amending the Law from 1993, establishing preference margins for products manufactured in the country in government procurement. The application of the new Law depends on complementary regulations. In July 2012, for example, a decree established the use of preference margins for medical products, according to the level of technological

complexity of the product. A next necessary step, still not envisaged by legislators, would be to set some kind of preference margin for local suppliers of specialized and general goods.

In fact, positive changes in this direction can already be observed in the studies. The regional public development bank Banco do Nordeste (BNB) started to apply some preference margin criteria for granting loans for the acquisition of medical equipment. Besides the BNB, the National Development Bank (BNDES) also created a financing program (BNDES Finame) for the acquisition of machinery and equipment. According to the decision of the Federal Government, funding for the purchase of machinery and equipment for the health system requires a minimum of 60% of the product value to be of domestic content. Preference margins for domestic products of 8% to 25% are part of the actions to stimulate domestic production within the national development policy (*Plano Brasil Maior*).

Innovation at the Institutional Level

Two of the studies highlighted successful experiences related to innovations that derived from different institutional arrangements at the state level. These converge with the challenges posed by the occupational structure of the territory and the need to provide universal health services vis-à-vis the concentration of the infrastructure of health services in the capital cities and large urban centers. The institutional/organizational innovations focused on bringing services and solutions to the countryside. Although simple, these can have a significant impact, helping to speed up the health service provision, avoiding unnecessary travels, and reducing costs for the national public health system.

The first case comes from Minas Gerais and was initially called Minas Telecardio. This was a pilot project of telemedicine in cardiology, started in 2006, which implemented the telecardiology service in 82 small municipalities. The project was designed by the public university hospitals of Minas Gerais, under the leadership of UFMG and the participation of the universities of the LIPS that was analyzed. Medical procedures did not suffer any modification. The main innovation brought to the health system was to rely on diagnostics from experts in a short period of time, given the transmission of clinical examination (electrocardiogram) via Internet. Moreover, this initiative also mobilized a set of incremental innovations in information technology. Based on its positive impact the program was gradually expanded, covering activities related to various other areas of medicine, constituting the current program Tele Minas Health.

Another important experience comes from the state of Bahia. The initiative was based on the recognition that getting the diagnosis constitutes one of the main challenges and barriers for patients to get access to treatments in oncology in the public system. The initiative was based on itinerant mammography equipment transported on a bus. This bus along with specialized technicians traveled through the regions of the state in which this kind of equipment is not available. As the study points out, this initiative contributed to a significant increase in the number of women aged between 50 and 69 who performed mammography.

Both experiences are relevant not only from the perspective of the beneficiaries, but also from the perspective of efficiency and cost saving within the public health system. All five cases show that hurdles for getting access to diagnostics and proper treatment in early stages of infirmities end up putting pressure on the public health system, since the patients' complications tend to evolve and require more complex and expensive procedures in the future.

If, on the one hand, these initiatives, especially telemedicine, reveal themselves especially promising to deal with the challenges of health care in a country with continental dimensions, some considerations should be made. As the study in Minas Gerais emphasizes, telemedicine is growing in importance because

of certain socio-economic aspects, such as the persistence of high levels of poverty, lack of access to qualified health services, shortage of human and material resources, the high costs of the health system and the importance of chronic disease in the epidemiological profile. In this sense, telemedicine does not act to solve these problems, just to alleviate its consequences. In addition, considering the importance of the strengthening of a cognitive territory, it is important to emphasize telemedicine tools as a complementary but not substitute for the development of capacities present and rooted in the territory. The opportunities and challenges for strengthening the local learning and capacity building process directed to the needs of the public health system constitute the focus of the concluding section.

CONCLUSION AND FUTURE RESEARCH

A look at the health production and innovation system from a territorial perspective helps to guide policy initiatives that may help to transform the great mobilization potential of this area into local development. Development in this sense encompasses both an economic and a social dimension. Learning and innovation dynamics that are connected to the needs of the territory, which mobilize local capabilities and build upon them, play a special role in this process. The five studies clearly show that technological development (and innovation in general) is not a neutral process. It is subject to characteristics and priorities of specific societies, groups within it and individual actors. When it comes to a system that is mostly financed by public resources and should serve collective goals there is a clear priority for the agenda: the building of a complex system envisaging an effectively universal and integral public health system. Along with it, there are many opportunities for nurturing local development and many challenges. As discussed in the paper, market forces and individual interests, if left on their own, may not (in most cases they do not) favor the achievement of the Constitutional principles of a universal and integral health system.

The research project and the five related empirical studies seek to offer some contributions to this debate.

The results show that the territorial embedding of the Health Economic-Industrial Complex and the broader innovation system related to it still involves great challenges. Due to space limitation, some of these were not properly discussed in this paper. We chose to focus on the learning, capacity building and innovation processes and the factor that influence this processes.

Even if not discussed in detail the set of challenges that were identified deserve to be cited:

- Definition of strategic systemic policies that link the national and the local sphere.
- Raise public spending in health, improve its efficiency and guide them strategically.
- Use the state purchasing power to stimulate the revitalization of the productive and innovative structure in the country and establish specific instruments for promoting these at the local level.
- Better articulation of the institutional network that conforms the public health system.
- Favoring a public health logic in detriment of business models directed by private agents.
- Strengthen the learning and capacity building processes, especially taking advantage of local specificities.
- Promote the productive and innovative structure within the local territory.

Based on the focus of this paper we take a deeper look at the last three aspects.

In many examples, we identified the conflict between the public and private logic in the health system⁴. Both from an analytical point of view and from a normative one it is important to consider the two sides of the health system as a vector of development. On the one side, it is an important dimension of industrial and S&T development and economic competitiveness. On the other side, it has an essential public and social service dimensions. The main challenge is for the state and society to balance the forces generating asymmetries and inequalities that are associated with the operation of business strategies and markets. This calls for a perspective focused on the political and institutional dimension and the mode these influence the way production, service provision and other activities are organized in each local territory. Conducive changes have to rely on the collaboration of public institutions in all administrative levels. As discussed in the text, funding and procurement policies on the part of public development banks and public programs for amplifying access to higher education, among other policies, may contribute to provide an increased supply of public and private services that are closer articulated to local social needs. Other important policy initiatives may involve:

- Modification of the pedagogical projects to be followed by higher education institutions, notably medicine, so as to strengthen the public logic of universal free health care and favoring the formation of professionals dedicated to preventive and communitarian health care;
- Prioritize international interaction of the HEIs with institutions from countries that opted for public and universal health care systems;
- Increasing the funding resources for medical research articulated to the local epidemiological profile and to local potentialities (e.g. in phytotherapies) and traditional knowledge.
- Creation of exclusive dedication regimes and proper incentive regimes to direct scientific and medical capabilities to the challenges of public health.

Another main challenge is to strengthen the learning and capacity building processes. The low innovative potential in most LIPSs is related to the fragmentation of the local cognitive territory and its limited articulation to the national health innovation system. In many cases, the service providing organizations limit their innovative activities to organizational changes and the incorporation of “closed packages”, although there are some important partnerships with universities and research institutes.

Thus, a suggestion given by the research of Bahia to reduce the problem of poor and peripheral regions is to direct efforts to technological upgrades and improvements that allow to rapidly opening new access points into the health system. This of course involves the interconnection of different types of innovations and a close institutional mobilization to allow these changes to take effect

On the other hand, an improvement in financing conditions for research and innovation is core to promote greater coordination between local, regional and national innovation system. The expansion and improvement of programs in support of innovation tend to have positive results in the medium and long term, also helping to overcome the distance between science and technology policies. However, as mentioned, this is not a neutral process. S&T and innovation promotion in the field of health reflects the broader pattern of innovation promotion in the country, which still overemphasizes the supply side and without a strategic guidance. Even if it is an open debate to what extent the state should ‘direct’ innovation efforts in certain directions, we can expect to find more consensus when it comes up to a public essential service financed by public resources. Thus, the main argument is that health (together with other essential public services) constitutes a special case where explicit influence should be exerted by the state.

At the level of industrial, S&T and innovation policy, subsidies and procurement connected to specific goals should be the norm instead of tax incentives. This means research funding should be directed to reduce problems related to the mismatch between scientific and technological development identified in the case studies. An example would be to support researchers to develop subsequent phases toward the introduction of product and process innovations. Support to costly phases of testing with patients should be very selective in terms of the potential impact on the public health system.

At the institutional level, the recently created Commission for the Incorporation of Technologies in the public health system (CONITEC) should set explicit requirements that converge with an efficient and cheap treatment of larger fractions of the population. Specifically with regard to the incorporation of new drugs and procedures, as well as the establishment of clinical protocols, it would be important to strengthen and expand the role of these institutions. There is a large potential to articulate the role of this institutional apparatus, on the one hand, with innovation and industrial policies and, on the other hand, with regional and local development policies. This institutional apparatus, established at the national level, could eventually be partially extended to the regional/local dimension, stimulating (via existing or potential capabilities) local developments that have direct relation to the needs of these territories. Local specific needs may be related to the natural environment, ethnic composition, socio-demographic and epidemiological profile, urban structures, productive structures, etc.

Further, one cannot expect efforts on the part of researchers (and learning processes in general) to serve a national/local public logic if the incentive structure is based on different meritocracy standards. On the one side, we find the research agendas to be strongly influenced by institutions and enterprises from developed countries. On the other side, the ‘*parnassian*’ ‘*publish or perish*’ productivity requirements directed to academics in the country make far less sense in the case of health. The objective quantitative measurements that exist for evaluating academic production should be more permeated by qualitative standards that set the public health system in the front stage.

Another main finding of the studies was the control local elites and other power structures exert over scientific and technological knowledge. As stated, it directly influences the profile of formation of future physicians and other professionals and therefore the way they offer medical, hospital and laboratorial services. Thus, the expansion of courses in medicine and other areas of health with a focus on socio-sanitary priorities is mandatory. In this context, the formation of general practitioners should be further stimulated, rather than the training of specialists, especially in relation to activities of preventive health care for low and medium complexity, and family medicine. This would contribute to a qualitative expansion of the required number of physicians and other specialists working in the public health system and could help to reduce the influence of the so-called private ‘*business model*’ as referred before.

Another suggestion made in the study of the LIPS in Paraíba is to favor the internationalization of HEIs, stimulating education and research activities in countries with public and universal health systems, in order to strengthen the training and policy guidance in this direction.

Regarding the mismatch between research conducted by faculty researchers and their assistance activities, with consequent low involvement of these professionals with practice in hospitals, an alternative would be the set of schemes of exclusive dedication.

The issue of power structures is also evident in relation to external forces exerted by the manufacturers of drugs and medical equipment, which contribute to shaping the business model of health service activity. A challenge to overcome this dependency is to promote a closer articulation with the S&T infrastructure that exists in the country, i.e. a better articulation of the local and national spheres of the health innovation system. This articulation, in line with increased resources for research, could help to

reduce the influence of these organizations in the training profile of physicians, direct research to issues concerning broader fractions of the population, but that are neglected due to its lower profitability (e.g. research related to epidemiological profile of each region).

Another dimension in which there is a need to overcome policies mismatches is related to the relationship between science policy and technology policy. This disconnection is related to poor coordination and limited information flow between different industrial segments of the Health Economic-Industrial Complex. Thus incentives schemes should be directed to building of more systemic ties within the LIPS's cognitive territories favoring cooperative initiatives at the regional and local level that involve firms from different segments and S&T organizations.. The research efforts should be able to mobilize the firms to develop specific solutions in a given territory. This may also contribute to reduce the "dependency" on multinational corporations that profoundly influence the direction of technological change in health care. Public policies directed to greater articulations within the LIPS can enhance the innovative capacity of firms and provide competitive advantages for local actors with positive impacts on the territory.

In this context, the creation of technology parks could be encouraged. A special incentive can be given to the relationship between information and communication technologies (ICTs) and health, given the scientific and technological capacities already achieved in the country in these areas. Several case studies proposed an expansion and improvement of the use of information technology (IT) to streamline access and treatment in health, especially in the poorest municipalities of the LIPSs. In this sense, tele-medicine is growing in importance but its role, in spite of extremely relevant, should be envisaged as a complementary tool in public health policies, not substituting the efforts to improve local capabilities.

In sum, the research efforts focusing on five different localities in Brazil showed that there is a potential for promoting systemic structures and relations on the local sphere, although the bulk of scientific knowledge and technological evolution is very concentrated in the national and world level. However, taking advantage of this potential in a country such as Brazil, characterized by enormous heterogeneity and diversity, requires the advancement of the territorial approach in the discussion of health-innovation linkages. Learning and innovation dynamics that are connected to the needs of the territory, which mobilize local capabilities and build upon them, play a special role in this process. Therefore, advancing the research on health production and innovation systems from a territorial perspective is an important component of a research agenda aiming to guide policy initiatives focused on transforming the great mobilization potential of this area into the local development.

When it comes up to considering the drivers of capacity building processes and of innovation, institutional and power dimensions play a far greater role than in other industries. It was shown that there is a complex interplay between public and private interests that have to be mediated by an institutional setup, which is itself complex and structured in multiple levels. This is another component of a future research agenda, which constitutes one of the most interesting and important fields of enquiry based on a systemic and interdisciplinary approach within social sciences.

Finally, there is an increasing understanding that the interaction between health systems and innovation systems can generate extremely positive synergies in terms of growth, efficiency and equity, thus constituting a significant link in a proactive strategy for inclusive development (Arocena and Sutz, 2012). Problems of exclusion in health can be transformed into sustainable demand for research and innovation stimulating the use of existing capabilities in developing countries. Thereby enhancing the understanding on how to induce the interaction between health systems and innovation systems for social inclusion is another central element of a future research agenda in this field.

KEY TERMS AND DEFINITIONS

Capacity Building: Refers to the accumulation of knowledge and abilities by individuals and organizations, based on formal and informal learning processes. The capability of firms enables them to develop and reproduce more advanced productive and innovative practices, leading to an increase of their endowment of tangible (equipment, infra-structure) and intangible resources (knowledge, abilities, competences) and, therefore, fostering their competitiveness.

Cooperation: The general meaning of cooperation is ‘working together’, involving relations of mutual confidence and coordination at different levels among the actors. In local productive systems, different types of cooperation can be identified, including productive cooperation for the attainment of economies of scale and scope; improvement of quality and productivity; and innovative cooperation, which leads to the reduction of risks, costs, time and, especially, to interactive learning, increasing the potential for the creation of productive and innovative capabilities.

Governance: The different patterns of coordination, intervention and participation in the processes of decision making of different actors (the State, in its various levels, companies, citizens, workers, non-governmental organizations, etc.); and to the diverse activities associated to the organization of production and commercialization, as well as to the process of generation, dissemination and use of knowledge.

Innovation: The process by which organizations incorporate knowledge in the production of goods and services that are new for them, not mattering if they are or not new for domestic or foreign competitors. In the innovation economy, the main focus of analysis falls upon technical changes and other associated changes, which are considered to be fundamental for the understanding of the factors that make organizations, sectors, regions and countries develop faster than others.

Learning: Cumulative process, by which the organizations (through their human resources) acquire and amplify their knowledge, refine their searching procedures and their abilities in developing, producing and commercializing goods and services.

Local Innovative and Productive Systems – LIPSs: Groups of economic, political and social actors, situated in the same territory, developing correlated economic activities and that present expressive productive, interactive, cooperative and learning connections. LIPSs generally include companies (producers of final goods and services, suppliers of equipment and other inputs, industrial services, commerce, clients, etc.), cooperatives, associations, and representations and other organizations dedicated to the training of human resources, information, research, development and engineering, promotion and financing.

Territory and Territoriality: Generically, the idea of territory refers to the geographical portion appropriated by a group of humans or animals, or by an individual, seeking to secure their reproduction and the satisfaction of their vital necessities. There are several meanings for the word territory. All conserve the idea of a personal or collective dominium in different contexts and levels: the house, the office, the neighborhood, city, region, nation, and planet. Each territory is, therefore, shaped through the combination of internal and external conditions and forces and should be understood as part of a spatial totality. The territory cannot be reduced to its material or concrete dimension, presenting various dimensions such as (a) Physical – concerning its natural characteristics and resources (such as climate, soil, relief, vegetation and subsoil), as well as those resulting from the use and from the territorial practices of social groups; (b) Economic – through the physical organization of the economic production processes – what is produced, how it is produced and who produces; (c) Social and political – representing a mean through which social integration occurs and domination and power relations are established – how and who dominates or influences it; (d) Symbolic – including the affective and cultural bonds of identity of the individual or of a social group with its geographic space; (e) Cognitive – referring to the conditions for the generation, use and diffusion of knowledge.

ENDNOTES

- ¹ Unfortunately space limitations do not allow us to explore this literature and its implications for research methodology. For a detailed discussion of the LIPS framework applied to studies focusing on inclusive development see Matos et al. (2012).
- ² The complete research reports for the Five studies can be found in Portuguese in: <http://www.redesist.ie.ufrj.br/p4/>
- ³ The legislation, that implemented the universal and integral public health system, is little more than two decades old. In historical perspective this is a rather short period for building up an entire system for providing health for 200 million people in a country with continental size. Although there is a long way ahead for fully meeting the constitutional assignment, this system is in fact constantly improving. The set of studies presented in this paper seek to provide some input for this ongoing process.
- ⁴ The detailed discussion of all these aspects can be found in the complete research report in: <http://www.redesist.ie.ufrj.br/p4/>

ABSTRACT

Climate change is expected to affect the distribution, prevalence and life cycle of several infectious diseases. This scenario is relevant to Morocco since the country is considered by many IPCC assessments reports as a climate change hotspot with a high vulnerability to many expected impacts. Given this existing vulnerability, this chapter aims to highlight relevant vector-borne diseases, the risks of their reemergence in many vulnerable regions and the pressing need to understand their dynamics within a context marked by knowledge gaps and limited scientific evidence; underline the problematic aspects of health adaptation to climate change and the current difficulties in terms of policy and governance to manage climate-health linkages; and finally undertake an assessment of Morocco's adaptive capacity from a health perspective and formulate recommendations for effective climate-health governance and policy.

INTRODUCTION

The current realization that human beings need to be concerned about the only 'life-support system' that the Earth and its environment provide stems perhaps in part from the fact that, until fairly recently, the evolution of humankind was largely dependent on the quality of the environment and the resources it provides in terms of water, food, and favorable health conditions. These are as vital as ever, despite

DOI: 10.4018/978-1-5225-1674-3.ch005

current levels of technology and apparent resilience in the face of often degraded environments in many parts of the world. Today, the necessary conditions for maintaining human security – i.e. water quality and quantity, food security, and health – are under threat as a result of numerous human-induced factors; among these, climate change is certainly one of the more durable aspects of anthropogenic disruptions to natural resources (Beniston 2010). It is currently recognized that with the constant increase of the planet's temperature, there are, and will be, more frequent and severe floods, droughts, storms, and heat waves; these changes to Earth's biophysical system will exacerbate and extend the rates and ranges of many diseases and overall contribute to poor health among all populations (Friel et al. 2011).

Therefore, coupled with other environmental risks, climate change poses a serious threat to the progress made towards global health and development goals in recent decades. This challenge will make efforts to ensure the conditions in which people can be healthy more difficult in a myriad of ways (Wiley 2010). Moreover, not only does climate change carry a direct and indirect health warning, it is already contributing towards widening the gap in health inequalities between people living in the developing and developed world. In other words, climate change health impacts will – perversely, unjustly and inequitably – affect those in our society who are most disadvantaged and who arguably have contributed least to it – certainly in terms of their consumption of natural resources. Thus, and according to Friel et al. (2011), without a lessening of background rates of diseases, the multiplier effects of climate change on health outcomes will greatly exacerbate existing health inequities between and within countries, which poses a major additional challenge to international development.

For Wiley (2010), climate change acts primarily as an intensifier, and to some extent a redistributor of existing threats to health. More precisely, climate change is expected to directly affect many environmental determinants of health – mainly water, air, weather, oceans, and ecosystems (Portier et al. 2010) – which may exacerbate exposure to natural disasters and disease-carrying vectors, access to safe and potable drinking water, and food security. Similarly, Boxall et al. (2009) asserts that weather and climate factors are known to affect the transmission of water and vector-borne infectious diseases. Some linkages between climate and health are fairly obvious, such as the impact of weather-related natural disasters, whereas others are less obvious and may be neglected by policymakers, such as the indirect impacts of natural disasters, especially on mental health (Wiley 2010).

Addressing the health impacts of climate change is especially challenging because both the surrounding environment and the decisions that people make influence health. In real-life situations, a host of other factors come into play in determining vulnerability including biological susceptibility, socioeconomic status, cultural competence, and the built environment. In a world of myriad 'what if' scenarios surrounding climate change, it becomes very complicated to create wise health policies for the future because of the uncertainty of predicting environmental change and human decisions. The need for sound science on which to base such policies becomes more critical than ever (Portier et al. 2010).

Within a Moroccan perspective, the main health vulnerabilities to climate change include the following: risk of reactivation of certain diseases sensitive to climate change (such as malaria, bilharzia, typhoid, leishmaniasis, dengue and cholera); possibility of re-emergence of infectious diseases, vector-borne diseases as well as diseases and deaths related to extreme weather events, especially among the most vulnerable groups; increased water and food-borne diseases; increased incidence of respiratory infections and allergies due to air pollution and sudden weather events and rising temperatures which contribute to the increased volume of ozone at ground level and precipitate the start of the pollen season; natural disasters such as floods which cause damage (affecting agriculture, livestock and real estate), deaths and illnesses suffered by victims and their families; etc.

Instead of covering all health impacts of climate change in Morocco, this chapter aims to focus on many infectious diseases that are expected to change their geographical or seasonal patterns and incidence due to climate change and variability. More specifically, climate change will likely affect the distribution, prevalence and lifecycle of several vector-borne diseases – such as Malaria and Leishmaniasis – and water-related disease – such as Schistosomiasis, and this scenario is relevant to the Moroccan context. These diseases still ravage lives in many developing and less developed countries and are likely to have a major human health burden in the coming years due to climate change and other factors. However, and despite this alarming fact, there is still limited specific scientific evidence to support policy-making processes in many countries.

In Morocco, infectious diseases are still a public health problem and the situation may be more complicated in light of climate change. Due to legal requirement to report notifiable diseases, the number of cases – both indigenous and imported – is continuously recorded for Malaria, Schistosomiasis and Leishmaniasis and showed an increase of the latter. This chapter aims to identify vector-borne diseases that are highly sensitive to climate change in Morocco, the risks of their reemergence in vulnerable regions; highlight the pressing need to understand the dynamics of these diseases, especially in a context marked by limited and uncertain scientific evidence regarding the health vulnerability to climate change; underline the problematic aspects of health adaptation to climate change and the current difficulties in terms of policy and governance action to manage climate-health linkages; and finally undertake an assessment of Morocco's adaptive capacity within a health perspective while formulating recommendations to effectively adapting the health sector to climate change and developing an effective climate-health governance and policy.

RELEVANT CLIMATE SENSITIVE INFECTIOUS DISEASES IN MOROCCO

Parasitic diseases still pose a public health challenge in Morocco. Their spread is very closely tied to risk factors – climatic, ecological, and socioeconomic – and other factors, such as urbanization, agricultural practices, beyond health authorities' traditional sphere of influence. Climate change is imposing a burden that is unevenly distributed across populations. The most vulnerable populations are in worse positions to effectively face these challenges because they have a limited ability to adapt to changing conditions. In particular, vulnerability in this context is linked to the emergence of vector-borne-diseases: Leishmaniasis, Malaria, and Schistosomiasis, which can be life-threatening. Therefore, there is an urgent need to understand their life cycle, habitats of reservoirs, micro niche of arthropod/insect vectors in the Moroccan context by using an eco-epidemiological approach.

Leishmaniasis

Leishmaniasis is a complex disease caused by *Leishmania* species and transmitted by a Phlebotomine sand fly (Diptera: Psychodidae) (Figure 1). Two forms are known, cutaneous and visceral Leishmaniasis. The main reservoirs are dogs for Zoonotic Visceral Leishmaniasis (ZVL), rodents for Zoonotic Cutaneous Leishmaniasis (ZCL) and human for Anthroponotic Cutaneous Leishmaniasis (Figure 1) (ACL) (Rioux et al., 1982; Nejjar et al., 1998; Pratlong et al., 1991; Kahime et al., 2014).

Actually, three parasite species co-exist in Morocco:

Figure 1. Simplified Life cycle of Leishmaniasis

- *Leishmania infantum*, causes mainly ZVL and transmitted by species of the subgenus *Larroussius*. It is widespread in the whole country and is more frequent in its northern part (Kahime et al., 2014, 2015a); *L. infantum* can cause Cutaneous leishmaniasis (CL) as well even if it is a rare condition with a few sporadic cases in the North of the country (especially in Sidi Kacem province) with little epidemiological data available (Kahime et al., 2015b).
- *L. major* causes ZCL with *Phlebotomus papatasi* as the vector in pre-Saharan area (Rioux et al., 1982, 1986; Kahime et al., 2014); and
- *L. tropica*, causative agent of ACL is widespread in northern and central areas, especially in semi-arid regions with *P. sergenti* as the vector (Guilvard et al., 1991; Pratlong et al., 1991; Kahime et al., 2014).

Malaria

Malaria is a mosquito-borne infectious disease caused by parasitic protozoans of the genus *Plasmodium* (*P. vivax*, *P. malariae*, *P. ovale* and *P. falciparum*) and is transmitted by female mosquito vectors of the Anopheles species. The cycle of *Plasmodium* is carried out in several stages which spread between mosquitoes and humans (Figure 2).

Malaria raged in Morocco for centuries and was an endemic disease in the majority of provinces. In 1960, a domestic program to fight the disease was launched. It allowed to control the situation after 40 years of bitter struggle. By 1999, malaria was occurring as sporadic cases of *Plasmodium vivax* in some residual foci in the north. The epidemiological assessment undertaken by the Moroccan Ministry of Health showed a shift towards the elimination of indigenous cases and the last indigenous case was reported in 2004. Morocco is now WHO certified Malaria free but imported cases are reported constantly.

Figure 2. Simplified life cycle of Malaria

In Morocco, *Anopheles labranchiae* is the main vector of malaria. In common with leishmaniasis, it is the female (vector) that bites when it needs a blood meal before laying eggs. The vectorial capacity of *A. labranchiae* is considerably high during the summer which corresponds to the rice cultivation period in northern Morocco (Faraj et al., 2008).

There are two areas with high risk of transmission: The north foci (Al Hoceima, Taounate and Chefchaoune) and the center (Beni Mellal, Khouribga and El Kelaa) (MMH, 2004; Trari and Carnevale, 2011).

The risk of malaria resurgence in Morocco is higher because of the possible presence of parasite in human and invertebrate hosts in the last malaria foci, numerous imported cases and the presence of the main vector of Malaria in Morocco.

Schistosomiasis

Schistosomiasis is a disease caused by parasitic worms belonging to the class of trematodes and genus *Schistosoma* (*S. haematobium*, *S. mansoni*, *S. japonicum* and *S. intercalatum*). The parasite develops successively in two hosts: mollusk and human (Figure 3). This parasite is commonly found in ponds, streams and irrigation canals, housed in freshwater mollusks, and infests humans through the skin via contact with contaminated water (Figure 3).

In Morocco, the disease had spread in the oases in the south and along the southern side of the Atlas (MMH, 1980). The majority of cases have been filed in the Province of Tata, Chtouka, Taroudant, and Errachidia (WHO, 2012b). In recent years, many *S. haematobium* foci proved unstable and some even disappeared. However, creating large water supply for irrigation may lead to the onset of new foci.

Despite the existence of monitoring programs and adequate health services, cases of Malaria, Leishmaniasis and Schistosomiasis are still recorded in Morocco. As shown in Table 1, Leishmaniasis is the most reported disease and all cases are indigenous. In contrast, all Malaria cases are imported. For

Figure 3. Simplified life cycle of Schistosomiasis

MMH, 2014.

*Imported cases.

Schistosomiasis, the number of indigenous cases is rarely associated with the risk of introduction of new species, which is linked to travelers or immigrants from countries where these species are endemic.

These diseases constitute a real social problem in Morocco because they disproportionately affect the poor, particularly those in vulnerable housing and environmental conditions. Loss of income and healthcare costs exacerbate the economic situation of already-disadvantaged households (Kahime et al., in press). Urban population growth, responsible for the spatial expansion of cities, creates enormous need for community facilities and equipment related to decent housing, access to clean water and sanitation and environmental preservation. The vulnerability of populations to these disease risks varies across spatial and temporal scales in response to environmental change, economic development dynamics, social capital, demographics and population structure. Understanding the interactions between human health and the environment is quite complex. In fact, the very term environment can be confusing because it is used in various acceptances. The ecosystem approach to human health is distinguished from traditional approaches by integrating all determinants of health, namely economic and environmental factors and community needs.

CLIMATE CHANGE IMPACTS ON INFECTIOUS DISEASES: THE CASE OF MOROCCO

Anthropogenic climate change may directly affect the behavior and geographical distribution of mosquito vectors and the lifecycle of the parasite, and thus change the incidence of the disease. Indirectly, climate change could also have various effects by influencing environmental factors such as vegetation and the availability of breeding sites (Martens et al., 1995).

As the climate has an important influence on environmental and socio-economic components, the juxtaposition of many of socio-economic factors e.g., poverty, economic degradation over time may convincingly increase as result to climate change. This change could, depending on the region, have adverse impacts on water resources, agriculture, biodiversity, ecosystems, food and health security.

A wide range of infectious diseases may change their geographic range, seasonality and incidence due to climate change, but there is still limited and uncertain scientific evidence about the extent of health vulnerability to climate change. For example, over the past decade, the epidemiological situation of CL has changed significantly. It is acquiring an increasingly epidemic status with geographic expansion to previously free areas and the emergence of new foci in several provinces of Morocco. 24 804 cases of zoonotic *L. major* CL and 16 852 cases of *L. tropica* anthroponotic CL were recorded between 2004 and 2013 in Morocco (Kahime et al., 2015b). ZCL acquires an increasingly epidemic status with geographic expansion into previously free areas in several provinces of South-East Morocco (Kahime et al. in press). Whereas, ACL has an extensive geographical distribution (Kahime et al., 2015b).

The leishmaniasis lifecycle, parasite-reservoir-vector, evolves depending on geographic regions and is sensitive to environmental changes that can affect the parasite, the reservoir and the vector, as well as their dynamic interaction and territorial expansion (Bounoua et al., 2013). Seasonal patterns and the correlation between the vector density and the number of cases have been documented (Felicangeli et al., 1998). Weather and climate variables also play an important role in leishmaniasis incidence as they can constrain or exacerbate favorable conditions for the disease, such as an acceleration of the development of the parasite or synergistic changes in reservoir and vector populations that cause an explosion in the vector population. For example, increase in precipitation may increase the vegetation foliage, and thus the number and quality of breeding sites for both rodents and sandflies (Yates et al., 2002; Bounoua et al., 2013).

Distribution and seasonal activity of malaria are also sensitive to climate factors and impact the local capacity to control the disease. Malaria is one of the few climate-sensitive diseases that has been modeled by many research groups, which facilitates a thorough assessment of possible climate change effects using a multi-model inter-comparison (Caminadae et al., 2014). The distribution and population dynamics of malaria are probably more governed by abiotic than biotic factors (Southwood, 1977). Of the possible abiotic influences on the transmission cycle of malaria, temperature and rainfall are the most important; therefore, the situation could be exacerbated by climate change. Although this linkage is still uncertain, an increase in the incidence of malaria has been identified as a potential impact of climate change in South America (Lieshout et al., 2004) and Africa (Ebi et al., 2005). Climatic factors that feed into the phenomenon could have a direct bearing on the number of malaria cases. Actually, a number of studies have reported the association between malaria cases, rainfall and temperature (Bhattarai et al., 2007). For example, a study carried out in Ethiopia revealed an association of malaria with rainfall

and minimum temperature, the strength of which varied with altitude (Teklehaimanot et al., 2004). In South Africa, variations in annual cases of malaria were shown to be related to rainfall and temperature patterns (Craig et al., 2004).

According to McCreesh and Booth (2013), climate change will inevitably influence both the distribution of *Schistosoma* sp. and incidence of schistosomiasis in areas where it is currently endemic. Global warming is expected to be accompanied by perturbations in the global hydrologic cycle (Allen and Ingram, 2002), precipitation levels and pronounced changes in water availability (Allen et al., 2005). However, only a few attempts have been made to predict changes in the spatial distribution of schistosomiasis due to global warming; and the results have been conflicting (Martens et al., 1995, 1997). Thus, the nature and extent of climate change on the transmission of schistosomiasis remains poorly understood (Morgan, 2001). The lack of research in this field probably explains why climate change implications for schistosomiasis control and elimination have been largely ignored (McCreesh et al., 2015).

Snails of the genus *Bulinus* serve as the intermediate hosts of *S. haematobium* in Africa and the Eastern Mediterranean (WHO, 1990). These aquatic snails breed in waters (barrages, irrigation canals...), contaminated with infected faeces or urine from infected person or by infected wastewater, used also for irrigation. Water resources development schemes in certain areas, particularly irrigation schemes, can contribute to the introduction and spread of schistosomiasis. Consequently, intermediate hosts can determine the geographical area of schistosomiasis risk. In Morocco, the disease foci, especially in Beni Mellal, El Kelaa and Nador Provinces were linked to hydrologic programs for irrigation (barrages and irrigation canals and wells) in the 1970s (WHO, 2012b).

Potential impact of climate change on the transmission of schistosomiasis and other diseases must be juxtaposed to profound ecological, demographic, and socioeconomic changes. Also, it should be mentioned that, in Morocco, there is no study that addresses the relationship between malaria or schistosomiasis and climate change.

ADAPTATION TO CLIMATE CHANGE FROM A HEALTH PERSPECTIVE: CHALLENGES AND OPPORTUNITIES

Supported by a rapidly growing body of evidence, the health implications of climate change are widely covered at international meetings and used to demand action on climate change. However, while the health sector is well involved in adaptation strategies, mitigation efforts are anticipated to largely take place outside of the sector according to Lovell (2011). Nerlander (2009) asserts that proactive health adaptation strategies are needed to protect vulnerable people from climate change impacts on their health and well-being. This is true because reducing vulnerabilities and increasing resilience in general will help populations cope with climate change health effects. For Wiley (2010), adaptation to climate change requires a set of law, policy and governance tools (such as a purpose-built legal and policy framework designed to specifically address climate risks, which may provide particular models of governance and management for adaptation to climate change (Godden et al., 2013) that are very different from what environmental policymakers have typically employed in their mitigation efforts¹. However, to date, there has been limited research on how legal, institutional and regulatory frameworks can support and facilitate effective adaptation and responses to climate risks (Godden et al., 2013). While many factors influence resilience and the capacity to prepare for and respond to these risks, regulatory and policy frameworks remain significant drivers of collective and behavioral change.

In addition, adaptation of the health sector to climate change requires a continuous access of decision makers to relevant scientific evidence and information. Nevertheless, forecasting the impacts of climate change on human health is still limited because populations have different vulnerabilities to change and susceptibility to disease. This depends – among other factors – on hygiene practices, clothing, housing, and medical and agricultural traditions. Adaptation to the spread of disease is also determined by the economic level of a given population, the quality and coverage of medical services, and the integrity of the environments. Thus, human biological and psychological factors are primary determinants, but ecological and global systems are also involved, as are economics and access to health care, which shape the vulnerability of societies to disease. Shifts in environmental conditions that interact with the biology of disease agents can also exert profound effects. Changes in land use affect the distribution of disease carriers, such as rodents or insects, while climate influences their range and affects the timing and intensity of outbreaks. Changing social conditions, such as the growth of multimillion-inhabitant cities in the developing world and widespread ecological change, are today contributing to the spread of infectious diseases (Beniston 2010).

Adaptation to climate change is equated with the well-established concept of public health preparedness (Frumkin et al., 2008) and necessitates that traditional public health initiatives are integrated with weather warning systems, climate forecasts, and disaster preparedness. In addition, reducing vulnerabilities and increasing resilience to climate change includes strengthening health systems (Nerlander, 2009) because inadequate healthcare infrastructure contributes to the increase of vulnerability to the effects of climate change and reduces the adaptive capacity of nations (Patz and Kovats, 2002).

There are different adaptation strategies to reduce the vulnerability of human health to climate change. These strategies include measures taken before the observation of impacts (preventive measures), as well as other measures taken after the appearance of such impacts (corrective measures). In addition, adaptation may be the result of political decisions (planned adaptation), or it can be spontaneous (independent measures). In addition, adaptation in unmanaged natural systems is carried out by independent and corrective measures while the managed natural systems can take advantage from preventive measures and planned adaptation strategies. Many adaptation options may produce benefits beyond those associated with climate change; the rehabilitation and maintenance of the public health infrastructure for example is often considered the most important coping strategy, most profitable and most immediately needed.

For adaptation purposes, the World Health Organization has called on the health care sector to prepare for climate change impacts through efforts to increase resilience (CCGHC and Nova Scotia Department of Environment and Health Canada, 2013). In addition to continually engage in broader community discussions and initiatives around climate-related issues, the health care sector should constantly mainstream climate change into risk assessments and consider it when developing plans and activities. Health care and public health professionals and staff should be prepared for climate change by assessing risks from extreme weather events, readiness to manage climate-related infectious disease outbreaks or atypical cases and increasing understanding of how gradual shifts in weather can affect risk profiles. Moreover, adaptation strategies to reduce the vulnerability of human health to climate change should include public health training, monitoring, viable prevention and control programs, and more effective response systems in case of emergencies, including the setting up of multi-disciplinary health care teams to address the various health effects and implications of climate change. Furthermore, health care facilities can reduce risks of climate change through proper management of critical resources (e.g. pharmaceuticals, food, transportation, medical supplies and equipment) based on climate change considerations. A resilient health care facility is also one that commits to sustainable practices, such as water and energy conserva-

tion, promoting active transportation, and local food procurement. In investing in resilience activities in these areas, health care facilities can reduce operating costs and increase resilience in the community.

On another level, climate change will likely exacerbate already existing urban social inequities and health risks, thereby exacerbating existing urban health inequities. According to Neiderud (2015), urbanization leads to many challenges for global health and epidemiology of infectious diseases. In other terms, the rise of the new modern cities creates potential risks and challenges in the aspect of emerging infectious diseases. Risk factors in the urban environment could, for example, be the poor housing connected to inadequate water supplies, sanitation and waste management (these conditions contribute to a favorable setting for both rodents and insects which carry pathogens and soil-transmitted helminth infections²). Also, if buildings lack effective fuel and ventilation systems, respiratory tract infections can also be acquired. Contaminated water can spread disease, as can poor food storage and preparation, due to microbial toxins and zoonotic agents.

In addition, the new megacities can be incubators for new epidemics, and zoonotic diseases can spread in a more rapid manner and become worldwide threats. The density of inhabitants and the close contact between people in urban areas are often potential hot spots for rapid spread of infectious diseases such as severe acute respiratory syndrome (SARS) and the avian flu. Criteria for a worldwide pandemic could be met in urban centers, which could develop into a worldwide health crisis. Adequate city planning and surveillance can be powerful tools to improve global health and decrease the burden of communicable diseases, hence it must be in the mind of the governing bodies of these megacities.

Urbanization is both a cause of and potential solution to global climate change. Most population growth in the foreseeable future will occur in urban areas primarily in developing countries³. How this growth is managed has enormous implications for climate change given the increasing concentration and magnitude of economic production in urban localities, as well as the higher consumption practices of urbanites, especially the middle classes, compared to rural populations. There is still much to learn about the extent to which climate change affects urban health equity and what can be done effectively in different socio-political and socio-economic contexts to improve the health of urban dwelling humans and the environment. But it is clear that equity-oriented climate change adaptation means attention to the social conditions in which urban populations live – this is not just a climate change policy issue, it requires inter-sectoral action. Policies and programs in urban planning and design, workplace health and safety, and urban agriculture can help mitigate further climate change and adapt to existing impacts. If done well, these will also be good for urban health equity (Friel et al., 2011).

From a governance point of view, adaptation to climate change within a health perspective requires the consideration of many issues such as:

- Public health often depends on activities in other sectors. To ensure that climate change health effects are not overlooked, the health sector needs improved integration into strategic planning in sectors such as water, agriculture, and disaster management. This includes safeguarding the integration of health concerns into for example National Adaptation Programmes of Action (Nerlander, 2009). However, and despite emerging efforts to better integrate health and environmental objectives in international and domestic law and policy, scientists, policymakers, and advocates in these two fields remain regrettably cut off from each other (Wiley, 2010).
- Integration of health concerns into the law and governance of other related disciplines should be given high priority. Although scientific research has pointed to the interdependence of the global environment and human health, policymakers have been slow to integrate their approaches to

environmental and health concerns. A robust response to climate change will require improved integration on two fronts: health concerns must be given higher priority in the response to climate change and threats associated with climate change and environmental degradation must be more adequately addressed by health law and governance (Wiley, 2010). The call for integration is being heard, but to properly heed it will require that we carefully consider our health and environmental priorities and set forth a mutually beneficial agenda for protecting both. On international level, the mitigation/adaptation response paradigm currently evolving both within and beyond the United Nations Framework Convention on Climate Change (UNFCCC) is a potentially powerful framework for thinking about the integration of health and environmental concerns more broadly⁴. It may even be a useful way of thinking about global health law and governance with respect to other upstream determinants of health (Wiley, 2010).

- Public health planning and decision making need to shift from only focusing on relatively short term risks to the projected long term impacts of climate change. It will be increasingly important to address the links between climate and health at different time- scales. Already today we need to be better at dealing with climate variability and its related health effects. Improving our capacity to prepare and respond, through using for example early warning systems and seasonal forecasts, will allow us to be better positioned to address the challenges that climate change will bring. Long-term climate projections will be increasingly important to ensure that we are prepared for risks changing over time when planning resource allocation, building infrastructure and ensuring that surveillance systems are able to detect changing patterns of disease (Nerlander, 2009).
- Research gaps to increase the understanding of climate change and health should be identified so that mitigation of and adaptation to the environmental effects of climate change in the healthiest and most efficient ways can be facilitated. Filling these gaps in many countries like Morocco also requires the strengthening of the connections between traditional researchers (clinicians, biologists, epidemiologists) and other important researchers (like meteorologists and climatologists). Additionally, expanding the understanding of the often indirect, long-term, and complex consequences of climate change for human health should be a high priority and challenging research task for both developed and developing countries.

MOROCCO'S ADAPTIVE CAPACITY AND OPTIONS NEEDED TO EFFECTIVELY MANAGE CLIMATE-HEALTH ISSUES

As shown above, it is increasingly recognized that climate change will directly and indirectly impact human health and alter the way countries should protect their vulnerable populations. Worse, the adaptive capacity varies widely from one country to another, and within countries from one region to another. Developing countries, in contrast to rich countries, lack not only expertise, but also adequate resources and effective health systems capable of managing climate-health risks.

This is also true for Morocco which is expected, in addition to current health challenges, to face many public health concerns in the future due to many factors and pressures. The data accumulated over the past decades show that the country is very concerned by climate risks and its potential effects on many sectors, including public health (MMH, 2004, 2012). These data also reveal that climate change will not affect all regions in the same way: while climate-related diseases would affect vulnerable populations in general, rural areas will suffer more due to the various effects of floods and droughts and resource

depletion (the recent floods occurred in 2015 in the South of Morocco revealed the extent to which many regions are extremely vulnerable to climate-related disasters and the level of human and economic damage to be reached). This applies in particular to regions where livelihood is closely linked to natural resources (i.e. agriculture, forestry and fisheries). Malnutrition, largely as a result of poor access to food, either because of poverty or the declining agricultural productivity, can also cause various health impacts. Water supply conditions, already precarious in rural areas, could promote the development of water-borne diseases and this effect is likely to be exacerbated during periods of drought. However, changes in the distribution, extent, prevalence, incidence and seasonality of these diseases are to be expected in a context where the magnitude of change is difficult to determine with certainty.

With this prognosis, the state of the health system adds to the problem. It still suffers from many structural and organizational deficiencies which negatively affect its performance and governance. This includes: weak health infrastructure coverage; difficult access to care and health services; weak human and technical capacities with limited training and recruitment opportunities⁵; limited financing capacity of institutional actors (health costs 5.3% of GDP in Morocco, against 6.4% in Tunisia and 9% in OECD); inadequate prevention system; limited trust in the health system and professionals; low level of awareness, linked in part to a deficient educational level especially in rural remote areas, particularly about climate-sensitive diseases; difficulties related to health facilities' management methods; a drug policy relatively transparent when it comes to the determination of prices (which remain poorly harmonized with those applied in similar countries); insufficient partnership, especially between the public sector, private sector and civil society; strong centralization of decisions (which also refers to a kind of non-effective regionalization and the lack of autonomous management); and the persistence of certain health indicators below international standards (MMM, 2012).

Lemsioui (2012) highlights the insufficient consideration of natural risks in the national development plan, the lack of forecast-mapping studies of natural risks, the incomplete state of national legislation system and the absence of a framework-law on risk prevention. For the author, the cumbersome legislative system often prevents the advancement of risk management strategies of natural disasters. Meanwhile, the insufficient awareness of communities with respect to natural hazards and risk magnitude worsen the situation.

This situation may impede the implementation of effective measures to reduce the social vulnerability to climate change, especially in terms of health security. Therefore, the country, already facing many domestic problems with limited capacities to meet pressing social needs, may be more vulnerable face to climate change health impacts.

In order to foster health security in Morocco face to climate risks, adaptation options should aim to: strengthen the health system through upgrading of health facilities and the network of primary healthcare and the introduction of compulsory medical insurance; develop a robust epidemiological surveillance system; strengthen the programs against climate-sensitive diseases by promoting disease surveillance, screening and good patient management, the development of environments that promote health through sectoral programs; and strengthening intersectoral partnerships.

The universal health coverage, whose basic principle is the right to health, should also be a strategic priority. Morocco has recently engaged in this direction through the implementation of numerous initiatives – such as a medical assistance plan called RAMED⁶ which aims to reduce the effects of unexpected expenses related to healthcare on the poor (ANAM, 2013) – in order to ensure adequate access to health services, while minimizing health expenses and saving the most vulnerable populations from falling into extreme poverty. Two fundamental components are given priority: access to required health services and

financial protection to prevent the degradation of public health from leading vulnerable people to poverty. However, these initiatives are only a first step which must be strengthened through additional funding, outreach to all vulnerable social groups, and the implementation of appropriate governance measures.

In addition, populations need to be regularly sensitized and informed about climate-related health risks and its consequences. Training and awareness programs as well as capacity building for prevention and action against infectious diseases should be an integral part of adaptation options to be considered.

Insufficient or inadequate information on climate and health issues may prevent the adoption of a genuine strategic perspective. Thus, improving knowledge on climate-health issues (including studies analyzing and modeling the evolution of climate parameters and their impact on related notifiable infectious diseases) is needed to better understand the future and prioritize adaptation options. Also, allowing policymakers continuous access to viable and high quality information is crucial to good decision making. To do this, exchange between scientists, experts and decision makers should be institutionalized (via for instance setting up of a competence center for climate and health research, committees of experts, observatories, etc.). In addition, the government should encourage the development of a national expertise and strengthening the links between researchers, decision makers and professionals concerned by climate-health issues.

There is also the need to develop a strategic framework to manage climate change and health issues. Such a framework should enable a continuous exchange between research and policy spheres. The underlying approach consists of guiding all relevant actors during policy making and implementation and reciprocally help define research needs and priorities based on lessons learned from practices.

Given the diverse aspects of climate change-health issues and associated uncertainties, it is still difficult to analyze and investigate these issues. Therefore, caution is recommended in any work aiming to forecast and interpreting risks, especially that human health is in permanent interaction with ecosystems whose biotic and abiotic elements are affected by climate change (ONERC, 2007).

The establishment and improvement of early warning systems, including seasonal climate forecasting, have also become essential to support decision and policy-making processes. Similarly, it is useful to have a surveillance mechanism that can monitor extreme weather events and climate-related epidemics which may affect human health and safety.

Also, the adaptation strategy in the health sector should be guided by the equity imperative, which requires the involvement of all relevant stakeholders in engaged processes. Such involvement will ensure the inclusion of stakeholders' expectations in a spirit of solidarity and complementarity.

The management of climate-related health impacts requires the development of a 'multilevel governance' which offers a more flexible system and promotes the efficiency, consistency and economies of scale. In this governance framework, the health policy also includes action on socio-economic and environmental determinants of health (access to financial resources, nutrition, healthy environment, education, etc.). However, Morocco should gather many conditions to ensure the efficiency of this governance framework such as: Reforming its legal and policy framework related to health and environment; fostering the human rights approach within the health and environment areas; developing regional health and climate plans and strategies; mainstreaming health and climate change in social and human science research and teaching; bridging the gap between health/climate expertise and policy makers; promoting the full involvement of civil society actors in health and climate policy making and implementation processes, etc.

In addition to these, adaptation options to climate change in Morocco from a health perspective should focus on the following key priorities: The allocation of sufficient financial and human resources

according to public health needs while ensuring that these resources are distributed fairly in a spirit of regionalization; the establishment of adequate, operational and sufficient health infrastructure, covering the whole territory and ensuring a balance between regions and urban and rural areas; the development of a good health governance by adopting effective management methods, reforming health institutions, strengthening the network of primary healthcare, strengthening the compulsory medical coverage and the development of health professionals' capacities. To support the implementation of such option, Morocco may develop health-focused projects to be submitted to the UNFCCC for funding.

CONCLUSION

This chapter has attempted to demonstrate how infectious diseases in Morocco – mainly Leishmaniasis, Malaria, and Schistosomiasis – are expected to change their geographical or seasonal patterns and incidence due to climate change and variability. Given the gravity of these vector-borne-diseases, the analysis highlights the pressing need to understand its dynamics, especially in a context marked by limited and uncertain scientific evidence regarding the health vulnerability to climate change in Morocco.

In addition to this, the analysis underlines the problematic aspects of adaptation to climate change from a health perspective and the current difficulties in terms of policy and governance action to manage climate-health linkages.

Finally, and by reference to the Moroccan context, an assessment of the national adaptive capacity within the health sector has been undertaken. Relevant recommendations to effectively adapt to climate change and develop effective climate-health governance and policy have been formulated.

ENDNOTES

¹ Climate change mitigation strategies are also synonymous with health improvement, whether through improved housing, active transport, changes to patterns of food consumption or economic localization.

² Soil-transmitted helminth infections are among the most common infections worldwide and affect the poorest and most deprived communities. They are transmitted by eggs present in human faeces which in turn contaminate soil in areas where sanitation is poor. The main species that infect people are the roundworm (*Ascaris lumbricoides*), the whipworm (*Trichuris trichiura*) and hookworms (*Necator americanus* and *Ancylostoma duodenale*). For more information: <http://www.who.int/mediacentre/factsheets/fs366/en/>

- ³ About a century ago, only 20% of the world's population lived in cities, and in the least developed countries the percentage was only 5%. Approximately half of the world's population now live in these urban centers. The two inhabited continents, which currently are the least urbanized, are Asia and Africa, with respectively 48 and 40% of the population living in cities. These percentages are expected to rise dramatically by the year 2050 to 64 and 56% respectively (Neiderud, 2015).
- ⁴ The Paris Agreement recently adopted by the COP21 recognizes the links between climate change and health concerns: It recognizes the social, economic and environmental value of voluntary mitigation actions and their co-benefits for adaptation, health and sustainable development; and acknowledges that Parties should, when taking action to address climate change, respect, promote and consider their respective obligations on human rights, the right to health... (FCCC/CP/2015/L.9/Rev.1).
- ⁵ The remote geography of many rural areas in Morocco also creates additional challenges such as the retention and training of medical staff, the collection of health system data, and the provision of infrastructure.

Chapter 6

Nurses, Healthcare, and Environmental Pollution and Solutions: Breaking the Cycle of Harm

A. Elaine McKeown
Independent Researcher, USA

ABSTRACT

Many nurses may not be aware of the role that healthcare plays in the cycle of harm. Healthcare participates in the cycle of harm by mismanaging waste, using fossil fuel energy and offering meat-based diets. Lack of knowledge, resources and empowerment potentiate this participation. Greenhouse gas emissions from fossil fuel use and meat-based diets, with resultant water pollution, contribute to climate change. Climate change and healthcare source pollution in water from mismanaged waste, contributes to illnesses of community members. Once sickened, individuals come to the healthcare center for treatment. This illness care then contributes to more environmental pollution. Specific human health consequences of resultant water pollution and climate change will be discussed. With healthcare professionals collaborating with others concerned, the connections potentiating this cycle of harm can be broken. Recommendations will be offered for healthcare's forward movement to help create the solutions to the pollution.

INTRODUCTION

Nursing professional scope does include evaluating and correcting environmental factors to improve human health. From the Nightingale foundational concepts in the eighteen hundreds (Nightingale, 1969) to the American Nurses Association's (ANA) *Principles of the Environmental Health for Nursing Practice with Implementation Strategies* (American Nurses Association [ANA], 2007) a helpful framework is set for healthcare's forward movement into the twenty-first century.

Florence Nightingale was not only the founder of the modern nursing profession, she was a pioneer in recognizing the environment as a key factor in determining if a patient would recover from his wounds

DOI: 10.4018/978-1-5225-1674-3.ch006

or die. She reduced the death rate of those wounded in the Crimean War dramatically by providing a hygienic environment including clean water, clean air, clean linen and frequent wound cleansing followed by an application of clean bandages (Dossey, 1999).

According to the ANA (2007) there are ten principles of environmental health:

1. “Knowledge of environmental health concepts is essential to nursing practice.
2. The Precautionary Principle guides nurses in their practice to use products and practices that do not harm human health or the environment and to take preventive action in the face of uncertainty.
3. Nurses have a right to work in an environment that is safe and healthy.
4. Healthy environments are sustained through multidisciplinary collaboration.
5. Choices of materials, products, technology, and practices in the environment that impact nursing practice are based on the best evidence available.
6. Approaches to promoting a healthy environment respect the diverse values, beliefs, cultures, and circumstances of patient and their families.
7. Nurses participate in assessing the quality of the environment in which they practice and live.
8. Nurses, other health care workers, patients and communities have the right to know relevant and timely information about the potentially harmful products, chemicals, pollutants and hazards to which they are exposed.
9. Nurses participate in research of best practices that promote a safe and healthy environment.
10. Nurses must be supported in advocating for and implementing environmental health principles in nursing practice” (p.16).

The ANA’s principles most applicable to the current discussion include one, two, four, six, seven and eight. The writing of this entire chapter is built on principle one. This foundation in environmentalism will be demonstrated throughout the chapter. Also referred to in this chapter is principle two, the precautionary principle. According to principle two, healthcare workers do not need to wait until environmental conditions have caused irreparable harm to human health before taking action to mediate circumstances that could lead to such harm. Principle four talks about the need for multidisciplinary collaboration. In order to create a cleaner, safer and more sustainable future for humankind, this chapter will call on far-reaching professional networks to strive together to accomplish such an end. Principle six affirms that approaches to promoting a healthy environment respect the diverse values, beliefs, cultures, and circumstances of the patient and their families (ANA, 2007). This chapter will show environmental concerns are multinational and all cultural contexts are in need of solutions suited to individual regions, resources available and associated circumstances. Principle seven is about assessing the quality of the environment. As the chapter emphasizes, this environmental assessment is a legitimate and important part of a nurse’s scope of practice. Finally, principle eight emphasizes the right to know information about potentially harmful products and hazards. This right to know encompasses healthcare workers as well as the general community population. The current chapter will affirm that dissemination of this risk and hazard information can be an important part of a nurse’s role along with health education on measures that families can undertake to minimize their polluting behaviors. Recommendations will include discussion of who could take on this educational role and some suggestions and examples of how this could be done will be included.

BACKGROUND

This chapter will be discussing the part healthcare plays in adding to water pollution, environmental contamination and resultant climate change. Although much has been written on the existence of human-source climate change in other publications and the topic can be reviewed in chapter one of this book, a brief discussion is included here.

There is ever increasing evidence for human-caused climate change, according to McCarthy (2012) of the Union of Concerned Scientists. A critical piece of climate change is the shift in the parameters of the world's waters. The planetary water is being heated, melted and acidified. Convincing evidence includes deep sea warming, melting of millennium old ice shelves and lower Ph of ocean waters. All of this evidence is consistent with the rate at which heat-trapping gases, mainly carbon dioxide, is being released into and held in the lower atmosphere. Changes are now happening 100 to 1,000 times faster than at any time since humans have lived on Earth (McCarthy, 2012). Extreme weather events are increasing secondary to climate change. 2012 was the third most expensive year in recorded history for natural and man-made disasters with a price of \$166 billion in repairs. Superstorm Sandy alone is estimated to have caused \$70 billion in damages. Corn crop failures in the United States of America resulted in \$11 billion in losses, which is the largest ever recorded (Guenther & Balbus, 2015). Much of the reason for this weather-related detriment is that economies and infrastructures were designed for the more stable climate of the past. With the rapidly changing climate of today and the future, many areas will have difficulty with adaptation (Federal National Climate Assessment and Development Advisory Committee [FAC], 2014).

In addition to causing climate changes, such as extreme weather events, higher carbon dioxide levels from burning fossil fuels has a direct effect on ocean water. Carbonic acid is created when carbon dioxide interacts with ocean water. The ocean and carbon dioxide interaction causes the waters to become more corrosive and acidic. This increased acidity makes it more difficult for some aquatic animals to survive and reproduce. Resultant dropping numbers of some marine life, will in turn, impact the aquatic food chain, of which humans are the apex consumer (FAC, 2014).

While scientists continue to formulate projections of the future climate, observations definitely show that climate change is occurring and that the warming of the past five decades is mainly due to human activities that cause emissions of heat-trapping gases. These greenhouse gas emissions come predominately from burning fossil fuels, with additions from forest clearing and some agricultural practices (FAC, 2014).

OBJECTIVES

1. Explain how and why the healthcare community takes part in the cycle of harm.
2. Discuss the health consequences of resultant water pollution and climate change.
3. Explore how the healthcare system can help to create solutions to the pollution.

Objective One

Explain How the Healthcare Community Takes Part in the Cycle of Harm.

Figure 1. "Cycle City" by chapter author A.E. McKeown, 2015. The "Cycle of Harm" includes increased acidification and heating of ocean waters secondary to release of greenhouse gases. The cycle also includes chemical and biological contamination of fresh waters secondary to improper waste disposal. Humans suffer health consequences directly by consuming contaminated water and food or breathing contaminated air. Indirect human health consequences occur secondary to the weather extremes of climate change associated with greenhouse gases. People receiving treatment for resultant illnesses produces more pollution.

Mismanaging Healthcare Waste

Healthcare waste has several different distinct categories which include solid waste, biohazardous waste and chemical waste. The solid waste can be as much as ninety percent of hospital trash. It includes paper, cardboard, plastic, metal, glass, old tubing and intravenous lines. Larger items can also include used furniture, old medical equipment, packing materials, food service equipment and food debris (Shaner-McRae, McRae, & Jas, 2007). Even noninfectious substances such as food scraps can attract flies and become a microbial breeding place if not disposed of promptly.

Biohazard or red bag waste is about ten to fifteen percent of hospital waste. Contaminated sharps, or needles, should go in a hard sided red box along with other sharp, contaminated waste. Soft, contaminated materials, such as disposable, blood-soaked gowns, or gloves should go in a red biohazard

bag (Shaner-McRae et al., 2007). At times the waste is improperly sorted, leaving biohazard materials in with ordinary solid waste. This is a health hazard to staff disposing of infectious substances and an environmental hazard once in a land fill or other unprotected place of disposal. Dirty needles are the most serious and immediate threat to people, as they may transmit disease pathogens to individuals by an accidental puncture. World Health Organization (WHO) estimates that high income countries produce 0.5 Kg of hazardous waste daily per patient bed. Low income countries produce about 0.2 kg per bed per day (as cited in Hakim, Mohsen, & Bakr, 2014, p. 348). An example of healthcare trash not being sorted is related for illustration. In Egypt, Hakim et al. (2014) reports that health care related waste have recently become recognized as a major concern for healthcare facilities and for the environment. However in developing countries, it is noted that hazardous and non-hazardous waste is most often not separated, making the overall volume of contaminated waste much higher. This creates a health threat to municipal workers who handle garbage disposal as well as to the general public. Small scale incineration or autoclaving is what is most often used in countries where efforts are being made to deal with waste problems. Egypt is challenged to improve waste practices despite the Environmental Law Number Four of 1994 that was meant to deal with the issue. Some of the reasons for this ongoing waste management problem is weak enforcement and the healthcare worker's lack of knowledge of the legislation and lack of efficient waste segregation systems (Hakim et al., 2014).

Another category of waste, hazardous chemicals, are to be governed in the USA by the Resource Conservation and Recovery Act (RCRA) of 2007. RCRA regulations require a material safety data sheet (MSDS) to accompany each potentially hazardous chemical. This MSDS tells what is in the chemical, how to store it and what first aid measures to take if exposed. Individual instructions are to be followed for disposal of the substance as well (Shaner-McRae, et al., 2007). Any of these chemicals disposed of in a way unintended by the product-makers risks health consequences for exposed individuals. Toxic or hazardous chemicals may be used too liberally in hospital settings. Intensive care units may have the most toxic supplies due to a higher frequency of procedures performed. Huffling and Schenk (2014) call for the reduction or discontinuance of a number of substances. Among these is Triclosan, an anti-microbial used in soaps that is linked to thyroid disease. Furthermore, on the list of substances to avoid are phthalates and fragrances in personal care products that can alter fertility and hormone levels and cause headache and eye irritation respectively (Huffling, & Schenk, 2014). Any of the personal care products or soap mentioned could find their way into the water supply by being washed down the drain.

An example of freshwater contamination by hazardous chemicals is the case of the Great Lakes of North America. The Environmental Protection Agency (EPA) routinely monitors the Great Lakes for contaminants in fish and issues fish consumption advisories. Older, larger and fatter fish are considered the most toxic because they have had more time to absorb toxins from the lake water. The EPA monitors for a total of 39 chemicals, but the top concerns include mercury, and pesticides chlordane and dichlorodiphenyltrichloroethane (DDT). Pregnant women, nursing mothers and children are considered to be at greatest risk for adverse health outcomes secondary to fish consumption (Environmental Protection Agency [EPA], 2015).

A particularly problematic hazardous chemical waste comes from discarded pharmaceuticals. A notable category of environmental pollution from healthcare includes the contamination of the water supply by flushing wasted medications down the sewer. This policy of flushing wasted medications has been a healthcare standard of the past. However, this practice has now been shown to harm aquatic life and impose potential human health risks (McKeown & Pawloski, 2012).

Using Fossil Fuel Energy

Huffling and Schenk (2014) state that healthcare takes part in what they call the harming circle by use of resource and energy intense processes. For example, it is noted that the USA healthcare system produces eight percent of annual greenhouse gases released in the USA (Huffling, & Schenk, 2014). The healthcare system has many and varied branches which includes acute care centers, usually referred to as medical centers or hospitals, the outpatient centers or clinics, doctor's offices, home health agencies, public health departments, medical research centers and institutions of higher learning for health professionals, to name several prominent sectors of healthcare. All sectors of the healthcare system have varying amounts of energy and resource use. However, intensive care units (ICUs) in an acute care center are some of the most energy consuming practice areas. ICUs house five to ten percent of hospital patients, while accounting for twenty to thirty-five percent of hospital costs. Fossil fuel based energy use in these settings has serious human health consequences. The pollution that is formed when fossil fuels are burned include mercury and acid gases. Airborne contaminants created in the fossil fuel burning process can be inhaled or may be consumed as part of contaminated water or food sources after pollutants have precipitated out of the air. Acid gases are causative agents for respiratory illness such as chronic obstructive lung disease, asthma and bronchitis. The release of mercury into the environment is also a threat to human health, because it is a potent neurotoxin as well as a risk factor for developing fetuses and young children. The discussion previously on EPA monitoring for mercury levels in Great Lakes fish should be remembered. Besides these direct influences on human health, there are the less direct impacts caused by the release of greenhouse gases, which contribute to climate change. Climate change is a looming risk factor in lung and heart disease, infectious disease, displacement and other weather related illnesses and injuries (Huffling, & Schenk, 2014).

Offering Meat Based Diets

Another way that healthcare takes part in the cycle of harm in some locations is by relying heavily on meat based dietary offerings for staff and patients. Allied health researchers have documented how dietary choices are linked to greenhouse gas emissions (GHGEs) with major consequences of food choices. The example noted here is in North America. Analysis of meat-based compared with plant-based diets are coming to the forefront in the interests shared by public health, environmentalism, and nutrition (Soret et al., 2014).

Soret et al. (2014) compared the GHGEs associated with diets eaten in a large North America population to mortality rates according to dietary patterns in the same population. Three dietary patterns were studied which included vegetarian, semi-vegetarian, and non-vegetarian. Vegetarians were defined as individuals who ate meat less than one time a month. Semi-vegetarians were defined as individuals who ate meat more than one time a month, but less than one time a week. Non-vegetarians were defined as individuals who ate meat at least one time a week. The GHGE intensities of over two hundred foods were calculated through the individual food's life-cycle assessments. An established computer program, SimaPro software, was used for the analysis. This computer software is able to calculate the food's related output of global warming gases, including methane, carbon dioxide and nitrous oxide during the product's growth, care and processing into an edible form. Supplementary data was obtained, where needed, from previously published research on GHGEs and directly from food makers. The study participants were obtained from the data base of Adventist Health Study Two (AHS2) subjects. Study results showed,

with the use of the meat-based diets as a baseline, the average reductions in greenhouse gas emissions for semi-vegetarian diets was twenty-two percent and vegetarian diets was twenty nine percent.

Soret et al. (2014) concluded that differences in the caloric intake of meat provided nontrivial reductions in GHGEs and also improved health outcomes (Soret et al., 2014). This study found mortality rates were sixteen to seventeen percent lower among semi-vegetarians and vegetarians as compared with non-vegetarians (Soret et al., 2014).

Besides benefits to the climate, lowering the use of animal products in an individual's diet is important for that person's health. Meat-based diets are linked to poor health while plant-based diets have positive influence on human morbidity and mortality.

Explain Why the Healthcare Community Takes Part in the Cycle of Harm

Lacking Knowledge

Environmental problems in modern healthcare can be very challenging. As Shaner-McRae et al. (2007) of the USA explains, hospital wastes are more complex, diverse and hazardous than other industries. Hospitals have some of the most difficult and diverse types of waste to manage. For example, Mathias (2012) points out, most health professionals agree that it is better to keep pharmaceuticals out of the water supply. However, it is very difficult to understand and comply with pharmaceutical waste management requirements and take part with best environmental practices. Developing a plan can be difficult partly because of the large number of items in a hospital pharmacy. There can be as many as four thousand different medications to consider and all are not subject to EPA's Resource and Conservation and Recovery Act (RCRA). The EPA is a branch of the USA government instituted to create policy, such as RCRA, and facilitate activities that will conserve natural resources. However, some medications are covered instead under hazardous waste rules. It can be challenging to determine in which category a drug is included. Also, there are other rules for management of wasted controlled substances, such as narcotics. Narcotics are under the separate rules of the Drug Enforcement Administration (DEA) (Mathias, 2012).

Another common problem in healthcare is that often there is not a clearly defined person at the facility to take charge of the hazardous chemicals, the MSDSs and be responsible for meeting regulations for safe handling and disposal. The most common violation of RCRA rules in hospitals is the failure to identify hazardous materials at all (Shaner-McRae et al, 2007).

An example of healthcare staff lacking adequate knowledge of environmental issues and resources to promote positive change is reported by Silva et al. (2014). Silva et al. (2014) of Santa Cruz, Brazil states that there is a growing concern over the preservation of natural resources and public health associated with management of solid waste in health services (SWHS). Some measures have been taken to address the problem, such as a classification system to help identify potentially hazardous waste. The National Health Surveillance Agency (NHTSA) of Brazil classifies waste from health services as group A-potentially infectious, group B-chemical, group C-radioactive, group D-common residues and group E-sharps. The reason to group wastes is to better understand how to manage them. It can be seen that the mismanagement of waste can cause serious harm in higher rates of hospital-acquired infections and even in community wide epidemic secondary to contaminated ground water. In this study of 17 nursing professionals interviews were conducted and analyzed to identify how nursing professionals viewed waste management issues.

Data analysis identified two main trends. The first trend was the concept that mismanaged SWHS contributed to environmental damage. It was noted by participants that final disposition outside the hospital was a contributing factor to the problem, but participants were unable to identify where SWHS was routed after leaving the hospital.

The second trend was the acknowledgement that SWHS can create a risk to the public health. It was acknowledged by participants that SWHS deposit locations favor the emergence of harmful microorganisms. Overall, the analysis showed that although nurses have identified the improper disposal of SWHS as a problem, it was unknown to them how to seek solutions.

Brazil's National Survey of Basic Sanitation shows that 63% of Brazilian cities collect SWHS, while 18% of these cities use some type of waste treatment, 36% burn the SWHS in the open and 35% do not follow any type of treatment. The authors conclude that solutions to proper SWHS disposal must be a joint venture, including the government as well as the health care facilities (Silva I., Bonfada, Silva R., & Souza, 2014). This is a good example of the application of ANA's principle four that states that healthy environments need to be sustained through multidisciplinary collaboration (ANA, 2007).

Lacking Resources

At times staff may have knowledge of what could improve waste disposal practice, but lack resources to implement the ideas. The cost for disposal of contaminated materials is ten to twenty times as high as for disposal of regular non-contaminated waste. The caution is not to waste time and resources putting uncontaminated materials in red biohazard boxes or bags. It can cost as much as one to five dollars a bag to properly dispose of contaminated waste (Shaner-McRae et al., 2007). Besides the concern of proper use of the red bag and box system, in some areas such a system may not even be available.

As an example, discussion was given on the Basel Action Network (BAN) website concerning the financial constraints of waste disposal efforts in India. According to the website authors, one should understand that most developing countries do not have the facilities to either monitor or regulate toxins, especially in the narrow regulatory limits as have been set in the west. Such facilities are also extremely expensive, and a financial strain on regulatory agencies. The clinical incinerators still found in some countries need to be retired and steps taken to adopt cleaner technologies and practices as well as waste minimization (McRae, G. & Agarwal, 1999).

Funding availability, however, in healthcare sectors in such countries is very limited. Solutions must be able to address key problems, such as the management of contaminated needles and basic waste segregation. Solutions are needed which require low cost approaches rather than expensive technology centric ones. They must reflect the solutions feasible in the developing countries. The solutions should be those which are good for the next decade or two since financial investments, once made, are not easy to replace in a low cash situation (Basel Action Network and Health Care Without Harm, 2015).

Lacking Empowerment/Nursing Diagnoses

In the following discussion on lack of empowerment of healthcare workers, the concept of nursing diagnoses is introduced. Nursing diagnoses will be discussed in this chapter as related to environmental pollution and climate change. However, below one will see how a nursing diagnosis can be used to apply to nurses themselves.

Most readers are familiar with medical diagnoses that clearly state what problem the physician is to heal or correct. Besides the medical diagnoses, there are numerous nursing diagnoses that may have increased utilization in the future. In the realm of healthcare, the concept of nursing diagnoses embodies the idea that nurses can effectively and independently intervene on certain concerns, once the concern is clearly identified. The nursing interventions leading to the resolution of the concern can be more accurately identified and evaluated through this structured process. Nursing diagnoses are formalized and organized by NANDA International (NANDA-I) into 235 brief phrases that include defining characteristics, risks and related factors (NANDA International [NANDA-I], 2014). A drawback of nursing diagnoses is that they are not universally used and understood. Some nurses may find nursing diagnoses cumbersome to use or may find that it does not fit every health situation. Some nurses will not use any healthcare problem terminology system, or some may use a different system. One such alternate system is the Omaha system (The Omaha System, 2015). Using a terminology system is recommended to improve patient outcomes, however, whichever system is used, it is important to work within the prevailing system of one's own setting. One strong point of nursing diagnoses, which the chapter author will use, is that it gives nurses a framework to identify and thus effectively address a wide range of patient concerns. The more nurses are familiar with nursing diagnoses, the more that knowledge strengthens the profession and the individual nurses as well. Working knowledge of nursing diagnoses opens the door to more uniform and universal standards of nursing practice and more precise communication across practice groups and across geographical regions.

Many healthcare providers are concerned about environmental issues and yet find it difficult to do anything to improve practice or institute policies that have less negative environmental impact. Because of this growing phenomena, one author identifies this situation as suitable for labeling with the nursing diagnosis of Moral Distress in Nursing (Jameton, 2013). Moral Distress is a nursing diagnosis that is defined by NANDA-I as the response to the inability to carry out one's chosen ethical or moral decision. The defining symptoms or characteristics include fear, anxiety, and expressed anguish. The related factors described by NANDA-I that are most applicable to the current context include, conflict among decision-makers and conflicting information guiding ethical or moral decision making and loss of autonomy (NANDA-I, 2014). Usually the nursing diagnosis of Moral Distress is thought of as being applied in a clinical setting to one patient and their personal situation. However, the concept of moral distress can be applied to larger environmental concerns impacting healthcare as a whole. Since healthcare is large in scope and climate change is a major environmental problem, scaling down healthcare is inevitably a necessary step to help with mitigation of climate change. However, these issues are very challenging to discuss among health professionals (Jameton, 2013).

The following is an example of a group of 786 nurses in Ohio, USA that may fit within the nursing diagnosis of Moral Distress in Nursing. Polivka et al. (2012) reported on a group of public health nurses that perceived themselves as having responsibility to address health-related impacts of climate change but lacking the ability to address these impacts. When asked if their nursing division had the responsibility to respond to health related impacts of climate change, eighty-two percent agreed. When the same respondents were asked if actions can decrease the health-related impacts of climate change, sixty percent agreed. However, only thirty-five percent agreed their nursing unit has the ability to address health-related impacts of climate change and only sixteen percent agreed that their nursing unit was prepared to address the health related impacts of climate change. Polivka et al. (2012) referred to the ANA's precautionary principle which states that when there is uncertainty on an issue of environmental harm, the nurse is to err on the side of precaution and foster preparedness for climate change

and resultant health consequences. Polivka et al.(2012) concluded that public health nurses view the environment as under threat but recognize the limited resources and personnel available to devote to promoting environmental conservation efforts (Polivka, Chaudry, & MacCrawford, 2012).

Summary Objective One

The healthcare system takes part in the cycle of harm by improper handling of waste products. Contaminated biological waste or toxic chemicals may contaminate the water supply and circulate around the environment, when disposed of improperly. Also, healthcare can contribute to the cycle of harm by the production of greenhouse gases through fossil fuel energy use and consumption of meat based diets. This contamination can pollute water and air and add to climate change.

Healthcare staff may be lacking three key things needed to make a change in polluting behaviors. These three essentials are knowledge, resources and empowerment. Knowledge is needed of the problems and laws meant to protect the environment. Resources and finances are needed to replace obsolete or inadequate disposal systems. Empowerment is needed to have authority to request or manage improvements in the work place. Lacking the essentials of knowledge, resources and empowerment leads to participation in the cycle of harm.

Objective Two

Discuss the Health Consequences of Resultant Water Pollution and Climate Change.

Nurse's Knowledge of Climate Change and Human Health Consequences.

A study was done by Polivka et al. (2012), as noted above, to determine public health nurses knowledge and attitudes toward health related impacts of climate change. Respondents identified only five out of twelve health-related impacts of climate changes. The five climate change related health impacts acknowledged by the majority of public health nurses were vector-borne diseases, flooding related displacement, food-borne disease, mental health issues and air-quality related illness. However, the majority of public health nurses did not identify malnutrition and water availability-related illness as being part of their perception of health related impacts of climate change. Climate change has the possibility to alter normal human growth and development through malnutrition from low food supplies and increased agricultural chemicals used to encourage greater crop yields. Also the majority of public health nurses did not identify cold or heat related illness or water-borne infectious disease as expected climate related health issues. Public health nurses acknowledged that impacts of climate change would have serious health consequences in the next twenty years where they lived and worked. However, the nurses believed conditions would be worse in other parts of the USA and greater still in other parts of the world (Polivka et al., 2012).

Human Habitat Destruction and Health Risk Related to Climate Change

The following will illustrate a case in point where climate change is unfavorably impacting human health in western North America. Climate change is cited by Embrey et al. (2012) in the USA and Canada,

as being responsible for the pine forest ecosystems being dramatically changed by an unprecedented pine beetle infestation. This ecosystem change is expected to result in negative human health outcomes. First the environmental destruction is examined by Embrey et al. (2012) and then the human health consequences are discussed.

Both warmer winter temperatures and decreased frequency of cold days have led to a destruction of millions of acres of Rocky Mountain pine forest. This type of plant disease condition is referred to as an enphytotic event. An enphytotic event is defined as a condition with plant disease persistence in a plant population over a given period of time, as is similar to endemic disease in humans. The beetle infestation causes tree mortality by interacting with a virulent blue stain fungi. Together the insect and the fungi infestation cuts off the tree vasculature, causing loss of tree circulatory function and tree death. The beetle and the blue fungi tree infestations are usually kept in check by climate. Hot, dry summers allow more beetle larva to survive and the trees are often more stressed and therefore more susceptible to attack. The primary beetle infestation that started the current tree mortality began in 1996 in north central Colorado and 1999 in British Columbia. In 2008 the range of the pine tree beetle had increased to 35 million acres in the USA and Canadian Rockies. The reported 35 million acres was ten times larger than any previous such beetle infestation recorded. The insect range is expected to increase as the climate becomes more favorable to them with the warmer temperatures. Scientist believe that there is a potential epiphytotic event in the future. An epiphytotic event is when an endemic plant disease pathogen suddenly and rabidly affects many plants in a specific area, similar to an epidemic in humans. Evidence suggests that there is a potential fifty–eight million acres of forest at risk of dying by 2020 of beetle infestation (Embrey, Remais, & Hess, 2012). As of 2015 there is a reported pine beetle infestation from western Canada to Mexico. It is reported by the National Park Service of the USA that the effects of the beetles are evident in recent years on Colorado's western slope including the Rocky Mountain State Park. The park is just one small area where trees are dying secondary to beetle infestation. The task of dealing with the infestation is so large, the park's priority is focused on removing hazard trees that may fall and dead trees that become hazard fuel. Also high value trees near park offices, camping and picnic areas are sprayed to kill beetles (Rocky Mountain National Park, 2015).

The associated ecosystem services disruption has the potential to cause significant health impacts from a range of exposures, including increased runoff and water turbidity, forest fires, and loss of ecosystem services. Ecosystem services are the benefits to people from natural resources and processes that are supplied by the ecosystem and are in four categories. The four ecosystem service groups are regulatory, supportive, provisioning and cultural. Regulatory services include the ecosystems ability to regulate air, water and soil quality. Supportive services include nutrient regulation, climate stabilization, and biomass production. With the death of pine trees, the forest loses the ability to maintain the role as a carbon sink, which leads to increased concentrations of airborne greenhouse gases. Also, with tree death is the loss of the forest's ability to regulate water flows. This can result in too much or too little water available to people at different times of the year. Flooding and water scarcity can ensue. Provisioning ecosystem services include timber and pulp wood or other forest related products. If these forest products are not available, livelihoods are lost and property may devalue. Cultural services refer to recreational and aesthetic benefits enjoyed by visitors to the forest. If the forest is destroyed, the recreational and mental health benefits are lost along with related economic losses.

Fire risk is one of the biggest immediate health dangers to humans near the beetle devastated area. It is noted that fire risk may increase 10% in beetle infested forest areas. However, fire risk will vary with

the stage of forest mortality. Recently dead trees with needles attached have greater risk of tree top fires. Approximately two years after beetle attack, trees lose their needles and fire risk decreases temporally for a few years. About 10 years after beetle attack, trees will fall and increase risk of ground level fires (Embrey et al., 2012).

Inhalation of windborne smoke from forest fires can put humans at risk for compromised respiratory function many miles from the burn zone. Episodes of asthma and bronchitis are at high risk of occurring during the burning. Heat exhaustion and dehydration are also likely to occur for those closer to the burn zone. Water quality and dysregulation of amount of water presents health risks for the 33 million people who depend on the Colorado River for drinking water. Increased turbidity of run-off water from deforested land is associated with increased gastrointestinal illness. Other toxins are found in runoff from fires, such as heavy metals and noxious chemicals. More research need to be done on the influences of these chemicals on human health.

The pine beetle infestation highlights the need for public health to adopt an ecological, systems oriented view to anticipate the full range of potential health impacts from climate change and facilitate effective adaptation. Climate change is rapidly emerging as an ecological stressor with shifting ecosystem dynamics. Many ecosystems are likely to be fundamentally changed. These shifts could bring subsequent human health impacts (Embrey et al, 2012).

Climate Change and Energy Insecurity among Vulnerable Individuals

Hernandez (2013) explores the increasing incidence of extreme weather events attributed to climate change, along with the increasing energy prices, that may cause major health impacts problematic to the most vulnerable people. With low-income households there can be a situation where a family may have to choose to pay for food or heating bills. While having difficulty paying for heating, the lower income families tend to live in housing that is not well weather proofed, making it more difficult and expensive to keep warm. The effects of climate change can be seen in risks for respiratory illness such as allergies and asthma, nutritional deficiencies, loss of productivity and injury and mortality. The phrase energy insecurity has been coined to describe the phenomenon of allotting a disproportionate share of one's income to utilities while dealing with sub-standard housing that induces heat-loss. Energy insecure families have been found to eat less in winter months, with a ten percent reduction in calories in cold weather. Also, the same families often have barriers in making their home more energy efficient both because of high up front cost and because the majority of the time, they are renters with little decision-making authority on building upkeep. As the global climate crisis increases, its association with the built environment and the health of vulnerable groups warrants closer attention and problem solving (Hernandez, 2013). Hernandez (2013) is a good example of a nurse who evaluates the patient's environment and resultant health consequences. This is an illustration of the American Nurse Association's principle seven, which points out that nurses participate in assessing the quality of the environment in which they practice and live (ANA, 2007).

Physical and Mental Health Nursing Diagnoses Related to Climate Change

As described earlier in this chapter, there are numerous nursing diagnoses that may apply to illness or injury secondary to environmental contaminants. Patients may be coming to health care facilities in increasing numbers for resultant health problems as represented in the following nursing diagnoses.

The first group of nursing diagnoses include biological stressors and physical illness. The following six diagnosis will be discussed: Imbalanced Nutrition, Risk for Deficient Fluid volume, Contamination, Hyperthermia, Hypothermia and Risk for Infection. The nursing diagnosis of Imbalanced Nutrition: less than body requirements is defined by NANDA-I as an intake of nutrients insufficient to meet metabolic needs (NANDA-I, 2014). As explained earlier, crops may fail in some areas due to climate change's negative impact on agricultural conditions. This could easily result in less food available with resultant malnutrition for some people. Risk for Deficient Fluid volume is defined as the state of being vulnerable to experiencing decreased intravascular, interstitial and or intracellular fluid volumes, which may compromise health (NANDA-I, 2014). With a decrease in fresh water sources, some people may not have access to adequate amounts of safe drinking water. This lack of availability of adequate, safe water sources may result in fluid volume deficit related illness for people unable to obtain daily required fluid intake. Contamination is defined by NANDA-I as exposure to environmental contaminants in doses sufficient to cause health effects (NANDA-I, 2014). Contamination could be from many sources such as drinking water contaminated with fertilizers. More chemicals may be used to enhance crop production in an effort to produce adequate food. Hyperthermia and Hypothermia, is defined as core body temperature above or below the normal range, respectively, due to failure of thermoregulation. Hyperthermia and hypothermia both could be secondary to the extremes of environmental temperatures associated with climate change.

An additional important NANDA-I nursing diagnosis is Risk for Infection. Risk for Infection is defined by NANDA-I as being vulnerable to invasion and multiplication of pathogenic organisms which may compromise health. This could happen in connection to a disease outbreak secondary to flooding. The following is an example. The WHO reports typhoid fever as a serious disease infecting 22 million and killing about 216,000 people annually. Most of these cases were in Asia. Typhoid is caused by a bacterium, *Salmonella enterica*, and is passed through an oral-fecal route. Safe water for drinking and cooking and adequate sanitation systems are needed to avoid disease transmission. Typhoid vaccine use is also recommended by the WHO (World Health Organization [WHO], 2014). Climate change based flooding could easily overwhelm a marginal sanitation system, washing human waste into the drinking water supply. This would provide the oral-fecal route required for disease transmission. Also, standing water occurring after flooding allows for risk for vector-borne disease associated with insects that live or breed in water. These risks of infection include dengue fever, malaria, and yellow fever, to name a few (Montgomery & Elimelech, 2007).

The second group of nursing diagnoses will concern mental health issues. There are numerous diagnoses that could apply, however, three important mental health related nursing diagnoses will be considered in relation to pollution and resultant climate change. These three are relocation stress syndrome, impaired resilience and post trauma syndrome. Relocation stress syndrome is defined as physiological and or psychosocial disturbance following transfer from one environment to another (NANDA-I, 2014). The sea level rise expected with climate change will likely cause coastal flooding. Many people may find moving inland a necessity. Business and residences will be lost in the process. Such an unwanted move will put stress on all individuals involved. Impaired resilience is defined by NANDA-I to be the state of having decreased ability to sustain a pattern of positive response to an adverse situation or crisis, which compromises health (NANDA-I, 2014). Relocation stressors along with physical illness and economic losses may tax families coping skills to the limit. If the limit of coping is exceeded, the diagnosis of post trauma syndrome may become appropriate. Post trauma syndrome is defined as sustained maladaptive response to a traumatic, overwhelming event (NANDA-I, 2014). Some individuals may not be able to adjust to fast paced changes brought on by floods, fires and other disturbances secondary to climate

change. The cumulative stressors of food and water shortages and possible relocations to more inland locations may necessitate special mental health services to help stabilize those individuals most severely impacted.

Summary Objective Two

Climate change can influence human health in many different ways as shown in the Rocky Mountain pine beetle example. These influences are either direct, as in a heat stroke, or smoke inhalation, or indirect for example, by temperature extremes that cause crop failures and thus resultant food shortages and malnutrition. Other climate related health effects could be secondary to increased allergens and air pollutions, and altered patterns of infectious disease vectors secondary to increased flooding (Polivka et al., 2012). It is noted that nursing diagnoses can be well utilized in connection to treatment of environmentally related illness or injury, and that it covers both physical and mental health issues. Nurses' knowledge and empowerment are improved with use of a nursing language terminology system, such as nursing diagnoses. The above section is not an exhaustive discussion of all the possible nursing diagnoses that could apply to pollution related health problems.

Objective Three: Solutions and Recommendations

Explore how the healthcare system can help to create solutions to the pollution.

Educate Oneself and Others

Becoming aware of the issues through formal education, in-service training and informal exchange of information with colleagues is important. Then one can use what is learned to educate others. Many nurses and healthcare workers may still not be aware of the growing environmental crisis and the role that healthcare plays in the cycle of harm or of the laws in place to help protect the environment. Healthcare staff should all attend in-services when offered and, if necessary, present such in-services if not available otherwise in one's healthcare facility. Public health nurses and community health educators may be in the most favorable positions to educate the public on how to protect the environment. Information on how and why water and other pollution is hazardous to the public health should be explained to the community members. Inpatient care givers may have the opportunity upon discharge planning to include patient education on the importance of water purity, environmental conservation and the connection to their own health. Perhaps even an information pamphlet distributed at discharge could be helpful. Pharmacists have an opportunity to explain to patients, at time of medication pick up, how to properly dispose of drugs to avoid water supply contamination. Reverse distribution is one solution, where the unwanted medications are collected and sent off to be incinerated (Tucker, 2011). Dietitians have the opportunity to explain to patients, during a diet consult, how a lower meat diet can improve both their health and the environment. All health providers should look for opportunities in their daily duties to educate patients, the public or other staff members.

An example of successful teaching of staff is reported by Mosquera et al. (2014). In Spain, Mosquera et al. (2014) found that healthcare waste management training improved biomedical waste management. It was noted that in recent years, there has been a significant increase in healthcare waste generation.

Training interventions in advanced healthcare waste management improved the segregation of regulated medical waste. Such training can also reduce waste volume and cost of disposal. Mosquera et al. (2014) conducted a study of individuals who attended a waste management training session and analysis was done to compare the attendees' pre and post training waste management practices. The results showed that after the intervention, there was a significant reduction in the monthly average healthcare waste volume of six percent. Statistically significant differences in the pharmaceutical and infectious waste weight segregated before and after the training session were found. It was concluded that the healthcare waste management training improved hospital waste management at the facility, reducing the healthcare waste volume and costs (Mosquera, M., Andres-Prado, Rodriguez-Caravaca, Latasa, & Mosquera, M. E, 2014).

Successful teaching of patients is shown in one Luminary Project story. The Luminary Project is a web based effort associated with Health Care Without Harm to share stories of nurses who are making a difference in healthcare by lighting the way to environmental health. Trosch, patient care clinician, and Corna, clinical nurse specialist of Magee-Women's Hospital in Pittsburg, PA, USA, work in a busy mother and baby unit where 800 to 1,000 births occur per month. To educate the childbearing families they serve, their department began a Smart Start education program with prenatal through postpartum classes. While covering such typical topics as breast feeding, additional information was added on environmental hazards for children such as lead, pesticides, and second hand smoke. Besides the in-person classes, the families receive a brochure called *Rx for Prevention* to which they can refer for reinforcement of the information. In addition, the staff of the department underwent training so they could answer the new parent's questions related to creating a safe and healthy environment at home. This program began in 2005 and was added to in 2007 with recycling on the nursing unit and a green resource room for new parents with information on environmental concerns (Trosch, & Corna, 2015).

Not only does the healthcare community need to recognize the importance of the physical environmental quality for human health, another type of education is needed. According to Trasande et al. (2010) education is needed to improve healthcare providers' recognition and treatment of environmental contaminate victims. This will become more apparent as climate change related health problems and environmental toxin exposure become more common. Trasande et al. (2010) found that many pediatricians were unsure how to diagnose and treat environmental exposures. Because of increasing disease of environment origin a network of centers called Pediatric Environmental Health Specialty Units (PEHSUs) were established. The PEHSUs were opened with the support of the Centers for Disease Control (CDC) and the EPA. The Michigan chapter of American Academy of Pediatrics was surveyed about environmental health topics with a total of 362 participants taking part. The findings included the participants agreeing strongly that the role of the environment in health is great and that the magnitude of environmental mediated illness is increasing. It was found that only six percent knew about the PEHSUs and no pediatrician had made more than one referral. The same survey revealed that the physicians rated their confidence in management of lead exposure and second hand smoke high, while rating their confidence in management of patient exposure to pesticide, air pollution, mercury and mold as low. The authors concluded that the survey and analysis of data clearly showed a number of gaps in the protection of children from environmental hazards (Trasande et al., 2010).

Nursing diagnoses can be used to apply to teaching and learning situations. One of the associated diagnoses is Knowledge Deficit, which is defined as an absence or deficiency of cognitive information related to a specific topic (NANDA-I, 2014). This can be applied when healthcare staff lack sufficient knowledge of environmental issues related to healthcare. Another diagnosis is Readiness for Enhanced

Knowledge, defined as the presence or acquisition of cognitive information related to a specific topic which is sufficient for meeting health related goals but can be strengthened (NANDA-I, 2014). This diagnosis is related to the worker's willingness to learn new information.

Cut Greenhouse Gas Production at Work and at Home

One thing hospital dietary departments could do to improve patient health outcomes and help mitigate environmental damage, is to serve patients a lower meat content menu. Dietary consultations for patients to continue a more plant based dietary intake once out of the hospital, can be emphasized. Nurses and dietitians can educate patients on the personal benefits to their health as well as to the conservation of the environment. Patients and community members may not be aware that there are many sources of high quality proteins that are plant based, such as nuts, beans and tofu. Animal source non-meat proteins include dairy products and eggs.

Energy use, in hospitals, especially in the intensive care units, is very high (Huffling, & Schenk, 2014). However, there are a variety of ways to cut down on energy use and not compromise on patient care. Some of these energy saving ideas include selection of energy efficient electrical equipment, such as intravenous pumps that have a favorable energy star rating. Nurses may need to gain representation on the purchasing committee to influence these equipment decisions. Also, equipment can often be put in sleep mode or unplugged entirely when not in use. Room temperature setting were noted to be varied and energy consuming, as some areas require cool temperatures, such as operating rooms and other treatment areas require warmer temperatures, such as burn units. The nurse needs to work with facility management to arrange the optimum efficient central heating and cooling temperatures for patient care areas while minimizing energy expenditure.

Other energy saving measures could include making use of solar heating by leaving blinds open to let sunlight in on cooler days and vice versa on warmer days. Changing from incandescent to fluorescent or light emitting diodes (LED) can save energy on lighting. Use of occupancy sensors can also save energy by switching off lights when no movement is detected. However, occupancy sensors cannot be used in patient care areas or medication preparation areas for safety reasons. Nurses need to work with the Information Technology department about the use of computer energy. Can computers be put in sleep mode or turned off when not in use? If not, can the screen be switched off until needed again? Nurses can see that televisions in patient rooms are turned off promptly when not needed or wanted (Huffling, & Schenk, 2014).

Beyond the on the job related energy savings that health centers can undertake as described by Huffling and Schenk (2014), there is the consideration of reductions in fossil fuels usage in transportation to the place of employment. According to Shulman et al. (2012), residents of the USA emit an average of 21 tons of carbon dioxide into the atmosphere annually and transportation related emissions account for 28% of this amount (Shulman et al., 2012). Large healthcare centers employ thousands of employees, the majority of whom traditionally have arrived alone in their private vehicles. Most healthcare workers burn fossil fuels in their daily commute to work, as do workers in other professions. Car-pooling, riding a bike or taking public transportation to work, where feasible, would assist with mitigation of greenhouse gas emissions as well as traffic jams. For those who have primarily an office-based job, one could consider the possibility of working part time from home, for example, two days a week with computer and phone connections to the job. This growing trend is referred to as telecommuting. While on location at a job site, one could consider if convening a meeting across town is really necessary, or if a phone call could

serve the purpose as well. When getting a larger group of colleagues together from different locations, electronic teleconference meetings can be arranged complete with mutual viewing on screen.

When driving a private vehicle is necessary, a more fuel efficient model is preferable. Shulman et al. (2012) states that individuals could reduce their carbon dioxide emissions by nearly four tons annually by switching from a vehicle that gets 20 miles to the gallon of gasoline (mpg) to a vehicle that gets 40 mpg. Alternate fuel vehicles, such as electric powered cars, are becoming more commonplace. Most petroleum powered vehicles can be made to achieve better gas mileage if properly maintained and operated at lower speeds as appropriate. Employers could make a conscious effort to assist employees locating others residing in the same vicinity so that carpooling to work could be arranged among the participants. Providing preferred parking near the door for car pool vehicles is one way a health center can reward and encourage car pool formation. For those employees who feel that they can continue to work efficiently through a twelve hour shift, the employer can make such a schedule available. In this way a health worker who is on the job for three twelve hour days has completed thirty-six hour week and should be considered a full time employee with full benefits. This allows two days a week of gasoline use savings that is not needed for the employee to commute to work.

Create Less Waste and Use Better Waste Management at Work and at Home

Healthcare staff members need to know how to separate infectious waste and hazardous waste carefully, at the point of generation. Healthcare waste has several different distinct categories which each require different handling. Regular non-infectious solid waste can go in the general garbage bin but soft biohazard materials must be deposited in a red bag for disposal. At the same time, nonhazardous waste must not be in with the red bag waste. This will unnecessarily drive up cost of disposal. Sharp, biohazardous waste, such as used needles, should go in a waterproof, hard-sided red container for disposal.

Upstream management of waste refers to prevention by promoting more judicious use of hospital supplies when appropriate. It can also refer to avoidance of bringing hazardous chemicals into the system. Upstream waste management also can mean finding alternatives to harsh chemical cleaners. Mercury, polyvinyl chloride (PVC) and formalin are three substances that require changes in upstream hospital utilization. Phasing out mercury containing devices is a needed step because mercury is a neurotoxin. Hospitals can obtain help with creating a mercury-free environment through Hospitals for a Healthy Environment, whose web site is <http://www.h2e-online.org>. Other measures healthcare centers can take include avoidance of PVC containing products, which produce toxic smoke when burned. A needed waste management measure for formalin, a formaldehyde-based lab fixative, is to buy it in small prefilled containers that can help reduce waste, spillage and accidental exposure.

Recycling efforts and avoidance of prepackaged kits and paper gowns can cut down on waste. Solid waste items that can be reused should be divided out and recycled for home or other usage (Shaner-McRae et al., 2007). Waste can be avoided by not using prepackaged intravenous start kits, Foley catheter kits or similar prepackaged supplies. This will avoid the practice of discarding unused items in the kit. In intensive care isolation units there is a movement back to washable cloth isolation gowns to replace paper disposable gowns. This reduces paper waste a great deal. Further reduction of other isolation related waste can be accomplished by refraining from taking supplies or equipment into an isolation room until just before use (Huffling, & Schenk, 2014).

An example of a healthcare center making a waste-related positive change is seen in Australia. In Sydney, Australia, De Sousa et al. (2014) had concerns about clinical waste management in a 360 bed

acute care hospital. The following areas were examined: mass and volume of trash, space efficiency and logistics of trash containers. Infection and injury risk to staff operating the waste disposal system were also considered along with appearances of the system, cost and efficiency. The old system of 240 liter (L) trash bins was compared to a new system of 64 liter linerless reusable trash bins. Results showed inpatient workloads remained the same over the study. Staff evaluations showed a strong preference for the new system which was made available to all departments in the facility. Significance decreases were noted in clinical waste (CW) mass (53.2% less), CW volume (65.2% less), CW disposal costs (30.9% less) and labor (69.2% less). The new system was found to be more space-efficient and logistically improved. Waste segregation was markedly superior. Infection potential and injury risks seen with the 240 L system were eliminated. The study found that the use of a smaller, 64 L, linerless, reusable, hospital waste bin system had the potential to decrease costs, reduce clinical waste volumes, increase labor efficiencies, and minimize infectious potential and sharps injury risk. All of these improvements add to the quality of health care (DeSousa, Martin, & Grimmond, 2014).

Another good example of a health center being environmentally responsible is the Philippines Heart Center that took on a clean discharge water project. The center had approximately 15,000 patients in 2011 and had an average wastewater discharge of 540 cubic meters per day. In 2011 the Heart Center was appointed a member of the technical working group to revise the Department of Health's waste management manual. Through this process, the center updated its own facilities to support environmental responsibility. The Health Center built its own on-site wastewater treatment plant and all water is treated before discharge. Also the wastewater is used to irrigate the hospital grounds and future plans is to reuse it in the hospitals toilets (Health Care Without Harm, 2015).

Seek Empowerment through Collaboration with Others

All parties are needed to work together to obtain the global environmental sustainability solutions needed. All the sectors of the world compose a global community.

The problems of healthcare-source pollutant is not limited to one region of the world, but is wide reaching in scope. Many countries are looking at environmental issues with varying points of view, but with a common concern regarding health services waste management. This chapter's inclusion of a mix of countries also helps to illustrate the ANA's principle six which affirms that approaches to promoting a healthy environment must respect the diverse values, beliefs, cultures, and circumstances of the patient and their families (ANA, 2007).

In this context, the chapter author sees two applicable nursing diagnoses, which include the following examples. Ineffective Community Coping is defined by NANDA-I as a pattern of community activities for adaptation and problem-solving that is unsatisfactory for meeting the demands or needs of the community (NANDA-I, 2014). Also, Readiness for Enhanced Community Coping, is defined as a pattern of cognitive and behavioral efforts to manage demands that is sufficient for well-being but can be strengthened (NANDA-I, 2014).

Beneath the logistics and cost of better healthcare waste disposal and less resource depletion, the underlying challenges are in improving awareness of the problems and workers' empowerment to do something to improve waste management and resource conservation. Turning again to the concepts contained in nursing diagnoses, there are several nursing diagnoses besides Moral Distress, discussed above, that could apply to the current healthcare staff situation. Powerlessness is one such nursing diagnosis,

and is defined as a perception that one's own action will not significantly affect an outcome; a perceived lack of control over a current situation or immediate happening (NANDA-I, 2014).

Beyond nursing diagnoses is the concepts contained in the Nursing Intervention Classification System (NIC) (Bulechek, Butcher, Dochterman, & Wagner, 2013). NIC has 554 comprehensive, standardized nursing interventions, containing nearly 13,000 suggested activities to address varying nursing diagnoses. Interventions span both the physiological and psychosocial spheres. One such psychosocial nursing intervention suggested for the nursing diagnosis Powerlessness is Complex Relation Building (Bulechek et al., 2013). Even though this is usually in the context of nurse and patient interactions this could be applied in a broader way to colleagues who establish a mutually trustworthy relationship that promotes insight and behavior change.

Empowerment for improvement can be built by connecting and interrelating with other concerned individuals of various professions and world regions. Other professions hold key pieces of the environmental sustainability solutions sought by healthcare providers. With healthcare workers making connections to other concerned individuals, the connections potentiating the cycle of harm can be broken. These others in the health system can include dietary and facilities management, hospital buyers, pharmacist, information technology experts and hospital administrators. Outside the health system, many other professions, such as educators, architects, environmental specialist, conservation organizations, and public policy makers are concerned and want to look for solutions to create a sustainable environment for all.

The nursing diagnoses that can be used to describe this situation include the following: Readiness for Enhanced Relationship, which is defined by NANDA-I as a pattern of mutual partnership that is sufficient to provide each other's needs and can be strengthened (NANDA-I, 2014). Readiness for Enhanced Power, which is defined as a pattern of participating knowingly in change that is sufficient for well-being and can be strengthened (NANDA-I, 2014).

Joining established groups that work for environmental causes is a way to add individual efforts to a larger movement for change. There are many organizations, Sierra Club, Nature Conservancy and Ocean Conservancy, to name a few. There are also healthcare specific groups that are environmentally concerned such as Health Care Without Harm and Alliance of Nurses for Healthy Environments.

CONCLUSION

Nurses worldwide need environmental awareness and empowerment to manage healthcare-source pollutants properly. Beneath the logistics and cost of better healthcare waste disposal and less resource depletion, the underlying challenges are in improving healthcare workers' awareness of the problems and empowerment to do something about these issues.

Nurses, other healthcare workers and healthcare systems participate in the cycle of harm. The cycle of harm includes healthcare source pollution contaminating the environment, people becoming ill secondary to this pollution and the sickened individuals coming to the healthcare system, where more pollution is created during their treatment. All must work together to find solutions to the pollution created. No one country or world region has all the pollution-related problems or all of the needed solutions alone. Countries globally are becoming aware and striving to meet the challenges of energy use and proper waste disposal.

Nurses and other healthcare workers can prepare themselves and help to position their workplaces for the environmental related health concerns of the future. Healthcare professionals can also be leaders in role-modeling sustainable behaviors as well as in dissemination of risk and hazard information to our patients and the community at large, along with useful information of what an average household can do to mitigate pollution and climate change. There is reason to believe that the health professions can make a difference in mitigation of environmental degradation and minimize the resultant human health consequences that we will be called on to manage.

FUTURE RESEARCH

Further research is needed on best management of healthcare waste. Various approaches may be called for in different locals to fit the situation and finances available. More can be done on innovative ways to cut energy use in healthcare and thus lower carbon dioxide formation. More research and education needs to be done to prepare caregivers to recognize and treat illness or injuries related to environmental factors.

KEY TERMS AND DEFINITIONS

Contamination: Is defined by NANDA-I as exposure to environmental contaminants in doses sufficient to cause health effects (NANDA-I, 2014).

Cycle of Harm: Includes increased acidification and heating of ocean waters secondary to release of greenhouse gases. The cycle also includes chemical and biological contamination of fresh waters secondary to improper waste disposal. Humans suffer related health consequences. People receiving treatment for resultant illnesses produces more pollution.

Hyperthermia and Hypothermia: Are defined as core body temperature above or below the normal range, respectively, due to failure of thermoregulation.

Imbalanced Nutrition: Less Than Body Requirements: Is defined by NANDA-I as an intake of nutrients insufficient to meet metabolic needs (NANDA-I, 2014).

Ineffective Community Coping: Is defined by NANDA-I as a pattern of community activities for adaptation and problem-solving that is unsatisfactory for meeting the demands or needs of the community (NANDA-I, 2014).

Knowledge Deficit: Is defined as an absence or deficiency of cognitive information related to a specific topic (NANDA-I, 2014).

Moral Distress: Is a nursing diagnosis that is defined by NANDA-I as the response to the inability to carry out one's chosen ethical or moral decision. The defining symptoms or characteristics include fear, anxiety, and expressed anguish.

Post Trauma Syndrome: Is defined as sustained maladaptive response to a traumatic, overwhelming event (NANDA-I, 2014).

Powerlessness: Is defined as a perception that one's own action will not significantly affect an outcome; a perceived lack of control over a current situation or immediate happening (NANDA-I, 2014).

Readiness for Enhanced Community Coping: Is defined as a pattern of cognitive and behavioral efforts to manage demands that is sufficient for well-being but can be strengthened (NANDA-I, 2014).

Readiness for Enhanced Knowledge: Is defined as the presence or acquisition of cognitive information related to a specific topic which is sufficient for meeting health related goals but can be strengthened (NANDA-I, 2014).

Readiness for Enhanced Power: Is defined as a pattern of participating knowingly in change that is sufficient for well-being and can be strengthened (NANDA-I, 2014).

Readiness for Enhanced Relationship: Is defined by NANDA-I as a pattern of mutual partnership that is sufficient to provide each other's needs and can be strengthened (NANDA-I, 2014).

Relocation Stress Syndrome: Is defined as physiological and or psychosocial disturbance following transfer from one environment to another (NANDA-I, 2014).

Risk for Deficient Fluid Volume: Is defined as the state of being vulnerable to experiencing decreased intravascular, interstitial and or intracellular fluid volumes, which may compromise health (NANDA-I, 2014).

Risk for Infection: Is defined by NANDA-I as being vulnerable to invasion and multiplication of pathogenic organisms which may compromise health.

Chapter 7

Health Policy Implementation and Its Barriers: The Case Study of US Health System

Augustine Nduka Eneanya
University of Lagos, Nigeria

ABSTRACT

The chapter describes policy implementation components of a health system in United States of America and explains how they affect health outcomes (service delivery). It argues that implemented policies affect various components of a health system in terms of service delivery, workforce, information, financing, medical products, technologies, leadership and governance. Using health system as framework of analysis, the paper explains that the outcome of health policy implementation determines the availability, quality and equitability of program service delivery. The chapter goes on to argue that policy implementation barriers, such as demand-and supply-side barriers, market, insufficient resources, cultural barriers, imperfect communication, information, education, coordination, leadership and governance affect the poor and vulnerable groups in developed and developing countries from benefitting from public spending on public health policies and programs.

BACKGROUND

An important factor in socio-economic development of any nation is the extent to which that country is involved in healthcare delivery system. Good health is a vital factor of quality of life as well as a pre-requisite for achieving socially and economically productive lives of a nation. No government can function effectively without an appropriate health care system. Health care system is one of the basic institutions that is universal in nature and without which a society cannot survive. The World Health Organization Report, (2000) defines health system as comprising all the organizations, institutions and resources that are devoted to producing health actions. Health action in this context entails any effort, whether in personal healthcare, public health services or through inter-sectional initiatives, whose primary purpose is to improve health. Healthcare institutions consist of formal and informal organizations

DOI: 10.4018/978-1-5225-1674-3.ch007

where preventive, social and clinical services are rendered to the members of the society. Each of the institutions has specific aims and objectives even though they all exist to promote health, to prevent the occurrence of diseases, to bring about a peaceful end for those suffering from terminal disease, and to treat human illness. Most healthcare institutions form an arm of the government. Their social structure, therefore, follows the same pattern as other government institutions. Healthcare institutions form a large social system, and within this system are other large sub-systems. The systems vary from one country to another and even slightly within the same country.

The purpose of this paper, therefore, is to examine policy implementation by institutions of health care service delivery and barriers to effective outcomes. Specifically, the paper attempts to investigate how health policies support program activities of health institutions, such as; elimination of healthcare inequities; access to healthcare facilities, products and services; availability of finance infrastructures and other resources; provision of information and education to individuals and communities to medical products, facilities and services.

Consequent upon this, the paper is structured into five parts. Part one examines the introduction, purpose, clarification of concepts and underpinning theories of health policy implementation. Part two examines the inputs required in healthcare systems, such as; finance, structures and power relationships, equipment, personal and clients. Part three discusses the processes or series of activities that transform resources (inputs) into a desired product, service or output. Part four examines the outputs – direct result of the interaction between inputs and processes in the system, the types and quantities of goods and services produced by an activity, program or project.

Finally, part five identifies the barriers to effective health policy implementation and its implications.

CONCEPTUAL CLARIFICATIONS

Health System

Health system comprises all organizations, institutions and resources that are devoted to producing health actions. Health actions in this context refers to any efforts, whether in personal healthcare, public health services or through inter-sectional initiatives whose primary purpose is to improve health. It is an open system with three components of input, processes and outputs. Inputs required in a healthcare system include: finance, physical structure, equipment personnel and clients. The process refers to a series of activities that transform inputs (resources) into a desired product, service or output. The term output is used to describe the direct result of the interaction of inputs and processes in the system, the types of and quantities of goods and services produced by any activity, program or project. On the other hand, the term outcome refers to the result of the outputs, the effects or impacts. All these depend on how efficiently the system within the operating environment is administered and how the resources are managed.

Health Policy

According to WHO, it is the approach to medicine that is concerned with the health of the community as a whole. Health policy, in other words, refers to decisions, plans, and actions that are undertaken to achieve specific health care goals within a society. An explicit health policy can achieve several things:

it defines a vision for the future which in turn helps to establish targets and points of reference for the short and medium term. It outlines priorities and the expected roles of different groups; and it builds consensus and informs people.

In fact, the mission of health policy is to “fulfill society’s interest in assuring conditions in which people can be healthy.” The three core public health policy functions are:

- The assessment and monitoring of the health of communities and populations at risk to identify health problems and priorities;
- The formulation of public policies designed to solve identified local and national health problems and priorities;
- To assure that all populations have access to appropriate and cost-effective care, including health promotion and disease prevention services, and evaluation of the effectiveness of that care.

To be more precise, Health policy means more than a national law or intervention. Operational policies are the rules regulations, guidelines and administrative norms that governments use to translate national laws and policies into programs and services. Health policy can be defined as the decisions, plans and actions that are undertaken to achieve specific healthcare goals in a society. Health policy can also support program activities, such as elimination of inequities in healthcare delivery services or mobilization of community health workers.

Policy Implementation

Implementation, viewed broadly, means administration of law in which various actors, organization, states, local authorities, procedures and techniques work together to put adopted policies into effect in an effort to attain policy or program goals. For our purpose, implementation can be conceptualized as a process, outputs (series of activities) and outcome. As a process, it is viewed as a series of decisions and actions directed toward putting a prior authoritative federal legislative decision into effect by the state or local authorities or organizations. As an output, implementation can be defined in terms of the extent to which programmatic goals are supported, such as the level of expenditures committed to a program or the number of violations issued for failure to comply with the implementation directive. Policy implementation can be conceptualized as some measureable change in the large problem that was addressed by the program, public law, or judicial decisions (outcomes).

Implementation can be considered from Fullan(2007) glasses;Fullan (2007: 14) rightly notes that many change attempts fail because ‘no distinction is made between theories of change (what causes change) and theories of changing (how to influence those causes)’. Therefore, it is important to point out that policy change goes hand in hand with policy implementation. Mazmanian and Sabatier (1983: 20) define implementation as ‘the carrying out of a basic policy decision, usually incorporated in a statute but which can also take the form of important executive orders or court decisions’. A policy decision ‘identifies the problem(s) to be addressed, stipulates the objective(s) to be pursued and structures the implementation process’ (Sabatier and Mazmanian 1980: 540). Passing policies does not guarantee success on the ground if policies are not implemented well. Pressman and Wildavsky (1984) were the first ones to show that implementation dominates outcomes.

It is difficult to say which factors or conditions facilitate successful implementation since so much depends on the political, economic and social context. For instance, local factors (e.g. size, institutional

complexity) matter for policy responses (McLaughlin 1987). In this vein, Payne (2008) argues that only looking for general solutions and not acknowledging the particular context can lead to incoherent implementation efforts. Therefore, no ‘one-size-fits-all’ policy exists. However, this has not stopped some scholars from trying to come up with the most important factors for certain policy areas. To take the example of education policy, according to Payne (2008), successful implementation has been evidenced in schools where there is:

- Coherence
- Stability
- Peer support
- Training
- Engagement.

Successful system reform means that a small number of powerful actors are interacting to produce substantial impact (Fullan 2009: 108). Successful implementation implies that ‘agencies comply with the directives of the statutes, agencies are held accountable for reaching specific indicators of success, goals of the statute are achieved, local goals are achieved or there is an improvement in the political climate around the programme’ (Ingram and Schneider 1990). Local capacity and will matter for policy success; adequate resources and clear goals are important too (McLaughlin 1987). In addition, the implementation process is characterised by a ‘multi-staged, developmental character’ (McLaughlin 1987: 176).

Even if policy implementation appears to be successful, Fullan (2000) points out that there is no guarantee that success will last. In terms of the change process in schools, there has been strong adoption and implementation, but not strong institutionalisation. Fullan (2000; 2007) further notes that both local school development (which engage teachers and students) and quality of surrounding infrastructure are key for lasting success. But successful examples of policy change (in schools) are still in the minority (Fullan 2007). Changing policies is not sufficient if there is no ‘reculturing’ of classrooms (Fullan 2000; 2007). As a result, a number of conditions need to be satisfied to enhance the change of successful and sustainable implementation, though these conditions vary across systems. This adds to the difficulty of the whole process.

Top-Down and Bottom-Up Approaches

A widely used concept in the policy implementation (and change) literature distinguishes between top-down and bottom-up approaches. The two approaches vary in a number of areas, such as the role of actors and their relationships and the type of policies they can be applied to.

Top-Down Approach

Top-down theorists see policy designers as the central actors and concentrate their attention on factors that can be manipulated at the central level (Matland 1995). The most detailed top-down approach was presented by Sabatier and Mazmanian (1979), who identified a number of legal and political variables and then synthesised them into six conditions needed for effective implementation ranging from clear objectives, causal theory, legal structure of the implementation process, committed officials, supportive

interests groups to no undermining of changing socio-economic conditions (for more detail on these conditions, see Sabatier 2005: 19). In terms of policy areas, 'top-downers' usually prioritise clear policies (Matland 1995: 155).

Strengths and Weaknesses

One strength of the top-down approach is that it seeks to develop generalisable policy advice and come up with consistent recognisable patterns in behaviour across different policy areas (Matland 1995). But top-down approaches are criticised for only taking statutory language as a starting point and hence do not consider the significance of previous actions. The approach may be said to consider implementation as an administrative process and ignores or eliminates political aspects. The emphasis on statute framers as key actors is another source of criticism (i.e. local actors are not taken into consideration).

Bottom-Up Approach

Bottom-up theorists emphasize target groups and service deliverers, arguing that policy is made at the local level (Matland 1995: 146). These scholars (e.g. Hjern and Hull 1982, Elmore 1979) thus criticize top-down theorists for only taking into consideration the central decision-makers and neglecting other actors. The bottom-up approach, developed by Hanf, Hjern and Porter (1978), identifies the networks of actors who are involved in service delivery in one or more local areas and asks them about their goals, strategies, activities and contacts. It then uses the contacts in order to develop a networking technique to identify the local, regional and national actors involved in the planning, financing and execution of relevant governmental and non-governmental programs. This provides a mechanism for moving from local actors and decision-makers such as teachers or doctors up to the top policy-makers in both the public and private sectors (Sabatier 2005: 23). In terms of policy areas, bottom-uppers examine policies with greater uncertainty in the policy (Matland 1995: 155).

Strengths and Weaknesses

Among the benefits of the bottom-up approach is its focus on centrally located actors who devise and implement government programs, thus contextual factors within the implementing environment are important. Actors and their goals, strategies and activities need to be understood in order to comprehend implementation. Bottom-up approaches do not present prescriptive advice, but rather describe what factors have caused difficulty in reaching stated goals (Matland 1995). It is significant that strategies are flexible so that they can adapt to local difficulties and contextual factors. Nonetheless, bottom-up approaches have been criticised on two counts. First, policy control should be exercised by actors whose power derives from their accountability to sovereign voters through their elected representatives, but the authority of local service deliverers does not derive from this. Second, this approach tends to overemphasise the level of local autonomy (Matland 1995).

Combined Approach

Increasingly, the literature has focused on combining (micro-level variables of) bottom-up and (macro-level variables of) top-down approaches in implementation research in order to benefit from the strengths

of both approaches and enable different levels to interact regularly (Elmore 1985, Fullan 2007, Matland 1995, Sabatier and Jenkins-Smith 1999). Building on Matland (1995), Suggett (2011) develops a framework distinguishing areas by the level of political conflict about goals or intent of a policy, and the level of uncertainty about the means or actions to achieve the goal. The two-by-two typology captures how top-down and bottom-up approaches can vary according to policy areas.

For instance, strategies that use bottom-up approaches (e.g. networks and devolution) are more common in areas of low conflict but high uncertainty and lack of consensus about the means to achieve a goal – such as educational disadvantage (Suggett 2011:8). In contrast, strategies that use such top-down approaches as strong political direction and sound governance are more likely in areas of high conflict about the goal but relatively high certainty on how it might be implemented (e.g. taxation for a specific industry sector) (Suggett 2011: 8).

Strengths and Weaknesses

Combining the two approaches might thus draw on their main strengths while minimising their weaknesses. Policy implementation often takes place because a wide range of stakeholders interact between different levels – thus both central policy-makers and local actors on the ground are important for successful implementation. In addition, this combined approach allows for differentiating between various policy areas. For instance, while the suggested framework by Suggett (2011) in its current form could be further elaborated, it is a good start for differentiating between implementation strategies. It matters whether health care, taxation or education policies are considered. Even within policy sectors, implementation strategies are not the same for higher education and secondary education policies, for example (see Gornitzka, Kyvik and Stensaker 2005). As a result, implementation varies according to different content and type of policies.

Rational-Choice Theories

At times, researchers have looked for more sophisticated ways of theorizing about implementation by applying rational-choice approaches. In a nutshell, rational choice theories are based on the assumptions that actors have a fixed set of preferences and act rationally in order to maximise the attainment of these preferences. Politics is seen as a series of collective action dilemmas due to the lack of institutional arrangements to encourage cooperation. In addition, strategic interactions between actors determine political outcomes (Hall and Taylor, 1996, pp. 944-945).

Game Theory

One example of a rational choice approach is game theory which is ‘a mathematical treatment of how rational individuals will act in conflict situations to achieve their preferred objectives’ (Firestone 1989: 18). It is in particular helpful for theories that seek to clarify how coalitions build and pass legislation. The literature on implementation and game theory is still rather sparse in the political science literature (for exceptions, see Bardach 1977, Koremenos and Lynn 1996, O’Toole 1995). For example, Bardach (1977) considers implementation as a continuation of a political game from the policy adoption stage, but with other actors and other relations between actors. He analyses the type of games that actors apply in the implementation process in order to pursue their own interests. But these games distort implementation

from the legislative goals (Winter 2003: 213). Despite limitations, game theoretic models are helpful for exposing points of leverage for implementation managers.

O'Toole (1995) examines the use of rational choice theories (in particular game theory) in implementation research. He argues that while game theory might enhance inter-organizational management, it has some serious practical limitations which constrain what might be theoretically possible (O'Toole 1995: 43). There are several challenges in rational-choice approaches to implementation, such as uncertainty across different areas and the lack of institutionalization in the implementation setting (since many implementation networks are not highly institutionalized). But active and skilful multilateral implementation managers can successfully intervene at several points in a network context to reduce uncertainty and institutionalize cooperation. Such strategies include facilitating moves and linking games through signaling, commitment, and iteration; influencing preferences of actors and persuading them of the benefits to encourage cooperative outcomes; developing norms of trust and cooperation; and shifting the inter-unit structure to facilitate cooperation (O'Toole 1995: 47-51).

Also drawing on game theory, Firestone (1989) offers an education policy example by analyzing an ecology of games. Individuals compete in one or few available games, which can be in government, education, business, religion or news. This model borrows from ecology as species interrelate in their environment in different ways – through competition, cooperation or interdependence (Firestone 1989). Educational games are linked through flows between them: an downward flow of resources and regulation from legislature to classroom, and an upward flow of demands from educators as well as the general public (Firestone 1989: 19). Again, the temporal dimensions and context play an important role in the implementation of education policy. Local variation should be taken advantage of, and practitioners should experiment with different models at the local level (Firestone 1989).

Agency Theory

A different application of rational choice is *agency theory* - how principals delegate implementation to state agents - which has been applied in political science, economics and sociology (Kiser 1999). Different political science scholars such as (Kiewiet & McCubbins 1991, Weingast & Moran 1983) have focused on the monitoring of agents by principals in order to reduce drift in implementation. In contrast to the economics literature on this topic, political science pays attention to three issues: third parties, administrative procedures and multiple principals. But several questions remain unanswered, such as who exactly the principal is that is supposed to monitor the actions of the agents, and how agents are selected (Kiser 1999).

Strengths and Weaknesses

Rational choice theory proposes a parsimonious framework in which actors are rational in the pursuit of their preferences and interact strategically with other actors in the system. However, as John (2003: 485) argues, 'rational choice does not offer solutions for all cases and contexts'. The theory is better at explaining outcomes when preferences are settled, rather than clarifying the origin of preferences and the reason for change (John 2003). Game theory provides several advantages, such as a rigorous deductive theory and the potential to combine top-down and bottom-up approaches by treating all relevant actors as strategic players. But, as mentioned before, there are a few challenges, such as uncertainty and the lack of institutionalization (O'Toole 1995: 54). Overall, there is considerable potential to apply rational choice theories, including game theory, to implementation, especially when there are testable hypotheses.

CONCEPTUAL FRAMEWORK

This chapter, therefore, adopts health system as our conceptual framework of analysis as no single theory can help us explain health system variables. WHO (2000) defines health system as comprising all organizations, institutions and resources that are devoted to producing health actions. Health actions in this context refers to any efforts, whether in personal healthcare, public health services or through intersectional initiatives whose primary purpose is to improve health. Health system is an open system with three components of input, processes and outputs.

Inputs required in a healthcare system include: finance, physical structure, equipment, health information, technology, material resources, personnel, health policies and clients. The process refers to a series of actions or activities that transform inputs or resources into a desired product, service or outcome. The series of activities in the process include treatment, client education, community empowerment, official meetings and other health interventions. The term output is used to describe the direct result of the interaction of inputs and processes in the system, the types of and quantities of goods and services produced by an activity, program or project. It includes treated patient, efficient services, improved health status, community empowerment, trained staff, good quality of life and sanitation. On the other hand, the term outcome refers to the result of a process, including output, effects or impacts (Quality Assurance Project, TASC 2 Eritrea, 2003). All this depends on how efficiently the system is administered and how the resources within the operating environment. The enabling environment comprises the government, State, Local authorities, health institutions, socio-cultural and economic factors, regulatory quality control by government, rule of law, civil society, community, individuals, political stability and support, accountability and so on.

This conceptual framework is adopted because the analysis is not intended to identify causal pathway. The health system, which is an open system, is one of the basic institutions that are universal in nature and without which a society cannot survive. According to WHO,(2000), all health systems carry out the functions of providing or delivering personal and non-personal health services; generating the necessary human and physical resources; raising and pooling the revenue used to purchase services; acting as the overall steward of the resources, powers and expectations entrusted to them. The health system is, therefore, justified as our conceptual framework of analysis for this paper because large number of people and institutions are involved at different levels of health activities but are all working together to achieve the objective of improving healthcare delivery. The framework would enable us analyze and explain how different levels of government, organizations and community implement policies on health resource generation, financing, stewardship and service provision.

METHOD OF ANALYSIS

The chapter adopts qualitative research technique. The purpose is to select information that would help us describe and explain health policy implementation and barriers to its effectiveness. Data were collected from secondary sources. They include textbooks, journals, newspapers, internet and records. Data from these sources were analyzed using documentary data analysis, thematic analysis and content analysis techniques to elicit key concepts or themes. The concepts were coded and categorized into units of analyses: policy implementation of resources or inputs; policy implementation intervention process or series of activities; and policy implementation of outputs/outcomes (efficient services or improved

health status) and subsequent barriers. Now, let us examine these concepts in the context of the health-care service delivery.

HEALTH POLICY IMPLEMENTATION (RESOURCES OR INPUTS)

Formal organizations such as health institutions are made up of people and are set up to achieve specific goals and objectives. The attainment of these goals depends on the availability of resources in the right kind, quantity and mix. Ultimately, the attainment of the goals depends on proper utilization of resources. Resources are those inputs that help, support and/or have positive impact upon the achievement of organizational goals (Peretomode & Peretomode, 2005). According to them, resources can be categorized into human and non-human resources. Non-human resources can be further categorized into financial and non-financial resources. Non-financial resources include: facilities, structures, equipment, time, technology, land, transportation, organizational climate, geography, information, policies and so on.

The provision of health care services involves putting together a considerable number of resource inputs to deliver an extraordinary array of different service outputs. Finance is an important asset in healthcare delivery services. The performance of the health system depends ultimately on the knowledge, skills, and motivation of the people responsible for delivering services. It enables health institutions to train health workers, employ physicians, pharmacists, establish health clinics/hospital buildings, procure vehicles, equipment, procure vaccines, pay labor cost and invest on new program activity or project.

GOVERNMENT INTERVENTIONS IN IMPLEMENTATION PROCESS

Perhaps the most pervasive impact of government on the delivery of healthcare services in most nations is through regulation. There are many kinds of health-care regulations, namely: facilities, costs, quality and pharmaceuticals. Governments attempt to influence health-care delivery indirectly by providing financial support for certain activities, and directly attempt to move resources around in the health industry. One such attempt is through the regulation of “healthcare facilities and more comprehensive planning for the health needs of communities” (Peter, 1988:258). Another regulatory device is the control of costs in terms of making majority of expenses paid by a third party, such as “Blue Cross or Medicare or Medicaid” in America health care system (Peter, 1988: 258). For example, the regulation of health-care quality is another area of intervention by USA government in health policy implementation. The major public instruments used for regulating the quality of medical care are the Professional Standards Review Organizations (PSROs). These organizations are designed in part to monitor costs of services provided to Medicare Patients. Some PSROs have gone as far as to establish standard profiles of treatment for certain rather common conditions and then to question physicians whose treatment differs significantly from those patterns.

Furthermore, the USA government and other nations are deeply involved in the regulation of pharmaceutical industry and in the control of substances in food and water that are potentially harmful to health. The Food and Drug Administration (FDA) in USA and National Agency for Food and Drug Administration and Control (NAFDAC) in Nigeria are responsible for most of the drug regulation. The safety and effectiveness of a drug must be demonstrated by clinical trials. Associated with drug regulation in the Food and Drug Administration (FDA). Another issue relating to the regulation of pharmaceuticals is the

Health Policy Implementation and Its Barriers

regulation of tobacco, especially cigarettes. It has been observed that smoking cigarettes is harmful to health. It requires warning labels on to be placed on packages and forbid advertising on electronic media. Cigarettes and their regulations figure prominently in financing of health care, especially increased tax on cigarettes. Moreover, competitive mechanisms using market forces to produce desired changes in the health-service industry have been on the increase in recent times.

So, government should develop institutional capacities to ensure that appropriate uptake and integration of policies into existing activities. That is, integration of policy into private sector and community programs, such as: public-private partnership and community-based distribution network. These health policies can also support other program activities:

- Elimination of health inequities or mal-distribution of medical products or vaccines through increased mobilization and distribution of services, such as modern contraceptives and vaccines by community health workers.
- Conduct of media campaigns for improved public education and information on prevention, care and treatments; demand creation for services to marginalized populations and for population mobilization for health activities, programs or projects.
- Integration of policy can also be into sectors that contribute to health, education, agriculture, roads and so on.

HEALTH POLICY IMPLEMENTATION (OUTPUTS/ OUTCOMES)

Outcomes of these activities help increase accountability and identify implementation barriers. There have been reported cases of fraud, for example in America's healthcare system. Home-health fraud, such as charging for non-existent visits to giving insulin injections- got- so bad that the "Medicare and Medicaid Centres" (CMS), which run the programs called a moratorium on enrolling new providers in several large cities in 2013. Since tighter screening was introduced under "Obamacare", the CMS has stripped 17,000 providers of their licenses to bill "Medicare"- services meant for the elderly recipients. Thousands of suppliers also quit after being acquired to seek accreditation and to post surety bonds of \$50,000. It was reported that health-care fraud in America amounted to about \$272 billion in 2013 (www.businessdayonline.com).

Thus, the outcome of health policy implementation is improved health status for individuals and community. According to WHO, (2000), the main objective of health action or series of health activities, whether in personal healthcare, public health services or through inter-sectoral initiatives is to improve health. Health policy implementation outcomes, therefore, can be summarized as: efficient services, improved health status, treated patients, community empowerment, trained staff, good sanitation and good quality of life.

ENABLING ENVIRONMENT IN HEALTH SYSTEM

For efficient services to emerge from health policy implementation, accountability and transparent mechanisms should be well established, so that civil society can monitor the implementation process,

in terms of service coverage and quality, population coverage and equity, healthy behaviors by increased number of people.

BARRIERS TO EFFECTIVE HEALTH POLICY IMPLEMENTATION

1. **Economics:** The most commonly cited barrier to access to healthcare is economics. For example in USA, majority of medical care is still paid for privately. Those who lack the income or insurance to pay for medical care may not have that medical care. Many who are poor but not sufficiently poor to qualify are not eligible to receive Medicaid benefits. Many people do not have health insurance. The elderly poor who have access to Medicare as a result of their age must still pay for parts of their insurance, at a rate that may deter some taking full advantage of healthcare program. Even having insurance as well as not having it can present troubles. The principal problem is that it can minimize mobility in the economy. For example, if a person has a job that provides health benefits it is difficult for him or her to leave that job for one that may be better in other respects but does not offer insurance. Besides, if the new job does provide insurance, it may not cover pre-existing conditions, then moving between jobs may be possible.
2. **Demand and Supply Barrier:** On the demand side, the economic literature is dominated by adaptations of Grossman model that analyze individual investment and consumption decisions to improve health and utilize healthcare (Grossman, 2000). Demand is influenced by factors that determine whether an individual identifies illness and is willing and able to seek appropriate healthcare. The model levels to a demand for healthcare of a given quality that is determined by individual and community factors as well as the price of medical care and other similar goods. Individual (and household) factors include: age, sex and income. Demand barriers to utilization of healthcare include:
 - a. **Information on Health Care Choices:** This provides lack of knowledge of the providers.
 - b. **Education:** Low ability to assimilate health choices and negotiate access to appropriate providers.
 - c. **Education and Knowledge about the Characteristics of and Need for Medical Treatment:** Information and education are related to failures, either in the form of knowledge of healthcare choices or in the ability to utilize this information in an effective way.
 - d. **Indirect Consumer Costs Barriers:** Are the result partly of income distribution and partly of lack of mechanisms to spread risk across the population or across time (so that individuals can pay for care when they can afford it rather than at the time of illness). The effect of household choices in preventing access to care to certain members is likely to be mainly the result of intra-household inequity:
 - i. **Distance Cost:** Long and slow travel to facilities.
 - ii. Distances to facilities imposes a considerable cost on individuals and this may reduce demand.
 - iii. Opportunity cost need for patient and career to stop working for long periods in order to seek care.
 - e. Household preferences as a symmetric control over household resources.
 - f. Community and cultural preferences, attitudes and norms: reluctance to seek healthcare for women outside home; community resistance to using modern medical care to assist pregnancy.

For example, cultural barriers such as cultural norms, such as “purdah” restrictions can prevent women from seeking healthcare outside the home for themselves and their children (Rashid et al. 2001). The barrier is often raised still further when men provide services and has often offered as one reason why Asian women living in Western countries often make little use of healthcare services (Whiteford & SZelag, 2000). Such restrictions may also interact with other barriers. Community factors may include cultural and religious influences and other social factors that affect individual preferences. Community barriers may also be related to information failures where they arise as a consequence of a lack of information about what constitutes medical provision and how patients will be treated once at a facility. For example, information might be used to reassure female patients that they will be treated by a female doctor.

- g. **Input Prices and Input Availability:** Substitute products and services patients seek treatment through providers that are inappropriate for their condition such as drug sellers (Ensor and Cooper, 2004). Price is a complex variable and includes direct price and distance cost, opportunity(time) cost of treatment-since treatment can be time consuming and any informal payments made to the facility for commodities or to staff. Quality of staff may be absent because of the price of the wages and staff not attracted to the area.
- h. **Knowledge of Technology of Treatments:** Inability to treat disease with given technology.
- i. **Management Efficiency:** Poor quality of management training, lack of management systems.

The determinants of demand may generate barriers to utilization of healthcare services. Education and information assist to assimilate health messages and are important in determining demand. Finally, barriers may also interact with other demand barriers and act as important determinant of the willingness to travel long distances to obtain treatment.

Therefore, increasing demand is far more complex than simply the provision of health education advice or information but is also strongly related to the relative position and education are family members. Demand barriers present in low and middle-income countries and even richer countries can be found among vulnerable groups.

When it comes to supply, the provision of healthcare is, in many ways, a monopoly or cartel. Entry into the marketplace for potential suppliers is limited by licensing requirements and further controlled by the professions themselves, which limits the number of places available in medical schools. Thus, unlike other industries, the healthcare field makes it difficult for competition to develop among suppliers. One possible means for promoting competition is to break down the monopoly held by the medical profession by giving nurse practitioners and other para-professionals a greater opportunity to practice. The medical profession rather vigorously resists such changes. Hospitals do compete increasingly for patients, however, and with that competition has come some greater attention to the quality of care.

Moreover, price and quality of drugs and other consumables and weak cold chain may cause scarcity of supplies. Thus, supply barriers affect patients in obtaining treatments, especially for the poor and other vulnerable groups.

- 3. **High Medical Care Cost Barrier:** Medical-care costs are problem for government as well as for private citizens. In USA, half the total medical care bill is paid by government. Because decisions about health-care spending are made not by one government but by several, including several agen-

cies interested in healthcare, central government attempt to control medical costs have been diffused and encountered difficulty overcoming the technical and political power of healthcare providers. A number of factors have been identified as causing at least part of the increase in medical care costs. For hospitals, one factor has been a rapid increase in the cost of supplies and equipment. This has been true of large capital investments such as CAT Scanners, as well as more mundane items, such as dressings and surgical gloves. In addition, labor costs for hospitals have been increasing rapidly, as many professional and unprofessional employees unionize to bargain for higher wages (Aaron, 1991:8-37).

Besides, physician costs also have been rising, not as rapidly as hospital costs. In addition to general pressures of inflation in the economy as a whole, increases in equipment and supply costs, increased insurance paperwork, the increasing cost of medical malpractice insurance and the practice of “defensive medicine” to protect against malpractice suits by ordering every possible diagnostic procedure have all produced increases in doctors’ fees (Aaron, 1991: 45-47)

Finally, the method of payment increases the cost of medical care. Over 76 percent of the hospital costs and approximately 60 percent of all medical expenses in USA are paid by third party payers (Health Insurance Association, 1993)

4. **Quality Barrier:** In USA for example, both citizens and government must be concerned with the quality of medical care being provided. Citizens’ obvious expressions of concern about quality have been the increased number of malpractices suits and complaints against physicians and hospitals. State Medical Associations and their Review Boards and other professional organizations who are supposed to discipline their fellow professionals and friends, find it difficult to do so. Government concern about quality extends from the general social responsibility for regulating the safety and effectiveness of medicines and medical devices on the market to the quality of care provided to Medicare and Medicaid patients to perhaps a more philosophical concern with the efficacy of modern medical care as a remedy for the health problems of American citizens. Medical care is still a difficult product for which to judge quality. Little information on quality of medical care is available to the consumer about the quality of services consumer about the quality of services provided by individual physicians or hospitals. The public sector has been intervening to try to make more information available, but it is still difficult for the average consumer to make choices.
5. **Unequal Access Barrier:** Medical care is mal-distributed, that is, the areas and persons with the greatest needs for healthcare are not the areas and persons with the greatest access to care. For example, in USA, Hospitals, nursing homes, clinics, doctors, dentists and other healthcare professionals are disproportionately located in well-to-do urban and sub-urban areas, as the highest fees can be generated there. The residents of these areas have better access to care than do the poor and residents of rural areas. This phenomenon is particularly true for access to specialized institutions and personnel, but it is also true to a lesser extent, for general practitioners and basic care institution. Medical care is distributed on the basis of ability to pay rather than on need. The limited access pattern contributes to the poor health and shorter life expectancy of those who are poor or live in rural communities. Black infant and maternal mortality rates are nearly twice those of whites and comparable to many countries in the Third world. The average life expectancy for blacks is six years lower than that for whites (Cochran et al, 1986).

Unequal access is significant barrier to healthcare. Gaining equality in medical care is often difficult to the poor. Geography distantly plays a significant dual role in defining access to medical care. Urban areas are generally better served with doctors and hospitals that rural areas are. Aside from this, medical services would be even more pronounced if the areas of specialization of physicians and the standards and equipment of the hospital are considered. In some parts of USA, for example, high quality medical care may not be available even for someone who can afford it, without a substantial investment in travel. Thus, the relatively high rate of infant mortality in most low-and-middle-income countries is often taken as an indicator of poor access to medical care.

6. **Overspecialization of Healthcare:** Over specialization contributes to high cost of medical care as specialists charge more and use hospitals more than do general practitioners. For example, in USA as well as other developing countries, primary healthcare physicians, - family doctors and general practitioners constitute a small proportion of American physicians. Cardiologists Pediatricians, Urologists and other specialists are the dominant figures in the medical profession. Serious consequence from the predominance of specialists may help to account for the rather poor performance on measures of infant mortality and life expectancy relative to those of other developed nations, as these measures are more sensitive to high quality routine care than to sophisticated, exceptional procedures.
7. **Financial Inequities:** Another problem to healthcare is the financial burden imposed on many individuals and families by its high cost. The gaps in public and private health insurance are wide enough to let millions fall into financial disaster. In America, five to eight percent of the population has no health insurance, public or private. Fifty to sixty million persons have no major medical coverage. The result is that nearly ten percent of all families every year have out-of-pocket medical-gross income. Most of these families are poor, so that even \$1,000 out-of-pocket is a catastrophic expense. Almost half of all personal bankruptcies each year involve medical debts.

Moreover, unintended consequences are major concern, as health education policy contributes to the over-specialization of physicians and recent changes in that policy have not yet shown an effect. Public policy, again particularly Medicare and Medicaid, in American health system contributes substantially to the cost of escalation in healthcare. As health care policy reduces the financial burden on specific individual, it increases on specific individuals, and increases on the society as a whole.

Thus, the most important problem in healthcare, shared by many nations is its soaring cost to society. The chief causes of cost escalation in the United States, for example, are growing numbers of elderly, overspecialization, mal-distribution, third-party payments, modern medical technology, federal tax policy and the public's exaggerated expectations of medical science.

There are substantial problems with America healthcare policy. Many differences in quality and access to care still remain among various groups. Medicare and Medicaid have contributed to health care is inflated costs and have not challenged structural problems in its delivery. And neither regulatory policies nor Professional Standards Review Organizations (PSROs); Health Safety Agencies (HSAs); Health Maintenance Organizations (HMOs) have had the success hoped for in introducing rational co-ordination and cost control into the system.

CONCLUSION

Within the fundamental obligations of governments at federal, state and local authorities. The National Healthcare system should be developed to support in a coordinated manner a three-tier system of healthcare. Essential features of the system should be its comprehensive nature, multi-sectoral inputs, community involvement and collaboration with non-governmental providers of healthcare. The goal of health policy should be based on primary healthcare that is promotion-based, protective, preventive, restorative and rehabilitative to every citizen of the country within the available resources, so that individuals and communities are assured of productivity, social wellbeing and improvement of living standard.

Chapter 8

Antimicrobial Consumption and Multidrug Resistant Organisms in Intensive Care Units: Lessons from Saudi Arabia

Fouad Farouk Jabri
Alfaisal University, Saudi Arabia

ABSTRACT

Improper antimicrobial use and bacterial resistance can affect an entire community, threaten public health and create economic burdens and ecological consequences on societies. This chapter discusses the importance of counteracting this public health issue. In Saudi Arabia, the appropriate use of antimicrobial agents is of particular concern. The prescribing of broad-spectrum antimicrobials in hospital settings is not highly restricted, and antimicrobials are available over the counters in pharmacies. This unwise use provides a scenario for the emergence of bacterial resistance and subsequent public health concerns. In addition, there is a lack of representative epidemiological research on antimicrobial consumption and quantitative data linking consumption to the incidence of resistance. This chapter illustrates that the implementation and the success of the strategies that monitor and control antimicrobial consumption depend on the availability of information about the extent and patterns of antimicrobial consumption. It demonstrates the potentials and recommendations on obtaining antimicrobial consumption data using defined daily dose as a unit of measurement in Saudi hospital settings.

INTRODUCTION

Bacterial resistance has been a universal public-health concern for decades (Metz-Gercek et al., 2009; Monnet, Molstad, & Cars, 2004). Based on the increasing incidence of bacterial resistance, the insufficient availability of novel and effective antimicrobial agents, and the development of resistance against new agents, physicians will be unable to treat all infections (Bassetti et al., 2000; Gandhi, DePestel, Collins, Nagel, & Washer, 2010; Metz-Gercek et al., 2009; D Plonczynski & K Plonczynski, 2005; What are

DOI: 10.4018/978-1-5225-1674-3.ch008

the consequences of resistance?, 2010). Infections caused by antimicrobial-resistant microorganisms increase morbidity and mortality, length of hospitalization, and cost of health care (Jacoby et al., 2010). Under the title “Combat Drug Resistance,” the World Health Organization (WHO) selected bacterial resistance and its global spread as the theme for World Health Day 2011 (WHO-World Health Day, 2011; World-health-day2011 –brochure, 2011). This public health issue was chosen to stress its significance for good health and wellbeing (WHO-World Health Day, 2011; World-health-day2011 –brochure, 2011). The WHO and the European Commission recommend more research on understanding the development and drivers of bacterial resistance, and note the importance for rational approach to constrain it (Bronzwaer et al., 2002). On World Health Day 2011, the WHO issued a call for action: “WHO will call on everyone: policy-makers and planners, the public and patients, practitioners and prescribers, pharmacists and dispensers, the pharmaceutical industry, to think, act and take responsibility for combating drug resistance (World-health-day2011 –brochure, 2011)” and stated that “No action today, no cure tomorrow (World-health-day2011 –brochure, 2011).”

Antimicrobial agents are increasingly used to treat patients (Iosifidis et al., 2008). Today, antimicrobial agents are the most frequently prescribed therapies in hospitals (Rogues et al., 2004). Some studies claim that one-third to one-half of hospitalized patients receive antimicrobial therapy (Erbay, Bodur, Akinci, & Colpan, 2005; Vlahovic-Palcevski, Morovic, Palcevski, & Betica-Radic, 2001). The use of these agents is often inappropriate and because of their liberal prescribing and misuse, they increase the risk of adverse reactions, the need for additional medical attention, and place an unnecessary burden on the hospital pharmacy and other departmental budgets, and also are associated with the increased risk of the emergence of bacterial resistance (Arda et al., 2007). In intensive care units (ICUs), most of the patients are critically ill and are at higher risk than those in general hospital wards of developing and spreading infections, especially healthcare associated infections and infections by multidrug-resistant organisms. Thus antimicrobial agents are prescribed ten times more often in such units, are used by 60- 70% of ICU patients and account for a major part of the ICU drug expenditure (de With et al., 2006; Erbay et al., 2005; Jacoby et al., 2010). Vlahovic-Palcevski et al. (2001) reported that Simmons and Stolley came up with the following two questions: (A) have we reached the point where the enormous use of antibiotics is producing as much harm as good, and (B) are the risks beginning to outweigh the benefits?

The link between antimicrobial use and bacterial resistance has been reported in many reports from single hospitals and from multicenter studies (Fridkin & Gaynes, 1999). According to Alfandari, Bonenfant, Depretere, and Beaucaire (2007) and Cristino (1999), a steep rise in bacterial resistance is linked to the therapeutic (empirical and definitive) and prophylactic use of antimicrobial agents in the individual patient, the hospital, and the community. However, the excessive prescription of such medications to hospitalized patients is associated with a higher prevalence of antimicrobial-resistant bacteria in hospital wards than in the community (Benko et al., 2009). D Plonczynski and K Plonczynski (2005) reported that if the patterns of overconsumption are not stopped, newer therapies may fail due to the development of bacterial resistance. Therefore, the use of available antimicrobial agents should be carefully targeted and well regulated to moderate the initial emergence of bacterial resistance and slow the transmission of resistant microorganisms (Bassetti et al., 2000; Metz-Gercek et al., 2009). In addition, effective primary prevention strategies, combating the threat of bacterial resistance and improving antimicrobial prescription practice require auditing the management of antimicrobial prescription, surveying of both antimicrobial consumption and bacterial resistance, providing education on their relationship, monitoring the impact of infection control measures, ensuring greater involvement from the pharmacist and

continually educating healthcare professionals (Meyer, Schwab, Gastmeier, Rueden, & Daschner, 2006; D Plonczynski & K Plonczynski, 2005; Wise 2006; Yamashita, Louie, Simor, & Rachlis, 2000). Thus, a multidisciplinary approach involving hospital leadership is needed to counteract this problem and improve antimicrobial prescription practices (Fridkin & Gaynes, 1999). Strategies to stop the development of bacterial resistance should be implemented early because once resistance happens, it is irreversible or slow to reverse; therefore, the faster we act, the slower the rise in bacterial resistance rates (Barbosa & Levy, 2000; Livesey & Chiew, 2006; Meyer et al., 2006; Willemsen, Bogaers-Hofman, Winters, & Kluytmans, 2009; WHO, World Health Organization, 2001).

Information about the use of antimicrobial agents allows clinicians and healthcare administrations to understand local and national trends and enables them to develop and update prescription policies that aim at effective use of antimicrobial therapy. To obtain reliable data on drug consumption, the WHO endorsed the Anatomical Therapeutic Chemical classification (ATC) and the Defined Daily Dose (DDD) system (ATC/DDD) (WHOC – History, 2009). The ATC system classifies the drugs according to the organ or organ system they act on and according to the pharmacological and therapeutic properties of the drugs (dos Santos & Lauria-Pires, 2010). The DDD is a unit of measurement that expresses drug use (WHOC – Home, 2011). The ATC/DDD methodology allows comparisons to be made from data about drug use statistics at local, national, or international levels and has become the gold standard for drug utilization research (Vlahovic-Palcevski, Gantumur, Radosevic, Palcevski, & Vander Stichele, 2010; WHOC – Home, 2011). Refer to the “Anatomical Therapeutic Chemical Classification System and Defined Daily Dose” section for more details.

BACKGROUND

Bacteria are prokaryotes (i.e., they lack a membrane-bound nucleus or any other membrane-bound organelles) in the Bacteria domain and the Eubacteria Kingdom (Shargel, Mutnick, Souney, & Swanson, 2007). Bacteria can be classified according to genotype and/or phenotype. The genotype classification classifies bacteria based on a specific region of DNA (16S ribosomal RNA) (Mandell, Bennett, & Dolin, 2005). The phenotype classification classifies bacteria according to (a) morphology, (b) staining properties, (c) bacterial cell shape and arrangement, and (d) other classification parameters (Shargel et al., 2007). Under the morphology (i.e., by size, shape and structure) classification, bacteria can be classified according to either the culture morphology and/or microscopic morphology. Staining properties classify bacteria by Gram staining (e.g., Gram-positive and Gram-negative), acid-fast staining. The bacterial cell shape and arrangement facilitate the classification of bacteria into cocci (spherical), bacilli (cylindrical). Scientists can also classify bacteria according to other parameters, such as motility, flagella type, and presence or absence of spores or capsules.

MECHANISMS OF BACTERIAL RESISTANCE AND GENE DISSEMINATION

Mechanisms of bacterial resistance were not understood in the 1940s and early 1950s (Evans & Brachman, 1998). Presently we have more insight into the bacterial mechanisms that spread resistance genes (Barbosa & Levy, 2000).

Intrinsic Resistance

Bacteria are intrinsically resistant to antimicrobial agents by a number of different mechanisms, including the lack of the target site for an agent, possession of a chromosomally encoded resistance mechanism that inactivates the agent (e.g., resistance to penicillin arises because of a chromosomal β -lactamase agent in *K. pneumonia* strains), or permeability issues that prevent the agent from reaching its target site (e.g., resistance to some β -lactam antimicrobial agents arises because they cannot cross the cell membrane and reach their site of action in Gram-negative pathogens, especially *Pseudomonas* spp) (Evans & Brachman, 1998; Gillespie & Bamford, 2003).

Acquired Resistance

Previously, susceptible bacteria developed resistance to antimicrobial agents through two major mechanisms: (a) random chromosomal mutations or (b) acquiring a new genetic component that encoded for a resistant protein (Evans & Brachman, 1998; Reid, Rubin, & Whiting, 2001). An example of random chromosomal mutation is gene remodeling that alters bacterial components and thus prevents the binding of antimicrobial agents to their target sites of action (Reid et al., 2001). Acquiring a new genetic component (i.e., new DNA) causes antimicrobial agents to lose their effectiveness through five major pathways: (1) chemically modifying the antimicrobial agent that leads to its inactivation (for example, the production of the enzyme β -lactamase destroys the main β -lactam ring structure of some antimicrobial agents), (2) decreasing or preventing the penetration of the antimicrobial agent into the bacterium cell by changing the permeability of the bacterial cell envelope; (3) preventing antimicrobial agent from binding to its site of action by modifying the structure of the target site in the bacterium cell; (4) developing an alternative metabolic pathway other than that inhibited by the antimicrobial agent; and (5) developing efflux mechanisms that pump the antimicrobial agents out of the cell, thus preventing them from reaching their target sites of action (Barbosa & Levy, 2000; D Plonczynski & K Plonczynski, 2005).

MECHANISMS OF GENE DISSEMINATION

After randomly developing resistance and surviving, bacteria replicate through cell division, the most common mechanisms for bacterial replication, which occurs several times a day. Thus, the previously mentioned mutations can be rapidly transmitted to subsequent generations of bacteria, and mutant microorganisms quickly dominate the population (D Plonczynski & K Plonczynski, 2005). According to Evans and Brachman (1998), transmission of resistance determinants between bacteria can be achieved through chromosomal mutations, plasmids, transposons and integrons.

Accumulation of Chromosomal Mutations

Transformation occurs when a bacterium takes up pieces of DNA and incorporates them into its genome. Propagation of the altered gene may lead to the emergence of resistance in the bacteria (Barbosa & Levy, 2000; Gillespie & Bamford, 2003).

Acquisition of Plasmids, Transposons, and Integrations

Conjugation occurs when antimicrobial-resistance genes carried on plasmids (circular extrachromosomal pieces of DNA) are transferred from one microorganism to another (Gillespie & Bamford, 2003). One example is the transfer of the plasmid-mediated multidrug-resistance phenotype from *Shigella* species to *E. coli* (Evans & Brachman, 1998). Transposons and integrations are transposable genetic materials that can carry resistance genes and have the ability to move between the chromosome and plasmids and from one bacterium to another via cell-to-cell (conjugal) contact (Gillespie & Bamford, 2003). Dissemination of resistance determinants via transposons and integrations is faster than via plasmids (Evans & Brachman, 1998).

Microbial Resistance: A Worldwide Public Health Problem

Resistance to antimicrobial therapies is a natural biological phenomenon (WHO-World Health Organization, 2001) and it may develop against any antimicrobial agent (Kolar, Urbanek, & Latal, 2001). However, due to its increasingly high prevalence and rapid spread of multidrug resistant strains in addition to the shortage of new antimicrobial agents, resistance has become a major worldwide public health concern that necessitates international approaches (Bronzwaer et al., 2002; Dimina et al., 2009; Hsu et al., 2010; Meyer et al., 2006; Naaber, Koljalg, & Maimets, 2000; Pelle, Gilchrist, Lawson, Jacklin, Franklin, 2006; WHO, World Health Organization, 2001). Resistance to antimicrobial therapy has developed not only among pathogenic microorganisms but also in many commensal microorganisms (i.e., microorganisms that are normally are harmless) (Willemsen et al., 2009). Bacteria can evolve and optimize their genetic arsenal to develop resistance against antimicrobial agents and thus survive and multiply in the presence of the antimicrobial agents at concentrations much higher than the therapeutic concentrations used clinically (Barbosa & Levy, 2000; D Plonczynski & K Plonczynski, 2005; Reid et al., 2001; Shargel et al., 2007; WHO, World Health Organization, 2001).

Bacterial resistance has been recognized decades ago (Vlahovic-Palcevski et al., 2001), and it has become a worldwide problem (Camberlin & Ramaekers, 2009; Naaber et al., 2000) that has challenged the management of infections in hospitals (Yamashita et al., 2000). Currently, outbreaks of resistant microorganisms are common in hospitals (Yamashita et al., 2000) and some of these microorganisms resist nearly all available antimicrobial agents (Leibovici et al., 2001; Vlahovic-Palcevski et al., 2001) making treatment of infections due to resistant bacteria a difficult task in the majority of hospitals worldwide (Lopez-Lozano et al., 2000). In the U.S., 70% of the bacteria in the hospitals resist at least one antimicrobial agent (Furtado, Perdiz, & Medeiros, 2008). Controlling the increasing prevalence of antimicrobial-resistant pathogens is a major issue in health care settings (White, Friedrich, Mihm, & Bosso, 2000) and the emergence of these microorganisms poses a significant challenge for clinicians, infection-control personnel, and hospital administrators (Fridkin et al., 1999). The rise of bacterial resistance against antimicrobial agents in current use is a real threat to human health, and according to the WHO (WHO-World Health Organization, 2001; Willemsen et al., 2009), it impacts on health care expenditure worldwide.

Antimicrobial resistance and multidrug-resistant bacteria are major determinant factors for morbidity, mortality and additional costs in hospitals and are associated with hospital-acquired infections, prolonged hospital stays, increased antimicrobial consumption, treatment failure, human suffering and lost productivity (Bosso, Mauldin, & Salgado, 2010; Camberlin & Ramaekers, 2009; Hsueh, Chen, &

Luh, 2005; D Plonczynski & K Plonczynski, 2005; Iosifidis et al., 2008; Jacoby et al., 2010; Kuster et al., 2008; Velickovic-Radovanovic, Petrovic, Kocic, Antic, & Randelovic, 2009; Vlahovic-Palcevski et al., 2001; Yamashita et al., 2000; WHO, World Health Organization, 2001). For example, treating vancomycin resistant *Enterococcus faecium* bloodstream infections costs \$27,190 more than treating vancomycin-susceptible *Enterococcus faecium* infections ($p = .04$), and this shows the impact of resistance on health care expenditures (Stosor, Peterson, Postelnick, & Noskin, 1998). In addition, the direct and indirect annual U.S. expense for health care due to infections with resistant microorganisms is approximately \$5 billion (Bosso & Mauldin, 2006). Without a doubt, the emergence of bacterial resistance to antimicrobial agents will limit our ability to treat human illness and may affect our capability to overcome large outbreaks of infectious diseases (Evans & Brachman, 1998). According to Furtado et al. (2008), preventing bacterial resistance and the dissemination of multidrug-resistant organisms, reduce the morbidity, mortality, and costs of health care.

Treating infections especially in ICUs is becoming more difficult (Bennett & Brachman, 1998). The highest rates of bacterial resistance are found in ICUs (Gandhi et al., 2010). Phase I data from the ICARE project (Intensive Care Antimicrobial Resistance Epidemiology) and many other studies showed higher rates of bacterial resistance in ICUs than in other hospital settings (Fridkin et al., 1999; White et al., 2000). The mortality rate in patients admitted to ICUs can be more than 25% and it can exceed 40% in patients with complications (more than one-third of patients admitted to ICUs are complicated cases) (Bennett & Brachman, 1998). In ICUs, bacterial resistance increases the risk of mortality (Gandhi et al., 2010). In fact more than 20% of nosocomial infections are acquired in ICUs, even though these units are small (less than 5% of hospital beds) and care for fewer patients (less than 10% of inpatients) (Bennett & Brachman, 1998). In the ICUs, the financial burden of healthcare associated infections is high (Gandhi et al., 2010). Patients in ICUs are more prone to nosocomial infections and colonization by resistant pathogens, and they may initiate outbreaks of resistant organisms in hospitals due to the severity of their illnesses, prolonged hospitalization, and higher nursing index, the recurrent use of invasive devices and the massive consumption of broad spectrum anti-infective agents (Bennett & Brachman, 1998; Fridkin & Gaynes, 1999; Meyer et al., 2004a; Meyer et al., 2004b; Yamashita et al., 2000). Many of these infections are associated with multidrug-resistant organisms (Jacoby et al., 2010). Therefore, the likelihood of the emergence and spread of multidrug-resistant organisms in ICUs is very high (Meyer et al., 2004a). The expenditure on medications in ICUs comprises 40% of the total hospital drug cost (Gandhi et al., 2010), and the highest consumption of antimicrobial agents are in this type of hospital settings (Gandhi et al., 2010). Patients in these units receive antimicrobial agents more frequently and in greater quantities than any other patients in the hospital (Bennett & Brachman, 1998). These units are often the target of surveillance programs and restrictions in the use of antimicrobial agents (Yamashita et al., 2000).

Antimicrobial Agents

Before 1928, infectious diseases were the major cause of mortality (D Plonczynski & K Plonczynski, 2005). The introduction and use of penicillin caused a decline in the rate of deaths from infectious diseases (D Plonczynski & K Plonczynski, 2005). The discovery and consumption of antimicrobial agents were a revolution in the medical sciences. They have been used for decades to successfully prevent some infectious diseases, suppress the transmission of others, and cure a variety of diseases, including diseases with high mortality rates, such as puerperal fever, pneumococcal pneumonia and bacterial meningitis (dos Santos et al., 2007; Vlahovic-Palcevski et al., 2001). Antimicrobial agents were previously known

as “miracle drugs (Dong, Yan, & Wang, 2008).” Their aim was to control infections without harming the patient (Reid et al, 2001). These treatments alter bacterial processes that are not present in human cells (selective toxicity), thereby hindering the metabolic processes of the bacteria but not of the individual hosting that microorganism (Gillespie & Bamford, 2003). Antimicrobial agents are either bactericidal or bacteriostatic (Shargel et al., 2007). Shargel et al. (2007) define bactericidal agents as those agents that kill the pathogens, whereas bacteriostatic agents that merely inhibit their growth or reproduction cycle. Whether the antimicrobial agent will combat the causative pathogen effectively is determined through performing susceptibility tests (Shargel et al., 2007). The minimum inhibitory concentration for an antimicrobial agent is the lowest concentration that prevents microbial growth after 18-24 hours of incubation (Shargel et al., 2007). The minimum bactericidal concentration for an antimicrobial agent is the lowest concentration that decreases bacterial density by 99.9% (Shargel et al., 2007). There are more than 200 antimicrobial agents that are available for clinical use (Bassetti et al., 2000). The major classes of antimicrobial agents include: aminoglycosides, carbapenems, cephalosporins, fluoroquinolones, macrolides, metronidazole, penicillins, sulfonamides, and tetracyclines.

Following the clinical introduction of antimicrobial agents in the 1940s to treat infectious diseases, antimicrobial agents have been increasingly consumed and misused not only in humans but also in veterinary medicine, plant agriculture and aquaculture (Barbosa & Levy, 2000; Kuster et al., 2008). In the U.S., the total consumption of antimicrobial agents is around 23×10^6 kg per year (Levy, 2002). This amount is equally divided into two parts. As 11.5×10^6 kg is consumed by humans, and the remaining part is utilized in agriculture and as growth promoters (Levy, 2002). The amount provided to human is generally administered parenterally in hospitals and orally in the community (Levy, 2002). In hospital settings and among inpatients, antimicrobial agents are the most prescribed therapies (15 – 30% of all consumed medications) (Velickovic-Radovanovic et al., 2009). Available data indicate that antimicrobial agents are prescribed to more than one-half of hospitalized patients (Vlahovic-Palcevski et al., 2001). Up to 40% of inpatients are treated with systemic antimicrobial agents and the use of antimicrobial agents in hospitals is increasing (Bennett & Brachman, 1998). Unfortunately, and according to Raveh et al. (2006), 15-40% of antimicrobial use is improper. And Erbay et al. (2005) found that antimicrobial consumption was inappropriate for 47.3% of antimicrobial agents used in a tertiary care hospital in Turkey. In addition, Velickovic-Radovanovic et al. (2009) reported that up to 50% of antimicrobial agents used by hospitalized patients are prescribed inappropriately.

Antimicrobial agents have been used for more than 50 years (Bennett & Brachman, 1998). Over that time, there has been continuous development and introduction of new antimicrobial agents. Unfortunately, each introduction is eventually followed by the emergence of bacterial resistance, thus changing past physicians’ beliefs regarding these ‘wonder drugs’ and their ability to end the problem of infectious diseases (Barbosa & Levy, 2000; Bennett & Brachman, 1998; Evans & Brachman, 1998; Vlahovic-Palcevski et al., 2001; WHO, World Health Organization, 2001). With environmental exposure to antimicrobial agents, bacteria may be destroyed or mutated (i.e., produce inheritable changes in a genomic sequence) and evolve to pathogens that are resistant and more virulent (D Plonczynski & K Plonczynski, 2005). Consumption of antimicrobial agents is increasing over time, and their widespread overuse increases hospital costs and results in the emergence of bacterial resistance, which is increasing at an alarming rate and this may limit our future ability to control infections and could return us to a life without effective antimicrobial agents (D Plonczynski & K Plonczynski, 2005; Iosifidis et al., 2008). Currently, among the available antimicrobial agents for clinical use, there are no agents for which resistance has not been reported (Evans & Brachman, 1998). Both improper antimicrobial consumption and bacterial resistance

threaten public health and create economic burdens and ecological consequences on the society (Meyer et al., 2004b; Willemsen et al., 2009). According to the WHO (WHO-World Health Organization, 2001), the appropriate use of antimicrobial agents is defined as “*the cost-effective use of antimicrobials which maximizes clinical therapeutic effect while minimizing both drug-related toxicity and the development of antimicrobial resistance.*” With the current rise in resistance rates and the dwindling development of new antimicrobial agents, there is likely to be a lack of effective therapies against some pathogens within the next years; in fact, we may be moving toward the post-antimicrobial era (Naaber et al., 2000; Vlahovic-Palcevski et al., 2001; WHO, World Health Organization, 2001).

THE RELATIONSHIP BETWEEN ANTIMICROBIAL CONSUMPTION AND RESISTANCE TO ANTIMICROBIAL THERAPY

There are several interacting factors that determine the dynamic development of bacterial resistance to antimicrobial therapy, such as frequent administration of broad-spectrum antimicrobial agents, prolonged exposure to antimicrobial agents and treatment failure (wrong agent, dose, etc.), utilization of invasive devices and procedures, poor quality of available antimicrobial agents, patient compliance and other patient factors that are difficult to measure (e.g., site of infection and host status) (D Plonczynski & K Plonczynski, 2005; Frank et al., 2006; Livesey & Chiew, 2006; Mutnick, Rhomberg, Sader, & Jones, 2004; Velickovic-Radovanovic et al., 2009; Vlahovic-Palcevski et al., 2001; White et al., 2000). Table 1 summarizes some of these factors according to Wenzel (2003). The interactions between these interrelated variables have not yet been fully explored (Wenzel, 2003; WHO, World Health Organization, 2001) and ranking these variables according to their importance in influencing the prevalence of resistance is

Table 1. Some of the interactive factors that determine the dynamic development of bacterial resistance to the antimicrobial therapy

Factors Related to the Antimicrobial Agents	Dose
	Number of agents
	Length of therapy
	Antimicrobial spectrum
	Pharmacokinetics
Factors Related to the Patients	Foreign bodies
	Immunity status
	Vaccination history
	Normal flora
Factors Related to the Environments	Total antimicrobial use/threshold
	Infection control measures
	Cross transmission
Factors Related to the Organism	Mechanisms of resistance
	Ease of gene transfer

(Wenzel, 2003)

unclear and difficult and varies among different pathogens (Wenzel, 2003). However, most researchers of antimicrobial resistance regard the inappropriate and widespread consumption of antimicrobial agents as the main driver for bacterial resistance (Fridkin & Gaynes, 1999; Livesey & Chiew, 2006; Meyer et al., 2006; Naaber et al., 2000; Wenzel, 2003; White et al., 2000; WHO, World Health Organization, 2001). There is a considerable body of evidence that supports the causal relationship between the clinical consumption of antimicrobial agents and the increasing rates of bacterial resistance (Jacoby et al., 2010; Livesey & Chiew, 2006; Velickovic-Radovanovic et al., 2009; Wenzel, 2003).

Several researchers using different methodologies have evaluated the link between the consumption of antimicrobial agents and the emerging of resistance in microorganisms (Mutnick et al., 2004). There have been longitudinal studies, case-control studies, and ecologic studies at the cross-national or national levels that used community data, hospital data, or both (Iosifidis et al., 2008). The overall consumption of antimicrobial agents in the hospital and community settings significantly contribute to the escalating rates of bacterial resistance (Dimina et al., 2009; Hsu et al., 2010; Leibovici et al., 2001; Pelle et al., 2006; Polk, Fox, Mahoney, Letcavage, & MacDougall, 2007). Reports from around the globe show that excessive consumption of antimicrobial agents correspond with high rates of bacterial resistance, which is obvious in Spain, France, the United States, and Greece; on the other hand, low consumption in Nordic countries (the Netherlands, Norway, Denmark, and Sweden) corresponds with low rates of resistance (D Plonczynski & K Plonczynski, 2005; Naaber et al., 2000). According to Raveh et al. (2006), bacterial resistance is a function of the volume of antimicrobial consumption: i.e., as more antimicrobial agents are consumed, the rate of emergence of resistant pathogens becomes greater. Levy (2002) and Patterson (2001) reported that both the quantity and pattern of consumption of antimicrobial agents are clearly related to the emergence of multidrug-resistant organisms.

The Need for Surveillance of Antimicrobial Consumption

Many international institutions, governments, clinicians, policy-makers and civil societies are searching for initiatives to fight the emergence and dissemination of bacterial resistance (dos Santos & Lauria-Pires, 2010; Loeffler, Garbino, Lew, Harbarth, & Rohner, 2003). Although the relationship between antimicrobial consumption volumes and the development of bacterial resistance is complex, we can stabilize and contain bacterial resistance in local areas (Burke & Pestotnik, 1999). According to Meyer et al. (2006), until we are fully aware of the interactions between factors that determine the development of bacterial resistance, wise consumption of antimicrobial agents should be seen as the single most important measure to control bacterial resistance. Therefore, to simplify the resistance phenomenon, we need to focus on the consumption of antimicrobial agents and the spread of resistance gene because if neither were present, the problem of bacterial resistance would not exist (Levy, 2002). To tackle the problem of increasing prevalence of bacterial resistance, both the WHO and the European Commission promote the reasonable and intelligent use of antimicrobial agents (Meyer et al., 2006; Meyer et al., 2004b). In France, national recommendations suggest limiting “overuse” and “misuse” of antimicrobial agents to control the emergence of bacterial resistance (Mandy, Koutny, Cornette, Woronoff-Lemsi, & Talon, 2004). There are many methods to optimize antimicrobial consumption (Cristino, 1999; Furtado et al., 2008; Vlahovic-Palcevski et al., 2001). Some of these methods include education programs for health care providers, introduction of order form and automatic stop orders, formulary restriction, antimicrobial use evaluations, use of antimicrobial agent assessment team, pharmacist intervention, or using national or international guidelines for antimicrobial drug use (Furtado et al., 2008; Vlahovic-Palcevski et al.,

2001). Whatever the best method, its implementation and assessment of its success, and determining the magnitude of the resistance problem, largely hinge on drug utilization research and understanding patterns of antimicrobial consumption, particularly in ICUs (dos Santos et al., 2007; Fridkin & Gaynes, 1999). Without information about the extent and pattern of antimicrobial consumption, it is difficult to build strategies, detect problems, set priorities, control use, and evaluate the effectiveness of policies (Janknegt, Oude Lashof, Gould, & van der Meer, 2000; Popova, Popova, & Guencheva, 1997).

Having antimicrobial consumption data and monitoring bacterial resistance is essential in learning more about resistance trends and the relationship between antimicrobial consumption and development of resistance. Such information allows for the establishment of parameters for evaluating actions that improve antimicrobial consumption and prevent the emergence and dissemination of resistance (dos Santos & Lauria-Pires, 2010; Metz-Gercek et al., 2009; Yamashita et al., 2000). And according to Gandhi et al. (2010), assessing antimicrobial consumption in ICUs allows the measurement of the relationship between the consumption of antimicrobial agents and the emergence of bacterial resistance. Moreover, antimicrobial agents are expensive medications and the budgets of hospitals are markedly influenced by the consumption or overconsumption of such agents. Therefore, measuring antimicrobial consumption provides valuable data for the administrative departments, heads of clinical departments and other hospital staff. Surveillance of antimicrobial consumption is helpful in developing policies to control the consumption of antimicrobial agents, increasing treatment quality, decreasing the risk of bacterial resistance, and cutting unnecessary treatment and hospital expenditures (Dimina et al., 2009; Ruef, 2006).

The 1998 European conference “The Microbial Threat” emphasized the importance of international comparisons of antimicrobial consumption and bacterial resistance surveillance data (Velickovic-Radovanovic et al., 2009). The Centers for Disease Control and Prevention (CDC) and the National Foundation for Infectious Disease sponsored a workshop that proposed recommendations for hospitals, encouraging them to collect data on the consumption of antimicrobial agents to reduce the emergence and spread of antimicrobial-resistant microorganisms (Fridkin & Gaynes, 1999; Fridkin et al., 1999). A decade ago, Austria began collecting data on antibiotic resistance and antimicrobial consumption after the 1999 European Antimicrobial Resistance Surveillance System (EARSS) and the 2001 European Surveillance on Antimicrobial Consumption (ESAC) (Metz-Gercek et al., 2009). Recently, the European Council Recommendation, the French government, and many other organizations have recommended that the consumption of antimicrobials be studied in hospitals (Jacoby et al., 2010; Rogues et al., 2004; Vander Stichele, Elseviers, Ferech, Blot, & Goossens, 2006). And according to many professionals and international organizations that are concerned about the increasing rate of bacterial resistance, surveillance of antimicrobial consumption at the local and national levels is essential (Polk et al., 2007; Wenzel, 2003). However, in many countries, there is shortage in the availability of data on antimicrobial consumption and bacterial resistance (Barbosa & Levy, 2000). In Saudi Arabia there is a shortage of representative epidemiological studies on antimicrobial consumption and quantitative data linking the consumption to the incidence of resistance.

THE ANATOMICAL THERAPEUTIC CHEMICAL CLASSIFICATION (ATC) SYSTEM AND DEFINED DAILY DOSE (DDD)

To assess antimicrobial consumption, the specific metric that best monitors consumption has not been identified (Gandhi et al., 2010; Polk et al., 2007). In addition to current hospital information technol-

ogy, it is not always possible to measure actual antimicrobial consumption, on individual or aggregate levels; thus it is necessary to depend on “best-guess” estimates of the consumption of antimicrobial agents (Mutnick et al., 2004). To analyze drug consumption, the Norwegian Medicinal Depot developed the ATC classification system, which is now under the responsibility of the WHO Collaborating Centre for Drug Statistics Methodology and has become the most widely used, and most useful, classification system (Hutchinson et al., 2004). The DDD methodology is the most common methodology for reporting drug consumption and it has been applied to report antimicrobial consumption by the CDC Project ICARE and the CDC National Nosocomial Infection Surveillance Project (Gandhi et al., 2010; Polk et al., 2007). The ATC system classifies drugs by dividing them into different groups according to the organ or organ system they act upon and the pharmacological and therapeutic properties of the drugs (dos Santos & Lauria-Pires, 2010). For example, Table 2 illustrates how amoxicillin is classified according to the ATC system. The South Australian in-hospital antimicrobial utilization surveillance program (2001) and the ESAC Project (2001) are examples of programs that use the ATC/DDD system (Livesey & Chiew, 2006). According to Mandy et al. (2004), the Générale de la Santé (French Public Health Office) news-letter recommends DDD as one metric that could be used for expressing antimicrobial consumption. The WHO and the Infectious Diseases Society of America recommend that hospitals use the ATC system and the DDD per 100 or 1,000 bed-days as the standard unit of measurement for monitoring antimicrobial consumption (Kuster et al., 2008; Livesey & Chiew, 2006; Polk et al., 2007). Also one of the recommendations for good antimicrobial practice in acute hospitals was to analyze and report antimicrobial consumption using the WHO DDDs as the numerator and bed days as the denominator (Nathwani, 2006).

The basic definition of DDD, extracted from the WHO Collaborating Centre for Drug Statistics Methodology, is as follows:

The DDD is the assumed average maintenance dose per day for a drug used for its main indication in adults. (WHOCC - Definition and general considerations, 2009)

The DDD is a unit of measurement that expresses drug consumption independent of the sale price and package size of the medicinal product (Natsch et al., 1998; Wenzel, 2003). Its value estimates the amount consumed independently of the dosage form and price of the drug (dos Santos & Lauria-Pires,

Table 2. ATC system classification of amoxicillin

ATC Classification	ATC Category	Description
J	General anti-infectives for systemic use	1st level (anatomical main group)
J01	Antibacterials for systemic use	2nd level (therapeutic main group)
J01C	B-lactam antibacterials, penicillins	3rd level (therapeutic/pharmacological subgroup)
J01CA	Penicillins with extended spectrum	4th level (chemical/therapeutic/pharmacological subgroup)
J01CA04	Amoxicillin	5th level (subgroup for chemical substance)

2010). However, the DDD is a technical unit of measurement, and its value may not mirror the real daily dosage most frequently consumed and should not be taken as a standard for appropriate use (Vlahovic-Palcevski et al., 2010). The WHO states, *“It should be emphasized that the defined daily dose is a unit of measurement and does not necessarily reflect the recommended or prescribed daily dose. Doses for individual patients and patient groups will often differ from the DDD and will necessarily have to be based on individual characteristics (e.g., age and weight) and pharmacokinetic considerations. (WHOCC - Definition and general considerations, 2009)”* For nearly every antimicrobial agent, the WHO has assigned DDD values that are updated and published on their official web site (<http://www.whocc.no/>) every year (Dellit, 2007; Kuster et al., 2008; Vlahovic-Palcevski et al., 2010). Calculating antimicrobial consumption according to the DDD methodology involves summing the total number of consumed (purchased, dispensed, or administered) grams of the antimicrobial agent during a specified period and dividing this total by the WHO-assigned DDD (Gandhi et al., 2010). The ATC/DDD methodology has become the gold standard for valid and reliable drug consumption research and DDD per bed-days can be used to compare data about drug consumption statistics between institutions at local, national, or international levels, independent of the formulary differences, drug potency and hospital census (dos Santos & Lauria-Pires, 2010; Vlahovic-Palcevski et al., 2010; WHOCC –Home, 2011). Polk et al. (2007) stated that *“development of DDD methodology has been a major advance in attempts to promote standardized comparisons.”*

The DDD methodology has advantages and disadvantages. According to Polk et al. (2007), the main advantage of this method is that it allows standardized comparisons of aggregate antimicrobial consumption across a wide range of institutions in different localities and countries. This metric has been used by many national and international organization to assess consumption (Polk et al., 2007). DDD also helps to estimate antimicrobial consumption when automation of administration records and access to electronic pharmacy data is limited (Polk et al., 2007). In addition, the DDD methodology has been used to link antimicrobial exposure to bacterial resistance (Polk et al., 2007). However, dos Santos and Lauria-Pires (2010) mentioned that the DDD methodology does not apply to pediatric patients and does not consider prophylactic consumption use. In agreement with Polk et al. (2007) they also discuss that this method is not accurate in translating consumption in patients with renal failure because if the administered daily dosage is reduced due to renal impairment, the DDD methodology will underestimate antimicrobial exposure. In addition, Polk et al. (2007) said that changing the recommended daily dose without revising the approved DDD will lead to a different estimate of antimicrobial consumption. When comparing use over time, confusion may occur because approval of new dosages of existing drugs may lead to different WHO-established DDD values for the same drug (Polk et al., 2007). Furthermore, using DDDs as a measure of antimicrobial consumption could result in an overestimation of consumption (Kern et al., 2005; Ruef, 2006).

Reported Correlations between Antimicrobial Consumption and Bacterial Resistance

Both the volume of antimicrobial agents and the way in which they are consumed in hospitals and community have been associated with the increasing prevalence of bacterial resistance (Barbosa & Levy, 2000; Gentry, Flournoy, & Reinert, 2002; Iosifidis et al., 2008; Kuster et al., 2008; Meyer et al., 2004b; Willemsen et al., 2009). Although there is substantial evidence supporting the hypothesis that total antimicrobial consumption is the main driver in selecting bacterial resistance, the relationship

between antimicrobial consumption and bacterial resistance is not a simple correlation (WHO-World Health Organization, 2001). Research examining the relationship between antimicrobial consumption and bacterial resistance showed varying results, including both positive and negative correlations. Some studies reported significant correlations, while others found no correlation. For example, the National Nosocomial Resistance Surveillance (NNRS) Group, one of the earliest surveillance networks of antimicrobial consumption among multiple hospitals, used antimicrobial purchase information as a measure of antimicrobial consumption and simple linear regression to examine the relationship between antimicrobial consumption and resistance (Wenzel, 2003). In 1992, the NNRS group made one of the first observations to support the quantitative association between antimicrobial consumption (ceftazidime purchase in 18 hospitals) and resistance (against *Enterobacter cloacae*) from a hospital network (Wenzel, 2003). Seven years later, the group found a significant association between the purchase of levofloxacin and resistance levels for *P. aeruginosa* (Wenzel, 2003).

In February 2000, the German Surveillance of Antimicrobial Use and Antimicrobial Resistance in Intensive Care Units (SARI) was developed to investigate antimicrobial consumption and its link to bacterial resistance. It was supported by the Ministry of Science and Education in Germany as part of the Spread of Nosocomial Infections and Resistant Pathogens (SIR) research network (Meyer et al., 2006; Meyer et al., 2004b). By December 2004, Project SARI included data on antimicrobial consumption and resistance in 40 ICUs from different German hospitals (Meyer et al., 2006). From February 2000 through June 2003, data from 38 ICUs (medical, surgical, and interdisciplinary ICUs) showed a significant correlation between consumption of ciprofloxacin and methicillin-resistant *Staphylococcus aureus* (MRSA) and between imipenem consumption and imipenem-resistant *P. aeruginosa* (Meyer et al., 2004a). Data from ICARE showed that higher consumption of third-generation cephalosporins, ureido/carboxy penicillins, and vancomycin in adult ICUs, when compared to non-ICU areas, were correlated with higher rates of the respective resistant organisms among isolates from ICU patients compared with non-ICU inpatients (Fridkin & Gaynes, 1999; Fridkin et al., 1999). The development of resistant Gram-negative bacilli in a neonatal ICU was related to the empiric consumption of an amoxicillin-cefotaxime combination (Barbosa & Levy, 2000).

The consumption of fluoroquinolones correlated with the prevalence of MRSA (Livesey & Chiew, 2006). The rate of carbapenem consumption was significantly correlated with the prevalence of imipenem resistance among *Acinetobacter baumannii* and *P. aeruginosa* isolates (Iosifidis et al., 2008). Rahal et al. (1998) reported a significant increase in imipenem-resistant *P. aeruginosa* correlated with a significant increase in imipenem consumption. Consumption of third-generation cephalosporins was correlated with the prevalence of MRSA (Livesey & Chiew, 2006). After reducing hospital consumption (parenteral and oral) of cephalosporins in a 500-bed medical center, Rahal et al. (1998) reported a significant reduction in nosocomial, plasmid-mediated, cephalosporin-resistant *Klebsiella* infection and colonization. Patterson et al. (2000) showed that low levels of ceftazidime consumption was associated with a decrease in ceftazidime-resistant *K. pneumoniae* in two university-affiliated hospitals. A significant positive correlation was reported between consumption of cefepime and resistance in *P. aeruginosa* (Frank et al., 2006). The rate of aminoglycoside consumption is significantly correlated with the prevalence of amikacin resistance *E. coli*, *P. aeruginosa*, and *K. pneumoniae* isolates (Iosifidis et al., 2008). A significant positive correlation has been reported between consumption of gentamicin and resistance in *K. pneumoniae* (Frank et al., 2006). Using the logistic regression line to examine possible correlations between hospital consumption of antimicrobial agents (expressed as DDD) and resistance, a multicenter, four-country study carried out by Frank et al. (2006) showed significant positive correla-

tions between the consumption of ampicillin and resistance in *E. coli*, consumption of piperacillin and resistance in *E. coli*, consumption of piperacillin and resistance in *K. pneumoniae*, and consumption of piperacillin-tazobactam and resistance in *K. pneumoniae*. The study included more than 6,000 patients and reported that increasing consumption of some antimicrobial agents is correlated with rising resistance rates. Some studies did not find a significant relationship between cephalosporin consumption and bacterial resistance. For example, Iosifidis et al. (2008) found a non-significant correlation between the rate of third-generation cephalosporin consumption and the prevalence of ceftazidime resistance in Gram-negative bacteria. According to Willemsen et al. (2009), there is no significant correlation between the consumption of first- and second-generation cephalosporin and cefuroxime-resistant *E. coli*. The correlation between the rate of fluoroquinolone consumption and the prevalence of ciprofloxacin resistance in Gram-negative pathogens was not statistically significant (Iosifidis et al., 2008). However, Livesey and Chiew (2006) found a significant positive correlation between the consumption of ciprofloxacin and the incidence of ciprofloxacin-resistant *P. aeruginosa* and a negative correlation between ciprofloxacin consumption and ciprofloxacin-resistant *E. coli*. On the other hand, Willemsen et al. (2009) reported a significant positive correlation between the consumption of ciprofloxacin and the incidence of ciprofloxacin-resistant *E. coli*.

Antimicrobial Consumption and Bacterial Resistance: The Saudi Perspective

In Saudi Arabia, prescribing broad-spectrum antimicrobial agents in hospital settings is not highly restricted, and antimicrobial agents are available over the counter in pharmacies, like other merchandise. This imprudent consumption provides the worst scenario for the emergence of bacterial resistance.

The incidence of bacterial resistance and the consumption of antimicrobial agents vary among hospitals and countries (Bassetti et al., 2000; Camberlin & Ramaekers, 2009; Naaber et al., 2000). Because bacterial resistance reflects local practices, it is important to have data on resistance trends and antimicrobial consumption in particular settings (Barbosa & Levy, 2000; Iosifidis et al., 2008). Information from individual hospitals about the relationship between the amount of consumption and resistance within specific wards allows for the development of targeted intervention programs (Willemsen et al., 2009). This idea is promoted by the Infectious Diseases Society of America, the special task force of the American Society for Microbiology, and a joint committee comprising members of the Society for Healthcare Epidemiology of America (White et al., 2000). Monitoring trends in antimicrobial consumption and bacterial resistance is beneficial both at the local as well as national levels (D Plonczynski & K Plonczynski, 2005) and such information allows healthcare administrations to understand national and local trends and it enables them to develop and update prescription policies to ensure effective consumption of antimicrobial agents. In Saudi Arabia, a research team at King Abdulaziz Medical City in Riyadh (KAMC-Riyadh) studied the consumption of ten clinically important antimicrobial agents as well as the incidence of infections with multidrug-resistant Gram-negative organisms (Jabri 2011). KAMC-Riyadh surveillance particularly examined the correlation between antimicrobial consumption rate and the incidence of infections with multidrug-resistant *P. aeruginosa*, and infections with multidrug-resistant *K. pneumonia* in four different adult ICUs (Jabri 2011).

Only ICUs were included in the KAMC-Riyadh surveillance study. As previously stated, the highest rates of bacterial resistance are in the ICUs and the likelihood of emergence and spread of multidrug-resistant organisms is very high in these units. In addition, containment of bacterial resistance in such settings is more important than other hospital areas (Loeffler et al., 2003). Only adult ICUs were in-

cluded in this surveillance. At that time Pediatric ICUs were not included in the surveillance because the WHO DDD methodology is less well defined in the pediatric population, and there is no standard for antimicrobial consumption in neonates (dos Santos & Lauria-Pires, 2010; Polk et al., 2007). Four different adult ICUs were selected to reflect a range of clinical activity, patient compromise and antimicrobial prescribing practices.

The multidrug-resistant organisms of concern in this surveillance are multidrug-resistant *P. aeruginosa* and multidrug-resistant *K. pneumoniae* because (1) Gram-negative pathogens are becoming more resistant to current antimicrobial therapies (Bennett & Brachman, 1998) (2) *P. aeruginosa* and *K. pneumoniae* are leading causes of healthcare associated bloodstream infections (El Amari, Chamot, Auckenthaler, Pechere, & Van Delden, 2001). The problem with *P. aeruginosa* organism is that it does not only have intrinsic resistance to many antimicrobial agents but it is also highly capable to develop new resistance mechanisms (Kato et al., 2001; Pena et al., 2009). The incidence of infections with multidrug-resistant *P. aeruginosa* in acute care settings is increasing at a worrying rate (das Neves, de Lorenzo, Almeida, & Fortaleza, 2010). *K. pneumoniae* is one of the most frequent bacterial infections in ICUs, and multidrug-resistant *K. pneumoniae* is a serious therapeutic and epidemiological problem in ICUs (Sekowska et al., 2010). Multidrug-resistant *K. pneumoniae* poses a considerable health concern and interventions to prevent its emergence are crucial (Patterson et al., 2000). These pathogens not only resist most β -lactam antimicrobial agents via the production of extended-spectrum β -lactamase (ESBL) or AmpC-type β -lactamase, but their resistance to β -lactams is also often associated with resistance to aminoglycosides, trimethoprim-sulfamethoxazole, and fluoroquinolones (Patterson et al., 2000). In addition, many reports indicated that Gram-negative organisms, especially *P. aeruginosa* and *K. pneumoniae*, contributed to the development of hospital acquired infections in KAMC-Riyadh more than reported by the National Healthcare Safety Network (NHSN) (Al-Dorzi et al., 2010; Balkhy et al., 2010; El-Saed et al., 2011). Moreover, the antibiograms in KAMC-Riyadh shows that resistant to both organisms is very high (El-Saed, 2011).

In KAMC-Riyadh surveillance, the choice of antimicrobial agents was made by their importance in the treatment of infections caused by Gram-negative organisms. In addition, only antimicrobial agents for systemic use were included to ensure that any prescribed amount from the pharmacy was almost administered in the ICUs.

Between May, 2010 and December, 2010, the results indicate that the patterns of antimicrobial consumption of the ten selected agents in the four ICUs were not uniform. Nevertheless, the most consumed antimicrobial agents in the four ICUs were similar. The data showed that the most consumed agents in the selected ICUs are broad-spectrum antimicrobial agents such as meropenem and piperacillin-tazobactam. Some significant correlations between the consumption of some antimicrobial agents and the incidence of multidrug-resistant organisms were demonstrated.

In KAMC-Riyadh, ceftazidime, ciprofloxacin, imipenem, meropenem and piperacillin-tazobactam are restricted antimicrobial agents (Qahtani, 2011). The approval of an infectious disease consultant is required to get these agents prescribed by physicians. However, except for imipenem, prescriptions for these agents were higher compared to the other observed antimicrobial agents. Except for the cardiovascular ICU, meropenem was the most consumed agent in the ICUs under surveillance. Meropenem accounted for more than 50% of all DDDs in the burn ICU, the medical surgical ICU, and the neurosurgical ICU. Piperacillin-tazobactam was the second most consumed agent except in the cardiovascular ICU where it was the most consumed antimicrobial agent out of the ten selected agents. Piperacillin-tazobactam

accounted for more than 40% of all DDDs in the cardiovascular ICU. Among cephalosporins, cefotaxime and cefepime were not commonly prescribed in the four studied ICUs.

Ceftazidime was ranked as the third most consumed agent in the cardiovascular ICU, but its consumption was not common in the other ICUs. The possible toxicity and the necessity for measuring serum concentrations of aminoglycosides could explain the minimal aminoglycoside consumption in the four studied ICUs. Total aminoglycoside consumption was mainly due to gentamicin consumption. Amikacin was not prescribed in either the cardiovascular ICU or the neurosurgical ICU. Among fluoroquinolones, the preference towards prescribing ciprofloxacin over moxifloxacin was obvious in all ICUs analyzed. Although not appropriately studied, the general patterns of consumption and the extensive consumption of meropenem and piperacillin-tazobactam imply that no attempt was made to formally assess the appropriateness of antimicrobial prescribing patterns, and antimicrobial consumption did not appear to correspond to the bacteria isolated from patients with infections. Erbay et al. (2005) reported that antimicrobial consumption in a tertiary care hospital was inappropriate for 47.3% of antimicrobial agents, most obviously in surgical ICUs. The mean length of stay in the studied ICUs was different and ranged from 5.4 days to 13.6 days. As recommended by Kuster et al. (2008), KAMC-Riyadh study reported the rate of antimicrobial consumption in two formats. The DDD per 100 bed-days and DDD per 100 admissions. The DDD per 100 bed-days format may adjust for different patient-stays in different areas. Expressing the antimicrobial consumption as DDD per 100 admissions is more likely to correct for extreme values in areas with long patient-stay times. For example, the medical surgical ICU had the highest total consumption of the ten antimicrobial agents selected for this surveillance when the consumption was expressed as DDD per 100 bed-days but not when it was expressed as DDD per 100 admissions. Expressing the consumption using the admissions data as the denominator resulted in the burn ICU having the highest total consumption rate. This result may be due to the long mean length of stay in the burn ICU. However, the DDD per 100 admissions is more likely to correlate with the incidence of bacterial resistance (Kuster et al., 2008).

The aggregate data on consumption rates of amikacin, ceftazidime, and imipenem in the medical surgical ICU at KAMC-Riyadh showed lower consumption rates than reported by das Neves et al. (2010) in two medical surgical ICUs (medical surgical ICU # 1 and medical surgical ICU # 2). The rate of consumption of ciprofloxacin in medical surgical ICU at KAMC-Riyadh was 9.1 DDD per 100 bed-days, whereas das Neves et al. (2010) reported 3.4 DDD per 100 bed-days in medical surgical ICU # 1 and 11.3 DDD per 100 bed-days in medical surgical ICU # 2. However, the version of the WHO Guidelines for ATC classification and DDD Assignment used in das Neves et al. (2010) study was not clearly mentioned. As different versions of the “WHO Guidelines for ATC classification and DDD assignment” may assign different DDD values, it is important to know which versions were used for proper comparisons between studies. Comparing antimicrobial consumption (in DDD / 100 bed-days) in the medical surgical ICU at KAMC-Riyadh with that at Hospital de Clinicas de Porto Alegre, Jacoby et al. (2010) reported 91.6 DDD / 100 bed-days, while KAMC-Riyadh surveillance had 84.8 DDD / 100 bed-days. However, the antimicrobial agents under study were not similar to the ones in the KAMC-Riyadh surveillance. In KAMC-Riyadh surveillance, carbapenem (imipenem and meropenem) consumption rates (in DDD / 100 bed-days) in the medical surgical ICU and the neurological ICU were shown to be 12 times (46 versus 3.8) and more than 13 times (42 versus 3.1) the consumption reported from the National Nosocomial Infections Surveillance system in medical surgical ICU and neurosurgical ICU respectively (NNIS. National Nosocomial Infections Surveillance (NNIS) System Report, 2004). However, the following issues should be considered: (a) the National Nosocomial Infections Surveillance data were from 61

medical surgical ICU and 11 neurosurgical ICU, (b) they used the 2004 WHO DDD values whereas KAMC-Riyadh surveillance used the 2011 version of the “WHO guidelines for ATC classification and DDD assignment” (unfortunately, being unable to find the WHO-assigned DDD 2004 version, no comparison was done to verify if its DDDs are similar to the 2011 version), (c) the time of the study should be considered as the pattern of antimicrobial consumption changes with time.

In 2004, carbapenems were relatively new medications when compared to 2010. Moreover, bacterial susceptibility in 2010 is not as it was in 2004. This difference in the rate of consumption may be because of bacterial resistance to other agents were less and thus there was no need for prescribing carbapenems. The previously mentioned carbapenem consumption rate in the medical surgical ICU (46 DDD / 100 bed-days) in KAMC-Riyadh surveillance was much more higher than the three rates reported by dos Santos and Lauria-Pires (2010) in three medical surgical ICUs at three different hospitals (HSL = 17.5; HRC = 25; HRT = 25.7) using the 2005 version. However, the consumption rate (DDD / 100 bed-days) of cephalosporins was higher in the three ICUs (HSL = 21.9; HRC = 43.5; HRT = 26.4) than in the medical surgical ICU (2 DDD / 100 bed-days) at KAMC-Riyadh. But in KAMC-Riyadh surveillance, cephalosporins included cefotaxime, ceftazidime, and cefepime whereas their cephalosporins included ceftriaxone, ceftazidime, and cefepime (unfortunately, being unable to find the WHO-assigned DDD 2005 version, no comparison was done to verify if its DDDs are similar to the 2011 version). The medical surgical ICU in KAMC-Riyadh surveillance had approximately three times the use of meropenem (43.2 versus 14 DDD / 100 bed-days) and around three times the use of carbapenems (46 versus 15.5 DDD / 100 bed-days) than reported by dos Santos et al. (2007) in their medical surgical ICU. But in their study, dos Santos et al. (2007) did not state if ertapenem, imipenem, or both were added along with meropenem. The medical surgical ICU at KAMC-Riyadh administered fewer amount of ciprofloxacin (9.1 versus 13 DDD / 100 bed-days) and aminoglycosides consumption in KAMC-Riyadh unit was less by more than three times (2.5 versus 9.5 DDD / 100 bed-days). Again, KAMC-Riyadh surveillance studied only amikacin and gentamicin but it was not clear which agents were analyzed in the study done by dos Santos et al. (2007). In KAMC-Riyadh surveillance, pooled means of ciprofloxacin consumption rates (6.7 DDD / 100 bed-days) and imipenem (1.8 DDD / 100 bed-days) in the four adult ICUs were lower than what reported by Meyer et al. (2004b) (10.4 and 4.9, respectively) in 35 different ICUs (10 medical, 11 surgical, and 14 interdisciplinary). However, the pooled means of carbapenems (imipenem and meropenem) consumption rate in KAMC-Riyadh surveillance was four times higher (35 versus 8.4 DDD / 100 bed-days). According to Meyer et al. (2004b) the German SARI ICUs had higher carbapenems (imipenem and meropenem) consumption than the US American ICARE/AUR (Antimicrobial Use and Resistance) ICUs. In KAMC-Riyadh surveillance, it has been demonstrated that a medical surgical ICU in a Saudi hospital administered larger quantities of carbapenems than ICUs in other countries. Differences in the versions of the “WHO guidelines for ATC classification and DDD assignment” and not reporting the type of the ICUs that were included or the list of antimicrobial agents, hinder more consistent comparisons. However, such comparisons are useful for the establishment of initial parameters. The striking differences in antimicrobial prescribing practices in different countries underline the need for improving the quality of antimicrobial prescribing.

In KAMC-Riyadh surveillance, the incidence of infections with multidrug-resistant Gram-negative organism in the medical surgical unit was higher than the incidence of such infections in the neurosurgical and cardiovascular ICU. This high incidence correlated with higher antimicrobial consumption in the medical surgical ICU than in the other two ICUs. This shows that high antimicrobial consumption in a single unit may promote resistance. During the surveillance period, the incidence of infections

with multidrug-resistant *K. pneumoniae* was higher than that for multidrug-resistant *P. aeruginosa*, and this was mostly constant over time. The general incidence of infections with multidrug-resistant *P. aeruginosa* (0.17 positive cultures per 100 bed-days) was higher than that reported by das Neves et al. (2010) (0.048 positive culture per 100 bed-days), although KAMC-Riyadh surveillance included only four ICUs, while das Neves et al. (2010) study included 18 different hospital units. As already stated, das Neves et al. (2010) study included two medical surgical ICUs: medical surgical ICU # 1 and medical surgical ICU # 2, with incidences of multidrug-resistant *P. aeruginosa* infections of 0.18 per 100 bed-days and 0.24 per 100 bed days, respectively. The incidence of infections with the same pathogen in the medical surgical ICU at KAMC-Riyadh was similar (0.26 per 100 bed-days) to what was reported by das Neves et al. (2010).

Higher rates of infections with multidrug-resistant organism are linked to the extensive consumption of antimicrobial agents, both in prophylaxis and in therapy (Bassetti et al., 2000). In KAMC-Riyadh surveillance, and among the ICUs, the consumption rates of some antimicrobial agents significantly correlated with the incidence of infections with multidrug-resistant *P. aeruginosa* and multidrug-resistant *K. pneumoniae*. For example, there was a significant positive correlation between the rate of consumption of imipenem and the incidence of infections with multidrug-resistant *K. pneumoniae* resistant to imipenem. A significant negative correlation was obtained between the gentamicin consumption rate and the incidence of infections with multidrug-resistant *K. pneumoniae*. However, the correlation between the consumption rates of other agents and the incidence of infections with multidrug-resistant *P. aeruginosa* and *K. pneumoniae* resistant to those agents were not statistically significant. For example, the rate of consumption of imipenem was positively correlated with the incidence of infections with multidrug-resistant *P. aeruginosa* resistant to imipenem but this correlation was not statistically significant. Hsueh et al. (2005) found a significant positive association between the consumption of carbapenems (imipenem and meropenem) and the incidence of infections with multidrug-resistant *P. aeruginosa* in the hospital, particularly in ICUs. das Neves et al. (2010) reported a significant positive correlation between the consumption rate of imipenem among 18 hospital units for adult patients and infections with multidrug-resistant *P. aeruginosa* ($r = 0.87, p < .001$). The analysis of KAMC-Riyadh surveillance showed negative correlations between the rate of consumption of ciprofloxacin and the incidence of infections with multidrug-resistant *P. aeruginosa* resistant to ciprofloxacin ($r_s = -0.48, p = 0.233$). das Neves et al. (2010) reported a significant positive correlation between the ciprofloxacin consumption rate and the incidence of infections with multidrug-resistant *P. aeruginosa* ($r = 0.71, p = 0.001$). However, the routines for performing culture and the definition of multidrug-resistant organisms were not similar in the two studies. Moreover, there could be some differences in the breakpoints between the methods that may have contributed to some of the differences in the results. Furthermore, in the correlation analysis of KAMC-Riyadh surveillance, the rate of consumption was expressed as DDD per 100 admissions, whereas das Neves et al. (2010) used DDD per 100 bed-days to express the consumption rate. In addition, the correlation that was found in the analysis of KAMC-Riyadh surveillance was in an individual ICU while the analysis done by das Neves et al. (2010) focused on the overall consumption and resistance within the 18 hospital units studied.

Jacoby et al. (2010) reported no correlation between fluoroquinolones consumption and multidrug-resistance *Pseudomonas* spp. However, their expression of antimicrobial consumption in the correlation analysis was not consistent. Sometimes they express it as DDD per 100 bed-days and sometimes as DDD only. The matched case-control study performed by Paramythiotou et al. (2004) showed that the length of ciprofloxacin therapy was an independent risk factor for infections with multidrug-resistant *P.*

aeruginosa resistant to ciprofloxacin in ICU patients. However, their definition of multidrug-resistant *P. aeruginosa* was not the same as the definition used in KAMC-Riyadh surveillance. Previous exposure to ciprofloxacin was not associated with an increased risk of resistance to ciprofloxacin in the case-control study conducted by El Amari et al. (2001) which aimed to determine whether recent exposure to antimicrobial agents was associated with an increased risk of bacterial resistance toward these drugs. However, Fortaleza, Freire, Filho, & de Carvalho (2006) stated that case-control studies that investigate risk factors for bacterial resistance have major methodological problems, and the effect of antimicrobial consumption could be confounded by individual patient characteristics or length of hospitalization. Jacoby et al. (2010) was able to find significant correlations only when they performed correlation analysis on multidrug-resistant organisms in ICU and antimicrobial consumption at the hospital level. But they did not find similar correlations after considering antimicrobial consumption at the ICU level. Data from ICARE revealed that heavy antimicrobial consumption was not always correlated with high prevalence of bacterial resistance (Cristino, 1999). In addition, the relationship between antimicrobial consumption and bacterial resistance may vary even within the same antimicrobial class (MacAdam, Zaoutis, Gasink, Bilker, & Lautenbach, 2006). Therefore, studies that examined the relationship between antimicrobial consumption and bacterial resistance have shown variable positive and negative correlations. Some studies obtained significant correlations, while other found no correlation. These variations in the reported correlations coincide with the point that the relationship between antimicrobial consumption volumes and the development of bacterial resistance is complex and not a simple correlation (Barbosa & Levy, 2000; Burke & Pestotnik, 1999; Iosifidis et al., 2008; Meyer et al., 2006; WHO, World Health Organization, 2001), although there is a substantial body of evidence considers the total antimicrobial consumption as the main driver in selecting resistance (WHO-World Health Organization, 2001). Difficulties in quantifying antimicrobial exposure and methodological variations among studies have led to different conclusions (Iosifidis et al., 2008; Wenzel, 2003). Furthermore, there are several interacting factors other than antimicrobial consumption that determine the dynamic development of bacterial resistance to antimicrobial therapy and may account for changes in the epidemiological behavior of the organisms and may have confounded the results of KAMC-Riyadh surveillance and other research on the correlation between consumption and resistance. For example, the transfer of patients within and among medical institutions, infection control measures, the level of bacterial resistance in the community, antimicrobial residues in the environment (Iosifidis et al., 2008; Levy, 2002) different bacterial resistance mechanisms among different geographical areas, the patterns of antimicrobial prescription in these areas (Fortaleza et al., 2006) and other poorly explored factors (WHO-World Health Organization, 2001). Age is another factor that can confound the results of observational studies examining the relationship between antimicrobial consumption and bacterial resistance (Lipsitch, 2001).

Failure to control for confounders, study biases, and lack of uniformity in susceptibility testing and in defining bacterial resistance may contribute to the inability of reporting interdependence (Hsu et al., 2010). In addition, the following are likely to have exerted some influence over the results of KAMC-Riyadh surveillance and may explain why some of the obtained correlations in this surveillance were not significant: (a) the characteristics of the studied ICUs, (b) the antimicrobial restriction and infection control policies, (c) previously existing infections acquired in the community, (d) the ability to buy antimicrobial agents without a prescription in Saudi Arabia, and (e) results could be affected by the short duration of the study. The ability to buy antimicrobial agents without a prescription may contribute to inappropriate consumption of these agents, thereby leading to the emergence of bacterial resistance.

According to Gulbinovic et al. (2001), the consumption of antimicrobial agents in the outpatient setting have influence on bacterial resistance more than the influence that is exerted by the consumption of these agents in the hospital. Regarding the duration of the study, longer surveillance period is needed to allow for seasonal variations and more incidences of infections with multidrug-resistant organisms that yield meaningful statistics and facilitate proper analysis of the data. Studying the correlations between antimicrobial consumption rates and incidence of multidrug-resistant *P. aeruginosa* or *K. pneumonia* could not be performed in some of the selected ICUs in KAMC-Riyadh surveillance because of lots of zeros in the microbial resistance data. For example, the correlation between consumption rate of ciprofloxacin and incidence of infections with multidrug-resistant *K. pneumonia* resistant to ciprofloxacin was not examined in the cardiovascular ICU (Table 3).

Another example was from the burn ICU where the correlation between consumption rate of piperacillin-tazobactam and incidence of infections with multidrug-resistant *P. aeruginosa* resistant to piperacillin-tazobactam was not analyzed (Table 4).

Because there are many possible interacting factors that determine the dynamic development of bacterial resistance to antimicrobial therapy and because of several confounding factors that may affect the emergence of multidrug-resistant organisms, it is not easy to establish relationship between antimicrobial consumption and antimicrobial resistance. Therefore, finding a correlation signifies that it is almost certainly of major importance and indicates that controlling the antimicrobial consumption will affect the emergence of antimicrobial resistance (Livesey & Chiew, 2006). Studies that evaluate the link between the consumption of antimicrobial agents and the emergence of bacterial resistance in microorganisms should be performed using similar methodological approaches and standards in several settings (Fortaleza et al., 2006) for the corroboration of findings. For example, studies should differentiate between infections and colonization and between hospital-acquired and community-acquired infections.

The research that was performed in KAMC-Riyadh has several limitations, including the small number of studied units and the short duration of the study (8 months). The consumption of antimicrobial agents could have been quantified by other measurement units (e.g., day of therapy) that may have some advantages over the DDD methodology (Polk et al., 2007), however, the DDD methodology is recom-

Table 3. Consumption rate of ciprofloxacin (DDD/100 admissions) and incidence of infections with multidrug-resistant K. pneumonia resistant to ciprofloxacin (per 100 admissions) between May 2010 and December 2010 in the cardiovascular ICU at KAMC-Riyadh

Month	Consumption Rate of Ciprofloxacin	Incidence of Infections with Multidrug-Resistant <i>K. Pneumonia</i> Resistant to Ciprofloxacin (per 100 Admissions)

December	1435.7	0

mended by the WHO and many other organizations, it is applied all over the world, and investigators in this field are well aware of any potential limitations. The data for the correlation between antimicrobial consumption and incidence of infections with multidrug-resistant organisms were collected at one medical center, and the ICUs were chosen by convenience and may not reflect situations in other hospitals. Another limitation is that in some of the ICUs, and because of the short duration, a relatively limited number of multidrug-resistant Gram-negative organisms were recovered therefore data from such ICUs were not analyzed for correlation. To study the extent and patterns of antimicrobial consumption and their relationship with bacterial resistance, consumption and resistance data must be obtained over a sufficient period of time to account for seasonal variations and to have meaningful statistics by having both reasonable consumption data and more number of bacterial isolates. Furthermore, KAMC-Riyadh surveillance included most but not all of the antimicrobial agents that are used in the ICUs. For example, the surveillance did not include vancomycin which aids the spread of multidrug-resistant *P. aeruginosa* even though it is not active against *P. aeruginosa* (das Neves et al., 2010). In addition, and because only aggregated pharmacy data were available at KAMC-Riyadh, the antimicrobial consumption rates and bacterial resistance data were aggregate data and could not be related to patient and disease; thus, no inference of the distribution of exposure and effects could be made with respect to the individual patient (ecological fallacy). Therefore, the correlations between the consumption of antimicrobial agents and the incidence of multidrug-resistant organisms should be interpreted with caution. The ecologic nature of KAMC-Riyadh surveillance has its disadvantages. This study and similar studies, only suggest potential correlations. Thus a cause and effect relationship between the rate of antimicrobial consumption and the incidence of multidrug-resistant Gram-negative organisms cannot be concluded. Establishing an etiologic relationship may require other research methodology. However, ecological fallacy does not invalidate the analysis of aggregate data, and ecologic studies suggest links between antimicrobial consumption and bacterial resistance and may identify relationships that are missed in individual base studies (das Neves et al., 2010; Iosifidis et al., 2008). das Neves et al. (2010) explained that there is a sound argument for conducting ecological studies on this topic because several factors contribute to the spread of multidrug-resistant organisms.

According to Gould and Van der Meer (2005), many studies used aggregated antimicrobial consumption and resistance data. In addition, to counteract the increasing rates of resistance in bacteria, many organizations have recommended that aggregate data on the consumption of antimicrobial agents at the local and national levels should be measured and analyzed together with bacterial resistance data to develop strategies that aim at appropriate consumption of antimicrobial agents (Hsueh et al., 2005; Jacoby et al., 2010; Polk et al., 2007; Ruef, 2006). Unevaluated confounders such as inappropriate dosages, different case-mixes, and prevalence of cross-transmission may have affected the results. Unfortunately, KAMC-Riyadh surveillance could not distinguish between community- and hospital-acquired infections due to the unavailability of data. Data on patient severity or invasive procedures were not available and should have been added in the analysis, but this was beyond the scope of KAMC-Riyadh surveillance. Finally, differences in indications for performing cultures and time between admission and culture were unknown.

In linking the consumption of antimicrobials in hospitals to resistance in these settings, there are several areas for further refinement of the data such as the exclusion of prophylactic consumption from the antimicrobial consumption data and community-acquired infections from the antimicrobial resistance data. Unfortunately, because of the unavailability of data, these exclusions were not possible in the current KAMC-Riyadh surveillance. Also, data collection should be extended for a longer period of time. The influence of antimicrobial consumption on bacterial resistance to other agents also needs to be explored. Cost-effectiveness analyses of antimicrobial consumption that include the cost of bacterial resistance should be performed. In addition, the analysis could be refined by applying time-series analysis and the autoregressive integrated moving average (ARIMA). This way of analysis offers advantages over correlation analysis or simple liner regression (Bosso & Mauldin, 2006). With this type of analysis, we can model the relationships between antimicrobial consumption and bacterial resistance and reveal temporal relationships. According to Lopez-Lozano et al. (Lopez-Lozano et al., 2000), this analysis allows researchers to (1) “quantify the fraction of the resistance series explained by the past behavior of both the resistance and use series”(2) estimate the delay that exists between variations in antimicrobial consumption and subsequent variations in bacterial resistance, and (3) quantify the effect of antimicrobial consumption on the percentage of bacterial resistance. This type of analysis was not performed in KAMC-Riyadh surveillance because of its short duration and limited data points. According to Monnet et al. (2001), investigating the relationships between antimicrobial consumption and bacterial resistance by time-series analysis requires a minimum of 60 observations or time intervals or approximately 15 years of trimester-level data, 5 years of monthly data or about 1 year of weekly data.

KAMC-Riyadh surveillance emphasized on the importance of assessing the consumption of antimicrobial agents in the hospitals especially in the ICUs in order to improve the quality of antimicrobial prescribing and investigate the correlation between antimicrobial consumption and bacterial resistance to counteract the upward trend in bacterial resistance. Monitoring trends of antimicrobial consumption and providing data on bacterial resistance patterns are recommended to both explore any link between antimicrobial consumption and incidence of bacterial resistance and to recognize areas with heavy antimicrobial consumption. These studies can then provide feedback to clinicians and practitioners in order to develop interventions to control the high expenditure on such expensive medications and establish a national surveillance system. This surveillance is an important way to solve local problems of antimicrobial prescribing and counteract bacterial resistance. As previously mentioned, both have global consequences. Further on-going surveillance studies will follow trends in antimicrobial consumption and help in identifying changes in bacterial resistance.

FUTURE RESEARCH DIRECTIONS

The discovery of antimicrobial agents was ranked second among the “greatest medical advances since 1840. (Hsu et al., 2008)” However, increasing bacterial resistance and the slowing of the development of new antimicrobial agents have weakened the clinical usefulness of antimicrobial agents (Hsu et al., 2008).

The emergence of antimicrobial resistance and multidrug-resistant bacteria are major determinant factors for morbidity, mortality and costs in hospitals, and the increasing rate of bacterial resistance is becoming a major worldwide public health concern that necessitates international approaches. To reverse the emergence of bacterial resistance, according to Levy (2002), the focus should be on one factor at a time instead of switching from one issue to another so as not to aggravate the overwhelming nature of the resistance problem. The seriousness of bacterial resistance, the importance of appropriate antimicrobial therapy, and the fact that there is a decrease in the development of new antimicrobial classes should be stressed in more detail in the curriculum of medical schools (e.g., colleges of medicine, pharmacy, nursing, public health). More information should be gathered about the perceptions of healthcare providers on antimicrobial therapy and the impact of the pharmaceutical companies on clinicians for prescribing expensive antimicrobial agents. Ongoing education of hospital staff regarding the use of broad-spectrum antimicrobial agents is needed. Healthcare providers, hospital administrators, and policy makers should be aware of the antimicrobial resistance problem and how multidrug-resistant organisms increase the mortality and morbidity and waste healthcare money. They should also be aware that as more antimicrobial agents are consumed, the bacterial resistance problem becomes larger; thus, improving the consumption also improves patient outcomes, reduces antimicrobial resistance, and decreases the overall cost (CDC - Why Inpatient Stewardship? - Get Smart for Healthcare, 2010). Hospital policies should mandate infectious disease consultation prior to the prescription of antimicrobial agents and 3-5 days subsequently, after obtaining laboratory results and/or clinical changes that could influence the treatment. Prescribing any of the broad-spectrum agents without obtaining approval should be abandoned to control the high cost of such agents and the incidence of multidrug-resistant organisms. Clinicians should consider cycling antimicrobial agents, especially when new ones are available for clinical use. This approach, and especially in the ICUs, has been seen as one way to control bacterial resistance (Furtado et al., 2008). Traditional infection control measures alone are likely insufficient to prevent the emergence of multidrug-resistant Gram-negative organisms.

Antimicrobial selection and antimicrobial pressure are important factors in the prevention of such pathogens (Patterson et al., 2000). Combining the two approaches is important for preventing the occurrence of multidrug-resistant organisms, but according to some studies, controlling antimicrobial consumption is the most important intervention (Patterson et al., 2000). However, especially in the ICUs, infection control procedures should be enforced. Health professionals must be advised to wash their hands between patient visits to reduce the spread of infection and, thus reduce the need for antimicrobial agents. The active involvement of pharmacy, infection control, and microbiology personnel should be implemented in an attempt to improve the appropriateness of antimicrobial choice. Both the total amount of antimicrobial agent consumed and how it is consumed are critical, and inappropriate consumption of antimicrobials through unnecessary therapy, inadequate dosing, poor adherence, poor drug choice and sub-standard antimicrobial agents may have as important a role in increasing resistance as over-consumption (Gulbinovic et al., 2001; WHO-World Health Organization, 2001). The Saudi Ministry of Health should mandate collecting and reporting antimicrobial consumption trends across Saudi Arabia. Because the antimicrobial stewardship programs have proven to improve patient outcomes, reduce bacte-

rial resistance, and decrease hospital expenditures (CDC - Why Inpatient Stewardship? - Get Smart for Healthcare, 2010), the Saudi Ministry of Health should enforce each healthcare facility to implement an antimicrobial surveillance and antimicrobial stewardship program to monitor and assess prescribing trends and bacterial resistance rates. Likewise, healthcare providers, hospital administrators, policy makers should work on implementing and actively support antimicrobial surveillance and antimicrobial stewardship programs. The consumption of antimicrobial agents in the community may contribute to the emergence and spread of bacterial resistance in hospitals (MacDougall, Powell, Johnson, Edmond, & Polk, 2005). Therefore, the Saudi Ministry of Health should also consider regulating antimicrobial consumption in the community and these agents should be regulated by legislation to require a prescription before they can be obtained and should not be available as over the counter medications. Finally, pharmaceutical industries should be encouraged to develop new antimicrobial agents with new targets that block the mechanisms of resistance.

WAY FORWARD AND RECOMMENDATION

Obtaining antimicrobial consumption data using the DDD methodology in the Saudi hospitals is possible and recommended, especially for ICU settings. A standardized approach is required in order to allow meaningful comparisons of antimicrobial consumption at the local, national, and international levels. The analysis of antimicrobial consumption data in terms of DDDs is useful for antimicrobial surveillance studies, aids in the implementation of antimicrobial stewardship programs and can explore the relationships between antimicrobial consumption and bacterial resistance patterns. An expanded hospital antimicrobial agent consumption database is necessary for adequate planning. Understanding the link between antimicrobial consumption and bacterial antimicrobial resistance is an essential step towards optimizing antimicrobial prescription policies and counteracting the problems of bacterial resistance.

Hopefully, clinicians and other health-professionals will consider the consequences of prescribing antimicrobial agents on the emergence of bacterial resistance. A cross-country comparison of the antimicrobial prescribing patterns and the incidence of resistance from patients in ICUs are necessary. It is important for more data to become available on antimicrobial consumption and bacterial resistance from communities, hospitals (outpatient and inpatient) and other medical centers in the region to achieve the benefit of making the correlations, identifying useful interventions, and benchmarking. Although Burke (1995) wrote, "Despite the multifactorial nature of antibiotic resistance the central issue remains quite simple: the more you use it, the faster you lose it", we believe that further studies are required to consider the role of factors other than antimicrobial consumption (e.g., adherence to guidelines for doses and duration of antimicrobial therapy, infection control practices, utilization of invasive devices and procedures, poor quality of available antimicrobial agents, and patient compliance) in predicting resistance to antimicrobial therapy.

KEY TERMS AND DEFINITIONS

Anatomical Therapeutic Chemical Classification (ATC): A system that classifies the drugs according to the organ or organ system they act on and according to the pharmacological and therapeutic properties of the drugs.

Antimicrobial Therapy: Therapy that aims to control infections by altering metabolic processes in bacterial cells without harming the patient.

Bacteria: Prokaryotic microorganisms that lack a membrane-bound nucleus or any other membrane-bound organelles.

Bacterial Resistance: A natural biological phenomenon that may develop to any antimicrobial agent allowing the bacteria to survive and multiply in the presence of the antimicrobial agent even in concentrations much higher than therapeutic concentrations used clinically.

Defined Daily Dose (DDD): A unit of measurement that expresses drug consumption.

Intensive Care Units: Units that care for critically ill patients through intensive observation, diagnosis, and therapeutic procedures.

Surveillance of Antimicrobial Use: Measuring antimicrobial consumption patterns that provide valuable data to develop policies to control the consumption of antimicrobial agents, increase treatment quality, decrease the risk of bacterial resistance, and cut unnecessary treatment and hospital expenditures.

Chapter 9

Genomics Applications in Public Health

E. William Ebomoyi
Chicago State University, USA

ABSTRACT

In the transformation of health, through genomics applications in public health, many of the disease burdens which were incriminated for low life expectancies are being scientifically challenged. However, efficient environmental sanitation played a major role in the eradication of hitherto life threatening vector-borne diseases. However, the outbreaks of emerging infectious diseases and chronic and degenerative conditions pose new challenges. Dr. Zerhouni, the former director of the National Institutes of Health meticulously identified the aging phenomenon. Health disparities and emerging and re-emerging infectious diseases and emerging non-communicable (obesity) as the precursors new health problems which demand innovative strategies. He has suggested, as key of the components of the future paradigm, the four Ps which comprise predictive, personalized, preemptive and, participatory techniques to combat national and international public health challenges. This innovative approach is currently being utilized to preempt the onset of many chronic and degenerative diseases.

INTRODUCTION

Having read this chapter, the learner should be able to:

- Provide a conceptual framework for innovations, and capacity building in genomic technology
- Assess existing infrastructures for genomic technology
- Assess the background of genomic workforce
- Specify genomic applications with reference to genetic diseases, and
- Develop logic model to integrate genomics into public health centers.
- Discuss the genomic characteristics of BRCA1 and BRCA2 mutations
- Advocate the adoption of the Health Belief Model for the dissemination of health education worldwide to prevent the onset of breast cancer in women

DOI: 10.4018/978-1-5225-1674-3.ch009

- Access pertinent sources of health information about breast cancer and assistance for at-risk patients in developed and developing nations
- Emphasize the importance of health education of the public using female humanitarian with high international profile to mitigate the impact of breast cancer
- Accentuate the impact of precision (P4) medicine in preventing and managing the lethal consequences of breast cancer

GENOMIC APPLICATIONS IN PUBLIC HEALTH

Based on epidemiological trends and scientific clinical observations, genomics is bound to play significant role in public health. Genomics as the study of the entire human genome is poised to have numerous role not only on public health but create the incipient stage of scientific revolution which is about to improve clinical medicine while as well accentuate the relevant of preventive disciplines and behavioral interventions in the clinical management of the health problems of healthcare consumers worldwide. Genomics is a branch of biological science which focuses on the development and application of very effective mapping, sequencing and bioinformatics computational techniques. Scientists trained in genomics and other molecular biologists apply large-scale molecular techniques for linkage analysis, physical mapping, and sequencing of genomes to generate detailed data which are subjected to analysis using high-speed computer facility.

The new international tools of genomics include the high-throughput deoxyribonucleic acid (DNA) sequences, genotyping machines and large-scale DNA arrays (DNA chips). These scientific tools have the capacity to analyze thousands of genes promptly and accurately. These devices can be used to study the cells of virtually all living organisms. To reiterate a typical genome is the entire collection of chromosomes which are present in the nucleus of each cell of an individual organism.

In nations where there are adequate technological resources, genomic science continues to revolutionize public health as we move into the 21st century. As a result of the numerous milestone accomplished in sequencing the human genome, public health career is steadily becoming a pre-eminent preventive medicine discipline. Evidenced-based public health activities are now obvious in neonatal screening for genetic, chronic and degenerative diseases. Besides, genomics now plays significant impact in environmental health in enabling scientists to identify microbial agents which can be applied to identify microbial agents for carbon dioxide sequestration which is a predominant greenhouse gas. Two decades into the 21st century, the highly industrialized nations are now able to comprehensively utilized the anticipated benefits of genomics in molecular medicine, microbial genomics, risk assessment, bioarcheology, anthropology, evolution, and human migration. Innovative DNA identification process are now being retroactively applied to free incarcerated prisoner who were present in heinous crime scenes but had nothing to do with specific crimes. Genomics technologies are now being applied to revolutionize agriculture, livestock breeding and bioprocessing

We must reiterate that the completion of the human genome sequencing (HGS) sponsored by the U.S. Department of Energy and the National Institutes of Health (NIH) is comparable to the feat associated with theory of relativity propounded by Albert Einstein in the 20th century. In 1915, Einstein completed his general theory of relativity, a theory of gravity which demonstrates more precision than that of Sir Isaac Newton. Besides, Einstein also illustrated that photoelectric effects involving ejection of electrons from metal by action of light can be explained, if light has particle nature as well as wave characteris-

tics. These discoveries have many and varied implications in engineering, physics, electronics and our understanding of the global planetary systems (Einstein, 2000). However, the contrast with the human genomic sequencing involved the individual feat of Einstein whereas in genomics, the main collaborative group includes scientists at the NIH, the U.S. Department of Energy, and numerous scientists from the European Union, Japan, and China. This scientific team is now described as the International Human Genome Sequencing Consortium (IHGSC). Seven years span, post-completion of the human genome project, biology not only assumed the status of a pre-eminent science, but in the industrialized nations, genomic technology canners emerged, commercialization of genomic-oriented medical establishments was developed, and biotechnological enterprises flourished. They were developed to focus on the domestic health needs and environmental challenges of these nations. Inadvertently less emphasis was placed on the endemic diseases and teething economic problems of the developing nations. Against this background, the study described here, was designed to: compile technological centers and anticipated benefits of genomics which are required to meet the needs of developed nations, characterize the imminent technological set-backs in developing nations in the age of innovative genomic science, explore the impact of inadequate access to Internet and associated communications network as the underlying factors which exacerbate poverty, ignorance, and diseases in developing nations, and illustrate the relevance of a seamless linkage among governments, industries, academic institutions, venture capitalists, and enlightened public in developing nations to harness the medical and commercial benefits of genomic science.

Genomic Technologies and Resources

Once the HGS was accomplished by April 2003, new genomic technologies start-up companies were established. These innovative companies include the 454 life sequencers manufactured by Roche Diagnostics (Branchford, CT), chromatography and electrophoresis, gene amplification, capillary analysis, polymerase chain reaction tests, microarray sequencing and isoelectric focusing, high-performance computing equipment, broadband infrastructure, data visualization equipment, biophotonics, robotic equipment, vision science equipment, climate research atmospheric science equipment, and bioprocessing engineering equipment, among others. A comprehensive list of this state-of-the-science technology was reported by Ebomoyi and Srinivasan (2008).

The U.S. Department of Energy (2008), in its microbial genome program emphasized the applications of genomic technologies in molecular medicine, microbial science, risk assessment activities, bio archaeology anthropology, evolution and human migration pattern. Additional applications of genomic resources consist of forensic science, agricultural development especially livestock breeding and bioprocessing.

In order to facilitate the process of data storage, data mining and processing, the U.S. Department of Energy at its Oak Ridge National laboratory recently upgraded a CrayXT5 high-performance computing system by transforming it to the "Jaguar" supercomputer as the world's fastest. This computer is the most powerful computational machine for finding solutions to some of today's intricate and tantalizing problems. This upgrade consumed 19.9 million dollars under the U.S. Recovery Act, 2010 (Tripp & Grueber, 2011). At the NIH, new powerful DNA sequencing technologies were developed; the transformation of genomics from technology to biology-driven science was amplified. By 2007, genes responsible for some of the leading causes of death were sequenced and the precursors of 10 most common diseases in the United States were identified in a span of three years. New ways of monitoring personal environmental exposures were scientifically characterized.

Japan has also established a viable genomic institute; and the government continues to invest colossal sums of money to develop authentic technologies and build competent molecular sciences workforce. Recently, the high-speed large capacity disk array system was installed in one of the nation's genome institutes. This computational machine was developed to handle copious amounts of data and maintain the capacity to save such data. Besides the data backup capability, their new computer has the capacity to protect sensitive research data from unexpected loss. The intrinsic goal of the Japanese human genome center is to contribute to human society through the development of efficient diagnosis of illnesses, prevention and the application of effective therapeutic interventions to meet the needs of the society. Besides, Japan now leads the world in fermentation technologies and is growing plastic car parts from bacteria and plants.

Beijing Genomic Institute (BGI) is one of China's leading research facilities on through put sequencing-based profiling tools; and the institute is committed to excellence in genome sciences. BGI continues to conduct a large-scale genomic research in bioinformatics; genome dynamics and genotyping with over 100 bioinformatics specialists. Research scientists at BGI have focused their investigations on the Human Hap-Map project, the super-hybrid Rice Genome project, silkworm genome, chicken genome variation in collaboration with U.K. and U.S. partners and the Sino-Danish pig Genome project.

Other technologically savvy developing nations such as Brazil, Korea, and India have directed their research interest on their pharmaceutical industry; systematically using genomic science and bioinformatics to develop agriculture, chemicals, bio defense and energy. Brazil now leads the world in bio-fuels and the prevention of citrus diseases. Korea continues to invest in cloning and tissue engineering. As these technological initiatives occur at exponential rate in the developed nations, we continue to observe imminent set-backs in developing nations owing to incessant political crisis and economic hardship.

Innovations in Capacity Building in Genomics Technology

The relevance of innovations in capacity building in genomic technology has become very crucial. This crucial nature arises because of the prohibitive cost of utilizing the sophisticated services associated with HGS, which are the components of personalized, predictive and preventive medical services. The genomic infrastructures are those tools which provide essential services to the international scientific community for basic and applied research. To augment the list summarized in Table1, genomic infrastructures include the 454 life nanotechnologies, libraries, databases, biological archives, scrupulously clean rooms, communication networks, research vessels, satellites and aircraft observation facilities, coastal observatories, telescopes, synchrotrons and accelerators, broadband access and integrated data system among others (United States Department of Energy, 2008; Ebomoyi, 2005).

The recently developed nanotechnology has applications for micro-fabrication and nanofabrication of complex structures from patterning and processing designs which are used to test finished products which include microelectronics to integrated optoelectronics and silicon-based and compound semiconductors (Table 1).

Nanotechnology involves the science and technology that creates or manipulates materials at the nano scale. In genomic and biotechnology industries, nanotechnology exploits novel properties associated with matter in minute size (<100 nm) to produce novel medical and diagnostic products and more effective bio-drugs. Nanomaterials can deliver radioactive compounds for radiotherapy or diagnosis, nanocapsules, magnetic nanoparticles for detoxification use, and nano porous electrode materials for artificial retinal implants among other medical interventions (Borst&Borst, 2008).

Sources: United States Department of Energy (2008); and Ebomoyi(2005).

The challenge of enhancing innovation in genomics technology in United States involves tripartite collaboration between the government, medical scientific institutions and the existing commercial companies (venture capitalists). To illustrate, the Michigan Center for Genomic technology has developed, and now provides full genomic services by utilizing expression analysis involving microarrays, Affymetrix gene chip arrays, Illumina, bead chip arrays, Agilent gene expression arrays custom oligoarrays, and quantitative reverse transcription (RT)-polymerase chain reaction tests. In many genomic applications (e.g., the widely used microarray chips from Affymetrix), samples of RNA rather than DNA are analyzed directly. Therefore, the measurement of RNA transcripts represents the measurement of gene expression, which is a very dynamic process which is influenced by a number of host and environmental factors.

Innovations to enhance genomic technology at U.S. federal level, is not a trivial issue; because the National Human Genome Research Institute (NHGRI), an arm of the NIH, is committed to making DNA sequencing faster and more cost effective. By 2006, a total sum of 13 million dollars was earmarked for biomedical and clinical research investigators to speed the development of innovative technologies that could reduce the current prohibitive cost of DNA sequencing. The investigators are expected to investigate techniques to expand use of genomics in medical research and health care. NHGRI had conceived of multiple practical mechanisms of innovations to make sequencing faster and more cost effective. Since

1990, over 380 million dollars have been invested to develop and improve DNA sequencing technologies. In a gradual but systematic process, investment on innovation has yielded so many dividends, because the cost of sequencing has now fallen more than 50-fold over the past decade (Genome.gov, 2006). In fact, the vision of NHGRI is to reduce the cost of whole-genome sequencing to 1,000 dollars or less. It seems axiomatic, that most insurance companies will find this amount, reasonable for many insurance companies to pay health care providers. Currently, NHGRI continues to solicit revolutionary research proposals on genome sequencing technologies that unequivocally state as their goals, the development of breakthrough technologies that will make a human-size genome to be efficiently sequenced for 1,000 dollars or less and at the same time adopt methodology that complies with the NIH's competitive and rigorous protocols (Spencer, 2006; Genome.gov, 2006).

Besides, the serendipitous benefits of globalization have facilitated the process of disseminating innovative precision medicine to the developed, developing and least developed nations worldwide. The authors provided a list of potential humanitarian agencies from which indigent patients could solicit assistance to ensure that their positive diagnostic test for breast cancer gene(s) does not culminate in their imminent death sentence. Finally, recommendations were made about compliance with stringent exercise schedules and consumption of diet rich in polyphenols and other photochemical nutrients to sequester lethal gene chromosomes, while enhancing those genes that code for graceful aging.

PRECISION MEDICINE (THE P4 MEDICINE)

Precision (P4) Medicine and Screening for the Incipient Stages of Breast Cancer

The complete set of inherited genetic materials is encoded in our DNA. During reproductive behavior, the parents' sperm and egg (DNA) combine to contribute to a genome an entire amount of genetic information to the fertilized embryo. Scientifically, since the same amount of genetic information is present in the cells which eventually make up an organism, humans are usually at risk of having single-gene diseases inherited from parents or carry complex diseases which parents have in their genes. Global genomic epidemiology attempts to assess the frequency of occurrence of specific genetic and complex diseases in several parts of the world. Whereas, genomic epidemiology is the link uniting the intersection between genetic and molecular epidemiology. It focuses on the determinants and distribution of diseases and injuries in human population (Ebomoyi& Ebomoyi, 2014).

Global Genomic Epidemiology of Breast Cancer

In the 21st century, the global incidence of breast cancer has risen due to the inadvertent impact of globalization, inherited gene chromosomes, ingestion of alcohol, and smoking behavior in both developed and developing nations. Currently, breast cancer has become by far the most common cancer diagnosed in women worldwide. An estimated 1.38 million women in the world were diagnosed with breast cancer in 2008 and this statistic accounts for 23% of all cancers diagnosed in women. The newly diagnosed cases of breast cancer are usually higher in the developed than in the developing nations. However, as a result of innovative genomic medical interventions and in spite of the higher frequencies of the incidences of

diagnosed breast cancers in the industrialized nations, more women in developing nations will encounter higher frequencies of death from the disease. Boyle and Levin (2008) emphasized the role of multiple risk factors in the incidence of breast cancer worldwide. While incidence is generally higher in the developed nations than in the developing nations, breast cancer incidence has increased in the last decade in developing nations due principally to globalization, acculturation, and exposure to environmental carcinogens, reproductive behavior, use of exogenous hormones, as well as to a sedentary lifestyle, and the inertia to breast feed and being nulliparous mothers. By 2008, the incidence data ranged from about 20/100,000 in Eastern Europe and West and North Africa to 90/100,000 in Western Europe. The nations with the highest incidence statistics are the highly developed Denmark and Belgium (101/100,000 and 109/100,000, respectively).

Economic Impact of Breast Cancer

In assessing the economic impact of cancer worldwide, the American Cancer Society (2008), report by Boyle & Levin revealed how cancer has the most devastating economic impact of any cause of mortality in the world. The total economic impact of premature death and cases of morbidity attributed to global cancer statistics has been estimated to be 895 billion dollars as of 2008. This statistics represents 1.5% of the world gross domestic product (GDP). The economic catastrophe attributed to cancer is nearly 19% higher than heart disease, the second leading cause of death worldwide, which involves an economic loss of between 895 billion dollars and 753 billion dollars, respectively, even without including the direct medical costs. By far most crucial, the lost years of life and economic productivity due to cancer represent the single most crucial drain on global economy compared to other etiological agents of death including heart disease, HIV/AIDS and other infectious diseases (Boyle & Levin, 2008).

The economic loss from the 15 top global causes of death indicates that cancer by far exceeds the other diseases listed in Figure 1. A recent report has vividly revealed that breast cancer, lung cancer, and colon/rectal cancer account for the largest economic costs on an international scale. Use of innovative genomic medical science can lead to prevention, early detection, and effective treatment of cancer which could save numerous lives.

Genomic Sequencing of BRCA1/BRCA2 and Associated Genes

Hereditary breast cancer (BRCA1 and BRCA2) involves deficiency of the DNA repair system and breaks by homologous recombination, which triggers cancer susceptibility genes leading to breast cancer and ovarian cancer. A detailed epidemiological profile of BRCA1 and BRCA2 has been provided elsewhere; it must be emphasized that by the year 2030, the use of innovative genomic technology, geneticists and modern genome epidemiologists will have the capacity to identify numerous genes that predispose at-risk patients to early detection of those deleterious gene chromosomes (Ebomoyi, 2011).

Innovative genomic sequencing technologies and other molecular diagnostic techniques have shown *BRCA1* and *BRCA2* are not the only genetic mutations that increase the risk of breast cancer. The other recently sequenced genes include TP53, PTEN, STK11/LKB1, CDH1, CHEK2, ATM, MLH1, and MSH2. The genome-wide association studies (GWAS) of breast cancer recently identified multiple single-gene nucleotide polymorphisms (SNPs) that are associated with increased incidence of breast cancer in the general population. Some of the alleles at the three of these SNPs in FGFR2, TNRCq, and

Figure 1. Breast cancer (C50): 2008 estimates

Source: <http://info.cancerresearchuk.org/cancerstats/faqs/#How>

MAP3K increase the risk of breast cancer for BRCA1 and BRCA2 mutation carriers. In the general population, besides those reported with higher prevalence rates, three specific SNPs rs3817198 at LSP1 and rs13387042 at 8q24 have also been shown to associate with onset of breast cancer (Malone et al., 2011; Antoniou et al., 2009).

Genomic Sequencing of BRCA1/BRCA2

In genomic medicine, BRCA1 and BRCA2 are not the only genetic mutations that increase the risk of breast cancer. Innovative sequencing recently revealed many other genes such as the TP53, PTEN, STK11/LKB1, CDH1, CHEK2, ATM, MLH1, and MSH2. The GWAS of breast cancer recently identified multiple single-gene SNPs that are associated with increased incidence of breast cancer in the general population. Some of the alleles at the three of these SNPs in FGFR2, TNRCq, and MAP3K create increase the risk of breast cancer for BRCA1 and BRCA2 mutation carriers. In the general population, beside those reported with higher prevalence rates, three specific SNPs rs3817198 at LSP1 and rs13387042 at 8q24 have also been shown to associate with onset of breast cancer (Malone et al., 2011; Antoniou et al., 2009). These recently detected mutations account for only a fraction of hereditary breast cancer. These genes mutations account for at least 5% to 10% of the total ovarian cancers among Caucasian women in the United States. BRCA2 is located on chromosome 13 and the risk of developing breast

cancer in women diagnosed with BRCA2 mutations is similar to the risk of BRCA1 patients (Antoniou et al., 2009). The GWAS of breast cancer continue to identify multiple SNPs, which are associated with increased risk in the general population. A detailed account of such global genomic study is beyond the scope of this project.

Mortality Statistics in the United States

The American Cancer Society gave an estimate of 562,340 cancer deaths in the United States, made up of 292,540 males and 269,800 females (American Cancer Society, 2009). Cancer sites in men for which African-American recorded deaths (313.0/100,000) by far exceed those of their Caucasian counterparts with rates of 230.7/100,000. In the United States, the money expended on cancer alone by the government is over 104 billion dollars annually. The National Cancer Institute gave an estimate of new cases of cancer each year to be 1,221,800 (Mariotto, 2011).

As revealed by the American Cancer Society, over 90% of all cancers are not necessarily genetic in nature (American Cancer Society, 2009). This group of cancers includes breast, lung, stomach, colon, skin and prostate cancers. The etiological agents of these cancers are largely due to tobacco and environmentally induced. These etiological agents are age, use of excessive amount of alcohol, exposure to radiation, chemotherapy, hormone therapy, immunotherapy, radionucleotides. The warning signs of the cancers are sores that do not heal, consistent history of breast cancer in the family, unusual bleeding, lump in the breast, changes in the size of warts, and chronic cough. Genomics interventions and the application of magnetic resonance imaging have revealed the genetic association between BRCA1 and BRCA2 and the onset of ovarian cancer. There are various malignant growths that begin in the breast with ductile carcinoma and lobular carcinoma portraying stage 1, stage 2, and stage 3, which are most receptive to primary and secondary prevention, and prophylactic treatment if detected early (Figure 1). From epidemiological studies, gender is the single most important risk factor for breast cancer, but that does not rule out the onset of breast cancers in males. Family history and genetic etiology are common with BRCA1 and BRCA2. The hormonal replacement therapy, iatrogenic-induced radiation therapy, obesity are also causes of cancer. However, the crucial and most effective intervention against cancer is early detection through breast self-examination, clinical assessment, and mammograms performed at least twice a year. The non-modifiable risk factors are the inherited genes, intra-familial characteristics, parity, age, exposure to radionucleotide, reproductive history, menstrual history, and ethnicity. The modifiable risk factors include obesity, ongoing exercise, breastfeeding, use of alcohol, hormone replacement therapy, use of birth control pills, and infertility or parity status.

Coping with Trends in the Escalating Cost of Breast Cancer

Angela Mariotto reported that the cost of management of cancer could exceed 200 billion dollars by 2020 (Mariotto, 2011). Although the incidence and survival of cancer have improved in recent years, more expensive technology and the changing population characteristics have contributed to the increasing cost of cancer treatment. With the elderly population constantly growing, the cost of cancer management will continue to increase. By 2011, the NIH has projected the cancer costs could reach 158 billion dollars in 2020 (United States Department of Health and Human Services, 2011). Using the demographic data on U.S. population, medical expenditures for cancer in the year 2020 could be very costly due principally to the use of the newly developed tools for cancer diagnosis, treatment, and follow-up.

The environment, diet, and other haplotype characteristics influence gene mutations, which account for at least 5% to 10% of the total ovarian cancers among Caucasian women in the United States and in other parts of North America. Antoniou et al. (2009) reported that BRCA2 is located on chromosome 13 and the risk of developing breast cancer in women diagnosed with BRCA2 mutations is similar to the risk of BRCA1 patients.

After the accomplishment of the HGS by March 23, 2003, many industrialized nations invested their resources to train the new generation of molecular biologists, bench scientists, clinicians, and other behavioral scientists. As a result of the lethal impact of breast cancer and the global financial loss sustained from death and morbidity associated from breast cancer, it is imperative that the Health Belief Model (HBM), which is most applicable and culturally relevant, be applied in disseminating health education to prevent the incipient stages of breast cancer by sensitizing at-risk patients to the predictability of breast cancer from family history analysis. The cautionary caveats echoed by Epstein (2006) focused on the training of clinical medical geneticists, which he emphasized may not suffice to practice innovative genomic medicine. He provided a synopsis of the current training which consists of Mendelian disorders, dysmorphology, chromosomal disorders, inherited metabolic diseases, the multifactorial basis of complex diseases such as breast and ovarian cancer, and cardiovascular diseases, which are caused by high penetrance and susceptibility genes (Epstein, 2006). To function as an effective practitioner of genomic medicine, sound cognitive and eclectic training of medical geneticists and primary care physicians must include population genetics, quantitative epidemiology, bioinformatics, pharmacogenetics, and intensive instruction in population risk assessment, and the ethical legal and social implications of genomics is imperative.

Adoption of the Health Belief Model to Disseminate Global Health Education

Modern genome epidemiologists and prevention research scientists routinely assess logically and statistically, the theoretical models that are most applicable in explaining individual health behaviors that could maximize public health worldwide and minimize the harm associated breast cancer worldwide. The most appropriate model for controlling the incidence of breast cancer is the HBM developed by Geoffrey Hochbaum and associates (Rosenstock, 1966). In fact, among the other behavioral theories, hardly do we find many of them that have transcended cultural and national boundaries as the HBM, the social cognitive theory (SCT) by Albert Bandura and the Innovation Diffusion Model by Rogers (Bandura, 1977).

This theoretical model was developed in the 1950s to explain why medical screening programs offered by the U.S. Public Health Service were not very successful (Hochbaum, 1958). The original concept focused on how human health behaviors are determined by personal belief or perception about a given disease. To Hochbaum (1958), a person's perception is influenced by the range of intrapersonal perceptions affecting a given behavior. That perception which depends on personal factors involves the level of education, and the parental background of the individual. The person's phenomenological experience about the agonizing knowledge that one's mother encountered the morbidity associated with breast cancer and eventually died from the disease can trigger psychological outburst of painful memories. The major theoretical constructs are illustrated in Figure 2. The key components of the HBM consist of perceived susceptibility to a disease such as breast cancer. Genomic interventions and the application of the magnetic resonance imaging have revealed the genetic association between BRCA1 and BRCA2 and the onset of breast cancer and with imminent onset of ovarian cancer. The associated etiological

Figure 2. Natural history of breast cancer

agents for breast cancer are family history, age, use of excessive amount of alcohol, exposure to radiation, chemotherapy, hormone therapy, immunotherapy, radionucleotides, and use of birth control pills, physical inactivity, obesity, and ingestion of dietary lipids. The warning signs of cancers are sores that do not heal, unusual bleeding, solid lump in the breast, changes in the size of warts, and chronic cough.

Family history and genetic etiology are common with BRCA1 and BRCA2. Hormonal replacement therapy, induced radiation therapy, and obesity contribute to the onset of breast cancer. However, the crucial and most effective intervention against cancer is early detection through breast self-examination, analysis of family history, clinical assessment, and mammograms performed at least twice a year by a competent oncologist.

Perceived Seriousness of Breast Cancer

Scientific data reported by the Worldwide Breast Cancer Organization (2013) have revealed how nearly 1.5 million people were diagnosed with breast cancer. In fact, breast cancer is not only the most common cancer in women internationally, but it is also the main etiological agent of death from cancer in the world. As a result of the egress of technological development, even with the high incidence rate in industrialized nations; 89% of the women diagnosed with breast cancer are still alive, five years post-diagnosis. The United Kingdom and the United States have one of the highest incidence rates worldwide, making these nations a priority for breast cancer screening awareness. The mortality associated with the developing nations is probability one of the highest in the world because of late stage of diagnosis and the inadequate medical resources required for the management of breast cancer. Regarding perceived susceptibility, the (International Agency for Research on Cancer, World Health Organization, 2013) emphasized one third of these cancer deaths could be decreased if early screening leads to early detection and prompt medical treatment. On a global context, this implies nearly 400,000 lives which could be saved yearly. The impact of precision medicine which consists of predictive analysis of family history, preventive program, personalized treatment, and participatory activities must be accorded the requisite priority so as to save the lives of women worldwide (World Health Organization, 2012).

Very comprehensive data derived from genomic epidemiology, molecular biology, and oncology have revealed scientific indicators about the high case fatality rate associated with the breast cancer. The incidence and prevalence of breast cancer occur in epidemic proportion not only in United States, but also worldwide. Scientifically, there are several genetic variants of breast cancer. The disease is literally incurable; the disease is associated with the deadly ovarian cancer. The morbidity and mortality associated with the various variants of breast cancer genes demonstrate a heightened concern that the perceived seriousness of breast cancer cannot be overstated. The perceived seriousness of breast cancer should motivate female of child-bearing age to consider participating in regular screening for breast cancer using the services of a qualified oncologist.

Modifying Variables

The major modifying variables identified are the demographic characteristics, socio-psychological and structural variables. BRCA1 and BRCA2 and ovarian cancer affect virtually those women who carry the lethal genes through intra-familial linkages with affected mothers. The World Health Organization (2013) and the American Cancer Society (2012) have confirmed how breast cancer affects a broad spectrum of women with family history of this disease irrespective of their level of education, social class, personality, and education level. However, knowledge about the disease is crucial in internalizing the crucial impact of innovative genomic technology, which has the potential to prevent and save human lives when they are proactive and knowledgeable about the perceived threat of the disease, such as breast cancer, which is very lethal.

The perceived threat of BRCA1 and BRCA2 and ovarian cancer and their variants are extremely high. Epidemiological studies have confirmed that there are the high case fatality and morbidity rates associated with breast cancer. (CDC, 2015)

Professor Geoffrey Hochbaum (1958) meticulously suggested that health behavior is influenced by cues to action. To him, cues to action, are specific events, people, innovative discoveries that motivate people to change their behaviors. Today, innovative genomic epidemiology consistently reveals several lethal variants of BRCA1 and BRCA2 and ovarian cancer. Today, we are able to observe recent diagnosis of a family member with BRCA1 and BRCA2. Besides, we participate in mourning the death of mothers and aunts who are dying from BRCA1 and BRCA2 and ovarian cancers. Among the various cues to action, the most powerful motivating cue is the death of one's mother more so, when a daughter has tested positive (a case of True Positive) for the BRCA1 and BRCA2 gene chromosomes. The probability of having BRCA1 mutation is between 1 in 500 and 1 in 800. The incidence of BRCA2 mutation is even lower. However, among individuals of Ashkenazi Jewish background, there is an increased incidence of BRCA1 and BRCA2 mutations (Kunjumodeen, 2011).

Globalization has exponentially advanced the impact of mass media campaigns and Internet resources which keep flourishing to alert at-risk women to the crucial role of Ms. Angelina Jolie, a humanitarian known for her magnanimity and her international profile of being a mother of six children, a daughter to a mother who died from breast cancer. "The Oscar-winning actress recently revealed in an emotional state that she underwent a double mastectomy earlier this year after a blood test showed she was genetically susceptible to cancer." She further affirmed: "The truth is I carry faulty gene, BRCA1 which sharply increases my risk of developing breast cancer and ovarian cancer." I decided to be proactive and to minimize the risk as I could; I made a decision to have a preventive double mastectomy." (Angelina, 2013; Donnelly; 2013).

In this century, prevention research scientists, geneticists, and the medical scientific community will be moved with so much awe and appreciation to observe the singular act of courage, the vivid and empirical demonstration of cue to action by Ms. Angelina Jolie. Her courageous initiative should accord precision medicine the attention it deserves. Therefore, the international scientific community, medical administrators and world leaders need to create the necessary platform to integrate genomic medicine into conventional medical and public health practice worldwide.

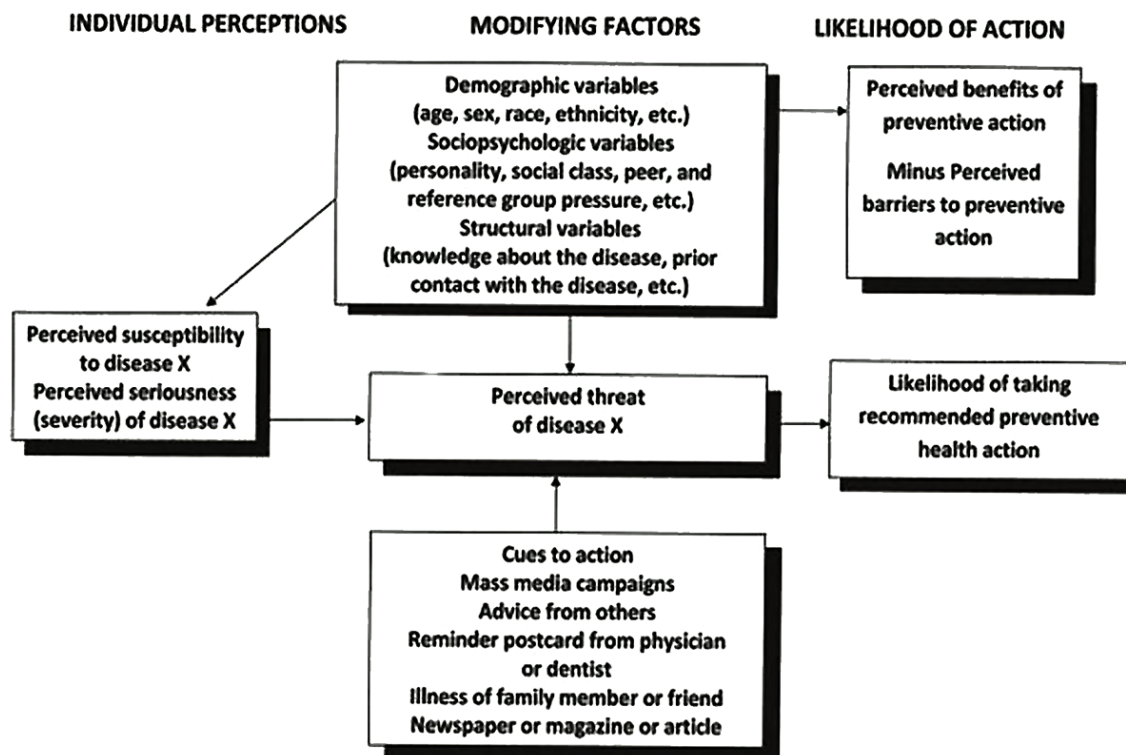

The federal Centers for Disease Control and Prevention (CDC) have intensified their efforts to alert the public by creating global awareness about the unacceptable morbidity and mortality statistics of breast cancer and the ethnic disparities associated with death from this preventable disease.

Apart from postcards mailed to clients by their family physicians, there is a high frequency of public health service announcements mass media campaigns designed to protect the public. Health education programs are provided in many churches whereby volunteer health professional teach the congregation members about the availability of inexpensive screening services being performed in nearby clinics (Figure 3).

Likelihood of Action

Using this framework, the likelihood of taking action, such as screening for breast cancer, could be quite high. On reflecting on commonsense and scientific theory, Hochbaum (1992) maintained that scientists

Figure 3. The Health Belief Model (Hochbaum, 1958)

need to be mindful about Kurt Lewin's widely cited pronouncement that "there is nothing as practical as a good theory."

Self-Efficacy

When the HBM was conceptualized in the 1950s, the concept of self-efficacy was not a component of the model. A plethora of studies by several socio-psychologists created the impetus to incorporate self-efficacy (Rosenstock & Stretcher, 1997). Dr. Bandura (1977) integrated self-efficacy, which he defined as the conviction that one can successfully execute the behavior required to produce the outcome. It is also described as one's ability to perform a certain task or specific function. Self-efficacy, which Bandura (1988) later described as SCT, explained that behavior is determined by expectancies and incentives:

- A. Expectancies about environmental cues; that is, the belief about how events are connected;
- B. Expectancies about the consequences of one's own actions (that is, opinions about how individual behavior is likely to influence outcomes), which is described as outcome expectations; and
- C. Expectancies about one's own competence to perform the behavior needed to influence outcomes.

Based on Bandura's views, incentive (or reinforcement) is defined as the value of a particular object or outcome. The outcome in this discourse, is preventing the deadly consequences of breast cancer.

In personal communication with Bandura (2004), he passionately echoed how the development of self-efficacy in daughters at-risk cohort is developed through parental nurturing, instilling confidence and a sense of self-worth in one's children to enable them to develop based on their genetic endowment. The lived experiences of the children enhance their cognitive, psychosocial, and emotional growth which allows people to make valid informed choices in life about health enhancing behavior such as compliance with preventive medicine.

Perceived Benefits of Preventive Action

The likelihood of taking the desired action is contingent on the perceived benefits of preventive action. Regarding breast and ovarian cancers, the awareness of preventing mortality and morbidity associated with these diseases outweighs the multiple barriers to taking the relevant action such as primary prevention, which includes monthly breast self-examination. This process provides a relatively simple, low-cost technique of early detection that can be performed more frequently than the clinical breast cancer examination. This practice is very crucial for those women with a family history of breast cancer.

The perceived barriers to primary prevention are cost of physician visits for the overwhelming number of women worldwide that are financially indigent. Additionally there are numerous clinical sites, which are not readily accessible to the public, and the cost of radical mastectomy, which could be in the range of 30,000-40,000 dollars. In the United Kingdom, Sumby (Ajmc.com, 2013), who was considering the U.K. for treatment, stated, "Unfortunately, I just received the estimated cost of treatment and it is a whopping 150,000 dollars; where is a 27-year-old with no insurance expected to get such an amount from?" The cost of medical management of BRCA1, BRCA2 and ovarian cancer is prohibitive, mostly if one is medically isolated or without health insurance. This financial hardship is very common in many parts of the world particularly in the developing and least developed nations found predominantly in South East Asia and Sub-Saharan Africa.

In order to mitigate the fear of most at-risk patients, the following list provides the numerous sources of health education to assist at-risk women about the sources of primary prevention and financial assistance in order to be proactive in taking the recommended action in the age of genomic scientific medicine.

IMPACT OF PRECISION (P4) MEDICINE

Biological and Genetic Basis for Personalized Medicine

Powerful and sophisticated genomic technologies have created hitherto unknown innovations to improve genomic medicine. Besides, numerous value-added scientific benefits derived from genomics are now revolutionizing the treatment of patients who suffer from breast cancer. To illustrate, high-throughput technologies, computational frameworks, and molecular biological science and bioinformatics techniques currently facilitate the examination of biological systems in unbelievably copious details. Comprehensive genomic profile of patients which include epigenome, the transcriptome, the proteome, metabolome, and antibodyome, among others, are valuable in the predictive, preventive, personalized, and participatory care of cancer patients.

The recent act of courage demonstrated by Ms. Angelina Jolie, an actress and a humanitarian, in complying with the clinical tenets of precision medicine must be recognized, publicized, and carefully recommended. Besides, Ms. Jolie recently donated the sum of 200,000 dollars to the Malala Fund, an organization for the education of young girls. The recipient informed the audience, which included Hillary Clinton, “I invite all of you to support the Malala Fund and let us turn the education of 40 girls into 40million girls.”(The Guardian, 2013)

In the era of genomic science, insights about precision medicine have been professionally analyzed. According to Dr. Elias Zerhouni, the former director of the NIH, the new medicine must anticipate and interrupt the disease process, thereby preventing the patient from being overwhelmed by the actual disease burden (Ebomoyi, 2010). (Institute for Systems Biology, 2010), defined (1) a predictive approach as the development of probabilistic health projection for a person based on their DNA and protein expression; (2) preventive medicine is the creation of interventions or therapeutic that will prevent a disease; (3) personalized medicine refers to treating individuals based on their unique human genetic variations; and (4) participatory medicine implies a patient’s active, informed involvement in their medical choices, treatment, and acting in partnership with their health care providers. The various accomplishments of effective sequencing of DNA from many types of cancer including breast cancer enable many physicians and competent oncologists to effectively treat at-risk patients even at the incipient predictive stage of their BRCA1 and BRCA2 with effective medical intervention. With pharmacogenomics, chemotherapy is personalized. In the participatory phase, patients are engaged in cooperative network which consists of healthcare providers, the patients and their family members (Zerhouni, 2007).

Health Education Implications

From the Joint Committee on Health Education and Health Promotion Terminology (2001), health education was defined “as any combination of planned learning experiences based on sound theories” such as the HBM, SCT, and the Diffusion of Innovation Model developed by Rogers and Associates. Based on Breslow’s (1999) reaction, “each individual person has a degree of health that may be expressed as a place in the spectrum.” From that perspective, promoting health must place emphasis on enhancing people’s capacity for living and protecting themselves from breast cancer and other chronic and degenerative diseases.

Global health initiatives to minimize the overwhelming mortality and morbidity associated with breast cancer must utilize the international mass media campaign process. The existing global television

networks associated with the Global Health Council, which has linkages with several academic institutions in the world has a duty to include the cancer prevention education in their series of programs. There is have a resounding obligation to inform international viewers about the lethal impact of breast cancer and how innovative precision medicine can drastically reduce the medical, economic, and emotional distress associated with breast cancer (Global Health Council, 2013). Evidenced-based and balanced scientific discourse is required to educate the global community about the importance of genomic innovative medical care. Culturally sensitive, health education videos should be developed; ensuring that learning resources are tailored to suit the religious, economic, educational and societal norms of nations worldwide. The overarching themes must focus on the improving the health status of at-risk women and mothers of child-bearing age. Medical administrators and political leaders worldwide need to develop the requisite platform for integrating genomic medicine into conventional medical practice and public health systems

In 1965, the Centers for Medicare and Medicaid program were established in the United States. The two centers became the major sources of insurance for the elderly and the indigent population. These two programs must be revised to accommodate and reimburse services for predictive, preventive personalized and participatory services. We must emphasize, genomics has revealed the molecular underpinnings of etiology of BRCA1 and BRCA2 and associated lethal gene chromosomes. It is imperative that physicians, nurses, and other clinicians be retrained to become more competent in the provisional of personalized medicine. In providing health education to abate the incipient stages of breast cancer, breast self-examination need to be performed at least twice a month. The advantages of the cultural observances of many societies involving prohibition of alcohol and tobacco use by women need to be encouraged.

Researchers who conducted extensive nutritional studies at Johns Hopkins Medical School recommended consumption of fruits, vegetables, and whole grain, which had been analyzed to contain phytochemical nutrients with antioxidants and antiestrogen. The identified anticancer vegetables include cruciferous vegetables as broccoli, cauliflower, kale, cabbage, and Brussels sprout. The leafy vegetable which are also quite protective consist of lettuce, spinach, Swiss chard, endives, beet greens and romaine. The umbelliferous vegetables are celery, parsley, fennel, carrots, and parsnip.

Vegetables that are the alliums are garlic, onions, shallots, chives, and leeks. The legume series include soybeans, peas, chickpeas, lima beans, peanuts, and dried beans and lentils. The cucurbitaceous group of vegetables includes pumpkin, squash cucumber, muskmelon, and watermelon.

The most appropriate exercise for cancer survivors include walking, bicycling, swimming, aerobic jogging elliptical machines, dancing, and circuit training. The American Cancer Society (2012) recommends at least 30 minutes of exercise at least four days a week. The health promotion initiatives most appropriate for cancer survivors are gardening, shopping, and household chores. These physical activities have the potential to improve human self-esteem, physical fitness, body composition, and overall quality of life. By far most crucial is for all cancer survivors to avoid a sedentary lifestyle, and the use of tobacco and alcohol.

Prevention research scientists, physicians and other educators have the responsibility to alert and solicit the support of the World Health Organization (WHO), the United Nations Educational, Scientific and Cultural Organization (UNESCO), and the United Nations Children Emergency Fund (UNICEF) about the singular importance of harnessing the medical innovation from precision medicine to combat breast cancer ensuring that the services provided are tailored to the crucial needs of women in both the isolated geographical villages and urban parts of the industrialized nations.

ABSTRACT

U.S. regions are expected to follow the national trend towards investment in renewable energy as part of their electricity portfolio. The progress of energy portfolios that typically involves traditional methods, such as centralized nuclear and coal-fired generation, and towards cleaner- and renewable-source generation will impact economic growth and public health. Renewable electricity production must strike a balance among cost, reliability, and compatibility. The economic and health benefits obtained from developing an efficient energy portfolio make renewable energy alternatives an important consideration for regions endowed with natural resources. A portfolio mix of production method that considers the economic benefits while limiting adverse health and environmental impacts is attractive. This research proposes a System Dynamics simulation framework to support policy-making efforts in assessing the impact of energy portfolios. The authors demonstrate the utility of the framework by means of analyzing data that pertain to the U.S. Hampton Roads - Peninsula Region.

1. INTRODUCTION

The development of the modern economies has been significantly influenced by the availability of energy derived from abundant fossil fuels (Toman and Jemelkova 2010). The growing demand of the industrialized and emerging economies suggests that requests for affordable energy is likely to remain (Sorrell, Speirs et al. 2010). Electricity generation is traditionally classified as non-renewable (i.e., conventional)

DOI: 10.4018/978-1-5225-1674-3.ch010

and renewable (i.e., non-conventional) sources. Non-renewable sources of energy production include fossil fuels that are extracted from finite deposits. Nuclear fuel may also be included in this category. Electricity production and distribution from non-renewable sources contribute to particulate air pollution which has been related to health threats, climate change, and reductions in the quality of the built environment (Haines, McMichael et al. 2010).

Since renewable sources are derived from primary sources such as wind and solar energy, they have been termed ‘clean’ sources (Bilgen, Kaygusuz et al. 2004). It has been contended that the utilization of these sources may have comparatively fewer public health effects while maintaining and inducing economic growth since stimulates job creation, and therefore, consumption (Johnstone, Haščič et al. 2010, Wei, Patadia et al. 2010, Timilsina, Kurdgelashvili et al. 2011). However, there are limiting issues associated to the utilization of these sources that include economies of scale, incompatibility with existing power infrastructure, reliability, and negative impacts on viewscape (Jacobsson and Johnson 2000, Painuly 2001, Jacobsson and Bergek 2004).

The development of wind and solar electricity as a sustainable source of energy may have a positive impact on both health- and environment-related issues for a region. These forms of electricity production are becoming widely accepted as reliable as advances in engineering and technology are progressively becoming more efficient. The cost of renewable energy production, many forms of which may be produced domestically if not relatively close to the point of consumption, may be insulated from the severe price swings associated with a heavy reliance on fossil fuels (Akella, Saini et al. 2009). However, there may be economic cost associated to growing regional portfolio’s share of renewable sources. Fossil-based energy production generated electricity is still at a substantial competitive advantage cost-wise relative to its renewable-based energy production counterparts (McVeigh, Burtraw et al. 2000, Palmer and Burtraw 2005). Some have disputed, though, that these shortcomings stem from the fact that the market cost for electricity generated from fossil fuel does not consider critical exogenous variable of energy production related to poor air, water, and ground quality and the attendant public health issues (e.g., Ratliff and Smith (2005)). That is, external to the compilation of the price of electricity to the consumer are the quality of life and medical costs imposed upon the communities. Internalizing these externalities into the cost of fossil-based electricity would, intuitively, lessen the price competitive advantage of fossil- over renewable-generated electricity.

Although the identification and quantification of these factors external to those parties explicitly involved in the transaction may be difficult and counterintuitive to established approaches, the inclusion of these externalities into the cost structure may be necessary for informed policy formation (Haines 2001, Hirschberg, Heck et al. 2004, Oikonomou, Becchis et al. 2009). These costs may be borne by the consumers either directly or indirectly (Menegaki 2008).

The increased production and distribution costs related to newly emergent renewable energy production is largely transferred to the consumer in the costs of goods and services (Menanteau, Finon et al. 2003). Likewise, educational and governmental institutions are also large consumers of energy whose costs are essentially passed along to taxpayers (Owen 2006). Potentially, this may generate an adverse economic effect for the region since an increasing portion of a regional income is spent on energy, therefore, leading to less available resources for investment or purchasing of goods and services. In addition, some territories such as the US territory may present dissimilar sources for renewable energy among endowed regions. Thus, if a region becomes a net-exporter of electricity generated by renewable sources, regional job creation and retention of wealth may materialize (Lund and Münster 2003). An evaluating

structure that acknowledges these relevant interactions is an important goal in reducing uncertainty and informing policy makers.

The goal of this paper is to provide a framework that characterizes an energy portfolio and enables the evaluation of relevant social and environmental impacts that stem from different combinations of energy generation, transportation, and distribution methods. This framework allows explicitly modeling the intersection between potential near-future electric energy portfolios and public health. The inclusion of health-related externalities is essential in assessing the costs of alternate energy source portfolio combinations.

A feasible energy portfolio evaluation that exhibits a reduction of negative health impacts over time assists on creating a favorable public perception towards an electricity generation portfolio. Public endorsement is required to guarantee that further investment flows can be enticed. Although desirable, these measures cannot be independently verified with actual data due to a lack of physical significance attached to them. Nevertheless, they have interpretational relevance and hence are key indicators of interest for policy makers.

To demonstrate the functionality of the proposed framework, the model is both calibrated and simulated using actual data from the U.S. Hampton Roads - Peninsula Region for the years 1996 through 2002. The utility of the suggested framework is confirmed by means of executing a theoretical case study that presets several project investment scenarios.

The following sections of this paper provides a background on traditional views on evaluating energy portfolio, explicate the components that form energy portfolio model, followed by a brief example illustrating the approach. The results stemming from these scenarios are provided. We then revisit and summarize the contributions of this work.

2. BACKGROUND

The production cost of fossil-based generation of electricity has been known to fluctuate greatly over relatively short periods. Short-term instability and uncertainty in oil and natural gas prices may stem from geo-political circumstances as well as both speculated and real disruptions in the supply chain. The cost of renewable energy production, many forms of which may be produced domestically if not relatively close to the point of consumption, may be insulated from the severe price swings associated with a heavy reliance on fossil fuels (Ayompe, Duffy et al. 2011).

Energy portfolio planning has been conventionally viewed as an investment decision problem in which the energy enterprise has to choose among available portfolio options to maximize profits within the context of acceptable risk. It has been typically addressed using the 'least cost approach' in which the production method with the least 'standalone' cost is selected to expand the existing grid.

The Mean-Variance Portfolio (MVP) theory in this context argues that the presence of high priced (often renewable) sources of electricity generation and distribution in a portfolio may not necessarily imply an increase in the overall portfolio price. This may be explained as the portfolio is conditioned upon a reduction in the price uncertainty (risk) involved with such alternatives. The MVP method for evaluating electricity portfolios that assumes a relative stability in the fossil fuel prices and low rate of technological progress and innovation is employed by Awerbuch (2006). Marrero and Ramos-Real (2010), Westner and Madlener (2010), and Guerrero-Lemus, Marrero et al. (2012) also applied MVP theory in which it is considered the average costs and the risks associated with alternative combina-

tions for generating electricity. A recently a detailed report utilizing the MVP theory in the context of a Brazilian electricity generation mix is found in Losekann, Marrero et al. (2013). However, nowadays, the application of these techniques may be limited given the volatile nature of fuel prices (Sunderkötter and Weber 2012). Major world's economies have experienced the adverse economic and political effects stemming from fluctuations in the price of fossil fuels. Thus, it may be argued that assessments of electricity generation options require a more comprehensive 'portfolio analysis' perspective as conventional analysis present substantial limitations in characterizing the uncertain and complex nature of the energy scenarios over time.

Environmental and health concerns have become essential considerations in the energy generation decision-making process. For example, based on perceptions of the public health and the environmental impacts, nuclear power and waste disposal facilities have long been the target of public hostility (Ferreira and Gallagher 2010, Spence, Poortinga et al. 2010, Corner, Venables et al. 2011, Visschers, Keller et al. 2011, Hartmann, Apaolaza et al. 2013). Greenberg and Truelove (2011) indicate a strong public opposition to locate coal fired and nuclear power generation in their vicinity. In contrast, acceptance is relatively higher for renewable energy production in the form of wind power (Swofford and Slattery 2010) and solar (Kaldellis, Kapsali et al. 2012). However, renewable energy production may still face opposition (see West, Bailey et al. (2010) and Bidwell (2013)), although the reasons are varied (see Musall and Kuik (2011), Shamsuzzoha, Grant et al. (2012), and Read, Brown et al. (2013)).

Emissions stemming from fossil-based electricity generation are a primary health concern for local and federal governments. For example, in the U.S. Virginia, on average, the state produced 4.3 lbs of sulfur dioxide, 1.7 lbs nitrogen oxide, and 1,254 lbs carbon dioxide per megawatt hour generated (EPA 2010). Urban areas tend to have higher carbon dioxide emissions relative to rural areas (O'Neill, Liddle et al. 2012). Emissions from coal-fired power plants have long been recognized as contributing to the respiratory conditions, hospital admissions among adults and children, premature births (Yogev-Baggio, Bibi et al. 2010, Cropper, Gamkhar et al. 2012, Liu, Lessner et al. 2012) and premature mortality (Cropper, Gamkhar et al. 2012). Urban air pollution stemming from the combustion of fossil-based fuels is characterized by atmospheric gases and particulate matter. Short-term exposure to airborne particulate matter (PM) in our urban environments has been associated with adverse pulmonary health effects and respiratory distress, for both children and adults (Franck, Herbarth et al. 2011, Maestrelli, Canova et al. 2011, Yeh, Chang et al. 2011, Saravia, Lee et al. 2013). The composition and size of this airborne matter, usually in the form of breathable particles in the range of 10µm or less, allows it to enter the respiratory system resulting in any number of symptoms including wheezing, coughing, infection, and impaired lung function. The literature widely agrees that electricity generation from renewable sources has fewer adverse health-related effects relative to traditional gas- and coal-fired plants mainly due to differences in type and quantity of emissions.

Uncertainty in the availability and cost of fossil fuels contributes to heightened risk that may not be compatible with assuring long-term sustainability in shareholder value. In addition the vagaries of public opinion contribute heavily to the regulatory environment; decision-making processes are vulnerable and responsive to public perception. The impact of electricity generation and distribution on public health and the environment are essential cornerstones in the public's perception. Public objection regarding environmental pollution has become more inclusive covering viewscape spoilage, built environments and neighborhood property values, grid reliability, and wildlife habitat infringement. Simply, the question of what combination of energy generation and distribution network is appropriate has become multifaceted and the most inexpensive option is no longer accepted *prima facie* as the optimal option.

The above discussion illustrates the benefits of portfolio-based analysis of electricity generation and distribution using methods such as MVP as well as relevant aspects related to impacts of energy production. These approaches are yet unable to address the changing decision-making environment over time within which regulatory energy policy and public perception forms. Public participation and consensus are modern components of our public decision-making processes (Rowe and Frewer 2000, Beierle and Cayford 2002, O’Faircheallaigh 2010, Kleinman, Delborne et al. 2011). Energy policy issues are multi-objective and involve competing interests and stakeholders (e.g., utilities, investors, government agencies, and public representatives). Most analysis methods provide limited benefit when it comes to capturing the contribution of participation and consensus building in energy portfolio formation. This paper suggests using a simulation framework to be able to capture and assess complex elements of the decision-making process, e.g., public health, environmental, and economic impacts over time. This characterization forms a framework for evaluating decisions related to the formation of an electricity portfolio through a holistic basis and with due consideration for specific economic and public issues.

3. RESEARCH QUESTIONS AND APPROACH

An evolution in portfolio mix away from traditional methods of generation and towards cleaner- and renewable-source generation can be expected to impact the externalities associated with public health, thus affording the region a ‘health dividend’ (McCartney, Hanlon et al. 2008). In particular, U.S. regions and states can be expected over the next several decades to mirror the trend, seen nationally across many other states, towards experimentation and application of innovative renewable energy approaches as part of its electricity portfolio. However, it is uncertain the various impacts on the intersections between public health, environment, and economic growth stemming from different energy portfolio mixes.

Although the implementation of these programs is attractive from the institutional perspective, the outcomes are less known. As pointed out above, many studies model the population and economic impacts at a macro level while disregarding price volatility and health impacts over time. Thus, this study suggests a System Dynamics framework that allows users to investigate the short- and long-term dynamics associated with adopting various energy portfolio mixes. Furthermore, it allows decision makers to assess prospective adjustments to regulatory policies that may affect cost-benefit relationships among alternatives.

The proposed simulation model allows examination of energy combinations that consider health and environmental impacts while simultaneously considering its economic effects. Größler, Thun et al. (2008) argue in favor of using system dynamics structures for investigating this type of managerial issues since this approach acknowledges feedback loops, accumulation processes, and delays that actually exist and are commonly found in complex problems. The model provides useful managerial insights into how the initial estimates of the energy generation may change as equilibrium among the cited variables are established.

In order to accomplish the central objective, this study will seek to address following specific research questions through proposed model and analysis:

- What are the relevant components of the energy portfolio that considers health, environment, and regional economies?

- What interdependencies are critical for evaluating the performance and sustainability of the energy portfolio mix of an affected region?
- How does a proposed system dynamics framework provide a means to characterize and evaluate energy portfolios?
- What forces create mismatch between supply and demand and how to address this mismatch and potential barriers to energy portfolio?

To provide a response to these questions, it is critical to analyze the effects of different parameters over time. The optimal mix of parameters within an electric energy production, storage, and distribution system designed to maximize efficiency alone may be quite different from a complex mix that balances efficiency with public health. System Dynamics has been extensively used as a reliable approach that captures and analyzes the dynamic, complex interaction among dissimilar subsystems (Sterman 2000).

The use of System Dynamics to analyze complex issues related to energy is not anew. It has been used as a framework to study renewable energy within broader systems (Gravouniotis and Bauen 2008, Gravouniotis, Bauen et al. 2012), e.g., to analyze countries' energy situations (Ballardin, Di Giulio et al. 2008); to determine the best strategy to meet future energy demand while reducing CO₂ emissions (Jogleka and Graber-Lopez 2008); to model changes of energy intensity in residential sectors (Jamshidi 2008). In addition, researchers have successfully included in System Dynamics models searching mechanisms that allow plausible combinations of parameters that optimize a set of goals (Graham and Ariza 2003).

This paper suggest using a System Dynamics approach that includes: (1) identifying electric energy generation sources that have the potential to be included within a near-future electric energy portfolio, (2) defining the public health costs associated with each component of the electric energy sources, (3) modeling the interactions among the source-components and their associated public health costs to produce a best-feasible energy portfolio solution, and (4) simulating and analyzing the proposed energy portfolio.

4. POLICY ENVIRONMENT

The Environmental Protection Agency's Clean Air Interstate Rule (CAIR), targeting largely the eastern half of the United States (east of the Mississippi), compels states to permanently reduce NO_x and SO₂ emissions to predetermined caps by the years 2009/2010 and 2015. Virginia's NO_x reductions, relative 2003 levels, constitute roughly a 53 percent decrease by 2009 and a 61% decrease by 2015 (1.5m and 1.3m tons, respectively). SO₂ reductions are 45 percent by 2010 and 73 percent reductions by 2015 (3.6m tons and 2.5 m tons, respectively). The Clean Air Mercury Rule (CAMR), national in scope, sets for petroleum-based electricity facilities allowances that may be bought and traded in efforts to meet targets set for 2010 and 2018. Conceptually, Environmental Portfolio Standards (EPS), common in many states, set targets for the percentage of electricity sold within the state that must be produced by renewable sources. The State of Virginia itself has set a nonbinding Renewable Portfolio Standard (RPS) for utilities with the state-wide goal of 12 percent of energy sales to be derived from renewable energy by 2022 with an emphasis on solar initiatives (more precisely, 12 percent of 2007 base year sales by 2022 (State of Virginia 2007).

An important number of US States are now covered by renewable energy/electricity standard (RES), with a total of twenty-eight already, which have approved RPS (Solangi, Islam et al. 2011). These standards contain targets for the proportion of a state's portfolio of electricity sources that must be gener-

ated by means of renewable energy. A region's evolution towards a more diversified portfolio of energy sources may be viewed as laudable due to a string of expected benefits derived from such evolution. These benefits may include less dependence on foreign oil, decreased degradation of the environment inclusive of global warming, and a range of community and environmental health issues (Johansson and Burnham 1993, Romm and Ervin 1996). However, given the potential diversity in the composition of a region's electric energy generation and distribution system, there may be great variation in the public health impact (Ratliff and Smith 2005).

The latent renewable energy potential for a region, stripped of other concerns, is driven by geography. Some regions, due to climate, elevation, and proximity to water, may be relatively rich in a particular potential renewable and deficient in others. Some regions have witnessed an emphasis of interest in solar photovoltaic applications due to climate, while others with conducive topography may have a stronger suit in land-based wind- and hydro-generated electricity, and still others with proximity to oceans and bays have entertained offshore wind- and tidal-generated electricity. Secondary to geography, the focus on type of renewable energy source may be conditioned by current land use (e.g., competition with agriculture, urbanization, state and national parks and recreation areas, etc.), public acceptance of altered viewsapes (e.g., horizon containing wind farm turbines, transmission and distribution lines, etc.), and wildlife protection/conservation efforts (e.g., facility encroachment on protected or fragile ecosystems).

Within U.S. Southeastern Virginia there has been, for example, considerable discussion of the potential for offshore wind initiatives within the context of the impact of altered viewsapes on tourism and property values. The intensity and direction of these secondary drivers on the penetration of renewable energy sources into the marketplace has been, and will continue to be, a product of balance struck within the political system. The goal here is not to predict which combination of energy sources will be employed to serve Southeastern Virginia but, rather, to develop a tool that provides referential information regarding the various impacts of likely energy portfolios.

5. THE FRAMEWORK

The model characterizes the electric energy generation sources and their potential to be deployed within the evolving portfolio. This entails considerations of two broad categories, the first of which is the variety of potential energy sources such as nuclear, coal, oil, natural gas, solar voltaic, wind, biomass, municipal solid waste landfill gas, hydro, tidal, and thermal. The electricity production model used in this paper is applicable to thermal power stations only. Thermal power stations may utilize a variety of fuels like coal, light oil, heavy oil, natural gas, and municipal solid waste. The second consideration is the magnitude or centrality of the energy production within any of these energy sources. A distributed-laden system may contain a decentralized network of energy production sites as may be employed in a residential distributed photovoltaic (PV) energy arrangement or may be spatially concentrated to a utility scale as found in concentrated solar power (CSP). A national clean energy smart grid may direct energy long distances over high voltage lines from a renewable-rich region to requiring regions.

The design and construction of traditional electric energy systems has been heavily influenced by the desire to generate reliable, cost-efficient electricity, often at a distance from urbanized areas. The emphasis on cost efficiency led to reliance on energy-rich – and emission-laden – fossil fuels and a more centralized system of production. The public health impact of such an approach has been well documented. For example, for several decades it has been acknowledged that fine particle emissions generated from

the combustion of fossil fuels in the generation of electricity contributes adversely to the health of the residents of a region (Responsibility 2009). But other forms of energy production, including renewable energy sources, while attractive relative to fossil fuels, may have other definable public impacts as well (Krewitt, Friedrich et al. 2002, Rabl and Dreicer 2002). For example, the physical location of a biomass fuel production site, concentrated solar power site, or the more distributed placement of PV and the associated storage and transmission infrastructure (Ferrey 2007) may condition property values and the built environment.

The built environment may condition retail options, recreational choices, and availability of medical venues, all of which may be connected to our health. Collectively, the placement of an electricity network will surely impact the qualitative environment, viewscales, green space, public space, and property values (GAO 1995, Akella, Saini et al. 2009). Further, these changes in the landscape may have disparate impacts upon traditionally underserved populations. Unlike standard assessments of proposed portfolio mixes, our approach captures and quantifies the qualitative public health concepts that traditionally have not been considered an optimal energy source mix within a portfolio.

5.1. Electricity Portfolio Model

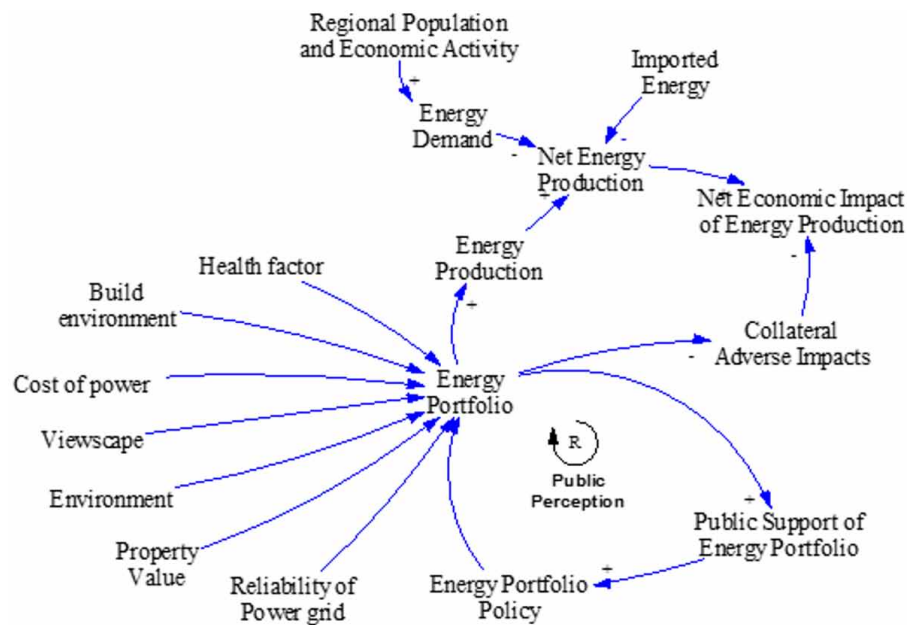

The energy portfolio comprises the electricity generation methods for the particular studied region. The size of each generation facility is characterized as a proportion in the portfolio. The size also determines the relative impact of the generation method on the critical grid attributes and the resulting effect on the grid. The electricity portfolio is primarily shaped by the energy policy and public assessment. Regional Energy Demand and Production is traditionally characterized to estimate the region as either a net importer or exporter of electricity. The net import/export of electricity effect has an economic impact which justifies a region's investment in electricity production.

Energy Demand represents the electricity requirements of a region expressed as a function of the regional population. Utility customers may be household or commercial, with the commercial customers consuming significantly higher amounts of electricity. However, the commercial activity can be assumed as a function of population. As such, the total demand of electricity is expressed as a function of population and per capita electricity consumption (household and commercial). In terms of generation, thermal power plants may utilize specific combinations of the aforementioned type of fuels depending on availability and cost. Also, a number of heat units are consumed to produce one unit of electricity depending on plant efficiency. Assuming constant plant efficiency, electricity produced may be modeled as a function of the quantity of each type of fuel burned and the respective heat content per unit. Figure 1 presents a causal loop diagram that integrates the public health and economic assessment within the energy portfolio. A brief explanation of main components follows.

5.1.1. Portfolio Dimensions

The central idea of the proposed approach is to suggest a mechanism that aids in evaluating each generation method considering the relative importance of relevant attributes. Based on the energy portfolio literature and the context discussed above, the following portfolio dimensions have been deemed as significant in terms of the impact that generate on energy portfolios:

Figure 1. Causal-loop diagram

- **Reliability:** This factor represents the capability of a particular source to supply electricity with minimal and predictable interruptions. Generally, conventional sources of power are known to have higher reliability. Renewable sources such as wind and solar are known to be less reliable. Other factors that may influence reliability are fuel availability and the risk to supply disruptions;
- **Impact on Build Environment:** Neighborhoods in the vicinity most type of power plants and distribution infrastructure contribute to poor build environment. Power plants are likely to cause air and noise pollution. The local water sources may also be affected. Perceived radiation concerns are associated with nuclear plants, while wind power generation may contribute to noise pollution. In many cases, power plants will have a negative impact on the surrounding residential communities;
- **Impacts on Property Value:** The value of properties in the vicinity of power plants is likely to depreciate as they lose their attractiveness and perception that proximity may increase health risks. This may not be an issue if the plant is located in an industrialized zone or away from residential populations. The relative impact of this factor also depends on the type of power plant under consideration as well as the initial value of the properties impacted;
- **Impacts on Viewscape:** Obstructions of hill views or interruptions of horizon views from beaches are considered viewscape degradation. This particularly is an issue with wind power generation. This factor may have negative impact on tourism as well as on high valued properties in the vicinity. This may generate public opposition;
- **Cost:** A portfolio that contributes to an overall increase in the electricity cost is likely to draw public criticism. Generally, conventional sources are known to be the most inexpensive. However, as mentioned previously, other approaches like MVP may be able to lend economic justification for costly renewable sources, especially in light of highly fluctuating fossil fuel prices;

- **Environmental Impact:** This factor considers the likely environmental impact of the proposed project. This depends on the awareness among the public on environmental issues. It is anticipated that this factor will have a strong influence on public support for the portfolio under consideration;
- **Public Health Impact:** This factor attempts to take into account the wider impact that electricity generation has on wellness;
- **Cost Impact Evaluations:** This dimension captures the assessment of the aforementioned factors using a monetary cost perspective. The results are deducted from the net anticipated economic benefit of the proposed portfolio project. In spite of the limitations imposed by capturing these costs, attempts are made to include and evaluate such factors. Such attempts are a critical necessity to evaluate potential environmentally sustainable energy generation;
- **Net Economic Benefit:** The net economic benefit factor forms a basic framework for evaluating the net economic impact of the proposed portfolio. Export of electricity from the region is considered as a positive economic impact, while import of electricity is considered as a negative impact. Similarly, public health and environmental cost impacts are deducted from the net economic benefit.

5.1.2. Evaluation Scheme

The evaluation scheme employed in this framework is centered on calculating the Scored Net Benefit and expressed as a weighted sum of the grid attributes as described above. Thus, different portfolio combinations may be evaluated on the basis of their performance on the 'Scored Net Benefit' factor. Furthermore, the factors indicated above are used to rate each type of power on each on reliability, build environment, property value, viewscape, and cost using the Likert scale (1-5).

The score is then multiplied by the share of that particular power type in the portfolio. This calculates the contribution of that power type in the overall score of that particular factor. The power types considered in this paper include Renewable power, Fossil Fuel power, and Nuclear power. The environmental factor is expressed as a function of the share of renewable energy in the portfolio. Then, cumulative scores obtained from factors per type of power type are determined. Each of these factors is multiplied by a weight assigned by subject matter expert (SME) to take into account the relative importance of each factor in public support and the resulting values are added together to get the final value of 'Scored Net Benefits.'

Notice that the development of a mathematical rigorous economic and environmental analytical framework is beyond the scope of this paper. This framework provides measures of performance relative to cost benefit of competing portfolios. Although this framework is not designed to provide prediction in real terms, it provides a starting point to incorporate and develop more sophisticated economic measures of performance. The scheme suggested in this work may assist decision makers in anticipating likely reactions to particular electricity portfolios in the consensus-building and decision-making process.

6. CASE STUDY

U.S. Virginia as a whole, and Southeastern Virginia specifically, can be expected over the next several decades to follow the trend towards the application of state-of-the-art renewable energy method as part of its electricity portfolio. The portfolio of sources employed in the generation of the total megawatt

hours produced state-wide includes coal-fired (38.7 percent), natural gas-fired (18.8 percent), petroleum-fired (1 percent), nuclear (35.9 percent), hydroelectric inclusive of pumped storage hydro (3.2 percent), and other renewables including geothermal, photovoltaic, wind, municipal solid waste biogenic, and biomass (2.2 percent). Exclusive of pumped storage hydroelectric, in total renewables account for just 3.8 percent of the electricity generation.

Currently, there is negligible solar and wind contribution to the power grid serving greater Hampton Roads. While the region's potential for engaging renewable energy sources has not yet been realized, there are technological, geological, atmospheric, cultural, and social parameters that place practical limits on both the state and region's capacity to evolve its energy portfolio towards renewable energy generation. Despite the technological advances in the design and construction of wind, solar and geothermal systems within the past 40 years, the initial capital cost to purchase and install many of these systems make them, in the short term, less economically attractive relative traditional sources of power such as coal and natural gas (Karmis, Abiecunas et al. 2005). Government regulation can help spur the development, adoption, and implementation of clean coal technologies, but their emissions are still greater than other generating technologies (Center 2000). Despite these very real constraints, the size of the region's appetite for electric consumption has grown by roughly 3 percent per year. The Virginia Energy Plan, adopted by the state in the Fall, 2007 and extending through 2016, seeks to slow this rate of growth (especially through energy conservation) as well as increase electricity production to meet the expanding demand.

6.1. Energy Sources

The U.S. Hampton Roads region is home to three coal-fired plants, two natural gas plants, and one of the state's two nuclear power plants (the plant, in Surry County, contains two reactors). Aside from nuclear, coal is the state's primary resource for electricity generation. While the majority of Virginia's coal resources are located in the Central Appalachian Basin (Dickenson, Wise, and Buchanan Counties), roughly one-third of the coal consumed for electric power generation comes from the nearby coal fields in West Virginia and Kentucky. In addition to this 'imported' coal, in total nearly one-fifth of the electricity consumed within Virginia comes from neighboring states. In this context, the model includes as energy sources: load production, Wind, Photovoltaic, Landfill Gas, Hydro Electric, and Biomass.

6.2. Public Health

The complexion of the energy system is dependent, in part, on advancements in technology and the public's acceptance of the risks and costs associated with adopting the technology. The availability and access to affordable technology condition public health. In less developed regions, fuels such as wood, charcoal, and coal may be used for cooking and heating within the home, contributing to poor indoor air quality and associated poor health conditions. In more developed regions where the combustion of fuel is centralized and the generated electricity is distributed, the health-related impact stemming from proximate biomass conversion within the home is reduced (Wilkinson, Smith et al. 2007).

The current system is dominated by the coal- and gas-fired generation of electricity at centralized locations and the high voltage transmission across long distances to stations where it is distributed at lower voltage within a localized system. Relative to pre-centralized energy generation, the use of petrochemical products and the centralized generation of fossil-derived electricity has contributed substantially to better health and increased quality of life (Wilkinson, Smith et al. 2007, Frumkin, Hess et al. 2009).

In addition, modern industrialized nations have seen gains in energy efficiency (e.g., decreases in the amount of energy to produce a lumen of light, propel an automobile, transport via airplane a person or cargo across the continent, or heat a typical residence). However, these efficiencies have also coincided with the overall growth in both affluence and energy consumption which, in turn, implies increased emissions stemming from combustion of fossil-based fuels (Tatum 1994).

Combustion produced emissions associated with electricity generation is a primary health concern. On average, the state produced 4.3 lbs of sulfur dioxide, 1.7 lbs nitrogen oxide, and 1,254 lbs carbon dioxide per megawatt hour generated (EPA 2010), although urban areas tend to have higher carbon dioxide emissions relative rural areas (Parshall, Gurney et al. 2010). Emissions from coal-fired power plants have long been recognized as contributing to the respiratory conditions and hospital admissions among adults and children (Cifuentes, Borja-Aburto et al. 2001, Peel, Metzger et al. 2007, Szyszkowicz 2008) and premature mortality (Hermann, Divita et al. 2004).

Urban air pollution stemming from the combustion of fossil-based fuels is characterized by atmospheric gases and particulate matter. Short-term exposure to airborne particulate matter (PM) in our urban environments has been associated with adverse pulmonary health effects and respiratory distress (Dockery, Ware et al. 1982, Ezzati, Lopez et al. 2002, Dockery 2009). The composition and size of this airborne matter, usually in the form of breathable particles in the range of 10 μ m or less, allows it to enter the respiratory system resulting in any number of symptoms including wheezing, coughing, infection, and impaired lung function. We can place an economic valuation (from a statistical life approach) on the premature mortality, illness, loss from work, and occupational exposure associated with the various combinations of electricity sources within an energy portfolio (e.g., Bird, MacIntosh et al. (2004), and Levy, Baxter et al. (2009)).

Electricity generation from renewable sources has fewer detrimental health-related outcomes relative to traditional gas- and coal-fired plants due to differences in type and quantity of emissions. While particulate matter in the form of air pollution possess a particular burdensome health concern, the construction and maintenance of the power systems including the transmission and distribution systems impose occupational hazards (Bird, MacIntosh et al. 2004) as well as the potential for accidents and terrorism (Karmis, Abiecunas et al. 2005).

Health disorders among the residents proximate conventional electricity generation, especially thermal power plants, have long been attributed to the presence of the plant. A host of disorder may arise due to air and water pollution resulting from power plants. In the present study, an attempt is made to statistically model the relationship between particulate pollution caused by thermal power plants and the occurrence of asthma in the surrounding area (measured by the asthma discharge rate).

Fine particulate matter (PM_{2.5}) has been known as a dominant cause for aggravating asthmatic conditions in patients with this disease. Sources of PM_{2.5} can be broadly classified as mobile and point sources. The major mobile source of PM_{2.5} is vehicular traffic (on and off road) while a major point source are power plants. Laden, Neas et al. (2000) have reported that PM_{2.5} emissions from mobile sources have greater impact on public health as compared to non-mobile sources. However, they also warrant that the results need further validation. Hence, this study initially assumes that the emission from the power plants have a less impact as compared to mobile sources. This is accomplished assigning relevant weights to the respective emission source. As indicated by Laden, Neas et al. (2000), investigation to validate this assumption in this context is necessary.

Modeling Energy Portfolio Scoring

The PM2.5 emission from a thermal power plant will depend on the type of fuel burned. This relation has been expressed as multi factor regression in the present study. Modeling the emission factors for other point sources, mobile sources are beyond the scope of this study.

6.3. Data

Energy production rates are obtained from 1996-2006 and consider monthly plant-level data on generation, fuel consumption, stocks, and fuel heat content from utility and non-utility power plants (EPA, 2013). These data points are collected monthly from a model-based sample of plants. A regression-based imputation procedure is used to estimate state and national totals from the sample. After the end of the calendar year, annual data is collected from all plants not in the sample. The facility level data is for the most part observed data collected from the survey frame. Values for some observations may be estimated since either the facility did not respond in whole or part to the survey, or the observed data failed edits and could not be corrected or verified. In such case, the estimation procedure involves using a regression technique to determine generation values. Theoretical values include those assigned for a weighted evaluation scoring process that involves key portfolio attributes: Health factor, Build Environment, Environmental factors, Property Value, Reliability of Power grid, Viewscape, and Cost of power.

6.4. Numerical Analysis

The ability of the framework to support decision-making processes is evaluated in terms of its capacity to generate reliable output data by providing a simulation-based scoring method. The expectation is that the output data from the simulation model reflects actual data, thus, simulated values from the proposed model are generated without utilizing the actual values of the same parameter.

Three measures of performance in terms of energy production, public health, and environmental impact are thermal power generated, emission from power plant, and the asthma discharge rate per ten thousand population. Table 1 exhibits PM2.5 emissions for the Hampton Roads while Table 2 display the actual versus simulated values for power generation. The simulated values are based on regression equations generated to model the relationship between the corresponding predictors and response. These equations are embedded into the model and measures of performance are collected after model execution.

Table 1. Actual vs. simulated PM2.5 emissions

Year	Actual Emission PM2.5	Simulated PM2.5 Emission	Difference
1996	607	556	8.44%
1997	553	598	8.17%
1998	1,301	1,312	0.88%
1999	1,465	1,426	2.67%
2000	1,393	1,390	0.23%
2001	1,686	1,698	0.72%
2002	2,159	2,138	0.95%

Table 2. Actual vs. simulated power generation

Year	Actual Data (MMBTU)	Simulated Data (MMBTU)	Difference
1996	2,532,448	2,502,136	1.20%
1997	2,504,799	2,497,177	0.30%
1998	3,778,792	3,812,902	0.90%
1999	4,166,928	4,087,986	1.89%
2000	3,560,256	3,596,655	1.02%
2001	5,014,009	4,908,059	2.11%
2002	574,553	502,363	12.56%

The comparison of actual and simulated values demonstrates a very close match which is expressed in the column *Difference*.

Comparison of actual and simulated asthma discharge rates is shown in the Figure 2. These results indicate that there is a reasonable match between actual and simulated values trend-wise. The deviation observed at some points can be attributed to other factors that are known to affect asthma patients but are out of scope of this study (e.g., natural factors like pollen, weather conditions such as humidity and temperature). However, as described by its behavior, the model is capable of mimicking asthma discharge rates for the region, which may be used to assess the impact of combinations of energy sources on such public health.

The primary parameters of interest in the output of the simulation are the ‘Expenses for the region’ from the portfolio and the ‘Net Benefit’ considering both public health and environmental impacts. Three potential theoretical scenarios that represent different portfolios combinations subject to discussion, adjustments, and approval from stakeholders may be described as follows. The scenario 1 represents a rather conservative energy portfolio that denotes a potential status quo of the current situation in which weights corresponding to Health, Build environment, Environmental, Property Value, Reliability of Power grid, Viewscape, and Cost of power factors are relatively low and maintained constant. The sec-

Figure 2. Actual vs. simulated asthma discharge rates

ond scenario represents a moderate situation in which a relative importance is assigned to Health and Environmental factors while it assumed that reasonable investments are realized in the cleaner technology energy sector. The third scenario portrays a situation in which substantial importance is given to Health and Environmental factors accompanied by significant investments in renewable energy-generating technology that decreases the importing of energy from other regions. In the first scenario, is assumed that revenue is limited to \$6.22 per unit produced. The revenue value per unit produced is assumed to be \$6.67 and \$7.24 for scenarios 2 and 3 respectively. These values assume an increase in the development and implementation of regional renewable technologies that decreases the necessity of the region to import energy from other states. Due to increases in regional energy consumption, increases in the magnitude of revenue per unit generated in the region are assumed. Results from the simulated environment in terms of net benefits for the region are exhibited in Figure 3.

As indicated, these measures cannot be independently verified with actual data since their lack to physical significance linked to them. Nevertheless, they have interpretational relevance, and hence, are relevant indicators of interest. Net Benefits for the region, shown in Figure 3, as stated before, stimulates public perception of the value of renewable electricity grid serving the affected population. Since the public is the ultimate customer for the grid, their perception is an important consideration in portfolio investment decisions. As expected, the conservative scenario (Scenario 1) does not show any significant change as the time goes by. In contrast, the moderate and significant renewable energy-generating investment situations show larger net benefits for the region as the time progresses. Clearly, the risk of the third scenario is higher as this scenario assumes that higher investments in renewable energy-generating lead to improvements in the reliability of the grid and obtainable economies of scales. Benefits of renewable energy for population health and the environment are largely documented in the literature. For example, as fewer particles are discharged in the environment due to the use of renewable energy technology, the expenses for treatment of asthma patients are expected to decrease for the region. As the number of people who suffer asthma decreases, the higher is the probability of incorporating these individuals to the regional workforce. It is widely known that this increase in the workforce leads to an increase in consumption and the revenues generated by taxes paid by these individuals that ultimately impact the economic growth of the region. The expenses for the theoretical scenario for region are presented in Figure 4.

Figure 4 indicates that Regional expenses decrease by scenario as more renewable energy portfolios are implemented. The linear increase observed in each scenario may be attributed to the increase of energy consumption in the region. The scenario that presents the most conservative portfolio costs more to the region since it assumes that renewable technology is marginally developed. This cannot offset the cost generated by importing energy from other regions. Scenarios 2 and 3 show cost improvements as the region becomes less energy-dependent from other regions while embracing renewable-energy technologies that positively impact the quality of life of the citizens that reside in the studied region. As indicated above, this scenario also assumes that an increase in the dependability of renewable portfolio is realized, and thus, potential economic efficiencies may be developed.

7. CONCLUSION

The evolution of an electricity portfolio does not take place within a static regional environment; it is expected that the region's demand for electricity will grow over the coming decades, despite conservation

Figure 3. Trend for net benefit

and efficiency. Growth in the share of the region's electricity generation stemming from renewables (and less carbon-intense methods) does not necessarily assure a decrease in related disease and chronic conditions. It is conceivable, with the expansion in demand, that even modest growth in renewable-generated electricity may cover only this increased demand, let alone the replacement of electricity generated from retiring coal-fired plants or less-emissive gas-fired plants. The complexity of the system is evident: there is an imperative to meet existing demand as well as the anticipated growth in demand, but this is within the constraints of the EPA's regulations and emissions caps, maintaining reliable and affordable electricity, and improving the quality of public health. The diffusion across the U.S. Hampton Roads region of less carbon intense forms of electricity production may not solely be a matter of technology, but one of cautious acceptance as the socio-political environment weighs the competing cost-benefit claims relating to economics and community health.

Embedding an optimization model that efficiently explores the complex decision space is proffered to find the optimal values considering the nature of the energy sources, storage, and transmission, as well as the health within communities. Thus, we envision developing and incorporating the most effective

Figure 4. Expenses for the region

optimization technology to determine the set of values that solve the multiple and conflicting goals of maximizing energy efficiencies, minimizing non-renewable fuels, while minimizing socio-economic impact. Thus, future research includes embedding and adjusting a goal-seeking structure that assist in finding the values that strike these balance between these conflicting variables. An investigation of the elasticity related to relevant variables is required to accomplish this goal.

Chapter 11

A Framework to Analyze Variation of the Satisfaction of Patients for Outpatient Needs: A Case of West Bengal, India

Arnab Jana

Indian Institute of Technology Bombay, India

Noboru Harata

The University of Tokyo, Japan

ABSTRACT

This study explored outpatient healthcare seeking behavior in India and estimated predisposing and enabling factors that influenced the satisfaction derived from the health care activity. The study assumed that if these gaps are fulfilled in the local facilities, this might invigorate lesser popular public providers within the neighborhood. The study was conducted in the state of West Bengal India. A multilevel framework was developed to incorporate factors affecting the satisfaction of the healthcare activity. Analysis revealed dependency on regional facilities and extensive traveling. Excessive traveling affected satisfaction negatively whereas in cases where respondent availed services from local primary health centers had positive impact on satisfaction. On the route to daily activity, ability to visit referred facility and visit to facility with modern amenities often triggered satisfaction. Segmented policy designed to fulfill these preferences might be indispensable to enhance local sufficiency.

1. INTRODUCTION

Ensuring availability, accessibility, affordability and acceptability of health care facilities might facilitate outpatient needs in developing countries. Providing appropriate health care facility within the neighborhood is a necessity to incubate self-sufficient neighborhoods and to enable outpatient health care activity. Health care seeking behavior in developing nation like India depicts a complex tradeoff manifested by variations in selection of health care facility and travel patterns. It is generally hypothesized that demand

DOI: 10.4018/978-1-5225-1674-3.ch011

supply mismatch (*enabling factors*) often instigate search for opportunity based on *predisposing* factors, further influenced by *needs* (Andersen, 1968). Traveling for longer period, dependency on existing social networks, & delay endorses low acceptability and mismatch of expectations especially due to defunct and dilapidated state of the health care facilities plagued with lack of trained medical personnel. In the context of India, detouring of the local facilities have been observed and reported (Duggal, 2001), consequently, local public health care facilities often are unable to attract consumers (K. D. Rao, Peters, & Bandeen-Roche, 2006) and remain underutilized.

In India, governmental initiatives have often been criticized for concentrating more on building health care infrastructure while neglecting policy measures to assure quality and integrate hierarchy and referral systems (Nundy, 2005). As availability of public facilities were being ensured, Ergler, Sakdapolrak, Bohle, and Kearns (2011) based on their study in India, reported that availability of health care facilities (HFs) within walking distance is a necessity but does not ensure satisfactory access. Inability to provide patient centered facilities (for details see (Jayasinghe et al., 2008; Stewart, 2001)) often expanded the gap, generating mistrust and forsaking of the service, in both urban and rural areas (Hammer, Aiyer, & Samji, 2007) highlighting 'acceptability'. Private HFs although are often accused of inequity and consumer exploitation (Purohit, 2001), attracted patients as it filled in the gaps, by providing user friendly interfaces. It has been reported that between 1986–7 and 2004, the absolute expenditure per outpatient visit and inpatient visit in rural and urban areas have increased phenomenally (K. S. Rao, Selvaraju, Nagpal, & Sakthivel, 2005). However it should be noted that all public facilities, including general outpatient wards or specialized services, offer services at nominal prices (Kumar et al., 2011). In this context, the field surveys conducted in West Bengal, India, yielded the following observations: It was observed that although the local public facilities might be cheap, but overall health care seeking episode often remained incomplete due to defunct medical equipment or unavailability of prescribed medicines. Therefore, consumers tend to (1) undertake additional commuting to other facilities and (2) often spent beyond their expected limits, with undesired consequences such as health shock (Mahal, Karan, & Engelgau, 2010). Regional public services were mostly overcrowded and the patient to doctor contact time was relatively low. Those visiting private general physicians (GPs) incurred higher out of pocket expenditure but experienced satisfactory contact period. People in general opined that single window health services (enablement) often added to higher satisfaction as it reduced insecurity and uncertainty.

Inherently, patients and their family often undertook complex trade-off to engage in health care activity. Predisposing factors such as preferences, attitude, and trust played a vital role in health care seeking behavior and often affected the overall satisfaction of the health care seeking activity. Researchers often regarded satisfaction as a function of expectations and experiences of the users (McKinley & Roberts, 2001; Thompson & Sunol, 1995) and considered satisfaction as an indices of service delivery and means for evaluation of the HFs (Baker, 1996). In this purview, it can be argued that higher satisfaction might assure continued use of the selected medical service (Jang, Kim, & Chiriboga, 2005; Thomas & Penchansky, 1984). For outpatient health care activity, enablement factors such as, wait for an appointment, ease of access to information, and sympathetic communication, is reported to affect satisfaction significantly (Salisbury, Wallace, & Montgomery, 2010). However, there are limited numbers of studies that looks into interaction of the predisposing and enabling factors on the satisfaction of the outpatient health care activity in developing nations, under variable constraints and tradeoffs. Our quest in this research is to (1) assess the role of predisposing and enabling factors on satisfaction of health care activity, (2) analyze the interaction of the factors at two levels, namely patient level and HF level and (3) formulate strategies to improve the user ship of public HFs.

The following sections are organized as follows. In the second section, the suggested methodology and the data is described. Section three elaborates the results of the application of the suggested framework on West Bengal, India, following a discussion on the policy implications. The final section concludes the study.

2. METHODOLOGY AND RESEARCH FRAMEWORK

In line with the ‘Andersen’s utilization of health care model’ (Andersen and Newman, 2005; Andersen, 1995), the authors argue that two distinct levels of interactions interplayed in the health care seeking process: Firstly, the ‘predisposing’ characteristics of the patients and secondly the ‘enabling’ factors (extrinsic health care facility characteristics). It is evident that the enabling factors influence the health care seeking processes at the individual (patient) level. Hence, the constructs are defined at different levels, and the hypothesized relations between these constructs operate across different levels. Identification of the factors at both levels might be helpful in health care infrastructure planning and policy formulation, while improving 4As on one hand and increasing the user-ship of local public HFs on the other. Table 1 describes the predisposing and enabling factors used in the analysis and following sections describes the variables briefly.

The “self-rated satisfaction” was considered as the dependent variable. The respondents were asked to answer the following question “Rate the satisfaction of the health care seeking activity considering travel and health care activity in the scale of 1 to 5?” Following the rule 1 = highly unsatisfied and 5 = highly satisfied.

Variable depicting location based socioeconomic status, ‘enabling’ travel characteristics and associated social interaction and collaboration, ‘predisposing’ characteristics of the patients and the ‘need’ have been included at the patient level. It is noteworthy to mention that the authors did not consider the educational parameters as Muller (2002) pointed out that the lack of a high school education accounts for an income inequality effect.

Demographic data and socioeconomic status - In accordance with the brimming disparity between urban and rural areas in India and differential price indexes, the authors defined the location into three sub groups namely, urban, rural and suburban; and economic status into two subgroups namely ‘poor’ and ‘others’. Economic segregation were derived based on: Occupation pattern such as ‘poor’ were represented by temporary labor jobs, rickshaw pullers, workers at unorganized sectors etc., whereas those with permanent jobs, regular wage earners, professionals and entrepreneurs were classified as other. The economic classification was further verified with respect to type of cooking fuel used. Those using firewood, coal, coke and dung cakes were classified as poor. The location based economic variables were thus subdivided into six groups (see table 1).

‘Enabling’ travel characteristics and need for social interaction variables have been incorporated as follows:

- One-way travel time from patient’s residence to the selected HF
- Type of trip; which was segregated as local trips or regional trips, where local trips are those which are restricted within one’s own neighborhood/district, whereas, regional trips are those which are beyond one’s own district or even state (but within country) (Bardhan, Varghese, and Jana, 2015).

A Framework to Analyze Variation of the Satisfaction of Patients for Outpatient Needs

Table 1. List of variables

Variable Name	Description	
IID	Patient code	(n=125)
HID	HF code	(n = 42)
Overall Satisfaction	Dependent Variable; Revealed satisfaction of the patient Scale: 1= Strongly dissatisfied (4%); 2= dissatisfied (17.6%); 3=neutral (24.8%); 4=satisfied (45.6%); 5=Highly satisfied (8%)	
Predisposing factors (Individual Characteristics)		
Travel time	One way travel time from the patient's residence to the chosen HF (in minutes).	(μ=29.33; σ=48.68)
Number of companions	Number of accomplice in the trip	(μ=1.10; σ=0.76)
Automobile Availability	Number of motorized vehicles available in the household	(μ=0.85; σ=1.02)
Trip	Type of trip; 0 = same day; 1 = multi day	
Location and Economy	Socio economic segregation based on the location aspects. 1 = Urban Others (35.2%); 2 = Urban Poor (16%); 3 = Suburban Others (20%); 4 = Suburban poor (8%); 5 = rural others (16.8%); 6 = rural poor (4%)	
Need		
Disease typology	1 = long term non critical illness (D1); 2 = long term critical illness (D2); 3 = short term non critical illness (D3); 4 = short term critical illness (D4);	
Enabling Factors depicting availability, accessibility, affordability, and acceptability (4As)		
Connectedness	1 = if the reason of selection of doctor is accessibility; else 0	(μ=0.26)
Goodwill	1 = if the reason of selection is reputation of the doctor ; else 0	(μ =0.50)
Price	1 = If the relative price of the chosen HF is cheaper; else 0	(μ =0.36)
No other option	1 = if the patient is familiar with the HF or knows somebody in the HF; else 0	(μ =0.40)
Referred	1 = If the patient have been referred to the HF ; else 0	(μ =0.21)
Family Doctor	1 = If the visited doctor is family doctor; else 0	(μ =0.66)
Modern amenities	1 = if the reason of visit is the higher LOS; else 0	(μ =0.18)
On the route	1 = if the HF falls on the route to the work place; else 0	(μ=0.17)
Convenient timing	1 = if the chosen HF falls within the convenient time of the patient and the respective companions; else 0	(μ=0.30)
Collaborating households	Number of participating households in the health care episode	
Enabling Factors (Characteristics of the HF)		
Provider	Typology of service provider; 1 = Public and 0 = Private	
LOS	Level of service of the HF 2 = LOS-2; 3 = LOS-3; 4 = LOS-4; 5 = LOS-5;	
Overall cost	1 = Low; 2 = Medium; 3 = High The overall cost of the health care activity has been calculated taking into account the cost of transportation, health care service, medicine and allied diagnostic checkups. Assuming that the price component associated with the travel and other allied are indispensable, the authors converted the continuous cost variable into categorical variable by agglomerative hierarchical clustering method (Clatworthy, Buick, Hankins, Weinman, & Horne, 2005) in R (version 2.15.2). We divided the data into three cluster based on the squared Euclidean distance between the pair of objects measuring (dis) similarity between pairs.	
Waiting time	Waiting time of the patient at the HF. (in minutes)	(μ=43.99; σ=32.04)

A Framework to Analyze Variation of the Satisfaction of Patients for Outpatient Needs

- Number of motorized vehicle (two and four wheelers) available in the household.
- Information on accomplice and interaction among different households in activity

Measuring predisposing and enabling variables constituting availability, accessibility, affordability, and acceptability (4As) - The purpose was to understand the influence of subjective and cognitive understanding of the patients on variables such as, ease of access, familiarity, quality of service and price.

- Accessibility:
 - a. Connectedness & spatial accessibility - if the reachability of the HF is considered high
 - b. Trip chaining - on the route to daily activity and
 - c. Temporal accessibility – if no rescheduling of general activity is observed by the patient and companions.
- Acceptability
 - a. If the selection was due to the unavailability of the preferred HF,
 - b. If referred by a well-wisher
- Availability
 - a. No other options
 - b. Reputation or goodwill,
 - c. Availability of modern facility and required amenities and
- Affordability
 - a. Expected price suiting the budget of the patient.

2.1. 'Enabling' Health Care Characteristics (Facility Level)

To analyze the effects of the health care infrastructure on the patients, following variables were considered: the type of service provider (public or private), the LOS of the service provider, activity wait time at different HFs and the reported total expenditure towards the health care activity. Cost of service becomes imperative due to unavailability of outpatient medical insurance system. However, the public health care service fee is nil in rural primary health centres (PHCs), public health care dispensaries in urban areas charged a nominal registration fee. In most of these public facilities, diagnostic tests are also conducted free of charge with certain documentation and provide medicines free of cost to the patients depending on availability. In private facilities, there is a cost component associated with all the services.

Considering the ordinal nature of the dependent variable, the authors applied ordinal probit regression technique on a hierarchical data. Ordered probit models have been quite widely used to analyze self-rated responses in patient and consumer satisfaction (Carlsena & Grytten, 2000), health status (Rivera, 2001), and severity analysis (Abay, 2013; Yamamoto, Hashiji, & Shankar, 2008). Application of multi-level models has been effective in several health care and related researches (Ichida et al., 2009; Murayama, Wakui, Arami, Sugawara, & Yoshie, 2012; Oshio & Kobayashi, 2009). Additionally multi-level models could be instrumental in analyzing patient's experience and satisfaction. Moreover, this methodology might be appropriate for avoiding atomistic fallacy (Hox, 2002), ecological fallacy (Freedman, 1999), introduction of independent variables from different levels and to allow interaction of variables between levels. The model assumed that the regression coefficients apply equally to all contexts (Goldstein, 2003; Luke, 2004). For example, individuals visiting different HFs, presumed that the given selection

would yield higher satisfaction over the others and this selection was again a function of several enabling characteristics of the HF itself.

To analyze the effects of the ordinal responses, it was assumed that there was an unobserved latent variable (∂) which was related to the actual response through the “threshold concept”. In this research as there are five responses (see Equation 1), hence threshold values $\partial_1, \partial_2, \partial_3$, and ∂_4 were assumed, where $\partial_0 = -\infty$ and $\partial_5 = \infty$.

$$Y_{ki} = \begin{cases} 1 & \text{if } -\infty \leq Y'_{ki} \leq \partial_1 \\ 2 & \text{if } \partial_1 < Y'_{ki} \leq \partial_2 \\ 3 & \text{if } \partial_2 < Y'_{ki} \leq \partial_3 \\ 4 & \text{if } \partial_3 < Y'_{ki} \leq \partial_4 \\ 5 & \text{if } \partial_4 < Y'_{ki} \leq \infty \end{cases} \quad (1)$$

Based on the research quest, there were $k = 1, \dots, N$ level-2 (HFs) and $I = 1, \dots, n$ level-1 units (patients) nested within each HF (level-2 units). The mixed effect regression model for the latent response variable Y_{ki} could be thus written as follows (Equation 2):

$$Y_{ki} = x'_{ki}\beta_k + w'_{ki}\alpha + e_{ki} \quad (2)$$

where w_{ki} is the $p \times 1$ covariate vector and x_{ki} is the design vector for r random effects, both vectors being for the i^{th} level-1 unit nested within HF level-2 unit k . α is the $p \times 1$ vector of unknown fixed regression parameters, β_k is the $r \times 1$ vector of unknown random effects for the HF level-2 unit k , and e_{ki} were the model residuals. The distribution of the random effects was assumed to be multivariate normal with mean vector μ and covariance matrix Σ_p , and the residuals were assumed to be independently normally distributed with mean = 0 and variance σ^2 . Due to the increasing nature of the ordered classes, the interpretation of the model's primary parameter set α was as follows: positive sign indicate higher satisfaction level as the associated variables increase, while the negative signs suggested the converse.

2.2. Study Area and Data Collection

The study was conducted in the state of West Bengal, India. Administratively the city of state of West Bengal is divided into several districts, where each districts housed its own administrative headquarters. These administrative headquarters are the majorly urban nodes housing state and district health care facilities. The survey was conducted in few wards of Kolkata Metropolitan city (KMC), in the suburban areas of KMC and in the rural areas in adjoining district of KMC. Kolkata is the administrative capital of the state West Bengal India and houses major health care research institute and hospitals. A detailed health infrastructure survey was conducted followed by questionnaire survey in November 2012. The study area exhibited the presence of different service providers offering varied level of services (LOS). The LOS of the providers were calculated on basis of the variables such as number of beds, number of doctors, number of departments or specialization, number of diagnostic tests that can be conducted at the facility and availability of medicine. Each of the service providers were differentiated into five major levels, where, G5 (state hospital and above) or P5 (multi-specialty private hospital) being the highest

LOS and G3 (PHC) or P2 (General Physicians (GP)) being the lowest LOS considered in the research. These included some of the large public medical college hospitals to sub-health centers and vice versa for the private services as well.

A paper based close ended questionnaire survey was designed to capture the health care seeking behavior of the respondents. A total of 125 samples were collected. A household was selected if any of the resident members undertook outpatient health care seeking tour in last one month from the date of survey. The survey considered cases based on the following conditions, (1) if the age of the patient was above 18, and (2) did not considered diseases and ailments such as maternal care and pregnancy, psychological disorder, accidents and burns. In addition to the socio-economic and socio demographic information, data pertaining to the perceived impression of health infrastructure in the neighborhood, health care travel activity diary of the individual and the companions were collected. Respondents visited 42 different HFs. The disease typology was categorized into four classes as proposed by Kato, 2011, namely: long term critical (D1), long term non-critical (D2), short term critical (D3) and short term non-critical (D4). The cross tabulation of the data showed that 32% of the respondents visited HFs within the neighborhood. 53.6% travelled to other neighborhood within the district, out of which 76.1% had at least one companion. Remaining 14.4% travelled beyond the district and were accompanied by at least one companion.

3. RESULTS

In the random intercept and slope (base) model, the patient level predisposing variables corresponding to the activity, such as numbers of accomplice and household characteristics like automobile availability and travel time were tested on the overall satisfaction of the health care episode. Analysis of the three covariates, emphasized that the travel time had a negative effect on the satisfaction, whereas, automobile availability and number of companions, had a positive effect on the satisfaction levels. The effect of ‘travel time’ and ‘automobile availability’ on satisfaction level of patients did not differ across HFs, whereas, the effect of number of accomplice was significant. The model 1B was formulated as follows:

$$Y_{ki} = \beta_{k0} + \beta_{k0} Ncomp_{ki} + \alpha_0 + \alpha_1 Ncomp_{ki} + \alpha_2 Travtime_{ki} + \alpha_3 Auto_{ki} + e_{ki}$$

where the vector of the unknown parameters β_i in the mixed effect regression model was extended to include both intercept and slope effects.

The intra-cluster correlation coefficient (Killip, Mahfoud, & Pearce, 2004) for the model was calculated to be 0.292, which indicates that 29.2% of the variance could be attributed to the differences between HFs. The between HF variance reduced from 0.41 to 0.33, which suggested that distribution of patients by number of companions differs from HF to HF. Based on the findings from the previous model, we a series of models were constructed to infer the contextual impact on the satisfaction level of the patients (see Table 2 & 3). Travel time and support for the activity, i.e. number of companions were retained in the model, being the compulsory part of the activity. Subsequently, ‘location based socio-economic variables’, outpatient trip typology as undertaken by the patients, and the 4As that prompted the health care activity were incorporated discretely in random intercept models. The multi-day tours might have

Table 2. Model incorporating 4As

Fixed Effects	Estimate	t value

Number of companions	0.02	
Deviance	289.44	

Note: '****' 0.001 '***' 0.01 '**' 0.05

a lower satisfaction with respect to the same-day tours, but overall effects were not significant. It was observed that in most cases the destination of the multi day tours were metropolitan urban areas (patients mainly visited Kolkata). Hence, there remained a possibility of mixing the purpose of the trip with social activity (visiting relatives and extended family such as family member immigrated to the city for job or other purposes) and retail activity in addition to health care activity. However, it should be noted that trip typology, economical factors and locational parameters did not affect satisfaction level significantly.

In spite of connectedness being a prime accessibility factor, it exhibited an insignificant yet negative impact on the satisfaction derived from the overall activity, this might be linked to other enabling factors influenced by health care infrastructure itself, such as, pricing, goodwill and type of services offered and so on). The variable 'HFs on the route to the mandatory activity' was found to be positive and significant, whereas 'convenient timing' for the patient and his/her companions was positive but insignificant. Inability to visit preferred HF decreased satisfaction and trips to a HF as there was 'no other option' had a negative effect. Reputations of the HF, such as the goodwill and the availability of modern equipment, had a positive effect whereas price had a negative effect on overall satisfaction. Availability of modern facilities as understood by the patient and their family often affected satisfaction significantly.

Table 3. Results of the models depicting the patient level and HF level characteristics

3.1. Analyzing the Role of Individual Characteristics and HF Level Characteristics on the Satisfaction

The estimation results of two ordered probit models (a) based on predisposing individual characteristics (patient level) and (b) based on enabling HF level attribute are presented in Table 3. At the patient level: the urban, suburban and rural poor had a relatively negative satisfaction level with respect to the 'others', however, it was not significant. The typology of service providers, LOS of the HF, overall expenditure pattern of the health care activity at the chosen HF, and the waiting time at the respective HFs were incorporated. Prolonged waiting time, did not affect the satisfaction significantly.

The estimation results of the interaction of the patient level and HF level variables are presented in table 4. The interaction between travel time and typology of HFs showed some intriguing results, high-lighting locational disparity among several types of service providers.

Table 4. Result of the model incorporating interaction

Fixed Effects	Estimate	t value

4. DISCUSSIONS

It was observed that under the given supply situation, the mean travel time to the health care facility varied with respect to LOS chosen, such as for GP: time ($\mu=18.13$; $\sigma=17.15$); for private multispecialty & general hospital: time ($\mu=40.40$; $\sigma=62.09$); for general and multi-specialty public medical college hospitals: time ($\mu=76.56$; $\sigma=86.09$). Although travel time to the facility exhibited negative relationship with overall satisfaction, but for GP and PHC the relationship was not significant. Therefore if the existing PHCs are upgraded to fulfill the ‘need’ of the users; it might lead to local sufficiency, curbing the travel needs. The health care seeking survey revealed that travel to particular facility was governed by the seriousness of illness as well. The factor of uncertainty based on previous experience that the local PHCs/GPs might not be able to provide adequate treatment, often triggered selection of facility with higher LOS. Constraints like restricted mobility, unavailability of specialist especially for NCDs (Non-communicable diseases), and unavailability of laboratories also affected the selection.

Models depicted that the effect of travel time to GP was positive and significant, whereas in case of higher LOS (for both public and private providers), it was negative and significant. Distinct differences in the user ship of the public and private providers offering higher LOS facilities were observed. 82% of the people attending the public service can be categorized as ‘poor’, whereas for the private counterpart the user ship of ‘poor’ was almost null. Moreover, it seemed that the public facilities in suburban areas were yielding negative satisfaction with respect to their rural counterparts. This might be due to the predominance of private providers in suburban areas.

4.1. Policy Intervention

With regard to the inadequacy of the “expectation-fulfillment” (Baron-Epel, Dushenat, & Friedman, 2001), we tried to emphasize on the predisposing and enabling characteristics that might be affecting the satisfaction. It had been already been pointed out that distance to HFs in India negatively affected the demand for outpatient health care needs, and demand was found to be price and income inelastic (Sarma, 2009). Moreover availability of HFs essentially did not corroborate utilization (Nair, Thankappan, Vasan, & Sarma, 2004). These additionally suggested that without essential upgrade, new facilities might be underutilized. The default growth of private HFs (Costa & Johansson, 2011) has a close connection with the underperformance of the public facilities.

Following the results of the estimated models, the major causes of dissatisfactions were travel time, availability of desired services and facility, amenities housed within a health care facility and cost, we suggested policy interventions to (1) improve utilization rate of the neighborhood HFs, (2) reduction of travel demand for outpatient needs. Another motive was to reduce the regional tours and decrease mobility based dependency. We propose infrastructure scenarios, which might be instrumental in reducing out of neighborhood trips and companionship (Jana, Harata, Kiyoshi, & Ohmori, 2014), consequently lowering out-of-pocket expenditure.

This study shows that to facilitate 4As, it might be essential to: (1) Upgrade the existing facility especially the PHCs and the sub-health centers in the rural and urban areas to house ‘modern amenities’ thereby ensuring utilization and enhancing ‘goodwill’; (2) Allocate transportation facility especially in the rural areas, where the availability of impromptu rented services is a rarity, this might ensure ‘well connected; and (3) Instigate self-sufficiency of neighborhood while reducing travel demand at the source, initiation of the telemedicine services might an alternative. Moreover, telemedicine would be resourceful in communicating with specialist, which could instill the perception of ability to communicate with desired resources. This can be achieved through better outreach programs and design policies for segmented target groups such as elderly. In this regards, it is noteworthy to mention interventions such as ‘National Programme for Health Care of the Elderly’ (NPHCE) by Ministry of Health and Family Affairs, Government of India, which seeks to address “accessible, affordable, and high-quality long-term, comprehensive and dedicated care services to an Ageing population” (Ministry of Health and Family Welfare, 2011). Currently the ‘Rashtriya Swasth Bima Yojna’ an insurance scheme initiated by Ministry of Labour and Employment, Government of India aims to provide insurance to population below poverty line in India, however, such schemes are not applicable for outpatient needs. Moreover the ‘National Urban health mission 2013’ and ‘National Rural Health Missions 2005’ have been formulated to undertake necessary architectural corrections, to reinvigorate the defunct and dilapidated health care facilities and house them with adequate medical personnel at the same time upgrade and modernize the facilities.

As in most cases, it was observed that regional tours initiated from the neighborhoods where there was unavailability of emergency service. People tend not to take risk but to travel to the HFs operational with greater time window. Hence, it might be prudent to initialize greater time window or strengthen emergency services in selected PHCs depending upon the existing infrastructures and population density.

5. CONCLUSION

This paper explored the variation of the satisfaction of patients availing different HFs for outpatient needs. Analysis revealed the importance of enabling 4As on satisfaction, emphasizing the needs to design policies towards enhance of availability, accessibility, affordability and acceptability (4As). Understanding the factors that affected the selection of health care service is prudent for future health care provisioning. In the resource constrained countries like India, the research framework proposed might provide base for prioritization of health care development policies. Based on the knowledge of the author, this is perhaps the first study on developing country like India, on which both the predisposing characteristics and enabling characteristics have been estimated simultaneously emphasizing 4As. The paper points out the need for segmented approach of policy intervention to meet the needs of the diversified socio economic groups in developing nations.

There are several limitations in this study. Firstly, models would have been more sensitive, if they were segmented, based on 'socio-economic classifications' and further validated with segmented models based on 'tour type'. In this study, the authors could not perform such analysis owing to sample size, which remains a major task for future research. Secondly, the scenario of 'do-nothing' was not considered in this research; there remains a job for future undertaking. Thirdly, the strategies described have not been validated with respect to the existing health care policies and five-year plan of India. Fourthly, although the strategies have been based on certain statistical findings, but there is a need to evaluate with larger perspective of socio-economic dynamics. Additionally people's feedback and acceptance of these strategies needs to be carefully analyzed and sought.

Chapter 12

Promoting Health Literacy in Global Health Care

Kijpokin Kasemsap

Suan Sunandha Rajabhat University, Thailand

ABSTRACT

This chapter emphasizes the prospect of health literacy; the evaluation of health literacy level; health literacy and health communication; health literacy and health information; and the current issues of health literacy in global health care. Good health literacy is important because patients are living longer and experiencing a wider range of health issues. Health professionals must commit to promoting for improved health literacy in health care organizations and should establish the specific health care goals toward improving health literacy in strategic plans, performance plans, programs, and educational initiatives. Health professionals can utilize a broad range of health communication strategies to ensure patients understand their options and share their health care decisions. Through health education and training, effective health information can help promote patients' health literacy level in global health care.

INTRODUCTION

Health literacy is recognized as the important domain in a conceptual model of health promotion (Šramová, 2015) and is related to the effective health indicators that include self-reported health, daily functioning, risk for hospitalization and death, and use of health care services (Bostock & Steptoe, 2012). Nowadays, reliable health information is essential and currently easily available to most patients in the health care industry (van der Vaart et al., 2012). Low health literacy is the important problem in low and middle-income countries as these countries have high poverty rates and low rates of health education (Keikelame & Swartz, 2013). Patients with low health literacy have poor knowledge about their illness, experience difficulties in accessing health care, have poor self-care, have lower levels of quality of life, and have poor health outcomes (Elliot & Shneker, 2009), including higher risk for premature deaths (Barnett & Kaske, 2012).

The communication between health care professionals and patients should encompass educating patients about the knowledge and the processes to enhance the quality of care in health care settings

DOI: 10.4018/978-1-5225-1674-3.ch012

(Kazandjian, 2012). To prepare for the transition from pediatric to adult-oriented health care systems, adolescents must develop the ability to obtain, process, and understand basic health information; make appropriate health decisions; and effectively interact with health care professionals (Huang, Tobin, & Tompane, 2012). Health literacy is an important factor in health disparities (Morrison, Brousseau, Brazauskas, & Levas, 2015). Al Sayah et al. (2013) stated that inadequate health literacy has been found to adversely affect health outcomes, especially in low-income patients with chronic diseases. Berkman et al. (2011) indicated that routine screening for inadequate health literacy in health care settings has led to an increased interest in health literacy evaluations.

Suitable health care interventions (e.g., materials written in plain language and brief counseling approaches) effectively improve the parent's health knowledge and medical adherence (DeWalt & Hink, 2009). Low health literacy is associated with individuals from lower socioeconomic groups, among older persons and racial minorities (Bautista, Glen, Shetty, & Wludyka, 2009), and from those living in rural areas because of low education levels, high unemployment rates, low wages, and lack of health insurance (Wood, 2005). Patients must have the ability to obtain, process, and understand the basic health information and services through health education and training regarding health literacy (Peerson & Saunders, 2009).

This chapter aims to bridge the gap in the literature on the thorough literature consolidation of health literacy. The extensive literature of health literacy provides a contribution to practitioners and researchers by describing the current trends and issues of health literacy in order to promote the health care literacy in global health care.

BACKGROUND

Health literacy first appeared in the 1974 paper calling for minimal health education standards for all grade levels in the United States (Mancuso, 2009). Since then, a stream of descriptive research has sought to examine the concept of health literacy, its measurement, and the problem of low health literacy in the health care industry (Schulz & Nakamoto, 2013). There has been a growing interest in the concept of health literacy, together with an increased emphasis on the individual's responsibility for health and self-management of chronic illness (Salmon & Hall, 2004). While health information has the potential to increase patients' knowledge and equalize the effective communication between patient and health care provider, availability of information does not automatically lead to the involved patients (McCray, 2005).

Inadequate health literacy is more extensive among the elderly, those with lower levels of educational attainment (Kutner, Greenberg, Jin, & Paulsen, 2006) and with chronic disease (DeWalt, Berkman, Sheridan, Lohr, & Pignone, 2004). Omachi et al. (2013) stated that limited health literacy is related to poor outcomes in many chronic diseases. Inadequate health literacy is associated with poorer self-management skills, less successful navigation of the health care system, and higher mortality (Herndon, Chaney, & Carden, 2011). Paiva et al. (2014) indicated that health literacy should be higher in physicians, followed by health researchers, people with a similar academic degree in areas which are non-related to health, and people with the lower levels of education attainment.

Although the skills of patients are important, health literacy also includes health care providers and caregivers (Grice et al., 2013). Low health literacy has been reported to have a great impact on the interactions between patients and health care providers (von Wagner, Steptoe, Wolf, & Wardle, 2008). Improving health literacy requires health care providers and health care organizations to clarify com-

munication, provide support for creating health-related skills, and organizational changes to reduce demands on patients. Health care providers should evaluate their patients' level of health literacy in an attempt to improve health outcomes by means of effective interventions (Lee, Lee, Kim, & Kang, 2012). Recognition of patient's health literacy ability can help health care providers find the communication approaches that fit their health-related needs.

SIGNIFICANT ASPECTS OF HEALTH LITERACY IN GLOBAL HEALTH CARE

This section highlights the prospect of health literacy; the evaluation of health literacy level; health literacy and health communication; health literacy and health information; and the current issues of health literacy in global health care.

Prospect of Health Literacy

Health literacy refers to a range of health literacy capacities that affect health-related behaviors and clinical decision making (Sharp et al., 2013) and is correlated with health status (Sentell & Braun, 2012) and health behavior in modern health care (Ishikawa, Nomura, Sato, & Yano, 2008). Social networks among health care providers and patients can provide health information that influence and support health behaviors in the health care industry (Goodman et al., 2012). High levels of health literacy without a high degree of patient empowerment creates an unnecessary dependence of patients on health professionals, while a high degree of empowerment without a corresponding degree of health literacy poses the risk of dangerous health choices (Schulz & Nakamoto, 2013).

Health literacy is a multidimensional phenomenon that involves the comprehension of oral as well as written information (Mazor et al., 2012). This is an important omission because oral communication is essential to most physician–patient encounters, as well as to media channels, such as television news (Mazor et al., 2012). The ability for self-care requires understanding and utilizing health-related information, as well as informed decision making (Lee et al., 2012). Variables, which have been shown to predict the higher health literacy levels are the presence of a chronic condition (Jovic-Vranes, Bjegovic-Mikanovic, & Marinkovic, 2009), income (Pizur-Barnekow, Doering, Cashin, Patrick, & Rhyner, 2010), and perception of individual's own health status (Jovic-Vranes et al., 2009).

Willis et al. (2014) indicated that strategies found to be associated with the improved organizational capacity for delivering the health literacy services are categorized into three perspectives (i.e., government action, organizational/practitioner action, and partnership action). Government action includes developing policies to reinforce social norms; setting standards for education; conducting research; and measuring health literacy levels. Organizational/practitioner action relates to the appropriate models of leadership regarding both high-level government engagement and distributed leadership. Partnership action includes collaborations with media outlets, those producing electronic materials, community organizations, and school-based programs (Willis et al., 2014).

Health literacy has been linked to disease self-management and various health outcomes, and can be separated into components of functional, communicative, and critical skills (Lai, Ishikawa, Kiuchi, Mooppil, & Griva, 2013). Functional health literacy is different by age, marital status, employment, education, material status, self-perception of health, and health status (Jovic-Vranes & Bjegovic-Mikanovic, 2013). In addition to the ability to read and write text, functional literacy includes the ability to apply the

content of the text to relevant activities (Sharp et al., 2013), information processing, working memory, problem-solving skills, and quantitative ability (Nutbeam, 2008).

Cancer is a complex and prevalent disease, and primary and secondary prevention are recognized as the major factors in controlling cancer morbidity and mortality (American Cancer Society, 2010). Understanding of cancer prevention and messages is essential if such messages are to be successful in helping individuals make decisions about health behaviors (Mazor et al., 2012). Inadequate health literacy predicts negative outcomes specific to cancer control, including poor understanding of cancer risk (Brewer et al., 2009) and the need for screening, as well as lower rates of participation in cancer prevention efforts (Lindau, Basu, & Leitsch, 2006). Cancer patients with poor health literacy tend to be diagnosed at a later stage (Bennett et al., 1998) and to have difficulty providing informed consent for treatment (Davis, Williams, Marin, Parker, & Glass, 2002).

Inadequate health literacy is most prevalent among those reporting poor health (Speros, 2005). Older people (Ginde, Weiner, Pallin, & Camargo, 2008), men (Parikh, Parker, Nurss, Baker, & Williams, 1996), people with a lower level of education (Downey & Zun, 2008) show lower levels of functional health literacy. Improved awareness of health literacy issues among adolescents with chronic disease is needed among health care providers and health care systems in modern health care (Huang et al., 2012). Patients with lower health literacy tend to have less understanding of their illness (Gazmararian et al., 2006), higher psychosocial distress (Sharp, Zurawski, Roland, O'Toole, & Hines, 2002), poorer self-reported health (Lindau, Tomori, McCarville, & Bennett, 2001), worse health outcomes (Schillinger et al., 2002), higher rates of hospitalization (Baker et al., 2002), higher health care costs (Eichler, Wieser, & Brugger, 2009), and higher risk of death (Sudore et al., 2006).

Evaluation of Health Literacy Level

To gain the insight into patients' health literacy level, it is essential to properly measure the health literacy skills (Shaw, Ibrahim, Reid, Ussher, & Rowlands, 2009). Most instruments of health literacy measures need to be evaluated by a health professional, which is time-consuming and unfeasible in clinical practice. Underlying constructs and content of the existing instruments vary, and only few instruments are based on the proposed definitions and underlying models of health literacy (Pleasant & McKinney, 2011). In addition, most existing health literacy measures focus primarily on reading health comprehension, while health literacy comprises more than only functional literacy, namely the skills to utilize health information in an effective manner (Jordan, Osborne, & Buchbinder, 2011).

An important trend toward developing the measures that capture health literacy level within a specific context has been growing (Kim et al., 2012). For example, there are the health literacy measures that focus on diabetes management (Nath, Sylvester, Yasek, & Gunel, 2001), asthma (Apter et al., 2006), and genetics (Erby, Roter, Larson, & Cho, 2008). The disease-specific health literacy tools are more useful when they are effectively applied to a group of patients in need of managing a specific chronic illness (Nielsen-Bohlman, Panzer, & Kindig, 2004). The disease-specific health literacy tools can provide health care providers with the useful assessments of patients' educational needs and can function as the effective evaluation tools for the targeted disease-specific interventions (Kim et al., 2012).

Evaluating health literacy is vital to design the health education program (Chang, Hsieh, & Liu, 2012). Han et al. (2011) stated that accurate evaluation of health literacy is the first step toward understanding and emphasizing health issues related to individual's low health literacy. Health professionals should

conduct the health literacy evaluation for adolescents before designing health education programs for those with low health literacy to develop health literacy skills toward performing health-promoting behaviors (Chang, 2011). Ownby et al. (2014) indicated that in order to evaluate intervention effectiveness and provide a method to evaluate health literacy as a construct, it is necessary to measure it.

The most broadly utilized measure of health literacy is the Test of Functional Health Literacy in Adults (TOFHLA) (Parker, Baker, Williams, & Nurss 1995). The Rapid Estimate of Adult Literacy in Medicine, or REALM (Murphy, Davis, Long, Jackson, & Decker, 1993), asks that patients read aloud a list of health-related words. The REALM is a word recognition test comprised of medical terms and is believed to capture a component of functional health literacy (Sharp et al., 2013). REALM requires less time to complete than the TOFHLA, but does not evaluate whether the patient understands what individual reads or numeracy skills (Ownby et al., 2014). Common measures of health literacy (e.g., TOFHLA and REALM) may introduce discomfort and embarrassment particularly in clinical settings, especially for those with inadequate health literacy (Al Sayah, Williams, & Johnson, 2012).

The TOFHLA has been found to be an effective tool for identifying people with inadequate functional health literacy, however it takes up to 22 minutes to conduct. (For a quicker evaluation of people's health literacy, the S-TOFHLA was developed, involving two prose passages with a total of 36 cloze items and four numeracy items. The total time to conduct the S-TOFHLA is 12 minutes or less (Baker, Williams, Parker, Gazmararian, & Nurss, 1999). Numerous studies have employed the S-TOFHLA to identify predictors of health literacy. In addition to the S-TOFHLA, the Newest Vital Sign (NVS) is the health literacy evaluation tool that is developed for utilizing in primary care settings (Heinrich, 2012) and requires three minutes to administer (Sharp et al., 2013).

Health Literacy and Health Communication

Health literacy researchers are currently examining other components of the health context, such as the complexity of health materials, the demands and assumptions of health institutions, and the communication skills of health professionals (Rudd, 2010). Research in health communication, specifically in patient-physician health communication, has greatly contributed to physician practice and training (Passalacqua & Segrin, 2012). The understanding of the relationship of health literacy to health status is essential to develop health communication and health education efforts for older adults in nursing practice (Kim, 2009).

Health communication between health professionals and patients, and between health educators and the public, is necessary in order to have the ability to improve health outcomes (Smith & Duman, 2009). The use of language which the patient is comfortable with is critical for improving health literacy level (Nemutanzhela & Iyamu, 2016). The increasing attention has been devoted to a patient-centered approach to health communication (Rosenthal, 2008). Several studies have found an association between high health literacy and better patient-physician health communication (Mancuso, 2010). Oral communication between physicians and patients has been shown to affect the patients' knowledge, motivation, decision making, engagement, empowerment, and health (Schonlau, Martin, Haas, Derose, & Rudd, 2011).

To improve patient-physician health communication, interventions must be tailored to the patients' health literacy level (Mullen, 2013). Many intervention studies have aimed to improve health outcomes by developing computer programs and establishing telephone follow-up systems aimed at patients with low health literacy (Long & Gambling, 2012). Innovations in health information technologies have en-

abled researchers in the patient-physician communication to expand beyond face-to-face interaction to include communication by phone and online between encounters (Fortney, Burgess, Bosworth, Booth, & Kaboli, 2011).

Health Literacy and Health Information

With the increasing availability of connected health care organizations through modern technology, important health information can be easily accessible at the point of care (Taweel, 2016). Health literacy is a complex phenomenon involving access to health-related information to improve the health-related decision making, behaviors, and outcomes (Wawrzyniak, Ownby, McCoy, & Waldrop-Valverde, 2013). Patients' inability to utilize health information for their own benefit causes a gap between the expectations laid on them to participate in their own health care, and their actual health literacy skills (Jordan, Buchbinder, & Osborne, 2010). This health care-related gap should be narrowed by adapting the reading level of the provided health information on the one hand, and by increasing patients' health literacy level through health education on the other hand (van der Vaart et al., 2012).

In health care organizations, there is an increasing amount of health information (Pereira, Portela, & Abelha, 2016). Health information is an important component of the health care services (Sriganesh, 2013) and for patients to understand and engage in the management of their health conditions (Ishikawa & Yano, 2008). Information behavior perspectives can enrich the conceptual base of health literacy, contributing a deeper understanding of people's use of health information in the context of their lived experience with health conditions (Souden & Rubenstein, 2010). Simmons et al. (2015) indicated that public health nurses should understand the high utilization of anonymous sources, particularly for mental health information, and focus efforts on helping individuals navigate the health care-related resources to ensure they obtain the accurate health information about symptoms.

The potential to collect, organize, integrate, and disseminate health information from a multitude of sources enables health analytics to improve the current health status of communities (Raghupathi & Raghupathi, 2013). The application of online health information empowers people to utilize the online health services (Mano, 2014). The incorporation of a credible online health information resource into school health education curricula is a promising approach for promoting health literacy (Ghaddar, Valerio, Garcia, & Hansen, 2012). Gutierrez et al. (2014) stated that despite the growing body of health information available online, patients with limited health literacy may lack either Internet access or skills necessary to utilize this information.

Gilmour et al. (2012) stated that developing patient competency in evaluating online health information should be recognized as an integral aspect of illness management education. Organizations that embed the practices of human capital and competency across a range of human resource management activities effectively create and develop a boundary spanning culture connecting with various organizational disciplines in the global knowledge economy (Kasemsap, 2016a). As health care services increase in significance, the knowledge acquired and used in executing its services becomes vital (Iyamu & Mkhomazi, 2016). The goal of health care knowledge management is to provide the effective, optimal, and timely health care knowledge to physicians and especially to patients whenever and wherever they need it, to support them in making effective patient care decision and promoting health literacy level (Akaichi & Mhadhbi, 2016).

Creating health information and make it readable by physicians has become the crucial task in modern health care (Peixoto, Domingues, & Fernandes, 2016). Health education is essential to enhance the

mental health knowledge, thus reducing the health literacy-related stigma and improving the effective access to health care (Kelly, Jorm, & Wright, 2007). Numerous approaches to providing literacy-sensitive health care have been proven effective, such as distributing health education materials written at 6th grade literacy levels or below (Robinson, Calmes, & Bazargam, 2008), providing visual information to explain medication regimens (Yin et al., 2008), and providing audio-recorded health instructions (Doak, Doak, & Root, 1996).

Health care-related education materials using pictographs provide the effective strategies in improving the discharge education for the low-literate older adults in the acute health care settings where nurses have primary responsibility as the first line of health care providers (Choi, 2011). Stigma around health literacy-related mental illness has two aspects (i.e., public stigma and self-stigma). Public stigma refers to the negative prejudicial attitudes and discrimination toward individuals with mental illness endorsed by the general population, while self-stigma describes an individuals' internalization of these negative attitudes and beliefs (Corrigan & Rao, 2012).

Health care-related illustrations are frequently utilized in health information, for example in materials about cancer (King, 2015). People typically learn better from text-illustrated information compared to text only (Mayer, 2002). Using illustrations is recognized to positively affect the individuals' attention to the health message (Delp & Jones, 1996) and understanding of information described in the message (Brotherstone, Miles, Robb, Atkin, & Wardle, 2006). People with limited health literacy have shown to benefit from the illustrated messages (Meppelink, Smit, Buurman, & van Weert, 2015), and the application of illustrations is recommended for this target group (Doak et al., 1996).

Current Issues of Health Literacy in Global Health Care

Health care policies and programs are needed to respond to the extent and impact of low health literacy in global health care (Jovic-Vranes & Bjegovic-Mikanovic, 2013). Low health literacy has been shown to be associated with a limited health vocabulary and it limits how individuals understand the concept of screening and their awareness of its benefits (Pagán et al., 2012). Low health literacy is widespread in the elderly, those with low socioeconomic status and minority groups (van der Heide et al., 2013) and is recognized as a strong contributor to health inequalities (Sudore et al., 2006). Socioeconomic status is strongly associated with health status (Hoffman-Goetz, Meissner, & Thomson, 2009). Lindquist et al. (2011) indicated that seniors themselves often have low health literacy, which suggests the greater requirement for caregivers to have adequate health literacy.

It is essential that health care providers understand the role that they have in the identification and promotion of health literacy to encourage the optimal health outcomes (Carollo, 2015). For the patient with low health literacy, the stigma associated with the condition has the potential to negatively impact communication with the clinician and staff, reduce the effectiveness of health care, and impact the quality of care and quality of life (Carollo, 2015). Successful health care management requires an effective partnering among clinicians and health care providers who have the responsibility to identify what is occurring with the patient regarding effective health care interventions, and the patient's responsibility to correctly adhere to the prescribed intervention (Mayer & Villaire, 2007).

To address health literacy in the technology-rich health care environment, there is a strong need for the effective computer-based tools to evaluate health literacy level (Collins, Currie, Bakken, Vawdrey, & Stone, 2012). Electronic health literacy is composed of two types of skills: general skills and specific skills (Institute of Medicine, 2009). General skills include traditional literacy (e.g., reading, writing,

and numeracy), media literacy (e.g., media analysis skills), and information literacy (e.g., information seeking and understanding). Specific skills include computer literacy (e.g., information technology skills), health literacy (e.g., health knowledge comprehension), and science literacy (Institute of Medicine, 2009). Electronic health information is emerging as a source to effectively manage own health (Yim, Khuntia, & Argyris, 2015). Increased public access to electronic health information and a shift in modern technology to more user-driven content significantly require communication technologies that support the patient as a partner at the center of the health care system by providing information access and assistance when and where it is needed (McCray, 2005).

Kamimura et al. (2013) indicated that health literacy education, mental health services, and social support are the significant health services needed by the free clinic patients to achieve better health. Health skills can be successfully introduced in adult learning environments (Diehl, 2011). However, the majority of online health information is difficult to read and understand, which is a problem for people with limited health literacy (McInnes & Haglund, 2011). Not everyone benefits from the abundance of information because selecting, understanding, and applying health information requires the adequate health-related knowledge and skills (Fransen, van Schaik, Twickler, & Essink-Bot, 2011). Smith et al. (2014) stated that health literacy skills are important for people affected by cancer as they are exposed to the complex treatment and follow-up care information.

Inadequate health literacy levels have been linked to a myriad of health-related outcomes, including increased mortality, lower physical functioning and quality of life, suboptimal utilization of health services, decreased capacity for disease self-management, elevated risks of medication errors, and increased health care costs. Low health literacy is related to inappropriate medication intake and an inability to understand health labels and health-related information (Berkman et al., 2011), and such health perspectives generate the poor treatment adherence. Across conditions of diabetes and cardiovascular disease, poor medication adherence and disease self-management have been recognized as the possible mediators between low health literacy and inadequate disease outcomes (Nam, Chesla, Stotts, Kroon, & Janson, 2011).

Fry-Bowers et al. (2013) indicated that comprehensible child health information is vital to any parent. Positive child health outcomes result from effective communication between a parent and their child's health care provider (Hart, Kelleher, Drotar, & Scholle, 2007). Effective communication encourages trust in the therapeutic relationship, improves parental satisfaction with care, promotes adherence to health care regimens, and increases the parental disclosure of psychosocial concerns (Rosenthal et al., 2007). Parent-provider communication, particularly within the context of pediatric ambulatory care, is not ideal. Parents with limited education and economic perspectives, members of racial minority groups, and non-English speakers are at risk for poor communication with health care providers (Bloom, Cohen, & Freeman, 2011). Substantial racial and ethnic disparities exist for the health care provider elicitation of parents' developmental concerns and for experiences of family-centered care (Guerrero, Rodriguez, & Flores, 2011).

FUTURE RESEARCH DIRECTIONS

The classification of the extensive literature in the domains of health literacy will provide the potential opportunities for future research. Limited health literacy affects patients of all ages, races, incomes, and education levels, but its greatest impact is among lower socioeconomic and minority groups, where it

underlies health disparities. Health education is a social science that draws from the biological, environmental, psychological, physical and medical sciences to promote health and prevent disease, disability and premature death through education-driven voluntary behavior change activities. Health education is the development of individual, group, institutional, community, and systematic strategies to improve health knowledge, attitudes, skills, and behavior.

Communities of practice (CoPs) help promote a growing cycle of knowledge sharing activities that allow for the members to regularly meet, reflect, and evolve in the knowledge management environment (Kasemsap, 2016b). The use of social media can result in better communication and collaboration (Kasemsap, 2016c). Total quality management (TQM) practices in quality performance has the potential to improve organizational performance (Kasemsap, 2015). Facilitating both health literacy and health education in the health care industry with the utilization of CoPs, social media, and TQM practices will be the valuable issue for future research direction.

CONCLUSION

This chapter explained the prospect of health literacy; the evaluation of health literacy level; health literacy and health communication; health literacy and health information; and the current issues of health literacy in global health care. Good health literacy is important because patients are living longer and experiencing a wider range of health issues. Health literacy measures to be conducted by health care providers are very important in order to know the patients' health literacy level and prepare the health care education toward increasing the patients' health literacy level and promoting the quality of care. Training health care staff will increase the awareness of the need for addressing health literacy and improve their health care-related skills for communicating with the public.

Health professionals must commit to promoting for improved health literacy in health care organizations and should establish the specific health care goals toward improving health literacy in strategic plans, performance plans, programs, and educational initiatives. Health professionals can utilize a broad range of health communication strategies to ensure patients understand their options and share their health care decisions. Implementing health care metrics for health care organizations will help establish the accountability for health literacy activities. Promoting patients' health literacy skills means they are better able to take care of their health and engage with the health care systems. Through health education and training, effective health information can help promote patients' health literacy level in global health care.

KEY TERMS AND DEFINITIONS

Communication: The two-way process of reaching mutual understanding, in which participant not only exchange information, news, ideas, and feelings, but also create and share meaning.

Health Care: The act of taking the preventative or necessary medical procedures to improve a person's well-being.

Information: The data that is organized for a specific purpose and presented within a context that gives it meaning and relevance.

Knowledge: The understanding of a circumstance gained through experience.

Literacy: The ability to read and write.

Patient: A person who is receiving medical care, or who is cared for by a particular doctor or dentist when necessary.

Skill: The ability acquired through the deliberate, systematic, and sustained effort to smoothly and adaptively execute the complex activities.

Understanding: The knowledge about a situation.

ABSTRACT

Patient engagement is based on the assumption that making patients co-producers of their health might enhance their satisfaction and responsibility with the healthcare system and it is strictly linked with the health provider choice. Making patients active participants in their healthcare is considered a crucial component of high-quality healthcare services. Quality of care is a central concern for health systems: accountability, transparency, and public reporting are some key factors in promoting healthcare improvement. In the healthcare field, public reporting is one of the major tools in supporting patients' decisions making process, by providing structure, process and outcome measures. We performed a web-based analysis of the major initiatives of public reporting in order to highlight their main characteristics: properties (public or private), data source (health providers, ad hoc surveys, etc.), general information reported (i.e. size, language spoken, amenities), doctors' information, patients' ratings (satisfaction / experience), clinical indicators.

INTRODUCTION

In this chapter, moving from the link between quality in healthcare and patient/consumer engagement, as driving concept, we deeply explain interactions between some challenging topics in the healthcare sector: quality of health care, accountability, transparency and public reporting.

In the first part of the chapter, more theoretical, we provide a synthesis of the literature about the topics.

DOI: 10.4018/978-1-5225-1674-3.ch013

Patient engagement – borrowed from the marketing conceptualization of consumer engagement – is based on the assumption that making patients/clients co-producers of their health might enhance their satisfaction and responsibility with the healthcare system, by improving positive clinical outcomes and reducing health delivery costs (Graffigna, Barello, & Triberti, 2015).

A recent report on patient engagement in health care, identifies an Engagement Behavior Framework, as a qualitative description of the behaviors that individuals must perform to optimally benefit from their care, based on ten types of tasks, that deals with the healthcare process as a whole, from the choice to the payment of providers, from health promotion and prevention to the end of life planning (Center for Advancing Health, 2010).

Making patients active participants in their healthcare is considered a crucial component of high-quality healthcare services. Since 2001, the Institute of Medicine's report "Crossing the Quality Chasm" (2001) has been recognizing patient-centered care as an essential dimension of high-quality care (Clancy, 2011). In 2006, the World Health Organization indicates patients and the population engagement as one of the six domains of quality interventions (World Health Organization [WHO], 2006).

Wide definition of quality and quality improvement and a focus on quality measurement are proposed.

Several formulations of quality definition are both possible and legitimate: all the stakeholders involved in the healthcare sector consider different aspects of quality of care depending on where they are located in the systems of care and on the nature of their responsibilities.

Avedis Donabedian, known as the founder of the theory of quality in healthcare stated that "quality of care is the kind of care that is expected to maximize an inclusive measure of patient welfare after one has taken into account the balance of expected gains and losses that attend the process of care in all its parts" (Donabedian, 1980). His definition can be synthesized by this quote: "Do only what is useful (effective theory), in the best way (effectiveness) with the least cost (efficiency), for who (accessibility), and only to those who really need (appropriateness), making do care who is competent to do it (competence), obtaining the best results considered (satisfaction)" (Donabedian, 1980).

Quality of healthcare has been one of the most challenging issues for researchers for many years. Taking part from quality of healthcare definition, other streams of research emerged: quality assessment or measurement, quality improvement, measurement of quality improvement approaches, and many other still appears. Furthermore, quality of healthcare dominates and leads public policy agenda, so that it has been defined as a process for making strategic choices in health systems, as World Health Organization stated in the subheading of a report published in 2006 (WHO, 2006). Thus, quality of healthcare connects with one of the most important Public Health movement of the last decades, the Clinical Governance, that promotes continuous quality improvement by creating an environment in which excellence in clinical care will flourish (Sally & Donaldson, 1998) and many other current concept, such as accountability and transparency, that encompasses procedures and processes by which healthcare organizations try to reach their goals in terms of quality improvement.

On the patient side, this reflects on better clinical experiences, greater appropriateness of care, increased trust in the patient-physician relationship. Moreover, patients own more information that make them able to choose the providers that better meet their needs, aware about the care they receive and involved in their health plans, becoming engaged in their health and care. Public reporting has a great role in this frame, as it refers to the publication of information and reports on the quality of care delivered by providers, that could support patient choices.

Patients have to decide whether and when to seek care, which plans and providers meet their needs, how to manage their health (Clancy, 2011). Provider choice is one of the most important patient engage-

ment pillar. But, are patients informed about the best care that they could receive? Do they know how to choose hospitals, health plans or professionals to address their healthcare needs? Are there tools able to support and guarantee aware choices?

Usually patients choose providers who meet criteria such as geographic access, personal style, often advised from friends or family. Preferences for characteristics vary across patient, and they also vary depending on the type of provider to choose (e.g. hospitals, primary care doctors, home care or care home providers) (Kumpunen, Trigg, & Rodrigues, 2014). It would be better if patients will use also comparative performance information, from public reporting initiatives, to identify the provider that better meets their need.

In the second part of the chapter, moving from this theoretical frame, we will present the result of a web based analysis aimed at comparing major initiatives of public reporting, classified by the following characteristics: properties (public or private), data source (health providers, ad hoc surveys, etc.), general information reported (i.e. size, language spoken, amenities), doctors' information, patients' ratings (satisfaction /experience), clinical indicators.

PATIENT ENGAGEMENT AND QUALITY IN HEALTHCARE

Western societies are facing some changes of scenario at the economic, social, and environmental levels that reflects also on the healthcare sector calling for revisions in policies and interventions (Graffigna et al., 2015). The economic crisis, the ageing of populations and the rise of chronic conditions are just some of these challenges that every country should take on in order to improve systems sustainability. Promoting patients engagement in healthcare management, by supporting them in the decision-making and in enacting healthy behaviors, is one of the actionable intervention for achieving such goals.

Why “engagement”? The word engagement derives from the verb “to engage” that “implies a dynamic and relational context, in which two parties agree on the goals of an action and on the phase of its process” (Graffigna et al., 2015). It has been introduced in the healthcare field not long ago to indicate a renewed partnership between different actors and institutions involved in health and care management (Hibbard, Stockard, Mahoney, & Tusler, 2004). The expression patient engagement has been borrowed from the marketing conceptualization of consumer engagement that refers to the (potentially positive) attitude of a consumer toward brands, products, services, or even media events (Gambetti & Graffigna, 2010).

The concept of patient engagement is based on the assumption that making patients/clients co-producers of their health might enhance their satisfaction and responsibility with the healthcare system, by improving positive clinical outcomes and reducing health delivery costs (Graffigna et al., 2015). It can be seen as a key qualifier of the exchange between the demand (i.e. citizens/patients) and the supply (i.e. healthcare system) of healthcare services in the different phases of the care processes. Understand and manage the strategic levers that sustain patient engagement is crucial to innovate healthcare systems and to improve their sustainability (Graffigna et al., 2015).

It seems that patients engaged in their health and care may reach better quality of care and patient/health provider relationship, thus improving patient's clinical indicators and compliance to recommended treatments; on the contrary, patient not engaged in their health and care may cause waste of resources and poor clinical outcomes (Greene & Hibbard 2012; Graffigna et al., 2015).

The concept of patient engagement can be seen as an evolution of Patient Centered Medicine.

Patient Centered Medicine replaced the historical dominant bio-medical paradigm, bringing back “patients’ voices” at the center of the healthcare processes. Even though it has been shown that Patient Centered Medicine contributes to clinical effectiveness improvements and psychological sustainability of care practices, it has not always been translated into real practice, usually as a resistance to organizational change. Nevertheless, if involvement and participation of consumers/clients of healthcare services have to be seen as a priority, patient engagement could be useful, as a qualifier in the exchange between the “demand” and “supply” of healthcare (Graffigna, Barelo, Riva, & Bosio, 2014).

A recent report on patient engagement in health care, identifies an Engagement Behavior Framework, as a qualitative description of the behaviors that individuals must perform to optimally benefit from their care, based on ten types of tasks, that deals with the healthcare process as a whole, from the choice to the payment of providers, from health promotion and prevention to the end of life planning (Center for Advancing Health [CFAH], 2010). Making patients active participants in their healthcare is considered a crucial component of high-quality healthcare services.

The World Health Organization identifies patients and population engagement as one of the six domains of quality interventions. It is defined as critical to quality improvement, because individuals and communities play many roles within health systems. In fact, directly or indirectly, they finance care, work in partnership with health workers to manage their own care, they are sometimes the arbiter of what is or is not acceptable across all the dimensions of quality. Thus, ensure patients and population engagement is seen as a challenge, the heart of all policies and strategies for quality improvement. Policies and strategies to this end are likely to improve health literacy, self-care, and patients’ experience with the health system. Patients and population would be involved in the governance of the health system, influencing decision-making through their views and preferences and sharing responsibility for their own health. New interventions in quality must take into account these strategic fundamentals (WHO, 2006).

QUALITY IN HEALTHCARE

Quality in Healthcare: Definitions, Dimensions, Measurement

Quality of patient care is a central concern for health systems, especially in an era of unprecedented financial constraints, and rising demand and expectations. Thus, the focus on quality has intensified because of the concern that healthcare is costly, may sometimes be dispensed inappropriately and inequitably, and varies unduly among physicians and location.

The gap between the quality of healthcare possible and that currently provided has been referred to as a chasm. The reason why health systems globally frequently fail to provide patients with quality healthcare have been proposed as follows: an increase in chronic conditions, poorly organized systems for healthcare delivery, limited use of information technology, and the increased complexity of care as a result of medical advances (Institute of Medicine [IOM], 2001).

What is quality of care? How can it be defined? Quality is a complex and multi-faceted concept which have been defined in many different ways for the last decades. Several formulations of quality definition are both possible and legitimate: all the stakeholders involved in the healthcare sector consider different aspects of quality of care depending on where they are located in the systems of care and on the nature of their responsibilities. For example, doctors may consider medical outcomes or processes; economists may focus on social welfare, including features that consumers happen to care about, but that clinicians

do not (i.e. appearance and size of hospital rooms); health plans may reflect on concepts of preventive care or organizational efficiencies (Wong, McNamara, & Greenberg, 2004; Cantù & Tzannis, 2011).

Firstly, quality can be referred both to healthcare and health systems. First of all, it reflects the extent to which an healthcare service or product produces a desired outcome (Runciman, Merry, & Walton, 2007). Furthermore, quality can be defined as a principle to assess if health system is performing well in its mission to improve health (National Health Performance Committee [NHPC], 2001). Avedis Donabedian, known as the founder of the theory of quality in healthcare, defined “Quality of care” in 1966 in its article, “Evaluating the Quality of Medical Care” (Donabedian, 1966) that has been cited by 4428 authors during the last 50 years. His revised definition stated that “quality of care is the kind of care that is expected to maximize an inclusive measure of patient welfare after one has taken into account the balance of expected gains and losses that attend the process of care in all its parts” (Donabedian, 1980). His quality definition can be synthetized by this quote: “Do only what is useful (effective theory), in the best way (effectiveness) with the least cost (efficiency), for who (accessibility), and only to those who really need (appropriateness), making do care who is competent to do it (competence), obtaining the best results considered (satisfaction)” (Donabedian, 1980). Furthermore, Donabedian highlights three principal quality dimensions:

- The structure (organizational quality), the static part of the system, the equipment
- The process (professional quality), the behaviors of personnel and customers on a scientific, ethic and social basis (diagnostic procedures, continuity of care, professional standards, comfort, privacy, etc.)
- The outcome (perceived quality) that is the evolution of the patient’s health due to the care process (Donabedian, 1988; Cantù & Tzannis, 2011).

In the following years several authors gave highlighting definitions across a continuum of more or less operational and generalizable dimensions, such as: “excellence” (Samuel, Grant, & Irvine, 1994), “expectations” or “goals which have been met” (Ellis & Whittingham, 1993; Steffen, 1988), “zero defects” (Crosby, 1979) and “fitness for use” (Juran, 1988; Campbell, Roland, & Buetow, 2000). Nevertheless, the “Hippocratic Oath” seems to be one of the link between all the definitions of quality in healthcare provided, surely the oldest and the most complete one.

It was 1990 when the US Institute of Medicine, by assuming that healthcare ought to be safe, effective, patient centered, timely, efficient and equitable, introduced the well-known definition of quality: “the degree to which health services for individuals and populations increase the likelihood of desired health outcomes and are consistent with current professional knowledge” (IOM, 1990).

The Institute of Medicine’s definition relates quality to the goals of the healthcare system. Quality of care is often defined trough individual dimensions or components that allows recognizing its complexity: when viewed in combination the dimensions offer more specific definitions of quality (Campbell et al., 2000). Table 1 shows main dimensions according to some of the most important definitions of quality of care (Campbell et al., 2000).

For the World Health Organization quality is made by six areas or dimensions:

- Effectiveness, as adherence to evidence base medicine and improvement of health outcomes for individuals and communities, based on needs;
- Efficiency, as maximization of resources use and reduction in wastes;

Accountability and Public Reporting

Table 1. Quality in healthcare: main classifications through dimensions (Modified by Campbell et al., 2000)

Donabedian (1990)	Maxwell (1992)	HSRG (1992)	O'Leary and O'Leary (1992)	Campbell et al. (2000)	WHO (2006)
	Accessibility	Accessibility	Accessibility	Accessibility	Accessibility
		Patient centredness	Patient perspectives		Patient centredness
Effectiveness	Effectiveness	Effectiveness	Effectiveness	Effectiveness	Effectiveness
Efficiency	Efficiency	Efficiency	Efficiency		Efficiency
		Continuity/ Co-ordination	Continuity		
Efficacy			Efficacy		
Acceptability	Acceptability				
Equity	Equity				Equity
Legitimacy					
		Comprehensiveness			
	Relevance				
					Safety

- Accessibility, as the ability to face medical needs in a timely and geographically reasonable manner, provided in a setting where skills and resources are appropriate;
- Patient-centeredness, taking into account preferences and aspirations of individual service users and cultures of their communities;
- Equity, avoiding discrimination because of personal characteristics such as gender, race, ethnicity, geographical location, or socioeconomic status;
- Safety, minimization of risks and harm to service users (WHO, 2006).

Appropriateness is another important quality dimension. The UK Department of Health, introducing appropriateness, defined the quality of care as: “doing the right things (what); to the right people (to whom); at the right time (when); and doing things right the first time. Such a document also stressed on patient centeredness in quality appraisal, thus including the degree to which healthcare interventions are delivered responsive to patients’ needs and preferences” (Department of Health, 1998).

Quality definition is preparatory to quality measurement: it is essential to reach an agreement on the element that constitute it before starting quality assessment, otherwise the risk is to court disaster (Donabedian, 1988).

The relevance of healthcare quality measurement is well-known for a long time. Famous is the quotation attributed to Florence Nightingale: “The ultimate goal is to manage quality. But you cannot manage it until you have a way to measure it, and you cannot measure it until you can monitor it” (Eagle & Davies, 1993).

At present, measurement and evaluation of the quality of health systems/ organizations is aimed mainly at determining the degree to which health systems successfully pursue the objectives of maintaining and increasing the health status of the population and how the health system respond, both in structural and organizational terms, to the expectations of all those who benefit. At national and international level, it

should be noted that the emergence of problems related to the restructuring of health systems must be framed within the broader context of crisis in welfare states.

Quality of care refers to the level of performance that characterizes the healthcare provided. Such a quality can be assessed with quantitative measures, where delivered healthcare is compared with the healthcare that is expected/ought to be delivered, sometimes referred to indicate care or quality standards. Measures of quality of care would encompass, for example, measures of effectiveness and patient satisfaction or patient-centeredness. Mortality, morbidity, and patient satisfaction were identified as key criteria for assessing the quality of care (Hinshaw, 1992).

Patient satisfaction is both a dependent variable of quality of care and a predictor of subsequent health related behaviour, since satisfied and dissatisfied health care consumers behave differently (Ware, Davies-Avery, & Stewart, 1978; Pascoe, 1983; Ware & Davies, 1983; Tzannis & Nadin, 2011). Satisfied patients lead to higher levels of profitability, market share and, likely, to higher levels of clinical outcomes (Greenwich, 1993).

As quality measurement is a costly and time consuming activity, indicators must be selected that contribute to an aggregate understanding of health-care quality is imperative. Sources of information would include administrative/clinical data collected by healthcare providers and patients' reports collected through population or patient surveys, the so-called patient reported outcome measures (Streiner & Norman, 2008).

Quality Improvement

It seems dramatically clear that healthcare will not realize its full potential unless change making becomes an intrinsic part of everyone's job, every day, in all parts of the system. John Øvretveit defined quality improvement in healthcare as a better patient experience and outcomes achieved through changing provider behavior and organization through using a systematic change method and strategies (Øvretveit, 2009). Such a combined and unceasing efforts of everyone -healthcare professionals, patients and their families, researchers, payers, planners and educators- is important to make changes that will lead to better patient outcomes, better system performance and better professional development (Batalden, 2007).

Actually multiple strategies and tools to improve quality exist but which one works?

Groene, Kringos and Sunol on behalf of the DUQuE Project (2014) identified seven ways to improve quality in hospitals:

- Align organizational processes with external pressure
- Put quality high on the agenda
- Implement supportive organization-wide systems for quality improvement
- Assure responsibilities and team expertise at departmental level
- Organize care pathways based on evidence of quality and safety interventions
- Implement pathway-oriented information systems
- Conduct regular assessment and provide feedback.

In most reports emphasis is placed on crosscutting issues such as oversights and leadership, building support systems for quality improvement and providing the necessary resources for high quality care to be provided. Approaches on quality improvement has been developing into a major strand of research during the last decades.

Accountability and Public Reporting

Common approaches to quality improvement (Boaden, Harvey, Moxham, & Proudlove, 2008) came from industrial approaches:

- Total Quality Management, defined as a participative, systematic approach to planning and implementing a continuous organizational improvement process (Kaluzny, McLaughlin, & Simpson, 1992)
- Business Process Reengineering that is the redesign of systems and processes used to produce, deliver and support patient care in order to achieve improvements in organizational performance within a short period of time (Carmichael, 1994)
- Plan- Do- Study- Act (PDSA) cycles, small tests of change in which a change practitioner will plan a test of change (plan), carry out the change (do), study the results (study) and act on them in the next cycle of change (act) (Deming, 1986)
- Lean Thinking that is an integrated system of principles, practices, tools and techniques focused on reducing waste, synchronizing work flows, and managing variability in production flows (Joosten, Bongers, & Janssen, 2009)
- Six Sigma defined as “an organized and systematic method for strategic process improvement and new product and service development that relies on statistical methods and the scientific method to make dramatic reductions in customer defined defect rates (Linderman, Schroeder, Zaheer, & Choo, 2003)
- Statistical process control, that leads to quality improvement by learning through data and is based on the theory of variation (Carey, 2003).

But, which approaches are likely to really improve quality of care? Unfortunately, no clear evidences still exist on this topic. A systematic review synthesizes existing evidence on interventions to improve quality of care in an hospital based setting. It shows that that despite the very large volume of literature on quality of care improvements, only a few hospital interventions have a theoretically based design or implementation. Studies varied from small scale improvements for specific patient groups to large scale quality improvement programs across multiple settings. Interventions were usually divided into two categories: interpersonal and technical. Interpersonal interventions sought to improve patient satisfaction and tended to be implemented by nursing staff while technical interventions were generally implemented by physicians and reported measurable improvements in medical outcomes for patients with specific illnesses (Conry et al., 2012).

Towards a Clinical Governance Approach

Quality of healthcare is not only one of the major strand of research of the last decades but also on important topic for the government all over the world. It dominates and leads public policy agenda, so that it has been defined as a process for making strategic choices in health systems, as World Health Organization stated in the subheading of a report published in 2006 (WHO, 2006). Thus, quality of healthcare connects with one of the most important Public Health movement of the last decades, the Clinical Governance, that promotes continuous quality improvement by creating an environment in which excellence in clinical care will flourish. The introduction of clinical governance aimed at improving the quality of clinical care at all levels of healthcare provision (Sally & Donaldson, 1998).

Each intervention aimed at improving Clinical Governance is likely to positively influence healthcare quality and consequently appropriateness of care (Specchia et al., 2015). Quality of care permeates many other current concept, such as accountability and transparency, moreover linked to Clinical Governance, that encompasses procedures and processes by which healthcare organizations try to reach their goals in terms of quality improvement.

ACCOUNTABILITY AND TRANSPARENCY

Measuring quality of healthcare is a key factor to promote improvements in the delivery of care and to increase accountability and transparency (Chassin, Loeb, Schmaltz, & Wachter, 2010). On the other hand, implementing public health policies based on accountability and transparency of the actions can encourage quality improvement and the ability for people to make informed choices.

Over the years, various definitions of accountability in healthcare have been given. It has been defined as the activity of “taking into account and responding to political, commercial, community, and clinical/ patient interests and expectations” (American Hospital Association Board of Trustees, 1999). Furthermore, it may be defined as the process by which health leaders pursue the objectives of efficiency, quality, and access to meet public interests and expectations (AHA Board of Trustees, 1999). In general, accountability is the obligation of individuals or agencies to provide information about, and/ or justification for, their actions to other actors (Brinkerhoff, 2003). Therefore, a subject is accountable if he reports, explains, or justifies something on which he is responsible and has the duty to answer (AHA Board of Trustees, 1999).

Given the relevant role of the healthcare organizations for the society as a whole, expectations on their activities and capability to provide good quality healthcare services and to be performant is very high and not only limited to specific legal and regulatory standards. Healthcare organizations are responsible for a broad range of activities including patient care, community services, and business functions and have to be accountable for a series of activities. First of all they have to taking into account the expectations and interests of their different stakeholders. Furthermore, of great relevance, they have to measure and evaluate their performance in multiple areas, including quality, access, efficiency and finance, continuously improving their performance in each of these areas. Finally, they have to communicate their performance to the stakeholders (AHA Board of Trustees, 1999).

Individuals and institutions that have interest in healthcare providers' accountability are many: purchasers and payers of healthcare services, patients, advocacy groups, regulators, stockholders and lending institutions, health policy makers, practitioners, hospital staff/employees, media, and generally the community. They expect that the institutions that provide healthcare services will act in the best interests of the people who need its services and provide safe, effective and high quality care (AHA Board of Trustees, 1999).

In this perspective, accountability could represent a fundamental issue to implementing health reforms and improving health systems performance (Brinkerhoff, 2003).

In all the health systems there are different types of relationships among different actors, that may partially vary according to the healthcare system type. Principal speakers of these relationships are health ministries, insurance agencies, health services' public and private providers, legislatures, finance ministries, regulatory agencies (Brinkerhoff, 2003), exercising a mutual role of control, cooperation and reporting. In the healthcare area, main domains of accountability are: professional competence, legal and

ethical conduct, financial performance, adequacy of access, public health promotion, and community benefit (Emanuel & Emanuel, 1996).

The most relevant element of accountability is answerability, according to the idea that to be accountable means to have the obligation to answer questions regarding decisions and actions. There are two levels of accountability: the first deals with the need to be informed, the second deals with the need to know and understand the reason of a choice and its implementation. The need to be informed implies a one-way transmission of information from the accountable actor to the actor who needs to be informed. The need to know and understand the reason implies a two-way transmission of information, requiring a dialogue between the accountable actor and the overseer actor.

In these terms, the informing aspect of answerability that characterized accountability, deals with the idea of transparency in a democratic government (Brinkerhoff, 2003). To be transparent mean give access to public data and information, building the capacity of civil society to monitor the management of resources, and on the other side the capacity of government to implement effective policies.

Accountability refers to three different areas: financial accountability, performance accountability and political/democratic accountability. Financial accountability concerns laws, rules and regulations regarding financial control and management, focusing on allocation, disbursement and utilization of financial resources. Performance accountability concerns performance measurement and evaluation, focusing on healthcare services, outputs, and results. It is linked to financial accountability because of financial resources are essential to product services for citizens. Political/democratic accountability deals with mechanisms to ensure that government plans are realized and respond to citizens' interests (Brinkerhoff, 2003).

These three specification of accountability are linked with its objectives. Control of use and abuse of public resources is directly related to financial accountability. Support and promote improved healthcare services delivery and management is linked with performance accountability. Finally, belonging to all accountability's specification, is the assurance that resources are used and authority is exercised according to appropriate and legal procedures, professional standards and societal values (Brinkerhoff, 2003).

Transparency is considered a driver of public service reform worldwide. It derives from theories of civic responsibility of the 1980s. Though there is a growing interest in transparency in healthcare sector, as it may be a predictor for services and productivity improvement, transparency is not yet widely implemented (Henke, Kelsey, & Whately, 2011).

The IOM (2011) defines healthcare transparency as “making available to the public, in a reliable and understandable manner, information on the healthcare system's quality, efficiency and consumer experience with care, which includes price and quality data, so as to influence the behavior of patients, providers, payers and others to achieve better outcomes”.

The American College of Physician (2010) identifies eight major domains of healthcare transparency:

- Clinical quality and safety, that deals with structure, process and outcome measures;
- Resource use, expressed as episode of care, yearly and per capita costs, number of hospital bed days, etc;
- Efficiency, measured as clinical quality outcome related to resource utilization;
- Patient experience of care, typically relived by ad hoc survey;
- Professionalism, measured as qualifications, professional standing and training;
- Healthcare system/ facility recognition accreditations for meeting national standards, that deals with accreditation;

- Financial relationship between physicians, other healthcare professionals and industry, measured by public reporting of relationship;
- Health insurance company processes, expressed in terms of medical loss ratio, efficiency of claims processing, criteria for preferred provider status.

Transparency might impact on six areas: accountability, patients' choices, productivity, quality of services delivered, social innovation and economic growth (Henke et al., 2011). In fact transparency forces healthcare regulators to be accountable; guides informed choices thanks to the availability of comparative and complete information; drives providers to efforts effective and cost-effective services, encourages patients to be more informed, transforming the relationship between patients and providers; opens new opportunities for public and private providers, stimulating competitiveness.

Many potential benefits from increased healthcare transparency emerged both for patients and health systems, like improving availability of information needed to make informed healthcare choices, increasing trust in the patient-physician relationship and improving quality, safety and efficiency due to competition and availability of clinical benchmarks (Colmers, 2007; Collins & Davis, 2006; Snyder & Leffler, 2005). Furthermore, above all in publicly funded and administered healthcare systems, transparency is considered a main value: professionals and the other health sector employees must behave professionally and ethically, avoiding to commit fraud, accept bribes, or leak confidential information.

In the early part of the twentieth century, Codman (1975) promoted the importance of publicly reporting the results of hospitals activity in order to promote quality improvement, physician learning and patient choice, inspiring the current healthcare transparency movement.

The most recurring information showed about hospitals performance are: clinical quality as adherence of services provided to evidence-based, structured, clinical process or positive health outcomes benchmarks or guidelines), resource use (both structural and human resources) and experience of care (patients' view of the care received from providers). Even though it's well known that transparency could increase healthcare quality, many hospitals aren't ready to face the transparency challenge, staying reluctant to disclose their performance data.

Transparency is more than access to healthcare data: information to be effective must be shown in a way that reflects different users' abilities to understand and use information. Data should be not too much detailed and complex, not too much aggregate (IOM, 2010).

Moreover, transparency can encourage the practice of results based management in healthcare. In particular, there are three primary aspects of transparency relevant to management practice: information disclosure, clarity and accuracy

Finally, it's useful not to confuse transparency for knowledge: transparency causes an increase in knowledge, it may facilitate knowledge, but it's not knowledge itself (Schauer, 2011).

PUBLIC REPORTING IN HEALTHCARE

Definitions and Objectives

In the healthcare field, a well-trodden path to provide transparency and to be accountable is the public reporting. There is growing interest in public reporting of information on the quality of healthcare delivered by different providers (i.e. physicians, hospitals, health plans), as it is strictly linked to the account-

ability of health systems and transparency of information and processes. It has become an increasingly common health policy tool (Faber, Bosch, Wollersheim, Leatherman, & Grol, 2009), both in publicly and privately funded systems.

Public reporting of performance information and feedback to providers is one of the major approaches to improve quality of care, because on the one hand allows to evaluate your own performance, on the other pushes the comparison with other providers; moreover, allowing patients to make informed choices stimulates competition. Furthermore, information supports patients' and users' decision making process, facilitating choices in selecting providers that best meet needs and preferences (Rice, 2001; Kumpunen et al., 2014), by comparing differences across them. Information on the quality of providers should be accurate and timely accessible (Victoor, Delnoij, Friele, & Rademakers, 2012).

Many author and national agency provide definitions of public reporting.

Public reporting refers to the publication of information and reports on the quality of care delivered by providers. Information is made available on the internet, on paper and in other formats for use by patients and users (Kumpunen et al., 2014).

It is defined as the way to promote high quality and efficient healthcare delivery and to increase the transparency of quality information enabling disparities in access to such information (Cacace, Ettelt, Brereton, Pedersen, & Nolte, 2011). It is also a strategy to address quality and cost making available to consumers, payers and healthcare providers information about performance and insurance plans and it should provide information on patient's satisfaction (James, 2012).

Actually, the Agency for Healthcare Research and Quality public reporting definition is the most widespread: "Public Reporting is data, publicly available or available to a broad audience free of charge or at a nominal cost, about a healthcare structure, process or outcome at any provider level (individual clinician, group, organization)" (Totten et al., 2012). The main objective of Public Reporting is to help actors of the health system to be accountable by spreading information about their performance in order to enable their stakeholders to make informed decisions and to support patients in choosing their own provider. Furthermore, it should promote healthcare quality improvement encouraging providers' competition and behavioral change (Cacace et al, 2011).

A Theoretical Framework: The Berwick Model

In public health field, information systems involve three kind of actors: patients or users, providers and regulators. Given the relationship between these three types of subjects, the main lever to induce quality improvement is providers behavioral change (Berwick, James, & Coye, 2003). This behavioral change could be induced acting on the side of demand for health services or on the side of production of health services, linking the processes of measurement pathways to the processes of improvement. According to Berwick's framework, exist two principals through which measurement and reporting can induce providers behavioral change: improvement through selection and improvement through selection (Berwick et al., 2003). The first pathway is based on the assumption that information on healthcare services' quality enables patients or users to select providers according to quality criteria, making informed decisions on their providers. Furthermore, regulators may use the information on quality to make decisions on payment, activating incentive mechanisms such as reward for high quality performance or penalty for low quality performance. In the second pathway, healthcare services' quality information is used by providers themselves to identify underperformance or good performance areas in order to stimulate competition on services quality and to act an organizational behavioral change.

These pathways may stimulate behavioral changes only if there is providers' intention to compete and maintain or increase their reputation (Cacace et al., 2011). The will to be competitive with other providers and to maintain a good reputation to attract patients should stimulate behavioral changes aimed at improving performance.

It is also important to observe that providers have two different kind of functions on two different levels. First of all, they are information users in order to make decisions about their operative strategy and organization, on the other side they are the main information providers and target audience of information systems and their capacity to produce information is decisive to healthcare quality. On the second level, in more operative terms, providers do not only react to the output of information systems, such as outcome indicators, they also produce information to make possible these comparisons and stimulate competition and quality improvement (Cacace et al., 2011).

Furthermore, it is relevant to note that the literature has suggested that patients choose their healthcare providers considering a wide range of services' characteristics: in addition to the quality of care or positive evaluations of the outcomes, could also affect other non-clinical elements such as the proximity of the provider, good ancillary services (food, cleanliness, etc.) or a previous experience (Kumpunen et al., 2014). A relevant aspect is the measurement of patient expectations and perceptions. This represent a valuable dimension of the process by which the quality of health care service is evaluated. Administrators should understand the areas in which expectations are particularly high so that the service delivery process can be tailored to meet those expectations (Babakus & Mangold, 1992).

Main Characteristics of Public Reporting: Indicators and Availability

A public reporting system is based on a set of indicators through which provide information to different stakeholders. The first important step to take when building a system of public reporting is to identify a set of indicators suitable for measuring the activity. In healthcare, public reporting of services' quality is strictly linked and influenced by the multidimensionality of quality, so it is necessary to identify different indicators able to measure all the quality dimensions. Usually, three types of indicators are used in order to monitoring quality of healthcare services: structural measures, process measures and outcome measures (Donabedian, 2005).

Structural indicators monitoring structural, technological, organizational and professional resources of healthcare providers, measuring tangible aspects, such as number of physician for patients, bed's occupancy rate or operating rooms' utilization rate. They are easy to measure and probably are the more easily to understand for patients. Process indicators measure the appropriateness of the care process and usually are classified into organizational process indicators that measure volumes (i.e. number of admissions; length of stay), waiting times for services and continuity of care, and professional process indicators that measure appropriateness of care decisions, correctness of execution and timeliness of care. Outcome indicators measure the health status of a patient resulting from care process, highlighting a change of health status, for example in terms of mortality or morbidity, but also in terms of quality of life or satisfaction. Often it is too difficult to link both structural and process indicators outcomes measures, making an integrated interpretation.

Data can be reported at different levels of care: physician level, measuring the quality of care provided by a single healthcare professional; hospital ward or specialty level, measuring a team performance; hospital level, measuring the entire organization performance.

The use of public reporting could encourage physicians or providers to adopt opportunistic behaviors, in terms of selecting services or patients in order to obtain better results, or to focusing on the clinical care that are monitored, omitting provision of other important care. A solution to try to avoid these behaviors is the utilization of risk and case-adjustment methods in calculating indicators (Kumpunen et al., 2014).

Generally, the data used to public reporting may come from three kind of sources: administrative, surveillance and *ad hoc* (Kumpunen et al., 2014).

Health administrative databases are information flows for monitoring the delivery of health services in which data are routinely collected to produce administrative reports. Despite their goal was predominantly the accounting, they have proved to be the best sources available as regards the aspects of monitoring accessibility and completeness of care. Health surveillance databases aims to routinely collect to detect anomalies or changes in providers activities or performance.

Health *ad hoc* databases are realized to collect specific information about an event that needs to be monitored, so data are collected specifically to monitor some aspects of quality and performance. Intervals for collecting data may vary according to the kind of information to provide: routine collection, regular intervals collection or *ad hoc* collection (Kumpunen et al., 2014).

Always more frequently a source of healthcare quality information is represented by patients or users themselves. In fairly recent times it occurred the development of a number of sites or blogs where patients give information, exchange opinions and make ratings. These kind of initiatives have both many vantages and disadvantages. For example, patients who directly received care can comment many aspect of care process, also not included in conventional surveys. On the other side, patients may not have technical or specific knowledge on some complex aspects of care and it is very difficult to verify identity and credibility of those who write a comment. Furthermore, given the complexity of understanding statistical information, it may happen that anecdotal personal information are favored in making choices (Trigg, 2011).

One of the most common and easily available source on healthcare quality information is Internet that makes possible a direct and fast access to information. This way of access allows to have ever up to date information, being able providers to timely updates them. Furthermore it is possible to create web sites customized to the users' preferences and easy to consult. However, the use of Internet could exclude to the access of healthcare quality information people without internet availability or unable to use it (Kumpunen et al., 2014).

The Evolution of Public Reporting In Healthcare

The great interest in quality management and improvement in healthcare induced systematic assessment and international benchmarking of quality of care provided. Many quality or performance assessment frameworks implemented at national, regional or local level have been developed as quality or performance improvement is possible only if measurement is fulfilled (Cacace et al., 2011). Measurement allows for monitoring effectiveness, guarantee patient safety, support decision-making and insurance value for money among other things (Smith, Mossialos, & Papanicolas, 2008).

Moreover, data on the quality of healthcare, compared between healthcare providers, has been publicly widespread producing the public reporting phenomenon. The first important public reporting initiatives date back to the 1980s and were developed in the United States: the publication of mortality rates by the Health Care Financing Administration (today Centers for Medicare and Medicaid Services) in 1986 and the New York State and Pennsylvania's Cardiac Reporting Systems in 1989 and 1992 (Schneider

& Epstein, 1998; Shahian et al., 2011). Afterward, many other high-income countries, especially in the West, have experienced public reporting in their healthcare systems (Faber et al., 2009).

The effects of the first implementation of public reporting varied widely among providers: many sustained that data did not take into account some patients' characteristics (i.e. age, comorbidities) that might influence their performance (James, 2012).

Actually, though there is a great number of public reporting websites they differ in many characteristics. First of all, websites should be managed at local, regional or national levels and should be operated by different stakeholders (i.e. governments, insurers or commercial organizations). Websites should be targeted at purchasers, regulators, providers or patients. Even the contents vary: not only performance information, that are the most common from waiting times to more complex clinical and patient experience indicators, but also information about structure, facilities and so on (Kumpunen et al., 2014).

There are, additionally, significant differences between public reporting due to healthcare system model. In example, in some insurance funded systems some data must be published (e.g. hospital admissions in Germany) and those are used at national level, regional or insurance level. In private insurance systems, like the United States one, where there is an high fragmentation of public reporting initiatives, a larger quantity of administrative and quality data are available, that makes the use of information more complex for all the stakeholders (Marshall, Shekelle, Davies, & Smith, 2003; Kumpunen et al., 2014).

Effects of Public Reporting In Healthcare

Which are the real effects of public reporting since its implementation? Is it able to support stakeholders' decision making and patients in choosing their own provider? Does it allow healthcare quality improvement?

Public reporting is supposed to: support and empower consumers/ patients to choose their provider and/or to share their opinions or preferences; help purchasers in their decision making processes, choosing providers that create value reaching population health goals; increase self-regulation among providers (Leatherman & McCarthy, 1999).

How should public reporting improve healthcare quality?

At first public reporting might help patients and referring physicians select high-quality providers. This happens if patients access the information, are able to understand the quality rankings and believe them and act on the information itself or if referring physicians use it. Even though patients and referring physicians don't use it, purchasers should use public reporting data in order to select or establish providers' contracts. Then rated providers should react to public reporting by improving the quality of the delivered care in three different ways: remediation (providers change their practices to improve quality); restriction (providers stop supplying care for which they rated poorly); removal (low-quality providers exit the healthcare market). It might also encourage quality competition, so that providers might compete on quality to maintain or improve their market share. Finally, public reporting might improve providers' accountability (Werner & Asch, 2005).

How Does Public Reporting Improve Healthcare Quality?

The growing interest in public reporting leads many authors to investigate the use and impact of publicly released performance data. Conflicting results emerged. A recent systematic review highlighted that outcomes' heterogeneity and moderate evidence's strength make it difficult to draw definitive conclu-

sions. Particularly, public reporting seems to have a positive impact on quality measures, although quality varies across plans or patients' subgroups. As regards harms or unintended negative effects, more evidence of no harm than evidence of harm emerged, especially on access. Providers seem to react to public reporting by changing positively their behavior, though evidences are scant and not available for all settings. Regardless of the setting, public reporting appears to little or no influence the selection of health services providers by patients, usually because they do not know that quality information is available, the information do not meet their needs or are not available when needed or are not understandable. It determines an effect if it is used by some subgroup of patients (i.e. younger, more educated patients). There is a few evidence about which report characteristics affected the impact of public reporting on any outcome. Some evidences show that public reporting is more effective in competitive markets and if referred to providers with initial lower scores (Totten et al., 2012). Intermediate and ultimate healthcare outcomes could be influenced by the way in which healthcare data are publicly reported. There are some specific examples of report characteristics that seems to be associated with public reporting effects:

- Acceptable/ appropriate: data should be believable, high quality and accurate
- Accessible: reports should be understood by target populations; it deals both with format, language, and graphics and advertising and promotion
- Actionable: on the patient side reports should help in keeping a decision; on the provider side (individuals or organizations) reports are related to factors they can influence (Totten et al., 2012).

The cost-effectiveness evaluation of a public reporting initiative is difficult, because a comparison between public reporting and other quality improvement intervention in terms of costs, benefits and risks is needed. The costs of public reporting typically include development of measures, methods and information systems, data collection and preparation, analysis and auditing, and public dissemination and education (Leatherman & McCarthy, 1999). More detailed analysis is needed to address this issue.

Analysis of the Major Initiatives of Public Reporting

The concept of patient engagement is based on the assumption that making patients co-producers of their health might enhance their satisfaction and responsibility with the healthcare system (Graffigna et al., 2015) and it strictly linked with the health provider choice. In the healthcare field, public reporting is one of the major tools in supporting patients' decisions making process, by providing structure, process and outcome measures. Nowadays, many public reporting initiatives exist that differ in some characteristics such as: the management that can be at local, regional or national levels, the property that can be public or private (i.e. governments, insurers or commercial organizations), the target (i.e. purchasers, regulators, providers or patients), main contents (i.e. performance information, waiting times patient satisfaction), the healthcare system model.

A web-based analysis of the major initiatives of public reporting was performed in order to highlight their main characteristics: properties (public or private), data source (governmental, not governmental, ad hoc surveys) and type of data reported (general information, doctors' information, patients' satisfaction). Two independent reviewers searched public reporting websites. The information was collected in an *ad hoc* database. The reviewers solved disagreements through discussion to reach a final consensus. Only public reporting websites in English or Italian were searched, as the languages spoken by the reviewers. Furthermore, public reporting initiatives if they did not allow comparison between providers.

Forty-one public reporting websites were identified, but only 18 were searched because in English or Italian. The excluded one were public reporting initiatives from Netherland, Denmark, Germany, Finland, Sweden and Norway. This is one of the major limit of our analysis as they could add further information about different items considered.

Seven out of 18 websites were subsequently excluded as they did not allow comparison between providers.

The analysis was conducted on 11 public reporting websites: 8 from the United States, 2 from Great Britain and 1 from Italy. Table 2 shows main characteristics of public reporting initiative investigated. Nine out of 11 were private initiatives, 2 were public. The property did not influence the data source

Table 2. Main characteristics of public reporting initiative investigated

Public reporting website	State	Web-site	Properties	Data source	Aim
United States: Medicare.gov	USA	http://www.medicare.gov/	Public	Governmental data	To find providers and compare the quality of their care
Leapfrog	USA	http://www.leapfroggroup.org	Private	Ad hoc surveys	To promote transparency through data collection and public reporting initiatives
U Compare Healthcare	USA	http://www.ucomparehealthcare.com/	Private	Governmental data. Ad hoc surveys	To help people make better decisions about their healthcare choices
California Nursing Home Search	USA	http://www.nursinghomeguide.org/NHG/nhg_txt_home.lasso_	Private	Governmental data. Ad hoc surveys	To help people search for a nursing home in California
National Committee for Quality Assurance (NCQA)	USA	http://www.ncqa.org/HomePage.aspx_	Private	Ad hoc surveys	To help people select a health plan or physician
US News Health	USA	http://health.usnews.com/	Private	Governmental data	To provide consumer guides that include rankings of hospitals, nursing homes, health plans
The American Hospital Directory	USA	https://www.ahd.com/	Private	Governmental data. Not governmental data	To provide information about hospitals
Quality Check	USA	http://www.qualitycheck.org/consumer/searchQCR.aspx_	Private	Not governmental data	To providing meaningful information about the comparative performance of accredited organizations
NHS Choices	GB	http://www.nhs.uk/Pages/HomePage.aspx_	Public	Governmental data. Ad hoc surveys	To create a new information, feedback, transactions and participation service delivered through mobile apps, SMS, phone lines and online channels
Dr. Foster	GB	http://myhospitalguide.drfoosterintelligence.co.uk/	Private	Governmental data	To use information to improve lives
Doveecomemicro	IT	http://www.doveecomemicro.it/	Private	Governmental data. Not governmental data	To find providers and compare the quality of their care

utilized: 8 out of the 11 websites used governmental data, of which 5 combined governmental data and other data source (not governmental or ad hoc surveys), 2 websites used only ad hoc surveys and 1 website used only not governmental data.

Regarding the type of data reported, all the public reporting websites investigated showed general information about providers such as structural and/ or processes indicators, 5 reported also information about doctors, 2 reported data also about patients' satisfaction /experience ratings and 6 reported also clinical indicators. Only the NHS Choices website showed all the type of data searched. The California Nursing Home Search and Quality Check reported only general information about providers.

As regard the aim of the public reporting initiatives searched, the interest in supporting patients choices showing providers information emerged as a common feature.

CONCLUSION

As a result of what was discussed, it emerged that involving patients in decisions about their health is a crucial component for the quality improvement of healthcare services. As previously mentioned, the IOM's report "Crossing the Quality Chasm" has been recognizing patient-centered care as an essential dimension of high-quality care (Clancy, 2011). In 2006, the World Health Organization indicates patients and the population engagement as one of the six domains of quality interventions (WHO, 2006).

Being patient involved and engaged, strictly connected with healthcare quality improvement, is important to stimulate strategies to make informed patients and able to take informed decisions about their health.

A well-recognized strategy to inform patients is the public reporting of health care information. This kind of strategy is relevant on a side to allow patients to take informed decisions on healthcare services according to their needs, on the other hand to guarantee accountability and transparency in provision.

As mentioned, accountability have to represent a fundamental issue to improving health systems performance and transparency increases benefits both for patients and health systems, improving availability of information needed to make informed healthcare choices, increasing trust in the patient-physician relationship and improving quality, safety and efficiency due to competition and availability of clinical benchmarks.

Public reporting of performance information and feedback to providers is recognized as one of the major approaches to improve quality of care, thanks to the possibility for providers to evaluate your own performance and to make a comparison with other providers and for patients to make informed choices. Furthermore, well designed public reports help patients making informed choices. Public reports seem to improve citizens and health consumers empowerment (Totten et al., 2012; Silenzi et al., 2013).

Because of the relevance of public reporting in improving quality of care and stimulating patient engagement, there are many public reporting initiatives, across different countries, that differs for many characteristics. In this chapter we reported the results of a web based analysis aimed at comparing major initiatives of public reporting, classified by the following characteristics: properties (public or private), data source (health providers, ad hoc surveys, etc.), general information reported (i.e. size, language spoken, amenities), doctors' information, patients' ratings (satisfaction /experience), clinical indicators. The results show that main common feature is the declared aim of all the initiatives analyzed: to support patients' choices showing providers information, despite consistent differences in properties of the initiatives or data sources.

In conclusion we believe that a good strategy aimed at informing patients about providers' performance through initiatives like public reporting websites could represent a way to improve healthcare quality, stimulating accountability of providers and transparency of decisions and making patients co-producers of their health.

KEY TERMS AND DEFINITIONS

Accessibility: The opportunity to have access to the care according to our healthcare needs.

Answerability: Responsibility for explaining or justifying one's actions.

Clinical Governance: Systematic approach to maintaining and improving the quality of patient care within a health system.

Disclosure: The act or process of revealing. Public disclosure is a situation in which an organization makes information available by publishing it.

Effectiveness: The capability of producing a desired result. In medicine, effectiveness relates to how well a treatment works in practice.

Efficiency: The ability to do things well, successfully, and without waste. Efficiency in healthcare is the capability to use resources to get the best results in terms of care with the less waste of resources.

Equity: The absence of avoidable or remediable differences among groups of people, whether those groups are defined socially, economically, demographically, or geographically.

Evaluation: Is a systematic determination using criteria governed by a set of standards.

Section 2

Tools and Technologies

This section presents an extensive coverage of various tools and technologies available in the field of Public Health and Welfare that practitioners and academicians alike can utilize to develop different techniques. These chapters enlighten readers about fundamental research on the many tools facilitating the burgeoning field of Public Health and Welfare. It is through these rigorously researched chapters that the reader is provided with countless examples of the up-and-coming tools and technologies emerging from the field of Public Health and Welfare. With 13 chapters, this section offers a broad treatment of some of the many tools and technologies within the Public Health and Welfare field.

Chapter 14

The Role of Management Accounting Systems in Public Hospitals and the Construction of Budgets: A Literature Review

Carla Marina Pereira de Campos

ABSTRACT

The role of management accounting systems (MAS) in the construction of budgets in the public health sector has been one of the least studied topics in the international literature. Furthermore, several studies have confirmed the loss of relevance of traditional approaches to budgeting due to the need to implement techniques that are more performance-oriented. Since public hospitals are organisations that depend significantly on public funds, with substantial impacts on governments' budgets, the pressure for reducing expenditures is strong, causing increased difficulties in hospital management. In order to analyse the role of MAS in the preparation of hospital budgets, this chapter presents a literature review on this topic. This review allows to understand the loss of relevance of traditional budgeting techniques and to present alternative approaches. In this process, the implementation of different kinds of budgeting is heavily influenced by governments and professionals. Nevertheless, the research on this topic is still very scarce, evidencing the need to continue studying it.

INTRODUCTION

The relevance of the information produced by management accounting systems (MAS) in public or private organisations is currently widely recognised. Like in the private sector, also in the public sector several organisations operate in an environment where cost information can be classified as a strategic resource for long-term financial sustainability. The imbalance in government accounts, due to excessive expenditures, and the complex nature of several public sector organisations – a reality of our days, make management accounting an urgent need also for these organisations.

As to the environment of the health care sector, a set of features must be pointed out, distinguishing this from other sectors, namely, the strong component of ethical judgments, uncertainty, economic inefficiencies and, ultimately, the conviction that health, together with the values of human life, is not measurable. Nevertheless, health care costs must be identified, planned, managed and controlled.

The increase in public health expenditure in recent decades has been a great concern in most of the Organisation for Economic Cooperation and Development countries. According to Organisation for Economic Co-operation and Development ([OECD], 2014), in 2012, the total health expenditure in Portugal corresponded to 9.5% of the Gross Domestic Product (GDP), slightly above the average for all member countries (9.3%).

This progressive growth of health expenditure is mainly due to: technological and scientific progress achieved in this area, which has led to significant improvements in services; the increasing use of prescription drugs; the growing prevalence of treatable chronic diseases; among other factors (Kaplan & Porter, 2011; Lapsley, 2001; Shortell & Kaluzny, 2006). As a result, people can now live longer and healthier lives.

The public sector is the main source of health financing in virtually all OECD countries (OECD, 2014). According to the same source, in Portugal in 2012, 65% of health expenditures were financed by public funds, i.e. taxes.

The changes made on the budget preparation methods have been one of the major responses of the Portuguese Government to this issue. Such changes include, for example, the implementation of the “program-contracts” in the health care sector. It is expected that, among other things, the budget promotes accountability in outcome management, as well as performance evaluations.

The budget has a central role in public sector management. This document relates to a specific period of governance and presents a set of expenditures and revenues that policy makers intend to carry out in the various budget items. Wildavsky (1975) argues that the budget is a vital element of any government because it reflects the action plan in the implementation of public policies.

Although some empirical studies show that the budget is one of the most important tools in planning and controlling organisations, there is an ongoing debate about the usefulness of traditional budgets (Abernethy & Brownell, 1999; Uyar & Bilgin, 2011; Tayles, Pike & Sofian, 2007). There is a growing recognition, by several authors, of the limitations of conventional budgets (Abernethy & Brownell, 1999; Andrews & Hill, 2003; Anessi-Pessina, Barbera, Rota, Sicily & Steccolini, 2012; Finkler & Ward, 1999; Hansen, Otley & Van der Stede, 2003; Hanninen, 2013; King, Clarkson & Wallace, 2010; Libby & Lindsay, 2003, 2010; Marginson & Ogden, 2005; Mikesell, 1995; Neely, Sutcliffe & Heyns, 2001; Sandino, 2007; Tayles, et al., 2007; Uyar & Bilgin, 2011). Some suggestions for improvement point to other budgeting approaches such as “performance-based budgeting” (PBB) (Andrews & Hill, 2003; Kong, 2005), “zero-based budgeting” (ZBB) or “priority-based budgeting” (PYBB) (Chartered Institute

for Public Finance and Accounting [CIPFA], 2006; Tayles et al., 2007; Worrall, Collinge, & Bill, 1998), and “activity-based budgeting” (ABB) (Hansen et al., 2003; Pinto & Santos, 2005).

In the health sector, the strong pressure from governments for reducing public expenditures and rationalisation of resources is an incentive for carrying out reforms to achieve a greater sophistication of MAS (Arnaboldi & Lapsley, 2005; Young & Pearlman, 1993). In this context, the ability to anticipate and respond to opportunities and pressures in organisational management is critical for obtaining the desired results. But is the public health care sector in Portugal prepared for these new requirements?

In recent times, the literature on management accounting has given more attention to budgeting and the role of MAS as a diagnosis tool in managing performance assessment (Helden, 2005; King et al., 2010; Tayles et al., 2007; Uyar & Bilgin, 2011). Additionally, there is a small number of empirical studies that analyse the relationship between MAS, contextual variables and performance (Abernethy & Brownell, 1999; Ezzamel, Robson & Stapleton (2012); Hammad, Jusoh & Oon, 2010; Johansson & Siverbo, 2014; Pizzini, 2006). However, the issue of adequacy of MAS to budgetary techniques used in the public sector, particularly in the health care sector, and its relationship with organisational performance, has been scarcely researched.

The purpose of this chapter is to present a literature review on the role of MAS in the preparation of hospital budgets, namely advancing how the introduction of new approaches to budgeting has evolved in this context. Additionally, the chapter also summarises some of the contributions made in the Portuguese public hospitals setting.

The next section offers an overview of the relevance of the MAS in the health care sector and the subsequent sections describe the role of budgets in MAS and the relevance loss of traditional budget techniques. The concern is to explore alternative budgeting approaches and analyse the main contributions that have been made to the Portuguese health care sector. The final section will comment on the main results of a literature review on the role of MAS and budgets in public hospitals.

THE RELEVANCE OF MANAGEMENT ACCOUNTING IN THE HEALTH CARE SECTOR

Considering the complex nature of health care, management accounting in this setting has assumed an important place and high visibility in the literature. The increase in average life expectancy, the development of new medical treatments and the latest advances in technology seem to have led to an unstoppable rise in health care costs all over the world (Kaplan & Porter, 2011; Lapsley, 2001; Shortell & Kaluzny, 2006).

Alongside these aspects, other factors such as the highly complex nature of health care organisations and the relevance of technical and hierarchical authority play an important role in the development of accounting information systems and, ultimately, in the quality of services provided. In recent years, these factors have received special attention by health authorities (Finkler & Ward, 1999; Hammad et al., 2010; Nyland & Pettersen, 2004).

Within the existing official health care organisations, hospitals tend to stand out due to their size and complexity. In Portugal, according to a survey carried out by the National Statistics Institute (Instituto Nacional de Estatística [INE], 2012), for the 2007-2011 period, only the general and specialised hospitals belonging to the public sector (including Corporate Public Entities, so-called EPE hospitals) were

responsible for 38%, on average, of current health expenditure (7% more than in the 2000-2008 period (INE, 2010)).

Data obtained by Brignall (1997), Hammad et al. (2010), and Pettersen and Nyland (2004) show that hospitals, defined as complex health care providers, have services which are sometimes difficult to define. According to these authors, the size, the institutional context and the complexity of these services explain most of the obstacles found to measure performance, results, and calculate costs. For example, in Portugal, the mandatory implementation of the Analytical Accounting Plan for hospitals (PCAH), since 1996, includes the deployment of hundreds of cost centres (Leite & Rodrigues, 2010). Hence, hospitals are expected to invest in the development of MAS, improving decision-making processes and operational planning and control, promoting economic growth, as well as high degrees of efficiency and effectiveness.

Traditionally, the use of MAS has not been a major concern within the public sector, health care in particular, given the inevitable costs and the lack of profit-oriented objectives. Additionally, it is also true that the value of human health is priceless. However, the need to manage and control the rising costs and rationalise resources, which are scarce, has placed a great deal of importance on the current role of MAS in hospital organisations (Kuchta & Ząbek, 2011; Pizzini, 2006).

Kaplan and Porter (2011) believe that if something cannot be measured, it cannot be managed or improved. Drury (2004) also argues that the main purpose of management accounting is to provide organisations with valuable information supporting managers in decision-making processes and promoting operational efficiency and effectiveness. The importance of management accounting has been highlighted in the literature, as it enhances the decision-making process (Drury, 2004), the flexibility to serve different purposes (Pizzini, 2006), taking into account the costs associated with a specific decision context (Smith, 2007).

Some international studies have considered the introduction of both management accounting and control techniques, and performance evaluation measures as the most significant changes in the accounting systems of the public sector over the past few years (Eriotis, Stamatiadis & Vasiliou, 2011; Jackson & Lapsley, 2003).

Finkler and Ward (1999), Jackson and Lapsley (2003), and Nyland and Pettersen (2004) argue that MAS are essential tools in the production of relevant information to support the decision-making process in management, budget control and accountability. For example, Jackson and Lapsley (2003) studied the use of management accounting techniques in the public sector. They found out that the activity-based-costing (ABC) method was the most used method for calculating costs, mainly in the health care sector. Following the same line of thought, other authors have also advocated the advantages of the application of the ABC method in hospitals: *... one of the most important contributions of the ABC method is that it helps improving financial decision making, as well as other decisions at the level of reorganisation and service provision* (Moreno, 2007, p. 122).

In Poland, the study conducted by Kuchta and Ząbek (2011) confirms the usefulness of ABC for hospitals, as it allows: the evaluation of resource consumption and its distribution among different organisational units; the analysis of the existing variations between budget planning and execution; and the implementation of activities that add more value to the organisation.

Ramsey (1994) states that hospitals should be allowed to increase or eliminate production lines and services in order to meet the needs of citizens and create value. The author presents three pillars that support the functioning and utility of MAS in hospitals: (1) increasing cost efficiency without reducing quality of medical services; (2) maximising internal resources through the internal management of

production lines and services; and (3) identifying opportunities for continuous improvement. Hence, Pizzini (2006) claims that cost reduction, performance improvement and profit increase can all be achieved if hospitals also focus on direct cost containment, instead of focusing only on the promotion of administrative efficiency. However, the author also pinpoints that detailed information does not itself reduce health care costs.

Despite the growing importance of MAS in the health care sector, which have been greatly emphasised in the international literature (Finkler & Ward, 1999; Jackson & Lapsey, 2003; Kuchta & Ząbek, 2011; Nyland & Pettersen, 2004; Ramsey, 1994), there has been some discussion on the fact that cost awareness in public social services has not been considered as important as in the services provided by private entities. Pizzini (2006) argues that the effective costs of health care services are unknown. The author adds that hospitals only use MAS with the main purpose of gaining external credibility. This view is also supported by Pettersen (1995) who argues that accounting information can serve the purpose of maintaining legitimacy, mainly because budgeting is often misaligned with operational services. By studying the ambulatory health care services in Poland, Kuchta and Ząbek (2011) also found that most of the existing problems are due to the lack of accurate information on costs, leading to inefficient management.

Some of the issues which have been emphasised in the literature are based on the belief that management accounting aims to provide awareness of the costs arising from the activities carried out by health professionals within a hospital setting, since they are responsible for the highest consumption of resources, especially in the case of doctors and nurses (Hill, 2000). Nyland and Pettersen (2004) argue that there is still a long way to go before medical decisions legitimise information about costs. The authors also add that most of the professional groups see accounting information as useful if related to performance evaluation systems and incentive schemes.

A study conducted in England by Jones and Dewing (1997) confirmed that the awareness of hospital costs and revenues was based on accounting abstraction, with very little or no contribution of health professionals and directors. The interaction between managers and professionals is considered by some authors as tense and dichotomous. The reason for this relates to the fact that managers are more concerned with organisational aspects, such as efficiency, economy and cost imposition, whereas health professionals are more focused on the provision of medical care guided by a set of ethical principles. For example, Hewison (2002) showed the complex relationship existing between these two groups of professionals, challenging managers to reconsider a change in their leadership style. This author encourages managers to assume the role of a mentor and facilitator in finding solutions to problems, together with health professionals.

Most of the difficulties found in measuring and controlling health costs are: legitimacy issues (Pettersen, 1995; Pizzini, 2006); problems in production of accounting information by a large group of professionals who are not interested in these issues (Hewison, 2002; Jones & Dewing, 1997; Nyland & Pettersen, 2004); and a reduced use of such information in decision-making (Kuchta & Ząbek, 2011; Leite & Rodrigues, 2010; Pizzini, 2006). However, management accounting is still an important system of information in hospital settings all over the world.

In Portugal, under the New Public Management (NPM) wave, several changes have occurred in the legal status of hospitals, mainly due to the application of private sector management methods and greater accountability. These reforms, along with the conviction that public service management models were inefficient (Leite & Rodrigues, 2010), have favoured the need to improve management accounting and control in hospital settings.

Until the 1980s, in the Portuguese health care sector, there were a few incentives to invest in this kind of systems (Pereira, Sá & Jorge, 2009). The main objective of the management accounting systems that were implemented was to produce information on costs for external supervisory bodies, such as the Central Administration of the Health System (ACSS), mainly for financing and budgeting purposes. However, with the introduction of financing mechanisms based on the assignment of fixed values for each service (Diagnosis Related Groups – DRG), hospitals became responsible for the existing inefficiencies. Old management methods have been challenged by the growing demand for greater transparency in public expenditure and the increasing emphasis given to results, without neglecting the quality of the services provided to the community. This explains why MAS have assumed such an important role in Portuguese hospitals over the last few decades (Barros & Simões, 2007; Leite & Rodrigues, 2007, 2010; Pereira et al., 2009).

Despite the relevance of this issue, research studies in the health care sector are still scarce in Portugal. The few studies that have been conducted recognise that the role played by MAS in the Portuguese public hospitals is quite limited, since information providers mostly limit themselves to comply with the legal requirements issued by the supervisory bodies, neglecting the internal value of that output.

Leite and Rodrigues (2010) analysed 26 Portuguese EPE hospitals and concluded that standard cost indicators show inefficiencies from hospital to hospital. However, a sole cost benchmarking analysis is not sufficient since features of each organisation should be considered, such as its context, complexity, and clinical data. The authors conclude that political, cultural and social factors are more important than efficiency, making cost standardisation irrelevant to management.

In a study on the role of management accounting practices in performance monitoring and evaluation of Portuguese EPE hospitals, Leite and Rodrigues (2007) identified other gaps, such as: the low level of implementation of the PCAH; the lack of guidance in the calculation of profits and in the establishment of parameters for budgeted costs and the lack of management indicators for efficiency evaluation.

The implementation of new management accounting techniques is not a panacea for solving, by itself, the inadequacies found in the management of Portuguese hospitals. But, it is also true that strong institutional pressures to reduce costs in a context of financial crisis is a motivation for carrying out reforms to ensure greater sophistication of MAS (Arnaboldi & Lapsley, 2005; Young & Pearlman, 1993). Therefore, the challenge is to develop transversely new concepts, practices, and ways of addressing problems, promoting the active collaboration of governments, managers and health care professionals. But is the health care sector in Portugal prepared for these new challenges?

MANAGEMENT ACCOUNTING SYSTEMS AND BUDGETS

The definition of the objectives of management accounting systems (MAS) for the public sector by the International Federation of Accountants reinforce the importance of budgeting as a planning and control tool (International Federation of Accountants [IFAC], 2000). According to this organisation, the pressures set by governments for budget cuts in tandem with public service improvement, require extensive knowledge of the entities' cost structures. For better decision making, the full use of management accounting is crucial (IFAC, 2000, p. 5).

In recent decades, the international literature has come to recognise the budget as one of the main vectors in performance evaluation and innovation of MAS, especially in those organisations facing strategic change (Abernethy & Brownell, 1999; Anessi-Pessina et al., 2012; Ezzamel et al., 2012; Jo-

hansson & Siverbo, 2014), with particular emphasis on the health care sector (Abernethy & Brownell, 1999; Jackson & Lapsley, 2003; King et al., 2010; Lapsley & Wright, 2004; Macinati & Rizzo, 2014).

Abernethy and Brownell (1999) argue that an appropriate response of MAS is essential for the survival of organisations. Based on the data collected in 63 Australian public hospitals, the authors emphasize the value of using budgets adjusted to strategic changes, especially at the level of goal-based performance, performance evaluation and greater accountability of managers. The budget is, thus, considered a core pillar in most MAS, representing an important tool for the coordination and communication of the strategic priorities of top management to low-level management.

Considering the tight connection between contingency factors, budgeting practices and the performance of organisations, King et al. (2010) presented relevant evidence for Australian primary health care units. From 144 answers in a universe of 988 members of the Australian Management Practices Association, they found that the contextual factors identified by contingency research are useful to identify budgeting practices and the extent of such use. In addition, the authors have presented evidence of the relationship between budgeting practices and performance. They concluded that the performance evaluation of an activity is related to the choice of budgeting practices.

From the point of view of both top managers and policymakers, Macinati and Anessi-Pessina (2014) confirm most of King et al.'s (2010) results through a recent questionnaire that was mailed out to all Italian public health care organisations. Their findings mostly suggest that cost-containment strategies encourage more sophisticated MAS. Furthermore, the use of MAS is directly and indirectly influenced by contingency, organisational, and behavioural variables. The authors also found a significant positive relationship between MAS use and financial performance.

In a bottom-up analysis, Wickramasinghe (2015) also reflected on management accounting and health care budgets. His analysis of Sri Lankan health care reform suggests that: *cost accounting acts as a mediating instrument: it begins to loosen the old Keynesian post-colonial bureaucratic budget confinements, creates a social space for individuals to consider cost-saving experiments, and addresses wider policy concerns about hospital resource management* (Wickramasinghe, 2015, p. 323).

Following this thought, another study on the use of budgets in the health care sector draws attention to the level of motivation of the clinical management of an Italian hospital, in the pursuit of participatory budgeting and its connection with individual and organisational performance (Macinati & Rizzo, 2014). The results show that the budgetary participation motivates clinical managers to comply with budget targets. They also conclude that budgetary participation can shape the culture of these agents, increasing the level of their identification with organisational goals. Based on this result, the authors emphasise the idea that committed clinical managers are more likely to use budgetary information, therefore suggesting that the convergence between individual and organisational goals should be seen as a key element in management accounting and control systems.

Similar to Macinati and Rizzo (2014), Johansson and Siverbo (2014) also draw attention to the surprising problem of the reduced number of studies analysing the design, the use and the effectiveness of budget control systems in the public sector. For these authors, the budget and budgetary control are the main goal of planning, control and accountability in the public sector. The budget deviations in this sector represent an important performance dimension. The study analyses the current political and institutional pressures regarding the performance of public organisations, to prevent them from overspending or falling below budget. Based on the information collected from the analysis of 196 Swedish municipalities, it was concluded that in a more turbulent budgetary environment, the implementation of strict budgetary control is the functional response that increases the probability of complying with

the budget targets. However, if the budgetary turbulence is only marginal, municipalities tend to carry out activities similar to those of the previous year, and the implementation of strict control mechanisms has no effect on budget deviations. According to Johansson and Siverbo (2014), the most significant contribution of their work was the assessment of the impact of the political and institutional environment and tight budget control on budgetary performance.

Beyond the health sector in particular, public sector in general has been the object of international research, with the aim of analysing the changes and innovations deriving from the adoption of management accounting practices. The diffusion and innovation of MAS has assumed, in the public sector, a new importance due to the reforms occurring in the context of NPM (Jackson & Lapsley, 2003; Lapsley & Wright, 2004). In addition to cost calculation methods and performance measurement tools, the main innovations also include budgeting techniques.

The work developed by Lapsley and Wright (2004) demonstrated the power of political and governmental influence in the adoption of these techniques. Based on a questionnaire made to 258 members of Scottish organisations in the public sector, the authors concluded that, from the several budget techniques used, the resource management technique (RM) was the most popular, with 34% of public organisations using this tool.

The introduction of new budget practices in institutional change settings, with a very distinct and competitive logic, served as a basis for the study of Ezzamel et al. (2012). The authors divided their empirical analysis into two stages: in 1990 and in 2011, including the tensions identified between the reforms carried out in the education sector in the UK (primary and secondary education), which led to the materialisation of the business logic (the dominant logic), as well as the professional and governance logics. Based on the neo-institutional theory, the authors observed the introduction of new budget practices centred in the allocation of resources and in the creation of centres for budget accountability, aiming to understand the role of MAS in institutional change processes, especially after the Education Reform Act 1988. The budget changes materialised a business logic which, in turn, allowed restructuring the schools. Since the management model used by the local education authorities was no longer efficient, the new budgetary process introduced new budgetary planning and accountability practices, involving teachers and school principals.

Planning and management modernisation processes in the public sector emphasise the relevance of adopting new management mechanisms and techniques. In addition to the innovations observed in financial accounting and in techniques used to support daily management (Hood, 1991; Lapsley, 1999), budgetary reforms were also carried out. The role of budgets was considered key in MAS and administrative management (Anessi-Pessina et al., 2012). According to these authors, management reforms in the public sector promoted the budget as an essential tool in supporting organisational action, creating cost limits by nature, function and responsibility centres; defining functions in decision-making; specifying criteria and parameters for service provision, monitoring and performance evaluation and aligning the individual interests with those of the organisation.

As a result, the administration of public entities and their management accounting and control systems have gained greater relevance in recent years. In addition, the need to improve and redesign alternative budget formats has increased significantly (Abernethy & Brownell, 1999; Anessi-Pessina et al., 2012; Finkler & Ward, 1999; Hansen et al., 2003; King et al., 2010; Marginson & Ogden, 2005; Sandino, 2007; Tayles et al., 2007; Uyar & Bilgin, 2011).

The Role of Management Accounting Systems in Public Hospitals and the Construction of Budgets

It is in this environment of institutional pressures for more efficient performance in resource allocation in the public sector that researchers draw attention to the urgent need to go beyond existing budgeting models, creating new definitions, objectives and interpretations of budgets, one of the main vectors of MAS.

The following table (Table 1) summarises some of the key studies discussed in this section indicating the object of study, problem, main results, theories and approaches used, and the publication journal.

Table 1. Empirical research on budgets and management accounting systems

Budgetary participation does not directly influence the use of budget information, but the latter is encouraged by the level of budget goal commitment which, as a result, is influenced by the positive motivational consequences of participative budgeting (Macinati & Rizzo, 2014: 228).	Goal-setting theory	HP

RELEVANCE LOSS: TRADITIONAL BUDGETING TECHNIQUES AND ALTERNATIVE APPROACHES

Since 1990, the Governmental Accounting Standards Board has emphasised the need to strengthen the development of new management accounting practices in the public sector. These practices are intended to provide a better performance measurement, helping to achieve governmental goals (Governmental Accounting Standards Board [GASB], 2005).

Anessi-Pessina et al. (2012) conducted a study on budgetary practices within the European public sector based on the analysis of papers published in international journals in the field of management accounting. The aim of the study was to identify the different dynamics of two reference periods: (1) the 1980s – a period characterised by studies which focused on the analysis of the budgeting process, and (2) the 1990s – a period when studies became more focused on the changes of budgeting processes. In the first period the main aim was to contribute to the existing body of research on budgeting in the public sector. In the second period, the aim was to contribute to the body of scientific knowledge and to improve the understanding of ongoing reforms. The present research is included in this second phase and aims to provide valuable insights into the major paradigm shifts in budgeting processes.

Traditional-Based Budgeting (TBB)

From an international perspective, most of the studies carried out over the last decades in the field of management accounting have assumed, with rare exceptions, that budgets have a diagnostic role (Abernethy & Brownell, 1999; King et al., 2010). According to this approach, budgets seem to fulfil the traditional role of allocating available resources.

As a result, several studies address the general issue of budgeting and the fact that the traditional budgets (line-budgeting) have lost relevance (Abernethy & Brownell, 1999; Andrews & Hill, 2003; Anessi-Pessina et al., 2012; Finkler & Ward, 1999; Hanninen, 2013; Hansen et al., 2003; King et al., 2010; Lindsay & Libby 2003, 2010; Marginson & Ogden, 2005; Mikesell, 1995; Neely et al., 2001; Sandino, 2007; Tayles et al., 2007; Uyar & Bilgin, 2011). Some proposals for enhancement point to alternative budgeting approaches, namely “performance-based budgeting” (PBB) (Andrews & Hill, 2003; Kong, 2005), “activity-based budgeting” (ABB) (Hansen et al., 2003; Pinto & Santos, 2005), and “zero-based budgeting” (ZBB) (Akten, Giordano & Scheiffele, 2009; Finkler & Ward, 1999; Lapsley & Wright, 2004; Pyhrr, 1973, 1977; Wildavsky, 1975) or “priority-based budgeting” (PYBB) (CIPFA, 2006; Tayles et al., 2007; Worral et al., 1998).

According to Faria (2010), in Portugal, the current budget process can be characterised as traditional, with an incremental basis (functional departments based on line-items) and a rigid expenditure structure (budget appropriations). Furthermore, the implementation of performance management is still incipient. Therefore, the need to control inputs, to promote accountability in outcome management, and to undertake systematic performance evaluations and assessment of budgetary outcomes, require changes in the budgeting process, such as behaviours and the redefinition of the information systems.

Traditionally, similarly to what happens in Portugal, most governments have decided to adopt the incremental budgeting approach. In this technique, the budget preparation for the following year is based on the approved budget for the current year plus an increased amount considering inflation. This is the simplest budgeting method, in which the main focus of the incremental approach is the input control (Andrews & Hill, 2003), promoting a system of accountability and budget execution control (Pinto &

Santos, 2005). However, as this technique is based on the budget approved for previous periods, it does not promote medium and long-term planning or the effective achievement of objectives, regarding the use of available resources or their efficient allocation.

Therefore, in traditional budgeting the definition of the amount of resources to be allocated to the various public entities or departments is based on patterns of previous periods, including marginal additions. The decisions made and the priorities established in the past are more likely to remain unchanged in the future. The reassessment of the needs and priorities of subsequent periods does not take place, meaning that this kind of budget does not promote strategic options, maximisation of value, opportunity and efficiency in resource control, evaluation of results and performance.

Mikesell (1995) draws attention to the fact that incremental budgets tend to emphasise the adequate utilisation of available funds, as they are not prepared to enhance the best decisions in the allocation of resources. Accordingly, the author argues that the public sector traditional budget appeared in a period when the main concern in budget preparation and control was essentially the prevention of fraud and corruption. Although more recently governments have progressed beyond this stage, the traditional approach is still present in the current budget practices.

The study by Neely et al. (2001) presented the most cited weaknesses of traditional budgeting. Some of the major disadvantages identified in the study were: the lengthy process, the high preparation costs, and mainly the lack of focus on strategy. The study also highlights the fact that this budgeting model does not favour the increment of the organisations' value, given its strong focus on cost reduction and departmental barriers.

Similarly, Hansen et al. (2003) also highlight the emphasis given to financial measures in these traditional models. According to the authors, this is related to the concentration of efforts in reducing costs, more than value maximisation.

In a more recent study, developed by Uyar and Bilgin (2011), the disadvantages of the traditional model are also highlighted. The excessive time spent in the management process is one of the gaps of the traditional model. Some findings suggest that the traditional planning and budgeting processes may consume up to 20% of the whole management time (Libby & Lindsay, 2003).

Consequently, some authors regard this technique as a "relic" (Hanninen, 2013) since it prevents some historical reactions but it cannot be adapted to the changes and current requirements of organisational management. Similar results were discussed by Libby and Lindsay (2010) in their study. The authors report that the traditional budget does not consider strategy. Additionally, it is expensive and slow at detecting problems, becoming obsolete very quickly.

Performance-Based Budgeting (PBB)

The new budgeting approaches take place in this scenario of relevance loss of traditional models. The advantages of the implementation of the PBB approach are also evidenced by Kong (2005) in a study on USA public administration. The central question raised by the author was: what is new about PBB when compared to conventional budgeting techniques (incremental line-items)? The author identifies three key vectors in the conventional public budgeting structure: the allocation of resources, organisational management and citizens. Incremental line-items budgets are mainly focused on the allocation of resources, including financial, human, and technical resources. The first versions of PBB were, according to the author, connected with organisational elements, including the definition of key objectives, political goals and activities. Later versions, in the 1990s, focused on the outputs, service quality and

citizen's satisfaction. The author could not guarantee that the change from a traditional to a PBB model could be done in a short period of time since PBB has a long term view.

With the aim of studying performance evaluation, Andrews and Hill (2003) developed a study on the performance-based budgeting (PBB) technique, comparing it to the traditional approaches. They concluded that most American states had carried out reforms on PBB implementation, yet very few presented behavioural changes resulting from such reforms, both in terms of overall development and of response to new incentives based on performance or on resource allocation. The authors also explain that the PBB approach is applied simultaneously with traditional techniques, influencing the type of PBB to be implemented, rather than complementing existing budgetary practices.

It can be concluded that the effectiveness of the PBB technique is enhanced when the old budgeting systems are totally replaced, as observed in the experiences carried out in the States of Florida and Virginia. These states included (Andrews & Hill, 2003: 152): management accounting and auditing systems based on performance; adjustment of the existing budgeting systems to strategic changes, according to the specificities of the various bodies (tailoring model); introduction of responsibilities in required levels of performance; and behavioural uniformity in budget compliance, which should include simple rules, clarity and seriousness in the announcement of performance expectations by budget managers.

As discussed earlier in this chapter, the traditional budgeting process is not designed for managers to evaluate and rethink their models of action or to evaluate their performance if, for example, economic recession persists. Contrarily, most of the current budgets are anchored to the budgets of previous periods, improved only by the adjustment to the rate of inflation or the specific trends of products or services (Akten et al., 2009).

Activity-Based Budgeting (ABB)

Activity-based budgeting (ABB) also emphasises outputs and value creation. Many authors argue that ABB is the most common alternative technique to the traditional approach. This approach provides a high level of detail, when compared to other techniques (Pinto & Santos, 2005).

According to Hansen et al. (2003), the financial guidance of traditional budgets is, undoubtedly, problematic. In other words, they do not favour the understanding of financial data by operational managers. Furthermore, if the top-down process is not aligned with the activities, the budget cycle should respect the preparation of financial budgets after the operational budgets are prepared. The idea is to create a new budgeting model that allows for greater flexibility in the organisation while dealing with unexpected events, emphasising thus the importance of operational planning (Hansen, 2011).

ABB highlights communication and internal cooperation since it focuses on activities rather than on responsibility centres, showing the imbalances, the useless activities and other information that can be used to enhance operations where resources are actually needed (Pinto & Santos, 2005).

Even though this model is oriented towards continuous improvement, with an emphasis on the outputs, the ABB process is still a relatively new concept and its practical advantages are yet unknown. Hansen et al. (2003) draw attention to the lack of scientific evidence to support its benefits and its pragmatic viability.

Zero-Based Budgeting (ZBB) and Priority-Based Budgeting (PBB)

Zero-based budgeting (ZBB) technique seeks to overcome the criticism that is usually attached to the TBB. The concept of ZBB emerged in the 1960s to address the failures of incremental budgeting (Drury,

2004). This denomination was used for the first time by Pyhrr (1973), who developed the process for Texas Instruments. Due to its success in the private sector, this model was also applied in the preparation of the 1973 budget by the Governor Jimmy Carter in the State of Georgia.

Drury (2004) defined this technique as an approach where all activities are justified before the decision on the amount of resources to be allocated to each activity. In the ZBB approach, the focus is given to programs or activities instead of focusing on the functional departments (typical of traditional approaches).

According to Finkler and Ward (1999), the four main objectives of the ZBB approach are: (1) to analyse the activities performed within the organisation, (2) to understand the origin of those activities, (3) to study the most efficient and effective way to accomplish those tasks, and (4) to identify the vital activities of the organisation and their cost. The authors also highlight the ZBB focus on budgeting expenditure, identifying another positive aspect of this technique: the special emphasis given to non-acceptance of longstanding government budget surpluses.

Many articles were published in the 1970s about the ZBB technique, even though the number decreased rapidly in the early 1980s (Drury, 2004). Currently, they are almost non-existent (Tayles et al., 2007). The gap between the years of successful research and present research has obscured the theory and the practice of ZBB technique, together with the political burden involved.

Several academics have provided a few reasons for this lack of success; the powerful message that “the expenses have to be fully justified”; excessive bureaucracy; high costs; professional awareness and consequent long procedures (Drury, 2004; Tayles et al., 2007; Worrall et al., 1998). Success will depend, according to Worrall et al. (1998), on the implementation of a solid strategic process.

Wildavsky (1975) presented an unsuccessful case in the US Department of Agriculture. The reasons for failure were mainly: the allocation of specialised human resources for the exhaustive and systematic task of identifying priority needs; the need to justify things from scratch, even though that was not possible with programs that could not be replaced or changed and, finally, the non-acceptance, felt by the professionals, of the economic rationality logic, pressured by the constant monitoring of the tasks performed, even though they recognised the advantages of this technique.

On the other hand, the study by Akten et al. (2009) presented a positive experience in the application of the ZBB technique. The authors identified a European telecommunications group which, in the implementation process, began to disaggregate their expenses into “logical decision units”, considering new types of expenses, such as capital expenditures (for example, building a third generation network). Each decision unit of capital expenditure was classified into the following categories: (i) reviewing, (ii) maintaining, and (iii) cutting down capital expenditures. The authors discussed the financial priority of each capital expenditure and its alignment with the company’s strategy. After a few interactions, the company reached the goal of reducing capital expenditures by about 20%.

Pyhrr (1977) summarised the main goal of the ZBB technique, which was based on two key issues: (1) efficiency and effectiveness of the activities carried out by an organisation, and (2) the possibility of eliminating or reducing organisation’s activities to afford new programs or simply help reduce the budget.

Drury (2004) argues that the ZBB approach assumes that the need to present the different expenses related to the activities in a ZBB ensures the allocation of all resources on a “cost-benefit” basis. Following this principle of allocation, organisations and governments will be one step closer to ensuring “value-for-money”, questioning old assumptions and implementing a systematic analysis tool which might, for example, be able to declare the abandonment of unproductive contracts, projects or programs. Nevertheless, supported by the bottom-up strategy, the implementation of the ZBB technique implies the justification of all expenses, therefore introducing a certain economic rationality.

Lapsley and Wright (2004) argue that the adoption of new techniques of accounting and management control is largely stimulated by the government. After analysing the Scottish health care sector, the authors concluded that the ZBB technique was the most used by these bodies: *The health care sector made particular use of budgeting techniques, with organisations using zero-based budgeting (ZBB) as well as one or other of management (RM) and activity-based management (ABM). In contrast, its use in local authorities and government agencies was much lower, with over half of these organisations not using any of these techniques* (Lapsley & Wright, 2004, p. 358).

According to this study, the National Health Service units are under high pressure to ensure any future savings and efficiencies. The adoption of the ZBB technique is defended by the government to establish areas of cost savings. On the other hand, according to managers of health care organisations, the ZBB technique is complex and time consuming (3/4 months to be completed), with very low returns for the organisation. Nevertheless, one of the main results of the interviews carried out in this study classified the ZBB technique as one of the most efficient techniques within the MAS.

The debates about the pros and cons of the ZBB approach have been mostly supported by empirical research (Akten et al., 2009; Pyhrr, 1977; Wildavsky, 1975). But, research on the ZBB approach has become scarce, namely from the 1980s. Despite the relevance loss in this period, ZBB seems to have again become an interesting research challenge with the main purpose of producing empirical knowledge about this technique and assess its effectiveness within organisations, namely, within the health care sector. As this sector becomes more complex, with increasingly higher costs, the need for new and better management accounting methods and tools also becomes stronger, especially for the entities which are subject to government pressures.

The priority-based budgeting (PYBB) approach is a technical extension of the zero-based budgeting (ZBB) approach. The main objectives of the PYBB model are to emphasise corporate priorities in line with budget increasing. According to the Chartered Institute for Public Finance and Accounting (CIPFA, 2006) its mode of operation is based on the review of current departmental services and its evaluation requires the definition of some parameters: purpose of the services; standards for the provision of services and operating alternatives for such services. It is based on the analysis of these parameters that the items of expenditure for each unit of revenue will be ranked, which is a beneficial and highly expected factor for management decision makers.

Within this approach, Worrall et al. (1998) demonstrated that the laws of a local government in the UK favoured, among other aspects, the implementation of strategic priorities. The authors relate strategy-based budgets with the PYBB technique. In their study, it was concluded that 60% of the analysed councils had submitted a strategic plan, although there was no consensus on the definition of “strategic management”. The authors classified “strategy” as the management of a set of activities that will meet priority objectives based on values of equality and local democracy in detriment of more “sophisticated” purposes which were less adjusted to the real needs of organisations. As resources become scarcer, local political forces tend to focus more on their priorities. Even though many bodies are still acting according to the paradigms of the 1970s, there is strong evidence that most governments are rethinking the process of strategic definitions to achieve a mutual consensus on the effectiveness of the achieved results.

In order to provide a synthesis of the main advantages and disadvantages of the different budgeting approaches analysed in the present study, Table 2 was prepared.

Table 2. A comparison of different budget styles

Budget Style	Strengths	Weaknesses	Research
Traditional budgeting (incremental, line-items)	Simplicity, inexpensive.	Lack of strategy link; focus on margins; the cuts are arbitrary; delays in procedures	Andrews & Hill, (2003); Anessi-Pessina et al. (2012); Mikesell (1998); Neely et al. (2001).
Performance-based budgeting	Focused on outputs, quality of service and citizen's satisfaction.	Few changes in behaviour	Andrews & Hill (2003); Kong (2005).
Activity-based budgeting	Emphasis on outputs and value creation, reduction of bureaucracy; focus on activities and on the operational plan.	Reduced practical implementation; little knowledge of its real advantages.	Hansen et al., (2003, 2011); Pinto & Santos (2005)
Priority-based budgeting	Budget connected with strategy; global and participatory perspective.	Laborious, difficult to implement.	CIPFA (2006); Tayles et al. (2007); Worral et al. (1998).
Zero-based budgeting	Resources needed in a "cost-benefit" basis; focus on programs and activities; economic rationality.	Complexity in implementation, high costs, excessive bureaucracy, procedural delays.	Akten et al. (2009); Finkler & Ward (1999); Lapsley & Wright (2004) ; Pyhrr (1973, 1977); Wildavsky (1975)

WHAT CONTRIBUTIONS HAVE BEEN MADE TO THE PORTUGUESE HEALTH SECTOR?

Government management standards have changed over the last years and Portugal is no exception. In 2008, the OECD highlighted the need to restructure the Portuguese budgeting process: *The adoption of approaches oriented towards budget and management performance is of utmost importance for Portugal* (OECD, 2008, p. 4). Nevertheless, OECD (2008) proposes that this implementation is based on three main stages: a first stage where a medium-term budget program is developed (corresponding to a legislative period – 4 years – which is already included in the current Portuguese legal budget framework – paragraph 2 of Article 21-A of Law No. 41/2014); a second stage, which included the development of performance information for the various programs and ministries and the identification and creation of the necessary information systems; and finally a last stage in which performance information should be gradually integrated in the decision making process.

Following the meeting of the Council of Ministers held in April 2015 (Portuguese Government, 2015), Portugal approved a new draft budgetary framework for 2016, which follows the guidelines of the current budgetary framework (Law No. 41/2014) and the international and European standards. Nevertheless, this proposal provides an integrated budgeting system, implying a change in the whole structure and composition of the Budgetary Framework Law regarding its principles and rules, implementation and control systems. Based on this draft, Portugal intends to give emphasis to those programs which are focused on results rather than on resources, meaning that the program budgeting is not necessarily a way to reduce public spending. Its main objectives are the improvement of the accountability of the sectoral ministries in a logic of top-down budgeting, and ensure that the program budgeting is, in fact, focused on results that can be evaluated using the most relevant indicators.

Furthermore, the medium-term horizon recommended by OECD (2008), and apparently accepted by the Portuguese government, contributes to the stability and credibility of these urgent reforms.

In the public health care sector, the budget of Portuguese hospitals was based on the previous year's funding for many years. According to Amaro, Borges, Candoso, Ferreira and Valente (2008, p. 1):

... in 1997 a new activity-based resource allocation model was adopted, the case-mix² was introduced (inpatient and ambulatory surgery were classified using Diagnosis Related Groups - DRG) and a growing portion of the budget was based on the prevision of the hospitals activity (from 10% in 1997 to 50% in 2002).

In 2002, with the corporatisation of some Portuguese hospitals, the traditional public sector hospital was replaced by corporate public entities, adopting new legal statutes, with private management techniques and procedures. Moreover, the financing of public hospitals started to be made mostly from current transfers from general government on a contract performance basis. This model of financing is established according to a contract performed between three entities: the Ministry of Health, represented by the Central Administration for the Health System (ACSS), the Regional Health Administrations (ARS), and Hospitals.

Major and Magalhães (2014) argued that the retrospective type of financing was over because the hospital activities were no longer funded by the Portuguese state, as occurred in the past. The state intended to only provide funding to the activities contracted by the ACSS and hospitals at the beginning of each calendar year (a prospective nature). Therefore, after consulting the State Budget and the funds allocated to the health care sector, the Ministry of Health shall define, a priori, the hospital production amount to be "bought" annually for each hospital.

Contracting has been an important process used to improve performance within the Portuguese health care sector. It aims to encourage providers to increase quality and efficiency of services, especially when facing the dilemma of the increase of health care needs, due to demographic factors and technological progress, on one hand, and the urgency to reduce expenditures, on the other hand. The hospital should commit itself to establish quantity and quality goals for particular activities (to be negotiated among all entities involved) and the budget should only cover expenditures that can be justified (Lopez-Valcarcel & Perez, 1996).

Hence, the "program-contracts" have emerged, establishing a commitment between the purchaser (hospital) and the funder (ACSS), in which the hospital budgets for the subsequent year shall depend on the performance outcome of the previous year. Thus, if the hospital produces more and, therefore, overexpends what is stated in the "program-contracts", it will not be reimbursed by the Portuguese State in accordance with the new management model adopted for the National Health Service (NHS).

To ensure that such goals and contractual clauses are respected, the monitoring of contracts should be supervised and precisely regulated by the State (Araújo, 2005). The most important attraction of the "program-contract", according to Lopez-Valcarcel and Perez (1996, p. 378), is that health planning becomes easier mainly due to the link established between hospital activities and the epidemiology goals previously included in the health agenda, and the possibility to allow planners to benchmark health care levels across different locations.

Valente (2010, p. 39) also highlighted several advantages for all agents involved in this process. According to the author, this model has *introduced dynamism, improved knowledge regarding supply and demand, promoted information sharing between those responsible for the distribution of resources and the care providers, being an incentive to the accountability of all stakeholders involved in the process by the way resources are expended.*

Despite the relevance of contracting and the performance-oriented logic involved, there has been some discussion about the gaps found in this process, mainly due to the identification of the activity costs.

The study conducted by Borges et al. (2010) allows to understand the importance of implementing a costing system tailored to the needs of the different actors involved: *A costing system allows a better understanding of costs as well as a growing awareness of the limitedness of financial resources, making it essential to any health care system* (Borges et al., 2010, p. 112). The authors researched the reasons why the Portuguese Ministry of Health launched, in 2007, the ABC project in five pilot hospitals within the NHS. They explained the numerous advantages of the ABC method, especially at the level of cost calculation per activity, identifying the most prominent advantages, and their ability to provide clues for a more efficient utilisation of resources. Despite all the advantages found, the study also detected some gaps related to the recent implementation of the ABC project in the pilot hospitals, which, at the time of the study, had only been concluded in three of the five national hospitals that integrated the initial group. The definition of the activities, the identification of activity and cost drivers, the involvement of professionals with different profiles and their fear related to performance evaluation were the main challenges and difficulties of this project.

Despite these arguments, the importance of the management accounting tools and budgeting techniques is undeniable, as stated in the study of Vicente, Major, Pinto and Sardinha (2009) on the role of management controllers in Portugal. The authors concluded that budgets and the deviation analysis are the most prominent tools in Portugal (as in the United Kingdom).

The strong institutional pressures resulting from the current economic and financial environment and from the deficit in current government accounts impose stringent measures related to public hospital budgets. The adoption of new legal statutes by Portuguese hospitals, with the improvement of greater performance and accountability, implies the implementation of management accounting tools that meet the essential needs of budget discipline. But there is still a long way to go! Quoting “The European Public Health Alliance” (EPHA, 2014, p. 5) *activity to control healthcare expenditure growth and implement hospital reform in Portugal is said to be ‘ongoing’ in the draft budget, but details are not given.*

FINAL REMARKS

The public sector evolves in a complex organisational environment with an increasing pace of change in recent years. In a context of organisational reforms, new public management paradigms and current pressures from governments, for greater and more effective rationalisation of resources, the change in MAS is inevitable.

It is true that when the governments’ control is very tight, little room is left for the implementation of strategic changes. However, assuming a causal link between management accounting practices, institutional pressures and performance, the reforms carried out in the public sector have encouraged the introduction of new approaches to MAS, namely in budgetary techniques, considered a key factor in improving organisational performance.

Budgets are a major feature of MAS. Currently, it is clear that these information systems are totally dependent upon the achievement of the organisations’ priorities and strategic objectives, whether public or private. Some literature findings suggest that MAS use is directly and indirectly influenced by contingency, organisational, and behavioural variables (Abernethy & Brownell, 1999; King et al., 2010; Macinati & Anessi-Pessina, 2014).

Considering this interaction, the literature review in this chapter has reflected the need to integrate new budgeting approaches due to the inefficiency of traditional techniques. Until a few years ago, the incremental line-items budgetary approach seemed to be sufficient, because public expenditure was fairly stable. The imbalance in current government accounts tends to influence organisations to define and rethink the management accounting practices of the last years (Jackson & Lapsley, 2003; Lapsley & Wright, 2004). Macinati and Anessi-Pessina (2014) suggested that cost-containment strategies lead to more sophisticated MAS.

Budgetary techniques can also be used as important tools for the interactive implementation of strategy, activity management, learning, dialogues and output analysis (PBB ABB, ZBB or PYBB approaches). For example, with the potential implementation of the ZBB technique in the public sector in Portugal, already incorporated in the government's budget legislation since 2012, and with the priority-based interaction, it is possible to promote new attitudes, concepts and practices which are more appropriate to face the current institutional challenges.

In the health care sector, much of the international empirical research to date has concluded that the successful implementation of the alternative budgeting approaches will depend on the willingness of governments and professionals to accept these changes. In this scope, there is a recent important scientific contribution to this chapter, considering the authors reflect on the gap that one wants to fill: *Reforms of the public health-care sector have emphasised the role of management accounting. However, there is little systematic evidence on its use and benefits* (Macinati & Anessi-Pessina, 2014, p. 98).

Despite the governmental initiatives, such as the corporatisation of some hospitals and the implementation of “program-contracts” in the Portuguese scenario, and despite the academic studies on the role of MAS, there are indeed still few empirical research studies that examine how the MAS can contribute to the implementation of alternative budget techniques that are more output and performance oriented.

KEY TERMS AND DEFINITIONS

Activity-Based Budgeting: Budgeting technique that involves determining which activities incur costs, establishing the relationships between them, and then deciding how much of the total budget should be allocated to each activity.

Case-Mix Index: Ratio that represents the production of a hospital in relation to other hospitals in terms of their highest or lowest proportion of patients with complex pathologies, and the number of resources used.

Diagnosis Related Groups: Financing system based on the assignment of a fixed amount of cost for each hospital pathology.

Line-Items Incremental Budgeting: Budgeting technique in which the budget is prepared in an incremental approach, taking previous periods as a reference. In this system the focus is on inputs.

Performance-Based Budgeting: Budgeting technique in which budgets are prepared according to programs and the funding for each program is compared with expected results.

Program-Contracts: Commitment between the service provider (hospital) and the purchaser/funder (Ministry of Health), in which the hospital budgets for the subsequent year depend on the performance outcome of the previous year.

Value-for-Money: Analysis technique that assesses how resources are successfully transformed into valued outcomes.

Zero-Based Budgeting: Budgeting technique in which all activities are justified before the decision on the amount of resources to be allocated to each activity.

ENDNOTES

- ¹ Journals: AOS – Accounting, Organisations and Society; MAR – Management Accounting Research; HP – Health Policy.
- ² The Case-Mix Index (CMI) is the sum of the DRG relative weights divided by the total number of equivalent patients, namely:
$$\text{CMI} = \frac{\sum (\text{DRGi equivalent patients} \times \text{DRGi relative weights})}{\sum \text{DRGi- equivalent patients}}$$

ABSTRACT

The Laboratory Information Management System (LIMS) is recognized as a powerful tool to improve laboratory data management and to report human health as well as veterinary public health. LIMS plays an essential role in public health surveillance, outbreak investigations, and pandemic preparedness. The chapter aims is to provide an overview of LIMS use in veterinary fields as well as to report 20 years of experience of a Veterinary Public Institute in working with LIMS, illustrating the features of the LIMS currently in use in the institute and highlighting the different aspects that should be considered when evaluating, choosing, and implementing a LIMS. In depth, the chapter illustrates how LIMS simplifies the accreditation path according to ISO IEC 17025 and the role in the epidemiology and veterinary public health. For this aspect, it is very important to collect clear data, and for this reason, a LIMS has to activate formal checks and controls on business rules. To facilitate this issue, an interconnection between LIMS and other applications (internal or external to laboratory) could be improved to allow automatic data exchange. At the same time, the unique data encoding at national/international level should be used.

DOI: 10.4018/978-1-5225-1674-3.ch015

INTRODUCTION

The Istituto Zooprofilattico Sperimentale dell'Abruzzo e del Molise "Giuseppe Caporale" (IZSAM) is a public health institute with administrative and managerial autonomy, which operates as a technical and scientific arm of the Italian State and the Abruzzo and Molise Regions, performing analytical work for the public veterinary services and providing the technical and scientific collaboration necessary to enable them to carry out their functions in the field of veterinary public health.

The main tasks of the Institute, as defined by the Italian legislation, are experimental research into the aetiology and pathogenesis of infectious diseases of domestic and wild animals; hygiene in animal breeding and livestock production; tests for laboratory diagnosis of animal diseases, tests for microbiological and chemical safety of food of animal origin destined for human consumption and livestock; epidemiological surveillance in the field of animal health and hygiene in the production of livestock and food of animal origin; production of vaccines, reagents and immunological products for the prophylaxis and diagnosis of animal diseases; consultancy, technical assistance and health information for breeders for the purpose of improving health standards and hygiene in livestock production; training for veterinarians and other operators in veterinary public health.

All the Institute's activities have been constantly certified and subjected to rigorous quality control since 1995, when the Institute became the first public veterinary body in Italy to be certified in accordance with international quality standards for performing laboratory tests in the chemical, microbiological, virological and serological fields (UNI CEI EN ISO/IEC 17025:2005– former 45001). Since 1991, the Institute uses a LIMS (named SILAB), which has the possibility to be constantly modified to suit the new health care needs and be adapted to the emerging technological innovations.

Taking advantage of these twenty years of experience, the chapter expresses some general considerations about the role played by LIMS in public health surveillance, outbreak investigations and pandemic preparedness.

The main objectives of chapter are to provide an overview of LIMS features, identify strengths, challenges and lessons learnt in terms of development, placement, use and maintenance as well as to illustrate the LIMS role in epidemiology and veterinary public health.

BACKGROUND

Veterinary services are essential to assure the health and welfare of both human and animal populations, as well as an optimal relationship between humans, animals and environment.

The slogan is ONE HEALTH - ONE MEDICINE. This approach recognized, already in the middle of the XX Century, that human and animals health are ONE and that it is more effective and efficient to prevent human disease working on animal population medicine. Moreover, it also led to the understanding that man and animals shared the same world and had a mutual influence with the environment they lived in (ONE PLANET).

The main missions of Veterinary services are to fight animal disease, including zoonosis, and to assure food security and safety worldwide with positive cost-benefit ratio for the international community, in particular:

Laboratory Information Management Systems

- To reach the absence of diseases, including zoonosis, as well as food security and food safety, as primary factors for the welfare of human beings.
- To increase the availability and the quality of proteins for the human population and help to decrease crop waste.
- To prevent human affections.

Health and welfare of both humans and animals are closely interrelated. In Italy, the role of veterinary medicine in food security, food safety and prevention of human diseases, has been recognized since 1888 through first “Health Code” (Act December 22, 1888, n. 5849), establishing the role of the provincial veterinarian, in the context of public health. Since 1946 the General Directorate for veterinary services was included in the Ministry of Health.

The public veterinary laboratories, as the Institute’s ones, are accredited in accordance with international quality standards UNI CEI EN ISO/IEC 17025:2005, for performing laboratory tests in different fields such as chemical, microbiological, virological and serological fields, while human health laboratories refer to ISO 15189 norm for accreditation. However, ISO 15189 meet the requirement of ISO/IEC 17025 and the principles of ISO 9001. ISO 17025 born from ISO guide 25 and from the experience in the use of EN ISO 45001 norm, which after became ISO/IEC 17025.

ISO IEC 17025 considers the processes related to the laboratory test results as well as the features of the system which support the analysis process itself. ISO 15189 deals with the processes inherent the pre-analysis activities, the processes inherent the analysis activities and those of the system in support of the analysis itself, as well as the processes concerning the post-analysis tasks (Montebelli & Pradella, 2010).

Accreditation according to the ISO 15189 specifies requirements for quality and competence in medical laboratories like ISO 17025 specifies requirements for quality and competence in all other labs.

Briefly, ISO 17025 meets the requirements of all ISO 15189 points that are referred to the management of laboratory activities, while the remaining points are covered with ISO 9001.

ISO 15189 includes additional requirements for the competence of medical laboratories, for example, in relation to the acceptance of patients, sampling and care of patients (including accommodation and environmental conditions), and considers also the post-examination processes. In addition, ISO 15189 is also more stringent than the ISO/IEC 17025 when requirements of other disciplines are considered, such as safety, security of the sensible data, environmental management.

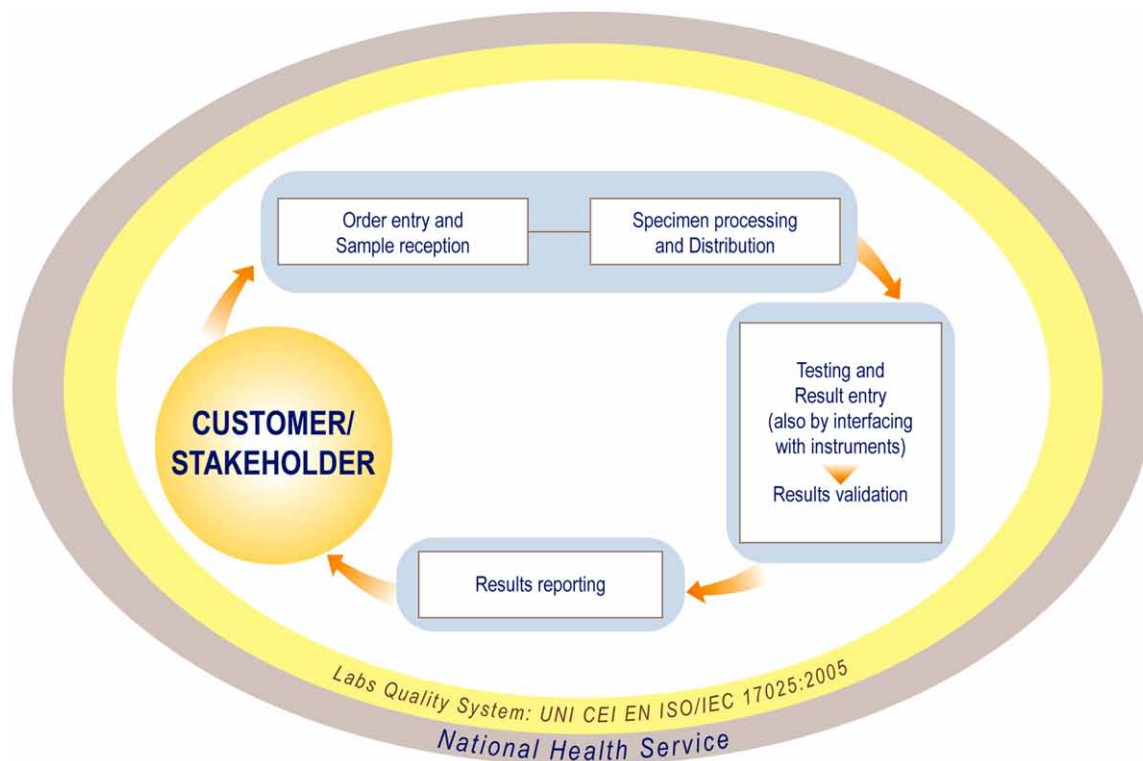

LIMS BASIC FUNCTIONALITIES

A LIMS should not be simply a software-based laboratory and information management system oriented to collect all data related with samples and tests. It should also provide the following basic functionalities (Figure 1):

Entry Order and Sample Reception

During the process of samples acceptance, all requests about samples to be tested are recorded. Data concerning the testing purpose, the area of competence (human or animal health, food safety, feed analysis, environment), the customer and other information concerning the sample (such as geographical origin, animal species, number and type of material) are recorded into the system.

Figure 1. LIMS context and basic functionalities (© copyright 2013, Patrizia Colangeli, used with permission)

At this stage, additional information may be requested (referential number of authorities report, number of aliquots, condition of the sample, type of container, etc.), when they are necessary for sample's management and epidemiological purposes.

Specimen Processing and Distribution

After univocal identification of the sample by the generation of a label including barcode, samples are distributed to the different departments to undergo the tests requested by the customer.

In order to cut down working time, samples distribution by groups may be automatically performed: the operator can select a distribution group (previously created on purpose), with which samples are distributed to all tests and laboratories included in the group.

Entered data and distributions are reported on electronic work-lists, which can be used both as data verification and as a working sheet.

Testing and Results Entry

The technician, after having received the coded samples, performs the required tests according to the assigned distributions and then enters results into the information system (data acquisition step). Where appropriate, he/she can insert interpretive comments.

Laboratory Information Management Systems

In some cases, data acquisition is done directly by interfacing the instrument used for analysis. In instruments that allow it, this connection may also be at 2 ways (from LIMS to instrument and vice-versa). Integration with laboratory instruments increase quality of data and reduce time for typing results and their validation.

At this phase, the system produces work-lists to facilitate batch processing and resulting and ‘pending result’ lists to track remaining orders.

Results Validation

After results are entered, the head of the laboratory validates data in order to comply with general and specific requirements and satisfy customer needs. Results cannot be communicated to the customer until data are not validated.

Results Reporting

At the end of the diagnostic route of the sample, the test report is issued and sent to the customer requesting the diagnostic tests. The test report varies according to the kind of tests performed.

The report is dispatched by e-mail or ordinary mail after having been signed (with electronic signature) by the head of the department.

For notifiable diseases, electronic alerts may be sent to local, regional and national level.

Data Enquiries

It is possible to have progress reports on registered samples by enquiring at any time the system (number of samples accepted, distributed, validated, etc...).

Data Security and Integrity

The application manages different levels of security for users. Each user has username and password, a role that assigns functionalities as well as the area of competence.

Other important issues concerning security are firewalls, antivirus/malware software, which has to be installed in each PC's, Uninterruptible Power Supply (UPS) for server and system for data backup and disaster recovery. Disaster planning is also a critical function that all LIMSs need to consider.

Domain Tables Management

An “ideal” LIMS should be code-oriented, and internal codifications used should be linked to descriptions. All codes and relevant descriptions are entered into domain tables; for example, all species of interest are codified so that in the data tables codes are reported, while in domain tables codes are linked to the relevant description and additional information. The management of domain tables is run by the application itself: some tables can be accessed by everyone (clients, users..); some others (tests, assays,...) only by departments heads or by Administrator role.

Management of Payment

The system needs to collect billing information, which may be different from those of the client, and interface with the billing system or directly issue the invoice.

OTHER FUNCTIONALITIES

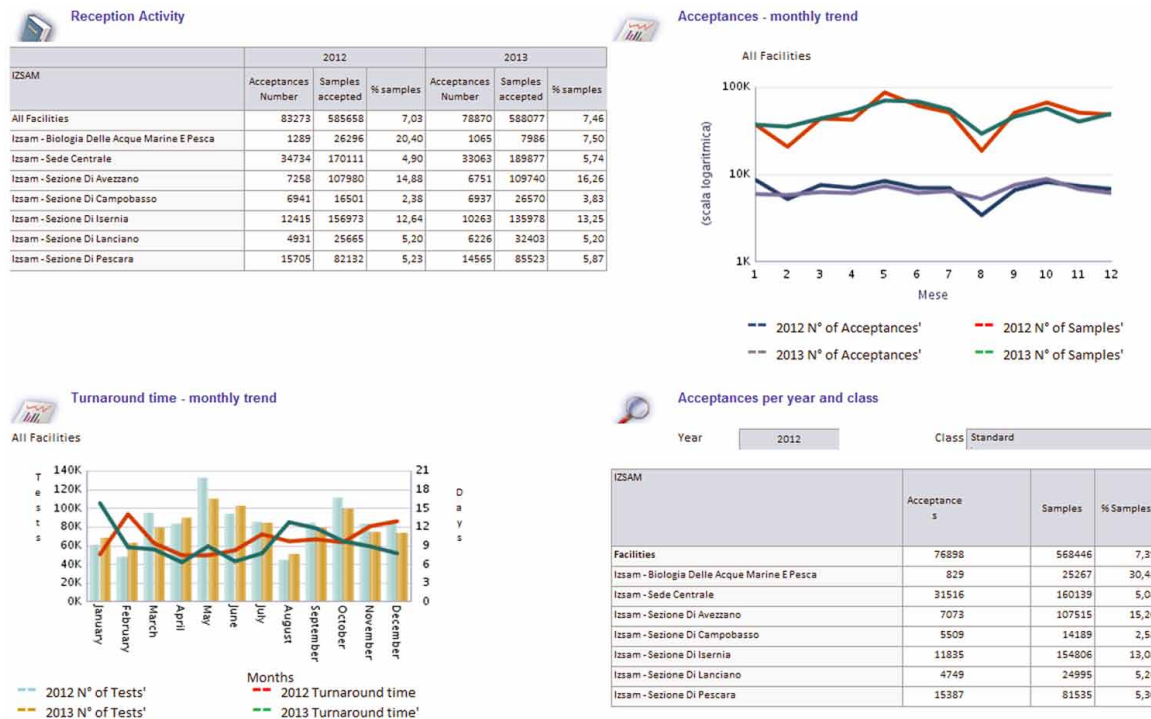

In addition to the basic functionalities, a LIMS may also contain other features, such as:

- A management tool: LIMS may also be able to monitor customer service in terms of the gap between actual response and expected time, technical efficiency in terms of gaps between actual time requested to perform a diagnostic test and the same time predetermined in standard situations, as well as able to collect data on the frequency of acceptance of samples and, analyzing these data, allows to adjust the presence of personnel (Figure 2).
- From an epidemiological point of view, LIMS may be an essential instrument since it may collect a considerable amount of data in the context of research programs, surveys, clinical investigations, control, and eradication programs. Usually it is difficult to make use of these data for epidemiological considerations, since it is not always given that data will be representative of the event under study. In the case of clinical investigations for leishmaniasis, for example, inferences about the disease status of the canine population are derived through the serological diagnoses on specimens submitted under suspect. This sample represents only a subset of the real animal population and the probability that an animal sampled is conditioned by several aspects such as its apparent health status, the decision of the owner to undergo his pet to a clinical examination and the decision of the clinician to carry out a serological examination. In this scenario, the output of the system is largely biased by all these variables in data collection. An example of data generated by a LIMS and suitable for epidemiological analysis may be represented by those collected in the context of the Italian eradication program for bovine brucellosis which has the objective to test periodically all the bovine herds existing on the national territory. This means that blood samples are collected from all cattle every year in order to screen for brucellosis. In this case, the output of the system may be considered as representative of the real situation in the field, given that the investigation is extended to all the susceptible population. In this scenario, the performance of the system in terms of sensitivity and specificity are measurable and less biased, and data provided by the LIMS may be useful for epidemiological considerations.

However, a LIMS may also play a key role in disease monitoring and surveillance. In this case, the system is designed to collect data not only related to the specimens sampled and their origin, but also other data of epidemiological relevance and related to the disease under surveillance. In this case, the surveys are intentionally targeted and, even if not all the susceptible population is tested, however, the information provided may be considered as representative of the disease under study. Indeed to collect data useful for epidemiological studies is necessary to clearly identify the aims of surveillance and define which data should be collected in which population.

An example of the application of LIMS to collect data concerning epidemiological surveillance is provided by the West Nile Virus (WNV) Italian surveillance program. The program includes operative

Figure 2. Reception activity trend: reports and graphs 2012-2013 (© copyright 2013, Patrizia Colangeli, used with permission)

procedures for collection of human, veterinary and entomological data, with the purpose to provide a surveillance system for early detection and monitoring of WNV circulation. The Italian national surveillance system for WNV includes data coming from active surveillance and data coming from passive surveillance. In particular, it collects data coming from:

- Screening of blood and hematopoietic stem cells donations in affected areas and screening of solid organ donations in the surveillance areas;
- Periodic blood testing of sentinel horses and chickens to check for seroconversion;
- Mosquito trapping;
- The collection of dead wild birds
- Periodic sampling of migratory birds found in humid areas.

In this context, the LIMS collects both laboratory data (as date of arrival of samples, type of samples, date of analysis, results of the analysis, analytical details) as well as epidemiological data as geographical coordinates of the sampling site, and relevant data concerning the animals (identification and age of the sampled animal, presence or absence of clinical signs etc.). In addition, in Italy, the information system for animal disease outbreaks notification called Animal Disease Notification System (SIMAN) is used to collect and dispatch to the competent Authorities data and information related to the WND outbreaks and to the surveillance activities (Colangeli, P., Iannetti, S., Cerella, A., Ippoliti, C., Di Lorenzo, A., Santucci, U., Simonetti, P., Calistri, P., & Lelli, R. 2011). SIMAN has useful epidemiological reporting

tools to monitor, manage and analyze data generated by West Nile Disease (WND) surveillance activities. In particular, the section “Report West Nile Disease” allows downloading the list of registered sentinel farms and animals, as well as the sampling activities performed and the laboratory results. The data stored into the SIMAN WND database, together with the data on human cases weekly provided by the Ministry of Health, are the source of information for the weekly National Epidemiological bulletin on WND published by the National Reference Centre for Exotic Diseases (CESME) on the official national website dedicated to WND (http://sorveglianza.izs.it/emergenze/west_nile/emergenze_en.html [17/02/2014]).

Less timely and incomplete reporting of diseases may result in reduced ability in rapidly detect and monitoring outbreaks, which may cause delays in implementing action on conditions that may affect large numbers of people. Enhancing the capabilities of LIMS systems would provide a valuable tool making possible the electronic report of data and thus their timely availability. In the context of disease surveillance system, LIMS represents a powerful tool to identify and monitor the occurrence of infectious diseases and other conditions of public health importance.

- A tool to increase data quality, since a LIMS activates both formal checks (*i.e.* on dates) and, especially, controls on business rules (temporal progression of dates, check on the correctness of combination of tests-methods-matrix-species-department). For this reason, the system should supply tables containing parameters and truth tables, manageable through software only by authorized users with a appropriate role. A LIMS should be able to suggest default values for sample compliance (like “Negative” or “Absent”, or “< 10”, etc.), standard operative procedures, unit of measurement, and so on. The application should offer an extensive use of drop down lists to reduce data entry mistakes and minimize transcription errors. Integration with laboratory instruments increase data quality and reduce time necessary for typing results and their validation. In addition, the user obtains standardized reporting of laboratory data.
- Interconnection between LIMS and other applications (internal or external to laboratory) to allow information exchange. Through web services, a LIMS is able to obtain data from different veterinary information systems both public and private and automatically store them. In the context of animal health, information about breeding farms (code, address, owner, etc.) can be read directly from the National Farm Identification and Registration Animal Database (I&R system). The procedure also allows verifying the information about a single animal at sampling stage like ear-tag, age or sex. The same interconnection should be possible in the context of food safety where a “Food Business Operators (FBO) register” exists. This feature allows providing, in real time, the validated results of diagnostic tests to the connected information systems.

In this way, a LIMS may thoroughly satisfy information needs that the Ministry of Health and other body (National Reference Centers, an international organization) require for a public laboratory. The term “information needs” concerns the periodic demand to supply aggregated or single data about specific diseases, control plans or contaminants (for example, monthly dispatch of data on GMO or rabies, annual data on pesticides, daily data on West Nile Disease, Bluetongue, etc.). To share these information is, therefore, necessary to map codes of different systems and ensure that the exchanged data have the same meaning (“semantic interoperability”).

Each information system should be always seen as part of a more complex system with which it should exchange data (Figure 3).

Laboratory Information Management Systems

Figure 3. Italian integrate veterinary information system (© copyright 2013, Patrizia Colangeli, used with permission)

In addition, an “ideal” LIMS should allow automatically and independently adding specific information about each disease surveillance plan or for other purpose. These additional data are important for different actors in the context of Animal Health Information System, like the National Reference Centers.

- As a Thesaurus: The pillar for an efficient system cooperation is the use of unique data encoding as much as possible approved and shared at national/international level like, in the context of animal health, OIE codes for diseases. A centralized and unique I&R system exists in Italy; it collects and univocally identifies each farm of main livestock species and each animal in the holding (only for cattle). A similar database, named “FBO register” is in progress for all other structures of interest (such as dairy factories, dealers, canteens, etc.). In the context of human medicine, standard terminology already exist (such as Logical Observation Identifiers Names and Codes (LOINC) and Systematized Nomenclature of Medicine - Clinical Terms (SNOMED-CT). The European Food Safety Authority (EFSA) is making the effort to unify and codify the variables involved in the food and feed sample identification (Standard Sample Description, currently at ver. 2.0) (<http://www.efsa.europa.eu/en/efsajournal/pub/3424.htm> [17/02/2014]) but the complete definition of a shared semantic and categorization in the veterinary field represent an effort to be still. The use of a thesaurus, starting from the necessity of the dialog among heterogeneous information systems allows managing the “knowledge” and simplifies its divulgation; moreover, it complies with the requirement to manage and maintain a set of sanitary codes aimed to allow all involved operators to use the same terms.

- As a tool for dematerialization. LIMS also may be a “paper-less” system, thus reducing paper and space needed for storing, as well as reducing fire risks. This means to remove sample reception register, all the paper support used to record raw data (register, technical notebook, worksheet, etc.), as well as test reports. Test reports are replaced by pdf files with digital signature, sent by e-mail and available also on line. Specimens are labeled with a bar code; paper working sheets are replaced by lists of specimens associated with tests to be performed by each department. These lists are visualized on computer screens, and digital models for registration of raw data are also available in all diagnostic departments.

The advantages of the system are based on the reliability of specimen identification and simplified access, through code readers, to specimen identification data. Writing and reading of the bar code take place automatically, eliminating possible errors. Furthermore, the labeling system allows the immediate traceability of all documents related to the specimen and the prompt availability of raw data.

The implementation of the system makes possible the simplification of many procedures, contributing to cut direct and indirect costs (paper handling and storing, document storage rooms, etc.) and improve efficiency in reporting (Colangeli, P., Ruggieri, E., Mercante, M.T., Ricci, L., 2013).

- As a support for the accreditation process: there is a worldwide trend for the progressive development of national and international veterinary laboratory networks. Central to this networking is the development of test standardization and harmonization, to ensure that test results from the participating laboratories are comparable.

A laboratory's fulfillment of the requirements of ISO/IEC 17025:2005 means that the laboratory meets both the technical competence requirements and management system requirements that are necessary to consistently deliver technically valid test results.

The need, for official laboratories, to respond to the requirements of ISO 17025, was determined by the obligation to implement the EEC Directive 93/99 and Regulation (EC) 882/2004. Then the public laboratories, like that of the Istituto Zooprofilattico Sperimentale, in order to meet the requirements of Community legislation have had to provide a quality management system. This system has to be structured in such a way as to make it possible to track the whole process concerning the sample, from its arrival in the laboratory to the production of test results on a sample analyzed and the issuing of the related test report.

The ISO 17025 standard allows ensuring that results are provided using competent personnel and official test methods or otherwise methods developed to the laboratory, in this second case the methods must be completely validated. In this area, the implementation of information systems is crucial to support technical activities, by means of software that would allow to have samples tracked at any time, also highlighting what you were doing on the same process.

It is in this sense important to develop an information system that could solve the problems relating to the identification of the sample, identifying them univocally, and also at the same time keeping track of all the operations related to the process, demonstrating not only the reliability of the result, but also the traceability of each step of the analysis process, including the different operators which have carried out each single step. For this reason the LIMS is a tool for traceability of sample and traceability of actions made on it (“who acted, how and when”), aspects which should be very difficult to keep under control

only with a paper recording system. Moreover, the information system supports the sample activities, allowing you to keep all documentation for each sample and all the results relating to the tests carried out on a sample.

Solutions and Recommendations

LIMS is a fundamental component of lab management; however, there are major challenges to face in order to correctly implement it:

- Lack of funding to purchase and maintain a LIMS (commercial or developed), and/or the hardware and network necessary to run it;
- Reluctance to improve knowledge in managing the LIMS, in particular by staff with low computer literacy;
- The frequent requests for customization made by the different users;
- Availability of skilled, motivated and trained personnel to manage the development and maintenance of LIMS.

The transitions to using a LIMS requires a highly-motivated staff, able to change old habits and accept a radical change in the methodological approach. The receptionist role becomes crucial to check sample conditions and to ensure the correct insertion of all data relating to accepted samples, pre-requisite of the entire flow of information. Indeed, an error in reception step has an impact on the whole process with effects that in some cases can have serious repercussions (management of disease outbreaks, incorrect billing etc.). For this reason, the interface between the LIMS and users should be as user-friendly as possible, in order to decrease the probability of input errors by operators.

An ideal LIMS should be web based to be accessible from different users at the same time, multi-language to avoid language barriers, and should offer a simple and intuitive user interface. Since different laboratories may not all operate in the same way, it is important that a LIMS matches the laboratory flow and has the flexibility to accommodate future changes in laboratory activities.

Appropriate network security policies are necessary to ensure that only authorized personnel have access to computing resources. These policies should encompass both users who work connected by local area network, as well as those who may be connected remotely. The ultimate purpose is to prevent unauthorized changes, deletions, or additions to customer data, as well as to prevent unauthorized disclosure of information.

Data integrity policies and procedures are important to ensure that the software that manages the data related to test and results of the laboratory would perform as expected and that changes are performed in a controlled and tested environment. The software should also record and track the changes made to the data by the operating laboratory personnel.

Frequent communications and engagement of end-users are very important not only during start-up, but also during LIMS's use. User manuals, available also on-line and provided with FAQ and suggestions, may obviously be useful, but also training could be important in order to increase trust and confidence in the software. In this context the role of a leader is also important that should be the referent for the management both of the technical and organizational aspects. Finally, the delivering of some incentives for the staff involved (money, awards, etc.) should not be excluded.

FUTURE RESEARCH DIRECTIONS

Since technological solutions are now available, the next efforts will all be geared up to improve the quality of data collected. The main objective is to limit the manual data entry; therefore the following steps may be necessary:

- Interoperability over a network with other application systems in order to read and capture what is already present in other systems (the same data is inserted only once);
- Interface with equipment used for analysis;
- Use of digital on-line forms to collect raw data;
- Use of standard data encodings and bar-code labels;
- Use of checks and rules about syntactic and semantic meanings (truth tables);
- Use of a Thesaurus for standard codes.

CONCLUSION

A LIMS enables laboratories to track samples from submission to reporting and can facilitate the linkage between diagnostic results and response in the field. This would strengthen diagnostic capacities when these are directly related to the ability of the laboratory to report results rapidly.

Moreover, there is a direct temporary correlation among the celerity of the diagnosis, the beginning of the therapy and the possibility of limit the disease spread, with a consequent reduction of money loss.

LIMS is now a fair mature IT technology; however the active role in supporting disease detection, surveillance and response to disease outbreaks is the target to be reached in the near future.

With the decreasing hardware and software costs (using open tools) and the growing availability of internet connections and LAN, the pre-conditions for laboratories to leave the paper tracking systems are today fulfilled. While implementing a LIMS is not a short-term investment, however, it could produce a long-term effect on the vitality of the laboratory for many years following installation.

A LIMS can be a powerful tool that gives the laboratory a competitive advantage over other laboratories, saving time and money. Benefits of LIMS implementation include faster turnaround times, automation, increased productivity, higher quality of data, electronic reporting, and integration with other enterprise databases. In addition, you obtain standardized reporting of laboratory data.

Although it is recognized that epidemiology and Laboratory Information Management Systems may play a central role in monitoring animal diseases having public health importance, unfortunately not all countries are in a position to have enough resources available to implement complex disease surveillance programs involving LIMS.

KEY TERMS AND DEFINITIONS

Animal Disease Surveillance: Aims to improve disease analysis, early warning and predicting disease emergence and spread. As a preventive measure, disease surveillance is aimed at reducing animal health-related risks and major consequences of disease outbreaks on food production and livelihoods.

Information System: The tool used to collect, filter, process, create, and distribute data. It consists of hardware, software, networks and operators.

Interconnection: Many organizations use multiple software systems for management. Different software systems often need to exchange data with each other. Interconnection is to link different systems to allow to exchange this data.

Laboratory Management System: A software-based laboratory and information management system that offers a set of key features that support a modern laboratory's operations.

Monitoring: Is the making of routine observations on health, productivity and environmental factors and the recording and transmission of these observations.

“Paper-Less” System: Is the work environment in which the use of paper is eliminated or greatly reduced. This is done by converting documents and other papers into digital form. Proponents claim that “going paperless” can save money, boost productivity, save space, make documentation and information sharing easier, keep personal information more secure, and help the environment. The concept can be extended to communications outside the office, as well.

Veterinary Epidemiology: Is principally concerned with the study of disease within populations (although it may also be used for investigation of issues such as animal welfare and productivity). Put simply, it involves the investigation of patterns of disease within a population, in relation to which animals are affected, the spatial distribution (i.e. location) of affected animals, and the temporal distribution of affected animals (i.e. animal disease surveillance patterns of disease through time).

Chapter 16

Developing SMS Health Messages for Pregnant Indigenous Australians Using Persuasive Technology

Reece George
University of Newcastle, Australia

ABSTRACT

While developed nations search for solutions to pay for the increasing financial burden of healthcare, developing nations provide a way forward in the deployment of innovative healthcare. Mobile SMS programs are low-cost and effective in supporting health services. Having been successfully used to address lifestyle factors directly affecting maternal outcomes, such as: smoking, physical activity, nutrition, substance use and psychological stressors. Of primary importance in the development of SMS behavior change programs to support the maternal healthcare of Indigenous Australian women, is cultural appropriateness; specifically, the cultural notion of 'women's business'. In traditional Indigenous Australian culture, it is senior women who teach young women about maternal health and it is considered offensive for anyone other than a senior woman to instruct women on such matters. This discussion will consider the challenges in developing maternal healthcare SMS messages that aim to satisfy both the culturally sensitive requirements in addition to the medical requirements.

INTRODUCTION

While medical science has made some remarkable discoveries over the past two centuries, the cost of healthcare for most developed nations has been growing faster than GDP and is therefore unsustainable (World Economic Forum 2013). Over the past two decades, the economics indicate the long-term sustainability of the healthcare industry by government funding is not achievable using the current models of healthcare delivery. In most developed nations, healthcare costs are increasing faster than national income to a point where the healthcare industry is considered by some to be amongst the most wasteful

DOI: 10.4018/978-1-5225-1674-3.ch016

sectors in the world (Harvard University, 2014; World Health Organisation [WHO], 2010; PricewaterhouseCoopers Health Research Institute, 2008). To pay for this increasing financial burden governments must deny funding to education, roads, and public safety, or eventually resort to increasing taxes.

There are also concerns for many people in developed nations being excluded from healthcare systems due to poverty, communication, ignorance and distance. Populations have increased, life expectancy has improved and the numbers of physicians and specialists have decreased (Sanabria, 2014). At the same time, the healthcare industry is reluctant to look outside its traditional approach to service delivery as such change undermines the power structures in governments, pharmaceutical companies, physician services and nursing systems (Thompson, 2012).

This is not a new problem; healthcare is not the first industry needing to improve quality and convenience while reducing costs. Neither is the health industry the first to resist change. In developing nations, where healthcare resources are low, innovative new models of healthcare are succeeding. These new models provide a way forward for developed nations in the healthcare delivery of tomorrow.

One such area needing improvement in Australia is Indigenous maternal healthcare. While much progress has been made in regards to Indigenous healthcare, it is essential that the Australia healthcare system continue to leverage existing technologies to reach people in need of care. In order to maximize the potential of mobile technology in the field of Indigenous maternal health, both cultural and medical requirements need to be integrated into the design methodology of the system. Specifically, this discussion will outline the issues surrounding a proposed low-cost SMS behavior change program, intended to inform and motivate Indigenous Australian women for positive pregnancy outcomes. This low-cost innovative healthcare model has proven effective in both developing and developed nations.

BACKGROUND

Healthcare Innovation

In Australia, Indigenous health expenditure was estimated to be \$4.55 billion in 2010–11, 3.7% of the total Australian health expenditure (Australian Institute of Health and Welfare [AIHW], 2013a). The average health expenditure per Indigenous Australian was \$7,995, compared with \$5,437 per non-Indigenous Australian (AIHW, 2013b). The Australian Government (44.8%) and the state and territory governments (46.6%) combined, funded 91.4% of the total health expenditure for Indigenous Australians in 2010–11. The non-government sector, which includes out-of-pocket payments by individuals, funded 8.6% (AIHW, 2013b). Health expenditure estimates for Indigenous maternal conditions in 2010–11 were \$144 million (AIHW, 2013a).

The cost of healthcare for Indigenous Australians compared to non-Indigenous Australians is not only more expensive but also the maternal health outcomes for Indigenous Australians are significantly worse than for non-Indigenous Australians (see next Section ‘Antenatal Care For Indigenous Australian Women’). An innovative system built on the principles of Indigenous methodologies may be well suited to the Indigenous Australian maternal healthcare setting.

In terms of cost savings to healthcare, Cannon et al. (2013) estimate the costs of inadequate antenatal care to remote Western Australian Indigenous communities. Their study modeled pregnancy events with adequate and inadequate care to reflect different outcomes. They reported the mean cost of pregnancy to be AUD\$8985. For adequate care, the costs were AUD\$7635 and for inadequate care AUD\$10,216. They

Developing SMS Health Messages

further estimated that for a rural community with “150 births per year, up to AUD\$123,082 may be spent to improve access to care at no extra cost to the total current expenditure” (Cannon et al., 2013, p. 313).

The cost of implementing SMS programs favors economies of scale. A study by Zurovac, Larson, Sudoi and Snow (2013) examined the costs and cost-effectiveness of a text message intervention in Kenya, which improved health worker adherence to malaria guidelines. While the application of the SMS intervention was different to one proposed here, the associated cost of setting up and running an SMS system is similar. They found that the intervention was both effective and inexpensive. Table 1 provides costs associated with scaling to regional and national coverage and outlines the reduced cost of each additional patient managed.

While healthcare systems in developed economies are grappling to find answers to their mounting financial issues, the future has seemingly overtaken them. Innovative delivery models designed and developed in resource-constrained environments, such as India, Africa and parts of Asia, demonstrated that it is feasible to improve access to quality healthcare at a fraction of the cost seen in the conventional healthcare delivery systems (World Economic Forum, 2010a). For example, the Aravind Eye Care System:

delivers quality eye care in India at a fraction of the cost through the use of focused ‘factories’ that eliminate any waste in the system, increase the productivity of expensive assets and trained work-force and focus on straightforward standardized procedures including cataract surgery and spectacle fitting. They have reached ~12 million in India (10% of total blind), and costs are only 1% of the equivalent service in the UK (albeit not adjusted for country specific factors) with surveys showing outcome quality is higher in India (World Economic Forum, 2010b, p.2).

After adjusting for purchasing power, so the figures are comparable, the Aravind Eye Care System in India performs at one-sixth of the cost of the NHS in the UK (World Economic Forum, 2013).

Bill Gates (2008), the founder of Microsoft and Co-chair of the Bill & Melinda Gates Foundation provided further insight into the way forward for the future of healthcare innovation;

Table 1. Cost-Effectiveness of Text Message Intervention, Under Three Implementation Scenarios, in Kenya, Africa.

Test Condition	Cost To Implement	Cost Per Additional Child Managed
As implemented under study conditions in study areas.	Intervention costs were 19,342 USD, of which 45% were for developing and pretesting text messages, 12% for developing text-message distribution system, 29% for collecting health workers’ phone numbers, and 13% were costs of sending text-messages and monitoring of the system.	0.50 USD
If the intervention was routinely implemented by the Ministry of Health (MoH) in the same areas.	Costs would be 28% lower (13,920 USD) due to lower costs of collecting health workers’ numbers.	0.36 USD
If the intervention was scaled up nationally.	97,350 USD, and the majority of these costs (66%) would be for sending text-messages.	0.03 USD (If the cost on the national scale was 400% higher than estimated, the cost per additional child correctly managed would be only 0.16 USD)

(Adapted from: Zurovac, Larson, Sudoi, & Snow, 2013, p. 52045)

Philanthropy and government aid channel our caring for those who can't pay, but the resources run out before they meet the need. But to provide rapid improvement for the poor we need a system that draws in innovators and businesses in a far better way than we do today. Such a system would have a twin mission: making profits and also improving lives for those who don't fully benefit from market forces (para. 31-32).

This notion of a 'twin mission' is partly observed in the Mobile Alliance for Maternal Action (MAMA) program in Bangladesh, known locally as Aponjon, meaning 'the dear one' in Bangla. Aponjon is an innovative public-private partnership that delivers maternal and infant health messages to mobile phones through the use of SMS and 60-second voice messages. MAMA Bangladesh (2014) reports that, "Aponjon is poised to become the first financially sustainable health information service utilizing mobile phones to improve health outcomes at national scale in a developing country" (p. 23).

To achieve this goal, 88% of Aponjon is currently financed by USAID, 7% by corporate social responsibility (CSR) funding at local and global levels, 4% by the Sponsor-a-Ma campaign and slightly less than 1% from user fees and advertising. For the long-term financial sustainability, the Aponjon project is planning to derive 40% of its funding from user fees, 20% from development agencies and the remaining from CSR, advertising and the Sponsor-a-Ma campaign (MAMA Bangladesh, 2014).

Innovation is simply defined by Anthony (2012) as "[s]omething different that has impact" (as cited in Harvard Business Review, 2012 para. 3). For the healthcare industry the opportunity exists for 'doing something different' within maternal health services which care for Indigenous Australian women. Yet, the challenge is implementation within an industry that is reluctant to embrace innovation. According to the World Economic Forum this is not a problem specific to the Australian healthcare industry but for developed nations in general. They report that, "the fundamental structure of healthcare systems – acute hospitals and physician offices – has barely altered in at least a century" (World Economic Forum, 2013, p. 13).

Others voice similar concerns. Topol, for example, describes the healthcare industry as:

remarkably conservative to the point of being properly characterized as sclerotic, even ossified. Beyond the reluctance and resistance of physicians to change, the life science industry (companies that develop and commercialize drugs, devices, or diagnostic tests) and government regulatory agencies are in a near paralyzed state, unable to break out of a broken model of how their products are developed or commercially approved (Topol, 2012, Introduction, para. 3).

Cultural Requirements

One cultural requirement discussed by Kendall, Sunderland, Barnett, Nalder and Matthews (2011) has a significant impact on the current study. They describe the insidious nature of "culturally insensitive research designs and methodologies that fail to match the needs, customs, and standards of Aboriginal communities" (p. 2). Kendal et al. refer to the "ample examples of contemporary research that has inappropriately required Aboriginal people to discuss sensitive topics that violate culturally determined gender roles or community structures of authority" (2011, p. 2).

Maher (1999) provided a summation of indigenous health beliefs, with a view "to aiding understanding by health professionals of their present attitudes and behaviors in regard to health care" (p. 229). Mayer explains one concept of traditional Aboriginal health beliefs, known as 'men's business/women's business',

Developing SMS Health Messages

In Aboriginal culture, there are clear-cut divisions between men's and women's role in society. Women's business includes all aspects of reproduction: menstruation, pregnancy, childbirth, contraception, abortion and female ceremonial business. Food taboos are still prevalent, especially during mourning, pregnancy, lactation and menstruation. Men's business involves hunting, conflicts, the land, male anatomy and male ceremonial business.

Breaches of these traditional divisions (e.g. female nurse washing elderly initiated male Aboriginal, a female nurse teaching an Aboriginal man self-catheterisation or a male doctor undertaking a vaginal inspection) is likely to cause great distress and 'shame'. Shame is a complex concept that is difficult to translate into non-Aboriginal English (Maher, 1999, p. 232).

A complementary view of 'women's business' connects traditional Indigenous Australian women's birthing practices with Aboriginal Law (Lore) and the Dreamtime. The *Dreamtime* is a spiritual belief system. Overstepping these traditions shows disrespect to Indigenous Australian culture at many levels:

Traditionally, Aboriginal women gave birth in the place where they were born, 'on country' with other women by their side. Young women learn about birthing and the Grandmothers Law from the older women during their first labour. Birthing is 'women's business' and intricately related to 'Aboriginal Law' and the 'Dreamtime'. The dreamtime explains creation and many of the rules and symbols are expressed in the myths and stories that are passed from generation to generation. The process of birthing is a process where the spirit of the land and the people come together, and the place where a person is born establishes their relationship to the land (Kildea, Wardaguga & Dawumal, 2004, The Centre, para. 2).

Understandably, some Indigenous Australian women "are no longer prepared to accept the affront imposed on their culture and personal dignity by conventional Western systems of managing childbirth" (Barclay Andre & Glover, 1989, p. 123). Knowledge about Indigenous Australian birthing belongs in the domain of Indigenous Australian women. It is not open knowledge. Researchers do not have the cultural qualifications to investigate or seek such knowledge without permission from senior Indigenous Australian women. This recognition respects the role of senior women within Aboriginal and Torres Strait Islander cultures (Shehan & Walker, 2001) and is critical in the success of an effective behavior change program.

A recent study by Bar-Zeev et al. (2014) reported that midwives experience a tension between their professional responsibilities and the cultural limitations of the women they care for. Midwives chose not to follow certain healthcare guidelines out of concern it would threaten the ongoing relationship with women. Had midwives discussed certain subjects, they were concerned women may not have returned for further treatment. One midwife reported:

Domestic violence, grog (alcohol) use and smoking are real big problems... but we (non-Aboriginal midwives) can't be the one trying to talk to them (pregnant women) about this... it needs to be health workers, the old ladies (Elders) doing all the talking... I feel like it always comes across like your shaming (embarrassing, humiliating) them if you bring it up... like pointing fingers... (Bar-Zeev et al., 2014, p. 293).

While this behavior may be viewed by healthcare as denying women appropriate care, from an Indigenous perspective these midwives are intuitively acting in a culturally correct manner. In traditional

Indigenous Australian culture, it is the senior women, including breeding women, Law-women and healing women, who teach young women about maternal healthcare (Bell, 1998), not healthcare services.

In an attempt to overcome this cultural dynamic, the current project proposes, firstly, to seek permission from senior Indigenous Australian women to proceed with the project, and, secondly, to include senior Indigenous Australian women as the major component of the SMS message writing process. In addition to having each message clinically approved by healthcare, the intention is to make each of the SMS messages appear as if they were written by a senior Indigenous Australian woman. The wording of the messages in this way aims to satisfy the cultural notion of ‘women’s business’, while upholding the medical standards of healthcare.

The complete development and deployment of the SMS system is outside the scope of this project. Instead, the current focus is on the writing and testing of the SMS messages themselves for cultural appropriateness. There are significant cultural challenges that require careful planning if the project is to succeed. From initial consultations with Indigenous Australian women, health professionals, IT professionals, educators and reviewers, the possible system weaknesses, in terms of cultural issues, are outlined in Table 2.

Antenatal Care for Indigenous Australian Women

In a developed nation such as Australia, which boasts one of the most efficient healthcare systems in the world (Bloomberg, 2013), why is it still necessary to emphasize the importance of caring for Indigenous women during pregnancy, after decades of priority status?

In Australia during 2011 there were 17,621 births registered where one or both parents identified as Indigenous Australian (Clarke & Boyle, 2014). Census data from the ABS (2011b) reported the number of people identifying as Indigenous Australian in NSW was 172,624, which represents 31.4% of the total Indigenous Australian population in Australia. From this total, 5,600 births were recorded in NSW, which was the highest number of registered Indigenous Australian births by any state (ABS 2011).

The birth outcomes for Indigenous Australians are significantly different compared to non-Indigenous Australians. There is a higher prevalence of smoking during pregnancy, hypertensive disorders, teenage pregnancy and gestational diabetes (Prime Minister’s Science, Engineering and Innovation Council 2008). Sullivan, Hall and King (2008) reported the maternal mortality ratio for Indigenous Australian women between 2003-2005 was 21.5 deaths per 100,000; for non-Indigenous Australian women the ratio was 7.9

Table 2. Possible Obstacles and Solutions To System Success

Item	Obstacle Identified	Possible Solution
3.1	Rejection of the SMS messages due to their cultural inappropriateness.	Inclusion of Indigenous Australian women fully in the development of the health messages.
3.2	Indigenous Australian women will not subscribe voluntarily.	(Outside scope of current project) The aim is to integrate the subscription process into the first antenatal visit.
3.3	The frequent changing of mobile phones and telephone numbers by the target audience.	(Outside scope of current project) Providing subscribers with business card size instructions on how to re-subscribe, if they change their phone number.
3.4	Indigenous Australian healthcare services may not be ready for mobile health adoption.	(Outside scope of current project) Seek out innovative maternal health services, interstate if necessary.

Developing SMS Health Messages

per 100,000. This maternal mortality ratio is more than two and a half times higher among Indigenous Australian women and known to be underestimated (Kildea, 2008 in Bar-Zeev et al., 2014). In addition, the perinatal death rate is twice as high for Indigenous Australian infants (17.3 per 1000 births) compared to non-Indigenous Australian infants (9.7 per 1000 births), as is preterm birth (13.3% v. 8.0%) and low birth weight (12.4% v. 5.9%) (Li, Zeki, Hilder, & Sullivan, 2012, in Bar-Zeev et al., 2014).

While many of the solutions to manage maternal health conditions require direct medical attention by healthcare services, implementing behavior change and educational programs via SMS can address lifestyle factors that directly impact on maternal outcomes. For example, Bar-Zeev et al. (2014) identified “that most perinatal deaths among Indigenous infants were attributed to antenatal factors that could be addressed through targeted primary healthcare interventions such as smoking cessation programs, to reduce the prevalence of low birth weight and preterm birth” (p. 294). However, it must be emphasized that such interventions are not intended to be stand-alone programs but are integrated into existing maternal health services.

The literature reports widely (Table 3) on successful SMS lifestyle change programs which parallel with many of the life-style issues reportedly impacting the health of Indigenous Australian women, including: lack of physical activity, poor nutrition, harmful levels of alcohol intake, substance use and higher psychological stressors (deaths in families, family violence, serious illness, financial pressures, contact with the justice system) (Bar-Zeev et al., 2014, Clarke & Boyle, 2014). By addressing such behavior issues via SMS, the project intends to empower pregnant Indigenous Australian women to make positive healthy choices.

Table 3. Lifestyle Factors Impacting Birth Outcomes Which Can Be Modified Using SMS Programs

Life-Style Change	Positive Results Reported From SMS Behaviour Change Research
Increasing Physical Activity	Fjeldsoe, Miller and Marshall, 2010; Sirriyeh, Lawton and Ward, 2010.
Weight Control	Haapala, Barengo, Biggs, Surakka and Manninen, 2009; Joo and Kim, 2007.
Diet Control	Soureti et al. 2012.
Management Of Anxiety Symptoms	Riva, Preziosa, Grassi and Villani, 2006.
Smoking Cessation	Rodgers et al. 2005; Brendryen and Kraft, 2008; Brendryen, Drozd and Kraft, 2008.
Alcohol Consumption Monitoring	Kuntsche and Robert, 2009; Weitzel, Bernhardt, Usdan, Mays and Glanz, 2007; Ríos-Bedoya and Hay, 2013.
Illicit Substance Abuse Monitoring	Maher et al. 2010; Muench, Weiss, Kuerbis and Morgenstern, 2012; McClure, Acquavita, Harding and Stitzer, 2013.
Therapeutic Communication For Emotional Disorders	Gerber, Stolley, Thompson, Sharp and Fitzgibbon, 2009; Haapala et al. 2009; Hazelwood, 2008; Kharbanda, Stockwell, Fox and Rickert, 2009; Leong et al. 2006; Prestwich, Perugini and Hurling, 2009.
Reminders To Take Medications	Mao, Zhang and Zhai, 2008; Strandbygaard, Thomsen and Backer, 2010; Miloh et al. 2009; Franklin, Waller, Pagliari and Greene, 2006; Vilella et al. 2004; Cocosila, Archer, Haynes and Yuan, 2009.
Appointment Reminders	Downer, Meara, Da Costa and Sethuraman, 2006; da Costa, Salomao, Martha, Pisa and Sigulem, 2010; Koshy, Car and Majeed, 2008.
Sexual Health Education	Perry et al. 2003; Lim et al. 2012; Levine, McCright, Dobkin, Woodruff and Klausner, 2008; Gold et al. 2011; Mitchell, Bull, Kiwanuka and Ybarra, 2011.
Contraception Adherence	Castano, Bynum, Andres, Lara and Westhoff, 2012; Hou, Hurwitz, Kavanagh, Fortin and Goldberg, 2010.
Family Violence Management	Howard, Friend, Parker and Streker, 2010.

SOLUTIONS AND RECOMMENDATIONS

The current project reports on the proposed adoption of a successful innovative healthcare model being implemented widely in developing nations. The model is low cost, does not require investment in expensive infrastructure and is effective in supporting existing maternal health services (Gazmararian, Elon, Yang, Graham, & Parker, 2013; Hoff, Nunez-Alvarez, Martínez, & Yvette, 2012; Kaleka, Olsen & Sweet, 2012; Evans, Wallace & Snider, 2012; Ding, Euler, Kennedy, & Greby, 2012; California State University, 2011). This relatively simple model sends three SMS messages per week to the mobile phones of pregnant women, with the intention of educating and motivating them towards improved birth outcomes.

The deliverable of this project is approximately 150 SMS behavior change messages intended to be sent to Indigenous Australian women during pregnancy. The message set will cover a time period from week 5 to week 42 of pregnancy. Messages are to be developed using established behavioral theory models, derived from Captoplogy, a discipline within human-computer interaction (Fogg, 2003). As a part of the message writing process, healthcare experts approve the message content for clinical accuracy. In addition, senior Indigenous Australian women, the traditional owners of ‘borning’ knowledge, are involved in the adaptation of each message, to make content more culturally appropriate.

The messages are to be written with the intention of being sent via Short Messaging Service (SMS). This reduces the length of each message to a maximum of 160 characters. SMS provides a simple and cost-effective solution for healthcare services to reach pregnant Indigenous Australian women. Mobile phone coverage is far more extensive than face-to-face medical facilities, which partly reduces healthcare delivery factors such as distance, communication, ignorance and lack of appropriate services. Furthermore, SMS is push technology, so women will not need to install new software on their phones to receive messages; the SMS is delivered to the mobile phone without any effort on behalf of the recipient. Neither do pregnant Indigenous women require new mobile phones with Internet access to receive messages; even outdated mobile phones can receive SMS.

In addition to specific behavior change messages, content includes information that medical professionals want women to know, for example, low-cost telephone numbers that link to free and low-cost services associated with the message topic, based on the mother’s location. Message topics include information on antenatal visits, nutrition, exercise, smoking, alcohol, drug abuse, medical conditions associated with pregnancy, labour, delivery, intimate partner violence, oral health, hygiene, baby development and other issues specific to Indigenous Australian women during pregnancy.

The development of the actual messages is viewed as the critical step in delivering effective behavior change (Fogg, 2009b). Once the messages are developed, low-cost 3rd party cloud services provide complete SMS management. A *cloud service* is any resource which is provided over the Internet. In other words, there are services available on the Internet to manage the storage and sending of scheduled SMS.

Example of SMS for Supporting Healthy Pregnancies

The following SMS examples have been made available by the Mobile Alliance for Maternal Action. MAMA’s adaptable messages are based on WHO and UNICEF guidelines and have been developed in close collaboration with a group of global health experts to reflect the most up-to-date, evidence-based global standards. One important feature about the MAMA messages is that they are ‘adaptable’. The generic messages are intended to be adapted to specific audiences and healthcare systems (MAMA, 2014).

Developing SMS Health Messages

As pregnancy is a nine-month cycle, MAMA message delivery is intended to parallel with the corresponding stages of pregnancy. For example, in week 5 of pregnancy the following message about morning sickness is sent, “Are you feeling sick? Most women do in early pregnancy. Try having some ginger, mint or lemon tea, and rest if you can” (MAMA, 2013, p. 1), in week 38 the following message is sent, “Low back pain is a sign that the baby is low down, ready to get born. Make sure you can get to the clinic in time” (MAMA, 2013, p. 44-5). The available SMS management software allows this type of message scheduling without specialised technical personnel.

Generally, the Australia healthcare system does not offer maternal services Indigenous women will accept, leading women to present later in their pregnancy for midwifery/obstetric care (56% in first trimester), attend fewer antenatal appointments and are less likely to have received health screening during pregnancy (Hunt, 2006; Panaretto et al., 2005; Rumbold & Cunningham, 2008, Australian Health Ministers’ Advisory Council, 2012). The MAMA (2013) core pregnancy SMS messages provide an example of a thoughtfully designed reminder message that not only ‘reminds’ but also ‘motivates’, saying “Going to the clinic will help make sure that you and your baby stay healthy. Find out where your nearest clinic is today” (p. 2). After adapting the wording to Australian culture, i.e., changing the word ‘clinic’ to ‘Doctor’ or ‘Dr’, such messages may also be effective in increasing antenatal appointments for Indigenous Australian women.

The California State University (2011) found that sending SMS medical warnings to American women was effective. While this effectiveness has not been tested on Indigenous Australian women, messages will include symptoms that a woman may not be familiar with. For example, a warning messages about the symptoms associated with pre-eclampsia are scheduled in week 27, saying, “Slightly swollen hands and feet are common in pregnancy. But if you have sudden swelling and headaches, go to the clinic” (MAMA, 2013, p. 30). Again in week 34, a second message on symptoms associated with pre-eclampsia is scheduled, saying “Sudden swelling of hands, face and feet is a sign of a problem. Tell your family, and ask them to take you to the clinic if they see this” (MAMA, 2013, p. 39). Such warning messages can be tailored to target the specific regional or community health needs.

Message content may also include concrete strategies to engage in healthy behaviour changes. To encourage a nutritious diet during pregnancy, for example, a message can include examples of nutritious food, “Eat well, so your baby will grow well. Try to eat some meat, eggs, bean or lentils every day and green vegetables and milk, yoghurt or soya” (MAMA, 2013, p. 3). The following type of message can be sent to discourage smoking, “Smoking harms you and your baby. If you smoke, your baby could be born weak and catch infections easily. Stop smoking and avoid smoky places” (MAMA, 2013, p. 11). To discourage alcohol consumption during pregnancy, “Drinking alcohol is bad for you and your baby. It could make your baby weak and ill. Don’t drink in pregnancy” (MAMA, 2013, p. 9).

While these messages examples may appear short and simple, a study on SMS pregnancy health intervention by the California State University (2011) reported, “women like receiving health information via text messages, and will act upon the knowledge they receive” (p. 2).

Additional message examples are available from Text4Baby, a US-based free text messaging service reportedly based on behavioural theory. Text4Baby has a large subscriber base with more than 320,000 people enrolling between February 2010 and March 2012 (Whittaker et al., 2012). Messages cover the period from early pregnancy through to the baby’s first birthday. The text messages are very generic but provide helpful advice on maternal health options and alternatives. For example the following messages were made available by the Healthy Babies Coalition (2012, para. 11) on the text4baby.org website:

- “Have you visited a Dr. or midwife (CNM/CM)? If not, make an appointment now. Call your health plan. Or 800-311-2229 to connect to low-cost care”.
- “Your baby is growing a lot! Baby is now the size of a lime & can open its mouth & move its tiny hands”.
- “If you have any signs of preterm labour--cramps, belly tightening, low back pain, bleeding, or watery, pink/brown discharge--call your Dr. right away”.
- “A seat belt protects you & your baby. Shoulder belt goes between your breasts & lap strap goes under your belly (not on or above). Wear it every time”.
- “Are you really in labour? Real labour won’t stop when you lie down or walk around. In real labour, the pains get worse & happen more often”.

A randomized evaluation provided evidence that specific health beliefs are changed by sending text messages to pregnant American women (Evans, Wallace and Snider 2012). Those exposed to Text4Baby messages were in agreement with the attitude statement ‘I am prepared to be a new mother’ (OR = 2.73, CI = 1.04, 7.18, $p = 0.042$) between baseline and follow-up. For those who had attained a high school education or greater, we observed a significantly higher overall agreement to attitudes against alcohol consumption during pregnancy (OR = 2.80, CI = 1.13, 6.90, $p = 0.026$). We also observed a significant improvement of attitudes toward alcohol consumption from baseline to follow-up (OR = 3.57, CI = 1.13 - 11.24, $p = 0.029$) (p. 1031).

The study highlighted that mothers were nearly three times more likely to believe that they were prepared to be new mothers compared to those in the no exposure control group. Commenting further on this study, William Evans, Professor of Prevention and Community Health at the School of Public Health and Health Services said “in addition to being more prepared for the arrival of a new baby, the pregnant women seemed more likely to understand the value of habits such as eating healthy foods or regular visits to a health provider or clinic” (The National Healthy Mother Healthy Babies Coalition, 2012, para. 5)

Another study by the National Latino Research Centre and the Department of Reproductive Medicine, at the University of California, investigated the satisfaction of 1,171 Text4Baby subscribers (912 English and 259 Spanish) in the San Diego area. The results indicated high satisfaction, improved interaction and increased access to health resources (California State University, 2011). More specifically, findings indicated that:

- Spanish speaking women reporting higher satisfaction scores than English speaking women.
- 63.1% of women reported that text4baby helped them remember an appointment or immunization that they or their child needed.
- 75.4% reported that text4baby messages informed them of medical warning signs they did not know.
- 71.3% reported talking to their doctor about a topic that they read on a text4baby message.

Martinez and Uekusa (2013) found that 44% of the Spanish-language participants lived in a zip code where over 25% of families live in poverty. Jordan, Ray, Johnson and Evans (2011) concluded in their paper, “Text4baby seems to be an excellent way to communicate with low-income women and new mothers who have limited access to critical prenatal and newborn information” (p. 210). This finding

Developing SMS Health Messages

may be an indication of parallel effectiveness with Indigenous Australian women in similar socioeconomic circumstances.

A recent systematic review of the literature by Poorman et al. (2014) focused on the use of SMS for maternal and infant health. A total of 48 studies included ‘... 30 randomized controlled trials; two non-randomized or partially randomized controlled trials; two cohort studies; three uncontrolled trials; five cross-sectional or ecological studies; three pilot studies; two historical case controls; and one focus group’ (Poorman et al. 2014, p. 2). The evidence presented in this study concluded;

The use of text messages to promote maternal health has tremendous potential to reach pregnant women and new mothers, particularly those with fewer resources. As we have shown, these women are more likely to use text messaging and to be at risk for poor birth outcomes that may be modified through appropriate text message interventions. These women are traditionally more difficult to outreach to with traditional communication methods, and thus this technology may be particularly valuable for this population (Poorman et al. 2014, p. 19).

Other evidence supporting this type of system is the investment of significant financial resources at various locations around the world. For example, the Mobile Alliance for Maternal Action (MAMA) is a public private partnership between USAID, Johnson & Johnson, the United Nations Foundation and BabyCenter, who have invested \$10m into similar SMS maternal health systems in Bangladesh, South Africa and India. The success of these programs has resulted in MAMA being included on the Annual Nominet Trust 100 (NT100) list, a global list of 100 inspiring ventures from around the world. Other projects included on the NT100 list include ‘... Freecycle, Random Acts of Kindness and Google’s self-driving car, alongside initiatives from emerging economies, including eCompliance, a revolutionary use of fingertip-readers to record tuberculosis treatment in India; philanthropic food-photo sharing app Feedie from South Africa and HarassMap, an anonymous crowd-mapping platform for sexual harassment in Egypt’ (MAMA 2014b, para. 4).

Operational Hardware and Software

The computer hardware required to run the SMS delivery system is available as an Internet service, often termed *Infrastructure as a service (IaaS)*, which displaces the need for on-premises servers, air-conditioned server rooms, backup and storage systems, and networks, not to mention the IT staff necessary to maintain them. Via the Internet, IaaS services provide the required hardware infrastructure within minutes (Rosen, 2010). See the textit.in example below.

The software required to manage SMS is also available in the cloud. This is known as *Software as a service (SaaS)*, which “refers to applications running on cloud infrastructures, typically delivered to the end user via a web browser” (Rosen, 2010, p. 26). The healthcare industry is not required to develop proprietary software or understand the underlying infrastructure or platform details. These systems require no programming knowledge to set up and costs are based on actual usage. The software collects and securely stores end-user registration data, can auto-reply to end-user messages and send feedback customised to the end-user’s current situation. For such SMS systems, Klasnja and Pratt (2012) conclude, the “diversity of these interactions provides evidence for just how flexible text messaging can be as a system for delivering health interventions” (p. 186).

By way of example, the textit.in service will reliably send 1,000 messages per hour from any global location with mobile phone coverage. Textit.in requires the additional purchase of an inexpensive Android phone and SIM card from a local carrier dedicated to this purpose. The mobile phone also requires Internet access via Wi-Fi or GSM data connection, or both. If one of the Internet connections drops out, the phone will switch to the alternative. To maximise reliability, the phone is placed geographically in an area with a strong network signal and a reliable power source (Nyaruka LTD, 2013).

Women subscribe to the system by sending an SMS text message containing 'Baby' to a mobile phone number. Upon receipt, the system automatically sends SMS prompts the mother to enter the baby's expected due date and postal code. The system then automatically sends SMS messages timed to the corresponding stages of her pregnancy.

Privacy

In NSW, privacy laws are regulated by the *Health Records and Information Privacy Act 2002* (NSW) (the 'HRIP Act'), which regulates health privacy, and the *Privacy and Personal Information Protection Act 1998* (NSW) (the 'PIIP Act'), which remains applicable to non-health information. As privacy policy is set by legislation, compliance with the HRIP Act is mandatory for the proposed SMS system (NSW Department of Health 2005).

Personal information is defined in Section 6 of the *PIIP Act* as:

If a person's identity cannot be ascertained from the information it will NOT be personal information, and the privacy laws will not apply. Unique identifying information such as name and address, photographs, biometric information including fingerprints and genetic characteristics will always be "personal information". A range of other information can also become personal information, if it is viewed in combination with other information, which together is sufficient to allow a person's identity to be "reasonably ascertained". (NSW Department of Health 2005, p. 11)

Legislative obligations are imposed on the health system by the HRIP Act. It applies to all people who work within the NSW public health system, who, in the course of their work, have access to personal health information. The HRIP Act covers all types of dealings with personal health information, including collection, storage, security, use, disclosure, access, transfer and linkage of records (See Table 4). They apply to personal health information in any format, including electronic and online formats as well as paper-based records. While different formats will require different approaches and procedures, the underlying principles remain the same.

While all reputable projects integrate strong privacy principles, it may not be strictly necessary for the current project to be subject to the PIIP Act because the identity of a person is not reasonably ascertainable from the information collected from each individual. This is due to the simplicity of the stored data set. Data input includes recipient's mobile phone number, expected due date and postcode. While the mobile phone number is assumed to be registered to a pregnant woman, there is also the possibility of the phone number being registered to someone else, such as another member of her household, as is often the case with teenagers. This lack of certainty protects the privacy of the individual. In other words, pregnancy health messages are probably being sent to the owner of the mobile phone but one cannot be certain.

Developing SMS Health Messages

Table 4. Summary of the Health Privacy Principles for Public Health Services in NSW, Relevant to the Current Project.

Principle	Description	Application to Current Project
Collection	Personal health information must be collected by lawful means and for a lawful purpose. The purpose must be directly related to, and reasonably necessary for, an organisation's functions or activities (NSW DoH 2005, p. 6).	Information is collected during the first antenatal visit. Personal information includes 1) mobile phone number, 2) expected delivery date, and 3) post code.
Security	Personal health information held by public health agencies must be securely housed and protected against loss or misuse. Information must be kept only as long as is necessary for the purpose (or as required by a law), and must be disposed of securely (NSW DoH 2005, p. 6).	Any SMS messages transmitted may be accessible by certain third-party organizations, such as cellular networks and SMS gateway services, which are used to transmit the messages. These organizations have their own rules, policies, and security measures controlling who has access to messages transmitted through their services. Data are retained until week 42 of pregnancy and then deleted from the database.
Access and Amendment	Organisations that hold personal health information must allow individuals to find out if they hold information about that individual, and, if so, what kind of information they hold, what it is used for, and whether and how the individual can access it. Individuals may request that their personal health information be amended to ensure that it is accurate, relevant, up-to-date, complete and not misleading (NSW DoH 2005, p. 6-7).	Due to the frequent changing of telephone numbers, individuals are provided with instruction on how to access and update their own information.
Accuracy	Organisations must take reasonable steps to ensure that the personal health information they hold is relevant, up-to-date, complete and not misleading (NSW DoH 2005, p. 7).	Personal health information is entered by the end-user.
Use	Personal health information can be used for the purpose for which it was collected, or for other purposes recognised by the Act. These include "secondary purposes" such as where there is consent for the use, the use is a "directly related purpose", for management, training and research activities, for investigation and law enforcement, or where there are serious and imminent threats to individuals or the public (NSW DoH 2005, p. 7).	The <i>telephone number</i> is relevant to the delivery of the SMS message, <i>delivery date</i> is relevant to the stage based messages, and <i>postal code</i> is relevant to customising messages to specific language groups and research activities.
Disclosure	The provisions for disclosure of personal health information are the same as those for use of this information (NSW DoH 2005, p. 7).	Full disclosure of privacy and security policies before subscribing to the system.
Anonymity	Provided that it is lawful and practicable, individuals should be given the option of not identifying themselves when dealing with health organisations (NSW DoH 2005, p. 7).	Individuals are not required to provide their names and addresses to use the system.
Trans-border data flows and data flows to Commonwealth agencies	As a general principle, personal health information must not be transferred to a Commonwealth agency or an organization in another state jurisdiction unless the receiving agency applies personal health information privacy policies and procedures substantially similar to those of NSW (NSW DoH 2005, p. 7).	This may become relevant if the project expands nationwide.

(Adapted from: NSW Department of Health 2005)

In regard to the end-user, a study by Häkkinen and Chatfield (2005) suggests that existing SMS etiquette treats messages as private, and people expect the receiver to understand the level of privacy from the message context. This phenomenon is quite interesting, as SMS is technically insecure: anybody can read them if they get your phone. However, this finding highlights a novel aspect on mobile culture, the support for the use of encryption or for visual privacy information to be sent as part of a text message was rejected by many respondents in favour of the social norms that currently preserve user privacy.

Persuasive Technology

In very general terms, ‘persuasive technology’ refers to technology designed to change attitudes or behaviours of specific audiences, through persuasion and social influence, but not through coercion. Persuasive technology is defined in the *Proceedings in First International Conference on Persuasive Technology* (2006) as:

Persuasive technology is the general class of technology that has the explicit purpose of changing human attitudes and behaviors. Persuasive technologies apply principles of social psychology in influencing people; principles of credibility, trust, reciprocity, authority and the like. ... The scope of technologies that hold persuasive potential is broader than ICT alone, and includes persuasive product design and architectural design, yet the interactive nature of computers uniquely enables user-sensitive and user-adaptive responding, allowing persuasive messages to be tailored to the specific user in question, presented at the right place and at the right time, thereby heightening their likely persuasive impact (Ijsselstein 2006, p. v).

The following behavior grid (Table 5) illustrates the psychological strategies most suited for use in persuasive technology via mobile phones. This table was prepared by B.J. Fogg, based on his experience in the field of mobile persuasion. In his paper, Fogg stresses that this work is preliminary and is not intended as a final map for mobile persuasion but as a generative tool, to highlight the potential of designing mobile persuasive experiences. (Fogg, 2009a) The current project intends to maximize the possibility of success by focusing on the types of behavior changes that have been identified in the grid as most suitable.

Row 1, ‘behavior for a period of time’ indicates a behavior change that extends for a fixed period of time. The change is not done once, neither is it a permanent change, it can last for three weeks, nine months, or two years. The period of time is irrelevant. The target audience knows the behavior has an end date. An example of this may be to ask women to stretch for five minutes a day, from week 20 until birth, in order to manage stress. Row 2, ‘behavior on a predictable schedule’ refers to a behavior change

Table 5. Behavior Grid Indicating Types Of Behavior Change Most Suited To Mobile Devices

		What Type Of Behavior Change?	
		A: perform existing behavior (familiar behavior)	B: increase behaviour (frequency, intensity, or duration)
On What Schedule?	1: behavior for a period of time (X has a duration)	Exercise for 30 minutes	Floss longer for two weeks
	2: behavior on a predictable schedule (X gets repeated periodically)	Gamble online each morning at 10am	Exercise with higher heart-rate each morning
	3: behavior is on cue (X is cued irregularly; it's a change in habitual response)	Drink water at each fountain you see	Write a longer thank you note after a dinner party
	4: behavior is at will (can perform x at any moment)	Check computer for viruses	Check for computer viruses more often
	5: behavior is always performed (X means change in habit, in way of being)	Maintain good posture	Think thoughts of appreciation

(Adapted from: Fogg, 2009a, p. 4)

that is repeated periodically on a schedule. The time period between performing the tasks is consistent; it can be daily, weekly or yearly. An example of this may be to ask women to visit their doctor every two months for antenatal check-ups. Row 3, 'behavior is on cue' refers to a behavior change that is performed on an irregular time schedule, as a habitual response, for example, washing hands before preparing meals. Row 4, 'behavior is at will', is a behavior that can be performed at any moment in time. Row 5, 'behavior is always performed' indicates a change of habit.

Column A, 'perform existing behavior' is behaviors which are already familiar to the target audience. The end-user knows the behavior, it's been achieved before. There are no surprises in performing this behavior, outcomes are known in terms of cost (in time, money, effort, and so on). Column B, 'increase behavior' are behaviors which are also familiar, however they are changing by increasing intensity or duration.

FUTURE RESEARCH DIRECTIONS

While this discussion may provide a novel and innovative idea for assisting Indigenous maternal health services, the bottom line to widespread adoption within healthcare is the evidence base. This is the first project of its type targeting the maternal healthcare of Indigenous Australians. As this is the preliminary stage of the project, no formal research has been completed other than the literature review. This is a proposal, not the verification or validation of a proven solution. While proven solutions may be preferred before implementation, proof should be readily achieved once implementation is realized.

The literature reports extensively on the successful outcomes of SMS in maternal health, however, the author has no direct evidence that this will be successful in an Indigenous Australian maternal health setting. Regardless of this significant fact, the reader can still retain confidence in the methodology employed by this project, to maximise the probability of success.

The coincidence of high adoption of mobile phones among the Indigenous Australian population and poor maternal health is considered by the author as a significant factor worthy of further investigation. Specifically, this technology approach has become possible due to a number of studies reporting on the rapid adoption of mobile phones, by Indigenous Australian communities (Taylor, 2012; Kral, 2010; Dyson & Brady, 2009; Department of Broadband, Communications and the Digital Economy, 2008; Tangentyere Council Research Hub and Central Land Council, 2007; James, 2006; Young, Robertson, Sawyer, & Guenther, 2005; Tiwi Land Council, 2004).

What Fjeldso and others (2012) noted in their study, is the widespread omission of details used in the development of behavior change messages, within the healthcare literature. This is a serious issue for those wanting to replicate successful behavior change projects. In the health sciences the end results are understandably the primary focus; in human-computer interaction (HCI) it could be argued that the method used to develop the system is of primary concern. Even when the outcome of a project is not favorable, when the process details are provided, it becomes possible to improve on the process itself. Granted, the application of this study is in the field of healthcare but it remains a technology project requiring a HCI methodology, not a healthcare approach. It is the intention of the current study to provide the process details.

Often, healthcare studies recommend a 'pre-testing' phase, requiring the target audience to receive health messages for an extended period. For example, Fjeldsoe et al. (2012) based their methodology

on the sequential multiple assignment randomized trial (SMART) method (Collins, Murphy & Stretcher 2007). Participation involved a one-on-one interview before and after the message testing period. While this method produces data on such things as the acceptable frequency of message delivery and the clarity of message content, it does not provide any data on whether the messages affected behavior, which is critical, before moving on to collecting scientific data (Fogg 2009b).

Instead, after the initial messages have been written, the next logical research direction is to test the messages to see if they affect behavior. The development of these behavior change messages is an iterative prototyping process not a scientific experiment. It allows the observation of how the target audience reacts to the messages. To achieve this type of behavior change test, after writing the initial messages, the messages are tested using variations, preferably the easiest and fastest variations first. Such tests may take two hours to set up, with a further two hours to put the test in motion. The results are then reviewed and new tests are prepared. It is at the completion of this stage that the SMS messages are ready for use in clinical trials. Yet, even at this stage, positive behavior change is not guaranteed, the messages have merely been developed to a point where they have the maximum possibility of success. (Fogg 2009b)

With the messages developed, formal scientific pilot testing can now proceed. However, the use of Randomised Controlled Trials (RCTs) at this stage is premature because ‘... RCTs often reveal little about *why* the technology under evaluation is or is not effective’ (Klasnja, Consolvo & Pratt 2011, p. 3066). Field studies, such as those used in HCI are recommended for testing technology systems designed for health behavior change, even short studies that contain a significant qualitative component uncover bugs in the system that can go undetected, even in lab-based usability testing (Rogers et al. 2007). Employing field studies to discover why the system worked or why it didn’t work is the way HCI researchers determine how to advance the system (Klasnja, Consolvo & Pratt 2011). In other words, during pilot testing, we are still optimizing variables affecting behavior change for the target audience. Only after the system has matured, an RCT becomes necessary to demonstrate that the new technology is effective.

In a practical sense, the researcher is also aware that no matter how impressive a new idea may be, it still requires a sustainable financial model. While this proposal presents an innovative solution, further research into a realistic financial model is required. There are a number of possible financial directions that can be explored. For example, financial support by individual hospitals, maternal healthcare services and state run maternal health programs. The program may also be distributed directly to consumers for free or low-cost, supported by advertisements and possible partnerships. It may also be possible to partner with the developers of medical sensors to combine SMS behaviour change programs with their products or developing our own wearable sensor device.

CONCLUSION

The primary issue to overcome in the development of a maternal health behavior change program for Indigenous Australians, is the cultural notion of ‘women’s business’. The clear-cut divisions between men’s and women’s role in Indigenous Australian culture needs to be incorporated directly into the design methodology i.e. Indigenous research methodologies. The voice of Senior Indigenous Australian women needs to be evident in the message content, in addition to the medical requirements. The other main barrier to implementation is the Australian healthcare industry itself, which is reluctant to embrace innovation.

SMS provides a stable and elegant solution, which can address lifestyle factors that directly impact on maternal outcomes. Captology, a discipline within Human Computer Interaction provides an established foundation for potential behavior changes that are most suited to mobile phones. Mobile phone coverage is far more extensive than face-to-face medical facilities and every mobile phone is SMS-capable. Furthermore, the Indigenous Australian community has a high rate of mobile phone adoption.

KEY TERMS AND DEFINITIONS

Antenatal: “Means ‘before the birth’, or during pregnancy” (Government of South Australia, 2007, para. 1).

Captology: “Is the study of computers as persuasive technologies. This includes the design, research, and analysis of interactive computing products (computers, mobile phones, websites, wireless technologies, mobile applications, video games, etc.) created for the purpose of changing people’s attitudes or behaviours. BJ Fogg derived the term *captology* in 1996 from an acronym: Computers As Persuasive Technologies = CAPT” (Persuasive Technology Lab, 2010, para. 1).

Cloud Services: “Means services made available to users on demand via the Internet from a cloud computing provider’s servers as opposed to being provided from a company’s own on-premises servers. Cloud services are designed to provide easy, scalable access to applications, resources and services, and are fully managed by a cloud services provider” (Webopedia, 2014, para. 1).

Human Computer Interaction (HCI): Dix offers this simple underlying principle for HCI, “the study of interaction between people and computers” (2004, p. 5).

Indigenous Australians: Are the Indigenous peoples of Australia.

Innovation: Is simply defined as “Something different that has impact” (Anthony, 2012, as cited in Harvard Business Review, 2012 para. 3).

Maternal Healthcare: “Is the health of women during pregnancy, childbirth, and the postpartum period. It encompasses the health care dimensions of family planning, preconception, prenatal, and postnatal care in order to reduce maternal morbidity and mortality” (Wikipedia™, 2014, para. 1).

Developing SMS Health Messages

SMS: “Stands for ‘short message service’ and is also called texting or text messaging. SMS messages or ‘texts’ are usually sent from one mobile phone to another, but can also be sent from some home phones. It is a quick and convenient way of sending a short message to someone” (BBC, 2014).

Wearable Sensors: Are small electronic devices that are worn on the user’s body for an extended period of time, significantly enhancing the user’s experience as a result of the product being worn. They contain advanced circuitry, wireless connectivity and at least a minimal level of independent processing capability. For healthcare and medical applications, devices require FDA or equivalent approval. They are used in monitoring of vital signs, as well as for augmenting senses (IHS Inc., 2013).

Women’s Business: “In Aboriginal culture, ‘women’s business’ includes all aspects of reproduction: menstruation, pregnancy, childbirth, contraception, abortion and female ceremonial business. The knowledge about Indigenous Australian birthing belongs in the domain of Indigenous Australian women. Breaches of these traditional divisions is likely to cause great distress” (Maher, 1999, p. 232).

Chapter 17

Health Information Technology and Quality Management

T. Ray Ruffin

*University of Phoenix, USA & Colorado Technical University, USA & University of Mount Olive, USA
& Wake Technical Community College, USA*

ABSTRACT

Even in healthcare and health information technology change will not vanish or disperse. Technology, civilization, and creative thought will drive this force increasingly forward. Health care managers will continue being judged on their ability to efficiently and effectively manage (Patton & James, 2000). The arena of Health Services Research (HSR) is trusted on by judgment deciders and the public is the principal basis of data on how thriving health systems are meeting this task (Steinwachs & Hughes, 2008). The goal of HSR is to deliver material that will ultimately lead to advances in the health of the community. HSR evaluation of quality of care has demonstrated it is an unspecified science and multifaceted, even though its description is comparatively simple (Steinwachs & Hughes, 2008). This article is to investigate the background, controversies, and problems surrounding Health Information Technology (HIT) Change and Quality Management including an overview of current changes and benefits of implementation. This will be coupled with solutions and recommendations, further research, and conclusion. This will enhance the field of research in leadership, change management, quality management, and health care.

INTRODUCTION

One of the most widely discussed areas in the health care field is improving the quality of patient-centered care within Health Information Technology (HIT). HIT allows for the all-inclusive management of medical information and the protected exchange between health care consumers and providers (U.S. Department of Health & Human Services, 2008). Health care comprises of the use and management of a profusion of information that must be collected, managed, reviewed, processed, and mined (McHaney, n. d.). With this in mind, HIT is proclaimed to be the solution to improve patient-centered health care and quality, while reducing cost within the medical industry (Hersh & Wright, 2008). There is an emergent agreement in the health policy community that cognizant and involved patients have a dynamic role to play in refining the quality of care that the United States (U.S.) health system delivers (Robert

DOI: 10.4018/978-1-5225-1674-3.ch017

Wood Foundation, 2007). A rising frame of research is commencing to offer solutions to that question, but there are also considerable holes in the research (Robert Wood Foundation, 2007). The foundation, content, and circulation of the health quality information that is currently available to consumers all vary widely. For instance, proportional evidence on quality performance for health plans has been accessible for some time in the form of the Health Plan Employer Data and Information Set (HEDIS) measures (Robert Wood Foundation, 2007). It is imperative to postulate relational characteristics of high quality care and ask patients to describe those involvements (e-Source Behavioral & Social Sciences Research, n. d.). It may also be useful to rate the extent to which care met patient expectations, but it is important to recognize that high satisfaction does not necessarily imply high quality (e-Source Behavioral & Social Sciences Research, n. d.). Even though HIT has the potential to transform the delivery of health care effectively and efficiently, health organizations continue to lack in this area.

A health organization has often been treated like a manufacturer who is advised that using cheaper materials can reduce manufacturing costs. The end result is that the manufacturer saves money on manufacturing costs but at the same time defects are accumulating and the results are subpar products. As we relate this to health organizations the ill effects of these short cuts are not externally evident, the health organization gives poor service or makes errors. Ultimately, health organizations fail in any of the countless ways in which organizations fail when they are poorly sustained. When health organizations operate inefficiently without proper funding, the odds become stacked against them.

Stakeholders will be described as individuals, affected continually in the health care administration, processes, and accompanying actions associated with its realism (Li, 2015). The effects may be through providers, employers, patients, and payers either in direct or indirect, including the populations where the health care facilities are located (Li, 2015). Those in the health care arena have a duty to cogitate the desires and anticipations of its stakeholders (Li, 2015). Managing stakeholder expectations is a method perturbed with cultivating project performance by sustaining the requirement of all stakeholders with applicable communiqué for every stakeholder requirements and problem perseverance when required (Project Management Lexicon, 2015).

Several other studies suggest that the adoption of HIT remains limited in certain functions (Poon, Jha, Christino, Honour, Fernandopulle, Middleton, & Kaushal, 2006). There have been limited studies conducted to determine which functionalities of HITs need implementation. Most studies concentrated on certain functionalities such as Computer Provider Order Entry (CPOE) or Electronic Health Record (EHR). CPOE is a set of clinical processes that incorporate technology to optimize physician ordering of medication and other required laboratory testing (Ormond, 2005). During a study by Minnesota Orthopedics Specialist, it was realized that vendor and local support during implementation was critical for success (O'Neill, 2007).

EHR is “related information on an individual that conforms to nationally recognized interoperability standards and that can be created, managed, and consulted by authorized clinicians and staff across more than one health care organization” (U.S. Department of Health and Human Services, 2008, p. 17). This definition has been updated to include a digital collection of patient health information compiled at one or more meetings in any care delivery setting and is often used to refer to the software platform that manages patient records maintained by a hospital or medical practice (Health IT News, 2013).

This leads us to look at the internal and external change. This is imperative for the change process and implementation of HIT. The internal reaction to change is the key point of discovery that requires learning something new, not just the acquisition of knowledge (Cameron & Green, 2004). Over time health organization management has avoided mentioning patient care and patient-related quality issues in either

a positive or a negative framework. Many administrators appeared to focus more on central management than on clinical operations. In doing so, they have missed opportunities to engage patients and families as allies, document patient satisfaction and positive social work outcomes, and identify systemic patient care problems. The Greek Philosopher Heraclitus said that “no man ever steps in the same river twice, for it’s not the same river and he’s not the same man” (BrainyMedia.com, 2009, para. 1). Some interpret that the river is the external world. The external world is ever changing; the “river” is never the same. Another way to interpret this is that the “man” who stepped in the river today is not the same “man” that steps in the river tomorrow due to change, evolution, or experience that relate to external facts and figures (Cameron & Green, 2004). Technology changes rapidly and maintaining the status quo, actually means falling behind, and health organizations cannot afford to do that in our technology-driven world.

Change will not vanish or disperse. Technology, civilization, and creative thought will maintain an increasing force forward. The pace of change has significantly increased since the days of the cave dweller who walked the earth until the “technology convergence” to the ox and horse. The world may not be spinning faster, however the people are (Patton & James, 2000). This article will investigate the background, controversies, and problems surrounding Health Information Technology Change and Quality Management, including an overview of benefits of implementation and strategies. This will be coupled with solutions and recommendations, further research and a conclusion.

BACKGROUND

Information Technology (IT) is a term that denotes the processing of data using a computer; the use of technologies electronically from computing, telecommunications, and the allocation of information in digital and other forms (Encarta® World English Dictionary, 2007). Specifically, it refers to the products, methods, inventions, and principles that are used to produce information (Kroenke, 2008). Information Systems (IS) is a term that denotes gathering of hardware, software, data, procedures, and masses that produce information (Kroenke, 2008). The American Hospital Association in 2006 conducted a survey acknowledging numerous barriers to HIT adoption. Initial costs (94%) and continuing costs (87%) were the most commonly reported barriers. Clinician acceptance (82%) and lack of interoperability with current systems (79%) also ranked lofty. To tackle the issue of interoperability, the U.S. Department of Health and Human Services (HHS) contracted with the Certification Commission for HealthCare Information Technology to certify HIT systems that meet standards for interoperability, functionality and security (Certification Commission for Health Information Technology, 2013).

The intricacy in measuring quality derives from cracks in our understanding concerning diagnosis plans, for which patients, which really increase the probability of anticipated health outcomes. Additionally, patients do not have to have the same anticipated health outcomes, resulting in changes in care for identical health problem, supplementary obscuring the measurement of quality of care. Quality measurement has progressed significantly, but it rests primary in its early development stage. The conceptual framework commonly pragmatic in evaluating quality derives from eons of research and the insightful analysis of Avedis Donabedian (Steinwachs & Hughes, 2008). The Doanbedian conceptual model for describing, analyzing, and evaluating the quality of care using three dimensions: (1) structure, (2) process, and (3) outcome (Steinwachs & Hughes, 2008). This model is useful in the assessment of health services and the accreditation of health care providers and organizations. HSR research tools can be useful in

scientific settings to increase clinical preparation and patient outcomes. These tools are used as part of quality improvement programs in hospitals, clinics, and health plans (Steinwachs & Hughes, 2008).

According to Nelson (2014) the ethical framework for Quality Improvement (QI) is based on the premise “to protect patients and foster the integrity of the organization” (p. 2) ensured by health care leaders. This ethical framework is very broad and leaves a lot to be desired. For example, foster the integrity of the organization can come down to a moral or ethical decision of the individual health organization. It is known that administrators must admit their part in affecting organizational ethics and grasp this chance to generate an environment that can reinforce the relationships and reputations on which their health organization exist (Paine, 1994). QI involves methodical and continuous activities that lead to calculable progression in health care services and the health status of targeted patient sets (U.S. Department of Health and Human Services Health Resources and Service Administration [HRSA], n.d.) The Institute of Medicine’s (IOM) expresses quality in health care as an uninterrupted connection among the level of improved health services and the sought after health outcomes of individuals and populations (HRSA, n.d.).

HEALTH INFORMATION TECHNOLOGY AND QUALITY MANAGEMENT CONTROVERSIES AND PROBLEMS

Medical errors are an enormous cause of the defective medical model in use today needing a frantic renovation (Shanafelt, Boone, Tan, Dyrbye, Sotile, Satele, West, Sloan, & Oreskovich, 2012). According to Shanafelt, Boone, Tan, et al., (2012) the bulk of health care givers witnessing errors made by their peers, seldom do anything to contest them. The field of health care is tremendously meaningful and the same time difficult and nerve-racking. An extensive percentage of American health care providers undergo burnout on the job, according to a 2012 study published in the Archives of Internal Medicine (Shanafelt, Boone, Tan, et al., 2012). Specialists appear to be at the utmost risk, when function in front line care (Shanafelt, Boone, Tan, et al., 2012). Shanafelt, Boone, Tan, et al. (2012) suggest burnout may wear down professionalism, effect quality of care, and escalate the risk of medical errors.

The countless estimates on medical errors point out numerous failures of the U. S. Health Care System (Andel, Davidow, Hollander, & Moreno, 2012). Quality and patient safety have traditionally been an ancillary issue for the majority of the nation’s hospitals (Andel, Davidow, Hollander, & Moreno, 2012). Life cycles for equipment are being prolonged as health organizations try to limit or cancel plans to purchase costly new technology. As health organizations look to cut cost with bulk medication, new purchasing processes denote acquiring of multi-dose medications instead of single dose vials and syringes. This has enlarged the number of medication errors (Andel, Davidow, Hollander, & Moreno, 2012). The Medicare program is paying for services health care providers charge, including the provider errors (Andel, Davidow, Hollander, & Moreno, 2012). Although there is no conclusive confirmation that the recent recession is having an influence on health care quality and patient safety, it may be having a negative effect (Andel, Davidow, Hollander, & Moreno, 2012).

The advantages of involuntary reporting include direct surveillance of providers and chart evaluation using initiate tools (Agency for Healthcare Research and Quality [AHRQ], 2014). Involuntary reporting remains a prominent foundation of information because they are normally readily accessible; it is frequently probable to attain thorough accounts of what went wrong (Murff, Patel, Hripcsak, & Bateset,

2003). The limitations of voluntary reporting are there not set procedures to review records. For example, in the studies the data was provided by a two-step review process (Murff, Patel, Hripcsak, & Bateset, 2003). If the health care provider's reviewers differ on if an adverse event occurred, the health care providers will try to come to an agreement or involve a third party (Murff, Patel, Hripcsak, & Bateset, 2003). Typically, only a minute portion of the charts are reviewed independently by two health care providers (Murff et al., 2003). Notwithstanding the effectiveness of voluntary reporting systems in other industries, voluntary reporting in health care has been relatively ineffective (Murff, Patel, Hripcsak, & Bateset, 2003).

Is it possible the medical industry has adopted HIT for financial gain through organizational efficiency more so than with patient-centered HITs being the secondary factor? There is some evidence that health organization fiscal accountability's "survival" mentality has the potential to compromise medical treatment and commitment to organizational efficiency at the expense of patients and their families (Mizrahi & Berger, 2005). Management is not exclusively looking for ways of maximizing production and transaction costs. Some organizations want to ensure they remain competitive and survive in the long term.

In their struggle to obtain legitimacy, organizations adjust to society according to a collective rationalization. As a result, institutionalized activities are durable, socially accepted, unwilling to change, and their survival is not directly linked to rewards or control (Ouedraogo, 2007). In a motionless flow organizations have a tendency to become complacent (Elearn Limited, Pergamon Flexible Learning, 2005). The need to confront this organizational complacency can be one of the major triggers for change. Working any length of time has shown the rate of change is increasing. For example, the huge change of Health Organizations in 2001 was compressed in a shorter amount of time. Table 1 is from Elearn Limited, Pergamon Flexible Learning (2005). Credit is also given to Grundy (1995) for the source of the information.

Organizations base change strategies on the past three to five years. The important issue is to base change strategies on the future and new recipes to combat change. Adapted from *Change Management*, by Elearn Limited, Pergamon Flexible Learning, 2005; and from *Breakthrough for Growth*, by A. N. Grundy, 2005. Table 2 illustrates how much organizations change over time in sweeping environments (Elearn Limited, Pergamon Flexible Learning, 2005). Credit is also given to Lynch (2000) from which the information was adapted.

The worst thing that organization's management can do is allow their ego to step into the driver's seat and dictate their responses by clinging to old methods without considering new ones. Not only will they be ineffective, they will look irrational in the process or weaken the organization (Nicholson, 2009). When it comes to managing change, research is the best solution. Do not manipulate the data to fit an

Table 1. Change recipes: Recipes refers to the established ways an organization anticipates and responds to change

Time	Past	Old markets, receipts, and competition
	Change	
	Present	Current markets, receipts, and competition
	Change	
	Future	Unfolding markets, new recipes, and future competition

Table 2. Health organizations objectives and strategies shift. Adapted from Change Management, by Elearn Limited, Pergamon Flexible Learning, 2005; and adapted from Corporate Strategy, by R. Lynch, 2000.

Period	Company Objectives	Management Priorities
Early to mid 1990s	Grow and maintain market dominance in health markets	Invest in Health Organization brand Increase service levels Launch regular new practices
Late 1980s to early 1990s	Survive the threat from competitors	Major cutbacks in cost base Divest nonessential parts of the organization
Mid 1990s and future	Restart growth	Acquire new Health Organizations Diversify into software and services, leading to HIT

intended agenda. The point is to work with the research data as objectively as possible. One approach by Katie Delahaye Paine describes the steps of effective research measurement as redefining measures of success: experiment, listen, measure, and learn (Nicholson, 2009).

According to Clarke and Donaldson (n.d.) a system overload is unavoidable. Restrained demand from those waiting for a promise of “free” or heavily subsidized services is expected. Health care professionals want to help people in need, but the sheer logistics of extended care delivery, the current and growing shortage of personnel, and limited resources will challenge the intentions of the policymakers who constructed the national health law. Reports have begun documenting a new, unprecedented shortage of nurses linked to growing demand for services, as well as drops in graduations from nursing education programs (Clarke & Donaldson, n.d.).

The “transformational” changes touted by the law’s champions will likely complicate and negatively affect health care workers and their ability to provide care. These changes will increase regulatory burdens, increase already heavy workloads, reduce payments, impose new penalties, and disregard personal preferences and values (Anderson, 2014). Change does not happen overnight and there will be some tremulous times.

The effect of managed care on quality of care has been problematic to assess, at least in part, because of the difficulty in reaching a common understanding of how quality should be measured. Quality has been defined as the degree to which health services for individuals and populations increase the likelihood of desired health outcomes and are consistent with current professional knowledge (Silberman & James, 2000). The definition of quality varies based on personal perspective, background, culture, and individual need. Regardless of definition, quality is demanded and oftentimes not provided. Many view quality health care as the predominant authority under which patient safety resides. For example, the IOM considers patient safety “indistinguishable from the delivery of quality health care.” Ancient philosophers such as Aristotle and Plato considered quality and its attributes (Mitchel, n.d.).

At first, IOM defined quality as the point at which health services for the society increase the likelihood of desired health outcomes and are consistent with professional knowledge (Mitchel, n.d.). This was transformed into to a definition of quality that appeared to be listings of quality indicators, which are terminologies of the standards. These standards are not necessarily in terms of the possibilities or conceptual clusters for these indicators. These clusters of quality indicators were and often continue to be comprised of the 5D’s, which are death, disease, disability, discomfort, and dissatisfaction, rather than more positive components of quality (Mitchel, n.d.). This is a starting part and the 5 D’s are better than nothing at all. This definition will be transformed again in the future.

A framework accentuates analysis of the voluntary reporting and detailing progression improvements ascending from analysis, rather than inspiring voluntary reporting for its own sake (AHRQ, 2014). When there is no data and metrics, there is no reference point to know how the health care organization is doing, not knowing how health care organizations compare to each other (Healthcare IT News, 2014). There is no way to judge whether health care organizations strategies are making a difference (Healthcare IT News, 2014).

OVERVIEW OF CURRENT CHANGES

The iron triangle of health care includes access, cost, and quality. All of them are dependent on each other. Likewise, altering one variable affects the remaining two. Computers had a parallel start progressing from a product only available to a few (due to cost and difficulty of the systems) to where computers are affordable, universal, simple to use, and of even better quality than the past (Liu, 2012). The important issue is that it took many years before computers became more affordable, powerful, and accessible (Liu, 2012). Now they have evolved in the forms of laptops, netbooks, and now smartphones and tablets. In the future health care will break the iron triangle and demonstrate that it is not a law but an observation (Liu, 2012). If a debate is started over which one is more important, there is no gain. When one is altered, it inevitably alters the others. The health care triangle is a series of relationship that exist together such as doctor, nurse, and clerical. One cannot function or complete their task without the other. Hopefully, in years to come these computer programs will lead to affordable, universal, and quality for HIT and health care overall.

BENEFITS OF IMPLEMENTATION

Health care expenditures have amplified dramatically during the past fifty years, mutually in total terms and as a share of Gross Domestic Product (GDP) (White House ERP, 2013). Expenditures in the U.S. health care segment computed over \$2.7 trillion in 2011, increasing from up the \$698.3 billion expended in 1980, increasing by a factor of 3.9. Health care expenditure in 2011 attributed for 17.9 percent of GDP, resulting in doubling of the shares from 1980 (White House ERP, 2013). These expenditures have led to Quality Management for Health Care System to make available a structure to aid health organizations in, communicating, monitoring, and incessantly advancing the whole health care delivery system (James, n.d.). At this point the nationwide atmosphere must utilize an extremely designed method in the quest for quality management (James, n. d.). This has resulted in indications that back the suggestion that a systematized system to achieve high quality care can be front-runner to lower health care costs (James, n.d.).

Health care organizations as a whole spend vastly on information technology, nevertheless the declared progress in patient safety and efficiency have not been recognized (Healthcare IT News, 2014). One of the more substantial problems concerning medical errors encompasses wasted and late diagnoses (Healthcare IT News, 2014). For example, inadequate ordering of appropriate tests or initiate return visits (Healthcare IT News, 2014). One purpose of this chapter is to first discuss why preventable medical errors are still a problem in the U. S. almost 20 years later after a 1999 report titled *To Err is Human*, which estimated that between 44,000 and 98,000 Americans died in 1997 as a result of preventable medical errors (Institute of Medicine, 1999).

SOLUTIONS AND RECOMMENDATIONS

Health Informatics (HIs) experts in a Delphi study ranked Business Process Reengineering (BPR) as one of the top research priorities for HI (Bliemel & Hassanein, 2004). The RAND Corporation developed the Delphi Method to forecast the impact of technology on business (RAND, 2014). The Delphi method surveys the opinions of “expert panels.” The research is conducted in three rounds, where the information is gathered, refined, and then fed back to the expert participants. The feedback stage allows issues to be sharpened and helps to highlight the major issues involved. Round one involves an in-house panel that seeks to identify the research questions for the experts. It also conducts a pre-test of the survey. The second round involves an examination of the issues by the expert panel. At this stage, additional items are often suggested that may have been overlooked. The panel responses and additional items are combined to the original questionnaire. In the third round, the panel makes judgments on the items. This sometimes takes the form of a multiple-choice questionnaire.

The goal is to come up with an expert consensus by reducing the range of responses (RAND, 2014). The results showed a process-oriented healthcare industry would benefit from BPR. BPR involves several organizational improvements that are enabled by electronic patient records and an inter-operating system (Bliemel & Hassanein, 2004). In which the focus is on achieving specific performance targets such as specific profit margins, clinical outcomes, quality improvements, or customer satisfaction. A health organization’s balanced-scorecard reports will indicate whether the organization is managing with acceptable results and provide a basis for assessing their managers’ performances and their roles in the organization’s success (Mizrahi & Berger, 2005). The growth and maturity of informatics has been a prime catalyst in positioning the health care industry for change. The Patient Protection and Affordable Care Act (PPACA) for instance, which puts in place comprehensive health insurance reforms that will roll out over four years and beyond (U.S. Department of Health and Human Services, 2013).

During the implementation of reform, informatics will serve as the foundation for all aspects of successful healthcare reform initiatives (Health IT News, 2013). Changeability addresses the positive question of what makes people and organizations good, and their ability to manage for the future. In tentative times, pressure for alteration is greater than ever (Cree, 2009). High performance health organizations compete on their ability to identify up-and-coming threats and opportunities, and to respond to them swiftly with well-informed decisions. The development of networks of longitudinal, comprehensive, and interoperable HIT offers opportunities for improving coordination of care and the usefulness of records, increasing competence of health care, and avoiding duplication of services (Leavitt, 2007).

These decisions must encompass business analytics. By understanding the process of analytics, healthcare providers have the insight necessary to make process adjustments in the future. To make excellent managerial decisions companies need access to information that encompasses not only company performance but also the broader competitive landscape (CFO Publishing Corporation, 2009). Informatics can increase options for treatments, reduce risks, improve processes, help with financial management, and ultimately improve patient care. It requires having the people, data, technologies, and processes necessary to mine the information and act upon it.

The Delphi study also identified electronic patient records and connected inter-operating systems as urgent research priorities (Bliemel & Hassanein, 2004). Having a physician or physicians who are passionate about the HIT is critical. The physicians who are salaried and committed to the HIT and clinical systems, is critical for success (Amatayakul & Hodges, 2006). The acquisition of new hardware and

software has the possibility to enhance a health care organization's potential to provide high-quality, cost-effective patient care.

Management must commit to open and honest disclosures of facts that not only help people understand the rationale for change, but also how it affects and benefits the organization (Nicholson, 2009). It is important for administrators to function well at three levels: the hospital/macro level, the internal (department or program) level, and the external/community level. They need to cultivate other staff leaders, redesign functions, prioritize goals, and promote internal communication to create a sense of professional pride and collective ownership (Mizrahi & Berger, 2005). These leaders need support from other leaders and from the professional and academic resources of major institutions to make their case. They must develop mutually supportive staff-driven activities, mechanisms to share information, ideas, resources about best practices, survival models, and methods of reorganizing roles and functions within and between hospital systems (Mizrahi & Berger, 2005). To compete effectively, health organizations must look beyond improving operating efficiency to improving their processes for managing performance (CFO Publishing Corporation, 2009).

To maintain cost, accountability, and fairness there should be a national standard of rate by the National Association of Insurance Commissioners (NAIC) to look into areas such as:

1. A definition of "rate filing" that includes new and renewed premium rates, any proposed rating formula, classification of risks, or modification of any formula or classification of risks;
2. A standard of review that places the burden of proof on the health insurance issuer to demonstrate that the proposed;
3. Ensuring that rate filing is not unreasonable, unnecessary, inadequate, or unfairly discriminatory (National Association of Insurance Commissioners [NAIC], 2010).

While, America's Health Agenda focused on these areas of concern to maintain cost, accountability, and fairness:

1. The implementation of electronic health claims, premium payments, referral authorizations by 2016;
2. The formation of a National Prevention, Wellness, and Public Health Council charged with developing a national strategy to improve the nation's health;
3. The creation of a grant program to support the delivery of evidence-based and community-based prevention and wellness services aimed at strengthening prevention activities (America's Agenda: Health Care for All, n. d.).

Touting these changes as being instrumental in reducing chronic disease rates and addressing health disparities, especially in rural and border areas (America's Agenda: Health Care for All, n.d.). This funding will support primary care training and capacity building. The development of training programs that focuses on primary care models such as medical homes and team management of chronic diseases (America's Agenda: Health Care for All, n.d.).

Public Health Institutes (PHIs) are nonprofit organizations that increase the public's health by modernizing, leveraging resources, and building partnerships across sectors including government agencies, communities, the health care delivery system, media, and academia (National Network of Public Health Institutes, 2010). Health System Strengthening (HSS) has become a major focus of the U.S. (Bloland,

Simone, Burkholder, Slutsker, & De Cock, 2012). The Role of Public Health Institutions in Global Health System Strengthening is critical for achieving major health goals in preventive care in the community.

The American Public Health Association (APHA) has created building blocks for the health infrastructure to gain funding for local, county, and city public health agencies to ensure that the health system is assessing and responding to public health needs for preventive care (American College of Physicians, 2012). Adequate, steady funding streams for the development and maintenance of local programs and activities are fundamental for the successful achievement of the goals of public health in the community. Funding by the government enables public health providers' access to resources that private clinicians may not have.

Health care can be provided through public and private providers. Public health care is usually provided by the government through national healthcare systems. Private health care can be provided through "for profit" hospitals and self-employed practitioners, and "not for profit" non-government providers including faith-based organizations (Basu, Andrews, Kishore, Panjabi, & Stuckler, 2012). Creating maintainable, operational linkages between the clinical and community settings can improve patients' access to preventive and chronic care amenities by developing partnerships between organizations that share a common goal of improving the health of people and the communities (AHRQ, 2014).

Table 3 is factors that lead to the requirement to implement health authorities' interconnection infrastructure. These factors may also be seen as the targets that are, and will be, accomplished. The table constitutes the functional requirements for the network infrastructure and evolving reformation and of current advances in the field of data communications. These factors include areas such as:

Table 3. Benefits of using information and communication technologies in the health care sector. From Implementation and Integration of Regional Health Care Data Networks in the Hellenic National Health Service, by Lampsas, Vidalis, Papanikolaou, & Vagelatos (2002).

Health Care Players	Benefits
Administration units	Policy development and decision-making are strongly supported by effective and on-time information gathering and distribution. Easier adaptation to eEurope challenges. Supply control; better budget monitoring. Overall improvement in the way citizens are served.
Hospitals	Increased efficiency in communication between hospitals, administration units, social security services, careers, physicians, and citizens. Personnel familiarization with information technologies through Internet-access operations. Patient-record traffic support. Reinforcement of the need to build Health Care Information Systems (HCISs) and local networks in hospitals. Utilization of the developed Intranets. Better information services for the citizens. Advanced telematics services (e.g., telemedicine applications in difficult-to-reach regions).
Health care personnel	Meets the increased need for telecommunications not only for medical, but also for compensation reasons. Participation in care chains and relevant coordination. Physicians' collaboration. Patients' history data retrieval. Continuing education services; familiarization with new technologies through special training programs. Interaction with patients to provide advice or prescriptions.
Citizens	Use of the Internet for health-related information retrieval. Information and communication technologies will increase interest in citizens' health-issues management. Creation of the appropriate infrastructure for future provision of special health services for specific population groups (e.g., in-house services for older people or patients with long-lasting attendance and nursing needs).

1. The regional structure of the administration services;
2. The treelike managerial structure of the health care units;
3. The active participation of general practitioners in the new system;
4. The need for transmission of sensitive EHR information and for interconnection with private pharmacies and the insurance system in the years to come;
5. The successive advances in Internet technologies (Lampsas, Vidalis, Papanikolaou, & Vagelatos, 2002).

One of the fastest ways to prove the return on investment from Lean or Six Sigma is to place emphasis on the elimination of waste from operations. Six Sigma is about those “critical few” variables that drive process performance, Lean is about the “trivial many.” Targeted initiatives such as the popular “5S” method have been credited with making significant improvements in the efficiency of the workplace by attacking the low hanging fruit or the trivial many in waste reduction (Lazarus, 2012). 5S is a method for organizing a workplace to maximize efficiency. The 5 steps, undertaken in order, according to Lazarus (2012):

1. **Sort:** Set aside all work-related tools for categorization and possible relocation;
2. **Set in Order:** Decide which tools are needed daily, weekly, monthly or less often. Organize the proximity of tools based on frequency of use;
3. **Shine:** Ensure workplace is sterile with adequate visual controls to support rapid identification of where resources are and how they are to be used;
4. **Standardize:** Leverage this work across the entire workspace. Use one workstation as a prototype, replicate, or expand. Use this as an opportunity to standardize all supplies and tools;
5. **Sustain:** Delegate ongoing responsibility for maintaining order. Post pictures to support rapid identification if any aspect of the organization effort has been compromised (Para 8).

Many healthcare organizations have added a 6th “S” for member “Safety” (Lazarus, 2012). Table 4 is a checklist for the prescription of a Robust Lean/Six Sigma Program, this shows what is needed to make Lean/Six Sigma Program successful, information.

Table 4. Checklist: Prescription for a robust lean/six sigma program, obtained from Lazarus (2012) para 6

Staff trained in both Lean and Six Sigma methods
Establish Return On Investment (ROI) expectations from portfolio of projects
Sponsor training for senior management
Visibility across enterprise for program and its achievements
Celebration and recognition for completed projects and project leaders
Implement formal handoff from project leader to process owner
Continue running control charts on all completed projects
Implement specification limits that identify if performance has regressed
Create governance for program to approve new projects
Communicate expectations for staff to complete at least one project annually (more if the staff are dedicated to performance improvement)

FURTHER RESEARCH

There should be further research on health organization in other countries such as the Canadian Health Care System, which is increasing their use of health technology assessment organizations including the Canadian Agency for Drugs and Technologies in Health (CADTH, a national body) and specialized provincial agencies in Alberta, Ontario, and Quebec. The organizations support and inform purchasing decisions, service management, and clinical practice (Thomson, Osborn, Squires, & Jun, 2013). The Danish Health Care System's 2007 structural reform centralized the administration of hospital care in order to enhance the coordination of service delivery and to improve quality and efficiency. They merged 14 counties to create five regions and reduced the number of municipalities from 275 to 98. The regions are currently reorganizing their hospital systems, closing or combining small hospitals, and building new hospital infrastructures (Thomson, Osborn, Squires, & Jun 2013).

The English Health Care System Clinical Commissioning Groups (CCGs) are replacing Primary Care Trusts as local health care purchasing organizations, introducing the National Health Service (NHS) Health and Social Care Act 2012. This allowed the NHS in England to take over day-to-day responsibility, and expanding the NHS into a role of Monitor to act as the economic regulator of public and private providers. The National Institute for Health and Clinical Excellence (NICE) sets guidelines for the NHS on clinically effective treatments, and appraises new health technologies for their efficacy and cost-effectiveness (Thomson, Osborn, Squires, & Jun 2013).

In the French Health Care System, the National Support Agency for the Performance of Health and Medico-Social Facilities provides guidance to institutions in need of structural changes and performance audits, and publishes dashboard indicators such as length of stay, occupancy, patient satisfaction, and incidence of bedsores. That is classified by category and type of medical activity. It is the only such public body in Europe. The Biomedicine Agency operates in four key areas:

1. Assisted reproductive technologies;
2. Prenatal and genetic diagnosis;
3. Embryo and stem cell research;
4. Procurement and transplant of organs, tissues, and cells (Thomson, Osborn, Squires, & Jun, 2013).

Moreover, research should be continued in the area of informatics. For example, the Supporting LIFE Project cultivates a low-cost implementation with extraordinary impact on the control of infectious diseases in Malawi (Department of Informatics, 2014). This is example of ongoing research projects by the Department of Informatics Lund University School of Economics and Management. This type of research will determine if informatics has the ability for organizations to understand their risk and cost profiles while ensuring the best care for patients. In conjunction with this research there should be a focus on health organizations' inequities, such as geographies and finances.

Computer networking opens many avenues to effective communication and collaboration amongst health care providers and organizations in the coordination and delivery of patient care (Ponemon Institute, 2014). For example, the increasing use of smartphones of today's society and the advancement of the Accountable Care Organization (ACO) model allows for the chance to update and revolutionize outdated communication in health care (Ponemon Institute, 2014).

Ponemon Institute (2014) study found three areas of opportunity that can be improved with communication and collaboration:

1. **Patient Admission:** Admitting one patient takes about 51 minutes, of which an average of 33 minutes (65 percent) is wasted due to inefficient communications. This translates into an annual loss of about \$728,000 per U.S. hospital;
2. **Emergency Response Coordination:** Coordinating an emergency response team takes an average of 93 minutes per patient. Of this time, an average of 40 minutes (43 percent) is wasted due to inefficient communications. This equates to an annual loss of more than \$265,000 per U.S. hospital;
3. **Patient Transfer:** Transferring a patient to another facility or home care/hospice takes about 56 minutes, of which an average of 35 minutes (63 percent) is wasted due to inefficient communications. The total annual cost of this waste is about \$754,000 per U.S. hospital (p. 2).

CONCLUSION

This article investigated the background, controversies, and problems surrounding Health Information Technology and Quality Management. An overview of current changes, benefits of implementation, solutions and recommendations, and further research rounded out the article. One universally accepted truth in organizations is the unavoidability of change. Another is that few organizations achieve the benefits they should due to not adequately planning change. This leads to the old adage organizations do not plan to fail, they fail to plan for change. Hospital boards approve millions of dollars for software, hardware, and consultants, but frequently the new positions required to build an effective team are not included in the approved budget. Numerous reports have indicated the importance of HIT. The question still remains as to how implementation will happen on a consistent level.

Change management, process and workflow improvement, comprehensive training, user support, and system ownership are all perilously important to HIT success, and therefore require funding. Informatics will allow organizations to understand their risk and cost profiles while ensuring the best care for patients. Informatics can be used across the broad spectrum of healthcare and is not limited to decision support functions. Management tools and techniques will help health organizations, if they hold their managers accountable for achieving targeted results. Effective communication of a well-deliberated plan is at the foundation of the management of employees during times of change.

Quality is a topic of concern among all health care organizations. Patients expect a high quality of care. Providers are scrutinized for the level of care offered. Health care professionals such as physicians take the Hippocratic Oath, swearing to uphold specific ethical standards. This includes treating the ill to the best of one's ability, preserving patient's privacy, and teaching the secrets of medicine to the next generation (Medical Net.com, 2014). However, as with most cases, money becomes a driving force with the marketing and targeting of the pharmaceutical companies to market their medications. It is easy for a health care professional to forget the main focus of quality care. Even payers are assessing the levels of quality present (or absent) among health care organizations.

An integrated program of change that allows for the incorporation Business Informatics (BI) or Health Business Informatics (HBI), Health Informatics (HI), Nursing Informatics, or simply "Informatics" is essential. Renovating care into quality care is the core of the clinical environment, and nurse leaders need to recognize the importance of emerging technologies (McHaney, n. d.). Nurse leaders should become involved in planning, designing, developing, implementing, and evaluating networks that will be used by nurses. This has led to a specialty area that integrates sciences of nursing, computer, and information called Nursing Informatics (McHaney, n. d.). This specialty area provides expertise in developing and

implementing Information Management Systems (IMSs) that can be used by nurses to enhance daily tasks and integrate various aspects of patient care. These techniques are used to seamlessly integrate technology and information that may be located within a geographical area or even across international boundaries (McHaney, n.d.).

Reforms have the ability to save money and lives in the long run. The future is dependent on programs such as the Inner City Health Clinics (IHC), launched by the Patient Protection and Affordable Care Act (PPACA) (Frykholm & Kennel-Shank, 2014). The Act included \$11 billion in new funds for clinics that serve neighborhoods where access to medical care is limited and many people are uninsured or underinsured. The expansion of community health centers is especially important in the 25 states that have accepted the expansion of Medicaid to people with incomes up to 133% of the federal poverty income level. The new term that will be used is “conduit to care.” When someone is identified through a screening as having a health problem, that person may be reluctant to follow up with a doctor. IHC’s outreach workers provide the follow up contact (Frykholm & Kennel-Shank, 2014). This approach is crucial to reaching people before their health problems get out of control. This is the kind of life-saving and cost-saving method that healthcare reform needs to thrive in the future. Telemedicine is also on the rise and has the opportunity to provide new cost-effective and efficient methods of delivering health care across geographical distances (Gupta & Saot, 2011). The overall benefit is tremendous; many consumers who never had insurance finally have access to it, or better coverage. The question that remains is whether the changes by the PPACA will force acute care organizations to integrate vertically with post-acute care providers (Shay & Mick, 2013).

Chapter 18

Twitter and Its Role in Health Information Dissemination: Analysis of the Micro-Blog Posts of Health-Related Organisations

Dan Dumbrell

The University of Sydney, Australia

Robert Steele

The University of Sydney, Australia

ABSTRACT

The utilization of micro-blog-based systems for the dissemination of health-related information offers a number of potential benefits. In this chapter, the authors describe a study of such micro-blog-based dissemination of health information by Australian health-related organisations through the manual categorization of over 4,700 tweets posted during a defined sample period. These tweets were analysed in relation to the sector of the tweeting organisation, health condition area, type of information in the micro-blog post, and level of retweeting. The particular category of public health-related tweets is also analysed in greater detail. This chapter differs from previous health and Twitter-related studies in that it: 1) seeks to characterize the overall and relative Twitter activity of health-related organisations for the sector across a whole nation, rather than collecting a sample matching a specific keyword or health condition; and 2) carries out a more semantically deep analysis of the content of those tweets, hence the manual analysis-based methodology adopted.

INTRODUCTION

Health information dissemination has undergone significant changes due to various technological advances. From originally being delivered through the use of posters, bulletin boards and newspaper articles as public health announcements, to dissemination via current traditional mass media (e.g. television, radio) and increasingly now by online means with the rapid uptake of the Internet. Contemporarily, with

DOI: 10.4018/978-1-5225-1674-3.ch018

the introduction and mass-adoption of social networking services (SNSs) by a significant proportion of online users, there are now additional and potentially powerful means of health information dissemination (Steele, 2011).

Twitter, a micro-blogging-based SNS with approximately 240 million active global users, contains useful features and characteristics such as: one-to-many interactions, 'up-to-the-minute' information dissemination, the ability of users to select accounts relevant for them to follow, and the capability of users to generate, receive and share information amongst themselves. This provides an efficient platform for potential Web-based information sharing and retrieval and Twitter can thus potentially aid in achieving the dissemination of health information. Recent reports by social media and marketing-based companies have found that Twitter currently has approximately 2.5 million monthly unique Australian visitors, and this number is rising rapidly (SocialMediaNews.com.au, 2014). The growing proportion of Internet users adopting Twitter, as well as the already widespread uptake of SNSs in Australia, indicates the significance of exploring this medium as a potential tool for health information dissemination.

This chapter will present a detailed overview of how Twitter is currently being used by health-related organisations in Australia, and the health conditions and types of health-related information that are being posted by different organisational sectors. Categorised health information mined from the sample of tweets is also further analysed for the purpose of exploring relationships between the types of disseminators and receivers of health information. The study aims to provide initial empirical data relevant to health organisation utilisation of social media for the health sector on a national scale, rather than necessarily across the entire 'Twittersphere'.

RELATED WORK

Due to the relatively recent introduction of health information-related micro-blogging, and the recent widespread national and global uptake of Twitter in general, the exploration of health and Twitter is still an emerging area of research. A previous health organisation-related study had found that of those public health department accounts within the US using social media, 86.7% had Twitter accounts (Thackeray, Neiger, Smith & Wagenen, 2012). The researchers of the study categorised tweets based on information presented, however they did not follow any links embedded within the tweets and thus did not analyse the information provided in the linked-to Web pages. This chapter will attempt to provide a deeper semantic analysis whereby micro-blog posts and the specific health conditions and types of information being conveyed will be explored and categorised according to both information presented in the tweet and the linked-to page indicated by any embedded URLs.

The tweeting and sharing of information on specific health conditions has also been explored in a number of works. Sullivan et al. (2012) analysed concussion-related tweets to investigate different themes (e.g. 'news', 'personal situation', 'inferred management') as well as to whom these types of information were being disseminated. Epilepsy-related information dissemination via Twitter has also been studied (Mcneil, Gordon & Brna, 2012), where researchers analysed and coded tweets into specific categories to describe the types of epilepsy-related information that was being tweeted. These studies added support that health information could be effectively disseminated via Twitter, but also found a minority of tweets sampled were actually informative in terms of health information. Other research articles have also examined Twitter and smoking cessation (Prochaska, Pechmann, Kim & Leonhardt, 2011), dental pain (Heavilin, Gerbert, Page & Gibbs, 2011) and pharmaco-surveillance (Bian, Topaloglu & Yu,

2012) - this again demonstrates that previous studies have tended to focus on specific health condition or health areas.

A previous cross-sectional study of SNS use amongst the Society for Assisted Reproductive Technology highlighted the growing influence of social media in relation to health-related issues and communication (Omurtag, Jimenez, Ratts, Odem & Cooper, 2012). Various clinics within the organisation had their online Websites evaluated and it was found that rather than consumers asking for information, health-related bodies were ‘pushing’ information through SNSs. This research also demonstrated that in addition to providing clinically relevant health information, SNSs included many other types of information such as ‘advertising’ (28%), ‘support’ (19%) and ‘irrelevant chatter’ (17%). Therefore it would be of interest to carry out similar categorisation and analysis on a more widespread social media platform, such as Twitter, to see if these information types are proportionally consistent.

The idea of influence or scale of dissemination on Twitter can be represented by the measure of how many times a tweet is retweeted, as well as the quantity of audience reached. Cha, Benevenuto and Gummandi (2010) found that Twitter accounts with large numbers of followers had many one-to-one interactions (i.e. mentions and replies), and retweeting was a more suitable way of representing influence of a user beyond a one-to-one interaction domain (i.e. broader community interaction and dissemination). Therefore, they suggested that the most influential users were those who had more of their tweets retweeted and mentioned, rather than judging the influence of an account based on the number of followers.

As mentioned, measuring the reach or dissemination of a micro-blog post or tweet can also involve identifying the retweeting accounts and their numbers of followers. Kwak, Lee, Park and Moon (2010) found from their dataset of 41.7 million user profiles and 106 million tweets, that any retweeted tweet reached an average of 1,000 users – regardless of the number of followers of the original tweeting account.

Whilst some of the studies mentioned have been carried out with non-health-related datasets, or were limited to specific health areas, our work will analyse health-related Twitter usage on a nation-wide basis and across all health topics. This work can be differentiated from previous work in that it analyses the use of micro-blogging across a whole sector (health in this case) for a country rather than selecting a particular narrower health area or topic and retrieving data corresponding to keywords matching that narrower area.

METHODOLOGY

Identifying Relevant Accounts

Accounts relevant to the study were found via a three-step method. With each step, identified accounts were examined to see if they met the inclusion criteria for our study (Table 1). First a search was conducted through the search function on the Twitter website (www.twitter.com) utilising health-related and appropriate keywords such as ‘health’, ‘nutrition’, ‘cancer’, ‘Australia’ etc. to find relevant accounts. The second step involved utilising the search engine Google (www.google.com) to identify additional relevant Twitter accounts that were not found from step one. Searches were performed using a combination of health-related keywords, for example the search ‘dementia Australia Twitter’ was entered into Google in an attempt to either uncover dementia-related Twitter accounts that were originally overlooked, or to ensure the search for relevant accounts was exhausted. In the third step, already identified accounts had their Twitter feeds and followers examined to uncover further relevant users that met the inclusion criteria.

Table 1. Inclusion criteria

Inclusion Criteria	Definition
Nationality	Self declared home location is Australia or is a known or deducible to be Australian-based
Representativeness	Accounts represent government health bodies or other health organizations (with the link to a relevant website provided in account description)
Topic of account	The account pertains to health information, either generically or in relation to a specific condition
Content of tweets	Accounts must have at least one health-related tweet or provide links to health articles
Activity	Accounts are currently active, as we defined as having tweeted in the month of February 2012
Number of followers	The number of Twitter followers for any given account was set to a minimum of 150

When considering the various factors required for the identification and inclusion of Twitter accounts, the following factors were considered:

- The specific details of accounts to be identified (according to inclusion criteria),
- Broad topic areas of accounts (i.e. health-related),
- The owner of the account (i.e. what organisational sector they came from).

Categorising Health Tweets

Individual tweets were grouped and generalized according to similarities for 1) specific health-related conditions (Table 2) and 2) type of tweet identified (Table 3). The first form of categorisation undertaken was in relation to health condition areas - for example, condition-specific tweets about 'skin cancer advice' and 'breast cancer research' were categorised under the umbrella health condition area of 'cancer'. To provide another dimensional view of the collected data, health-related tweets were also categorised according to the type of tweet, independent of health condition area, that the tweet pertained to. Referring to the above example, tweets about 'skin cancer advice' were categorised as 'public health advice' and tweets about 'breast cancer research' were categorised as 'research and project' type tweets.

Requirement for Manual Tweet Analysis within Methodology

It was deemed that various Twitter analytics tools (e.g. Twitonomy, TweetStats) did not have capabilities that would fulfil the required account identification process (nor the subsequent data collection and deep semantic analysis requirements of collected tweets), and hence a manual approach was adopted throughout the data mining and analysis of this study (Dumbrell & Steele, 2013). The three-step manual methodology provided the process whereby a substantive sample of the current health-related organisational Twitter users meeting these criteria in Australia were identified and compiled.

We identified that current Twitter analytics tools did not provide the capabilities of categorising and semantically-analysing tweets based on complex concepts such as 'public health advice', 'infectious diseases-related' or 'fundraising' and as such, manual categorisation and analysis by a researcher was required. In general, current Twitter analytics tools cannot provide analysis of tweet content based on

Table 2. Proportion of health condition-related areas of sector tweeting

	Gov (% of 388 Health Tweets)	FP (% of 1,071 Health Tweets)	NFP (% of 2,331 Health Tweets)	All Sectors (% of 3,790 Health Tweets)

concepts and semantics within the text of tweets. These analytics tools also do not contain the functionality to examine the Web pages linked-to by hyperlinks present in tweets, hence further necessitating the manual approach adopted.

GENERAL SECTOR CHARACTERISTICS

A total of 114 health-related Australian organisation Twitter accounts, meeting the inclusion criteria, were identified via the three-step process as described above. Three distinguishable organisational sectors were observed during the account identification process: government Twitter accounts, for-profit (FP) organisational accounts, and accounts that represented not-for-profit (NFP) organisations. The 114 identified accounts in the sample were thus categorised into these three sectors - it was found that there were 16 government, 27 FP and 71 NFP Twitter accounts present in the substantive national sample for this study (Figure 1).

The characteristics of each Twitter account were also collected – such as the number of tweets, accounts followed and following accounts. For comparative purposes, these characteristics were analysed proportionate to the number of Twitter accounts identified for a certain sector (e.g. the mean number of followers for accounts in a sector was the total number of followers divided by the number of accounts identified in that sector). When taking this into consideration, it was found that government health-related accounts had 2,347-followers on average per account, the highest of the three sectors. NFP accounts had

Figure 1. Proportion of different Australian health-related Twitter accounts identified

on average 1,975 followers per account, which was still a much higher average than compared to their FP counterparts that had the lowest number of followers on average, with a mean of 1,153 per account.

This low number of followers for FP accounts may be explained by a previous study (Sillence, Briggs, Harris & Fishwick, 2004) that had found Internet users to be more likely to reject sites they considered promotional or sales-based. Therefore, the reputation that FP organisations have (e.g. commercial, product-promotion) may make consumers less trusting of the information on their websites. . This may potentially be why FP Twitter accounts have a lower average number of followers than other sectors. In the sample of the 27 health-related FP organisation accounts, only 4.5% of tweets in the month of February were considered advertising or promotional-related. However, this was still the largest proportion of these tweet types when comparing to the NFP and government subsets

TWEETING CHARACTERISTICS BY ORGANISATIONAL SECTOR

A total of 4,787 tweets were found to have been posted from across the 114 identified accounts in the month of February 2012. Of these 4,787 tweets, 3,790 (79.2%) were categorised as health-related whilst the remaining 997 (20.8%) were non health-related. This is similar to results found for public health department Twitter accounts in the USA (Thackery et al., 2012). The tables below (Table 2 & 3) represent data that is the proportion of health-related tweets, and thus the analysis does not include the 997 non-health related tweets. As stated in the methodology section, these health-related tweets were looked at according to two separate dimensions and categorised into two separate tables – by health condition area (Table 2) and tweet type (Table 3).

When looking at health condition-related areas identified for the February 2012 sample period, it can be seen that a large proportion of these tweets were categorised under non-condition specific (i.e. developments in the particular health-related sectors without reference to a specific health condition, such as for example the progress of federal health reform). In absolute numbers there were 2,157 identified

tweets from the sample that dealt with such health information in a general sense, rather than relating to a specific health condition. Tweets categorised under this group made up more than half (56.9%) of all health-related tweets in the sample.

Outside of the non condition-specific tweets, the top 3 largest contributions to the health-related tweet sample by far were those of mental health (8.3%), nutrition (5.9%) and cancer-related (5.4%) areas. In fact, the next highest represented health-related areas (addictive substances and Indigenous health, both at 2.3% each) were much lower in percentage than these top three health-specific areas.

When comparing the three sectors, we also found that there were differences in the amount of tweeting of certain health areas within each sector. Government accounts tweeted most frequently about lifestyle-related topics (nutrition: 11.6% and fitness: 3.9%), addictive substances (4.1%), organ donation (3.6%) and infectious diseases (3.1%). Interestingly, nutrition-related information was by far the highest specific health area tweeted about by government accounts, and was also the highest proportion when compared to other sectors. The relatively high dissemination of addictive substance-related tweets might be expected as government bodies are frequently rolling out national campaigns for awareness of issues such as binge drinking, drunk driving and the effects of illegal drug use. With regards to the area of infectious diseases, the government also undertakes initiatives to educate and warn people about new or rapidly spreading diseases (e.g. the swine flu pandemics). However in the case of the organ donation-related tweets, the tweet dataset was taken during DonateLife week, which occurs in February. This provides an example of how even samples taken from over a month may potentially still be influenced by specific events occurring at that time which may cause sampling bias.

Similarly to government accounts, FP organisational Twitter accounts tweeted significantly about nutrition (8.5%) and mental health (6.4%) related areas. FP organisations also tweeted a larger proportion of cancer-related tweets than government accounts (5.0%). Also interestingly when comparing to the other two sectors, FP accounts had by far the largest proportion of tweets in health areas that could be considered to have commercial and profitable aspects. One of the most tweeted about health-specific topics from FP accounts were those related to the pharmaceutical area, which comprised 4.5% of total health-related tweets by this sector. This far outweighed the proportion of pharmaceutical-related tweets posted by government (0.3%) and NFP (0.4%) organisations, thus showing that FP organisations may possibly be tweeting about health-related areas more specific to their business goals (e.g. advertising, sales, etc.).

NFP organisations had the highest proportion of mental health and cancer-related tweets, at 9.4% and 6.2% respectively. This sector also tweeted proportionately more about Indigenous health, as 3.4% of their health-related tweets came from this area. This percentage was much higher when compared to FP (0.7%) and government (0.3%) Twitter accounts. These results may suggest that government accounts could tweet more about Indigenous health as government bodies both recognise initiatives and often provide funding in this area. Another significant area of tweeting based around a target group from NFP accounts is the dissemination of disability-related information. This category appears to be under-represented when considering tweets from government and FP accounts (both 0.0%), however when examining NFP organisations it was found that tweets about the disability health-area made up 2.1% of the total health-related tweets from NFP accounts.

There were a relatively small number of tweets for some widespread and significant health conditions affecting Australia. The National Health Priority Areas (NHPAs) is an initiative by the Australian government that aims to identify health areas contributing significantly to the morbidity and mortality rates of the population. Asthma, arthritis and musculoskeletal conditions, injury prevention and control

and obesity are four of the nine current NHPAs (Australian Institute of Health and Welfare, 2013) that are under-represented in the identified sample of health-related tweets. Asthma and respiratory disorders ranked as the lowest Twitter communicated NHPA representing only 0.2% of the entire health-related tweet sample, whilst arthritis and musculoskeletal conditions, the most active of these under-represented categories comprised only 0.6% of the total health-related tweets in the sample.

The four mentioned under-represented NHPAs had a total of 65 identified tweets in February 2012. Combined, these conditions contributed to only 1.7% of health-related tweets. Considering that these areas are considered of national importance, these numbers were notably low especially when compared to other NHPAs: cardiovascular health (51 tweets or 1.3%), diabetes (74 or 2.0%), cancer (204 or 5.4%) and dementia and mental health-related tweets (316 or 8.3%). Tweets in these more prominently identified NHPAs accounted for approximately one-sixth (17.0%) of the 3,790 health-related tweets identified in February 2012.

Table 3 was compiled from the same sample of 3,790 health-related tweets collected/analysed for the study (and also used to compile Table 2). This table however provides another dimension to view various proportions of tweet numbers by separating the identified tweets into the type of health information being provided.

FP accounts had 21.7% of their health-related tweets dedicated to providing 'organisational news' (news about the activities of that organisation), whereas NFP organisations tweeted a slightly lower percentage of organisational news as a proportion of their health-related tweets (17.0%). Governmental accounts tweeted significantly lower proportions for organizational news (6.7%) and promotion (0.5%). This suggests that FP accounts are particularly active in promoting developments within their organisations, and suggests an opportunity for government and NFP accounts to provide further organisational news-related tweets to potentially encourage further engagement between their organisations and health consumers.

Fundraising-related tweets alone contributed to approximately 10.2% of the total number of health-related tweets identified in February. Unsurprisingly, many of these tweets (361) came from NFP organisations. Throughout the analysis, Twitter was identified to be a frequent way for NFP accounts to communicate about fundraising, with 15.5% of their health tweets categorised under this type. This medium can potentially be a cost-effective method for NFP organisations to fundraise, especially when considering the costs of developing, promoting and advertising through various traditional media. In addition, the use of Twitter or social media for fundraising has the advantage of potentially reaching a more interested and targeted audience for the specific health area of fundraising.

One of the more interesting findings is that Twitter is already being widely used for 'public health advice' dissemination. Such tweets were defined as health information the consumer could use to potentially change relevant aspects of their current health behaviours. In our sample, 772 or one-fifth (20.4%) of health-related tweets in February fell under this category type. This was an anticipated beneficial function for micro-blog postings. In terms of proportion for a sector, government tweets are most dominated by public health advice with more than one-third (36.9%) of their health-related tweets being categorised under this type, indicating the current frequent use of government Twitter accounts to deliver health advice to consumers. It should be noted that both FP and NFP accounts also had substantial numbers of public health advice-related posts, with 21.1% and 17.3% respectively. Public health advice tweets were considered an interesting sub-sample of the overall sample to further analyse, given that this was a significant category in terms of number of tweets in addition to the high impact application of micro-blogging in relation to the communication of public health information.

PUBLIC HEALTH TWEETS AND THEIR DISSEMINATION

The dissemination, or sharing, of micro-blog postings on Twitter is done by a user-driven process referred to as retweeting. Retweeting is the act in which a user shares a tweet posted by another user to their followers, much like somebody forwarding an email to their entire address book. Dissemination of public health information is an interesting concept that has been examined in previous research (Dumbrell & Steele, 2012). The open nature of the medium by which this information is shared, as well as the interface characteristics of Twitter, allows for quantitative measures to be observed. These measures can include how many times a certain type of health information is retweeted, how many end-users this information reaches – and if these factors have any relation to the nature of information being shared or the initial poster of the information. This novel idea and practice of members of the public being involved in health information dissemination allows for users to not only share particular health information with others, but also pass subjective evaluation on that specific piece of information (i.e. is it worth sharing?). Figure 2 shows the frequency with which public health-related tweets from the sample were retweeted, whereas Table 4 compares absolute and proportionate retweeting frequencies throughout the sectors.

A total of 359 of the 772 public health-related tweets identified were retweeted. NFP accounts had more than two-fifths of their public health-related tweets (176 out of 403, or 43.7%) retweeted by

Figure 2. Retweeting frequency

Table 4. Retweeting frequency between sectors

	Government	FP	NFP
Number of Public Health Tweets	143	226	403
Proportion of Public Health Tweets in Total Sample (% of 3,790)	3.7%	6.0%	10.6%
Proportion of Public Health Tweets within Sector	36.9%	21.1%	17.3%
Number of Public Health Tweets Retweeted	99	84	176
Percentage of Retweeted Public Health Tweets / Number of Public Health Tweets within Sector	69.2%	37.2%	43.7%

other users. FP health-related organisations had the smallest raw number (84) as well as the smallest proportion of retweeted public health advice (37.2%) out of all three sectors, considering 226 of their tweets in February 2012 were public health-related. The government health-related Twitter accounts we identified were found to be the most successful in disseminating health information to the public. Of the 143 government posted public health-related tweets identified in February 2012, 99 were retweeted (approximately 70%). In fact, if taking into consideration the number of Twitter accounts per sector, it could be seen that government accounts had recorded on average a higher reach with their public health information (i.e. due to higher retweet rates and the smaller number of accounts found within this sector).

For this study we also considered the level of dissemination, or the “reach”, as an absolute measure of: the number of followers that would receive a certain piece of information, as well as the number of followers of an account that would retweet that piece of information. For example, if an account with 1,000 followers tweeted an article on dementia, and this article was retweeted four times by different accounts, then the reach of this information would be 1,000 plus the sum of followers of the four retweeting accounts (overlap between the followers of accounts not considered).

Table 5 outlines the number of users reached by retweeted public health tweets in our sample. As can be seen, NFP accounts had a larger total reach (283,302) when compared with government (241,320) and FP (223,444) accounts. When taking into account the average reach per account however, it can be seen that retweeted tweets of NFP accounts actually reached approximately three times less users per account (6,555) than both government (20,110) and FP accounts (17,188). Furthermore, when looking at the average number of users reached per retweeted public health-related tweet, it could be seen that FP accounts had a higher number of average users reached per tweet (2,725) with government accounts at the next highest (2,462) and NFP accounts having approximately 1,000 less average users reached per tweet than both the other two sectors at 1,610.

One of the issues found however was that there were a few retweeting accounts with an exceptionally high number of followers that could impact overall calculations of reach (i.e. outliers). For example, the Twitter account “Dr. Karl” had 147,971 followers at the time of data collection, and even though the account had only retweeted one tweet from a FP account, this increased the reach (total, average per account and average per tweet) of FP accounts by approximately three-fold (as shown in Table 6). Therefore it can be seen how outliers can have a significant impact, as one user with many followers can influence how many users will receive the tweet and the corresponding information presented in this tweet. This also raises the aspect of social media-based information dissemination being influenced by a small set of high-follower accounts and the implications of this for strategies to effectively and widely disseminate public health information via social media.

Table 5. Followers reached by retweeted public health tweets

	Government	FP	NFP
Total Reach	241,320	223,444	283,302
Average Reach per Account	20,110	17,188	6,555
Average Reach per Tweet	2,462	2,725	1,610

Table 6. Followers reached by retweeted tweets (minus outliers)

	FP	FP (Minus Outliers)
Total Reach	223,444	75,473
Average Reach per Account	17,188	5,806
Average Reach per Tweet	2,725	932

Table 7 represents the categorisation of accounts that had disseminated any of the 359 retweeted public health advice tweets. Government accounts did the least retweeting of public health advice tweets when compared to other account types with only 44 of the 890 (or 4.9%) retweeting accounts from the government sector. In addition, more than half of the retweets made by government accounts (23) were actually of public health tweets from other health-related government Twitter accounts identified. These numbers show how government accounts have low retweet numbers (potentially due to selectiveness), which may be because they tend to retweet information from other government bodies rather than information from other sectors.

On the other hand, accounts that represented various individual users (i.e. not organisation-based bodies) recorded the highest proportion of the 890 retweeting accounts; with 561 or 63.0% of identified public health information retweets being from individual users. FP organisations had the second highest amount of retweeting activity by organisations at 125 identified accounts, and NFP accounts had retweeted public health tweets only 88 times. The remaining 72 retweeting accounts were ambiguous as to whether they were associated with organisations or individuals, and hence were classified as ‘other’. These numbers are interesting, as they show low activity of government Twitter accounts when it comes to retweeting public health advice – but illustrate higher proportions of interaction by individual users who disseminate organisation-generated health information.

Table 8 outlines the differences between the number of links (URLs) present in public health-related retweeted and non-retweeted tweets. Government accounts had links present in all their retweeted tweets, however this proportion dropped to 87% when considering the links present in non-retweeted tweets. To a lesser extent, this was also found in NFP organisations, with only a 6.9% difference in link presence when comparing retweeted and non-retweeted public health tweets. FP organisation had links present in every one of their public health-related tweets (both retweeted and non-retweeted). It is also interesting to note that the amount of links present in public health-related tweets is two to three times greater than found in non health-related datasets in previous studies (Poblete, Garcia, Mendoza & Jaimes, 2011).

Table 7. Retweeting accounts

	Government Tweets	FP Tweets	NFP Tweets	Total
Retweeting Accounts				
Government	23	3	18	44
FP	38	26	61	125
NFP	29	4	55	88
Individual	146	104	311	561
Other	23	11	38	72
Total	259	148	483	890

Table 8. Percentage of links present in tweets

	Government	FP	NFP
Retweeted	100%	100%	91.9%
Non-retweeted	87.0%	100%	85.0%

The authoritativeness of online documents can be quantified to some extent by the Google PageRank function, which is an algorithm that calculates the importance of Web pages by considering both the number of incoming hyperlinks and the importance of the pages from which they are coming from. As can be seen in Table 9, the PageRank of public health-related tweets by Government accounts for both linked-to and the site home Web pages of linked-to pages are the highest when compared to those of FP and NFP organisations. The average PageRank of site home pages of linked-to pages from Government and NFP organisations were similar (6.8 vs. 6.3); with the average of site home Web page PageRank of public health-related FP tweets being the lowest of the three sectors (5.1). FP accounts actually had the lowest average overall PageRank counts of the three sectors, especially when looking at the average PageRank number of their linked-to Web pages (1.5). This may mean that FP organisations tweet links to pages that have generally less authoritative information than government and NFP organisations, and hence may explain why lower proportions of public health tweets are retweeted and to less users (Table 4 & 6). In addition it should be noted that even though FP accounts have links in 100% of their tweets (Table 8), with regards to public health information, this linked-to information is less authoritative than other sectors.

IMPLICATIONS

Our work found that the information being tweeted by health organisations was largely health-related, with only one-fifth of the data mined categorised as non health-related. On the contrary to the findings by Omurtag et al. (2012), the types of information provided by the sample of organisations identified throughout Twitter were minimally advertising or ‘irrelevant chatter’. With regards to influence, it was seen in our sample that government accounts were most influential as they had not only on average more followers, but also more reach (when removing outliers). This also highlights the impact of individuals with large followings on SNSs, as well as the growing role of the public in the dissemination and propagation of health information. As the population of online users grows, this also presents a further consideration in relation to privacy issues via the use of this medium for the retrieving and sharing of health information.

There are a number of implications for both government and private health organisations. In relation to government health services that generate online information, this work demonstrates areas where further micro-blog dissemination could occur (e.g. the four underrepresented NHPAs and general Indigenous health). Government organisations could utilise the availability of SNSs to further fill these gaps for health information. In addition, due to the influential and authoritative aspects of government accounts and Web documents, they can be harnessed more so as to act as powerful communicators of high quality health information. The policy implications that arise due to these possible changes will involve actions,

Table 9. PageRank of public health tweet web-links by sector

	Government	FP	NFP
PageRank of Linked-to Web Page	4.5	1.5	4.1
PageRank of Site Home Page of Linked-to Web Page	6.8	5.1	6.3

such as the reassessment of online responsibilities, quality filters and privacy controls for all entities involved. This is also important due to the greater involvement of the public in public health information dissemination, as appropriate policy procedures would potentially lead to greater community awareness and engagement in the use of SNSs for health information.

In relation to NFP health organisations, the usage for fundraising was demonstrated with our results. The use of SNSs for these purposes would not only be an additional method of raising funds through a more targeted and engaged audience, but also a more cost-effective approach for these organizations. Private health practices can also potentially increase community engagement by mirroring government account strategies, such as disseminating more important (or authoritative) Web documents. Our results also show that the presence of URLs in health-related tweets generally resulted in higher levels of dissemination than tweets without URLs. Health companies and organisations that want to increase their information reach can use this for potential future strategies for effective social media-based dissemination.

This work is also a step towards the further understanding of dissemination for the development of software tools and applications (Steele & Lo, 2009) to improve or optimize the coverage and targeting of public health information sharing and dissemination across a community, nationally or internationally.

LIMITATIONS

The limitations of such a study come from potential issues in sampling and analysis of Twitter accounts and tweets. Whilst manual methods were utilised to identify relevant accounts according to criteria, some organisation accounts may have been missed. Although our sample is substantive, we cannot claim to have an absolute representation of all Australian health-related bodies and organisations on Twitter, due to the limitations of the search functions themselves. As mentioned in previous sections, there is also a potential risk of bias when collecting tweets over a specific time period when certain health-related campaigns are occurring, thus increasing the prevalence of information related to this area and potentially skewing results. There is also the issue of verification of specific accounts on Twitter, as anybody in the world can create a Twitter account under an available name. Thus other third parties could potentially misrepresent organisations and government bodies that are not verified on Twitter, although this would have been detected during the identification of accounts in our study.

A difficulty in the categorisation of specific health areas was the complexity and factors of various conditions that could relate to more than one category. For example, tweets pertaining to the aged were generally categorized instead under the specific condition they related to (if they were about a specific condition). As shown in Table 2, there were a small proportion of aged-related tweets that were generically health-related (0.5% are classified under 'elderly'). However when taking into account specific categories that may be affected by age (i.e. chronic conditions such as osteoporosis and some cancers) it can be seen that the overall proportion of age-relevant tweets would be substantially higher. Nevertheless, there had to be a distinction within the categorisation process, whereby the information contained in the tweet was categorised according to whether the emphasise was semantically addressing the ageing population, or whether information was provided about the condition in general.

CONCLUSION

This chapter describes and analyses the Twitter activity of various Australian-based health-related organisation accounts during the month of February 2012. Specific criteria were utilised to identify and include active accounts that represented government, FP and NFP accounts based in Australia. The analysis and categorisation of tweets was carried out in two dimensions, and these were health condition and the type of information that was being tweeted. Further analysis was carried out on the specific sub-sample of public health advice tweets. The analysis in this chapter provides a step to understanding the overall dissemination by health organisations in the Australian context of health information via Twitter.

Future research may examine and analyse further aspects of health information dissemination via social media such as: whether relevant health messages reach the relevant target groups; the number and frequency of such messages; and the nature of dissemination and sharing of these messages by participating members. These issues can be explored throughout various population groups, such as looking at Australia as well as international comparisons to uncover similarities and differences.

ACKNOWLEDGMENT

KEY TERMS AND DEFINITIONS

Micro-Blog: A system with a blog-like nature, where incremental updates are provided over time, but for which the text updates are typically shorter.

PageRank: An algorithm introduced by Google that provides a search query-independent quantitative measure of a Web page's 'authority'.

Public Health Campaign: A type of media campaign where information which can include educational material is communicated to a population or sub-population to positively affect health behaviours, awareness or preventative actions.

Social Networking Service (SNS): A (typically online) service that allows the representation of an individual's profile information and the capturing of the links between individuals and their respective profiles.

Tweeting: The act of sending a micro-blog post (limited to 140 characters) within the Twitter system.

Twitter: A widely used micro-blogging application.

Twittersphere: The overall set of postings and communications within the Twitter micro-blog system.

Chapter 19

Health Information Technology and Change

T. Ray Ruffin

*University of Phoenix, USA & Colorado Technical University, USA & University of Mount Olive, USA
& Wake Technical Community College, USA*

ABSTRACT

Even in health healthcare and health information technology change will not vanish or disperse. Technology, civilization, and creative thought will drive this force increasingly forward. Health care managers will continue being judged on their ability to efficiently and effectively manage (Patton & James, 2000). The pace of change has significantly increased since the days of the cave dweller who walked the earth until the “technology convergence” of using the ox and horse as tools. This article is to investigate the background, controversies, and problems surrounding Health Information Technology and change, and will include an overview of current changes. This will be coupled with solutions and recommendations, further research, and conclusion.

INTRODUCTION

One of the most widely discussed areas in the health care field is improving the quality of patient-centered care within Health Information Technology (HIT). HIT allows for the all-inclusive management of medical information and the protected exchange between health care consumers and providers (U.S. Department of Health & Human Services, 2008). Health care comprises of the use and management of a profusion of information that must be collected, managed, reviewed, processed, and mined (McHaney, n.d.). With this in mind, HIT is proclaimed to be the solution to improve patient-centered health care and quality, while reducing cost within the medical industry (Hersh & Wright, 2008). It was not until 1994; the United States healthcare industry established information systems capable of handling a universal delivery system (Accenture, 2001). These Information Technology Systems (ITS) operated along enterprise and system boundaries in the Health care Delivery System (HDS). However, they fragmented by the proprietary business benefits of large vendors that wanted to control patient information (Accenture, 2001). Practical tools, especially computers, continue to be created and rapidly placed in

DOI: 10.4018/978-1-5225-1674-3.ch019

industry, the ability of organizations to accept, accommodate, and even embrace technology is moving at a varied pace (McHaney, n.d.). The health care industry has been one of the unhurried organizations to embrace the computer revolution in regards to patient care. However, health organizations have been using computers for years in business departments. Research has indicated that HITs represent tools or functions that help patients maintain their health through management of health information (Hudak & Sharkley, 2007). Even though HIT has the potential to transform the delivery of health care effectively and efficiently, health organizations continue to lack in this area.

A health organization has often been treated like a manufacturer who is advised that using cheaper materials can reduce manufacturing costs. The end result is that the manufacturer saves money on manufacturing costs but at the same time defects are accumulating and the results are subpar products. As we relate this to health organizations the ill effects of these short cuts are not externally evident, the health organization gives poor service or makes errors. Ultimately, health organizations fail in any of the countless ways in which organizations fail when they are poorly sustained (English, 1994). When health organizations operate inefficiently without proper funding, the odds become stacked against them.

Several other studies suggest that the adoption of HIT remains limited in certain functions (Poon et al., 2006). There have been limited studies conducted to determine which functionalities of HITs need implementation. Most studies concentrated on certain functionalities such as Computer Provider Order Entry (CPOE) or Electronic Health Record (EHR). CPOE is a set of clinical processes that incorporate technology to optimize physician ordering of medication and other required laboratory testing (Ormond, 2005). During a study by Minnesota Orthopedics Specialist, it was realized that vendor and local support during implementation was critical for success (O'Neill, 2007).

EHR is "related information on an individual that conforms to nationally recognized interoperability standards and that can be created, managed, and consulted by authorized clinicians and staff across more than one health care organization" (U.S. Department of Health and Human Services, 2008, p. 17). This definition has been updated to include a digital collection of patient health information compiled at one or more meetings in any care delivery setting and is often used to refer to the software platform that manages patient records maintained by a hospital or medical practice (Health IT News 2013).

This leads us to look at the internal and external change. This is imperative for the change process and implementation of HIT. The internal reaction to change is the key point of discovery that requires learning something new, not just the acquisition of knowledge (Cameron & Green, 2004). Over time health organization management has avoided mentioning patient care and patient-related quality issues in either a positive or a negative framework. Many administrators appeared to focus more on central management than on clinical operations. In doing so, they have missed opportunities to engage patients and families as allies, document patient satisfaction and positive social work outcomes, and identify systemic patient care problems. The Greek Philosopher Heraclitus said that "no man ever steps in the same river twice, for it's not the same river and he's not the same man" (BrainyMedia.com, 2009, para. 1). Some interpret that the river is the external world. The external world is ever changing; the "river" is never the same. Another way to interpret this is that the "man" who stepped in the river today is not the same "man" that steps in the river tomorrow due to change, evolution, or experience that relate to external facts and figures (Cameron & Green, 2004). Technology changes rapidly and maintaining the status quo, actually means falling behind, and health organizations cannot afford to do that in our technology-driven world (Rutsky, 1999).

Change management is a multidisciplinary group activity to provide optimum solutions to health care organization. Those responsible must have to access a wide range of skills and resources to change

the process of how an organization does business. The goal is to transform the organization efficiently with organizational change (Patton & James, 2000). Traditional change management emphasizes the significance of reinforcing and embedding desired changes in structures, processes, systems, target settings, and incentives. To be effective, these mechanisms are required to take into consideration that people do not always behave realistically (Aiken & Keller, 2009). Within the setting of a workshop, several parties involved (management consultants, business professionals, and managers) try to think of favorable alternatives to the business process as a whole or in parts. Information Technology (IT) specialists, change management experts, and other specialists then use the resulting process design to implement the new layout of the process within the organization.

Change will not vanish or disperse. Technology, civilization, and creative thought will maintain an increasing force forward. Health care Managers will continue to be judged on their ability to efficiently and effectively manage (Patton & James, 2000). The pace of change has significantly increased since the days of the cave dweller who walked the earth until the “technology convergence” to the ox and horse. The world may not be spinning faster, however the people are (Patton & James, 2000). This article will investigate the background, controversies, and problems surrounding Health Information Technology and change, including an overview of current changes. This will be coupled with solutions and recommendations, further research and a conclusion.

BACKGROUND

Information Technology (IT) is a term that denotes the processing of data using a computer; the use of technologies electronically from computing, telecommunications, and the allocation of information in digital and other forms (Encarta® World English Dictionary, 2007). Specifically it refers to the products, methods, inventions, and principles that are used to produce information (Kroenke, 2008). Information Systems (IS) is a term that denotes gathering of hardware, software, data, procedures, and masses that produce information (Kroenke, 2008). The American Hospital Association in 2006 conducted a survey acknowledging numerous barriers to HIT adoption. Initial costs (94%) and continuing costs (87%) were the most commonly reported barriers. Clinician acceptance (82%) and lack of interoperability with current systems (79%) also ranked lofty. To tackle the issue of interoperability, the United States (U.S.) Department of Health and Human Services (HHS) contracted with the Certification Commission for HealthCare Information Technology to certify HIT systems that meet standards for interoperability, functionality and security (Certification Commission for Health Information Technology 2008).

Networks are the infrastructure of the electronic world and are the platform for the transfer of information from one location to another. Networks can be any electronic device that is attached to computer system, providing a channel for information to be passed. There are two main types of computer networks: Local Area Networks (LANs) and Wide Area Networks (WANs). LANs are “computers connected in a common geographical location and have a common owner” (McHaney, n.d. p. 434). A WAN is “two or more over a large geographical area from each other and they are connected by leased telecommunications equipment” (McHaney, n.d. p. 434). Designing networks is a critical part of the design, development, and implementation of any health care information system. Organization size, needs, account budget and spending need to be considered (McHaney, n.d.). Injudiciously, many health organizations spend less money and end up with undesirable systems and the need to spend more money. Besides financial concerns, health organizations need to take into account growth of the company, future needs, the type

Healthcare Information Systems (HISs) to be implemented, number of employees using the system, and the amount of data to be stored, retrieved, and transferred (McHaney, n.d.). There have been many studies on the relevancy between the application of IT and organizational efficiency or firm performance. The results have shown a positive correlation between IT and firm performance (Albadvi, Keramati, & Razmi, 2007). Meanwhile, other researchers have not been able to find such a correlation. This is called a productivity paradox in the literature of IT and productivity. One way suggested of explaining the paradox is to consider intervening variables such as total quality management, reengineering of processes, and organizational infrastructures on the relations between IT and performance (Brynjolfsson, 2003). The highest productivity of IT will be realized when IT investment is integrated with complementary investments; new strategies, new business processes, new working practices, and new organizations all appear to be important. These changes will require a period of time-consuming reengineering and redesign of an organization in order to best utilize their IT investment.

Historically the level of the development of Information Technology (IT) systems has not been clearly known in relationship to HER implementation. Supporters of IT goals in their use of HIT use the objectives of the organization to achieve operational efficiency. The Institute of Medicine report key capabilities of an EHR System that identified a set of eight core care delivery functions that electronic health records systems should be capable of performing in order to promote greater safety, quality, and efficiency in health care delivery. These were reported by Key (2003) as follows:

1. **Health Information and Data:** Having immediate access to key information such as patients' diagnoses, allergies, lab test results, and medications would improve caregivers' ability to make sound clinical decisions in a timely manner.
2. **Result Management:** The ability for all providers participating in the care of a patient in multiple settings to quickly access new and past test results would increase patient safety and the effectiveness of care.
3. **Order Management:** The ability to enter and store orders for prescriptions, tests, and other services in a computer-based system should enhance legibility, reduce duplication, and improve the speed with which orders are executed.
4. **Decision Support:** Using reminder prompts and alerts, computerized decision-support systems would help improve compliance with best clinical practices, ensure regular screenings and other preventive practices, identify possible drug interactions, facilitate diagnoses, and treatments.
5. **Electronic Communication and Connectivity:** Efficient, secure, and readily accessible communication among providers and patients would improve the continuity of care, increase the timeliness of diagnoses and treatments, and reduce the frequency of adverse events.
6. **Patient Support:** Tools that give patients access to their health records, provide interactive patient education, and help them carry out home-monitoring and self-testing can improve control of chronic conditions, such as diabetes.
7. **Administrative Processes:** Computerized administrative tools, such as scheduling systems, would greatly improve hospitals' and clinics' efficiency, and provide more timely service to patients.
8. **Reporting:** Electronic data storage that employs uniform data standards would enable health care organizations to respond more quickly to federal, state, and private reporting requirements, including those that support patient safety and disease surveillance (Key, 2003).

This poses questions about the current level of HIT adoption and the operational effectiveness of HIT in a multiple health organization settings. Business Process Automation (BPA) involves the process of supplementing the manual process with the goal of decreasing costs and increasing efficiency (Pharmaceutical-Technology.com, 2009). There have been some negative connotations to technology-centered approaches to automation, which has led to the development of human-centered automation (Kaber & Endsley, 2004). Two proposed approaches dispute the traditional division of human automation task responsibility in complex systems. These approaches redefine the transfer of functions to people and automation in terms of a further integrated group approach. The first approach seeks to pass control back and forth between the human and the automation. The second keeps both the human and the automation involved in systems operations.

This allows the assigning of systematic functions to the human, computer, or both. This has spawned the Levels of Automation (LOA), which refers to the level of task preparation, routine interaction maintained between a human operator, and a computer in controlling a complex system. Below are the names of the 10 LOAs and a brief description:

1. **Manual:** The human performs all responsibilities as well as monitoring the state of the system.
2. **Action Support:** The system assists the operator with performance of the selected action, although some human control actions are required.
3. **Batch Processing:** The human generates and selects the options to be performed; they then are turned over to the system to be carried out without human intervention.
4. **Shared Controls:** Both the human and the computer generate possible decision options.
5. **Decision Support:** The computer generates a list of decision options, which the human can select from or the operator may generate his or her own options.
6. **Blended Decision-Making:** The computer generates a list of decision options, which it selects from and carries out if the human consents.
7. **Rigid System:** The system presents only a limited set of actions to the operator.
8. **Automated Decision Making:** The system selects the best option to implement and carries out that action based upon a list of alternatives it generates (augmented by alternatives suggested by the human operator).
9. **Supervisory Control:** The system generates options, selects the option to implement, and carries out that action.
10. **Full Automation:** The system carries out all actions (Kaber & Endsley, 2004).

Process automation is driven by either innovation or necessity. An example of the innovation in process automation was the implementation of the automatic transplanting machines during the growth period of the farming industry. This created expanding sales in the area of plug growing techniques. In spite of lower labor costs and only 12 to 16 weeks per year of useful production, the return on investment for first-generation transplanting was excellent for growers benefiting from good product margins on growing sales.

This also illustrates the domino effect of process innovation. A gain in productivity in one area necessitates changes in other areas in order to realize a net gain in volume of data or material handled. Incremental process changes are implemented by the necessity to control production costs in a rapidly changing market (Kanczak, 2008). As the use of IT in health care operations has matured, the need to

integrate software applications has become increasingly important. However, interoperability among these IT applications is hindered because the applications use different terminology and representations of the domain.

Business managers now face vibrant and multifaceted operating environments. Technologies and services, along with the organizations they sustain and provide for, are converging. As organizations and services converge, there is a growing realization that a holistic approach to the services is required (Patton & James, 2000). The packaging of what separates services into effective “consumer solutions” will continue for the near future (Patton & James, 2000).

HEALTH INFORMATION TECHNOLOGY ISSUES, CONTROVERSIES, AND PROBLEMS

Is it possible the medical industry has adopted HIT for financial gain through organizational efficiency more so than with patient-centered HITs being the secondary factor? There is some evidence that health organization fiscal accountability’s “survival” mentality has the potential to compromise medical treatment and commitment to organizational efficiency at the expense of patients and their families (Mizrahi & Berger, 2005). Management is not exclusively looking for ways of maximizing production and transaction costs. Some organizations want to ensure they remain competitive and survive in the long term.

In their struggle to obtain legitimacy, organizations adjust to society according to a collective rationalization. As a result, institutionalized activities are durable, socially accepted, unwilling to change, and their survival is not directly linked to rewards or control (Ouedraogo, 2007). In a motionless flow organizations have a tendency to become complacent (Elearn Limited, Pergamon Flexible Learning, 2005). The need to confront this organizational complacency can be one of the major triggers for change. Working any length of time has shown the rate of change is increasing. For example, the huge change of Health Organizations in 2001 was compressed in a shorter amount of time. Table 1 is from Elearn Limited, Pergamon Flexible Learning (2005). Credit is also given to Grundy (1995) for the source of the information.

Organizations base change strategies on the past three to five years. The important issue is to base change strategies on the future and new recipes to combat change. Adapted from *Change Management*, by Elearn Limited, Pergamon Flexible Learning, 2005; and from *Breakthrough for Growth*, by A. N. Grundy, 2005. Table 2 illustrates how much organizations change over time in sweeping environments (Elearn Limited, Pergamon Flexible Learning, 2005). Credit is also given to Lynch (2000) from which the information was adapted.

Table 1. Change recipes; recipes refers to the established ways an organization anticipates and responds to change.

Time	Past	Old markets, receipts, and competition
	Change	
	Present	Current markets, receipts, and competition
	Change	
	Future	Unfolding markets, new recipes, and future competition

Table 2. Health organizations objectives and strategies shift

Period	Company Objectives	Management Priorities
Early to mid 1990s	Grow and maintain market dominance in health markets	Invest in Health Organization brand Increase service levels Launch regular new practices
Late 1980s to early 1990s	Survive the threat from competitors	Major cutbacks in cost base Divest nonessential parts of the organization
Mid 1990s and future	Restart growth	Acquire new Heath Organizations Diversify into software and services, leading to HIT

Adapted from *Change Management*, by Elearn Limited, Pergamon Flexible Learning, 2005; and adapted from *Corporate Strategy*, by R. Lynch, 2000.

The American Hospital Association in 2006 conducted a survey acknowledging numerous barriers to HIT adoption. Initial costs (94%) and continuing costs (87%) were the most commonly reported barriers. Clinician acceptance (82%) and lack of interoperability with current systems (79%) also ranked lofty. To tackle the issue of interoperability, the HHS has contracted with the Certification Commission for HealthCare Information Technology to certify HIT systems that meet standards for interoperability, functionality, and security (Certification Commission for Health Information Technology 2008).

As the use of information technology operations has matured, the need to integrate software applications has become increasingly important. However, interoperability among these applications is hindered because the applications use different terminology and representations of the domain. These problems arise most highly for systems that must manage the heterogeneity inherent in diverse domains and integrate models of different domains into coherent frameworks (Gruninger & Menzel, 2003). For example, such integration occurs in business-process reengineering, where enterprise models integrate processes, organizations, goals, and customers.

Even when applications use the same terminology, they often associate different semantics with the terms. This clash over the meaning of terms prevents the seamless exchange of information among the applications (Gruninger & Menzel, 2003). Typically, point-to-point translation programs are written to enable communication from one specific application to another. However, as the number of applications has increased and the information has become more complex it has been more difficult for software developers to provide translators between every pair of applications that must cooperate during interaction. What is needed is some way of plainly specifying the terminology of the applications in a clear-cut fashion (Gruninger & Menzel, 2003).

Most industries in America have used IT to produce organizations that were more cost effective, efficient, and productive. Health care executives understood that to capitalize on these sources of funds their organizations required information systems that could mechanize the patient billing process and facilitate accurate cost reporting (Glaser & Wager, 2005). However, the truth of the matter is that health care has not reached this echelon (Dejack, 2005). Studies have shown the most frequent barrier to the customer's use of interactive health IT across studies was the lack of a perceived benefit. The lack of convenience was a significant barrier. In particular, patients were less likely to use systems requiring access to equipment or technology that did not fit flawlessly into their normal daily routines (Agency for Healthcare Research and Quality, 2008).

Correspondingly, overly burdensome data entry was perceived as a barrier. Several studies found that the level and timeliness of clinician involvement with the system was directly connected with patient

use; low clinician participation lead to low patient use (Agency for Healthcare Research and Quality, 2008). Technical issues often prevented consistent use of health IT systems, especially among studies conducted on early system prototypes. Although subjects were often provided with the technology for a research trial, several studies have identified that costs and access to the technology would serve as barriers to use of health IT beyond the study interval (Agency for Healthcare Research and Quality, 2008).

Paper records were used because of their simplicity, low implementation costs, and wide spread acceptance. According to Bates et al., the factors listed below necessitate change to HIT:

1. Current records are limited as to availability and can only be viewed by one person at a time.
2. Staff and other medical professionals are illegible to view medical records.
3. Medical records can increase to two or three volumes.
4. Inherent in the use of medical records are evaluation problems, low utility, and large overhead.
5. The use of medical records can impede decision making process (Bates, Ebell, Edward, John, & Mullins, 2003).

The fact is that without fail human beings think they are better than they are, an occurrence referred to in psychology as self-serving. For example, because frontline managers perceived changes as unfair to the customer, a significant number of them vocally bad-mouthed the merchant's policies to customers, and used price overrides to show their good faith even though it meant they were less likely to achieve individual sales goals. The results were customer attrition, price overrides sharply increased, and significant value was destroyed by the effort. In the pricing example described above the outcome was inherently fair and therefore the downward spiral described could have been avoided by carefully tending to employees' perceptions of fairness in the communications and training surrounding the changes.

The question is universal. It is hard to gather followers behind any idea that does not make logical sense, let alone one with undesirable consequences. If the masses are not buying the story perhaps it warrants a second look. Furthermore, the choice of language used to explain any change has to be well thought out at the beginning to gain trust and minimize doubt (Baylor, 2009). All new leaders, whether they are taking charge of a small partnership or a sprawling public corporation, want to know how to change the ineffective parts of the organization without undermining the parts of the organization that are working (Welch & Welch, 2009).

As boards and senior leaders realized some of the major holes in staffing, they rapidly moved to get approval to hire on the fly, and fill the holes with expensive consultants and vendor staff. In the meantime, everyone struggled to make these systems work. These projects had time delays while a team was assembled. The results was that organizations recognized that not having the right players in leadership positions was a restricted view for a critical, complex undertaking such as filling major roles in staffing. As a result, several senior positions have emerged that require unique skills.

The worst thing that organization's management can do is allow their ego to step into the driver's seat and dictate their responses by clinging to old methods without considering new ones. Not only will they be ineffective, they will look irrational in the process or weaken the organization (Nicholson, 2009). When it comes to managing change, research is your best friend. Do not manipulate the data to fit with your agenda. The point is to work with the research data as objectively as possible. One approach by Katie Delahaye Paine describes the steps of effective research measurement as redefining measures of success: experiment, listen, measure, and learn (Nicholson, 2009).

According to Clarke and Donaldson (n.d.) a system overload is unavoidable. Restrained demand from those waiting for a promise of “free” or heavily subsidized services is expected. Health care professionals want to help people in need, but the sheer logistics of extended care delivery, the current and growing shortage of personnel, and limited resources will challenge the intentions of the policymakers who constructed the national health law. Reports have begun documenting a new, unprecedented shortage of nurses linked to growing demand for services, as well as drops in graduations from nursing education programs (Clarke & Donaldson, n.d.).

The “transformational” changes touted by the law’s champions will likely complicate and negatively affect health care workers and their ability to provide care. These changes will increase regulatory burdens, increase already heavy workloads, reduce payments, impose new penalties, and disregard personal preferences and values (Anderson, 2014). Change does not happen overnight and there will be some tremulous times.

Quality is a topic of concern among all health care organizations. Patients expect a high quality of care. Providers are scrutinized for the level of care offered. Health care professionals such as physicians take the Hippocratic Oath, swearing to uphold specific ethical standards. This includes treating the ill to the best of one’s ability, preserving patient’s privacy, and teaching the secrets of medicine to the next generation (Medical Net.com, 2014). However, as with most cases, money becomes a driving force with the marketing and targeting of the pharmaceutical companies to market their medications. It is easy for a health care professional to forget the main focus of quality care. Even payers are assessing the levels of quality present (or absent) among health care organizations.

The effect of managed care on quality of care has been problematic to assess, at least in part, because of the difficulty in reaching a common understanding of how quality should be measured. Quality has been defined as the degree to which health services for individuals and populations increase the likelihood of desired health outcomes and are consistent with current professional knowledge (Silberman & James, 2000). The definition of quality varies based on personal perspective, background, culture, and individual need. Regardless of definition, quality is demanded and oftentimes not provided. Many view quality health care as the predominant authority under which patient safety resides. For example, the Institute of Medicine (IOM) considers patient safety “indistinguishable from the delivery of quality health care.” Ancient philosophers such as Aristotle and Plato considered quality and its attributes (Mitchel, n.d.).

At first, the Institute of Medicine (IOM) defined quality as the point at which health services for the society increase the likelihood of desired health outcomes and are consistent with professional knowledge (Mitchel, n.d.). This was transformed into to a definition of quality that appeared to be listings of quality indicators, which are terminologies of the standards. These standards are not necessarily in terms of the possibilities or conceptual clusters for these indicators. These clusters of quality indicators were and often continue to be comprised of the 5D’s, which are death, disease, disability, discomfort, and dissatisfaction, rather than more positive components of quality (Mitchel, n.d.). This is a starting part and the 5 D’s are better than nothing at all. This definition will be transformed again in the future.

Even though there is a better understanding, availability of technology, and preeminent minds working on the concerns of better access and lower cost for health insurance (Liu, 2012). This has given hope that rising concerns over connectivity can be dealt with at the same time by these preeminent minds. However, many Americans lack health insurance coverage at some point during any given year (Executive Summary, 2014). Health care quality fluctuates widely, even after controlling for cost, source of payment, and patient preferences. This demonstrates the distinct connection between access, cost, and quality.

UNDERSTANDING THE LEGAL SYSTEM AS IT RELATES TO CHANGE IN HEALTH ORGANIZATIONS AND HIT

The American legal system, although complex, was developed to establish order in society. This same system impacts health care organizations, which must adhere to various rules, regulations, laws, and statutes. The complexity occurs because these terms that can be intermingled and are confusing. When it relates to health care they can also be called health care reforms. An example is the Patient Protection and Affordable Care Act (PPACA), which is the most extensive change of the United States healthcare system since the passage of the Medicare and Medicaid in the mid-1960's (Altman, 1994). The goal of these reforms are to improve patient care and protection of patient rights (Panning, 2014). That is the same goal as the legal system: to enforce, improve, and protect the rights of citizens. As we move forward there will be a brief description of the terms rules, regulations, laws, statutes, and policy development and how they relate to health organizations and change.

Rules

In the American legal system a rule is a procedure or controlling conduct (Meriam Webster.com, 2014a). For example, the rules of the PPACA prohibit insurance companies from discriminating against anyone with a pre-existing condition, dropping your coverage if you get sick, billing you into bankruptcy because of an illness or injury, and limiting your annual or lifetime benefits (whitehouse.gov, 2014). If you look at rules that relates to health care they govern the ability for Americans to access and buy insurance. Within this context the PPACA relates to the law; however, within the law are rules.

Regulations

Regulations are orders prescribed by authority to regulate conduct (Meriam Webster.com, 2014b). For example the Health Information for Economic and Clinical Health (HITEACH) Act gives HHS the authority to write regulations (U.S. Department of Health & Human Services, 2014a). The purpose of the regulations is to regulate the development of a national health information technology infrastructure. The HHS has a Regulatory Agenda that is published each fall and spring. In the fall the HHS has a regulatory plan that condenses the main concerns for the year. The HHS has regulatory authority over a few areas, including: the Affordable Care Act, Health Information Privacy (HIPPA), and Human Research protection regulations (U.S. Department of Health & Human Services, 2014a).

Laws

The legal system refers to a law as a rule, which, if broken, can be enforced with criminal punishment or civil liability. These laws can be made by federal, state, and local legislatures, judges, the president, state governors, and administrative agencies (Meriam Webster.com, 2014c). In health organizations an example of this would be the Emergency Medical Treatment and Labor Act (EMTALA), which is a federal law mandating that anyone with an urgent medical need in an emergency situation is to be stabilized and treated, regardless of their insurance status or ability to pay (American College of Emergency

Physicians, 2014). EMTALA was enacted by Congress in 1986 as part of the Consolidated Omnibus Budget Reconciliation Act (COBRA) of 1985 (American College of Emergency Physicians, 2014).

Statutes

A statute begins as bill proposed by a legislator. It is referred to as a legislative act or a formal enactment by a legislature to forbid, direct, make declaration of an act or set forth governmental mechanisms (Meriam Webster.com, 2014d). For example, in healthcare HIPPA was an act amended to the “Internal Revenue Code of 1986 to improve portability and continuity of health insurance coverage in the group and individual markets” (U.S. Department of Health & Human Services, 2014b para 1). This was done to “combat waste, fraud, and abuse in health insurance and health care delivery, to promote the use of medical savings accounts, to improve access to long-term care services and coverage, to simplify the administration of health insurance, and for other purposes” (U.S. Department of Health & Human Services, 2014b para 1).

Policy Development

Governments, societies, and actions with the major intent to endorse, renovate, or uphold health as defined by the World Health Organization (WHO) is a health system (Bloland et al., 2012). Public health is a perilous part of the grander concept of health systems and has been defined as “what we as a culture do collectively to assure the conditions in which our society can be healthy (Committee for the Study of the Future of Public Health IoM, 1988). The United States health care system can be said to have numerous systems that operate independently and collaboratively at times (Rice, 2013). It is imperative to understand the United States public health infrastructure, which includes 3 key goals: improvement of health, creation of environments that promote good health, and promotion of healthy development and behaviors (Healthy People.gov, 2010).

OVERVIEW OF CURRENT CHANGES

The iron triangle of health care includes access, cost, and quality. All of them are dependent on each other. Likewise, altering one variable affects the remaining two. Computers had a parallel start progressing from a product only available to a few (due to cost and difficulty of the systems) to where computers are affordable, universal, simple to use, and of even better quality than the past (Liu, 2012). The important issue is that it took many years before computers became more affordable, powerful, and accessible (Liu, 2012). Now they have evolved in the forms of laptops, netbooks, and now smartphones and tablets. In the future health care will break the iron triangle and demonstrate that it is not a law but an observation (Liu, 2012). If you start the debate over which one is more important there is no gain. When you alter one it inevitably alters the others. The health care triangle is a series of relationship that exist together such as doctor, nurse, and clerical. One cannot function or complete their task without the other. This section will address two of the changes that have been seen in recent years to deal with HIT change and implementation of health care for all Americans. Hopefully, in years to come these computer programs will lead to affordable, universal, and quality for HIT and health care overall.

Health Information Technology for Economic and Clinical Health

Policies, health, and regulations affect various health care organizations. This section will discuss the Health Information Technology for Economic and Clinical Health (HITECH) Act of 2009. According to Bloom (2010) the HITECH Act of 2009 is an attempt to improve the performance of health care systems through the use of technology, such as EHRs. The HITECH Act is focused on health organizations using certified EHRs. The HITECH Act was touted to expand the federal government ability to establish a national electronic patient records system by 2014 (APA Practice Organization, 2014). This allowed the HHS the authority to institute programs to improve health care quality, safety, and efficiency through the advancement of HIT innovations and implementations (HealthIT.gov, 2014). The HITECH Act provides for enforcement, and penalties for violation, of privacy and security standards; including permitting enforcement through state attorneys general (APA Practice Organization, 2014). The following is a brief overview of implications to health care organizations, providers, and patients.

Implications to Health Organizations

As we move into 2015 the implication facing health organizations is substantial pressure to implement the HIT systems that have “certified” EHR applications and that fulfill the federal government’s definition of “meaningful use,” or risk significant financial penalties in the near future (Ford, Menachemi, Huerta, & Yu, 2010). To offset the pressure and cost, every hospital in the United States are eligible for a minimum of \$2 million with larger hospitals eligible for more funds to purchase and incorporate EHRs (Bau, 2011). With this in mind, health organizations such as larger hospitals located in urban areas and teaching hospitals are implementing EHRs at a quicker rate (Jha et al., 2009). In 2014 research found approximately 38% of possibly eligible hospitals achieved meaningful EHR implementation by the end of 2012 (Diana, Harle, Huerta, Ford, & Menachemi, 2014). The (HITECH) Act of 2009 is driving fundamental market and industry changes that health organizations need to be strategically poised to deal with and implement.

Implications to Providers

An implication of the HITECH Act of 2009 for providers is the requirement of certified EHRs. This requires providers to commit continued use of EHR technology over a period of years. There are no measurable thresholds and programmatic timelines (Joseph, Sow, Furukawa, Posnack, & Chaffee, 2014). However, the certification process for EHR vendors has reduced provider uncertainty by establishing an unbiased validation service to ensure that certain functionality is available. To ease this transition providers are eligible for payments ranging from \$44,000 to \$63,000 to use certified EHRs. However, providers have to meet certain criteria of “meaningful use.” To an extent that has put the market, and not the federal government, in the position of determining the vendors that will meet the providers needs with the financial incentives (Joseph et al., 2014). This forces training on operating these systems and in some cases has caused many providers to go into partnership and Limited Liability Corporation (LLC) practices, while others are being engulfed by bigger medial organizations.

Implications to Patients

Patient implications include reduced cost and better quality of care. The HITECH Act of 2009 supports health care quality improvement and cost reductions. This falls in line with the Patient Protection and Affordable Care Act. An example is the required functions of EHRs being aligned with “requirements for emerging models of health care delivery improvement, including ‘patient-centered medical homes,’ a term for health care providers who emphasize partnerships between patients and their physicians, and Accountable Care Organizations (ACO)” (Bau, 2011 p 1). The HITECH Act of 2009 has the ability to involve patients and health consumers in their own self-care, even rally entire communities into more patient self-awareness.

Patient Protection and Affordable Care Act

The PPACA was designed to reduce the large number of under and uninsured people in the United States by mandating that individuals obtain health insurance. This section will discuss strengths, weaknesses, opportunities, threats, and possibilities of this policy for the general population and for private businesses. The section will allow for engagement in future discussions and act as an eye-opener to the many areas of importance that are involved with the PPACA.

Strengths of the Patient Protection and Affordable Care Act

The intent of the legislation for the PPRCA was to escalate the availability of health care in the United States of America. The Act increases regulation of the health care industry, incentivizes the development of generic medicines (Public Law 2010, 111th Congress Public Law 148 2010, sec.7001), controls drug costs for Medicare patients by increasing government funding of pharmaceuticals (Public Law, 2010, 111th Congress Public Law 148 2010, sec.2501), and restricts the ability of insurance companies to refuse coverage on health grounds (Public, Law, 2010, 111th Congress Public Law 148 2010, sec.2705). It also mandates minimum coverage requirements for health insurance plans (Public Law, 2010, 111th Congress Public Law 148 2010, sec.1302 (b) (1)). The range of society qualified for government assistance has been enlarged so that more people at the lesser end of the economic scale will have access to health care (Public Law, 2010 111th Congress Public Law 148 2010, sec.2001). While taxation will improve funding of health coverage for those living near the poverty line, and for seniors through Medicaid and Medicare services. The overall strength of the Act is treating healthcare funding as a public service rather than a commodity to trade and purchase, allowing for essential medical service to society as a whole (Schoen, Osborn, Squire, Doty, & Applebaum, 2001).

Through this United States health care system will remain a predominantly private system (West-Oram, 2013). The world’s employers are strongly committed to creating a workplace culture of health to boost individual engagement and organizational performance. These have included a brand identity for their employee wellness programs and reduction in health insurance premiums (Rizzo, 2014).

Weakness of the Patient Protection and Affordable Care Act

Religious assemblies have complained about certain requirements of the Act. For example, the objection to the requirement that employer sponsored health insurance provide contraception is a demand

that Catholic organizations claims “violate consciences” (Dolan, 2012). Oppositions were raised to the mandate to purchase insurance, claiming that it will ultimately contribute to the funding of services such as abortion, which they deem immoral; violating their right to freedom of conscience (Bandow, 2012). For example the Amish community opposes vaccination, while the Jehovah’s Witnesses or Christian Scientists typically oppose “biomedical care” (West-Oram, 2013). Their argument seems to be based on the distinction that the church is separate from the state.

These weaknesses have a continued impact on the Act, and have been raising court cases. Petitioners have filed suits to the U.S. Supreme Court arguing that the requirement to purchase insurance violates the right to practice religion freely (United States Department of Justice, 2012). This could be seen as a weakness or a threat; however, since the PPRCA does include provisions for religious exemption from the purchase of insurance that has stood up in court. This is more of weakness that can be analyzed and dealt with during the growth of the Act.

Opportunities of the Patient Protection and Affordable Care Act

Health organizations and plans have reached a defining moment in the industry and their success depends on how they choose to proceed. Consciously implementing new tools and approaches, such as analytics and Electronic Health Records (EHR) integration, have the ability to craft balance within plans, and inform decision making and the use of resources as they seek to improve the health and well-being of their enrollees (Rizzo, 2014). Opportunities arise because powerful analytics serve as an informatics catalyst that can convert risk scores from a vulnerability to strength, drawing from multiple data sources such as EHRs (Rizzo, 2014).

As noted earlier the PPRCA gives the option to expand Medicaid to most people earning at or below 133% of the Federal Poverty Level (FPL) of the state. Those experiencing homelessness will greatly benefit from this policy change because most nondisabled adults were previously ineligible for Medicaid (DiPietro & Klingenmaier, 2013). Of the over eight hundred thousand patients seen in 2012 at federally funded Health Care for the Homeless clinics, approximately 60% were uninsured (DiPietro & Klingenmaier, 2013). This is an opportunity to increase the overall health care of Americans and lower long-term care in the future.

Threats of the Patient Protection and Affordable Care Act

The author believes the true threat to the PPACA is the buy in from the American public and private business. This has been evidenced on the federal HealthCare.gov exchange website with consumers facing problems getting needed information (Threats to reform growing, 2013). Due to these delays, and technology problems, it is projected that premiums will “go through the roof in 2015” due to the fact that the plan did not enroll enough young and healthy adults in the first year (Threats to reform growing, 2013). Many consumers that did enroll and purchased from the health exchanges have complained the cost of individual coverage is too high. This raises a question as to whether it is possible for all individuals to come together and get a corporate discount as they would receive in a business setting. This may not come to fruition; however, it is imperative that we understand that before health care can get better prices will have to rise. It refers back to the old saying: to make money, you have to spend money.

It has been publicized in the news that many companies like Wal-Mart issued statements that layoffs have been due to raises in health care cost. Franchise owners of chains like Papa John’s, KFC, Taco Bell,

Red Lobster, Olive Garden, Denny's, Longhorn Steakhouse, the Capital Grille, and Applebee's are laying off fulltime employees or cutting hours, blaming it on their inability to afford health insurance or to pay the fines for fulltime employees (Obama Care Facts, 2014). There should be more briefing and media coverage on Fox News and other resources such as crossroads GPS, Forbes, and Heritage Foundation to revitalize and persuade public view on the PPACA. This threat is real even though the PPACA assists small business with the ability to purchase benefits, and forces bigger businesses who don't want to provide benefits to treat their workers with respect (Obama Care Facts, 2014).

Possible Trends of the Patient Protection and Affordable Care Act

Data is quickly being archived; however, there is not much historical health data on enrollees. As the situation becomes more challenging to health organizations and plans, there is the possibility of inundating the health care system right when it gives the opportunity for benchmarking and procedural change. There are similarities and differences between the National Institute for Health and Clinical Excellence (NICE) found in the United Kingdom and the Independent Payment Advisory Board (IPAB) that was developed under the PPACA. The IPAB was created as provision under the PPACA as an instrument for controlling health care costs outside the influence of political procedures and forces. Establishing a 15-member IPAB to extend Medicare solvency and reduce spending growth through the use of a spending target system and fast track legislative approval process. The members are appointed by the President with the advice and consent of the Senate.

SOLUTIONS AND RECOMMENDATIONS

Health Informatics (HIs) experts in a Delphi study ranked Business Process Reengineering (BPR) as one of the top research priorities for HI (Bliemel & Hassanein, 2004). The RAND Corporation developed the Delphi Method to forecast the impact of technology on business (RAND, 2014). The Delphi method surveys the opinions of "expert panels." The research is conducted in three rounds, where the information is gathered, refined, and then fed back to the expert participants. The feedback stage allows issues to be sharpened and helps to highlight the major issues involved. Round one involves an in-house panel that seeks to identify the research questions for the experts. It also conducts a pre-test of the survey. The second round involves an examination of the issues by the expert panel. At this stage, additional items are often suggested that may have been overlooked. The panel responses and additional items are combined to the original questionnaire. In the third round, the panel makes judgments on the items. This sometimes takes the form of a multiple-choice questionnaire. The goal is come up with an expert consensus by reducing the range of responses (RAND, 2014). The results showed a process-oriented healthcare industry would benefit from BPR. BPR involves several organizational improvements that are enabled by electronic patient records and an inter-operating system (Bliemel & Hassanein, 2004). In which the focus is on achieving specific performance targets such as specific profit margins, clinical outcomes, quality improvements, or customer satisfaction. A health organization's balanced-scorecard reports will indicate whether the organization is managing with acceptable results and provide a basis for assessing their managers' performances and their roles in the organization's success (Berger, 2002).

The growth and maturity of informatics has been a prime catalyst in positioning the health care industry for change. The PPACA for instance, which puts in place comprehensive health insurance reforms that

will roll out over four years and beyond (U.S. Department of Health and Human Services 2013). During the implementation of reform, informatics will serve as the foundation for all aspects of successful healthcare reform initiatives (Health IT News, 2013). Changeability addresses the positive question of what makes people and organizations good, and their ability to manage for the future. In tentative times, pressure for alteration is greater than ever (Cree, 2009). High performance health organizations compete on their ability to identify up-and-coming threats and opportunities, and to respond to them swiftly with well-informed decisions. The development of networks of longitudinal, comprehensive, and interoperable HIT offers opportunities for improving coordination of care and the usefulness of records, increasing competence of health care, and avoiding duplication of services (Leavitt, 2007).

These decisions must encompass business analytics. By understanding the process of analytics, healthcare providers have the insight necessary to make process adjustments in the future. To make excellent managerial decisions companies need access to information that encompasses not only company performance but also the broader competitive landscape (CFO Publishing Corporation, 2009). Informatics can increase options for treatments, reduce risks, improve processes, help with financial management, and ultimately improve patient care. It requires having the people, data, technologies, and processes necessary to mine the information and act upon it.

The Delphi study also identified electronic patient records and connected inter-operating systems as urgent research priorities (Bliemel & Hassanein, 2004). Having a physician or physicians who are passionate about the HIT, who are salaried and committed to the HIT and clinical systems, is critical for success (Amatayakul & Hodges, 2006). The acquisition of new hardware and software has the possibility to enhance a health care organization's potential to provide high-quality, cost-effective patient care.

Management must commit to open and honest disclosures of facts that not only help people understand the rationale for change, but also how it affects and benefits the organization (Nicholson, 2009). It is important for administrators to function well at three levels: the hospital/macro level, the internal (department or program) level, and the external/community level. They need to cultivate other staff leaders, redesign functions, prioritize goals, and promote internal communication to create a sense of professional pride and collective ownership (Mizrahi & Berger, 2005). These leaders need support from other leaders and from the professional and academic resources of major institutions to make their case. They must develop mutually supportive staff-driven activities, mechanisms to share information, ideas, resources about best practices, survival models, and methods of reorganizing roles and functions within and between hospital systems (Mizrahi & Berger, 2005). To compete effectively, health organizations must look beyond improving operating efficiency to improving their processes for managing performance (CFO Publishing Corporation, 2009).

To maintain cost, accountability, and fairness there should be a national standard of rate by the National Association of Insurance Commissioners (NAIC) to look into areas such as:

1. A definition of "rate filing" that includes new and renewed premium rates, any proposed rating formula, classification of risks, or modification of any formula or classification of risks.
2. A standard of review that places the burden of proof on the health insurance issuer to demonstrate that the proposed.
3. Ensuring that rate filing is not unreasonable, unnecessary, inadequate, or unfairly discriminatory (NAIC, 2010).

While, America's Health Agenda focused on these areas of concern to maintain cost, accountability, and fairness:

1. The Implementation of electronic health claims, premium payments, referral authorizations by 2016.
2. The formation of a National Prevention, Wellness, and Public Health Council charged with developing a national strategy to improve the nation's health.
3. The creation of a grant program to support the delivery of evidence-based and community-based prevention and wellness services aimed at strengthening prevention activities (America's Agenda: Health Care for All, n.d.).

Touting these changes as being instrumental in reducing chronic disease rates and addressing health disparities, especially in rural and border areas (America's Agenda: Health Care for All, n.d.). This funding will support primary care training and capacity building. The development of training programs that focuses on primary care models such as medical homes and team management of chronic diseases (America's Agenda: Health Care for All, n.d.).

Public health institutes (PHIs) are nonprofit organizations that increase the public's health by modernizing, leveraging resources, and building partnerships across sectors including government agencies, communities, the health care delivery system, media, and academia (National Network of Public Health Institutes, 2010). Health System Strengthening (HSS) has become a major focus of the United States (Bloland et al., 2012). The Role of Public Health Institutions in Global Health System Strengthening is critical for achieving major health goals in preventive care in the community.

The American Public Health Association (APHA) has created building blocks for the health infrastructure to gain funding for local, county, and city public health agencies to ensure that the health system is assessing and responding to public health needs for preventive care (American College of Physicians, 2012). Adequate, steady funding streams for the development and maintenance of local programs and activities are fundamental for the successful achievement of the goals of public health in the community. Funding by the government enables public health providers' access to resources that private clinicians may not have.

Health care can be provided through public and private providers. Public health care is usually provided by the government through national healthcare systems. Private health care can be provided through "for profit" hospitals and self-employed practitioners, and "not for profit" non-government providers including faith-based organizations (Basu et al., 2012). Creating maintainable, operational linkages between the clinical and community settings can improve patients' access to preventive and chronic care amenities by developing partnerships between organizations that share a common goal of improving the health of people and the communities (Agency for Healthcare Research and Quality, 2014).

Table 3 shows factors that lead to the requirement to implement health-authorities interconnection infrastructure. These factors may also be seen as the targets that are, and will be, accomplished. The Table constitutes the functional requirements for the network infrastructure and evolving reformation and of current advances in the field of data communications. These factors include areas such as:

1. The regional structure of the administration services.
2. The treelike managerial structure of the health care units

Table 3. Benefits of using information and communication technologies in the health care sector

Health Care Players	Benefits
Administration units	<ul style="list-style-type: none"> • Policy development and decision-making are strongly supported by effective and on-time information gathering and distribution. • Easier adaptation to eEurope challenges. • Supply control; better budget monitoring. • Overall improvement in the way citizens are served.
Hospitals	<ul style="list-style-type: none"> • Increased efficiency in communication between hospitals, administration units, social security services, careers, physicians, and citizens. • Personnel familiarization with information technologies through Internet-access operations. • Patient-record traffic support. • Reinforcement of the need to build health care information systems (HCISs) and local networks in hospitals. • Utilization of the developed Intranets. • Better information services for the citizens. • Advanced telematics services (e.g., telemedicine applications in difficult-to-reach regions).
Health care personnel	<ul style="list-style-type: none"> • Meets the increased need for telecommunications not only for medical, but also for compensation reasons. • Participation in care chains and relevant coordination. • Physicians' collaboration. • Patients' history data retrieval. • Continuing education services; familiarization with new technologies through special training programs. • Interaction with patients to provide advice or prescriptions.
Citizens	<ul style="list-style-type: none"> • Use of the Internet for health-related information retrieval. • Information and communication technologies will increase interest in citizens' health-issues management. • Creation of the appropriate infrastructure for future provision of special health services for specific population groups (e.g., in-house services for older people or patients with long-lasting attendance and nursing needs).

From *Implementation and Integration of Regional Health Care Data Networks in the Hellenic National Health Service*, by Lampsas, Vidalis, Papanikolaou, & Vagelatos (2002).

3. The active participation of general practitioners in the new system.
4. The need for transmission of sensitive electronic health record (EHR) information and for interconnection with private pharmacies and the insurance system in the years to come.
5. The successive advances in Internet technologies (Lampsas, Vidalis, Papanikolaou, & Vagelatos, 2002).

FURTHER RESEARCH DIRECTIONS

There should be further research on health organization in other countries such as the Canada Health Care System, which is increasing their use of health technology assessment organizations including the Canadian Agency for Drugs and Technologies in Health (CADTH, a national body) and specialized provincial agencies in Alberta, Ontario, and Quebec. The organizations support and inform purchasing decisions, service management, and clinical practice (Thomson, Osborn, Squires, & Jun, 2013). The Danish Health Care System's 2007 structural reform centralized the administration of hospital care in order to enhance the coordination of service delivery and to improve quality and efficiency. They merged 14 counties to create five regions and reduced the number of municipalities from 275 to 98. The regions are currently reorganizing their hospital systems, closing or combining small hospitals, and building new hospital infrastructures (Thomson, Osborn, Squires, & Jun 2013).

The English Health Care System Clinical Commissioning Groups (CCGs) are replacing Primary Care Trusts as local health care purchasing organizations, introducing the National Health Service (NHS) Health and Social Care Act 2012. This allowed the NHS in England to take over day-to-day responsibility, and expanding the NHS into a role of Monitor to act as the economic regulator of public and private providers. The National Institute for Health and Clinical Excellence (NICE) sets guidelines for the NHS on clinically effective treatments, and appraises new health technologies for their efficacy and cost-effectiveness (Thomson, Osborn, Squires, & Jun 2013).

In the French Health Care System, the National Support Agency for the Performance of Health and Medico-Social Facilities provides guidance to institutions in need of structural changes and performance audits, and publishes dashboard indicators such as length of stay, occupancy, patient satisfaction, and incidence of bedsores, which are classified by category and type of medical activity. It is the only such public body in Europe. The Biomedicine Agency operates in four key areas:

1. Assisted reproductive technologies.
2. Prenatal and genetic diagnosis.
3. Embryo and stem cell research.
4. Procurement and transplant of organs, tissues, and cells (Thomson, Osborn, Squires, & Jun, 2013).

Moreover, research should be continued in the area of informatics. For example the Supporting LIFE Project cultivates a low-cost implementation with extraordinary impact on the control of infectious diseases in Malawi (Department of Informatics, 2014). This is example of ongoing research projects by the Department of Informatics Lund University School of Economics and Management. This type of research will determine if informatics has the ability for organizations to understand their risk and cost profiles while ensuring the best care for patients. In conjunction with this research there should be a focus on health organizations' inequities, such as geographic and financial.

Computer networking opens many avenues to effective communication and collaboration amongst health care providers and organizations in the coordination and delivery of patient care (Ponemon Institute, 2014). For example, the increasing use of smartphones of today's society and the advancement of the Accountable Care Organization (ACO) model allows for the chance to update and revolutionize outdated communication in health care (Ponemon Institute, 2014).

Ponemon Institute (2014) study found three areas of opportunity that can be improved with communication and collaboration:

1. **Patient Admission:** Admitting one patient takes about 51 minutes, of which an average of 33 minutes (65 percent) is wasted due to inefficient communications. This translates into an annual loss of about \$728,000 per U.S. hospital.
2. **Emergency Response Coordination:** Coordinating an emergency response team takes an average of 93 minutes per patient. Of this time, an average of 40 minutes (43 percent) is wasted due to inefficient communications. This equates to an annual loss of more than \$265,000 per U.S. hospital.
3. **Patient Transfer:** Transferring a patient to another facility or home care/hospice takes about 56 minutes, of which an average of 35 minutes (63 percent) is wasted due to inefficient communications. The total annual cost of this waste is about \$754,000 per U.S. hospital (p. 2).

CONCLUSION

This article investigated the background, controversies, and problems surrounding Health Information Technology. An overview of current changes, recommendations and solutions, further research, and a conclusion rounded out the article. One universally accepted truth in organizations is the unavoidability of change. Another is that few organizations achieve the benefits they should due to not adequately planning change. This leads to the old adage organizations do not plan to fail, they fail to plan for change. Hospital boards approve millions of dollars for software, hardware, and consultants, but frequently the new positions required to build an effective team are not included in the approved budget. Numerous reports have indicated the importance of HIT. The question still remains as to how implementation will happen on a consistent level.

Change management, process and workflow improvement, comprehensive training, user support, and system ownership are all perilously important to HIT success, and therefore require funding. Informatics will allow organizations to understand their risk and cost profiles while ensuring the best care for patients. Informatics can be used across the broad spectrum of healthcare and is not limited to decision support functions. Management tools and techniques will help health organizations, if they hold their managers accountable for achieving targeted results. Effective communication of a well-deliberated plan is at the foundation of the management of employees during times of change.

An integrated program of change that allows for the incorporation Business Informatics (BI) or Health Business Informatics (HBI), Health Informatics (HI), Nursing Informatics, or simply “Informatics” is essential. Renovating care into quality care is the core of the clinical environment, and nurse leaders need to recognize the importance of emerging technologies (McHaney, n.d.). Nurse leaders should become involved in planning, designing, developing, implementing, and evaluating networks that will be used by nurses. This has led to a specialty area that integrates sciences of nursing, computer, and information called Nursing Informatics (McHaney, n.d.). This specialty area provides expertise in developing and implementing Information Management Systems (IMSs) that can be used by nurses to enhance daily tasks and integrate various aspects of patient care. These techniques are used to seamlessly integrate technology and information that may be located within a geographical area or even across international boundaries (McHaney, n.d.).

Reforms have the ability to save money and lives in the long run. The future is dependent on programs such as the Inner City health Clinics (ICHC), launched by PPACA (Frykholm & Kennel-Shank, 2014). The Act included \$11 billion in new funds for clinics that serve neighborhoods where access to medical care is limited and many people are uninsured or underinsured. The expansion of community health centers is especially important in the 25 states that have accepted the expansion of Medicaid to people with incomes up to 133% of the federal poverty income level. The new term that will be used is “conduit to care.” When someone is identified through a screening as having a health problem, that person may be reluctant to follow up with a doctor. ICHC’s outreach workers provide the follow up contact (Frykholm & Kennel-Shank, 2014). This approach is crucial to reaching people before their health problems get out of control. This is the kind of life-saving and cost-saving method that healthcare reform needs to thrive in the future. Telemedicine is also on the rise and has the opportunity to provide new cost-effective and efficient methods of delivering health care across geographical distances (Gupta & Saot, 2011). The overall benefit is tremendous; many consumers who never had insurance finally have access to it, or better coverage. The question that remains is whether the changes by the PPACA will force acute care organizations to integrate vertically with post-acute care providers (Shay & Mick, 2013).

KEY TERMS AND DEFINITIONS

Accountable Care Organizations (ACO): Groups of doctors, hospitals, and other health care providers, who come together voluntarily to give coordinated high quality care to their Medicare patients (Center for Medicine & Medicaid Services.gov, n.d. para. 1).

Business Process Reengineering (BPR): Originated in the 1950s as large firms began to explore the potential impact of computers on the efficiency and effectiveness of their business processes. Different approaches, methods, and techniques have since appeared and constitute the foundations of BPR as it is presently known.

Change Management: A multidisciplinary group activity to provide optimum solutions to change the process of how an organization does business to transform efficiently with organizational change (Patton & James, 2000).

Electronic Health Record (EHR): Also known as Electronic Medical Records (EMR). Certification Commission for Healthcare Information Technology Commissioner meeting minutes of April 15, 2008 related that the work group addressing the terms EMR, EHR, and PHR would like to retire the term EMR and take the definition of EHR to present future vision (Certification Commission for Healthcare Information Technology, 2008).

Health in All Policies: A policy or reform designed to secure healthier communities, by integrating public health actions with primary care and by pursuing healthy public policies across sectors (The World Health Report, 2008).

Health Informatics: As defined by the U.S. National Library of Medicine, health informatics “is the interdisciplinary study of the design, development, adoption, and application of IT-based innovations in healthcare services delivery, management, and planning” (Ong, 2014 para 1).

Health Information Technology (HIT): The all-inclusive management of medical information and the protected exchange between health care consumers and providers.

Health Information Technology Interoperability: Defined as the “principal difference between an EHR, which can exchange information interoperably, and an EMR, which cannot” (U.S. Department of Health & Human Services, 2008, p. 14).

Health Sector Reform: An effort aimed at reconfiguring health services, dominant in the 90s in the framework of the New Public Management, typically including the following components: separating the roles of financing and provision and the possible introduction of a managed market; developing alternative financing mechanisms, particularly user charges and health insurance; decentralization; limiting the public sector and encouraging a greater role for the private sector; prioritizing the use of cost-effectiveness techniques (Collins, Green, & Newell, 2002).

Health Service: Any service (i.e. not limited to medical or clinical services) intended to contribute to enhancement of health or to the diagnosis, treatment and rehabilitation of sick people (World Health Organization, 1998).

Health System Strengthening (HSS): Any range of initiatives and strategies that improves one or more of the functions of the health system and that leads to improved health through improvements in access, coverage, quality, or efficiency (Islam, 2007).

Informatics: “Studies the representation, processing, and communication of information in natural and engineered systems. It has computational, cognitive and social aspects. The central notion is the transformation of information whether by computation or communication, whether by organisms or artifacts” (University of Edinburgh Informatics, n.d. p. 1).

ABSTRACT

Rabies is a neurodegenerative viral zoonotic disease that affects all warm blooded animals. It is estimated that about 99% of human rabies cases are caused by dog bites. High prevalence of rabies has been reported in different parts of Tanzania. The disease has continued to cause public health threat to the communities due to weak passive and active surveillance systems. The data piloted in this study was based on the information gathered from Kilosa district. The geo information collected was used to develop a geospatial based system that can easily show the hotspots of rabies. The use of WEB GIS is likely to strengthen disease surveillance in Kilosa and other Districts of Tanzania. This approach offers a model for sharing both human and animal diseases surveillance information. Adoption of this approach is likely to increase awareness and timely response to rabies incidences.

INTRODUCTION

Rabies is a viral neurodegenerative zoonotic disease that affects all warm blooded animals (Fitzpatrick et al., 2012). The rabies virus belongs to the Lyssavirus genus of the family Rhabdoviridae, and order Mononegavirales (Swai et al., 2010). The disease affect not only human being and dogs, but also other domestic and wild animals such as: cattle, goats, cats, horses, pigs, hyenas, jackals, lions, wild dogs, mongoose, primates and bats (Sambo, 2012; Swai et al., 2010; Swai et al., 2011). Rabies is endemic and has challenged the health systems in different developing countries; pausing a big challenge in both

DOI: 10.4018/978-1-5225-1674-3.ch020

human and animal health systems thus calling for one health approach to manage the disease in both human and animal (Mazet et al., 2009; Rweyemamu et al., 2013). From a global public health perspective, the domestic dogs are considered to be the main target for rabies control and principal reservoir for transmission of the virus to humans and domestic livestock (Mazigo, 2011).

Poorly coordinated rabies incidences reporting system to timely identify, prevent and respond to such cases remains one of the major challenge in establishing a sustainable surveillance system in Tanzania (Mazigo, 2011, Rweyemamu et al., 2013). Certainly, human deaths due to rabies can be prevented through delivery of prompt post-exposure prophylaxis (PEP) to bite victims (Cleaveland et al, 2002). Furthermore, the transmission cycle between humans and domestic dogs can be reduced through sustained mass vaccination programs of domestic dogs, strengthening the reporting system, detection of rabid animals, mapping of endemic areas and prompt response to treatment and prevention strategies (Blanton et al., 2006; Cleaveland et al., 2001; Cleaveland et al., 2013).

The application of ICT in rabies surveillance system in Kilosa district and other parts of Tanzania is very limited (Mboera and Rumisha, 2008). However advances in ICT observed in recent years increased possibilities for community members' involvement in rabies case identification, detection, alerting, monitoring, controlling and surveillance to reduce human deaths and hence minimize its socio-economic impact (Knobel et al., 2005). Application of ICT based rabies surveillance systems is likely assist the Veterinarians to sustain mass vaccination of domestic dogs, to keep records of vaccinated domestic animals and incidences of rabies in domestic animals; to enable public health workers, to create awareness on the magnitude of risks and steps to be taken upon exposure.

Thus, the overall objective of this study was to develop an effective, efficient and cost effective real time web based surveillance system for identifying, reporting, controlling and monitoring rabies incidences in Kilosa district, Morogoro, Tanzania. Specifically the study assessed the appropriateness of the real time rabies surveillance system for instant incidence identification, reporting, control, monitoring and surveillance. Ultimately the development of web based rabies surveillance system would enhance the capacity for; identifying, collecting and reporting of incidences to a central institution, aggregating and sharing data related to national rabies control using geographic web services and social media in appropriate combinations of traditional and novel media (including Internet based Google Maps, local radio and TV); livestock based organizations and the general public (Georgiadou et al, 2011).

SITUATION ANALYSIS

Rabies is one of major public health problems in different parts of Tanzania (Mwisongo et al., 2001). In Kilosa district, rabies has remained endemic for many years despite efforts to control it in domestic dogs (Bardosh et al., 2014). The district borders Mikumi national park thus allows interactions between humans, domestic dogs and wild animals. The presence of a human-dog-wildlife interphase in the district offers a unique environment for the persistence of the disease in the area (Sambo, 2012). In addition, lack of timely communication during vaccination campaigns has remained to be the major setback in such a way that many people especially in rural areas of Kilosa do not vaccinate their dogs on annual basis as required because such information do not reach them timely. Lack of awareness is also a problem; most people have limited knowledge on handling rabies cases and often they do not know what to do if their animals get infected (Mazigo, 2011). This is attributed to the traditional methods that are used in rabies surveillance in Kilosa District (Bardosh et al., 2014).

i. Dogs Vaccination against Rabies

Coordinated massive vaccination of domestic dogs against rabies is one of the most effect strategy for controlling the disease in communities with large dogs populations. Vaccination breaks the transmission cycle of the disease between dogs, other domestic animals and humans. Dog bites are the cause of almost all human rabies' deaths, with much smaller number of cases occurring each year from other domestic and wild animals (Hiby, 2012). Low vaccination success rate has been reported in different parts of Tanzania due to the fact that few people are aware of the vaccination campaigns thus on the day of vaccinating dogs only a small number of community members vaccinate their dogs while the majority remains un-vaccinated. This is partly caused by under reporting of the rabies incidences and lack of awareness of control measures (Mazigo, 2011).

ii. Post Exposure Prophylaxis

In humans the rabies is entirely preventable, by timely administration of Post exposure prophylaxis (PEP) to dog bite victims. Modern cell culture vaccines used in combination with rabies immunoglobulin's has been reported to be virtually 100% effective in preventing human deaths if administered promptly to rabies-exposed patients (Hampson et al, 2008). Availability of PEP in most health centers has remained a big challenge in Tanzania. For example in Kilosa district there are few health centers with PEP stocks for treating the affected dog bite victims (Mboera et al., 2001). In most cases bite victims have to travel long distances to the hospital to access PEP. This results to delayed administration of PEP and failure to adhere to treatment regimens. According to WHO guidelines, PEP is an emergency and as a general rule should not be delayed or deferred; does not have contraindications if purified rabies immunoglobulin and vaccine are used; must be applied using vaccine regimens and routes of administration that have been proven to be safe and effective. The 5 dose intramuscular regime is the most commonly used: one dose of the vaccine should be administered on days 0, 3, 7, 14 and 28 in deltoid region or, in small children, into the antero-lateral area of the thigh muscle. The 2-1-1 regimen may also be used whereby; two doses are given on day 0 in the deltoid muscle, right and left arm. In addition, one dose in the deltoid muscle on day 7 and one on day 21.

iii. Application of ICT Facilities in Diseases Surveillance Systems

For prompt detection and response to any disease outbreak, a sensitive surveillance system is indispensable. A well established communication system is the 'heart' of the surveillance system. The speed of communication which is most critical to contain or stamp out an outbreak, save lives, and prevent or minimize detrimental effect to the communities. It is challenging, however, to set up an effective communication system, and even more so in poorly established infrastructure in the developing countries like Tanzania.

Radios and Television

The media of communication to disseminate information on rabies to community members that is used in Kilosa district include the use of community radio. Kilosa community radio has played an important role in disseminating information on rabies outbreak and public health education to increase awareness

of people on the disease. Despite of the use of radio and television still the disease has continued to be a public health threat. One of the reason causing difficulties to control the disease include presence of a poor link between the Veterinary and humans healthcare departments resulting to un-timely communication of the rabies incidences (Mazigo, 2011; Mboera et al., 2001; Sambo, 2012).

Mobile Phone

In recent years mobile phones usage in Tanzania has expanded so much with almost every household owning a handset. Mobile phones are very useful means of communication (Sanga et al., 2014; Pascoe et al, 2012). This technology has been used in South Africa for monitoring and surveillance of rabies outbreaks, farmers phone or send messages to the State Veterinary offices to report any rabies case and Veterinarian or Animal Health Technician gives feedback to the farmer through the mobile phone (McCrindle and Masipa, 2010). This means of communication is rarely used in Kilosa. However, it is a very useful tool such that a diversity of users have the ability to call a medical practitioner or Veterinarian to communicate rabies incidences and this reduces the cost of farmers to travel to the Veterinary office to report diseases and deaths in either livestock or human being. The challenges for this technology in Kilosa district is poverty which hinder farmers to be able to own the mobile phones and pay for the service. However, the technology has some disadvantage such as illiterate farmers cannot use; if the farmer is illiterate would find it difficult to use the technology and for poor farmers it is difficult to afford buying a mobile phone (McCrindle and Masipa, 2010). Establishment and implementation of a web based rabies surveillance system which will be more efficient and effective in communicating and disseminating rabies related information is likely to improve rabies surveillance in the country.

RABIES SURVEILLANCE SYSTEMS

The majority of animal and human exposure to rabies virus can be prevented by raising public awareness about the rabies virus and how it is transmitted and prevented (Sambo, 2012). In case there is a person or animal which has been affected by the virus then appropriate Veterinary and health care personnel should be consulted. The Veterinary and human health Departments are responsible for giving education to people through seminars, newspaper, books, articles, journals and different mass media (Mazigo, 2011). Mazigo (2011) reported increasing trend in the number of reported cases in recent years at Bugando Hospital in Tanzania that was explained as an outcome of increases awareness on the consequences of rabies which has been conducted through different stakeholders; ultimately this has raised people's level of knowledge on the disease.

According to the World Health Organization (WHO) disease surveillance is defined as the continuous, systematic collection, analysis and interpretation of health-related data needed for the planning, implementation, and evaluation of public health practice (McNabb et al., 2002; Nsubuga et al, 2002; Kimaro and Nhampossa, 2005. Recent studies have shown that the human population boom in Africa appears to correlate well with the increase in the number of domestic dogs, and by conservative estimates, however the prevalence of human rabies is considered to be under-reported due to a weak surveillance system in place (Mazigo, 2011). In Tanzania, the under-reporting is largely attributed to poor surveillance systems and people's tendency not to report human and animal cases of rabies. Furthermore, there

is over-dependency on clinical diagnosis (in animals and/ or humans) that downgrade the reliability of rabies-surveillance systems. Certainly, these weaknesses have translated to poor planning of surveillance programs, resulting in shortage PEP and even when available may be accompanied with inappropriate administration, as well as delays in its administration (Mboera et al., 2001; Sambo, 2012). Although not as frequent as the inability to afford treatment, such scenarios have built a lack of trust in health facilities, as well as poor compliance with PEP regimens leading to human deaths that would otherwise be prevented.

IMPORTANCE OF RABIES SURVEILLANCE SYSTEM

Systematic collection, analysis and aggregation of quality rabies-related data is paramount to the success of all public health initiatives to fight against the disease (Cleaveland et al., 2013). This will consequently require a sound monitoring system of trends of rabies incidences and well established reporting system. The absence of correct and up-to-date data on incidences of rabies or in cases of a poor reporting system lead to futile prevention and control programs. The presence of reliable and functioning surveillance systems is necessary for the success of global health initiatives to fight against the rabies (Knobel et al., 2005). However, surveillance systems that collect useful and representative data in developing countries like Tanzania are not functioning well due to limited available resources, lack of knowledgeable staff, disorganization, and poor infrastructure for finding and reporting cases (Cleaveland et al., 2013). Furthermore, in Tanzania it has been estimated that around 23,709 humans sustained dog-bite injuries between 1990 and 1996, whereas 42,669 human dog-bite injuries were reported for the year 2000 (Mazigo, 2010; 2011; Bardosh et al., 2014). These reports suggest that there was either an increase in the number of cases or the extent of the problem was being underestimated in previous studies. However, untimely reporting and response due to poor communication networks remain to be the major obstacle for and effective and functional surveillance system (Table 1).

THE APPLICATION OF ICT IN RABIES SURVEILLANCE

In order to overcome the weaknesses of the traditional rabies surveillance system, there is a need to use the Information and Communication Technologies (ICTs) in the surveillance process. It is possible to reach a large number of people to create awareness about rabies through the use of mass communication medias such as Internet, face book, television, radios and other means of communication (Blanton et al., 2005). The ICT based rabies surveillance systems support easy awareness creation (i.e. sensitization) and a more rapid and timely reporting and response to zoonotic outbreaks (Thinyane and Foster, 2010). Furthermore, ICT facilitates communication between veterinary and human health services by making both Departments aware of rabies surveillance data. Zoonoses are certainly the most prominent example of diseases which require compulsory interaction between human and animal health Departments because of their dual affect on both livestock and humans (Zinsstag and Tanner, 2008). Introducing ICT will also be useful in determining vaccination schedules and tracking purpose.. Additionally the application of Geographical Information System (GIS) allows mapping of rabies hotspots so that the livestock Department can easily track implement control programmes (Blanton et al., 2005). It also can present rabies data

On Piloting Web-Based Rabies Surveillance System for Humans and Animals

Table 1. National Roadmap on Rabies Identification, Detection, Control, Monitoring and Surveillance System

Ministry of Livestock and Fisheries Development	<ul style="list-style-type: none"> • Purchase and distribute rabies vaccine • Check vaccine viability • Check vaccination coverage and certification • Ensure cold chain for storage of vaccines • Diagnosis – sample collection, submission, testing and characterization of viruses isolates • Review policy, laws regulations, guidelines, checklist and standards • Reinforce information network system from community to National level • Organize and supervise dogs population census • Law enforcement • Monitor and evaluate implementation of the rabies control strategy
Ministry of Health and Social Welfare	<ul style="list-style-type: none"> • Purchase and distribute human rabies vaccine • Annual supervision • Public awareness • Human rabies diagnosis • Active surveillance • Heightened awareness and training of front line workers • Policy review
Prime Minister's Office Regional Administration and Local Government	<ul style="list-style-type: none"> • Public awareness campaigns • Stray dog control • Support procurement of vaccines • Implement rabies vaccination campaigns • Support training of extension staff and farmers • Supervise establishment and maintenance of the Livestock Development Fund (LDF) by Local Government Authorities • Monitor and evaluate implementation of the rabies control strategy at district level • Raise awareness on the importance of the disease to the public by LGAs • Formulate by laws, which will be used as a tool for control of the disease • Conduct regular active surveillance of the disease at village level • Involve the Standing Committee at ward level on Education, Health and Water on rabies control • Collaborate with other stakeholders in implementing rabies control strategy
Ministry of Natural Resources and Tourism	<ul style="list-style-type: none"> • Improve knowledge on rabies • Capacity building at all levels • Vaccination vs rabies in interface areas (annual) • Awareness on rabies • Improve diagnostic capabilities of wildlife laboratories • Improve linkages neighbours and community • Formulation and reinforcement of Policy and Legislations • Undertaking collaborative research
Ministry of Justice and Constitutional Affairs	<ul style="list-style-type: none"> • Provide legal assistance in drafting by-laws and regulations regarding rabies control • Legal advice on issues related to rabies control strategy
Institutions	<ul style="list-style-type: none"> • Carry out operational research on rabies • Collaborate with other stakeholders in designing and implanting the rabies control strategy • Provide technical advice on rabies control • Develop and disseminate research findings • Train students in fields of rabies
Private Sector and Non Governmental Organizations	<ul style="list-style-type: none"> • Collaborate with other stakeholders in designing and implementing the rabies control strategy • Support procurement of vaccines

historically, which means the spread of rabies can be tracked not only based on region but also on time series (Hampson et al, 2008; Sita and Laksmi, 2012). The use of modern ICT especially GIS provide a platform for investigating the use of web GIS in supporting the report of Veterinary information during outbreaks. Such web GIS can help different stakeholders from public health and animal health as well as

law enforcement agents to visualize the cases of rabies on map in real time. The idea behind Web GIS is to provide a common platform of collaboration for all entities that are significant in dealing with rabies. The importance of early awareness and response measures when dealing with rabies incidences is very important. Rabies still poses a public health threat and quick communication and collaboration between various stakeholders is an important aspect in reducing the disease burden. Example of a project which implemented Web GIS is from South Africa where it aims at improving reporting and communication mechanisms through an ICT web based system (Thinyane and Foster, 2010).

Web based application is the best option than mobile based application because early study by Steinfield and Wyche (2013) argue that even though mobile phones have potential to improve the access of agricultural information and knowledge to farmers but still there are problems which hinder its effectiveness and efficiency. According to Steinfield and Wyche (2013), these problems are:

1. Farmers lack appropriate competence in using mobile phones.
2. Many farmers speak different native language while mobile based systems are in English or Swahili and this limit comprehension of messages by end users.
3. Low levels of literacy hinder successful use of mobile based systems.
4. Some rural areas have no access to electricity to keep phones charged and also, some remote areas have not telecommunication network, thereby reducing its availability for use with mobile based system.
5. Many farmers are reluctant to use the limited airtime credit they have to access mobile based systems.
6. Some culture and norms deny women to calling or texting strangers of the opposite gender, limiting their ability to benefit from mobile based systems.

A web-based GIS application of rabies provides a new resource for the rapid mapping and displays the dissemination of data on rabies cases in order to show information about any rabies infected area. Rabies cases are shown in the points form (markers) on the map based on the coordinates of locations. Each region is being displayed in different colors according to the number of rabies cases that occurred. This application can support relevant Government authorities to make informed decisions focusing on areas which have high rabies incidences. Also it is useful in determining vaccination schedules so that the Veterinary Department can easily track and determine priority areas for controlling the disease. It also allows retrospective review of data, which means the spread of rabies can also be tracked based spatial temporal patterns (Sita and Laksmi, 2012).

The emergence of modern technologies that support geospatial information gathering is of great use now. The use of open data kit that incorporates geoinformation has brought great advancements in geo sciences. For example, geoODK application (<http://geoodk.com/> accessed on 20-March-2015) can be used to collect georeferenced information and update of the data can be done instantly while at the field.

Thus, the developed Web GIS improves the functionality of the existing manual systems by developing an interactive and user friendly system that aims at improving reporting and communication through web. It can also help to create awareness to the people on areas where there is an outbreak of the disease. Furthermore, it can help to provide public education on rabies in an easy way. The system can be used by people to give information on rabies incidences. The information can include animal bites, cases of animal rabies, and cases of human rabies.

PILOTING WEB BASED RABIES SURVEILLANCE SYSTEM IN KILOSA DISTRICT

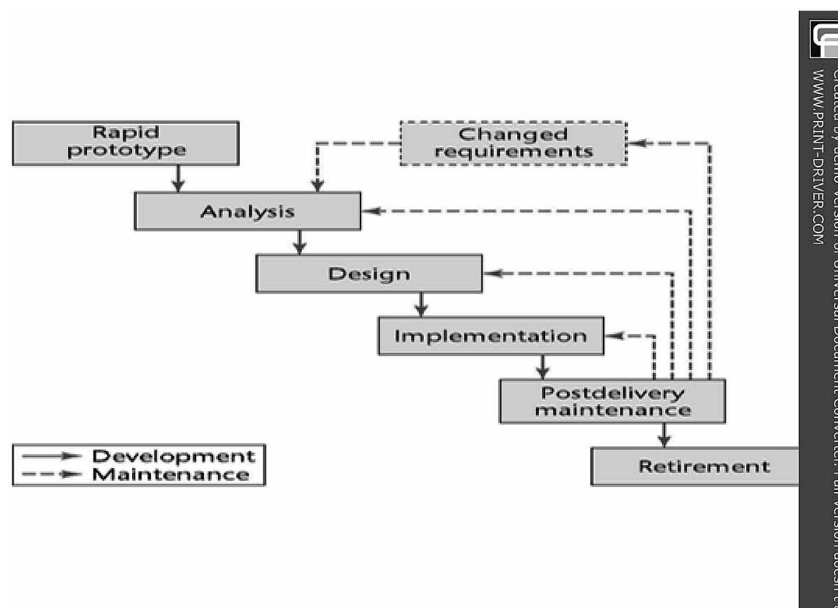

This study employed a mixed research approach as well as rapid prototype technique in development web based rabies surveillance system. The study was conducted in Kilosa district which is one of the six districts of Morogoro region in Tanzania. It is bordered to the north by Manyara Region, to the northeast by the Tanga Region, to the east by Mvomero District, to the southeast by Morogoro Rural District, to the south by Kilombero District, to the southwest by the Iringa Region and to the west by the Dodoma Region. According to the 2012 national census, Kilosa district had a total population of 438,175 whereby females were 219,797 while 218,278 were males (URT, 2013). Kilosa district is divided into wards and it has 35 wards (URT, 2013). Kilosa District has climatic conditions and fertile soil that provide conducive environment for agriculture activities such as food crop production and livestock keeping. It's in this district where Mikumi National Park is allocated as described in previous sections.

REQUIREMENTS FOR DEVELOPMENT OF ICT BASED RABIES SURVEILLANCE SYSTEM

Requirements were gathered from the users first by using interviews. Interviews are a good way to collect perception data from people particularly if there are small numbers of people whose views are to be captured. Key informants in Kilosa district were interviewed focusing role of ICT in diseases surveillance and questions were probing on necessary information on the rabies in the district.

The interview was used to collect information from village executive officers from villages around Mikumi National park. Other key informants who were interviewed were: in charge for District health

Figure 1. Requirements for development of ICT based rabies surveillance system

department, in charge for District veterinary health department, researcher from SUA Faculty of Veterinary Medicine researching on ecohealth (<http://tanzaniaecohealth.com/index.html>), Agricultural extension Officer from Kilosa District, Owner of rural Telecentre in Kilosa (KIRSEC) (<http://www.kilosaruralser-vices.net/>) and administrator of Kilosa Community radio. In addition semi-structured interviews were also conducted consisting of several key questions that helped to define the areas to be explored. Thus it allowed both the interviewer and interviewee to diverge in order to pursue necessary information on rabies in the district. For instance how people are aware of the disease, how is it transmitted, how is it prevented and rabies records keeping and transmission to different authorities within the district and beyond.

Also since the rapid prototype model was adopted to develop the web based rabies surveillance system thus the requirements that were missing from the prototype that was developed, both developers and the users used the prototype and determine what functionality that the prototype missed and what user and system requirements were to be added.

Interviews with key informants were used to probe the systems and user requirements which needed to be re-engineered in the prototype system during all phases of software development life cycle. The phases consist of analysis, design and implementation.

REQUIREMENT ANALYSIS

The requirements gathered from users by using interview and the prototype were analyzed to establish exactly what the system should do to solve the problem and gaps that were available within the district in respect to the disease. Thus from the analysis that was done then software requirement specification (SRS) document was prepared. Table 2 shows the data collected from secondary sources and were used to develop the system.

SYSTEM DESIGN

From the analysis above the system was designed in a way that it should answers the problems specified by the SRS document. System design comprised of architectural and detailed description of the design. Architectural or high level design aims to identify the modules that should be in the system, the specifications of these modules, and the interaction between the modules in order to produce the desired results. The specifications were carefully analyzed and a module structure that has the desired functionality was produced.

Detailed design involved going deep into specific modules of the system. The system design was broken down into 3 major modules (3-tier application), namely;

1. **Front-End Design:** This comprise of the user interface which links users and the system. Users can interact with the system using the series of interactive web pages as displayed through the web browser.

Table 2. Rabies Vaccination status in Kilosa District in 2012

Ward	Village	Human Population	Number of Dogs	Number of Dogs Vaccinated (% in Brackets)	Dog Bite Cases Reported	Suspected Rabid Dogs Killed
Kimamba	Kimamba "A"	7,249	177	171	12	2
	Kimamba "B"	6,271	165	0	0	0
Rudewa	Twatwatwa	2,704	905	50	9	3
Madoto	Mbwade	1,869	127	50	0	0
Tindiga	Malangali	4,247	70	0	0	0
	Tindiga	5,833	81	0	0	0
Kilangali	Kilangali	2,723	131	0	0	0
	Kiduhi	563	151	0	3	7
	Kivungu	4,179	102	0	0	0
Ulaya	Ulaya Kibaoni	3,673	189	40	0	0
	Mhenda	4,138	263	0	0	0
Mikumi	Mikumi	15,166	333	120	0	0
	Ihombwe	1,773	116	0	0	0
Kilosa town	Kilosa town	34,236	637	440	6	1
Ruhembe	Kidogobasi	4,562	227	0	0	0
Total		99,186	3574	871	30	13

2. **Application Design:** This is meant to provide communication between client and server. PHP scripting language (4 or higher) was used to fetch user queries from the browser into the database and retrieve the relevant rabies information back to the user on the web page.
3. **Back-End Design:** This comprises of the database. Database is where information about rabies is stored so that users can access them through front-end's user interface. The database was implemented using MySQL which is an open source relational database management system. It is based on the structure query language (SQL) and it is consistent, fast performance, high reliability and ease to use. *The locations were called using postGIS technology that calls georeferenced information from the MySQL database.*

SYSTEM IMPLEMENTATION

After the design of the system then it was implemented by using the MySQL database server in the back-end while JavaScript, CSS and HTML were used in the development of user interface. In order for the user interface to connect with database, PHP scripting language was used. In the front-end of the system JavaScript and CSS were used to create an interactive user interface. Google maps API capabilities were manipulated and used to locate the interactive information using Google maps and Javascripts. AJAX technology was incorporated to improve the interactivity of the maps through the browser. Some Google API classes were used to make easy the implementation of the technology.

DESCRIPTION OF USER INTERFACE AND THE SYSTEM IN GENERAL

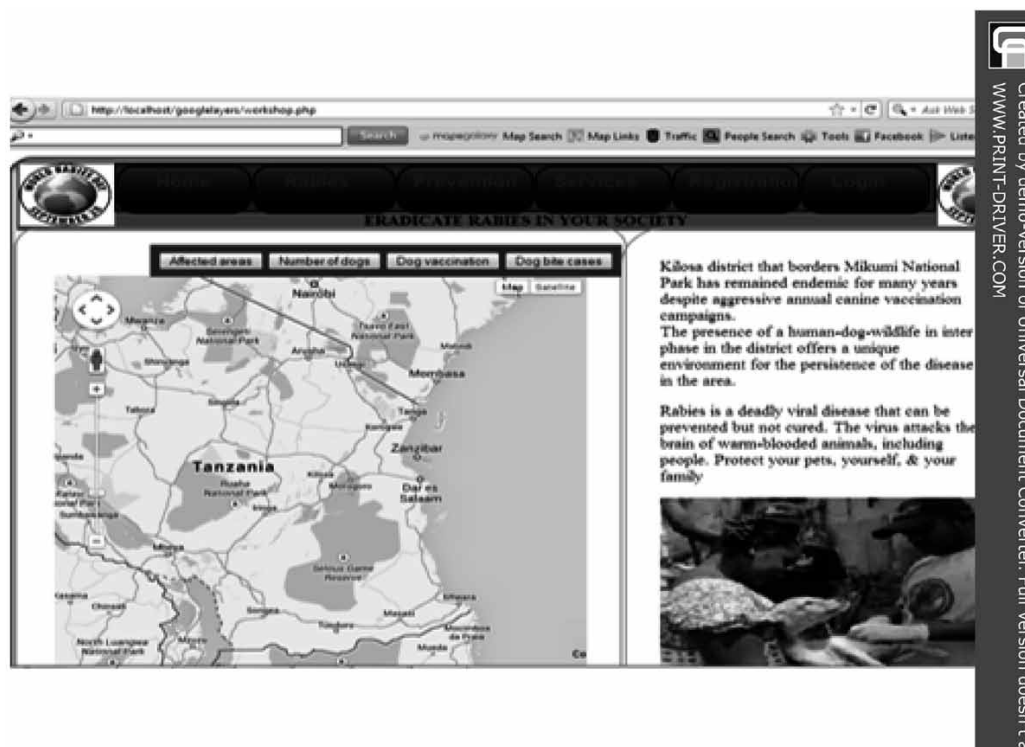

The web based rabies surveillance system allows users to update information that relate with rabies incidences such as reporting of areas that were affected by rabies, reporting if there was any rabid animal like dogs, etc. and viewing information on rabies. Figure 2 shows the interface of a web based rabies surveillance system.

From the interface (Figure 2), the user could view affected areas in map layer; this would let the user know which areas in Kilosa were mostly affected by rabies. These areas were identified by a green marker and by placing a cursor on it, the user could know the village name of the area. The Figure 3 below shows the snapshot for this.

From the interface (Figure 3), the user could view the number of dogs on map layer. This would let the user know how many dogs were available in a certain village. These areas were identified by a green marker and by placing a cursor on it the user could know the name of the area and by clicking the marker the number of dogs in the area would be displayed. The information displayed on Figure 3 relate to data collected from Kilosa presented in Table 2.

From the interface (Figure 4), the user could click the button of dog vaccination in map layer; this would let the user to know how many dogs were vaccinated in a certain village. These areas were identified by a green marker and by placing a cursor on it the user could know the name of the area and by clicking the marker the number of dogs that were vaccinated in the area would be displayed. The information displayed on Figure 4 relate to data collected from Kilosa presented in Table 2.

Figure 2. The interface of the Rabies Surveillance System

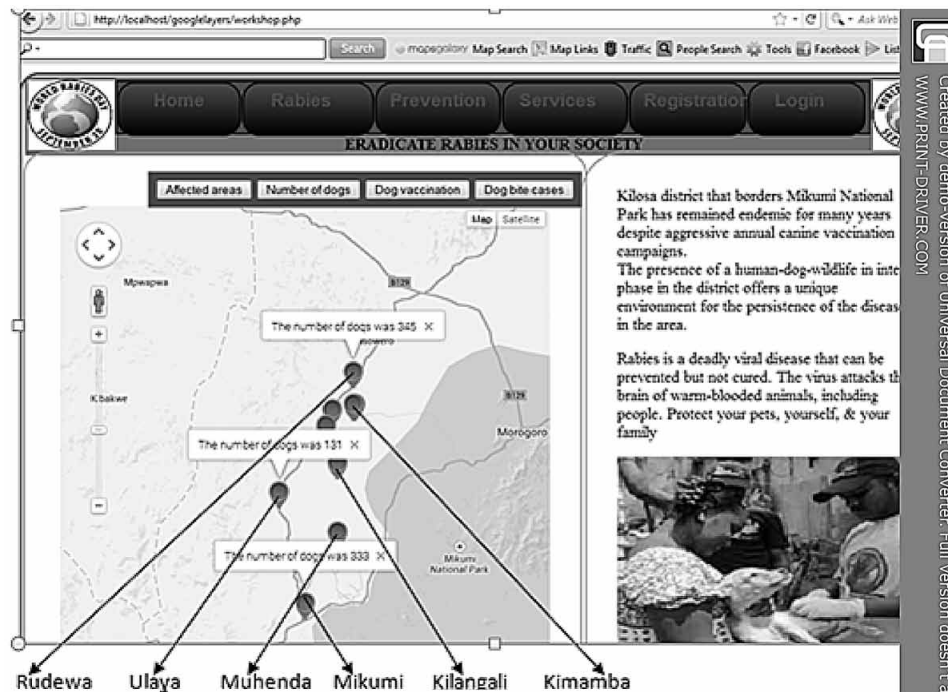

On Piloting Web-Based Rabies Surveillance System for Humans and Animals

Figure 3. The highly affected areas by rabies in Kilosa

Figure 4. The number of dogs within the village

Also from the interface (Figure 5) the user could click the button of dog bite cases in map layer; this would let the user know how many dog bite cases were reported in a certain village. These areas were identified by a green marker and by placing a cursor on it the user could know the name of the area and by clicking the marker the number of dog bite cases reported in the area would be displayed. The information displayed on Figure 5 relate to data collected from Kilosa presented in Table 2.

Thus, from these different maps (Figure 2, Figure 3, Figure 4, Figure 5 and Figure 6) a user could make analysis on which areas were affected by rabies and determine the reasons why certain areas were highly affected. Is it due to lack of dog vaccination program or is it because of poor reporting on rabies cases such as dog bite cases?

Even though the web based surveillance system for rabies is not a new field but what has been piloted here is the applicability of web based rabies surveillance system in identification, detecting, monitoring and controlling it in Tanzania (Mwabukusi et al., 2014). The preliminary results from this pilot research carried out in Kilosa District shows promising findings which have been reported in this book chapter. Thus, it is anticipated that new knowledge has been contributed in the areas of community informatics, health informatics and their applicability in both human and animal health (i.e. one health concept (Rock et al., 2009; Mazet et al., 2009). The developed system is different from other surveillance system for either animal health or human health which does not put human being at the centre of intervention (Brownstein et al., 2008; Rumisha et al., 2007; Mghamba et al., 2008; Mboera et al., 2001; Kimaro and Nhampossa, 2007 ; Waidyanatha and Prashant, 2010; Mwabukusi et al., 2014).

Figure 5. The villages showing the number of vaccinated dogs

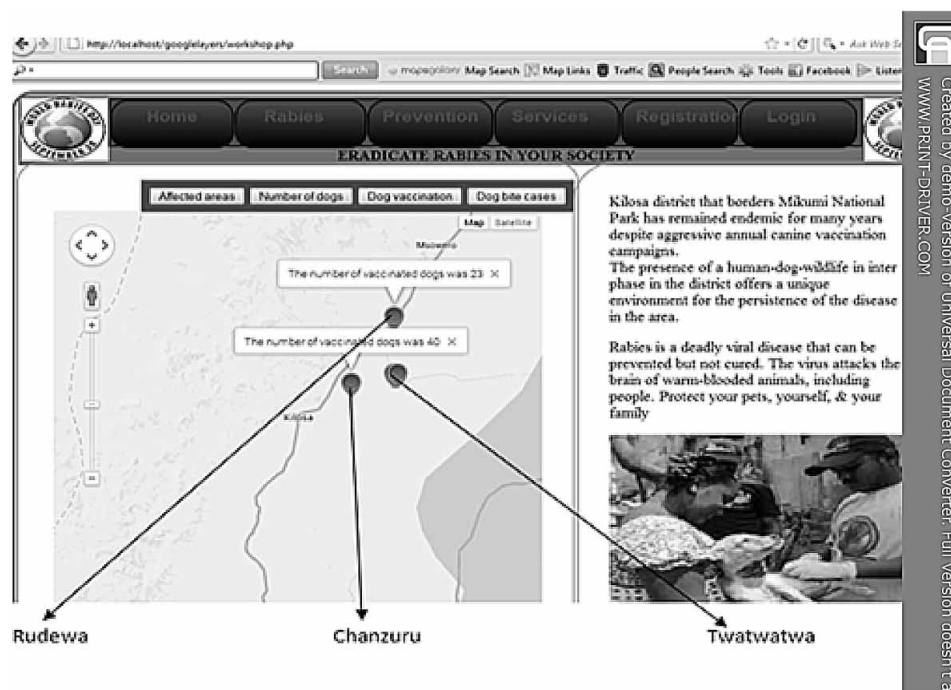

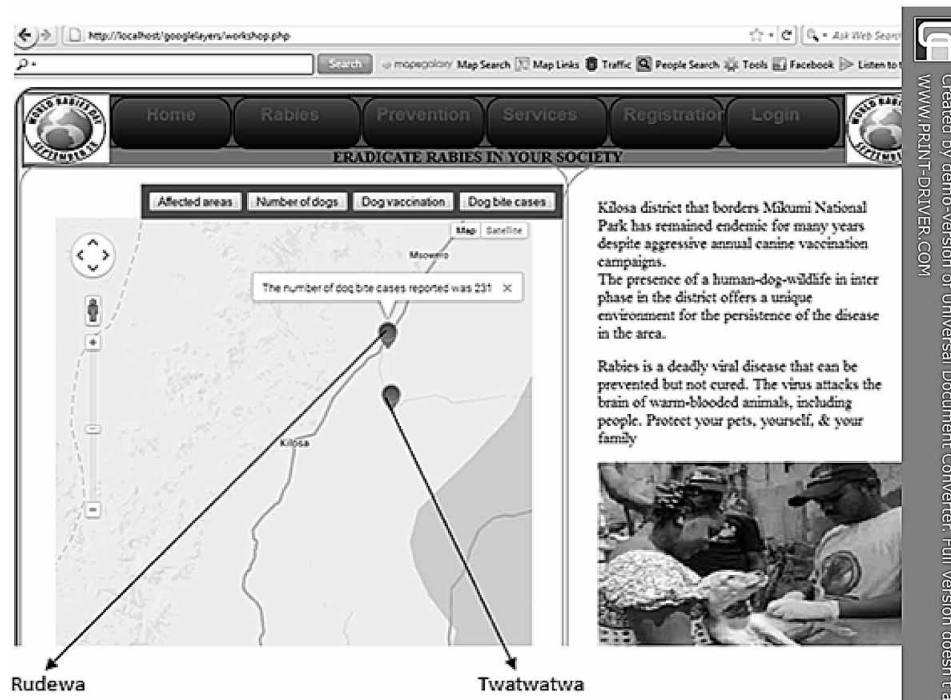

Figure 6. The number of dog bite cases reported

CONCLUSION

This study quantified and mapped the spatial and temporal dynamics in rabies incidences in Kilosa district, Morogoro region. Thus, the system provides rapid communication on rabies cases and it helps to increase awareness to the communities on the disease since literature shows that many people die due to rabies because of lack awareness of the disease and steps need to be followed upon encounters. The system described here allows quick communication and collaboration between Veterinary and medical Departments in Kilosa district which is very important in managing rabies at community level. Also from the web based rabies surveillance system has more unique features that includes layered maps whereby a user can navigate smoothly and make the geo-analysis of the affected areas by the disease and determine the reasons behind high infections. Also, the system administrator can use data from the database such as the village location data and the village details information to do geo-analysis of the disease impact in Kilosa. The areas with high rabies outbreak can be mapped and openly be viewed so that livestock department can easily track and set priorities for the control of the disease. The authors of this book chapter recommend that all line ministries should improve the identification, detection, alerting, monitoring, controlling and surveillance of rabies through the use of the developed web based system. The line ministries to be involved are Ministry of Livestock and Fisheries Development, Ministry of Health and Social Welfare, Ministry of Natural Resources and Tourism, Ministry of Justice and Constitutional Affairs and Prime Minister's Office - Regional Administration and Local Government as well as Private sectors and Non Governmental Organizations. Without unifying the efforts from different sectors (inter-sectoral) and disciplines (inter-disciplinary) it is difficult to address the problem of

rabies (<http://tanzaniaecohealth.com/index.html>). Future study will focus on evaluating the adoption of the developed system in Kilosa District. The evaluation of the system will base on technology, culture related values, competence and personal values.

Another area for future research study should be on improving the performance of web based rabies surveillance system by using openlayers instead of Google layers. Google maps are too slow for real time reporting (Waidyanatha and Prashant, 2010).

KEY TERMS AND DEFINITIONS

Disease Surveillance: Is an epidemiological practice by which the spread of disease is monitored in order to establish patterns of progression (http://en.wikipedia.org/wiki/Disease_surveillance).

Information and Communications Technology (ICT): Refers to all types of technology used to handle telecommunications, broadcast media, intelligent building management systems, audiovisual processing and transmission systems, and network-based control and monitoring functions (http://en.wikipedia.org/wiki/Information_and_communications_technology).

“Stakeholder” or “User” or “Actor”: Refers generically to organizations or community or individuals who use or exploit web based rabies surveillance system. While these types of users / stakeholders may have some different interests and perhaps different concerns based on scale of data involved, generally a corporate / organization and an individual user are going to have different expectations and concerns related to web based rabies surveillance system.

Surveillance: Is the monitoring of the behavior, activities, or other changing information, usually of people for the purpose of influencing, managing, directing, or protecting them (<http://en.wikipedia.org/wiki/Surveillance>).

ABSTRACT

The use of Social Networking Sites (SNSs) has become an integral part of daily life, particularly for adolescents. The chapter examines the negative impact of social networking sites and how they may expose alcohol-related consumption and behavior to young adults, especially college students. In particular, the focus is on the use of two specific social networking sites, Facebook and Twitter, and their association with alcohol use. The review of existing literature reveals that the depiction of alcohol use on social networking sites has a deleterious effect on alcohol use through the creation of positive social norms toward use and abuse. Further, the chapter looks at the Theory of Differential Association to explain the use of SNS as a pivot to increased alcohol use by adolescents and young adults.

INTRODUCTION

This chapter examines the use of SNSs by young adults, specifically college students, and further describes how these platforms might shape alcohol use amongst this age group, and in turn negatively impact social and academic aspects of their lives. Based on a systematic review of most recent studies conducted in the United States and elsewhere, the thrust is on synthesizing the manner in which SNSs facilitate underage drinking. The chapter offers comprehensive conceptual, theoretical, and empirical bases of association between use of SNSs and use of alcohol in adolescence and early adulthood. The chapter focuses on Edwin Sutherland's Theory of Differential Association (TDA) to explain the manner

DOI: 10.4018/978-1-5225-1674-3.ch021

in which interaction and socialization with peers in virtual communities facilitates formation of alcohol-identities and peer influence grouping. The TDA also explains why some adolescents are impacted by social media use negatively whereas others might experience socially desirable outcomes.

BACKGROUND

The alcohol culture in the United States has significantly increased in the past 25 years (Newport, 2010). Large amounts of alcohol consumption, or “binge” drinking, is connected to immediate fatalities and long-term health outcomes. While alcohol consumption varies between colleges (Lorant, Nicaise, Soto, & D’Hoore, 2013), on average four out five students drink alcohol, and about a half of college students who drink, consume four or more drinks in one sitting (Fact Sheets- Binge Drinking, 2012). The risk-taking behavior is developed through the positive outlook that is modeled from a direct or indirect encouragement of popular activities, alcohol consumption (Santor, Messervey, & Kusumakar, 2000). In addition, this deleterious culture is further amplified by print and media marketing. In one study, adolescents’ exposure to alcohol marketing increased their likeliness of drinking, and further increased consumption level for those already drinking (Bruijn, Angus, Gordon, & Hastings, 2009). With the new digital age, alcohol marketing has expended to various SNSs. This new environment allows for an additional source of exposure to alcohol, and builds the hypothesis of increased likelihood of alcohol consumption and abuse amongst young adults, especially college students.

SOCIAL NETWORKING SITES AND ALCOHOL CONSUMPTION

In recent years, the use of SNSs has become inescapable. As of May 2013, 72 percent of Americans use SNSs, a 5 percent increase from 2012; and amongst young adults ages 18-29, SNS use is 89 percent (Duggan & Brenner, 2013). There are many methods of using these platforms: entertainment, information sharing, socializing, etc. College students use SNS to extensively communicate: given that it allows them to connect and efficiently interact with their peers and instructors. These academic needs may involve sharing information related to group projects, brainstorming on common assignments, and organizing meetings with study groups. Unfortunately, they also allow creation of virtual meeting space to display shared interests relating to drinking behavior (e.g. parties, sporting events, games, etc.). Whilst there are many social networking sites used by young adults; for the focus of this study Facebook and Twitter have been analyzed.

The first platform, Facebook, was developed in 2004 for users at participating colleges and universities across the United States. Its exclusivity grew its popularity to a larger audience of users across the globe. Facebook users develop profiles to connect with friends, relatives, and other networks. Facebook functionalities range from photo-sharing, story-telling format for information sharing, and private messaging. As of recent, 86 percent of those in the 18-29-age bracket are Facebook users (Duggan & Brenner, 2013). Students in this age bracket may use Facebook to create open and private Facebook groups to share updates with their fellow peers on various academic related or social related events. Regrettably, in addition to many positive functions that Facebook’s platform can provide to college students, it can also allow students and other youth to interact and virtually connect for purposes other than academic.

A supportive evidence of increased drinking behavior, as a result of Facebook use by college students, is a study conducted collecting data on Facebook use by college students. In this study, the Alcohol Use Disorder Identification Test (AUDIT) scale was used as a screening tool to measure Facebook alcohol references. The study surveyed undergraduate students, ages 18-20 years, at two universities with public Facebook profiles. Researchers categorized the profiles into three categories: non-displayers, alcohol displayers, and intoxication/problem (I/PD) drinking displayers. The results of the study showed that those Facebook accounts whose profile owners displayed I/PD were more likely to face drinking problems on the AUDIT scale (Moreno, Christakis, Egan, Brockman, & Becker, 2012).

The second platform, Twitter, is an online micro-blogging platform that allows users to send 140-character messages, or tweets in real-time. Twitter has many functions for information sharing and encourages the use of hashtags (#), mentions (@), and retweets (RT) to its users. Hashtags are used to create conversations or information sharing around a specific topic. Popular and widely used hashtags often make the Twitter list of trending topics for users of a specific geographic location. The use of hashtags not only elevates the marketing of the user's tweet but also connects the user with other users of similar interest. The practice of mentions in tweets is to indicate a message to a specific user, which can include replying directly to that user (e.g., @johnsmith). The retweet function on Twitter is used to re-share what another user has tweeted.

According to recent data, about three out of ten (30%) young adults (18-29 year olds) use Twitter (Duggan & Brenner, 2013). Twitter is used for various academic purposes by college students and young-adults. Most evidently, in one study, Twitter was found to increase a number of positive academic outcomes, including: higher grades, positive engagement between instructor and student, and overall increased academic engagement (Junco, Heiberger, & Loken, 2011). However, similar to Facebook, whereas Twitter has its benefits for improved academic outcomes for students, it also is a platform that exposes students to alcoholic brands and behaviors. Researchers from the University of Western Sydney's School of Business studied the promotion of seven popular alcohol brands on Twitter over the course of six months. They discovered that these companies' tweets reached to a broader secondary audience through the retweets of their followers; an audience that could be under the drinking age. Indeed, the study showed hashtags were also effective in popularizing drinking during social events such as concerts or sporting events (Burton, Dadich, & Soboleva, 2013). This study is one example of ways Twitter may stimulate a positive display for alcohol consumption and exposure for both college students and young adults.

CONNECTION BETWEEN SOCIAL MEDIA AND DRINKING: THE THEORETICAL EXPLANATIONS

Studies have used many explanations to reason why young adults get involved in socially undesirable behaviors. Tickle, Hull, Sargent, Dalton, & Heatherton (2006) used Ajzen and Fishbein's (1980) Theory of Reasoned Action to explain how social influences, such as portrayal of influential characters smoking cigarettes and smoking by family members, predict adolescent smoking. A classic theory of deviance, Edwin Sutherland's Theory of Differential Association (TDA) offers the best explanation for linkage between increased use of social media and socially undesirable behaviors such as smoking and drinking. Some criticisms of Sutherland's theory (Akers, 1988; Matsueda, 1988; Warr & Stafford, 1991) might suggest TDA is less relevant due to new realities created by social media. Social media, and virtual

reality created with its help, play a decisive role in creating hyperreality (Baudrillard, 2012) for those living in the virtual reality. Consequently, young adults' responsibility to conform to mainstream societal norms weakens, because some youth are able to forget realities of the mainstream culture in favor of a simulation of reality created by sub-group norms, such as desirability of underage drinking, pre-marital sex, etc. Social media can facilitate seamless blending of reality and hyperrealist.

With increasing use of social media, parental control over adolescents is diminishing. Parents held much more control over adolescents in the absence of virtual meeting spaces. Who they met and were influenced by could be controlled by manipulating situations, so negative influence could be avoided. With social media facilitating togetherness and communications independent of physical presence, strict control is not possible. Even when parents and guardians are aware of associations causing negative influences, they are helpless in preventing networking. With virtual meeting places, parents can be deceived about the identities of others in the network. To complicate the matter, easily created fake identities can severely hamper efforts to prevent negative influences. Much like the real world, identity and impression management (Goffman, 1959) by hiding the undesirable characteristics and exaggerating more desirable characteristics also characterizes the cyber communities (Zweir, Araujo, Boukes, & Willemsen, 2011).

Theory-Based Explanations of Influence of Use of SNSs on Alcohol Use in Adolescence: Theory of Differential Association

Use of main propositions in Sutherland's theory helps understand the phenomenon in question relatively well. Sutherland would suggest that deviation from mainstream norms is a learned behavior. The primary learning about smoking and alcohol use often happens as youngsters learn these behaviors from their parents. Research on etiology of alcohol use shows that youth behavior is heavily shaped by parents' drinking habits; parents who are heavy alcohol consumers have children who are more likely to be involved in underage drinking (Armstrong, Ruttle, Burk, Costanzo, Strauman, & Essex, 2013). Perhaps more important is the influence of the secondary socialization of youth with their peers. Birds of feather flock together is true when it comes to underage drinking. Having friends who were deviant in general also increased the odds of underage drinking among youth (Armstrong, et al., 2013). Adolescent peer group identification is often clearly captured in their names making it easy for distinguishing self from others. Sussman, Pokhrel, Ashmore, and Brown (2007), through an exhaustive review of 44 peer reviewed studies on adolescent peer group identification in offline environments (e.g., school) showed that discrete peer group identities can be categorized into five life style categories; deviant group of adolescents was one of those five categories. This group was categories separately in 37 of the deviants 44 studies. The deviant group reported caring least about school work, school-related extra-curricular activities and preparation for career. Their engagement into tobacco alcohol, drug use was much higher in deviant group (Sussman et al., 2007). Risky behaviors are not really inherited and adolescents with no one to teach them about these behaviors cannot really invent them. Social media and networking created through this becomes a major source of learning.

The premise of the Differential Association Theory that humans learn deviant behavior through interaction and communications with others is perhaps most relevant in explaining the linkage between social media and youth behaviors like smoking and drinking. Social media as communication landscape is ever more popular and is maturing fast, offering diverse functions to facilitate communication (Kietzmann, Hermkens, McCarthy, & Silvestre, 2011). The communication landscape of SNSs works much like regular communication in that it results in social bonding and adherence to the "virtual" norms (Garas, Garcia,

Skowron, & Schweitzer, 2012). Consistent with Berger and Luckmann's theory of social construction of reality (Berger & Luckmann, 1966), norms evolve for social media users through frequent interactions and communications, gradually becoming routinized and leading to construction of their realities. Such communications facilitated by SNS may also play a latent function of learning of otherwise deviant behaviors like drinking and smoking by the youth. Social context, particularly availability of other underage drinkers to participate in drinking has been shown by research to increase underage drinking (Reboussin, Song & Wolfson, 2012).

The premise of the TDA proposes that the core of the deviant behavior learning happens within intimate personal groups. Subrahmanyam, Reich, Waechter, and Espinoza (2008), found that the online social networks of communications, particularly MySpace and Facebook, are not just popular means for connecting with other "emerging adults," the core of online communication networks is made up of intimate friends and family. Through online social interactions, participants co-construct the spheres of their virtual existence, but due to major overlap with the circle of off-line friends, psychological connections and social bonds are constructed through shared online and offline experiences. Online social networks are not only helpful in maintaining offline relationships; they are also used by some subgroups to find friends and romantic partners (DeHaan, Kuper, Magee, Bigelow, & Mustanski, 2013). Empirical evidence shows that online networking and instant messaging is done primarily with offline friends to converse about offline events being planned for the day or week. Social media, therefore, can be argued as a catalyst in promoting deviant behaviors through intimate circle of friends maintained by youth. Prior to the popularity of social media, tobacco industry and alcoholic beverages industry pushed the imagery of tobacco and alcoholic beverages through television and movies adds various other means (Arora, Mathur, Gupta, Nazar, Reddy, & Sargent, 2013). The imagery of smoking and alcohol use portrayed in movies can influence adolescents' attitudes, intentions, and behaviors towards initiating smoking and drinking as well as increased use. Positive imagery, such as drinking and smoking by credible lead characters holding prestigious social positions, particularly those portrayed as heroes gives a sense of social desirability of these otherwise socially undesirable behaviors. Tickle et al. (2006) used the theory of reasoned action to conceptualize their research by using data from 150 schools from New Hampshire and Vermont to examine the impact of smoking imagery in movies on adolescent smoking behavior. Viewing smoking in movies was among the most important predictors of underage smoking intentions and behavior. The increasing regulations against targeting of minors and underage individuals in cigarette and alcohol advertisements may have protected youth from aggressive targeting by these industries. However, the increased use of social media over the past decade or so, have created an alternative source of alcohol and cigarette imagery displays. By Sutherland's theory, indirect influences such as mass media might not have much influence in promoting deviant behavior.

For acting out deviance, association with deviant friends alone is insufficient. One must also have skills required to perform the deviant acts. For instance, for cigarette smoking or alcohol consumption, children and youth not permitted to buy cigarettes and alcohol through legal means need to have skills to acquire them through other means. Thus, the learning of deviant behaviors means having skills of committing the deviant acts, as well as justification and rationalization for those acts. The etiology of alcohol use among underage college students is complex, but SNS communications can be private enough to organize underage smoking and drinking occasions, thus, the skills can be obtained through online circle of friends to perform offline acts of deviance. Factors that affect student drinking include: student expectations and social pressure (National Institute on Alcohol Abuse and Alcoholism (NIAAA), 2013), particularly during freshman year, social factors, such as, involvement in fraternities or sororities

and peer behavior (Borsari & Carey, 2001; NIAAA, 2013; Testa, Kearns & Livingston, 2009), culture, e.g., race/ethnicity (Borsari & Carey, 2001; Metlife Foundation, 2013), and biological and psychological factors (Schulte, Ramo, & Brown, 2009). Location might also play an important role in underage alcohol consumption, with youth in rural areas reporting more frequent use and problematic use (Atav & Spencer, 2002; Borders & Booth, 2007).

Sutherland's theory would suggest that the specific direction of the motives and drives for alcohol use is learned from definitions of proscriptive and prescriptive norms about alcohol use. One factor that consistently predicts underage alcohol consumption is social norms, more specifically the misperception that peers are using alcohol at high rates (when compared to self-reported use) (Litt & Stock, 2011; Perkins, Meilman, Leichliter, Cashin, & Presley, 1999). Young adults who consume alcohol might subscribe to subgroup norms with alcohol use, even binge drinking, as socially desirable behavior (Ridout, Campbell, & Ellis, 2012). Young adults also consistently misjudge the frequency of alcohol use by their peers, which leads to increased beliefs that underage alcohol use is a normative behavior and increased alcohol consumption (Litt & Stock, 2011; Perkins et al., 1999). SNSs such as Facebook provide a unique platform for the development and maintenance of alcohol use social norms among college students. Adolescents with self-reported alcohol displays reported greater willingness to use alcohol, more positive attitudes toward alcohol use, and lower vulnerability to the consequences of alcohol consumption (Litt & Stock, 2011). Through sharing of alcohol-related images, comments, and videos and supporting alcohol related-advertisements (Anderson, De, Angus, Gordon, Hastings, 2009), young adults create and maintain intoxicogenic social identities as well as intoxicogenic digital spaces that further contribute to the normalization of underage alcohol consumption (Griffiths & Casswell, 2010).

The principal of differential association, the central premise of Sutherland's theory, demonstrates how social media might be more crucial facilitator of underage drinking and smoking than any other factors. The primary assumption is that a person's capability to perform deviant acts without worrying about violation of values, mores, norms, and laws depends on availability of a subculture or a counter culture often found among teenagers that will reinforce the non-conformity to mainstream cultural norms, and values as not only something normal but desirable. Peer influences in digital space enable youth create a hyperreality (Baudrillard, 2012), that blurs the line between what is desirable by mainstream culture and what is considered desirable by the simulation of social desirability within the closed circles of youth. Young adults who consume alcohol might represent a counter-culture with alcohol use as socially desirable behavior. Young adults also consistently misjudge the frequency of alcohol use by their peers, which leads to increased beliefs that underage alcohol use is a normative behavior and increased alcohol consumption (Litt & Stock, 2011; Perkins et al., 1999). SNSs such as Facebook provide a unique platform for the development and maintenance of alcohol use social norms among college students.

The premise that differential association may vary in frequency, duration, priority, and intensity is equally applicable to association through SNSs. Studies have shown that the frequency and intensity of alcohol use displays differ across users. For instance, Fournier and Clarke (2011) found that profiles of Facebook users varied considerably for percent of alcohol-related content, ranging from 0% to 29%. Variation was also found in motives for use of SNSs (Yang & Brown, 2013).

Learning of deviant behavior through association with other deviants and non-deviants comprises processes involved in form of learning. Those adolescents who belong to online peer groups involved in activities more in line with broader cultural norms can lead to socially desirable outcomes. For instance, adolescents who also include their parents in their social networking not only have stronger bonding with parents, their use of SNSs leads to better behavioral outcomes, improved pro-social behavior, and

reduced relational aggression (Coyne, Padilla-Walker, Day, Harper, & Stockdale, 2013). Also, social media specially designed for the young adults who are mentally impaired are known provide many positive functions for their leaning needs (Gowen, Deschaine, Gruttadara, & Markey, 2012). Social media is expected to actually help young adults to deal with their mental health problems through positive peer reinforcement (O'Dea & Campbell, 2011).

Social media can be also a deterrent to underage smoking and drinking. Just as social media can promote underage smoking and drinking, it can also be used as prevention. Social media can be used by those concerned with population health to post anti-smoking and anti-drinking messages. Twitter, Facebook, YouTube and other social media has increasingly been used by public health geneses to perform efficient monitoring using generated contents and educating fellow Tobacco control population education against to prevent smoking (Myslín, Zhu, Chapman, & Conway, 2013). Twitter offers large amounts of user centric information for public health professionals, reflecting perspective not available from surveys. Twitter data can be harvested with minimal effort on real-time basis (Myslín et al., 2013).

SOCIAL MEDIA, ALCOHOL USE, AND SOCIAL OUTCOMES

Research on college students suggests that references to and display of alcohol use (i.e., pictures of intoxication, alcohol brand images, comments regarding alcohol use) on SNSs are associated with self-reported alcohol use, perceptions of friends' alcohol use (Fournier & Clarke, 2011; Westgate, Neighbors, Heppner, Jahn & Lindgren, 2014), and increased risk for problematic drinking (Hoffman, Pinkleton, Austin & Reyes-Velázquez, 2014; Moreno et al., 2009; Westgate et al., 2014). Studies suggesting absence of relationship between alcohol use displays and alcohol use are rare, if any. On the other hand, the impact of imagery of drinking on youth attitudes and behaviors towards these habits is documented globally. Such imagery often glorifies and, in turn, promotes tendencies to engage in smoking and drinking, even though mainstream social norms are increasingly proscriptive of both underage smoking and drinking (Davey & Zhao, 2012).

The transition from childhood into adolescence involves interactions that are beyond small groups. In this age group, larger peer groups are involved, and the peer pressure tends to overshadow the parental controls and guidance. Even before the predominance of digital space in our lives, peer group pressures tended to have profound impacts on adolescents' attitudes and behaviors. Membership of one or more peer influence group is desirable for a multitude of functions associated with it. Such membership helps adolescents with finding emotional/instrumental support, foster friendships and social interactions (Brown, Eicher & Petrie, 1986). Peer influences are different in pre-adolescence than in adolescence, in that in the former, peer groups are defined on the basis of common activity, whereas in adolescence, peer group influence is global and far reaching, affecting attitudes, behaviors and engagement in illicit acts (O'Brien & Bierman, 1988). Peer influences are documented by many recent studies, particularly showing that alcohol use during adolescence is significantly a function of peer pressure and use of alcohol by peer groups (Becker & Curry, 2013; Boyd-Ball, Veronneau, Dishion, & Kavanagh, 2013; Huang et al., 2013; Mundt, Mercken & Zakletskaia, 2012; Visser, Winter, Veenstra, Verhulst, & Reijneveld, 2013).

Social media can enable youth to share their drinking stories online and photos of alcohol-use during parties. McCreanor et al., (2012) found that SNSs can create conducive environments for encouraging underage drinking. Virtual norms are constructed through online interaction and social construction of shared understanding of prescriptive and prospective principles of online behaviors. However, research

supports the premise that online behaviors and attitude are governed by same broader social norms prevalent in physical social world. This implies that in relationships built and maintained in virtual social environment, the group norms might be equally applicable in both social and virtual situations. By the same token, the youth norms formed through interactions at SNSs that govern drinking intentions, can lead to actual consumption of alcohol.

Alcohol use displays allow SNS users to explicitly declare their alcohol-identity, which is argued to be a crucial component of identity exploration for adolescents and young adults. Exaggerated alcohol identities, e.g. self-labeling “binge drinker”, are also a means of persuading others with similar identities to reach out for planning and acting out these identities (Ridout et al., 2012). Persuasive alcohol advertisement has been found to not only influence initiation of underage drinking but also to increase the risk of regular alcohol use, resulting in alcohol-related problems later in adolescence (Grenard, Dent & Stacy, 2013; Moreno, Briner, Williams, Brockman, Walker & Christakis, D.A., 2010).

Studies suggest that substantial amounts of alcohol-related content are found on SNSs (Fournier & Clarke, 2011). Alcohol-related content revealing alcohol identities significantly predicts underage alcohol consumption (Ridout et al., 2012). Empirical evidence supporting deleterious effects of adolescents’ networking in virtual communities with deviant peers is mounting. A large scale study of 1,563 10th-grade students showed that online connection with friends who display pictures of partying or drinking significantly increased the risk of both smoking and alcohol use in adolescence. The impact of alcohol displays on underage drinking was compounded when adolescents had social media connections with other adolescents who were also involved in drinking. In other words, independent of the influence of alcohol displays, the risk for alcohol use grew in the virtual company of other alcohol users, implying that friendships facilitated and maintained online had substantial peer influence (Huang et al., 2012). In one of the largest studies of young adults ($N=3,448$) in the United States, the quantity of alcohol content on social media websites was found to be a significantly predictor of alcohol and marijuana use (Stoddard, Bauermeister, Gorden-Messer, Johns, & Zimmerman, 2012).

Facebook users’ modalities of and attitudes toward alcohol consumption, and perceived vulnerability is impacted significantly by the norms about alcohol use posted on Facebook profiles. Litt and Stock (2011) found that young adults who are frequently exposed to alcohol use displays were likely to internalize the subjective norm about desirability of alcohol consumption, which increased their risk of actual alcohol consumption compared to adolescents less frequently exposed to alcohol use displays on Facebook. Studies indicate that social media presents a digital space that can be used by young people to communicate messages created for marketing of alcohol, thus, presenting an intoxicogenic social environment (i.e., an environment that promote alcohol use and abuse). The online networking can be used in other ways conducive to underage drinking, including to decide safe meeting places for drinking, communicate ways to consume alcohol, convey positive features of certain alcohol products, and to create a value system that is supportive of alcohol use. The communications can be accomplished through a variety of means, including digital photographs, short personal messaging, and online status titles (Griffiths & Casswell, 2010).

The prevalence of underage drinking is high enough to be considered a public health issue. Alcohol use among youth aged 12 to 20 years of age is common, with 10.4 million reporting that they drank alcohol beyond “just a few sips” in the past month (NIAAA, 2013). Roughly one-fifth of college students meet the criteria for alcohol abuse or dependence; however, seeking treatment is uncommon (i.e., 5%) (NIAAA, 2013). The rates are higher in some ethnic and age groups than others (Johnston, O’Malley, Bachman, Schulenberg, 2013; Nishimura, Hishinuma, & Goebert, 2013). Since initiation of drinking

in very early age increases the span of alcohol use during their life course and increases the risk for subsequent abuse of prescription opioids (Fiellin, Tetraault, Becker, Fiellin, & Hoff, 2012), the initiation in early teens is even more disconcerting. Empirical evidence indicates the percentage of students in 8th grade who have experienced alcohol is alarmingly at 30 percent in the US, whereas in 10th and 12th graders it is 54 percent and 69 percent respectively. The current use of alcohol within past 30 days is also of note. In 2012, respectively 5 percent, 6 percent, and 24 percent of 8th, 10th, 12th graders reported such heavy drinking (Johnston et al., 2013).

Unfortunately, alcohol related harms (i.e., negative outcomes related to alcohol use) are prevalent as well. According to NIAAA (2013), 1,825 young adults die in the United States alone from unintentional injuries each year. Further, 97,000 young adults report alcohol-related sexual assault or date rape each year (NIAAA, 2013). The ill effects of drinking are major public health concern even among adult populations, but increasingly among youth (Maimon & Browning, 2012). Underage drinking can lead to memory disorders and risk of such disorders is increased for individuals with family history of alcoholism (Silveri, 2012). Studies have also shown elevated risks of morbidity and mortality due to alcohol consumption by American youth and young adults. The negative consequences of underage drinking range from academic problems to intentional and unintentional injuries, and raised risk of mortality. It is imperative to prevent or delay the initiation of drinking, both from individual and public health point of views (Jones & Waite, 2013).

The use of social media and mobile internet offers many advantages but also ill-effects including cyber-bullying (Tokunaga, 2010) and use of alcohol, drugs and tobacco. Peer pressure resulting in alcohol use can lead to other undesirable social outcomes, particularly a decline in subjective well-being among young adults. (Kross et al., 2013) used several scales such as SWLS (Satisfaction with Life Questionnaire), Beck depression Inventory, the Rosenberg self-esteem scale and social provision scale to assess subjective well-being of adolescents, concluding that Facebook had negative impact on two aspects of subjective well-being:

1. How the participating adolescents felt moment-to-moment, and
2. Their level of satisfaction with life.

This study, therefore, concluded that rather than improving well-being, Facebook undermines it. In contrast, an earlier study presented slightly different findings. Kim and Lee (2011) studied 391 college students and found that for users with larger numbers of Facebook friends, use of Facebook led to improved subjective well-being. Kalpidou, Costin, and Marris (2011) had mixed results compared to the other two studies. Among first year college students, larger number of Facebook friends led to diminished academic adjustments, and lower self-esteem. Among students in their later years at college, this effect of Facebook on self-esteem and academic adjustment became positive, suggesting that younger adults are more vulnerable to negative consequences of Facebook.

Apparently conflicting evidence from the aforementioned studies may not be inexplicable. Since users' intensity of Facebook and other social media might differ, studies drilling down into details found that variation in how social media use impacts self-esteem might be attributable to intensity of both the use of social media and that of relationships (e.g., number of Facebook friends). To illustrate, a study of students at a large Northeastern university revealed that students with frequent visits of their Facebook scored better on Rosenberg Self-Esteemed Scale, indicating that they had higher objective self-esteem. This study also suggested that "selective self-presentation ... leads to intensified relationship forma-

tion” which influences impression of self-esteem in a negative manner (Gonzalez & Hancock, 2011, p. 79). In addition, although Facebook and other social media are used for relationship forming, the impact of connecting with friends through SNSs is also not the same for all because of differences in self-esteem independent of online relationships. Adolescents with low self-esteem who participate in online networking tend to consider it safer for self-expression, but end up antagonizing online friends and losing online peer support (Forest, & Wood, 2012). The principle of relative depreciation equally governs the cyber communities and peer groups in that communicating with or just looking at people with impressive profile attributes (e.g., pictures) can lead to negative self-evaluations (Haferkamp & Kramer, 2011). Also, the peer group is not always homogenous. Instead, an individual might have membership of multiple peer groups. For instance, Dolcini and Adler (1994) found that in their study, students had four different peer groups in the offline social world – Elite popular Black, Elite Smart, Elite Floaters, and Elite Outsiders, and there was a substantial membership overlap. Alcohol use varied significantly by type of peer group affiliation in this study.

Use of Facebook and other social media does not affect all youth in the same manner also due to variation in motives for use. Individuals’ motives for the use of certain social media are a product of their primary upbringing and socialization as well as secondary socialization influences, including peer pressure. These motives, in turn, predict the type of activities for which the use occurs, the nature of social adjustments adults and adolescents make, and effectiveness in accomplishing level of positive social adaptation. Research shows that Facebook is used by late adolescents (college students) for two primary purposes:

1. Relationship formation, and
2. Relationship maintenance (Yang & Brown, 2013).

Motives for use can include finding out more about someone the user had recently met, knowing with whom the other users maintain friendship, checking out possibilities for potential future friendships, developing romantic relationship, and finding more interesting people than offline friends. Relationship maintenance encompassed motives such as staying connected with college friends, and other acquaintances, maintain social ties rather than attempting to find new friends (Yang & Brown, 2013).

The connection between social media and underage risky behaviors is crucial to assess and consider in public policy because the use of SNSs has grown dramatically over the past decade, with a 233% increase from 2010 to 2011 in Facebook usage among college students alone (Alacron-del-Amo, Lorenzo-Romero, & Gomez-Borja, 2011; Corbett, 2011). Most (80%) college students use at least one SNS (Peluchette & Karl, 2008). Approximately half of those with SNS accounts log in to their site at least once per day (Peluchette & Karl, 2008), with roughly 34% spending more than an hour on their site (Espinoza & Juvonen, 2011). Young adults’ use of SNSs provides an avenue for communicating with friends, with young adults reporting an average of 196 contacts (‘friends’) (Espinoza & Juvonen, 2011; Ross et al., 2009). Most smart phones have apps that allow 24/7 access to social media sites, updates, postings, etc. Many people don’t logout, allowing alerts and messages to come straight to their phones at all times. Most young adult Facebook profiles are set to public (i.e., information is shared with the public – not just friends) (Lewis, Kaufman & Christakis, 2008), leaving open the possibility of negative outcomes related to public content.

CONCLUSION

SNSs play an important role in college students' lives, hence the development of Facebook for college students (Yang & Brown, 2013). Often, the literal moving away from parents and other family and friends, college students, particularly freshman, use SNSs to stay in touch with existing friends while connecting with new friends on campus (Yang & Brown, 2013). SNSs have come to play a vital role in adolescent peer group formation and dynamics. Adolescents of all ages use social networking to maintain connections with their peers and to make new connections to enhance their social networks (Yang & Brown, 2013). Social networking enables college students to maintain relationships, development new peer relationships, and manage social activities within their peer group (Lampe, Ellison, & Steinfield, 2006; Pempek, Yermolayeva, & Calvert, 2009; Subrahmanyam et al., 2008; Urista, Dong, & Day, 2009). Overall, SNSs serve an organizational function that allows college students to effectively manage their social networks (Yang & Brown, 2013). Females in particular use SNSs such as Facebook to manage friendships (Yang & Brown, 2013). However, SNSs might be even more important to adolescent males, who report greater sense of belonging as a result of SNS than do girls (Quinn & Oldmeadow, 2013).

Existing evidence on peer group formation supports the use of SNSs as a means to increasing interactions that extend beyond small groups, which results in increased opportunities for peer pressure. Peer pressure in virtual environments is evident through the posting of alcohol use displays (i.e., images including videos), endorsement of alcohol advertisements, and comments regarding alcohol use and alcohol-related events. Identifying oneself as a 'drinker' is considered by many young adults to be a socially desirable component of identity in a social networking environment (Ridout et al., 2012). Being known as a 'drinker' might be particularly important to young adult males, as evidence suggests males were more likely than females to post self-promoting pictures or comments involving alcohol (Peluchette & Karl, 2008). Overall, alcohol use displays on SNSs play a key role in the expression of identity for many adolescents and young adults, particularly during the college years.

Alcohol related displays are common on SNSs (Fournier & Clarke, 2011) and predict underage alcohol consumption (Ridout et al., 2012). Alcohol use displays create an environment in which youth misperceive the frequency of alcohol use among their peers (i.e., social norms theory), which results in increased use and abuse (Litt & Stock, 2011). Thus, based on their role in alcohol use among youth and young adults, available evidence suggests that use of SNSs contributes to the public health problem of underage drinking. Prevalence studies suggest that alcohol use is common among 12 to 20 year olds, with approximately 10 million reporting that they consumed alcohol within the past month. Additional public health problems related to alcohol consumption, such as driving under the influence and related unintentional injuries, sexual assault, and alcohol abuse and addiction, are prevalent among youth and young adults. Thus, the relationship between social media and underage alcohol use is ripe for consideration in the public policy arena, especially given the tremendous increase in social networking site use in recent years.

Research supports relationships between high rates of underage drinking in the United States and prevalence of alcohol harms among college students. Unfortunately, the control of virtual environments by parents is quite limited. Policy changes and legal implications cannot promise the prevention of using SNSs as forms of display for alcohol abuse amongst college students and young adults. Several theories give the benefit of understanding the linkages between increased use of SNSs and negative behaviors.

The strongest supporting theory in this study is TDA. The theory supports that deviant behavior occurs most often within intimate and personal networks (Sutherland, 1939). While SNSs also can be promising for prevention of poor health behaviors, further research and application is needed to guide its use for positive behavioral changes in alcohol attenuation.

Future Research Directions

Whereas existing evidence suggests a strong relationship between alcohol use displays on SNSs and positive attitudes toward underage alcohol use and related behaviors, little is known about the dynamics or mechanisms that underlie the relationships. For example, our review located no studies that extended the offline investigation of adolescent subcultures into the virtual world. Adolescent peer group formation has been studied extensively offline (Brown, Eicher, & Petrie, 1986; Dolcini & Adler, 1994; O'Brien, & Bierman, 1988; Sussman et al., 2007); however, studies on peer group formation in online environments are virtually nonexistent. SNSs naturally enhance adolescents' tendency to form social groups based on social similarities in social needs and behaviors. Our literature search found research on nature of peer group formation in offline interactions (Dolcini & Adler, 1994). Future research should use qualitative approach to explore the possible existence of adolescent subgroups in virtual environments and their perceived relationships with alcohol-related intentions and behaviors. Once possible subgroups are identified, segmentation (i.e., identification of unique subgroups) research using chi-squared interaction detection (CHAID) (Alfonso & Kaur, 2013) or cluster analysis techniques such as those used in the classification of social networking site uses in Alarcon-del-Amo et al. (2011) can be used to verify the continuation of offline peer groups into online communities. Cluster analysis techniques would allow for the identification of unique subgroups of young adults who use social networking sites. For example, cluster analysis could be used to test whether the concept of 'deviant' subgroups identified offline persists in virtual environments.

Most studies have used quantitative approaches to looking at the influence of SNSs on alcohol use. Qualitative methods are useful in exploration and identification of the mechanisms behind relationships (Creswell, 2009), such as the relationship between SNS use and underage drinking. Qualitative studies that look at the nature of online interactions and alcohol use are needed. Qualitative research methods such as focus group discussions or in-depth interviews could be used to gather young adults' perceptions of the influence of SNSs on their behavior and perceived relationships between online behavior and future outcomes. Currently there is no firm explanation of how alcohol use displays affect behavior. Specifically, future research should use qualitative research methods to identify risk and protective factors at play in the virtual world that might be associated with underage alcohol use. Quantitative research could then be used to verify the risk and protective factors identified using qualitative research and identify levers of change to target in intervention research.

Perhaps most important to address is the lack of theoretical frameworks used so far in the literature. The use of theoretical constructs is vital in the explanation of human behavior. Theories such as the one discussed herein (i.e., Edwin Sutherland's Theory of Differential Association) could be used to identify key constructs to measure in the exploration of mechanisms that explain relationships between alcohol use displays on SNSs and alcohol-related behavior and to interpret the results of both qualitative and quantitative research studies in this area. For example, quantitative studies could test the theoretical premise that young adults learn alcohol use related behaviors and skills through interaction and communication with their peers through social networking use. In turn, qualitative research could be used to explore the

principal of differential association in relation to alcohol-related displays on SNS and related behavior. More specifically, future research could explore values, mores, and norms expressed through SNS and their perceived relationships with alcohol-related beliefs, attitudes, and behavior.

Finally, there is a real need for intervention research in the area of social networking and alcohol-related behavior. As stated earlier, social media can be also a deterrent to underage drinking. There is very little research in the area of using social media to combat underage drinking. Future research should address this dearth through the identification of levers of change to target with social media interventions. Theoretically driven, mixed method research (Creswell, 2009) could be used to identify strategies that could be effective in changing online behavior and social norms. For example, qualitative research could investigate strategies for using social media to change social norms among youth and young adults, while quantitative research could be used to identify the most significant predictors of social norms to address with interventions. Further, media literacy could be effective in alerting youth and young adults to the influence of alcohol related imagery and behaviors and the virtual world that may influence their behavior (Bergsma & Carney, 2008). Media literacy could be used to educate youth on the role of SNS use and their behaviors. Strategies similar to those used in anti-tobacco prevention campaigns could be used to inform youth of the influence, for example, of virtual alcohol advertisements on their behavior. The potential for differential response to interventions based on gender should be explored in future intervention research, as males report higher rates of alcohol use displays on their SNSs (Peluchette & Karl, 2008) and also report a greater sense of belonging from social networking activities (Quinn & Oldmeadow, 2013). In light of this, gender specific intervention strategies might be required. Future research should seek to confirm this possibility.

KEY TERMS AND DEFINITIONS

Deviation: Deviation or deviance refers to departure from acceptable standards for behaviors, beliefs, and values.

Norm: Formal or informal rules created by a society or a subgroup through ongoing interactions that are used for determining appropriateness of behaviors, attitudes, beliefs, and values.

Peer Group: A social group of individual that are homogenous with respect to one or more socio-demographic characteristics such as age, education, occupation, etc.

Social Media: Web-based applications or platforms such as Facebook, Twitter, LinkedIn, MySpace, and Instagram, that are easily accessible by user, to allow interactive creation and sharing of contents.

Social Networking Sites: Web-based services that enable users to create public profiles and share contents with other users whose connections/profiles are made available within the same Website.

Social Outcomes: Positive or negative consequences for or changes in statuses, roles, and accomplishments that are important within the norms of a group.

ABSTRACT

Health is recognized by the Philippine constitution as a basic human right. The Philippines, compared to most Asian countries, produces more and better human resources for health. However, the Philippines are challenged by attracting and retaining staff in the under-served areas of the country. Philippine allotted 4.2-4.4% of its GDP to health from 2009 to 2011. Furthermore, considerable inequities in health care access and outcomes between Socio-economic groups remain. The Phil Health's limited breadth and depth of coverage has resulted in high levels of out of pocket payments. The implementation of the reforms in financing, service delivery and regulation which are aimed to tackle the inefficiencies and inequalities in the health system has been challenged by the decentralized environment and the presence of private sector, often creating fragmentation and variation in the quality of health services across the country.

INTRODUCTION

The Philippines is the second largest archipelago on earth with 7,107 islands. It is positioned on the western edge of the Pacific Ocean on the South-eastern rim of Asia (PHSDP, 2012). It is a member of the Association of South-East Asian Nations or ASEAN. The country is made up of three major geographical regions namely: Luzon, Visayas and Mindanao. It has a total of 80 provinces, 138 cities and 1,496 municipalities. In 2010, the population of the Philippines was 92.3 million, with a growth rate of

DOI: 10.4018/978-1-5225-1674-3.ch022

1.9% per year. Half of the population lives in the urban areas and of that, 44% live in slums (PHSDP, 2012). Christians make up the majority of the population and there is a Muslim minority concentrated in the southern part of the country. Additionally, the country is a home of 180 ethnic groups. Malays make up the majority and there are tribes of indigenous peoples in mountainous areas throughout the country (PHSDP, 2012).

Economically, the Philippines is considered as a developing country and is a lower middle-income economy in the South East Asia. Per capita Gross Domestic Product (GDP) is 2,918.13 US Dollars in the third quarter of 2013. The GDP growth rate is 7.025 in the same year. The annual per capital poverty threshold is P9,385 in 2012, slightly higher than that in 2009 which was P8,448. Average annual family income reached P206,000 in 2012, it is also higher than that of P173,000 in the year 2006. Unemployment rate in 2013 is 7.3% with a 0.3% increase from the 7.0% in 2012. Underemployment rate has decreased from 22.8% in 2012 to 19.2% in 2013 (NSCB, 2013).

The Philippines has had seven constitutions since 1897. In effect now, the one ratified by referendum in 1987, established a republican government patterned after that of the United States with a strong executive branch, a bicameral legislature, and an independent judiciary under a supreme court. It has had seven constitutions since 1897. In effect now, the one ratified by referendum in 1987, established a republican government patterned after that of the United States with a strong executive branch, a bicameral legislature, and an independent judiciary under a supreme court (PHSR, 2011).

Health service delivery is based on a Western biomedical model of health initially introduced during the Spanish colonial era and strengthened during American colonization. This Western system is superimposed on a pre-existing alternative model of health care based on a mix of folk and herbal medicines, religious beliefs, and traditional practices that has persisted throughout the country. Indicators of health status have steadily improved since the 1970s. The analysis of the country's demographic and health aspects show that it is going through a demographic and epidemiological transition, characterized by a decrease in fertility, increase in life expectancy and a substantial change in risk factors (PHSR, 2011). However, there is a high inequality in many health outcomes between socio-economic classes and disparities between geographical regions. The top five causes of death include heart and cerebrovascular diseases, malignant neoplasm, pneumonia, and tuberculosis. The top five causes of morbidity include acute respiratory infection, ALRTI and pneumonia, bronchitis, hypertension and acute watery diarrhoea (PHSDP, 2012).

THE PHILIPPINE HEALTH CARE DELIVERY SYSTEM

The Philippine health system has undergone changes and trends to meet the timely demand for it. In fact, there have been many legislative actions undertaken by the government to form the regulatory framework for the health system and public health in the country. Example of these are the Local Government code of 1991, National Health Insurance Act of 1995, Organ Donation Act (1991), Hospital Licensure Act, Pharmacy Act, Dangerous Drugs Act and many others.

Organization of the Health Care System

The Philippines provides recognition of health as a basic human right. Protection and promotion of the right to health of the people and instilling health consciousness among them have been guaranteed in the

The Philippine Health Care Delivery System and Health Expenditure

Article II, Section 15 of the Philippine Constitution. The Philippine health system consists of the public and private sector. The public sector consists of the Department of Health (DOH), Local Government Units (LGUs) and other national government agencies providing health services.

The Department of Health is the country's lead agency in health. The major mandate of DOH is provide national policy direction & develop national plans, technical standards & guidelines on health. It has a regional field office in every region and maintains specialty hospitals, regional hospitals and medical centers. It also maintains provincial health teams made up of DOH representatives to the local health boards and personnel involved in communicable disease control (NOH, 2005-2010).

With the devolution of health services under the 1991 Local Government Code, provision of direct health services, particularly at the primary and secondary levels of health care, is the mandate of LGUs. Under this set-up, provincial and district hospitals are under the provincial government while the municipal government manages the rural health units (RHUs) and barangay health stations (BHSs). In every province, city or municipality, there is a local advisory body to the local executive and the sanggunian or local legislative council on health-related matters (NOH, 2005-2010).

The passage of the 1995 National Health Insurance Act expanded the coverage of the national health insurance program to include not only the formal sector but also the informal and indigent sectors of the population. The program founded under the principle of social solidarity where the healthy subsidizes the sick and those who can afford to pay subsidize those who cannot. PhilHealth, a government-owned and controlled corporation attached to the DOH, is the agency mandated to administer the national health insurance program and ensure that Filipinos will have financial access to health services (NOH, 2005- 2010).

The private sector includes for-profit and non-profit health providers whose involvement in maintaining the people's health is enormous. Their involvement include providing health services in clinics and hospitals, health insurance, manufacture and distribution of medicines, vaccines, medical supplies, equipment, other health and nutrition products, research and development, human resource development other and other health-related services (NOH, 2005-2010).

Health Facilities and Services

The total number of hospital is 1,795. The 721 of this belongs to the government while 1,074 as private hospitals. The number of beds per 1000 population was 1.04 in 2008. The number of Barangay Health Stations (BHSs) was 17, 018 in 2008. And the Rural Health Units (RHUs) numbered 2,266 in 2005. In terms of government hospital beds, National Capital Region (NCR) has the most number of 27,779 beds followed by Region IV-A and Central Luzon at 9,459 and 8, 218 beds respectively. The regions with the least number of government hospital beds are Autonomous Region of Muslim Mindanao (ARMM) at 586 beds, CARAGA at 1,718 beds and Region IV-B at 2, 093 beds. The government hospital bed to population ratio is worst in ARMM with 0.17 per 1000 population while it is best in NCR with 2.47 per 1000 population. There is increasing trend in the number of BHSs from 15,343 in 2002 to 17,018 in 2008 and also an increased in the number of RHUs in the country from 1,879 in 2001 to 2,266 in 2005. NCR has the most number of RHUs while the Central Mindanao has the least number of RHUs. On the other hand, Region IV-A and Region IV-B have the most number of BHSs while NCR has the least (PSY 2004). On the average, each RHU serves around 41,000 people while each BHS serves around 5,100 people (PSY, 2004 & NOH, 2005-2010). Table 1 shows the number of beds and rate per 1000 population by region in 2008.

Table 1. Numbers of beds and rate per 1000 population by region, Philippines, 2008

Region	Number of Beds	Rate per 1000 Population
I Ilocos	4,163	0.84
II Cagayan Valley	2,779	0.86
III Central Luzon	8,218	0.84
IV-A CALABRAZON	9,459	8.83
IV-B MIMAROPA	2,093	0.73
V Bicol	4,156	0.76
VI Western Visayas	5,114	0.78
VII Central Visayas	6,190	0.92
VIII Eastern Visayas	2,845	0.67
IX Zamboanga Peninsula	2,909	0.87
X Northern Mindanao	4,858	1.16
XI Southern M.	4,580	1.08
XII Central M.	3,180	0.94
NCR	27,779	2.47
CAR	2,472	1.52
ARMM	586	0.17
CARAGA	1,718	0.70
Philippines	94,199	1.04

Source: Department of Health

The DOH has existing policy to provide services under the National Mental Health Policy, the National Policy on Oral Health, including the Minimum Essential Oral Health Package of the DOH for children 2-6 years, and to overseas Filipino workers. However there is also a very limited dental and rehabilitative service in the public sector. The 7.76 million overseas Filipino workers face a wide range of occupational, mental, reproductive and sexual health-related problems, but currently receive almost no education or information and variable levels of insurance and support. Public facilities from both national and local governments provide free services including medicines and laboratory work up during outbreaks (e.g measles, dengue and flu) and other public health related events (PHSDP, 2012).

Health Information system including surveillance of diseases and other public health events are recorded and reported from the local surveillance units and through the Philippine Integrated Disease Surveillance and response to the DOH national surveillance unit. This serves as the data bank for the analysis of the health status of the local community as well as the national data for the health profile of the country especially those that will need immediate notification to WHO as a commitment for the implementation of International Health Regulation (2005).

In 2012 the DOH released a new classification system of hospitals and other health facilities with specific guidelines for scope of services and functional capacity for each classification, and overall operating standards. There is also an ongoing effort to upgrade government health facilities in line with the goal to achieve universal coverage (PHSD, 2012).

The Philippine Health Care Delivery System and Health Expenditure

Table 2. Classification and characteristics of health facilities and services in the Philippines, 2012

Facility	Number	Characteristics
Hospitals		
General Hospitals Level 1 General Hospitals Level 2 General Hospitals Level 3 General Hospitals DOH Hospitals c. Specialty hospitals d. Other DOH Hospitals	70 16 54	<p>Most hospitals at all levels provide services for all kinds of illnesses, diseases, injuries or deformities. It has emergency and outpatient services primary care services, family medicine, pediatrics, internal medicine, obstetrics-gynecology, surgery including diagnostic and laboratory services, imaging facility and pharmacy.</p> <p>Hospitals Level 1 general hospitals also include: isolation facilities, maternity, dental clinics, 1 st level x-ray, secondary clinical laboratory with consulting pathologist, blood station, and pharmacy.</p> <p>Level 2 hospitals include level 1 services and departmentalized clinical services, respiratory units, ICU, NICU and HRP, high risk pregnancy unit, tertiary clinical laboratory, and 2 nd level x-ray</p> <p>Level 3 hospitals include level 2 services and teaching/training, physical medicine and rehabilitation, ambulatory surgery, dialysis, tertiary laboratory, blood bank, 3 rd level x-ray</p> <p>A tertiary hospital which specializes in the treatment of patients suffering from a particular condition requiring a range of treatment (e.g. Phil. Orthopaedic Centre, National Centre for Mental Health); patients suffering from disease of a particular organ or groups of organ (e.g. Lung Centre of the Philippines, Phil. Heart Centre); or patients belonging to a particular group such as children, women, or elderly (National Children's Hospital, Dr. Jose Fabella Memorial Medical Centre). Tertiary care facilities located all over the country serving as referral hospitals in the different regions of the country and providing anticipated range of tertiary services.</p>
Other Health Facilities		
Category A: Primary Care facility Category B: Custodial care facility Category C: Diagnostic/Therapeutic facility Category D: Specialized out-patient facility		<p>First contact facility offering basic services including emergency and normal delivery services. Includes: in-patient short-stay facilities, medical out-patients, overseas workers and seafarers facilities, and dental clinics.</p> <p>Provides long-term care for those with chronic or mental illness, substance/drug abuse treatment and rehabilitation, sanatorium/leprosarium, and nursing home facilities.</p> <p>Laboratory facilities, radiology including x-ray, and nuclear medicine facilities.</p> <p>Including for dialysis, ambulatory surgery, in-vitro fertilization, stem cell services, oncology and chemotherapy, radiation oncology, and physical medicine and rehabilitation.</p> <p>PNAC is a unit within the DOH responsible for promoting HIV/AIDs program and provides secretariat support to HIV/AIDs prevention and control, Diabetes Foundation, Heart Association and Philippine Coalition for the Prevention of NCDs are organizations with membership from the public and private sectors.</p>

Health Human Resource

Human resources for health are central to managing and delivering health services. They are crucial in improving health systems and health services and in meeting the desired health outcome targets. Human resources for health are enormous but unevenly distributed in the country. Most health practitioners are in Metro Manila and other urban centers. Compared to most Asian countries, the Philippines is producing more and better human resources for health (NOH, 2005-2010).

The number of physicians per 100,000 populations slightly increased from 123.8 in 1998 to 124.5 in 2000, which translates into one physician for every 803 people in 2000. The number of dentist per 100,000 populations almost remained unchanged at 54.2 in 1998 and 54.4 in 2000 or one dentist per 1,840 people in 2000. The number of pharmacists per 100,000 populations improved slightly from 55.8 in 1998 to 58.1 in 2000. This means one pharmacist for every 1,722 people in 2000. The number of

The Philippine Health Care Delivery System and Health Expenditure

Table 3. Summary of health services and providers in the Philippines, 2012

Health Services	Public Sector Provision	Private Sector Provision
Health promotion		
Health education Family planning Maternity care Child care Nutrition and food safety Lifestyle-related or non-communicable diseases Communicable diseases Environmental Health and sanitation	Health centres Barangay health stations National programs and agencies provide technical support Activities are highly variable and depend on the local government unit Community health teams provide education and information at family levels in the community. They also work with poor families to determine health needs, services available and receive PhilHealth benefits Hospitals conduct multi media health promotion activities in their waiting areas, lobbies and OPDs Some LGU-operated birthing facilities Include: Pre-natal care for mothers, Iron Anti-rabies for animal bite centres UHC/KP focuses on the 5Million poorest	Family and community practitioners, paediatricians, obstetricians, physicians and some subspecialists Some organized NGOs initiate activities Large-scale programs are rarely provided by the private sector
Disease Prevention		
Childhood immunization Tb, malaria, leprosy, filariasis, schistosomiasis, rabies, dengue fever, and SARS	Health centres Provincial hospital outpatient services and Animal Bite Treatment Centres National agencies provide technical support and supplies Support from the Global Fund for AIDS, Tuberculosis and Malaria Includes: Endemic areas are provided with anti- malaria drugs, schisto and filarial drugs, including soil-transmitted helminthiasis	Paediatricians clinics and private hospital outpatient services provide immunizations Private Animal Bite treatment Centres as stand alone clinics and those in private hospitals. Pulmonary specialists and some general practitioners participate in the DOTS program for
HIV and other Sexually Transmitted Infections (STI)	Display of IEC materials in some rural health units/ social hygiene clinics/city health offices; video showing in waiting areas	NGOs and Key Populations at higher risk for HIV Support Groups for Sex workers/Men having Sex with Men and People who inject drugs, and the young key populations conduct outreach work and peer education activities Some private hospitals display IEC materials; video showing in waiting areas
Environmental health and sanitation	Local governments, water districts, national agencies provide assistance in terms of water supply systems; sanitation systems; solid waste, hazardous waste, health care waste management systems; sewage and wastewater collection and treatment facilities; water and wastewater laboratories. DOH Environmental and Occupational Health Office provides technical support to LGUs.	Water utilities (e.g. Manila Water, Maynilad), NGOs for water and sanitation; water refilling stations, bottled water companies; solid waste and hazardous waste treatment and disposal services; septic tanks desludging services (e.g. Malabanan companies); sewage and wastewater treatment facilities; water and wastewater laboratories

Source: PHSDF, 2012

nurses per 100,000 populations almost remained constant from 442.7 in 1998 to 442.8 in 2000, a ratio of one nurse per 226 people for both 1998 and 2000 (SEAMIC, 2003 & NOH, 2005-2010).

In 2002, there are 3,021 doctors, 1,871 dentist, 4720 nurses and 16,534 midwives employed by LGUs. Other health personnel employed by LGUs consist of 3,271 engineers/sanitary inspectors, 303 nutritionist, 1,505 medical technologist, 977 dental aides and 2,808 non- technical staff. Assisting these health personnel at the grassroots are 195,928 volunteer barangay health workers and 54,557 birth attendants (FHSIS, 2002 & NOH, 2005-2010).

Table 4. Summary of health services and providers in the Philippines, 2012

Health Services	Public Sector Provision	Private Sector Provision
Diabetes, hypertension, cancer and mental health	Health facilities at LGU levels National NCD program of the DOH provides technical support to local government units Hospitals at municipal/city, provincial and regional levels also provide disease-prevention related activities (e.g. smoking cessation advice, wellness clinic, etc.) The medicines program – Compack - for NCDs targets the 5 Million poorest as part of UHC/KP commodity support	Private general practitioners and Specialists in clinics and medical centres provide education and prevention programs. Some are linked to NGOs such as Diabetes Foundation, Philippine Heart Association, Philippine Coalition for the Prevention of NCDs, among others Private mental health facilities
Primary services		
Outpatient, dental and laboratory services Disease programs like TB, Malaria, Dengue	Health centres Primary care hospitals other DOH-supported commodities – eg TB drugs, vaccines (DPT, OPB, measles, BCG, Hep B), also flu vaccines for indigent senior citizens	Clinics Hospitals
Secondary and tertiary services		
Outpatient, Inpatient and hospital care Laboratory and special procedures Acute and emergency care Dental care Mental Health	Secondary and tertiary care hospitals, including very specialized care Hospitals Some health centres and hospitals Hospitals	Secondary and tertiary care hospitals, including very specialized care Hospitals Most dental care is by private practitioners in clinics and some hospitals Hospitals, Clinic/halfway homes
Rehabilitative services		
Acute inpatient rehabilitation Long term care for the elderly and disabled Programs for the disabled Palliative care	Tertiary hospitals with specialist physicians and physical, occupational and speech therapists A few tertiary hospitals provide house visits and palliative care Some community-based care National Commission Concerning Disabled Persons coordinates implementation and enforcement of legislation A few tertiary hospitals Services are variable, highly dependent on the local government	Tertiary hospitals Some home-based care Several NGOs and foundations provide assistance This should be filled up. There are more of private partners doing work here. Hospitals

Source: PHSDF, 2012

The Philippines has traditionally been a major source of health professionals to many countries because of their fluent English, skills and training, compassions, humaneness and patience in caring. The country is purportedly the leading exporter of nurses to the world (Aiken, 2004) and the second major exporter of physicians (Bach, 2003). Although the country is producing a surplus of health workers for overseas market since the 1960s, the large exodus of nurses in the last four years has been unparalleled in the migration history of the country. While Filipino physicians have been migrating to the United States since the 1960s and to the Middle East countries in the 1970s in steady outflows, the recent outflows are disturbing because they are no longer migrating as medical doctors but as nurses (NOH, 2005-2010).

HEALTH EXPENDITURE

The Philippine health financing involves different financial sources, regulatory bodies and health services providers. Generally, the four main sources are government (national and local), Social insurance (government and private), user fees or out-of-pocket (OPP) and the donors. The sources coming from donors is also called grants are those that come from philanthropists and charity organizations. The Department of Health (DOH) and the National Health Insurance Program or PhilHealth. Health services providers as we know includes the hospitals, the doctors and nurses.

The total health expenditure per capita is 8.1% in 2011. It has an annual growth rate of 7.2% in the period of 2009 and 2011. The Philippine had allotted 4.2-4.4% of its domestic growth product (GDP) to health in the same period of time. This share rose slightly compared to 3.9% in 2007 (figure number), but remains relatively low compared with the WHO Western Pacific Region 2006 average of 6.1% this total health expenditure tallied an average annual growth rate of 9% in the period of 2009 and 2011.

The government total health expenditure on health amounted to 27% in 2011 from which 12.3% as a national government share and the remaining 14.7% by the local government share. From 2009 to 2011, the government expenditure on health has increased with an average annual growth rate of 14.6%. The government, as a whole, spent more on personal health care than the public health care each year from 2009 to 2011. More detailed expenditure accounts indicate that spending on hospitals dominated the government's personal health care expenditures.

In 1995, the National Health Insurance Program (NHIP) managed by Philippine Health Insurance Corporation (PHIC or PhilHealth) signaled the movement towards a single-payer Premium-based financing or insurance system. However, the current system continues to maintain a dual financing system existing parallel to each other (NOH, 2011-2016). This Social health insurance program, known as PhilHealth, increased its share of total health spending at an average annual growth rate of 18.5% from

2009 to 2011. Public funding through PhilHealth has been expected to set the incentive environment in order to have a greater leverage and drive forward health system performance. However, the share of 9.1% remains low in relation to the 30% target set by DOH in the 1999 health reform agenda to reduce out-of-pocket share of total health expenditure.

The private sector continues to be the dominant source of health care financing with financing with 63.1% share of the total health expenditure in 2011 and was slightly higher than the preceding year which was 62.8%. The private sector share on health spending has an annual growth rate of 11.7% from 2009 to 2011. Moreover, out-of-pocket or user fees continue to dominated the share of private sources and the total health expenditure as a whole with 57.2% and an annual growth rate of 11.6%. This trend of increased of OOP payments is quite alarming knowing that the Social insurance has been expanded in the recent years.

The high level of Out-Of-Pocket may lead to financial catastrophe and impoverishment. Table 5 validates the large contribution of OOP during confinement but it is significantly higher among patients confined in public facilities. Despite the safety nets, donations would still count as one of the major sources of financing.

Looking at the components of Out-Of-Pocket by quantile, more than half of the medical expenditure was spent on medicine. However, share of medicine on the total medical expenditure was consistently higher among the poor compared to their richer counterparts. Expenditure on contraceptives was also higher among the poor on household (Lavado & Ulep, 2011).

CONCLUSION

The health service delivery in the Philippines is based on a Western biomedical model. Health functions are generally devolved to provinces and municipalities. As stated above, health service has evolved into dual delivery systems of public and private provision, covering the entire range of interventions with varying degrees of emphasis at different health care levels. Health status has improved over the last decades. Among the indicators of this improvement are the decreased in the infant mortality rate, decreased prevalence of communicable diseases and the increased in the life expectancy of the Filipinos. However, there are still many problems and challenges the country has to solve. For the inequities

in access to health care services and outcomes between Socio-economic groups remain. This has been generally caused by the high cost of access and use of health care. Also, the high level of out of pocket payments brought about by the limited breadth and depth coverage of the PhilHealth, the country's social health insurance, is a heavy burden to the poor Filipinos. Despite being a major exporter of health workers, some rural and poor areas of the Philippines still face shortage of professional health workers. Thus, the government has to exert efforts in attracting and retaining staff in the under-served areas of the country. Another key challenge is the inefficiency in service delivery. This I believed is the result of an ineffective referral system and gatekeeping of the health system. Finally, reform efforts in financing, service delivery and regulation have been done to resolve these problems. However, implementation has been challenged by the decentralized environment and the presence of a large private sector, often creating fragmentation and variation in the quality of services across the country.

KEY TERMS AND DEFINITIONS

Department of Health: The Department of Health is the Philippine's lead agency in health. The major mandate of DOH is provide national policy direction & develop national plans, technical standards & guidelines on health.

Health: According to the World Health Organization (WHO), "health is more than just the absence of illness or disability, but also is physical, spiritual and social well-being."

Health Economics: Health economics can be defined as the application of the rules of economics to the health services. It can also be defined as the efficient use of the resources allocated to the health sector.

Health Expenditures: According to U.S. National Library of Medicine, health expenditures occurs the amounts spent by individuals, groups, nations, or private or public organizations for total health care and/or its various components. These amounts may or may not be equivalent to the actual costs (Health Care Costs) and may or may not be shared among the patient, insurers, and/or employers.

Health Care System: The World Health Organization defines health care systems as follows: "A health system consists of all organizations, people and actions whose primary intent is to promote, restore or maintain health. This includes efforts to influence determinants of health as well as more direct health-improving activities. A health system is therefore more than the pyramid of publicly owned facilities that deliver personal health services. It includes, for example, a mother caring for a sick child at home; private providers; behavior change programmes; vector-control campaigns; health insurance organizations; occupational health and safety legislation. It includes inter-sectorial action by health staff, for example, encouraging the ministry of education to promote female education, a well-known determinant of better health."

Out-Of-Pocket: OOP is defined as payments made for health care services by patients or households. In general, OOP cost refers health expenses that are not covered by insurance.

Philippine Health Insurance Corporation: Philippine's national health insurance program aiming to provide affordable health care for the population with site location, service and contact information.

Chapter 23

Socio-Technical Systems on the Move: Some Insights for Policy Activity

Sylvie Occelli

Istituto di Ricerche Economico Sociali del Piemonte (IRES), Italy

ABSTRACT

Because of the advancements in Information Communication Technologies (ICTs), and notably the increased spreading of Web 2.0 Internet-based services and mobile computing, an increasingly information-rich environment is made available, where new types of Socio-Technical Systems (STS) can be established. Due to the pervasiveness of ICT, designing and developing Socio-Technical Systems is raising an increasing interest also from a policy point of view. They play a crucial role in the improvement of the so-called soft-infrastructures, a main asset for delivering social innovation. Raising the performance of such an infrastructure, in fact, turns out to be a major challenge to be addressed in order to meet EU requirements for smart growth. In this chapter, a concept of STS is suggested, and its ICT-enabled implications for policy activity are highlighted. As an example, the concept is used for designing a collaborative platform for health knowledge exchange at a regional level.

INTRODUCTION¹

In everyday life, Information and Communication Technologies (ICT) and Internet access are progressively transforming the ways people gather information about their surrounding environment and interact with it (Atkinson & McKay, 2007; Castells, 2009; Horrigan & Rainie, 2002; Kwan, 2001; Dodge & Kitchin, 2004; Wellmann & Haythornthwaite, 2002; Townsend, 2001; Warf, 2001; Wilson & Corey eds., 2000).

These technologies alter the distance limits prescribed by social practices, thus allowing for a higher degree of accessibility. They are also time-adjusting as the time used in an activity can be freed for alternative ones. Furthermore, they affect the ways people perceive their surrounding environment and mediate human communication (Fuch, 2005). Finally, these features have an impact on activities which can be more easily segmented in tasks and spread out across space and time (Couclelis, 2009), although their ultimate effects cannot be easily explained.

DOI: 10.4018/978-1-5225-1674-3.ch023

Lately, in spite of or because of the persistent, critical situations for most national and regional economies, the new generation of ICT, and notably mobile communications and web 2.0 Internet based services, are again stimulating an upsurge of interest, as new facets of ICT potential are gaining momentum, i.e. ubiquity, knowledge sharing, co-creation.

The recent emphasis on digital connectivity shows that Internet is not operating at the expenses of the real face-to-face relationships. Rather, it is an additional means of communication that is being integrated in everyday life (Wellman, Quan-Haase, Boase, & Chen, 2003), and likely to deliver new types of relationships and relation opportunities (Fuchs, 2005; Quitney Anderson & Rainie, 2010).

As the penetration of ICT creates an increasingly rich information environment, questions about the influences of the interaction of technical and social networks also arise: how does it encroach on existing organizations, by giving access to a globalized and information leaden society. Moreover, how does it enable the establishment of novel, more socially affordable types of systemic entities, herein called Socio Technical Systems (STS)?

Although the notion is already well established in the literature (Berra & Occelli, 2009; Morris, 2009; Sayer & Jarradi, 2013), the current features of STS, and namely those connected with the knowledge flux associated with the networks of interacting ICT enabled agents, raise a renewed interest to sharpen its underpinnings and investigate its functioning.

This chapter is a contribution to such an endeavour. First, in the next section, a conceptual framework is suggested which highlights the components and organizing mechanisms of STS.

Then, having this framework as a background, reference is made to the findings of some studies undertaken in the Piedmont region, where since 2005 the Piedmont ICT Observatory (PICTO) has been monitoring the spreading of ICT among citizens, firms and local governments. Arguments are provided that STS are not just intellectual constructs, useful for a better understanding of current organizational changes, but have also an impact in supporting their developmental process in a more inclusive and informed way. This turns out to be particularly relevant for delivering public services and in this direction, attention is turned to health care, a domain which besides accounting for the largest share of the regional public spending is undergoing a number of organizational reforms. An application of the STS notion is then outlined to help conceiving a collaborative platform for health knowledge exchange and support a regional soft infrastructure for health care delivery.

In the final section, some remarks are offered about the design potential of STS. We argue that, in the near future, applications of the concept of STS in policy practices will multiply and STS representations will be progressively refined. In this context, some most promising research topics are mentioned.

SOCIO-TECHNICAL SYSTEM: AN OLD CONCEPT FOR A NEW KIND OF SYSTEMS

Background

The concept of Socio Technical System (STS) is a longstanding one, loosely applied to describe any kind of organization that is composed of people and technology.

Originally introduced in the fifties, as computing and human requirements evolved, it has been progressively refined (Eason, 2008; Trist, 1981; Withworth, 2009). Notwithstanding, the term has been used with varied nuances in the literature (see among many others Ackerman, 2001; Berra, 2007; Castells,

2004; Gallino, 2007; Geels, 2004; Graham & Marvin, 1997, 2001; Meyer, 2006; Kwan, 2001; Withworth & Withworth, 2010), underlying that the existing STS notions consist of two main principles:

1. The fact that the interaction of social and technical networks creates the conditions for successful (or unsuccessful) system organizational performance. This interaction can result partly from linear cause-effect relationships (such as those informed by design) and partly from non-linear, even unpredictable relationships. Whether designed or not, both types of interaction occur when socio and technical networks are made to work together;
2. The fact that, addressing each network alone (socio or technical), tends to amplify those network effects that are detrimental to the system's performance. A whole system approach is therefore needed to take into account the different wide-ranging effects.

In short, an STS is a comprehensive entity encompassing human and technological elements, communicating and interacting sometimes in non trivial ways by means of different social and technical (systems of) networks.

Although no supremacy is claimed by social and technological networks in shaping the STS system, each one plays a role insofar as their joint functioning must bridge the gap between two issues: social needs and technical performance, or between what human activity systems want and what the technology can offer (Ackerman, 2001).

Acknowledging the mutual constitution of the technological and social factors above described, requires uncovering the factors as well as the chain of events that underlie their co-evolution and ultimately drive system improvements or may cause failures.

First, an STS is grounded in multi-dimensional contexts which rest on historical, geographical and institutional aspects. An obvious, but often overlooked corollary is that for a situated human activity system, the existence of STS relies on the type of artefacts which, over time, technical progress makes available, and on the usages individuals and organizations make of those artefacts. Based on the fact that it depends on how technology is appropriate in social practices, aligning the operations of new technological functionalities and their usage by people and organization takes time (Orlikowski, 2002) and may create gaps among users.

Second, being embedded in socioeconomic processes, STS functioning results from the multiple network relationships which exist among its members and between those members and the external environments. The performance and reliability of technological networks (coverage, band-width, services) as well as the trustworthiness and responsiveness of the web of social networks are crucial features for the STS in order to operate and support its viability over time.

Finally, an STS requires forms of collective actions set up so that multiple parties who have a responsibility in managing the human activity system can pursue one of more shared goals. These goals are based on agents' own experience within the STS, they reflect the prevailing values belonging to the human activity system, and may result from a negotiation of agents' conflicting purposes.

A Conceptual Scheme of STS

When viewed through a time lens, it is evident that both technological and social profiles of an STS bear the unique prints produced by the development stage reached by the human activity system. In this respect, an overarching challenge raised by today globalized, multi-cultural, and networked society is

what some scholars have called the “creation of patterns of consensual human interactions” (Banathy, 2000, p. 481). While calling for an increasing inclusiveness, it also raises the question about the type of enquiry systems an STS has to adopt for guiding its own developmental process.

Interestingly, this is just what the current progress on ICT promises to fulfil by using the drastic increase in communications and online social interactions. ICT progress in fact turns out to be pivotal for making human activity systems better capable of adapting and reconfiguring themselves (Whitworth, 2009). While changes in the technological supplies can be taken up rather straightforwardly, technology adjusted social transformations, as mentioned above, are more difficult. Indeed, the inertia and rigidities observed in the working of many organizations are often recognized as a main impediment. The creation of consensual patterns, however, goes beyond the simple removal of barriers. It requires us to investigate the evolution of the determinants underpinning social interaction, and how the resulting patterns of these interactions permit the production (and re-production) of human activity systems and ultimately of the whole society (Sayer, 2005; Poli, 2010). Although a full discussion of these topics is beyond the scope of this chapter, some implications as for the STS’s profile are worth mentioning.

Worth noting is that an STS has an intrinsic capability of discerning what would be a desirable addition to the human activity system (Nelson, 2004). This is very different from that provided by truth or ideal seeking inquiring systems; the former being engaged into a search for what is true, the latter with what would be the ideal.

A salient aspect of this mode of enquiry is the existence of an explicit relationship between those engaging into the enquiry and those who have to be served from the results of the enquiry process (Rawling, 2004; Umpleby, 2007).

To support that relationship, therefore, we need an approach, herein labelled as mode III, to single it out from the truth or ideal seeking inquiring systems, and which yields knowledge of what is desirable (the design of the inquiry-action pairing) on behalf of key stakeholders, who would benefit from the outcome of that approach (the realization of the inquiry-action pairing) (Nelson, 2004).

From this prospective, the following aspects of an STS, though not exhaustive, can be emphasised:

- **Guidance:** In order to sustain itself, an STS takes advantage from steering, and namely from that complex, mindful, reflective and projective oriented activity humans can undertake (Tsoukas, 2005).
- **Pro-Activity:** STS agents are prone to engage into actions pro-actively, as they do not just respond to changes, but take actions they feel will improve the organization’s chances of moving towards the desired future (Whitworth & Whitworth, 2010).
- **Flexibility:** Any STS individual member is a reflexive and communicative agent who can modify his/her behaviour and knowledge, as a result of his/her participation in the network interactions². These changes in their turn affect the web of network relationships, and modify the STS overall pattern, thus impacting on the everyday practices of the organization.

These aspects are not a novelty in the recent literature on organizations and organizational changes. For example, an organization dealing with a mode III approach has been called an homeopoietic system, a term coined ten years ago by Rowland (2004) to indicate a complex creative system, where both designers and recipients participate in making the organization through collaborative relationships.

The acknowledgment that interpretative frameworks agents can build up to make sense of the surrounding environment is central in the recent tenets of socio-cybernetics (Scott, 2008). As maintained

by McIntyre (2003, p.7), in fact, the ways we understand the information about the world “shapes our perceptions about the world and our positions in interactions”.

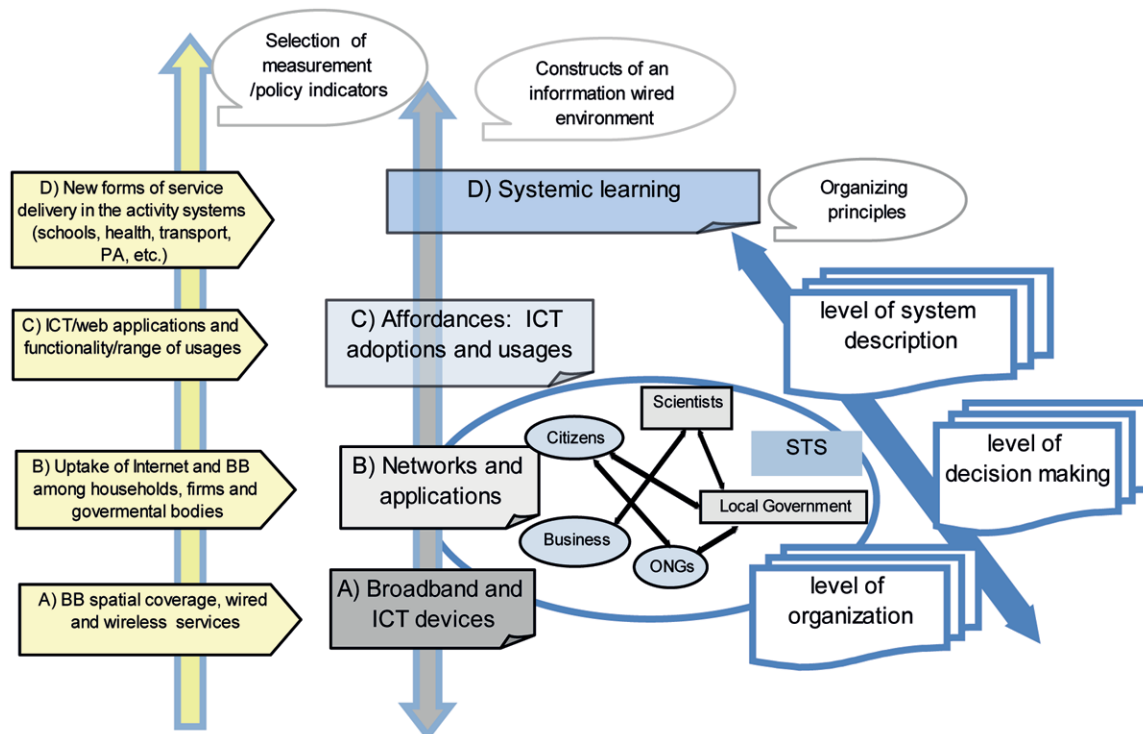

The joint consideration of the design and realization of the pairing inquiry-action, is at the core of meta-design (Fischer & Herrmann, 2011), an activity aimed at providing a framework where all stakeholders can contribute to the development of the functionality of an organization as well as to the evolution of its social and learning aspects.

When the generation process of the STS patterns is given primary attention, such an organization can also be understood as a Human Complex Adaptive System (HCAS), a system that, due to its interactions among the many elements of both socio and technical networks, can best adapt, evolve³, and, learn, enhancing its transformative capability (Holland, 2006).

To sharpen the arguments discussed so far, a descriptive framework which sheds light on the constitutive components (constructs) and organizing principles of an STS is suggested. These principles are shown in the scheme of Figure 1, which also indicates the main stakeholders involved in an STS and some measurement indicators conventionally used for monitoring the roll out of ICT programmes⁴.

In the diagram, the main components stem from a conceptual framework, which speculates that, in an information wired environment, STS consists of four interlinked constructs, related to: a) the technology, and namely the capacity of a vast array of different types of wired and wireless ICT and broadband technologies to interact with each other creating new efficiencies; b) the network effects, yielded when more usage of ICT services by any user increases the product’s value for other users (and sometimes all

Figure 1. A diagram of socio technical system: components, organizing principles and examples of measurement indicators

users); c) system affordances, which depend on the potentialities generated by the mediation role of ICT artefacts; d) systemic learning, which reflects a fundamental human activity rooted in humans' reflexive ability to make sense of their living experience (Occelli, 2006, 2008).

Two key dimensions underlie systemic learning: a) a human centred knowledge dimension, whose extremes are delimited by notions of completely transferable information (explicit knowledge) and non transferable information (tacit knowledge); and b) a technology centred knowledge dimension, which contrasts a notion of deliverable digital information and one which may be accessed as a result of the use of technological artefacts (computers, Internet, mobile phones, and so on).

How these two dimensions are related and co-evolve over time, while interacting with the other components of the information wired environment (technological artefacts, network effects and system affordances) is at the core of any STS. Indeed, as suggested, "Humans try to marshal the agency of machines to serve their own purposes, but cannot always anticipate or control the consequences. Outcomes are emergent from the interaction of both forms of agency, not from one alone" (Rose, Jones, & Trex, 2005, p. 147).

To make sense of STS organizing principles, one can adopt a multi-level system approach, in which the various system components and relationships are distinguished according to a threefold perspective⁵, associated with system description, decision-making and organization, Table 1 (adapted from Mesarovic, Macko, & Takahara, 1970).

System description means defining the 'observation window' adopted by the observer/analyst when looking at the system. The selection of strata depends on the agent's point of view, as she/he/it might be directly engaged in STS operations (endocentric view) or only indirectly concerned as an 'external observer' of the STS overall functioning (exocentric view). Both endocentric and exocentric views are involved in developing and operating within a STS. Depending on how agents engage in STS, as a participant or observer, different descriptive strata are likely to be pertinent (i.e., local vs. global, strategic vs. operational, general vs. specific). The point to note here is that crossing the descriptive strata increases the awareness of the STS functioning: moving up on the hierarchy, one obtains a deeper understanding of its significance, while moving down, a more detailed explanation is provided.

In accordance with the Mode III approach, this involves a line of enquiry, in which the consistency's requirements commanded by a system approach are specified enough to put them into practice and accommodate the needs of those who have to take actions (Rhodes, Murphy, Muir, & Murray, 2011).

How agents commit their actions over time entails considering the decision-making process occurring in a STS's organization. In many real life situations, in fact, acting in a timely way and better

Table 1. Perspectives in multi-level system approach

Perspectives (Types of Level)	Main Issues Involved
a. Level of description (description by strata)	Selection of strata depends on the observer (i.e., strategic, tactical, operational)
b. Level of decision-making (description by layers)	Identification of the functional hierarchy entailed in a choice process (search, selection/adaptation, evaluation)
c. Level of organization (description by echelons)	Definition of the structure of an organization (elementary units and their arrangements)

(Adapted from Mesarovic, Macko, & Takahara, 1970).

understanding a situation in order to cope with uncertainties are main motivations of decision-making. The communication flows enabled by STS networks provide agents with a unique support for meeting these needs.

First, at an individual level, feedback relationships across decision making functional hierarchy, are facilitated, thus improving the connections among the different decision layers, such as those related to the search and selection of alternatives, learning and adapting, and setting the performances and evaluation functions.

Second, at a system level, richer and faster communication flows help making system information more transparent and accessible, thus increasing the visibility and accountability of the functioning of the STS (Erikson & Kellogg, 2000), which over time enhance information trustworthiness and reliability and agents' intentions to engage into STS networks⁶.

It is worth noting that evaluation can result from the joint articulation of the system description and decision making perspectives. As a part of agent's reflexive ability, individual evaluation activities can play a role in generating values, the latter being abstract entities that are relevant at STS higher organizational levels (Miceli & Castelfranchi, 2000).

Carrying out assessments such as monitoring and providing justification for actions, furthermore, are valuable activities in themselves as they assist STS in nurturing an appreciative setting, e.g. a setting characterized by knowledge openness, self-creation and responsibility in giving meaning to human processes (the definition is taken from the work by Vickers as discussed in Checkland, 2005).

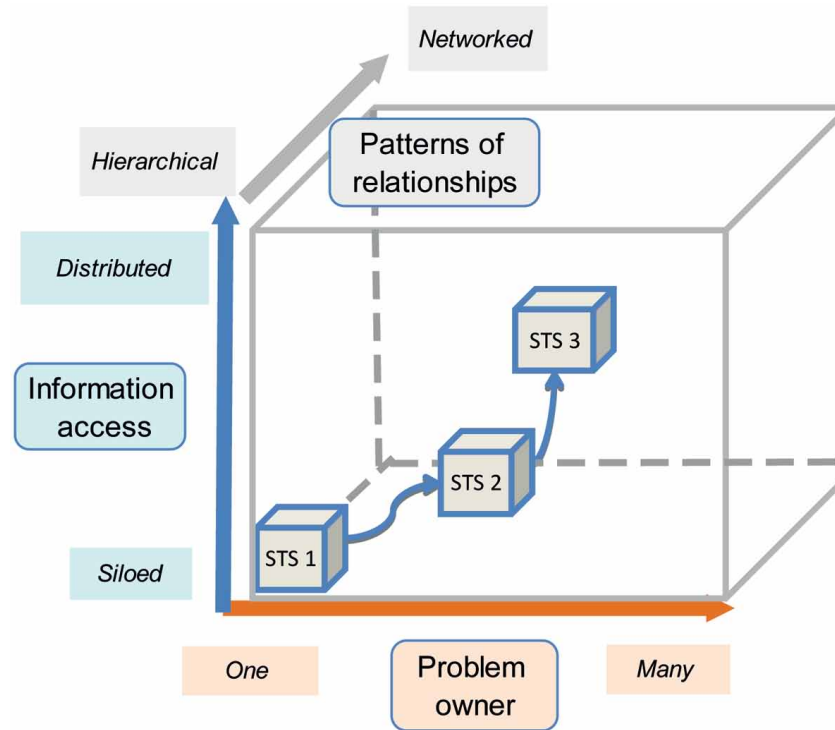

The third perspective deals with the STS structuring, and is concerned with how the whole STS organizes itself as a result of multiple interactions occurring among the agents (as interacting decision-making units). Broadly speaking, this structuring can be regarded as some logically consistent clustering of its elements as the organization searches for consistency in its internal processes and consonance within its environments (Mintzberg, 1980).

When considering the extents to which the power of decision-making is dispersed among its members (decentralization)⁷, different types of configurations can be observed. Although, as in the past, this structuring cannot occur independently of the contents dealt with in the other two perspectives, today ICT progress gives STS greater flexibility and makes the resulting configuration not easily accountable for by means of simple descriptive patterns (Sawyer, 2005). In this respect, the terms *adhocracy* (Mintzberg, 1980) and *networked individualism* (Wellman, 2002) have been suggested to account for this increased complexity in the organizational pattern. In the policy field, in particular, the terms *network governments* have been used to indicate the new possibilities to support innovation (such as the introduction of ICTs in government) and to personalize government-citizen relationships (van Dijk & Winters-van Beek, 2009).

On a conceptual ground, these configurations belong to a multi-dimensional space which, given certain conditions of ICT provision, is delimited by the articulation of the threefold organizing principles, and namely by the levels of system description, decision-making and organization. Although the limits of this are difficult to understand, some boundaries are likely to exist as a result of the traces produced by the paths the different agents may undertake as they take actions in the STS, e.g. they become problems' owners as they access/provide information and establish relationships and collaborate with other agents in order to address some of these problems.

To visualize the idea, diagram of Figure 2 shows how an STS configuration can evolve as changes occur along some selected axes of the multi-dimensional space, accounting for inclusiveness (one versus many problems' owners), type of interaction patterns (hierarchical versus networked) and information (siloes versus distributed).

Figure 2. A view into the evolution path of an socio technical system

PROVIDING GROUND FOR DEVELOPING AN STS FOR REGIONAL HEALTH CARE

The STS issues are especially relevant for innovation oriented growth paths as well as for delivering more effective public services above all in education, transportation and health. Not unexpectedly, they permeate the bulk of the arguments addressed in a recent report by the European Commission (van Welsum, Overmeer, & van Ark, 2012), which calls for both new narratives about ICT leveraged development (e.g., linking pro-active initiatives with long term strategy) and action capability (e.g., removing legal barriers, devising more open and flexible regulatory frameworks, and strengthening readiness to change) in order to collect the expected societal benefits of ICT impacts.

Indeed, over the last decade many facets of the STS components (see Figure 1) have been extensively investigated by several studies at national and regional levels, also spurred by the need to support ICT oriented policy initiatives (OECD, 2010). That was the case in the Piedmont region, where a five year policy program was put into place to roll out the regional broadband and an inter-institutional research team was created to monitor its progress (the Piedmont ICT Observatory).

As the program came to a completion in 2010, it can be said that some improvements were made in the establishment of an information based society. In spite of the distance which still separated Piedmont from the most advanced northern European areas, the regional achievements appeared very positive, above all, when regarded against the overall systemic profile of the region^{8,9}. Lately, however, the turmoil in the economy and uncertainties in the regional climate severely curtailed ICT uptakes and the gaps between Piedmont and the leading European regions re-opened (IRES, 2014).

In spite of, or maybe because of, the persistent socioeconomic difficulties, by this time a new stage in ICT development has been reached. A greater awareness about ICT potential exists, encouraged by the use opportunity offered by the latest ICT devices, such as apps, and wireless and mobile applications. More noticeably, evidence is mounting about the opportunity to lever ICT in driving regional development paths out of the current stagnating situation (PICTO, 2013). As a result, on the one hand, more tailored analyses are demanded to investigate how benefits of ICT use can be accrued to the different regional organizations. On the other one, it is apparent that conventional analyses of ICT diffusion processes have to be broadened to include additional STS components, such as systemic learning, and the application of STS organizing principles.

The health sector represents a domain where such an effort is most wanted. To date some work has already been done in order to study the diffusion of ICT in the Italian health sector at regional and national level (Osservatorio ICT in Sanità, 2014). The e-health issues however are still largely untapped. Attention has been primarily focused on the technological components and their uptake in the health practices only scantily addressed¹⁰.

As pioneered in a study more than ten years ago (Eysenbach, 2001), e-health encompasses more than a simple technological development. It is an emerging domain at the crossroad of medical informatics, public health and business. It refers to health services and information delivered or enhanced through ICT and the use of broadband connections¹¹. Underlying the term there is a far-reaching meaning which entails a state-of-mind, and a commitment for a networked purposeful mind-set, to improve health care locally, regionally, and worldwide by using ICT.

Overlooking this definition is likely to severely hamper the possibilities for e-health to deliver its benefits. In fact, as the recent report by the e-Health Stakeholder Group of the European Commission (2014)¹² highlights, disparities in both accessing to and providing services through the Internet can worsen already existing health inequalities.

The latter issue is of particular concern for the Piedmont region where, apart from the public spending constraints imposed by the austerity measures, the import of an ageing population is putting new strain on the health care system. According to the Italian National Bureau of Statistics, in 2011, population older than 65 in Piedmont accounts for 24% of the total population, compared with 21% in the whole of Italy and 18% in Europe 27, and is expected to reach 30% by 2040. Associated with ageing are chronic diseases which, as shown in Figure 3, in Piedmont are affecting an increasingly large shares of population, and the process is even faster than in the rest of the country.

The tension in the regional health system is augmented by the raising expectations about the quality of health and welfare services, which, in the recent time, have been seriously stifled. As shown in Figure 4, the share of Piedmont citizens who valued positively the performance of these services reduced palpably between 2011 and 2014, while those who gave a negative assessment grew substantially.

In this situation, it is expected that applying an STS notion might contribute to sharpen the regional e-health issues, and enhance the action capability of the different stakeholders. As graphically represented in Figure 2, the basic idea is that, the undertaking might enable the regional health system to move from STS1 towards STS2 and STS3. It is assumed furthermore that in the course of action, a wider and collaboratively based information infrastructure might be progressively established, allowing the health regional system to cope more effectively with health disparities and emergent priorities.

A number of works, which offer valuable insights about how an STS concept can inspire ICT applications in health care systems, already exist and they help tackling those issues, see for example Sittig and Singh (2010); Munson, Cavusoglu and Frisch (2013). Here reference is made to a study by Hesse,

Source: Indagine IRES sul clima di opinione dei cittadini piemontesi

Hansen, Finholt, Munson, Kellogg and Thomas (2010). This study supports a specific point of view by examining how various knowledge contributions, such as those associated with clinical, patient and public health information, combine to develop technology-mediated social participation for health care provision.

When referring to the descriptive framework of Figure 1, this point of view obviously overlaps with what in the above diagram has been identified as systemic learning component, and it shares the focus of the system description perspective as a leading STS organizing principle. In the present case, the main purpose of taking this stance is to develop an STS, allowing a Collaborative Environment for Health Knowledge Interchange (CEHI) at a regional level to be put into place.

The opportunity to create this environment primarily stems from the necessity to help solving the financial and organizational problems currently affecting the regional health system¹³. Two additional reasons, however, motivate the effort.

The first is related to the contrasting findings of PICTO studies. On the one hand, they confirm the relatively robustness of the ICT endowment by the main regional stakeholders¹⁴. On the other, they show a latent weakness; above all in the capacity of governmental organizations to take advantage from ICT applications (IRES, 2014).

They provide evidence that, whereas, data about many socioeconomic phenomena and processes are growing dramatically, thanks to ICT pervasiveness, the aptitude to make sense of them and use the extracted knowledge for actions is still limited and in some cases even overwhelmed by data overload (Inguaggiato & Occelli, 2014).

By extending and empowering the perspective of observation of regional health stakeholders, CEHI can help enhancing the previously mentioned capability.

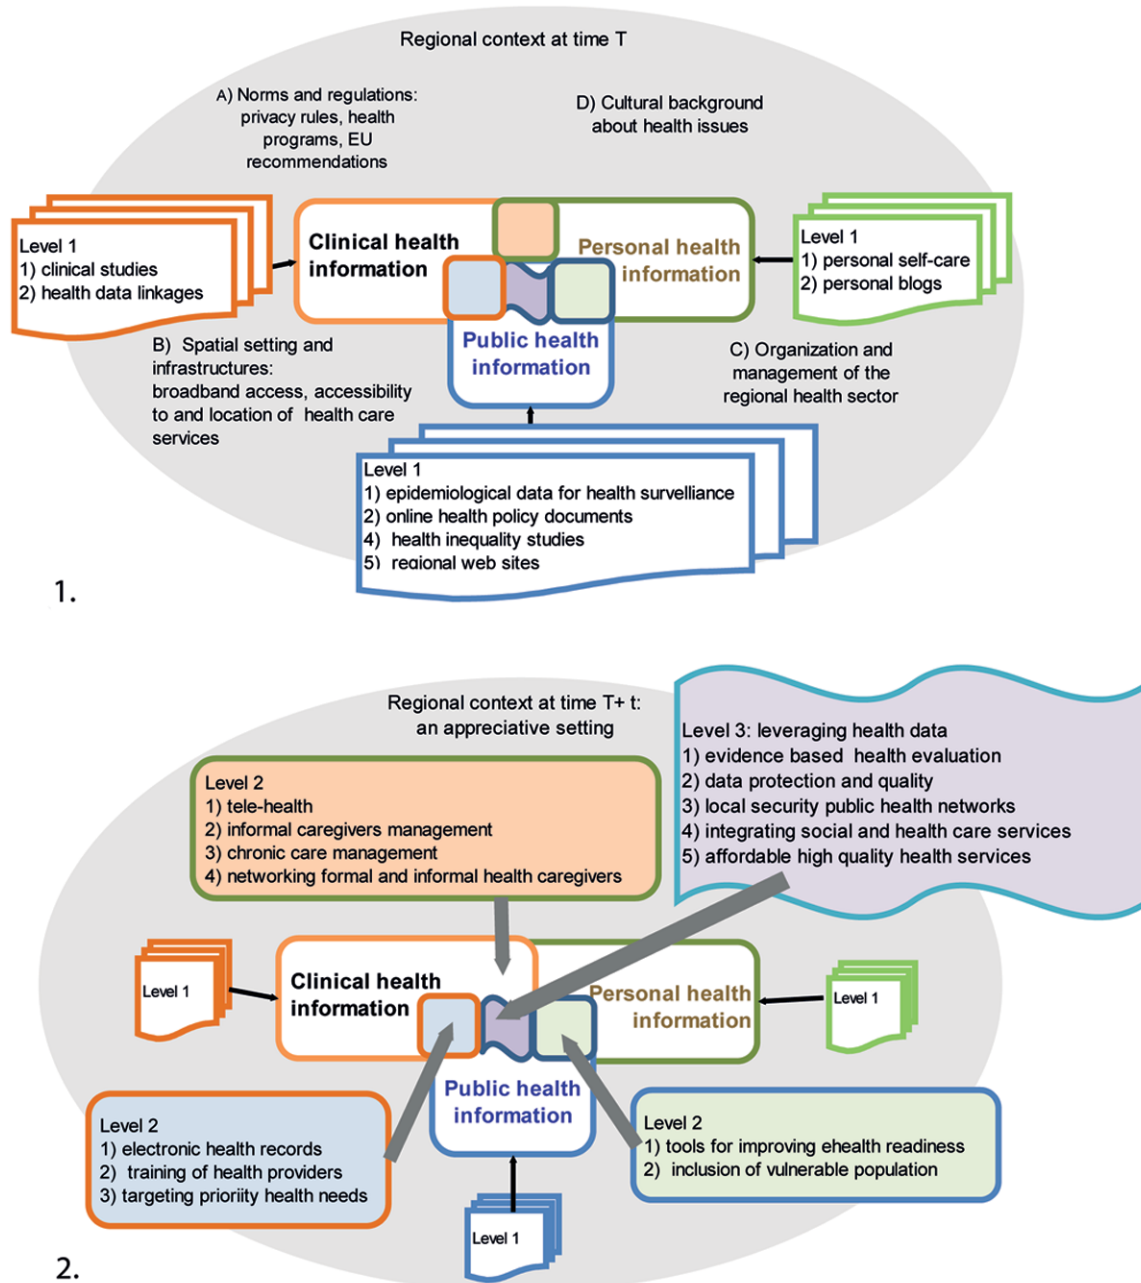

The second reason is suggested by the experience gained in some regional projects, and namely in that dealing with road safety (Boero, R., Grieco, A., Montaldo, C., Occelli S., & Tarditi, 2010; Occelli, 2012b). This project, in fact, has made it apparent how the interactions among ICT enabled policemen can deliver more consistent information flows about road crashes. The access to timelier and qualitatively better data, furthermore, has widened the possibilities for stakeholders to implement more effective countermeasures in the sub regional areas. Eventually, the establishment of a regional STS for road safety has created an environment where feedbacks from the different agents are more easily channelled and processed, and their outcome more timely inscribed in the policy domain concerning road safety.

Actually, developing a Collaborative Environment for Health Knowledge Interchange (CEHI) can be regarded as an application of meta-design at intermediate level (Fischer & Hermann, 2011). The latter being levels at which agents are aware of the possibility to become owners of health problems and engage in creating knowledge environment within which an STS can grow.

Of course, as mentioned earlier, such an endeavour builds upon some assumptions which, however, find evidence in existing studies about healthcare, and namely: a) the acknowledgement that a positive contribution to health care delivery can be brought about by improved partnership (Benson & Wright, 2006; Fauth & Mahdon, 2007); and b) The fact that stakeholder involvement and participation are indispensable for gathering the information evidence to document performance, better align health providers and engage service users in their care (Fauth & Mahdon, 2007).

Figure 5 sets out an attempt at outlining a stylized description of CEHI. Its purpose is simply to draw a framework for prompting the attention of health agents to make them participate in the project. The framework consists of three key components which are briefly outlined in the following.

Figure 5. A diagram of a collaborative environment for health knowledge interchange; a) situation at time T , b) situation at time $T+t$

1. *The type of health information according to the problem owners.* In the diagram three main types of information concerning clinical, personal and public sides of health are mentioned, each of which is representative of a main group of health stakeholders. Of course each group (and its pertinent information basis) is not a monolithic organization but it is composed of many diverse agents, interacting with each other, e.g. an embedded STS which can stand alone. Each group, therefore,

will have to be detailed further, in order to account for the agents' roles and competencies, e.g. doctor, nurse, caregiver, health providers, and so on, and for the window of observation a specific health knowledge requirement will call for, e.g., single patient, health care department, hospital.

2. *The maturity level at which e-health information is made available within CEHI.* It is assumed that both the content and flows of health information evolve over time as technology progresses and organizations get hold of it. The hypothesis builds upon some results of PICTO studies which summon that the maturity level in ICT usage, (this being associated with ICT familiarity and awareness of the effects of ICT applications), is a crucial enabler in siding the technological with the social networks within organizations. In the case of the Piedmont health care system, such alignment has progressed rather slowly and been carried out separately by each organization. That is why in the diagram there is a distinction between three possible maturity levels for e-health information to develop. These ideally reflect progressively more integrated health-care services. Level 1 responds to the basic information needs as expressed in the activities singularly undertaken by each main health problem owner (the ST 1 in Figure 2)¹⁵. By and large, it reflects the current state of e-health uptaken by the Piedmont health care organizations, (and as shown in Figure 5a), its overall pattern being a patchy one, characterized by heterogeneous situations across the regional sub areas.

Level 2 e-health information recognizes the fact that increasingly the solution of certain health questions cuts across different domains of competence. A new kind of information is often wanted, which in most cases can be obtained by linking and processing data produced by the different health stakeholders in carrying out their regular activities. To distinguish Level 2 from Level 1 information, we use a large umbrella term and call it 'augmented information'. In Piedmont a number of projects have been launched which aim to provide and exploit this kind of information. This is the case of a tele-health pilot project implemented in a Piedmont province, which aims to give home care to people with chronic diseases¹⁶ (in the diagram of Figure 5b this is represented in the link between clinical and personal health data). Another case is the pilot study for improving the road crash information system which, according to European recommendations, in the near future will have to be complemented with data about the health gravity of the people injured in these crashes. To meet this requirement road crash data, collected by policemen, have to be linked with the data of hospitalized people, recorded by health care professionals (in the diagram of Figure 5b, this makes reference to the linking between clinical and public health data).

Finally, a major initiative, launched by the regional health plan, sets the foundations for connecting clinical, public and personal health data. Its goal is to develop a regional platform, supporting back-office data interchange among public health operators, a citizen web-portal about health care services and clinical data interchange for specialists and general practitioners¹⁷.

Actually, the creation of health augmented information to improve health diagnosis, cares and prevention is a core challenge of big data analytics, a newly born computational field for analysing large data-sets. Intended to deal with the complexity, diversity and timeliness of data sets, the field has an untapped potential of value generation also for health care and it involves both the reduction of health cost pressure and the increase of health care quality (Groves, Kayyali, Knott, & van Kuiben, 2013; Institute for Health Technology Transformation, 2013).

Although the figures of Level 3 e-health information in Figure 5b are only indicative, nonetheless, they give a cue of what this highest information level could eventually mean for Piedmont health care system. First, they suggest that by enabling a cooperative environment, a trustworthy and reliable information health system can be set up, and a better integration among the different regional health stakeholders

achieved. More specifically, this type of information is expected to yield a better understanding of the relationships between treatments, outcomes and patients (O'Reilly, Loukides, Steele, & Hill, 2012), thus enabling more effective patient centred medical practices to be carried out (Sturmberg, 2012). Furthermore, in a context where a governance strategy of health information is progressively more warranted (Cohasset Associates & AHIMA, 2014), the on-going relationships within the CEHI create an environment conducive to the development of sustainable information governance programmes.

3. *The development context of CEHI.* The STS outline we made in the previous paragraph, made it evident that the characteristics of the context play a decisive role in developing a CEHI. In Figure 5a a number of determinants are mentioned. They account for the situation of the institutional background (norms and regulation), the endowments of physical capital (spatial setting and infrastructures), the structure and management of health care regional systems and the level of awareness of health issues by the general public. These determinants may act as both barriers and incentives to CEHI's growth. They are (however) themselves subject to change as, over time, results of the works carried out by CEHI are inscribed in the regional context. As the setting is expected to become more and more appreciative (Figure 5b), feed-back loops among level 1, 2 and 3 health information are likely to be acted upon more easily and the time used to implement transformation and improvement may also be shortened. This means that, although organisations embark on change and upgrading of their programmes, for different reasons their ability to see how close they are to the desired end state will increase.

CONCLUDING REMARKS

One of the central topics of this chapter is that STS and namely the interaction between ICT and social networks and the resulting knowledge flows yielded from it, are a main (although not unique) vehicle for structuring, in a participatory way, more resilient organizations.

They play, indeed, a crucial role in the improvement of the so-called soft-infrastructures, a main asset for delivering social innovation. A soft-infrastructure can be loosely understood as a mix of institutions and services producing those intangible assets which make up the social and human capital and which are so crucial in fuelling the socio-economic resources of an area. Raising the performance of such an infrastructure, in fact, turns out to be a difficult challenge to be addressed in order to meet the EU requirements for a smart growth (SCF Associated, 2009).

This chapter tried to show that the notion of STS is not just an appealing intellectual concept, but can have a practical relevance for accompanying policy activity and introducing innovative actions. Eventually, as pointed out, it stimulates novel thinking about how we conceptualize human activity systems, and at the same time it urges us to pay greater attention to the system of relationships entailed in policy practices. When applied to these practices, STS, and the underlying Mode III system approach, provide an environment where individual agents, who are interacting with each other, can properly shape the relationships across system descriptions, decision making and organizations. They are also able to find ways to create plausible solutions to the problems they are facing. Such an environment, would give agents the opportunity to design result based hybrid strategies by combining competition; to upgrade their individual competencies and cooperative socialization; to evolve their social synergies (Whitworth & Sylla, 2011).

Piedmont case studies, mentioned in the preceding section, provide evidence that STS concept, although still in an embryonic form, has an impact in the ways already existing regional governmental organizations work.

In most cases, however, the observed practices are primarily associated with the operations of ICT network and they mainly consist of mere substitutions of existing functionality with more cost-effective ones.

Indeed, so far an overall assessment is difficult to provide. On one hand, awareness about the opportunities likely to be associated with a region wide STS is increasing. On the other, it has been shown that for these opportunities to generate innovative transformations in service delivery and policy activities, the whole socio-informational linkages underpinning government organizations¹⁸ should evolve.

The argument in OECD (2011) that ICT usage should extend from disseminating information to establishing relationships between outside and inside government, clearly highlights the need to have a comprehensive view of the change in public organizations.

It is expected that, in the near future, applications of the concept of STS in policy practices will multiply and STS representations, such as those in Figures 1 and 2, will be gradually refined. The types of connections among the different multi-level perspectives involved in STS, however, will raise challenging research and policy issues. In this respect, two points, which will be likely to get attention in future research, are mentioned.

The first is related to the role an STS can play in creating an environment where policy actions can be designed on a shared basis, experimented and progressively refined as the (social) system learn to build itself. The arguments made in discussing the framework for Collaborative Environment for Health Knowledge Interchange gave the idea, although cursory, of a range of possibilities. A crucial concern in this respect is how to ensure (by design?) that participants both give to and get something back from the collaborative environment (Chi, Manson, Fischer, Vieweg, & Parr, 2010). This is probably just another way through which the STS core issue of aligning technological and social networks shows itself, but it is by no means less challenging.

The second point deals with the pattern requirements the structure of an STS (when understood as a Human Complex Adaptive system) should exhibit in order to be open and flexible enough for adapting policy measures, while maintaining the prospect of their full implementation. This is a thorny issue, which raises questions about system resilience and viability. An even sharper aspect, so far still untapped, is the definition and measurement of the public value which is likely to be associated with an STS pattern and the outcomes of its functioning.

A contribution for addressing the question is offered for example by Talbot (2008) which acknowledges that multiple and, in certain cases, conflicting public values exist. They can be understood and measured by considering five dimensions, e.g., trust and legitimacy, collectivity, security, personal utility and autonomy, which clearly overlap with some key aspects of STS¹⁹.

KEY TERMS AND DEFINITIONS

E-Health: A domain at the crossroad of medical informatics, public health and business.

Homeopoietic System: A term coined ten years ago to indicate a complex creative system, where both designers and recipients participate in making the organization through collaborative relationships.

ICT Diffusion: The process of ICT spreading in society at different organizational and spatial levels.

Multi-Level System: The acknowledgement that a system is not a monolithic whole but results from the interaction of components working at different organizational and spatial levels.

Policy Innovation: The process meant to foster and support improvements in the whole policy life-cycle.

Socio-Technical Systems: Organizations resulting from the dynamic intertwine of social and technical networks.

Soft-Infrastructure: A term highlighting the structuring role of human activities in supporting the functioning of a service.

ENDNOTES

- ¹ This chapter builds on the article by Occelli (2012a) and considerably extends some parts of the original version.
- ² The ICT component is considered as an agent too. Its definition is associated with a technology, information and functionality level.
- ³ As pointed out in Landini and Occelli (2010), HCAS is one of the most outstanding concepts which have emerged in the literature of the last 20 years. It is in fact a core idea that ties together most of the research domains converging under the large umbrella of complexity science. Its popularity across different fields may be ascribed to several reasons such as the capability of (a) metaphorically expressing a descriptive view, which eclectically embraces a number of aspects of a study system; and (b) instantiating that view in a methodological platform allowing for the operational implementation of a new ‘species’ of (MAS) models.
- ⁴ The definition of these indicators is based on the experience gained by the Piedmont ICT Observatory in monitoring the five year regional broadband program (PICTO, 2012, 2013). Over time they have been progressively refined to account for the efforts made by Piedmont’s organizations to catch up with the development trends in the European information society triggered by the Lisbon Strategy.
- ⁵ Of course other perspectives can be proposed depending on how a STS is conceived. For example, in discussing the designing of organizations, Mintzberg (1980) argues that the elements in organizational structuring tend to appear in 5.
- ⁶ As a result, coordination among agents is facilitated, and the co-ordinability (governance) of the whole STS networks can be improved. This has several implications: both social, i.e. the issues of deliberative democracy, and economic, such as the needs to improve the network efficiency by the administrative costs.
- ⁷ Decentralization itself can have different forms depending on the extent to which: a) the formal decision making power is delegated down the chain of line authority; b) power flows informally outside this chain and c) power is dispersed to different places for different decision processes or the power over various decisions is dispersed to the same place (Mintzberg, 1980).
- ⁸ The distinctiveness of ICT diffusion in Piedmont is highly dependent on the features of the regional system which deeply affected the speed and facets of the diffusion processes. These features are related to: a) the morphology of the regional territory, 2/3 of which is mountainous or hilly; b) a large number of local authorities (1206 municipalities); c) a polycentric urban system, consisting of a few larger cities (the province head cities) and a majority of small and very small municipalities (80% has less than 5000 inhabitants); d) an aging and low educated profile of the regional popu-

lation; e) a legacy to the car-based industrial sectors; f) the transition towards a more diversified economy in which technological and ICT based sectors are expected to play an important role.

⁹ As for ICT uptake in the regional system, a synthetic overview is provided in the following (Occelli, 2012a). When considering the target indicators of the European Digital Agenda on a comparative basis, Piedmont performs relatively better than Italy although it is still far from the most advanced North European regions. In 2013, broadband coverage and diffusion among households and firms are similar to those observed in Europe. E-commerce among citizens is lower than the European average, but as high as the European value among enterprises. As for inclusion, Internet users and diffusion among disadvantaged people in the region are approaching the target values. Access to transactional e-government services is still modest, although progress in delivering e-government services by local governments has been remarkable. Recently, more diversified dynamics of ICT adoption/appropriation by the different actors have been taking place also as a result of the economic downturn. For firms and local governments, weak positive changes have been observed as these mainly depend on adaptation requirements and resource constraints. Between 2010 and 2011, however, citizens showed a significant growth in ICT appropriation, which has never occurred in earlier periods. Progress in the regional sub-areas was also conspicuous. Between 2009 and 2011, ICT appropriation rates raised considerably in the lagging behind areas, thus reducing the digital gaps in the region. An acceleration of ICT take up has been observed in the metropolitan area, thus suggesting that a new cycle of ICT services (those related to web 2.0, social networks, mobile APs and cloud computing) is being triggered off in the area. Contrasting features in the regional profile are revealed when considering the measurement frameworks recommended by the Innovation Union and Youth on the Move initiatives. When exposed to the national hindrance in technological development and ICT diffusion, Piedmont situation reveals some positive albeit weak signals. The regional indicators of R&S spending in public sector and of venture capital investments in Piedmont are relatively low, but those of patents and technological exchange with foreign countries perform slightly better. Compared with the overall production system, innovative sectors (ICT, Digital Contents, High Tech Manufacture and Knowledge Intensive Services) seem to be more resilient to the crisis. ICT adoption in local governments has been mainly compliant with the Italian public administration laws, and weakly sensitive to citizens' demand.

¹⁰ Almost all municipalities and government offices in the region are now equipped with the basic ICT infrastructures and services (broadband, certified e-mail, digital signature and institutional websites). Although most office activities comply with e-government requirements, the interactivity level of online services is still under developed and limited to the provision of fill-in forms to prompt administrative procedures. The presence of ICT is the highest in the office procedures for core administrative services, such as taxes, demographics and financial services. These services are often managed independently within the administration. ICT applications are still limited in those services with fewer organizational requirements than services with greater organizational requirements. For a large number of municipalities, ICT equipments are perceived as expensive as they need investments, which can be afforded only by the larger administrations (PICTO, 2013). A considerable difficulty stems from the size of local governments where ICT competences are often missing (IRES, 2014).

¹¹ Findings by OECD (2010) show that the potential benefits that can result from ICT implementation in the health domain can be related to four broad categories of objectives: a) increasing quality

of care and efficiency; b) reducing operating costs of clinical services c) reducing administrative costs and d) enabling entirely new modes of care.

¹² To contrast e-health inequalities, the European Commission (2014) has put forward key recommendations concerning: a) the integration of e-health into overall health and social care system policy; b) access improvement and involvement of all stakeholders; c) the accommodation of diverse needs and reduction of technological pressure; d) the improvement of digital health literacy and enhancement of user education at all levels.

¹³ An overview of the Piedmont regional health system is available at http://www.regiotrend.piemonte.it/site/RESET2013_A4/RESET2013_cap5.5.pdf.

¹⁴ See the synthetic account in note 9.

¹⁵ As an example of level 1 health information by the public health organizations, we can mention the following websites: http://www.regione.piemonte.it/sanita/ep/relaz_san/salute.htmhttp://www.dors.it/el_focus.php?focus=B<http://www.cipespiemonte.it/>.

¹⁶ See: <http://www.aslvco.it/Progetti.asp?id=13> and <http://www.regione.piemonte.it/innovazione/images/stories/innovazione/dwd/robotti.pdf>.

¹⁷ This initiative is called “Sanità in Rete”, <http://www.sistemapiemonte.it/cms/pa/sanita/servizi/249-sanita-in-rete>

¹⁸ The issues are also part of the recent debate concerning the innovation possibility in the public sector (Gil-Garcia, 2012, Navarra & Cornford, 2007, Maier-Rabler & Huber, 2011, NESTA, 2008, OASIS, 2011, Talbot, 2008). Basically the current debate argues that innovation would ensue from an increased variety in the delivered services, whereby this would result from the inclusion of different and more pro-active types of actors as well as from a wider set of ICT-enabled service functionalities. The availability of more diversified and accessible service outputs therefore would help meeting people’s increasingly differentiated needs, thus improving the rate of success in achieving government effectiveness and efficiency. While acknowledging the requisite variety requirement provides a rationale for innovation, the processes by which the forms and contents of variety come about, and their deployment time, deserve specific insights as they are themselves sources of innovative change.

¹⁹ When referring to health, for example, Sturmberg (2010) makes a point that core values exist, e.g. the health of every patient, which remains unchanged in a changing world, that lead all the structural requirements and interactions of the healthcare system.

Chapter 24

Online Spatial HIV/AIDS Surveillance and Monitoring System for Nigeria

Peter Adebayo Idowu
Obafemi Awolowo University, Nigeria

ABSTRACT

HIV/AIDS has now become a big threat to the world generally, most especially the Sub-Saharan Africa region as it continues to increase drastically in the region. This disease has increased the poverty level of the countries in the region. In Nigeria, millions of people infected with this deadly disease are in their productive years between 15 and 49. This surge is having a negative effect on Nigeria and other Sub-Saharan Africa countries as it lowers life expectancy, slows population growth and social and economic effect on the country. Presently, health officers in Nigeria primarily rely on monitoring HIV/AIDS prevalence only among women attending antenatal clinics as that is the only source of getting data from HIV/AIDS patients. In the country, there is no electronic HIV/AIDS database, no electronic means of capturing HIV/AIDS data and no electronic monitoring of HIV/AIDS patients. This chapter presents a prototypical HIV/AIDS surveillance and monitoring system and the prototype was developed using Dreamweaver, PHP and MySQL. With this system, users could spatially query the pattern and distribution of any HIV/AIDS disease using any known location. Also, queries based on occupation, level of education, and gender among other things are possible with this system. Though the system was developed for Nigeria, it can also be extended to other countries within Sub-Saharan Africa region.

INTRODUCTION

HIV/AIDS has remained a global catastrophe that continues to threaten several nations around the world. The prevalence rate of HIV/AIDS has continued to increase drastically since the disease was discovered in the early 1980s. HIV/AIDS is globally recognized as an international disease as it spreads explosively across Asia and Africa. It is estimated that “90 to 95 percent of AIDS infections occur in developing countries, primarily in Sub-Saharan Africa where some of the world’s worst living conditions exist” (Enotes, 2012).

DOI: 10.4018/978-1-5225-1674-3.ch024

Globally, 34 million people were living with HIV/AIDS at the end of 2011. An estimated 0.8% of adults between aged 15-49 years worldwide are living with HIV/AIDS. One out of twenty adults (4.9%) is living with HIV/AIDS in sub-Saharan Africa accounting for 69% of people living with HIV/AIDS worldwide. Sub-Saharan Africa accounted for 71% of the adults and children newly infected in 2011 (UNAIDS, 2012).

HIV/AIDS has become a major problem in developing countries due to the fact that poverty has blocked the development of adequate health care facilities including problems with purchasing of HIV/AIDS drugs. In most developed nations, the high spread of HIV/AIDS has reduced because of their healthcare development, affordability of HIV/AIDS drugs, treatment and vast implementation of its preventive measures. While the risk of HIV/AIDS transmission is being controlled in the developed nations, the spread is increasing and worsening in developing nations with their limited public education about HIV/AIDS and the inability to fight the deadly disease.

Due to the magnitude of HIV/AIDS, nations throughout the world have developed National AIDS Programs (NAPs) based on the specific needs of the country's population. The World Health Organization (WHO), a United Nations agency, founded a global HIV/AIDS trust fund in 1987 to help fund the NAP programs. The NAP program focuses on the prevention of the transmission of HIV/AIDS through sexual intercourse, blood and blood products and unsterilized objects such as injection needles. The initiative has supported programs that reduce the transmission of the disease from mother-to-child and also fought against the stigmatization of HIV/AIDS patients (Ruxin *et al.*, 2005).

In Africa, the impact of HIV/AIDS is cumbersome on some of the poorest countries. Nine countries in Africa have about one tenth of their adult population infected with HIV/AIDS. At least one adult out of five is living with HIV/AIDS in three countries on the southern part of the African continent (Kembol *et al.*, 2011). In the Sub-Saharan Africa region which is heavily affected by HIV/AIDS than any other region in the world, "an estimated 22.9 million people are living with HIV/AIDS in the region which is about two thirds of the global total. In 2010, over 1.2 million people died from AIDS in sub-Saharan Africa and 1.9 million people became infected with HIV/AIDS" (Avert, 2012).

The HIV/AIDS epidemic in sub-Saharan Africa has been both a cause and consequence of under-development in many African countries. It is still one of the most significant health problems in many developing countries despite several control efforts. It remains a major cause of mortality in the region. The socio-economic problems of the HIV/AIDS epidemic are widely felt not just in the health sector, but also in the agricultural, educational, industrial and the economic sectors in general. The effects of the disease on the people have rolled back years of development progress achieved in the regions.

HIV/AIDS is a contributing factor to the level of poverty in some countries. The relationship between HIV/AIDS and poverty is most obvious when one looks across the countries; almost all the countries with the highest prevalence are poor. Africa, the poorest of all the continents, is the epicenter of the epidemic. The HIV/AIDS epidemic is often concentrated in marginalized populations and among people driven by economic need to engage in professions that increase the risk of the HIV/AIDS infection.

Poverty increases the vulnerability to HIV/AIDS and the denial of access to the antiretroviral therapy for those already infected with the disease. In affluent countries, most of those who need the treatment are receiving it, but in poor countries mostly in the sub-Saharan region, only a few who could afford to pay have received the treatment. As poverty fuels HIV/AIDS, so is the epidemic increasing poverty and threatening the economic growth and development of affected nations, thereby creating financial hardship for people, families, government and robbing the nation of people in their prime and most productive

years (Kembol *et al*, 2011). The impact of HIV/AIDS on individuals and families is enormous and this will get worse before it can get any better, even where the prevalence rate is falling. Moreover, much of this burden falls mostly on the poor.

The Nigerian health care system is poorly developed, with no adequate and functional surveillance systems. Public health not only functions to provide adequate and timely medical care but also to track, monitor, and control disease outbreak. The Nigerian health care system has had to manage several infectious diseases such as HIV/AIDS, malaria, tuberculosis outbreaks year after year. For decades now, epidemic diseases have been a threat not only to the lives of individuals but also to the nation as a whole (USAIDS, 2002).

Lack of database-related surveillance systems is a major cause of the widespread of HIV/AIDS in most of the affected countries. In Nigeria, the health care system is degrading. The provision of health access to the Nigerian people is 43.3% (Pharmacy & Bioallied Science, 2011). This can be attributed to the peculiar demographics of the Nigerian populace. More than half of the Nigerian population live in the rural area. About 70% of the health care is provided by private vendors and only 30% by the government (Pharmacy & Bioallied Science, 2011). Over 70% of drugs dispensed are substandard. More than half of the Nigerian population live below the poverty line and cannot afford the cost of health care.

Despite the fact that Nigeria has one of the highest prevalence rates of HIV/AIDs in sub-Saharan Africa, the country has no HIV/AIDS database that can be used to monitor, analyze, manage and control the spread of the disease. Health decisions can only be made with epidemiological data that is accurate and consistent. The control and management of a disease in any country, requires that the spatial and temporal rates and trends of the disease must be determined in order to gain insight into the geographic coverage and prevalence rate of the disease (Idowu, 2009).

Presently, in the sub-Saharan Africa region, there is no country that has a fully fledged HIV/AIDS surveillance system and a reliable or efficient way of capturing HIV/AIDS related data. In Nigeria, the only HIV/AIDS epidemiological data available is that of pregnant women obtained during ante-natal visits, but presently there are more people living with HIV/AIDS whose data are not on record. Therefore, no national database on HIV/AIDS is available. There is an increasing number of HIV/AIDS carriers in Nigeria by the day and a major reason for this is the absence of a fully fledged HIV/AIDS surveillance system that can collect data, analyze, and forecast HIV/AIDS in Nigeria. In order to accurately and efficiently monitor the prevalence rate of HIV/AIDS in any area in Nigeria, there is the need for a reliable and effective national HIV/AIDS national database and surveillance system.

In order to solve this problem of inconsistent and patchy HIV/AIDS data in Nigeria, this chapter presents a fully-fledged, effective and efficient web-based Geographical Information System for HIV/AIDS surveillance system which can be used to systematically capture health-related data. In order to develop this system, an existing HIV/AIDS disease surveillance data model designed for Nigeria was used. The surveillance system could be used in surveillance, monitoring and management of HIV/AIDS in Nigeria and it will also serve as a national HIV/AIDS database for Nigeria. With the system, data from everyone living with HIV/AIDS will be captured in order to make useful decisions, and provide information on the spatial location, and accurate statistics of people living with HIV/AIDS in the country, the most vulnerable age group, gender statistics, and mode of transmission. The carriers' biodata will also be on a national database, which will be used for surveillance, monitoring and prediction of HIV/AIDS in Nigeria.

BACKGROUND

This section of the chapter reviews the literature on some of the concepts. Section 2.1 discusses disease surveillance and commonly used methods in disease surveillance with the roles played by disease surveillance in the health sector. Section 2.2 provides information about state of health informatics in Nigeria. Section 2.3 discusses the origin of HIV/AIDS and gives some statistical information about HIV/AIDS globally. Section 2.4 focuses on HIV/AIDS in Nigeria and finally section 2.5 provides information about the existing health data models for Sub Saharan Africa and describes the strengths and limitations of the models.

Disease Surveillance

Disease surveillance describes the ongoing efforts directed to assess the health and disease status of a given population over a given period of time. It describes a system that provides useful information about disease status and sometimes it may imply that some form of directed action will be taken if the data show a disease prevalence or incidence above a certain threshold (Salman,2003).

Disease surveillance is a common terminology used by epidemiologists and it is often used interchangeably with disease monitoring. It is aimed at providing early detection and control of diseases. Disease surveillance systems will aid public health workers in providing useful information about diseases in a given location in order to discover the pattern of incidence in such a location which will eventually help in avoiding outbreaks of these diseases. Due to the movements of people and animals from one country of the world to another, diseases spread across geopolitical and international boundaries and this makes almost all the countries of the world vulnerable to these diseases. Though some developed countries have means of curbing and controlling diseases, most developing nations do not have records or information about the number of people living with these diseases in their country. While effective disease surveillance systems are important in all the countries of the world, they are currently lacking in most developing nations.

With a disease surveillance system, the health workers / physicians, in all the hospitals would be able to input patient information such as demographic data, diseases associated with each patient and information about the geographical location of each patient into the disease surveillance system. At the front end the epidemiologists, disease agents, policy makers and any other authorised users will be able to query, analyse, and view the distribution of the diseases, which will effectively help them to make useful decisions at any point in time.

Disease Surveillance Methods

In order to carry out disease surveillance effectively, specific methods must be employed. The following disease surveillance methods are the most commonly used (Harter *et al*, 1995; Disease Control Priorities Project, 2008):

1. **Sentinel Disease Surveillance:** This is a method whereby a small group of people are used as sample population for the entire population. In case of HIV/AIDS in Nigeria, the sentinel survey makes use of pregnant women that attend antenatal clinics. Sample reporting is a good way to use limited resources to monitor diseases in a particular location among selected population.

2. **Laboratory Based Surveillance:** This is used to detect and monitor infectious diseases. In the United States, the centres for Disease Control and Prevention maintain PulseNet, an Internet-based network of laboratories that make use of standard methods for identifying and reporting the genetic makeup of disease-causing agents. “DNA fingerprinting by pulsed field gel electrophoresis on disease bacteria isolated from humans and from suspected food using standardized equipments and methods is being performed by PulseNet participants” (Centre for Disease Control [CDC], 2006). PulseNet is moving to Asia, Latin America and the Pacific.
3. **Household Survey:** This can be used to monitor diseases if the surveys are consistent and repeated periodically. The survey allows certain households to be selected at random and the selected households will represent the whole population. Example includes the behavioural risk factor surveillance system in the United States (Disease Control Priorities Project, 2008).
4. **Integrated Disease Surveillance and Response (IDSR):** This collects communicable diseases data from both health facilities and laboratories. IDSR has several activities such as detecting, registering and confirming individual cases of disease, reporting the analysis used and feedback of data and preparing for the response to epidemics (Disease Control Priorities Project, 2008).

Roles of Disease Surveillance

A good disease surveillance system will require an electronic tool for collection of data that will be able to accurately synthesise, analyse and present data and information over time to health workers and stakeholders.

Disease surveillance systems play important roles in the health sector of both developed and developing nations (National Institute of Communicable Diseases, 2001) and some of the roles are:

1. **Early Detection of Epidemics:** The disease surveillance system when developed would allow the stakeholders to be able to quickly detect if a particular disease is becoming epidemic in a particular location so they could intervene. This would help Nigeria to reduce spread of diseases and the untimely death of citizens. In addition, by targeting support, it would assist in helping to prevent already overstretched health facilities from being overwhelmed - with the risk of collapse.
2. **Analysis and Interpretation of Data:** Analysis of the data and its interpretation would aid health workers to be able to identify and understand the spatial distribution of diseases so as to detect any location that might be a source of a disease epidemic. A disease surveillance system would help the country to be able to analyse and interpret the spread of any disease in line with organisational policy or depending upon the degree of danger such a disease can cause.
3. **Investigation and Confirmation of Cases/Outbreaks of Diseases:** With a disease surveillance system which would be developed using the proposed model, the spread of the disease can be easily identified. Health workers could investigate and confirm the reliability of the disease data from the disease surveillance system and take necessary action.
4. **Monitoring, and Controlling of Diseases:** A disease surveillance system would allow the health workers and stakeholders to be able to monitor the distribution pattern of any disease in Nigeria and control the disease as need arises.
5. **Planning and Allocation of Resources:** In order to plan and allocate health facilities in any country, there is a need to know what resources and facilities are required in all the locations in such a country. In Nigeria, with the disease surveillance system, the health ministry would be able to know

the type of health resources that are required in a location at a given period of time. Data from a disease surveillance system would aid in identifying areas that require additional health facilities such as hospitals. It would also be used to know where to deploy certain experts based on the type of diseases that are common in such a location.

6. **Estimated Magnitude of the Disease:** With the disease surveillance system, health workers would be able to know if a particular disease may likely become epidemic and take necessary intervention. For example, if in a local government area with population of 250,000, 5000 cases of cholera were recorded within one week, then there is a need to find out the root cause and take necessary action. But without a disease surveillance system it may be difficult to know the number of cases of this disease since a local government area comprises many towns and cities which are geographically separated from each other.
7. **Portray the Natural History of a Disease:** A disease surveillance system would also allow health workers to be able to have a history of disease in any location in the country. For example, if during the dry season, there are cases of cholera in a particular town, local government area or state, the stakeholder would have to be prepared to address what may cause a future occurrence.
8. **Determine Geographical Distribution of Diseases:** A disease surveillance system would allow the stakeholders to be able to view and query the distribution of diseases based on geographical location at a given period of time.

The main focus of this chapter is to present an effective disease surveillance and monitoring system for HIV/AIDS in Nigeria. Presently in Nigeria, there are almost no available epidemiological data to determine the geographical distribution of any diseases, most especially HIV/AIDS. The system was developed from an existing spatial disease surveillance data model for Nigeria.

Health Information System in Nigeria

Nigeria has one of the highest mortality rates in sub-Saharan Africa (WOCON, 2004), with a population of 140,003,542 (Nigerian Census, 2006) which is the highest in Africa but with an inadequate health care delivery system. According to Hyman & Silver in 2004 (Hyman & Silver, 2004), inadequate health care delivery gives birth to additional health risks, which means that the Nigerian population is highly vulnerable.

The history of health information systems in Nigeria started in the late 1980s when a collaborative research project between the Computing Centre of the University of Kuopio, Finland, the Obafemi Awolowo University, and the Obafemi Awolowo University teaching Hospital (OAUTHC), Nigeria (Idowu *et al*, 2003) was initiated and this initiative was part of INDEHELA (a long term research project on Informatics Development for Health in Africa details of which can be found at <http://www.uku.fi/indehela/>). The joint project produced a very rudimentary hospital information system based on the Veterans Administration's (VA) Admission Discharge Transfer, running on a stand-alone PC, which was in use at OAUTHC in 1991 (Daini *et al*, 1992). According to Daini *et al* in 1992, the group then organised the first International Working Conference on Health Informatics in Africa which was held on April 19-23, 1993 at Ile-Ife, Nigeria (Daini *et al*, 1992).

In the late 1990s, the Finnish / Nigerian research team decided to expand their rudimentary hospital information system with the aim of developing a comprehensive system suitable for use in all Nigerian teaching hospitals and medical centres. The plan then was that by 2001 all the teaching hospitals in

Nigeria would have Health Informatics Units which could make use of standardised software. In reality, though some hospitals have computer or IT units, these serve primarily to support word processing for typing pools and offices. Development of the commercial software 'Made in Nigeria Primary Healthcare and Hospital Information System' (MINPHIS) ran alongside the doctoral programme of one of the staff of the Department of Computer Science & Engineering, Obafemi Awolowo University, and was completed in 2004. Unfortunately, the system was not tested at OAUTHC and only five teaching hospitals and medical centres used the system as of 2007. The primary reason for this limited use is the cost of purchasing the commercial software. As the Finnish/Nigerian research team were working on a primary healthcare and hospital information system, a Norwegian and South African team focused on a district-level information management system (Anja, 2002).

Although there are other software packages developed for hospital use in Nigeria, most of this software is developed by researchers in Nigeria who identified the need for an electronic information system in the Nigerian hospitals, but almost all this software was never put into use. In 2003, the State Hospital Network known as SHONET was developed for sharing of hospital resources over the computer network in Nigeria. The philosophy behind the development of SHONET was to minimize the cost of running state hospitals; hospital resources such as personnel, laboratory and equipment would be distributed to various zones in the state. The allocation of the resources depend on the diseases that are common in the zone and whenever there is need for any of those resources in another zone within the system, the hospital equipment can then be allocated over the network (Idowu *et al*, 2003).

In 2004, another system was developed at the Department of Computer Science & Engineering, Obafemi Awolowo University, Nigeria. The system was developed for referral of patients from one hospital to another such that a patient's case file, referral note and medical examination result that were usually transferred manually from one hospital to another could be transferred over a computer network (Idowu *et al*, 2004). Of all this software, only MINPHIS is being used in a very few teaching hospitals in Nigeria.

HIV/AIDS

Human Immunodeficiency Virus (HIV) is the infectious agent that causes Acquired Immune Deficiency Syndrome (AIDS). AIDS is a set of symptoms and infections that result from the damage to the human immune system caused by HIV (Weiss, 1993). The origin of the virus has always been controversial; some claimed it originated from Africa whereas others claimed it originated from the United States of America (USA), however the first recognised cases of AIDS occurred in the USA in the early 1980s. "A number of gay men in New York and California suddenly developed rare opportunistic infections that seemed stubbornly resistant to treatment" (Chandra, 2008). By this time, AIDS did not yet have a name but it was discovered that all these men were suffering from the same syndrome. Shortly after this, the discovery of HIV was made (Chandra, 2008).

Human Immunodeficiency Virus and Acquired Immunodeficiency Syndrome (HIV/AIDS) has claimed well over 25 million lives. Almost 40 million people are living with the virus worldwide (UNAIDS, 2006) with an additional two million people yearly and more than one quarter are young people (WHO, 2006). HIV/AIDS is most commonly found in developing nations, to be specific sub-Saharan Africa. Sub-Saharan Africa hosts almost 65% of the world's HIV/AIDS population and almost 70% of people living with HIV/AIDS in this region are between the ages of 14- 49 years. Females are in the majority of people living with HIV/AIDS in sub-Saharan Africa. Worldwide, as at 2005, Swaziland has the highest prevalence rate and South Africa has about 5.5 million people living with HIV/AIDS (UNAIDS, 2006).

HIV/AIDS has reduced the life expectancy of the people mostly affected by over 20 years, increased their poverty level, and reduced the economic growth of their countries, which are mostly developing nations (UNAIDS, 2008). In Asia, where the infection rate is slightly lower than Africa, HIV/AIDS has led to greater loss of productivity than any other disease and is increasing the poverty level of the continent. It is predicted that by 2015, an additional six million households will be pushed into poverty if there is no quick response (Commission on AIDS in Asia, 2008).

According to UNAIDS/WHO (WHO/UNAIDS, 2008), more than 25 million people have died globally as a result of AIDS since 1981 and Africa alone has 11.6 million AIDS orphans. At the end of 2007, women accounted for 50% of all adults living with HIV worldwide and 59% of these women are from sub-Saharan Africa. People under the age of 25 account for half of the new HIV infections worldwide. Table 2.1 below gives the summary of the latest statistics of global HIV/AIDS estimates and Table 2.2 gives the regional statistics for HIV/AIDS as at end of 2007. Also globally during 2007, 2.7 million adults and children became infected with HIV. By the end of 2007, an estimated 33 million people were living with the HIV/AIDS virus globally as shown in Figure 1 and the year 2007 also saw two million deaths from AIDS.

Sub-Saharan Africa remains the region most heavily affected by HIV, accounting for 67% of all people living with HIV and for 75% of AIDS deaths in 2007. Almost all the countries in this region have a reliable means of epidemiological data collection. This necessitates the need for disease surveillance and monitoring system in Nigeria, which is the focus of this chapter. Figure 2 depicts the HIV prevalence rate

Figure 1. Global view of HIV infection as at end of 2007

Source: World Health Organisation/Joint United Nations Programme on HIV/AIDS

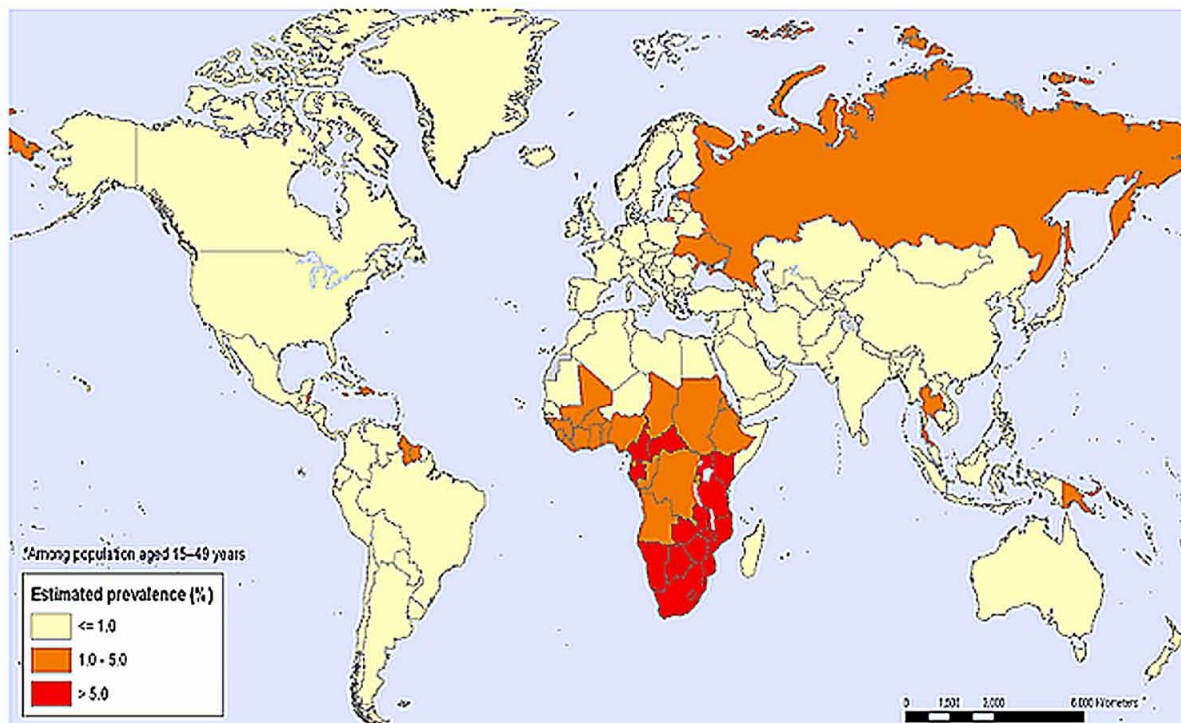

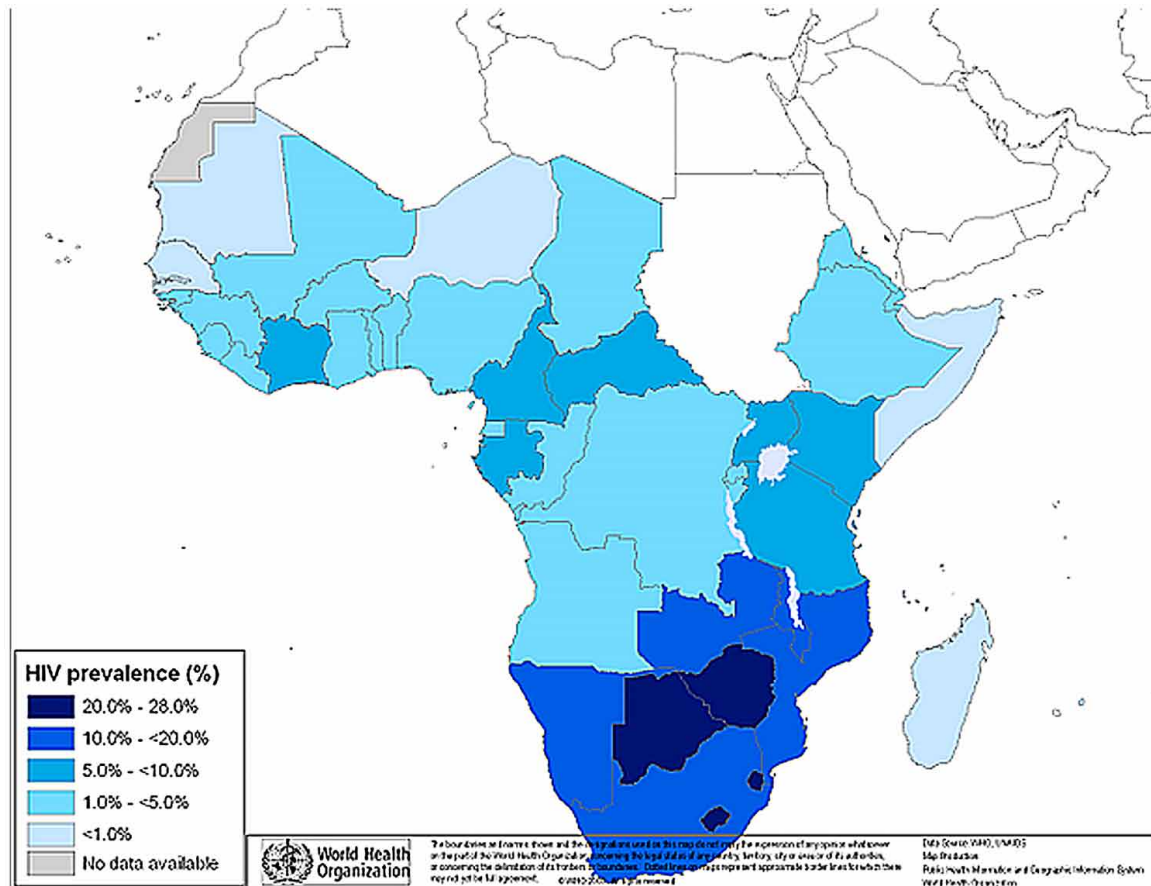

Figure 2. HIV prevalence (%) in adults in sub-Saharan Africa

Source: World Health Organisation/Joint United Nations Programme on HIV/AIDS

among adults in sub-Saharan Africa. The data used for mapping of HIV/AIDS in sub-Saharan Africa is based on sentinel surveillance. With the proposed data model, the development of a disease surveillance system would be possible.

However, some of the most worrisome increases in new infections are now occurring in populous countries in other regions such as Indonesia, the Russian Federation and various high-income countries. Globally, the percentage of women among people living with HIV has remained stable at 50% for many years, although women's share of infections is increasing in many countries (UNAIDS, 2007). Although it is quite difficult to know who the first person to be infected with HIV was, or how it spread from that person, the reality is that HIV/AIDS is now a deadly disease which has posed a lot of challenges to scientists all over the world.

HIV/AIDS in Nigeria

HIV/AIDS is one of the most rapidly increasing epidemics in Nigeria. It is quite difficult to give an accurate number of people living with HIV/AIDS in Nigeria because there is no mechanism to determine the number of people living with HIV/AIDS in the country. However, UNAIDS estimate that almost

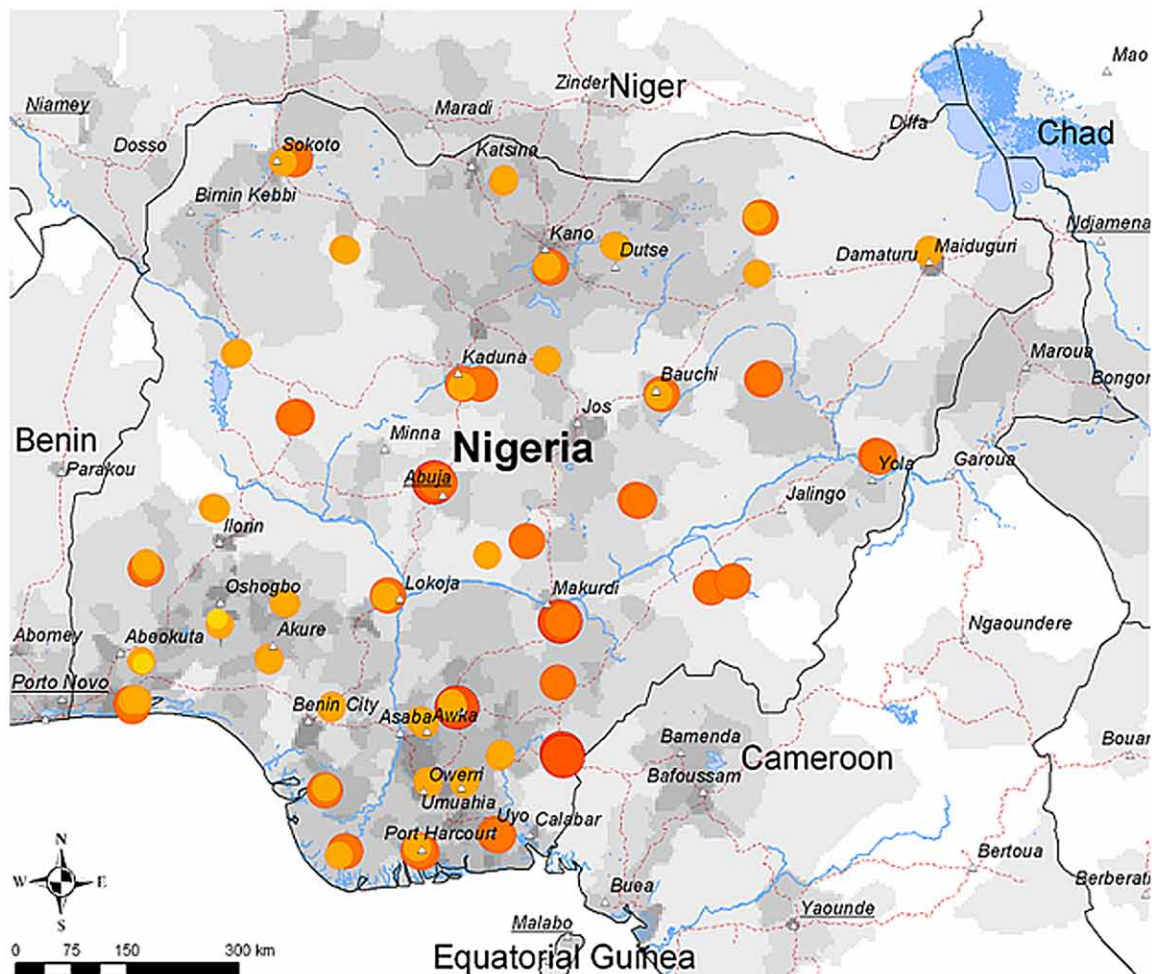

3.1 percent of adults between the ages of 15-49 are living with HIV/AIDS (WHO/UNAIDS, 2008). Although the Nigeria HIV/AIDS prevalence rate has reduced, the country still has the highest number of people living with HIV/AIDS in Africa (Utulu & Lawoyin, 2007). It was estimated that by the end of 2007 over 2, 600 people were infected with HIV/AIDS (WHO/UNAIDS, 2008).

More than 400,000 people died from AIDS in 2007 in Nigeria and women formed the majority of victims of this disease (Nigeria Tribune, 2008). The present means of HIV/AIDS data collection in Nigeria is based on sentinel surveillance among pregnant women and Figure 3 depicts the sentinel surveillance conducted among pregnant women between 2002 and 2006. This sentinel method of HIV/AIDS data collection is inefficient and cannot give an accurate estimate of people living with HIV/AIDS in Nigeria. So, in order to solve this problem, a disease surveillance system was developed to capture all required disease data, especially HIV/AIDS, and the location of people living with those diseases.

HIV/AIDS continues to be the most significant contributor to public health problems in Nigeria. HIV/AIDS has led to a decline in the life expectancy of Nigerians as it has done in other countries with high

Figure 3. HIV sentinel surveillance in pregnant Nigerian women

Source: World Health Organisation/Joint United Nations Programme on HIV/AIDS

prevalence rates of HIV/AIDS. The average life expectancy of Nigerian women reduced from 53.8 years to 46 years and men from 52.6 years to 47 years from 1991 to 1999 (WHO/UNAIDS, 2008). Nigeria is the 12th largest world producer of oil and the largest country in Africa, yet the poverty level of the country continues to increase. Nigeria is ranked 158th out of 177 on the United Nations Development Programme (UNDP) human poverty index (UNDP, 2008). These deadly diseases, especially HIV/AIDS, are one of the major contributors to this problem of poverty.

The first case of HIV/AIDS in Nigeria was identified in 1985 and was reported at an international AIDS conference in 1986 (Adeyi & Kanki, 2006). In 1987, the Nigerian health sector established the National AIDS Advisory Committee which was later followed by the establishment of the National Expert Advisory Committee on AIDS (NEACA). In 2001, the Nigerian government, under the leadership of President Olusegun Obasanjo established the President's Committee on AIDS and the National Action Committee on AIDS (NACA), and set up a three year HIV/AIDS Emergency Action Plan (HEAP) as well as hosting the organisation of African Unity's first African Summit on HIV/AIDS, Tuberculosis and other related infectious diseases (Adeyi & Kanki, 2006) in order to track the epidemic. The National Action Committee on AIDS (NACA), whose name was later changed to the National Agency for the Control of AIDS, emphasizes a multi-sectorial approach to AIDS and membership includes representatives from the Ministries, the private sector, non governmental organisations (NGOs) and networks of people living with HIV/AIDS. The State Agency Control of AIDS (SACA) and Local Agency Control of AIDS (LACA) were also formed to spread the local multi-sectorial response to HIV/AIDS.

Almost 80% of the HIV infections in Nigeria are transmitted through heterosexual sex, and 10% are through blood transfusions (Avert, 2008). Other means of transmission include mother-child transmission. In 2005, it was estimated that 220,000 children were living with HIV, and almost all of them were infected through their mothers (WHO/UNAIDS, 2008). The spread of HIV/AIDS in Nigeria does not exclude the Nigerian military. In recent developments in the last five years, no less than 94,000 cases of HIV/AIDS were reported in 24 medical military centres (Nigeria Tribune, 2008). The spread of HIV/AIDS among the military may be due to the fact that they are often not transferred from a particular location to another. The factors that contribute to the spread of HIV/AIDS in Nigeria are:

1. **Lack of Sex Education:** In Nigeria, sex is a private issue and its discussion is seen as inappropriate among teenagers. This has been a major barrier to reducing HIV and other sexually transmitted diseases in the country. According to UNAIDS in 2006 (UNAIDS, 2006), only 18% of women and 21% of men between the ages of 15 and 24 can correctly identify ways to prevent HIV transmission.
2. **Lack of Voluntary and Routine HIV Test:** According to WHO in 2007 (WHO, UNAIDS & UNICEF, 2007), only 6% of women, 14% of men and 1% of pregnant women were tested for HIV/AIDS. Moreover, in developed nations most people living with HIV/AIDS are not aware they are HIV/AIDS-positive (Williams, 2008). So in a country like Nigeria, with a high prevalence rate of HIV/AIDS, there is a greater need for people to be tested so as to ascertain their HIV/AIDS status in order to minimise the spread of the disease.
3. **Poor Health Facilities:** Most cities and towns in the country lack basic healthcare facilities and this makes it difficult to establish testing and prevention services. The hospitals that are capable of providing testing, contraception and treatment for sexually transmitted disease are few and the existing health facilities in these hospitals are inadequate.

4. **Poverty:** Poverty is another major cause of HIV/AIDS in Nigeria because, if the sex workers were gainfully employed in other professions, they might not resort to commercial sex, which is a significant cause of the spread of HIV in the country (Oyefara, 2005; Achebe, 2004).
5. **Lack of a Disease Surveillance System:** In Nigeria, there is almost no existing disease surveillance system in place and that is the focus of this thesis. If there were a disease surveillance system, the health workers would be able to monitor the spread and location of these diseases and intervene with the limited available resources. With this proposed disease surveillance data model, the development of a disease surveillance system will be possible and the health workers will be more able to monitor and manage the spread of HIV/AIDS and any other diseases in the country. Though the cost implications of disease surveillance may be high, in the long run it will minimise the cost of providing health services in the country.

Health Data Model

In order to develop a good public health system, there is a need for a reliable and efficient public health data model. A data model may be defined as a formal structured representation of real world entities. This representation is often focused on the definition of an object and its associated attributes (Business Intelligence Solution, 2004). It is neither a knowledge representation model nor a model representing processes. This type of model is most useful in identifying the data to be captured. It is an important area in the field of public health.

A health data model may be defined as the representation of subjects and their features within the health domain. There are two existing health data models for sub-Saharan African (SSA) nations namely the AMPATH Medical Record System Data Model (AMRS) and the Conceptual Data Model for Diseases Surveillance, Monitoring and Prediction in Nigeria (DSMPN). In this chapter DSMPN was used to develop the spatial HIV/AIDS surveillance and monitoring system for Nigeria.

Existing Health Data Models in SSA

1. Academic Model for Providing Access To Healthcare (AMPATH) Medical Record System Data Model

The AMPATH Medical Record System (AMRS) data model was developed in response to the need to address the growing number of people suffering and dying from HIV/AIDS in Kenya. In 2001, the partnership between Indiana University School and Moi University School of Medicine, Eldoret, Kenya led to the development of the Mosoriot Medical Record System (MMRS) which was adopted to serve as an HIV/AIDS database.

In 2003, WHO, USAIDS and other international organisations asked the developers to scale down the database to meet the needs of AMPATH and this led to the AMRS data model (Mamlin & Biondich, 2005). The aim of this data model is to meet the immediate need for an electronic medical record system to help scale up HIV/AIDS prevention and treatment. In addition, it aims to reduce critical human errors and support the research necessary to guide future efforts.

The strength of this model is that the model is already implemented using MySQL, Plone and Python; and the model makes use of coded data so as to allow both flexibility and scalability. One of the limitations of the model is that it only covers HIV/AIDS surveillance and focuses on Kenya alone, which

is what the model was developed for (see Table 2.1). The model also lacks spatial and environmental features, which makes it difficult to adopt elsewhere.

ii. Conceptual Data Model for Disease Surveillance, Monitoring and Prediction in Nigeria (DSMPN)

This model (DSMPN) was developed as a means of having a HIV/AIDS surveillance system that could be used for surveillance and monitoring of HIV/AIDS in Nigeria. The aims of the research according to Idowu (2010) were to identify and document the detailed information needed in order to develop an effective disease surveillance and monitoring system. It was also meant to enhance the existing health data model by providing support for flexible spatial data.

The model comprises three core components or subject areas, which provide required data for the development of the disease surveillance database. The components are party, location and health activity. The strength of the model is its spatial feature, which is not clear in any of the existing health data models. A major limitation of the model is its inability to cover environmental features.

Existing Disease Surveillance System

There are several disease surveillance systems and HIV/AIDS surveillance systems. Two disease surveillance systems and three HIV/AIDS-related surveillance systems are discussed below.

i. National Electronic Disease Surveillance System (NEDSS)

The National Electronic Disease Surveillance System (NEDSS) is a Surveillance System developed by the Centers for Disease Control and Prevention (CDC) and implemented across the United States of America, NEDSS is a system to improve the public health monitoring of diseases. NEDSS is a secure online framework that allows healthcare professionals and government agencies to communicate about disease patterns and coordinate a national response to outbreaks. This Disease Surveillance System was developed based on a framework/architecture that includes software, hardware, databases, data format standards and the internet (Gianfranco, 2001).

NEDSS is not an actual surveillance system in the traditional sense of the word. Rather, it is an internet-based system that, according to the CDC, will “electronically integrate and link together a wide variety of surveillance activities and will facilitate more accurate and timely reporting of disease information to CDC and state and local health departments” (CDC, 2011).

NEDSS aims to improve timeliness by establishing electronic reporting systems, which will hopefully reduce the reporting burden for many health care providers. It also aims to make surveillance data more accessible to health officials by having a central system for storing and accessing data. This is a monumental task, and many years and dollars have been invested in accomplishing it. The enormity of the task is due in part to the variety of data types and sources that make up the existing surveillance systems. Also, due to the use of the internet for reporting, it is necessary to develop specific security measures to address the confidentiality issues inherent in transmitting sensitive health information electronically. Conveniently, NEDSS provides users with the ability to query the data for surveillance purposes.

The system was created to bring about the sequential replacement and integration of existing stand-alone public health surveillance systems with a distributed system that is architecturally based on de-facto industry standards intended to simplify public health surveillance processes and to add additional

functionality that is not provided by the current systems. The primary aim of the system is a streamlined disease data collection, analysis, and reporting process. This process will improve the reporting timeliness, improved accessibility and availability of data, improve the efficiency of the system and give a better understanding and documentation of the processes used in surveillance. NEDSS focuses mainly on Infectious diseases, HIV/AIDS and STD, Tuberculosis and Immunizations.

In legacy systems, systems have been isolated from one another due to their different data standards, patient's privacy concerns, lack of tools for proper information exchange etc. Health departments received most of the public health data by mail and then transferred the data on the documents into the computer databases. These data transfers often occurred a long time after the disease incidence was first reported. Many of the diseases were under-reported, inaccurately recorded and not even properly documented for analysis. This motivated the need for a system that would integrate public health surveillance systems data, and process them in a secure environment. The system was then made up of five components:

1. Web-based modules that allow easy online entry and management of data sets, including demographic and disease data
2. A Web application server called Silverstream that supports these Web-based modules
3. An integrated database management system
4. Messaging software that allows electronic data interchange between state agencies and the CDC or state laboratories
5. Intranet-based authentication and authorization for security that is fully compliant with HIPAA regulations.

ii. National Notifiable Diseases Surveillance System (NNDSS)

The National Notifiable Diseases Surveillance System (NNDSS) was established by the Communicable Diseases Network Australia in 1990. The system coordinates the national surveillance of more than 50 communicable diseases. In this system, health reports are made to the state or territory health authority. The health data reported includes the record reference number, the state, disease code, the date of onset, date of notification to the relevant health authority, sex, age, indigenous status and postcode of residence. Generally, the notifiable diseases are reported electronically, but in some cases reports may still be made on paper forms that are submitted at the local level, compiled, and then reported to the state. Each state reports the number of notifiable diseases that occur to the CDC each week (North Carolina, 2012).

The quality and completeness of data compiled in the National Notifiable Diseases Surveillance System are influenced by various factors. Notification may be required from physicians, diagnostic laboratories or hospitals. The mechanism of notification of a particular disease may differ between states and territories. The proportion of cases seen by health care workers which are the subject of notification to health authorities is not known with certainty for any disease, and it may vary among diseases, between states or territories and over time.

iii. Unified Web-Based National HIV/AIDS Information System in China

The unified web-based national HIV/AIDS information system in China is a system that provides real time data to monitor HIV/AIDS by prevention and treatment program across China. It improved the efficiency of data collection, reports, analysis and use, as well as data quality and security. It is a powerful tool for a national HIV/AIDS program and this may serve as model for other countries (Yurong Mao *et*

al, 2010). Although the system is a web-based application, it does not have spatial features which make it different from the system developed from Nigeria. With spatial features, the system would allow spatial queries of the spread of the disease in any location.

iv. Integrating HIV/AIDS Surveillance into a Web-Based System That Includes Electronic Laboratory Reporting to Improve Case Reporting and Monitoring of HIV Care and Treatment Status

The integration of HIV/AIDS case surveillance into the TriSano system allowed Electronic Laboratory Reporting (ELR) to obtain laboratory information on cases. Data exports from TriSano were obtained for the evaluation of HIV and ELR. The initial evaluation included all reported laboratory results entered into TriSano during 2013, tabulated by disease, and included whether the lab results were entered manually or via ELR. Due to ELR being implemented in August 2013, another dataset containing only the laboratory results from the last third of 2013 was obtained. Analysis included cross-tabulation of the lab results entered and also the number of events created either manually or by ELR. These data support the benefits of integrating HIV/AIDs case surveillance into the TriSano system and the resulting improvements in completeness and timeliness of HIV/AIDS data because of ELR. These changes in the HIV/AIDS surveillance will improve our ability to monitor retention-in-care (Mietchen *et al*, 2014). The system is a web-based application but with some limitations, namely, it focuses on electronic laboratory reporting and it does not allow for queries based on people living with HIV/AIDS in a particular location.

v. Web-Based HIV/AIDS Behavioral Surveillance Among Men Who Have Sex with Men: Potential and Challenges

With more men who have sex with men (MSM) seeking sexual partners through the internet, the internet has been characterized as a newly emerging risk environment for HIV transmission. Meanwhile, the flourishing of gay websites provides a good opportunity for health professionals to conduct systematic HIV/AIDS behavioral surveillance among MSM. Effective methods to recruit online MSM users have been developed, and online surveys have suggested many practical advantages over surveys in the traditional gay community. Although surveys among MSM via the internet have a few limitations and risks, online surveillance can still be viewed as a feasible and convenient approach, especially in countries where the HIV/AIDS epidemic is concentrated in high-risk populations and where the conducting of such surveillance in traditional gay venues is difficult. This system is not actually an HIV/AIDS tracking system but HIV/AIDS behaviour surveillance system among gay men (Zhang *et al*, 2008) and the system lacks spatial features which is the major contribution of the system developed as described below.

METHODS

In order to develop the surveillance and monitoring system, Conceptual Data Model for Disease Surveillance, Monitoring and Prediction in Nigeria, (DSMPN) was used and the database developed using MySQL. In the process of developing the HIV/AIDS disease surveillance and monitoring database, different tables, files, records and fields were created. The MySQL in wampserver was used to create and populate the database.

The system was implemented using Dreamweaver, and PHP. Apache was used as the server to provide basic functionality of the web GIS. PHP was used as a scripting language to program the server side that manipulates the knowledge in the database. The web-based spatial HIV/AIDS surveillance and monitoring system (HSMS) for Nigeria was implemented on the HSMS architecture.

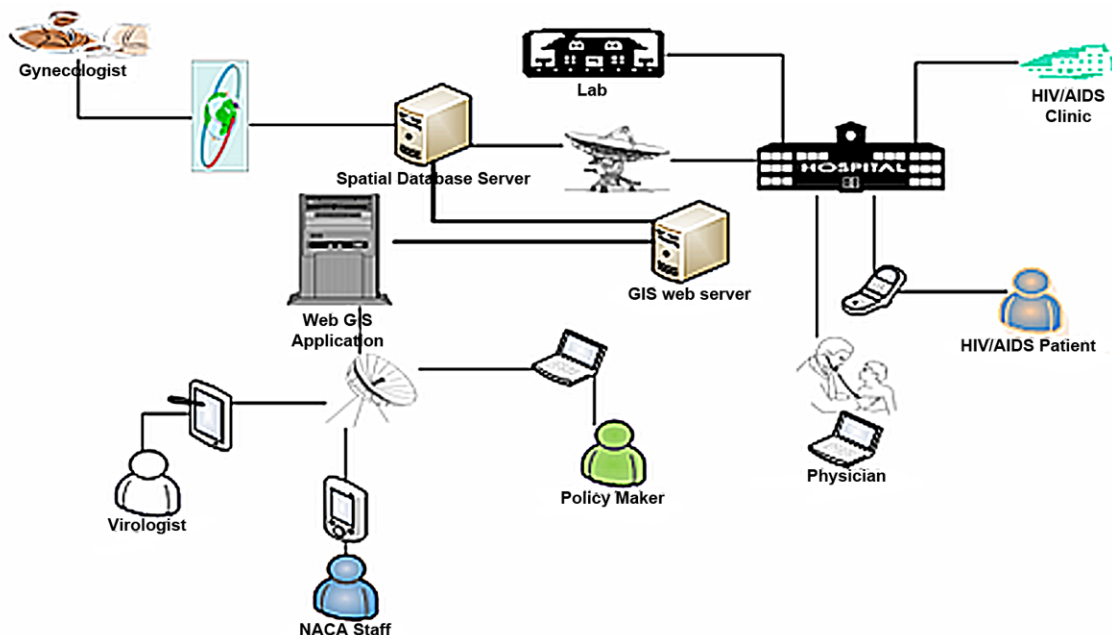

System Architecture

In the design of any system related to surveillance or tracking, there is a need for system architecture. In the HSMS, the design of the system needs to be easy, flexible and portable as much as possible. This allows users to be able to make use of portable computers, desktop computers, and mobile phones as web browsers to access the system. In this chapter, client-server system architecture is used and it is a thin client-server. The spatial HIV/AIDS surveillance and monitoring system has two components, namely, the server-side and client-side that run on the browser.

The system was modelled using client-server architecture. In the client approach, almost all the processing work was done on demand at the server end and the client task was to display data and information on the screen. In thin client-server architecture, the web browser is the client. This architecture was used because users would not be required to install any software on their systems except a standard web browser, which often comes with most computer operating systems and almost all the current standard mobile phones.

Clients would also not require any powerful computer systems; users could use any computer with a web browser such as laptop/notebook, mobile phone, and desktop computer systems. The servers would require a higher configuration (in terms of hardware) computer system because it would be regularly subjected to a heavy load. These would be the HTTP server, database server and webGIS server. Figure 4 below depicts the spatial HIV/AIDS surveillance and monitoring system architecture.

Figure 4. System Architecture of the HIV/AIDS Disease Surveillance and Monitoring System

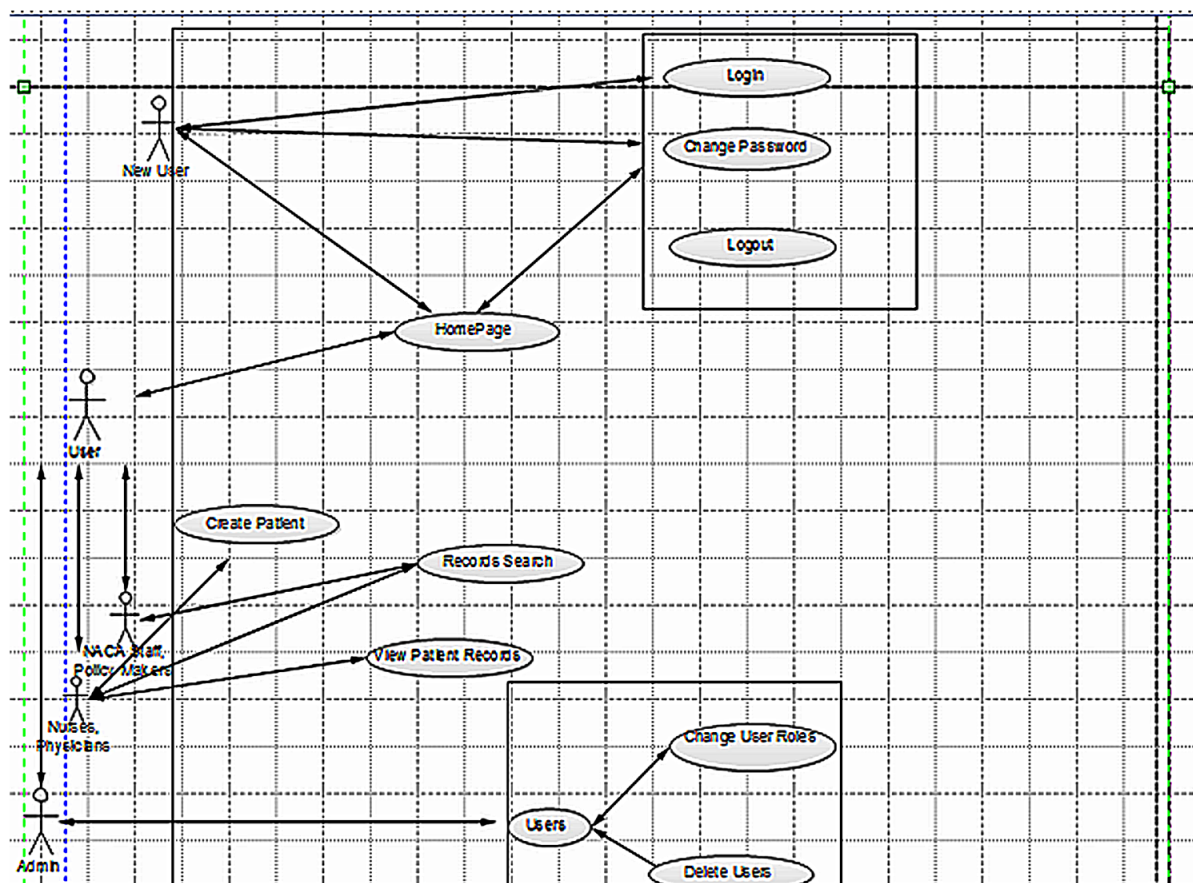

Use Case Diagram for HSMS

The use case diagram is used in presenting the system requirements of any proposed system. A use case is a realistic description of the workflow of the system and is used to explicitly describe the intentions and actions of users, i.e. to show how the proposed system works in practice. The interaction between actor and use cases is also described using the use case diagram. The use case diagrams of the spatial HIV/AIDS disease surveillance and monitoring system are shown in Figure 5.

The use case diagrams show how data will be entered and viewed from the spatial HIV/AIDS disease surveillance and monitoring system. Virologists and other stakeholders would be able to query any HIV/AIDS data based on any location in the country. Also, the virologists and other stakeholders would be able to capture and analyse all HIV/AIDS data of entire streets in the specified location into the health information system or national HIV/AIDS database. The online monitoring and tracking of HIV/AIDS status of all locations in Nigeria would also be possible. As a result, the system is capable of monitoring diseases that are paramount in a particular area.

Policy makers would also be able to view the HIV/AIDS status of any state, local government area, city/town, ward and street in the study area. Any authorised international organizations and non-gov-

Figure 5. Use case diagram for HIV/AIDS Surveillance and Monitoring System for Nigeria

environmental organizations would also be able to view the state of environmental health of any location in the study area and channel any health assistance to the appropriate location.

IMPLEMENTATION OF THE DSMS

User Interface Design

The user interface allows the user to navigate the surveillance and monitoring system and communicate with the database. The system design is simple enough for use by anyone with little knowledge of computing and since the targeted end users are virologists, physicians and other hospital staff in the study area, the system is user-friendly and made easy to use through the use of windows, interface menu and pointing devices (WIMP) which is very important in computer graphics design and architecture. Figures 6 and 7 depict the user interface which allows authorised users login into the system.

Figure 6. Homepage for HIV/AIDS Disease Surveillance and Monitoring System

Figure 7. Login Menu for HIV/AIDS Disease Surveillance and Monitoring System

Data Collection Menu

The Registration/data collection screen which is depicted in Figure 8 is used to capture the entire data of HIV/AIDS patients. It is categorized into sections namely the Bio-data, Personal Information, Contact Information, Other information, Work information, Relationship details, Health Diagnosis and Treatment. Each Section of this data registration captures its own specific patient records. This section allows users to capture information about an HIV/AIDS patient. It stores information about the general health of the patient. In this menu, the health officers and any other authorized users can log on to the HIV/AIDS surveillance application and add, edit and manipulate the data, while the external users such as the policy makers, NACA staff can only view the information.

Bio-data Menu

The Bio-data section captures the personal data of the HIV/AIDS patients. The data captured in this section includes the Title e.g. Mr, Miss, Dr etc, FirstName which captures the first name of the patient, the MiddleName captures the other name of the patient and the Surname captures the family name of the patient. The Bio-data section also captures the Date of Birth of the patient which in turn gives the age of the patient; the Marital Status captures the status of the patient which is susceptible to change. Also Gender, in this section of the bio-data, captures the sex of the patient. This information is obtained from the HIV/AIDS patient in confidence. The information captured on this screen is mostly contained in the party component with sub-classes such as the PersonName which contains information about the patient's Title, FirstName, MiddleName, Surname etc and this is depicted in Figure 9 below.

Figure 8. Data Collection Menu

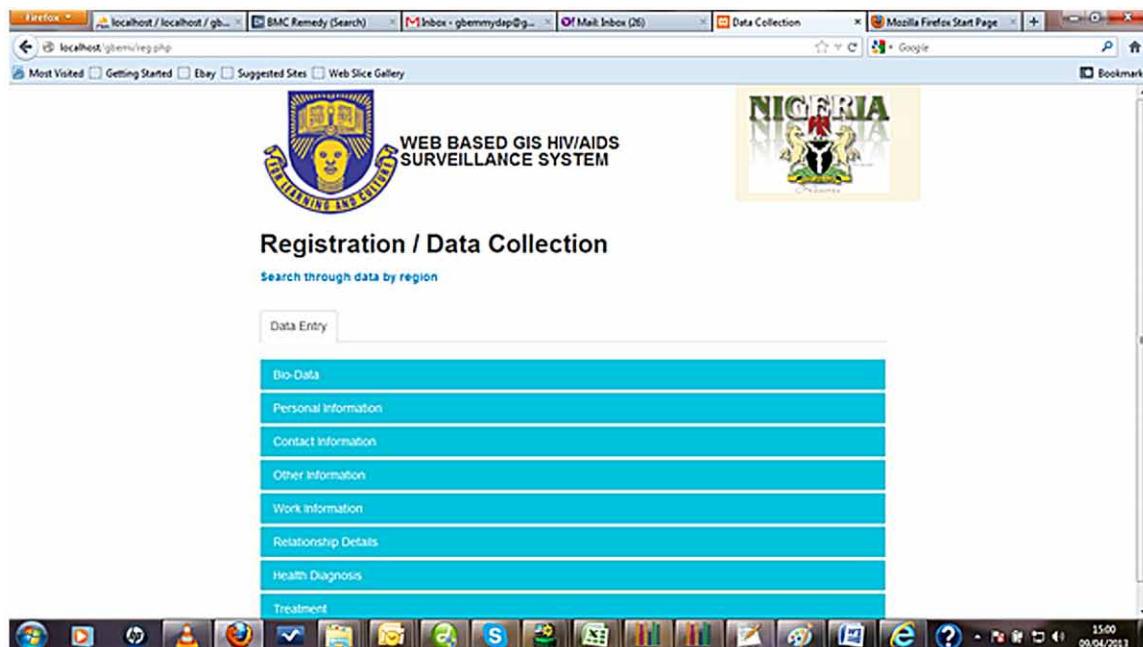

Figure 9. Bio-Data Menu

The screenshot shows a web form titled "Bio-Data" within a system interface. The form has a light blue background and is bordered by a darker blue header and footer. The header contains the text "Bio-Data" in white. The form itself contains several labeled input fields: "Title:" with a dropdown menu showing "Mr."; "FirstName:" with a text box containing "John"; "MiddleName:" with a text box containing "Alexander"; "Surname:" with a text box containing "Sawyer"; "Date Of Birth:" with a text box containing "12/03/1976"; "Marital Status:" with a dropdown menu showing "Married"; and "Gender:" with a dropdown menu showing "Male". A small "Next" button is located at the bottom left of the form area. The footer of the form area contains the text "Personal Information" in white.

Personal Information Menu

The Personal Information Section is for capturing the personal details of an HIV/AIDS patient and this is depicted in Figure 10. The section captures the education level of the patient, patient's occupation or profession, and religion. The ethnic group describes the ethnicity of the patient; the phone number captures the telephone contact details of the patient, the email address and website of the patient. Identification captures the valid means of identification of the patient and the identification number on the card. Also, the location of the patient is used to capture information about the geographical location of the patient. The information captured in this section comprises party and location components and subclasses such as the party holds patients education, occupation etc, PersonIdentifier contains information about means of identification and the ID Number, current PersonContactDetails subclass holds the email, telephone number and website and address and LocationRelationship gives the location of the patient during a particular period of time.

Contact Details Menu

The contact details screen is used to capture the contact details of a patient such as the house number of the patient, the street number, the city or town, the local government area, and the state in which the patient resides. The nationality of the patient is also captured to provide information on the number of non-citizens residing in Nigeria that are infected with HIV/AIDS, as depicted in Figure 11 below. The postal address of the patient is also captured. This form allows the contact details of HIV/AIDS patients to be captured extensively for proper and efficient monitoring and surveillance of HIV/AIDS in the different locations. This Contact Information form also comprises party and location components. The

Other Information

PartyLocation, Address and LocationRelationship subclasses capture the HouseNumber, StreetName, City/Town, LocalGovt, State, Nationality and the PostalCode of the patient. The location component is important in this HIV/AIDS Surveillance system because the occurrence of HIV/AIDS will be determined based on locations in Nigeria. Also, the surveillance and monitoring of the disease will be carried out based on locations.

Other Information Menu

The Other Information section captures additional information about the patient as depicted in Figure 12. This information includes the blood group and genotype of the patient. Also the section captures the history of any previous ailment/disease that the patient might have had. Any history of HIV/AIDS infection within the family will also be captured to realize imminent threats within the family. This form also accepts comments on the health related information about the patient. This form represents the party and Health Activity components of the data model. The Contact Information form also comprises the party and location components. The PartyLocation, Address and LocationRelationship subclasses capture the HouseNumber, StreetName, City/Town, LocalGovt, State, Nationality and the PostalCode of the patient.

Work Information Menu

This section captures work-related information to analyze the risk other colleagues at work are exposed to due to sexual relations or handling of instruments that can transmit HIV. This is depicted in Figure 13. The data captured in this section include the occupation of the patient, the office address, the city or town where the office is located, the local government area where the office is located, the state where the office is located and the duration of stay in the office. These records are obtained from the patient to

obtain work related information about the HIV/AIDS patient. The Work Information form also comprises the party and location components. The PartyLocation, Address and LocationRelationship subclasses capture the Occupation, OfficeAddress, City/Town, LocalGovt, State and the Duration the patient has been working in that particular location. This form gives the flexibility to users to query based on a particular occupation to know the total number of HIV/AIDS infected people within a profession and organization.

Relationship Details Menu

The relationship details section captures information about the patient's relationship status; this is depicted in Figure 14. The name of the patient's next of kin is captured, as well as the form of relationship with the next of kin. The total number of dependants the patient has will also be captured. If married, the total number of spouses will be determined, and in addition, the total number of active sexual partners will be captured to determine the level of risk posed by the patient through sexual transmission of the disease. The protection status of the patient will be ascertained so as to identify the risk of exposing others to infection. Also the spread control technique used by the patient should be known when relating or having sexual relations with uninfected partners.

Health Diagnosis Menu

The health diagnosis section captures the disease diagnosis and this is depicted in Figure 15. The date of diagnosis is the starting date of observation and the confirmation date is the date of the disease confirmation, usually after the observation date. The disease method description is the method by which the

Test Type: Blood Sample

Result Status Description:

Test Description:

Test Result Date: 12/03/2012

disease was confirmed in the patient. The disease status captures the status of the disease, and the stage which the disease has reached. The disease type represents the type of disease. The result type captures the description of the type of result and the test description specifies the description of the test taken by the patient. The test result date captures the date at which the test result is received. The Health Diagnosis

Information form also represents the Health Activity component. The Diagnosis subclass captures the DiseaseType, DiseaseDescription, DiseaseStatus, DiseaseDetectionMethod, DiseaseConfirmationDate and the Test subclass captures the ResultStatus TestDescription, ResultTypeCode and TestResultStatusDate.

Treatment Record Menu

The Treatment Details section captures the form of treatment undertaken by the HIV/AIDS patient and this is depicted in Figure 16. The access to antiretroviral (ARV) treatment is captured. This section captures the last treatment date of the patient, the type of treatment administered to the patient; also, the form of improvement noticed by the patient is recorded to know if progress is made in the administration of the treatment. The cost of treatment incurred by the patient over a period of time is also captured as well as the time interval between treatments. The Treatment Information form also includes the Health Activity component. The Treatment subclass contains TreatmentType, TreatmentDate, TreatCost and TreatmentInterval. The treatment subclass gives the flexibility to know the access to treatments and availability of antiretrovirals.

View Report Analysis by Region and Search Results Menu

The View Report Analysis by Region module of the HIV/AIDS disease surveillance system is used to query for the HIV/AIDS statistics in a particular region, and this is depicted in Figure 17. The map of Nigeria with all the 36 states is displayed for the user to select a particular state. The user clicks on a state and selects a particular local government to view the reports.

The Search Result module, which is depicted in Figure 18, is used to query the database for the records of HIV/AIDS patients captured for the purpose of analysis, monitoring, evaluation and surveillance of the disease. The data can be queried based on some criterion e.g. gender, which can be used to obtain the

records of HIV/AIDS patients that are either male or female within a particular location. Occupation can also be used as a search criterion; this selects records of people that are within a particular profession. The Education Level is also used as a criterion to spool the records of people that fall within a particular educational level in a particular geographical location.

DISCUSSION

The HIV/AIDS disease surveillance system was developed based on the adopted data model to capture comprehensive information about HIV/AIDS patients which will help monitor the spread of the disease and provide a national health database for Nigeria for monitoring and surveillance of diseases. This will also help in predicting and forecasting the distribution, pattern and prevalence rate of HIV/AIDS in Nigeria. The system will allow users to be able to spatially query any location in Nigeria. The system will be used to generate reports in any format based on query parameters for analysis and decision making. The HIV/AIDS disease surveillance system will go a long way in providing a healthcare advantage to Nigeria ahead of other sub-Saharan African countries.

With this HIV/AIDS surveillance system, health policy makers, disease agents or any authorized users would be able to login into the website and be able to view the pattern and distribution of any diseases. The users would click on the feature query menu and then click on a particular state in order to view all available information on any disease at a local government level or at a state level. Users can query a point of interest on a map in order to ascertain the pattern and distribution of HIV/AIDS in the vicinity of that location. A Web Feature Server could also be used to fetch the name of locations which have more than a certain prevalence rate for a particular disease, for example, to produce the name of a state or local government areas with more than 5% prevalence rates for HIV/AIDS.

The system would allow users to spatially query and view data on any disease in order to ascertain the patterns, distribution and prevalence rate of any disease such as HIV/AIDS, malaria, tuberculosis, etc in any location in Nigeria. Users will be able to select a polygon on the map and the features of the polygon such as the name of the state, population at risk and prevalence rates will be displayed. The system would also allow physicians/health officers in the hospitals to input patient information such as demographic data, diseases associated with each patient, information about geographical location of each patient and other related information into the system. This system would be able to keep information about any diseases in the country which eventually would make medical information about people living with certain diseases such as HIV/AIDS confidential (because only authorised users of the system would be able access the patients' records compared with paper files, in which clerks working with medical records unit could open the file and read the contents). Also epidemiologists, policy makers, and any other authorised users would be able to query, analyse, view and generate disease information based on street, town/city, local government area, year, population at risk, total number of cases, prevalence rate, sex, marital status, educational status and age distribution of disease carriers in the country.

In addition, the system will allow special queries based on some features, such as a query based on occupation, education level, mobility level among other things. The system will allow a physician or delegated health worker to input group data of people living with a particular disease at a particular location over a given period of time.

CONCLUSION

This chapter describes the development of a web-based GIS HIV/AIDS surveillance system for Nigeria. Due to the lack of database information on HIV/AIDS in Nigeria, the Conceptual Data Model for Disease Surveillance, Monitoring & Prediction in Nigeria was analyzed and a fully-fledged HIV/AIDS surveillance system was developed for surveillance, monitoring and management of HIV/AIDS disease. This enables health officers, epidemiologists and stakeholders to easily query the distribution and the pattern of any diseases in Nigeria.

The web-based GIS disease surveillance system was designed based on the Conceptual Data Model for Disease Surveillance, Monitoring & Prediction in Nigeria. The model identified and documented the detailed information needed in order to develop an effective disease surveillance, monitoring and management information system. The model uses three core components which are party, location and health activity. The party component of the model contains information about a person, groups and any features that are of interest to the health system, including physicians, epidemiologists, public health workers, hospitals, laboratories, patients, association of laboratory scientists, people living with HIV/AIDS. A health activity is the provision of a specific health service to a health service recipient by a service provider at a given place during a particular period of time. The location component contains information about the addresses and spatial positions associated with the other two core components that is Party and Health Activity. HL 7 codes were adopted and modified intensively in the Conceptual Data Model for Disease Surveillance, Monitoring & Prediction in order to allow interoperability and flexibility of the disease surveillance system.

The system was designed and developed to capture HIV/AIDS patients' information such as gender, occupation, religion, education level, marital status, ethnicity, mobility, race, address etc. The developed system will provide a national health database that will enhance the monitoring and surveillance of any disease in the nation.

KEY TERMS AND DEFINITIONS

Data Model: A formal structured representation of real world entities, focused on the definition of an object and its associated attributes.

Disease Surveillance: A system that provides useful information about disease status and sometimes it may imply that some form of directed action will be taken if the data show a disease prevalence or incidence above a certain threshold.

Geographical Information System: A computer based information system that combines people, hardware and software to capture, model, store, retrieve, share, process, and manipulate, analyze and present geospatial (geographically referenced) data for the purpose of decision making.

Health Information System: A system that integrates data collection, processing, reporting and use of the information necessary for improving health service effectiveness and efficiency through better management at all levels of health services.

Human Immunodeficiency Virus: An infectious agent that causes Acquired Immune Deficiency Syndrome.

Monitoring: A process of routinely gathering information on all aspects of the project.

Surveillance System: An electronic tool for collection of data that will be able to accurately synthesise data, analyse data and present data and information over time to stakeholders.

This work was previously published in Improving Health Management through Clinical Decision Support Systems edited by Jane D. Moon and Mary P. Galea, pages 28-58, copyright 2016 by Medical Information Science Reference (an imprint of IGI Global).

Chapter 25

Early Warning System and Adaptation Advice to Reduce Human Health Consequences of Extreme Weather Conditions and Air Pollution

Dragan Bogdanović

State University of Novi Pazar, Serbia

Konstansa Lazarević

State University of Novi Pazar, Serbia

ABSTRACT

The authors developed a multi-site Internet service to provide the public with real time information about local weather and air quality, how they may affect health, and how general population and different sensitive population groups can protect their health during periods of extreme weather conditions or increased air pollution levels. The information service is based on data obtained from the Republic Hydrometeorological Service of Serbia and Serbian Environment Protection Agency. Health warnings and recommendations are given separately for each AQI and heat index or wind chill index value, for each sensitive population group, as well as for the general population. The project is currently implemented on the website of the Institute of Occupational Health Niš and will be offered to other healthcare institutions in Serbia. Evaluation of the system should enable redefinition of heat and wind chill indices and air pollution threshold values if necessary. This chapter explores the service.

INTRODUCTION

Exposure to adverse weather conditions or high concentrations of air pollutants is associated with a wide range of acute and chronic health effects, especially in children, the elderly, and in patients with chronic diseases. Pyramid of the health effects of adverse weather conditions and air pollution starts from sub-clinical effects, continued with deterioration of organ functions, the appearance of new or worsening of

DOI: 10.4018/978-1-5225-1674-3.ch025

existing symptoms, increased use of drugs, activity reduction, an increased number of physician visits, increased use of emergency medical services, increased number of admissions to hospital treatment, and ends with the increased number of deaths.

The growing problems of climate change and air pollution have caused the development of a system for monitoring health risks and issuing warnings in many countries. In the U.S., the National Weather Service was developed, using the National Weather Hazards application to monitor, alert, and provide advice on risk due to the effects of many meteorological factors: snow, wind, floods, extreme heat and cold over the Internet (<http://www.nws.noaa.gov>). United States Environmental Protection Agency - EPA calculates and displays the Air Quality Index (<http://www.airnow.gov>) and issues warnings for increased concentration of pollutants in the air. In the UK, the website of the National Weather Service (<http://www.metoffice.gov.uk>) gives an overview of the current meteorological conditions and air quality index. Warnings are issued when the values of these factors are sufficient to pose a threat to human health and the presentation contains a number of recommendations regarding appropriate behavior and preparations for risk mitigation due to the effects of extreme weather conditions. Similar systems exist in other countries: Canada (<http://www.ec.gc.ca>), Australia (<http://www.bom.gov.au>), France (<http://france.meteofrance.com>), Germany (<http://www.umweltbundesamt.de>), as well as other countries.

Internet applications for weather and air pollution monitoring, as well as for providing health advice and issuing warnings have been developed, not only on national level, but also for regions of large countries (USA, Canada, China, Australia), as well as in many cities in the world.

Within the “New information technologies for analytical decision-making based on the organization of experiments and observations, and their application in biological, economic and social systems” project, funded by the Ministry of Education, Science and Technological Development of the Republic of Serbia, the first system for early warning and providing recommendations for reducing the adverse health consequences of air pollution and meteorological conditions is under development in Serbia. The system is interfaced with using a web application and is intended for use by the general population and vulnerable population groups in the cities of Serbia. At this stage, the system has been implemented on the website of the Institute of Occupational Medicine in Nis, and will be offered in other towns in Serbia.

BACKGROUND

Air Pollution

The earliest recorded problems with outdoor air pollution occurred due to burning fossil fuels in large cities (Brimblecombe, 1987). Industrialization and transport have led to an increase in the concentration of pollutants in the air. By the mid- twentieth century, there have been a few short-lived episodes in which exceptionally high levels of air pollution have influenced the occurrence of excessive mortality and morbidity. The most dramatic three episodes took place in the Meuse Valley in Belgium in 1930. (Nemery et al., 2001), Donora, Pennsylvania in 1948. (Davis, 2002) and in London in 1952 (Bell & Davis, 2001; UK Ministry of Health, 1954) These episodes prompted the authorities in many countries to start the research on the impact of air pollution on human health and to enact legislation that would improve air quality. These measures and activities have greatly contributed to alleviating the problem in the developed countries, but air pollution remains a serious, now global, worldwide problem, with

Warning System to Reduce Health Consequences of Extreme Weather Conditions

intense negative effects on public health (Ezzati et al., 2002) In many areas of the world, the levels of air pollution are still extremely high, as is the case in large cities of China and India (WHO, 2001)

While the impact of the extremely high concentration of pollutants was clearly visible during the above excess situations, contemporary studies of air pollution in developed countries give attention to the impact of much lower concentrations of pollutants.

Pollutants in the Outside Air

Particles

Many pollutants can, alone or in combination with others, affect the health of people, but over the last two decades particles (particulate matter - PM) are becoming the main subject of research (Brunekreef & Holgate, 2002). They represent a heterogeneous mixture of solid and liquid substances suspended in the air, which vary in size and chemical composition in space and time.

Natural and artificial sources of particles are: internal combustion engines, dust from roads, industry, metal processing operations, agricultural and construction activities, firing, clay dust, pollen, molds, forest fires and the burning of agricultural waste, volcanic emissions and sea spray.

There are thousands of elements and compounds that were detected in the particles at various locations, but the most common ones are: nitrates, sulfates, organic and elemental carbon, organic compounds (e.g., polycyclic aromatic hydrocarbons), biological substances (endotoxin, cell components), and metals (iron, copper, nickel, zinc and vanadium).

Due to the complex nature of the particles, their measurement, classification and regulation are based mainly on the defined size ranges. They are most commonly classified as the total suspended solids or TSP, particles that easily penetrate the tracheobronchial tree or PM₁₀ (aerodynamic diameter of less than 10 µm) and the fine particles that can reach alveoli or PM_{2.5} (aerodynamic diameter of less than 2.5 µm). More recently, the attention of researchers is focusing on ultrafine particles or UFP, with a diameter of less than 0.1 µm, which originate from combustion processes (Daigle et al., 2003).

Sulfur Dioxide

Sulfur dioxide (SO₂) is very irritating, colorless, soluble gas with an intense smell and taste. In contact with water, it produces sulfuric acid, which is responsible for its strong irritating effect on the eyes, mucous membranes and skin (Lipset, 2001). It can also cause narrowing of the airways and lead to an exacerbation of chronic lung disease symptoms and increased frequency of attacks in asthmatic patients.

The main source of this pollutant in the air is the burning of fuels containing sulfur, especially in power plants and diesel engines (the primary reason for the change in the composition of diesel fuel) and smelting of metal ores that contain sulfur. Sulfur dioxide oxidizes to sulfur trioxide, which, due to the strong affinity to water quickly turns into sulfuric acid (WHO, 1987).

Nitrogen Oxides

Nitrogen oxides are reactive compounds which include NO, NO₂, NO₃, N₂O₄, and N₂O₅. These compounds are commonly labeled with NO_x because a mixture of these compounds is usually present in the air.

Nitric acid in the gaseous state (HNO_3) is a major source of particulate nitrates and is produced when nitrogen dioxide reacts with hydroxyl radicals during the day, or when the nitrogen pentoxide reacts with water vapor during the night (U.S. EPA, 1993).

A large number of toxicological and epidemiological researches have focused on nitrogen dioxide, due to the fact that the creation of tropospheric ozone and other photochemical oxidants starts with the photolysis of nitrogen dioxide.

The main artificial source of nitrogen oxides in the air is the combustion of fossil fuels in motor vehicles and industrial processes. The high combustion temperature leads to the oxidation of atmospheric nitrogen, first to nitrogen monoxide, then to nitrogen dioxide. A typical daily pattern of nitrogen oxide concentration movement indicates a low base concentration with morning and afternoon spikes, due to the traffic rush hour.

Nitrogen dioxide and nitric oxide are naturally produced as a product of metabolism of bacteria, and in far lesser extent as a result of volcanic activity.

Carbon Monoxide

Carbon monoxide (CO) is a gas without color, smell and taste that links to hemoglobin with the affinity 250 times more potent than oxygen and is therefore affecting the reduction of systemic delivery of oxygen to tissues. Carbon monoxide also binds to cytochrome oxidase, which further adds to cell hypoxia, and is associated with the other extravascular proteins such as myoglobin, cytochrome P-450, catalase and peroxidase (Seger & Welch, 2001). On exposure to high concentrations, which usually occurs indoors, it leads to loss of consciousness, and high concentrations can lead to death. At lower levels of concentration, reduced oxygen transport may increase the risk of cardiovascular disorders and mental dysfunction.

Carbon monoxide is the product of partial oxidation of carbon. External sources include motor vehicles, motor boats, lawn mowers, chain saws and other equipment running on fossil fuels, and using fuel for heating purposes. According to the study on the measured concentrations of this pollutant, it is more often used as an indicator of air pollution resulting from the burning than it actually causes adverse health effects. However, under certain conditions, for example in poorly ventilated public garages, carbon monoxide can reach concentrations that lead to a significant increase of carboxyhemoglobin in patients with atherosclerosis or other diseases of the cardiovascular system.

Ozone

Ozone (O_3) is a highly reactive, colorless gas with a characteristic odor. Exposure to low concentrations is inevitable because ozone is formed in natural processes and during human activities. The negative effects of short-term exposure to high concentrations of this pollutant are the inflammatory response of the airways and increased sensitivity to allergens, such as pollen, resulting in reduced pulmonary function.

In the troposphere ozone is caused by the action of solar UV radiation on nitric oxides and reactive hydrocarbons, emitted by motor vehicles and many industrial sources (U.S. EPA, 1996).

Ozone concentrations are increased during hot, sunny days. Typical concentration profile in cities is characterized by a broad peak which lasts from late morning to late afternoon and early evening.

Biological Mechanisms of Action of Air Pollution

Estimated biological mechanisms of air pollution influence on cardiovascular and respiratory systems include direct effects on the cardiovascular system, blood, lung receptors and indirect effects expressed through pulmonary oxidative stress and inflammatory responses. Direct effects may arise from the action of agents that can easily pass through the pulmonary epithelium into the blood circulation, such as gases and possibly ultra fine particles - UFP (Nemmar et al., 2002a) together with the soluble components from PM_{2.5}. The activation of pulmonary neural reflexes due to the interaction of particles with lung receptors can also play an important role. Direct effects, under appropriate conditions, can contribute to instability of vascular plaques, or initiate a cardiac arrhythmia. These effects of air pollution are the likely explanation for the occurrence of rapid (within a few hours) cardiovascular responses such as increase in the number of acute myocardial infarction.

Less acute (up to several days) and chronic indirect effects may occur due to oxidative stress or pulmonary inflammation induced by inhaled pollutants. This, consequently, can contribute to a systemic inflammatory condition, which can, in reverse direction, activate hemostasis mechanisms and accelerate atherosclerosis.

Pulmonary and Systemic Oxidative Stress and Inflammation

Inhalation of air pollutants causes pulmonary oxidative stress and inflammation (Kelly, 2003). Lung exposure to high particle concentrations and ozone causes an inflammatory response as evidenced by the in vivo animal models (Godleski et al., 2002) as well as in vitro cell models (Li et al., 1996). The presence of PM_{2.5}-associated-metals is associated with acute changes in cardiovascular and respiratory physiology (Cakmak et al., 2014), and soluble metals in the particles contributes to the inflammatory process by increased oxidative stress (Ghio & Devlin, 2001). In addition, lung inflammation can occur by direct effects of ultrafine particles, which are independent of the transition metals or soluble components (Brown et al., 2000). Similarly, ozone provokes pulmonary inflammatory response through oxidative stress and deterioration of lung function (Samet et al., 2001).

In the studies it was established that the oxidative stress occurs after exposure to ultra-fine particles of coal and exhaust gases of diesel engines (Shukla et al., 2000) as well as PM_{2.5} (Sorensen et al., 2003). In vivo experiments on rats with the use of in situ hemiluminescence methods showed a rapid occurrence of oxidative stress in the lung tissue, but also in the cardiac muscle (Gurgueira et al., 2002). This can occur as a response to the presence of transition metals or of free radicals, which are known to exist in PM_{2.5} as a result of the atmospheric chemical reactions. Exposure to increased concentrations of PM_{2.5} is also associated with increased levels of markers of lipid and protein oxidation in the human blood. Free radicals also contribute to the development of pulmonary inflammation.

Oxidative stress triggers specific transcription factors, including nucleus factor B and the protein-1 activator that regulate the expression of genes producing cytokines, chemokines and other proinflammatory mediators.

The exhaust gases of diesel engines or their organic extracts may, through oxidative effects on mitochondria, induce apoptosis or necrosis of macrophages and cells of the respiratory epithelium, which may impair the ability to defend against infection and to increase the reactivity of the air passages (Li et al., 2003).

Larger particles, rather than fine, affect the release of endotoxin in a yet unsolved way, which also induces proinflammatory cytokines (Monn & Becker, 1999), increases the pulmonary inflammation and airway reactivity, increases the number of systemic immune cells, and reduces lung function.

Intrapulmonary responses stimulated by particles can also affect neurogenic inflammation. Sensitive neurons in contact with the irritating particles within the air passages can be stimulated to release neuropeptides (for example, substance P, a peptide that affects the calcitonin gene and neurokinin A), which initiate inflammation that involves the release of cytokines, secretion of mucus and vasodilation.

Neuropeptides act on various types of cells in the lungs, such as the epithelial and smooth muscle cells, which results in the modulation of inflammation, and increased air passage sensitivity. They also affect immune cells (polymorphonuclear leukocytes, lymphocytes, eosinophils, and others), which enhances the inflammatory response. In vitro experiments indicate that the receptors for specific irritants (vanilloid or capsaicin) in neurons are mediators of neurogenic inflammation associated with particles (Veronesi et al., 2000).

Several controlled exposition studies showed that the inhalation of particles (Nightingale et al., 2000), and ozone (Aris et al., 1993) causes both pulmonary and systemic inflammatory response in humans. One hour of exposure to very high concentrations of exhaust gases from diesel engines has caused an inflammatory reaction in the lungs of healthy adults. This response included an increased number of polymorphonuclears, T and B lymphocytes, mast cells and increased level of mediators of inflammation (Salvi et al., 1999).

Diesel engine exhaust gases enhance mRNA transcription of interleukin-8 (IL-8, the protein which draws polymorphonuclears onto the damaged location), and increased IL-8 and growth-regulatory oncogene amplify the airway inflammation (Salvi et al., 2000).

All of these controlled exposure studies indicate that particles can cause moderate pulmonary inflammatory response in healthy individuals, and increase the level of blood factors affecting coagulation, even without any damage to the lungs.

Some studies suggest the existence of a systemic inflammatory response after exposure to air pollution. In humans, exposure to the forest fire smoke (as measured PM_{10} and SO_2), at concentrations that did not cause changes in pulmonary function, have led to the stimulation of bone marrow to release immature polymorphonucleates into circulation (Tan et al., 2000). In an experiment on animals, in rabbits who intrapharyngeally received 5 mg of PM_{10} twice a week for 3 weeks, the production of polymorphonucleates in the bone marrow increased and they were released into the circulation (Mukae et al., 2001). PM_{10} exposure caused a diffuse inflammation in the lungs, with particles present in the alveolar macrophages, lung epithelial cells, and the walls of the air passages.

The Effects of Inflammation, Oxidative Stress, and the Increase of the Blood Factor

Exposure to air pollution can cause changes in the composition of blood, with possible serious consequences in patients with cardiovascular diseases. Seaton et al (1995) gave the general hypothesis that exposure to the particles causes alveolar inflammation, exacerbation of pre-existing lung disease, increases coagulation and with it the risk of adverse cardiovascular events. As already mentioned, a number of studies with the controlled exposure to particles showed an increase in cellular and biochemical markers of pulmonary and systemic inflammation.

Particles affect the increase of fibrinogen level (Ghio et al., 2003), key component of the coagulation and platelet thrombosis and major determinant of blood viscosity. Blood viscosity affects the severity of cardiovascular disease (Junker et al., 1998) and its increase depends on the increased levels of dissolved SO_2 and particles (Peters et al., 1997). Fibrinogen is also important as an independent risk factor for myocardial infarction.

Epidemiological data indicate possible effects of air pollution with particles on blood coagulation (Seaton et al., 1999). In contrast, Stark et al. (2013) have, in the semi experimental study conducted in adult healthy volunteers, found that the ex vivo creation of thrombin is associated with exposure to NO_2 , nitrates and sulphates, but not with suspended particles and oxidative potential of inhaled ambient air.

Of note is the fact that the prediction of death and heart stroke in middle-aged men according to the level of fibrinogen in the plasma may be influenced by the presence of other, inflammation-sensitive proteins (Peters et al., 2000a), which suggests that inflammation plays an important role in determining cardiovascular risk. In addition, platelet aggregation may further enhance the development of acute thrombotic formation after exposure to the exhaust fumes (Nemmar et al., 2003) from a diesel engine, and fine particles (Nemmar et al., 2002b). The mechanism responsible for the activation of platelets and fibrinogen increase is not fully understood. These findings still support the contention that air pollution can acutely increase the risk of thrombosis, which may further result in ischemic disorders.

Increased concentrations of IL-6 are associated with increased risk of cardiovascular events (Ridker et al., 2000) and mortality (Volpato et al., 2001). The levels of serum IL-6, IL-1 and stimulating factor of granulocyte macrophage colonies grow in healthy male subjects after exposure to air pollution from forest fires, and also grow in vitro with exposure of macrophages from human lung to PM_{10} originating from urban areas (Van Eeden et al. 2001). IL-6 is directly involved in the regulation of the C-reactive protein synthesis in the liver. This protein is a sensitive indicator of infection, injury and inflammation, and is associated with an increased risk of cardiovascular disease (Ridker, 2001). The concentration of C-reactive protein is directly related with the exposure to the total suspended particulate matter and PM_{10} (Peters et al., 2001a). The mechanisms by which C-reactive protein increases the risk of cardiovascular events have been the subject of intensive research. One possibility is that it weakens the endothelial vasoreactivity in patients with already diseased coronary artery (Fichtlscherer et al., 2000). In addition, the C-reactive protein can directly contribute to the development and progression of atherosclerosis by a number of mechanisms which include changes in the formation of foam cells, the entry of monocytes into the arterial walls, the stimulation of prothrombin tissue factors and expression of adhesion molecules (Bhatt & Topol, 2002).

Inflammation (proinflammatory cytokines, C-reactive protein, and components of innate immunity) plays a significant role in the development of atherosclerosis and plaque instability (Libby, Ridker, & Maseri, 2002). It is possible that air pollution affects the systemic inflammation, causing atherosclerosis progression during a prolonged period of time (Suwa, et al., 2002) as well as activating acute plaque instability and sudden cardiovascular events in short time intervals.

In rabbits with hyperlipidaemia which have been exposed to the particles, progression of coronary atherosclerosis and increased extracellular lipid depot creation occurred after 4 weeks (Libby, Ridker, & Maseri, 2002). Degree of the plaque formation correlates with the number of alveolar macrophages which conduct particle phagocytosis. These effects seem to be influenced by age, hypertension, hyperlipidemia, diabetes and other conditions associated with inflammation.

Changes in the blood vessels due to exposure to air pollution have also been proven. Inhalation of particles and ozone for 2 hours has resulted in a moderate vasoconstriction in healthy adult subjects

(Brook et al., 2002). Similarly, in rats, the small pulmonary arteries reacted by constricting to short-term exposure to high concentrations of particles (Batalha et al., 2002). It is assumed that acute systemic inflammation and oxidative stress act as the trigger for endothelial dysfunction which can lead to vasoconstriction (Bonetti et al., 2003).

For now, the mechanisms that lead to changes in the state of blood vessels are not clear. However, several studies point to the fact that air pollution affects the cardiovascular hemodynamics (Bouthillier et al., 1998).

Literature data indicate that the external air pollution increases the blood pressure in coronary rehabilitation patients (Zanobetti et al., 2002) and also in adults with pulmonary diseases (Linn et al., 1999). Arterial vasoconstriction is the probable explanation for the findings of the ULTRA study (The Exposure and Risk Assessment for Fine and Ultrafine Particles in Ambient Air) (Pekkanen et al., 2002). The levels of particles in the air for two days prior to physical stress testing were significantly related to the increase of ST-segment depression during testing. This finding suggests the hypothesis that air pollution has an effect on myocardial ischemia, which was confirmed in an experimental study on dogs exposed to high concentrations of pollutants in the air (Wellenius et al., 2003). The results also provide a possible explanation of the theory of the impact of airborne particles on the dynamics of acute myocardial infarction. The research has identified a significant association between onset of symptoms and acute (levels within 2 hours before symptoms) and subacute (mean concentration during the previous day) exposure to PM_{2.5} particles. Sudden arterial vasoconstriction (and / or possible endothelial dysfunction) can probably accelerate the emergence of acute coronary syndromes by initiating plaque instability or impairing myocardial nutrition in patients with existing atherosclerosis.

Cardiac Autonomic Nervous System

The impact of air pollution on mortality may be partially explained by its action on the autonomic nervous system. The ability to change heart rate (heart rate variability - HRV), a period of heart rate rest and blood pressure are regulated by the balance between the two parts of the autonomic nervous system: sympathetic and parasympathetic. Reducing the ability to change rhythm increases the risk of cardiovascular morbidity and mortality in the elderly, and in people with severe heart disease (Task Force of the European Society of Cardiology and the North American Society of Pacing and Electrophysiology, 1996). This conclusion was reached by analysis of heart rate by determining the standard deviation of the periods between normal R-R intervals, and the low frequency / high frequency relationship, measured with an electrocardiograph over a 24-hour period. Exposure to ambient particles reduces the ability to change rhythm (Magari et al., 2001). Reducing the parasympathetic influence on the heart may be an important mechanism of cardiovascular mortality increase due to tachyarrhythmias. Experimental studies of controlled exposure to air pollution confirmed the assumption that particles can impair the ability to change rhythm (Devlin et al., 2003; Pope et al., 1999). It has been found that the reduction of the ability to change rhythm occurs rapidly and in inverse proportion to the increase of the particle concentration.

It is not sufficiently clarified whether the observed short-term changes of the ability to alter the rhythm are in relation to the deterioration of cardiovascular outcomes and the initiation of serious arrhythmias in the long run. It is possible that for certain people, bradyarrhythmias caused by air pollution may affect sudden death.

Some evidence indicates that exposure to particulate matter causes clinically significant changes in the electrophysiology of the heart. The incidence of cardiac arrhythmias is associated with the PM_{2.5}

exposure in high-risk individuals (e.g., individuals with a artificial cardiac pacemaker). In a study on 100 patients who were observed for 3 years, it has been determined that the concentrations of nitrogen dioxide and carbon monoxide present in the air have been strongly linked with the artificial cardiac pacemaker malfunctions, and the soot exhibited somewhat lower effect (Peters et al., 2000b). Although this study was limited by a small number of high-risk patients and the lack of data on the device malfunctions, it points to the existence of possible adverse effects of particulate and gaseous pollutants on the balance of cardiac autonomic nervous system.

The study that used time series analysis to monitor the impact of particles on mortality (Hoek et al., 2001) supports this finding. It was proven that the risk of death from arrhythmia increases with the increase of the seven-day average concentrations of soot and particles.

The results of this study coincide with the result of a number of experimental studies on animals which indicate the induction of cardiac arrhythmia in the previously diseased animals (e.g., with pulmonary and systemic hypertension) that have been exposed to particles. In dogs exposed to particles for 6 hours for three consecutive days, an increase in the frequency of low and high heart rate frequencies occurred, as well as increased values of low frequency / high frequency relation (Godleski et al., 2000). Exposure to ashes produced by burning oil (component particles) led to tachyarrhythmias in rats (Wellenius et al., 2002). Such findings support the contention that air pollution may alter the balance of the autonomic nervous system in the direction of causing serious tachyarrhythmias. The mechanism of action remains unclear, but it is assumed that involves activation of pulmonary neural reflex arc, the direct effects of pollutants on ion channels of cardiac cells, or the consequences of systemic inflammatory status.

RESULTS OF PREVIOUS EXAMINATIONS OF AIR POLLUTION INFLUENCE ON MORBIDITY AND MORTALITY

Increased concentrations of pollutants in the air usually exert their negative impact on the health by worsening the symptoms of pre-existing cardiovascular and respiratory diseases. (Samet et al., 2000). The increase in relative risk for morbidity and mortality due to air pollution is relatively low compared to the confirmed risk factors such as hypertension, increased cholesterol levels, infections or smoking. Nevertheless, this is a serious health problem if the number of exposed and length of exposure (the whole human life) is taken into account.

In recent years a number of studies that suggest an association between air pollution and cardiorespiratory disease increases significantly (Pope et al., 2000; Vanos, Hebborn, & Cakmak, 2014; Franchini & Mannucci, 2009). The studies are mainly based on the study of the impact of short-term and long-term exposure to air pollution on health. Observations relating to the adverse effects of short exposure are more numerous. In these studies, widespread short-term resultant occurrences in the population (mortality, incidence of symptoms, hospitalizations and doctor visits for health care) are associated with short-term variations in the concentration of pollutants in the outside air, usually through the use of population-based time series analysis.

Fewer studies have focused on the study of the adverse health effects of long-term exposure. These studies include analysis of data (eg, total mortality and in some cases cardiovascular events) from large cohorts from different geographic locations that differ in composition and concentrations of pollutants in the outside air.

EFFECTS OF LONG-TERM EXPOSURE TO AIR POLLUTION

The first large, prospective cohort study that confirmed the negative health impact of prolonged exposure to increased concentrations of pollutants in the air was the Harvard Six Cities study conducted by Dockery et al. (1993). It has been shown that chronic exposure to air pollutants has an impact on cardiovascular mortality. In a cohort of 8111 adults over 14 to 16 years of observation, overall mortality ratio in the most polluted and least polluted city was 1,26:1,00. Additional analysis adjustments in relation to the selected individual risk factors: gender, educational level, occupational exposure, BMI, smoking, hypertension and diabetes did not significantly modify this relationship. Of all the pollutants, the increase of concentration of particulate matter (PM) and sulfates showed the strongest association with the disease.

Tracking the cohort by Pope and associates (1995), organized by the American Cancer Society (ACS) is the largest study of long-term effects of air pollution. In about 500 000 adult residents from all 50 states from the USA, chronic exposure to a mixture of pollutants in the air is associated with mortality statistics for a period of 16 years. ACS study has increased the level of control for associated factors by introducing new ones, such as diet and gaseous pollutants. The results showed that any increase in annual mean $PM_{2.5}$ concentration of $10 \mu g/m^3$ was accompanied by an increase in overall mortality by 4%, mortality from cardiopulmonary disease by 6%, and lung cancer mortality by 8%. Mortality was mostly associated with particles ($PM_{2.5}$), sulfate particles and sulfur dioxide. There was also an established dependence of cardiopulmonary mortality on average ozone concentrations for the 1982-1998 period. Educational level was a significant modifier in assessing the impact of particles on human health. People with low to medium education had increased risk of death and morbidity compared to those with higher education.

Hoek et al (2002) confirmed the importance of housing location within the city as the factor that can affect mortality from air pollution. In a cohort of 5000 adult patients observed for 8 years, exposure to pollutants originating from traffic caused the increase in mortality in the population of the city center in relation to the residents who live in less polluted urban areas. Of all the risk factors, living near busy roads was most strongly associated with cardiopulmonary mortality in this cohort (relative risk - RR: 1.95 and 95% IP: 1.09 to 3.52). This study also suggests that individual exposure to toxic components of air pollution can vary significantly among residents of a city.

Until recently, the specific causes of increased cardiovascular mortality due to long-term exposure to air pollution were vague. In the analysis of the ACS study, investigators point out the impact of particles on the specific causes of death (Pope et al., 2004). A statistically significant association between particulate matter ($PM_{2.5}$) and total cardiovascular mortality was confirmed by an increase in the concentration of $PM_{2.5}$ in $10 \mu g/m^3$ (RR: 1.12, 95% IP: 1.08 to 1.15) during long-term exposure. The highest risk was found for ischemic heart disease (RR: 1.18, 95% IP: 1.14 to 1.23), which also represents the most common cause of death. The risk of death from arrhythmia, heart failure and cardiac arrest has also increased (RR: 1.13, 95% IP: 1.05 to 1.21). No evidence for increased mortality from other causes was found (e.g., aortic aneurysm, diabetes, hypertensive heart diseases or any respiratory diseases). These results indicate that the pollutants in the air deteriorate both non-ischemic and ischemic cardiovascular diseases.

Data on the impact of long-term exposure to air pollution on mortality is largely derived from the United States. A research in England has followed 835,607 patients in the 2003-2007 period, and the concentration of particulate matter, nitrogen dioxide, ozone, and sulfur dioxide. The obtained results suggest that exposure to the above pollutants, except ozone, increases the risk of all-cause mortality. A stronger association was found with respiratory disease mortality, which is not in accordance with the

results of studies in the U.S., where the relationship was stronger between pollutants and mortality from cardiovascular disease (Carey et al., 2013).

In addition to the impact of the deterioration of the existing cardiopulmonary diseases, air pollution can also lead to an increase in the number of congenital heart defects. The biological mechanism of action of pollutants in their formation has not been clarified. Data from Eastern Europe, from areas that for many years have had high concentrations of pollutants originating from the industry, point to the possibility that high air pollution can affect an increase of the number of congenital heart defects (Smrcka & Leznarova, 1998). A recent study of birth registrations in Los Angeles found that the risk for ventricular septal defect increases by the dose-response principle with increasing exposure to carbon monoxide. Thus, the approximate relative risk (odds ratio - OR) for the second quartile compared to the first was 1.62 (95%IP: 1.05 to 2.48) for the third quartile 2.09 (95% IP: 1.19 to 3.67), and in the fourth quartile a whole 2.95 (95% IP: 1.44 to 6.05) (Ritz et al., 2002). A connection between valve defects, aortia and truncus and the levels of ozone was also noted. Particles and other pollutants measured did not show this correlation.

EFFECTS OF SHORT-TERM EXPOSURE TO AIR POLLUTION

The two largest studies so far to have analyzed the acute effects of air pollution are the National Morbidity Mortality and Air Pollution Study (NMMAPS) in the United States (Dominici et al., 2003) and Air Pollution and Health: a European Approach-2- APHEA-2 project (Katsouyanni et al., 2001).

The NMMAPS study followed the health outcomes for 50 million people in the 20 largest U.S. cities. Any increase in PM_{10} concentration of $10 \mu g/m^3$, was followed by increase of daily rate of general mortality of $0.21 \pm 0.06\%$, and mortality rate from cardiovascular disease of $0.31 \pm 0.09\%$.

APHEA-2 showed a slightly stronger association between adverse health outcomes and air pollution. With 43 million people in 29 European cities, the increase in daily mortality was 0.6% (95% IP: 0.4% to 0.8%) for any increase in PM_{10} concentration of $10 \mu g/m^3$. Mortality from cardiovascular disease was higher by 0.69% (95% IP: 0.31% to 1.08%) (Zanobetti et al., 2003).

Both studies have confirmed the differences in their findings in relation to the geographical region. In Europe, cities with warmer climates have shown a greater degree of influence of air pollution on mortality. On the other hand, NMMAPS study confirmed the greater impact in the northern than in the southern areas. Perhaps such differences between these studies were caused by different habits of residents: time spent outdoors, use of leisure time, as well as various ambient conditions, and differences in the composition of mixtures of pollutants (Smith et al., 2001).

Hundreds of small, short-term studies on the effects of acute exposure to air pollution have been published in the last decades, as presented by Brunekreef and Holgate (2002) as well as Pope (2000). Most frequently, the daily mortality rate, the number of hospital admissions (Linn et al., 2000) health care visits (Delfino et al., 1997), and worsening of symptoms (Schwartz et al., 1994) show an increase in line with the increased levels of air pollution. Observations in North America (Burnett et al., 1999) and Europe indicate a higher rate of hospitalization for all cardiopulmonary diseases. Number of hospital admissions due to heart failure and ischemic heart disease rose by 0.8% and 0.7% for every increase of PM_{10} of $10 \mu g/m^3$ (Morris, 2001).

More focused studies have shown an increased risk for acute myocardial infarction (Peters et al., 2001b), installation of artificial cardiac pacemakers (Peters et al., 2000b) and the finding of myocardial ischemia during stress tests (Pekkanen et al., 2002).

The extreme increase in air pollution has affected the increase in blood pressure during episodes of extended stagnation of air due to temperature inversions in Europe (Ibald - Mulli et al., 2001).

Bronchoconstrictory effects of sulfur dioxide are manifested mostly in people already suffering from asthma and chronic bronchitis. APHEA authors found a significant effect of this compound on the increase in mortality from respiratory diseases in almost all the cities of Western Europe (Katsouyanni et al., 2001).

The study of time series that examined the impact of air pollution on daily mortality in Austrian cities Graz and Linz has determined a correlation between nitrogen oxides and suspended particulate matter and daily mortality, including during summer when the concentrations of pollutants had lower values (Nurberg et al., 2013).

Studies in Seoul (Hong et al., 2002) and Taiwan (Tsai et al., 2003) indicated an increase of ischemic stroke incidence, which is directly related to the concentration of particles in the air.

The studies in Serbia have also shown that air pollution significantly affects the increase of the number of hospital admissions (Stankovic et al., 2012; Milosevic et al., 2010; Nikic et al., 2008) and mortality (Bogdanovic et al., 2006; Nikic et al., 2009) from cardiovascular and respiratory diseases.

THE INFLUENCE OF METEOROLOGICAL FACTORS

Air Temperature

The role of the center for body temperature regulation, which is located in the hypothalamus, is to maintain the temperature within an optimal range. At idle state, it is around 37° C, while during physical activity body temperature can rise to 38-39° C without any harmful effects on health. For the temperature to be within the physiological range, a balance between the creation and loss of body heat is necessary. The main source of body heat is metabolic activity, and there are other sources, such as solar radiation or various heaters. The means of body heat loss are convection-heat transmission to the surrounding air, conduction in contact with hard objects (e.g. floor), respiration, radiation and evaporation of sweat. Several mechanisms are involved in the regulation of body temperature, and the most important for heat loss are sweating and expansion of peripheral blood vessels, while muscle tremors and constriction of peripheral blood vessels are used to increase the temperature. To make the body temperature stable, the heat loss must be equal to the heat produced (Havenith, 2002).

Increased temperature can cause rash and redness of the skin, weakness, syncope and collapse. The basic mechanism of this phenomenon is the expansion of peripheral blood vessels and blood pressure decrease. In the absence of physical activity, the drop in blood pressure is greater because of the absence of muscle pump and the reduced flow of venous blood into the heart. Conversely, with increased muscle activity, blood pressure is maintained longer within the range of normal values, which creates the possibility of a further increase in body temperature, and when it reaches 40.5°C it can result in a heat shock, which involves cellular structure damage and dysfunction of the center for thermoregulation with a high risk for the occurrence of death. Heat stroke usually occurs in young and healthy people who are exposed to great physical strain at high temperature, for example at sporting events. The occurrence

Warning System to Reduce Health Consequences of Extreme Weather Conditions

is sudden, and there are very severe complications such as respiratory distress, kidney and liver failure and disseminated intravascular coagulation (Donoghue, 1997).

In addition to increased physical activity, the most important predisposing factors for the occurrence of adverse health effects of increased temperature were older age, lack of acclimatization, dehydration, use of drugs that affect the thermoregulatory center (phenothiazines, barbiturates), obesity, poor physical condition and wearing protective clothing to prevent evaporation.

Elderly people are more sensitive to high temperatures due to physiological changes in the thermoregulation center, associated cardiovascular diseases, poor physical fitness and decreased ability to create sweat (Basu & Samet, 2002; Havenith, 2001).

The process of short-term acclimation to increased temperature takes 3 to 12 days, and full acclimatization is achieved only in a few years. Short-term acclimation physiologically involves an efficient sweating mechanism (earlier onset, higher quantity and wider distribution) and increased peripheral circulation, and it takes a few weeks after stopping high temperature. Long-term acclimation involves reducing basal body temperature, heart rate and metabolic rate, and these adaptive changes are retained for years after cessation of exposure to high temperature (Havenith, 2002).

At increased air temperatures, a greater amounts of liquid intake is necessary. Dehydration or hypohydration rarely occur in young healthy people if they are able to drink sufficient amounts of water and other liquids. In the elderly the presence of chronic diseases (dementia, incontinence), restricted mobility and decreased functional capacity have caused chronic hypohydration to become almost a physiological condition. Therefore, older persons are susceptible to the action of very small meteorological and pathological stress influences (Mentes & Culp, 2003; Hodgkinson, Evans, & Wood, 2003).

Good physical condition is a protective factor against the occurrence of adverse events, both from increased and decreased air temperatures. It contributes to an increased cardiovascular reserve, ie the possibility of the cardiovascular system to enhance the blood supply of the target tissue as needed, which is a prerequisite for efficient thermoregulation. In the elderly, the decline in fitness leads to avoidance of physical activity, and that in turn causes an even worse physical condition. Additionally, elderly people avoid exposure to low and high temperatures, which diminishes the ability of acclimation to such conditions (Anderson, 1999).

Obesity is another factor that increases the risk of adverse effects of increased temperatures on health and often correlates with a poor physical condition. Adipose tissue conducts heat poorly so the subcutaneous tissue in obese patients acts as a thermal insulator between the body and the external environment. In obese people less metabolic activity per unit body weight leads to a higher degree of heating of the body, and when the temperature of the body increases in obese patients, more blood must be diverted to the peripheral blood vessels, which leads to a greater heart frequency and its stress. However, when the outside air temperature exceeds the temperature of the skin in obese people less heat is absorbed from the environment, which has a protective effect (Chan et al., 2001).

Low air temperatures affect the health of the people through a number of physiological processes. Stimulation of the skin thermoreceptors by increased sympathetic activity results in increased levels of catecholamines in plasma, peripheral vasoconstriction, tachycardia and increase in blood pressure. In addition, exposure to cold causes an increase in blood viscosity due to the increase in the number of red blood cells and platelets, as well as increased levels of cholesterol and fibrinogen in the plasma (Keatinge & Donaldson, 1995), and haemoconcentration yields occurrence or deterioration or existing thrombotic changes (Donaldson, 1997). Sudden death occurs as a result of rupture of atheromatous plaques due to hypertension and cold-induced coronary spasm (Donaldson & Keatinge, 1997). Because of bronchocon-

striction caused by inhalation of cold air the risk of respiratory disease increases, and decline of cellular and humoral immunity was also demonstrated (Schaanning et al., 1996).

The air temperature has a major impact on morbidity and mortality. Studies that examine the effect of this factor on health are many and varied (Kovats & Koppe, 1994). Some of them are estimating “excess deaths” occurred under the influence of heat waves. Excess mortality is calculated as the difference between the increased and “expected” mortality, or one that can be predicted for a particular period in a particular area, based on data from previous years. Heat-waves constitute a great health risk and they are associated with significant excess morbidity and mortality. Cardiovascular and respiratory diseases were reported as the most common causes mortality (Bogdanovic et al., 2013). Risk factors for heat-related death include older age, pre-existing diseases, living alone, living on the top floor, lack of air-conditioning, and being overweight (Semenza et al., 2008). Populations in regions where extremely hot weather is relatively infrequent are most vulnerable to heat waves owing to a lack of behavioral adaptations (Piranda et al., 2005). Heat waves could reveal or aggravate several adverse drug reactions in elderly (Sommet et al., 2012). During the heat wave the greatest increase in mortality rates is related to diabetes mellitus, chronic kidney disease and diseases of the respiratory, nervous and digestive systems. Malignant neoplasms and cardiovascular mortality accounted to the highest absolute numbers of excess deaths (Basagaña et al., 2011).

People with diabetes are particularly vulnerable to heat because their bodies are less capable of adjusting to increases in temperature due to impairment of their autonomic control and endothelial function (Schwartz, 2005). Persons with kidney disease have a reduced ability to retain fluids and electrolytes. This can make dehydration and overheating happen more quickly. Moreover, when the body gets warm, it moves more blood to the skin in an attempt to reduce body temperature. This reduces both the blood flow and pressure in the kidneys making them more prone to overheating and less able to function (Hansen et al., 2008a). The mechanisms underlying the higher heat-mortality risk among those with nervous system diseases include impaired self-care, inadequate medical care and physiologic vulnerability (Hansen et al., 2008b). Heat stress can lead to down-regulation of epithelial growth-factor signaling, intestinal epithelial injury, impairment of the intestinal epithelial barrier function and increased mortality due to gastrointestinal hemorrhage (Liu et al., 2009). Cardiovascular and respiratory deaths can be triggered by heat when the thermoregulatory mechanisms of the body, such as increased respiratory and heart rate, increased blood circulation and surface sweat, put an additional stress on already ill heart and lungs (Schifano et al., 2009).

Study of time series is an effective way to evaluate the effect of temperature and other climatic factors on mortality in long periods of time. The regression lines obtained in this study show higher mortality rates when the measured temperature values are above and below optimum, that is, they possess an approximately U-shape. The values of the optimum temperature suggest the best adaptation of populations to local weather conditions and vary from city to city (Keating et al., 2000). Thus, the average daily air temperature during which there is the lowest number of fatalities, that is, when the inhabitants are acclimated the most, is 24°C in Valencia (Ballester, 1997), and 10°C in Oslo (Skrondal, & Bjertness, 2001).

Literature shows that temperature has an effect on increasing mortality rates from cardiovascular and respiratory diseases as a stress factor associated with the body, which is already burdened with a chronic illness. In France, a heat wave from 1 to 20 June 2003 caused the greatest increase in mortality in persons older than 75 years (National Institute of Public Health Surveillance, 2003). In children and infants the risk of dying due to the effects of high temperature also increased. In the U.S., approximately 4% of deaths associated with the effects of high temperature related to children aged up to 4 years (Centers for

Disease Control and Prevention, 2002) People of lower socioeconomic status may be a more vulnerable group because of poor living conditions and lack of air conditioning (Smoyer, 1998).

The study of mortality data from 14 EU countries shows that the mortality rates in winter are significantly higher compared to the annual average (Healy, 2003). In Portugal, the increase in mortality in winter was 28%, followed by Ireland and Spain with an increase of 21%. The lowest variability was observed in Finland (10%), while the average increase in mortality in winter in all 14 countries was 16%. The occurrence of a large increase in winter mortality in countries with warmer climates is called the “paradox of winter mortality.” The most likely factor to explain this phenomenon is the method of construction of the residential buildings. In countries with higher average annual temperatures there is insufficient attention paid to heat insulation of households and they are therefore more difficult to heat in the winter when the temperature drops. In contrast, in countries with harshly cold climates, as is the case with Scandinavia, high-quality insulation is a construction standard, so that the temperature in the living space is easily maintained at the desired level (Clinch & Healy, 2000).

A study in England showed that mortality in persons older than 75 years during the winter months increases by 17% compared to the annual average, and that 8% of deaths in the elderly during winter is associated with low temperatures (Wilkinson et al., 2004). The mortality rate due to the effect of cold was 11% higher in women and by 20% in people whose medical history included chronic respiratory diseases, while the socioeconomic status did not show a significant influence.

The relationship between the mean daily temperature from June to August and mortality, particularly mortality from respiratory disease and mortality in the elderly was determined by examining the impact of the maximum daily temperature on mortality in 15 European cities (Baccini et al., 2008).

A study conducted in China in four different climatic zones has identified the connection between the high and low temperatures and an increased risk of cerebrovascular mortality in all climatic zones, but this relationship was significant only for low temperatures. It was also found that people who live in colder climate areas are more susceptible to the effects of high temperatures, and the ones from warmer climate areas are more susceptible to the effects of low temperature (Zhang et al., 2014).

Research in Serbia showed that Roma population had significantly higher excess winter mortality - EWM rate per 10,000 (129.2 vs. 76.6) for all causes, all respiratory diseases (26.5 vs. 8.0), and chronic lower respiratory diseases (23.0 vs. 5.2) in comparison to non - Roma population. Influenza and pneumonia related deaths Represented a small proportion of EWM in both populations. Cardiovascular EWM rate was slightly higher among non - Roma population. Regression analysis demonstrates that Roma ethnicity was associated with significant increase of respiratory rate EWM (regression coefficient (B) = 1:49, 95% CI: 0:45 to 2:54). There was no relationship between ethnicity and cardiovascular and all causes EWM rates (Blagojevic et al., 2012).

In addition to the impact on mortality, temperature changes also influence the increase of the number of hospital admissions and other indicators of morbidity. The project “Assessment and prevention of acute health effects of weather conditions in Europe” (PHEWE) was conducted in 16 major European cities with a variety of climate conditions, in which over 30 million people live (Michelozzi et al., 2007). The study included data on mortality and inpatient receptions in the 1990-2000 period. Each year is divided into winter (October to March) and summer (April to September) season. On average, the rate of overall mortality in the winter season was higher than in the summer season by 16%. The difference between the rates was lowest in Helsinki (10%), and highest in Valencia (22%) and Milan (21%). The rate of death from cardiovascular disease in the winter season was, on average, increased by 21% in Helsinki, by 7%, and in Milan for 34%. Death from respiratory disease in the winter season was on average 36%

more frequent, 21% in Athens and in Zurich as much as 68%. The number of hospital admissions for cardiovascular disease in the winter season was higher by 11%, in London and Dublin by 5%, and in Paris by 16%. Hospital admissions for respiratory disease in winter season were 42% more frequent, 22% in Ljubljana and 57% in Valencia.

Atmospheric Pressure

Atmospheric pressure is a direct result of the weight of air (Martin, 1999). At sea level and 0°C temperature the atmospheric pressure is 760 mmHg (101.3 kilopascals, or 1 atmosphere). Atmospheric pressure decreases with increasing altitude, but it also decreases with increase in the temperature and humidity so its value varies according to the changes in these parameters. On the other hand, atmospheric pressure value is directly correlated with the value of the partial atmospheric pressure of oxygen (PO_2), which amounts to 160 mm Hg absolute pressure of 1 atmosphere. Decrease of the atmospheric pressure value causes less oxygen in the inhaled air and lower blood oxygen saturation, or tissue and organ hypoxia. The optimal values of PO_2 range from 120 mmHg to 460 mmHg. PO_2 values below 120 mmHg represent the dangerous hypoxic zone and a further decline seriously endangers human life functions, leading to a sudden loss of consciousness when the PO_2 value drops below 76 mmHg, and death if PO_2 value drops below 50 mmHg. Hypoxia causes cells of the central nervous system and the myocardium to suffer the fastest. PO_2 values above 460 mmHg to 1500 mmHg is the zone of hyperoxia which the body tolerates well over a longer period of time (from a few tens of minutes to a few hours). PO_2 values greater than 1500 mmHg relatively quickly lead to the manifestation of the toxic effects of oxygen.

Mountaineers, people in aircrafts and caisson workers may be exposed to extreme changes in atmospheric pressure, and health effects of exposure to these changes are the focus of analysis of a number of studies. The studies of health effects of pressure changes as meteorological factors- the changes that commonly occur in the environment- are rare.

Epidemiological studies suggest that possible mechanisms for the influence of air pollution on health are reduced blood oxygenation and heart rate changes. In a study conducted in Utah (USA) (Dockery et al., 1993) it was found that exposure to particulate pollutants leads to a significant increase of heart rate, while decreased hemoglobin oxygen saturation was statistically significantly correlated with the concentrations of pollutants in males over 80 years of age. The same study demonstrated that value oscillations of the atmospheric pressure lead to small, but statistically significant changes in hemoglobin oxygen saturation, as well as heart rate changes. Any drop in pressure of 25 mmHg caused a drop in the measured level of saturation of 0.6 to 0.7%, while the frequency of the heart rate increased by 1.5 beats per minute.

A controlled experiment was conducted in Ukraine on 12 healthy volunteers who were exposed to mild fluctuations in atmospheric pressure, which otherwise often occur in nature (Delyukov & Didyk, 1999). Oscillation amplitudes of 30 to 50 Pascals were applied, and pressure frequency changes ranged from 0,011 to 0,170 Hz. Exposing subjects to such pressure oscillations lasting 15 to 30 minutes caused a significant change in concentration and short-term memory, breathing became deeper and slower, and the heart rate frequency was also reduced.

An investigation of the possible effects of variations in atmospheric pressure on mortality, in which the control of the influence of other atmospheric parameters was performed, was carried out in Madrid

Warning System to Reduce Health Consequences of Extreme Weather Conditions

(Gonzalez et al., 2001). Time-series analysis confirmed a significant correlation between anticyclone trend (high-pressure field from which spiraling winds originate) and mortality from circulatory and respiratory diseases.

The World Health Organization conducted the MONICA Project (MONitoring trends and determinants In CARDiovascular disease) in Lille (Danet et al., 1999), a city with moist ocean climate, and confirmed the existence of significant influence of atmospheric pressure- both decrease and increase- on the incidence and mortality of myocardial infarction.

Research in Serbia showed that the increased average daily values of atmospheric pressure for 1 mBar on the day when the event took place before and 7 days, were associated ($p < 0.05$) with the increase of the total risk of the occurrence of lower idiopathic extremity deep vein thrombosis (DVT) for 5.1% (0.7 to 9.8%) (Damjanovic et al., 2012).

Air Humidity

Absolute air humidity is the amount of water vapor in a given volume of air and is expressed in g/m^3 . Relative air humidity is the ratio of the amount of water vapor in the air sample at a certain temperature and the maximum amount of water vapor that can be contained in the same sample at the same temperature, and is expressed as a percentage. Warm air has a greater water vapor binding potential than cold air.

People are very sensitive to changes in humidity because it affects the process of evaporation of sweat. When the relative humidity reaches 100%, that is, when the air is fully saturated with water vapor, the process of evaporation is completely interrupted. As a result of this interaction, high humidity makes it difficult for the body to cool in the summer. The human body is best adapted for relative humidity of 40-60%.

The effects of low humidity are also significant in the winter. The cold dry air that passes through the respiratory system also heats within it. This heating increases the potential of air to absorb water vapor, which leads to the extraction of moisture from the upper airways and the dehydration of the epithelium of the nose, pharynx, larynx and trachea. Increasing the of the epithelial mucus viscosity reduces its defensive capability and influences the increased risk of viral and bacterial respiratory diseases.

In a study conducted in 12 U.S. cities, a significant correlation between relative humidity and the number of deaths from cardiovascular disease in general, acute myocardial infarction, obstructive lung disease and pneumonia (Braga, Zanobetti, & Schwartz, 2002) as well as the number of hospital admissions for cardiovascular disease (Schwartz, Samet, & Patz, 2004) has not been confirmed. Similar results were found in a study in Birmingham, where the temperature, pressure and humidity did not significantly influence the assessment of the impact of soot and sulfur dioxide on the number of hospital admissions for respiratory diseases (Walters et al., 1994). In contrast, examination of the influence of climatic factors on mortality from myocardial infarction on the territory of Athens showed that the average monthly value of relative humidity significantly affects the number of deaths from this disease (Dilaveris et al., 2006). On the territory of Athens, a significant correlation was established between the humidity and the number of emergency hospital admissions for acute coronary syndrome (Panagiotakos et al., 2004). A statistically significant correlation was confirmed only between the average monthly values of relative humidity and morbidity. A conclusion can be made that this weather factor takes longer to exert its effect on the cardiovascular system, in relation to changes in temperature and air pressure.

Other Meteorological Factors

In addition to the atmospheric pressure, temperature, and humidity, while assessing the acute impacts of air pollution on the health, some studies performed control of the effects of winds, clouds and precipitation.

The human body heats air molecules that surround it, transferring heat away from the skin. Under the conditions without air flow, a layer of warm molecules is held against the body and provides protection from colder air molecules. Wind removes this layer of warm air and in proportion to its speed body is cooling faster (Office of Climate, Water and Weather Services, 2001).

Stronger winds occur when large air masses are moving, and can affect health because they bring changes in weather conditions within very short intervals. Rapid changes in temperature affect the pH of the blood, blood pressure, diuresis and tissue permeability (Persinger, 1980). A study by the Climatological center of Canada has confirmed the increase of the rate of migraine attacks in the days when strong winds are blowing, barometric pressure drops, humidity rises and there are rapid variations of temperature (Cull, 1981). Rosen (1989) found that rapid changes in barometric pressure during the days with high winds are causing increased mortality from cardiovascular disease. On the other hand, the wind velocity influences the ventilation of housing, wherein due to smoking, firing, and cooking, the concentration of particles can be higher than the outside air.

The reduction of solar radiation caused by cloudiness may also cause adverse effects on human health. Increase of light levels leads to increased mental activity through stimulation of the autonomic nervous system and causes a general feeling of satisfaction. The sun's rays cause changes in neurotransmitter hormone synthesis, and increased production of epinephrine leads to physical and mental stimulation. In contrast, low light intensity leads to fatigue and sleepiness (Wolfe, 1981).

The largest number of previous studies on the health impacts of precipitation relates to the effects of snow. It was found that extensive snowfalls significantly impact the increase of death rates, as well as an increase in the number of hospitalizations due to cerebrovascular stroke and myocardial infarction (Faiche & Rose, 1979). The majority of negative health effects occurs three to eight days after the cessation of precipitation. The supposed mechanism of effect is the increased physical activity that snow requires (removal of snow, difficulty with walking, etc.). In men, the risk is higher than in women, probably because they are exposed to greater physical activities related to snow.

Rainfall has a limited impact on human health. Kalkstein proved that the overall mortality rate declines one day after a summer rain, and the supposed mechanism of effect is the indirect effect of lowering of high summer temperatures (Kalkstein & Valimont, 1986).

Precipitation and temperature also affect the shortening of the time spent outdoors, and the length of exposure to the outside air pollution.

OBSERVATIONS AND RESPONSES TO CLIMATE CHANGES

Growing concerns about air pollution and climate changing issues have introduced partnerships between weather services, civil protection agencies, and public health authorities in many communities to inform their residents about and protect them from the dangers of air pollution and weather to health. Major components of these systems are announcing advisories and implementing emergency measures when air pollution levels and forecast weather is expected to adversely affect the health of residents of a city or region.

Warning System to Reduce Health Consequences of Extreme Weather Conditions

We developed the first such system in Serbia, which issues information on meteorological conditions and air pollution, on the health risks due to the effect of these factors, and provides advice on reducing risk to both the general population, and particularly vulnerable population groups. At the same time, a database is being formed on the health consequences of unfavorable meteorological factors and air pollution, and the use of the system itself, which will allow the monitoring of the effectiveness of solutions and possible correction of limits of meteorological factors and air pollution for certain classes of health risks.

The system is a Web service that is used in the prevention of the consequences of the effects of adverse meteorological conditions and air pollution on health.

Our solution uses meteorological data that is retrieved via a direct link from the website of the Republic Hydrometeorological Service of Serbia (<http://www.hidmet.gov.rs>) and data on air pollution that are downloaded via a link from the website of the Agency for Environmental Protection of the Republic of Serbia - SEPA (<http://www.sepa.gov.rs>).

Meteorological data include temperature, air pressure, wind speed, and humidity. Based on the temperature values (T) expressed in degrees Celsius, and humidity (H) expressed in percents, the heat index (Hi) is calculated according to the formula:

$$Hi = T + 5/9 \times ((6,112 \times 10^{(7,5 \times T / (237,7 + T))}) \times H / 100 - 10)$$

Heat index values are, in relation to the level of health risk, divided into five classes: no risk (up to 26°C), caution (27 to 32°C), increased caution (33 to 41°C), danger (42 to 54°C) and extreme danger (over 54°C).

When the temperature is below 5°C, instead of the heat index, the wind chill index (WCi) is calculated, based on the temperature value (T) expressed in degrees Celsius, and wind speed (W) expressed in kilometers per hour:

$$WCi = 13,12 + 0,6215 \times T - 11,37 \times W^{0,16} + 0,3965 \times T \times W^{0,16}$$

This formula is used when the wind speed is greater than 2.5 kilometers per hour, and when it is lower, the wind chill index value is equal to the air temperature.

Wind chill index values in relation to the degree of health risk are divided into five classes: no risk (above 4°C), low risk (4 to 6°C), moderate risk (-7 to -17°C), high risk (-18 to -28°C), and very high risk (below -28°C).

The average 24-hour values of sulfur dioxide (SO₂), nitrogen dioxide (NO₂), particulate matter up to 10 micrometers in diameter (PM₁₀), carbon monoxide (CO) and ozone (O₃), expressed in micrograms per cubic meter (µg/m³) are classified in five classes of air quality index (AQI) in accordance to the limits defined by SEPA.

For the final classification of air quality index, the concentration of the least favorable pollutant is used. When the concentrations of pollutants are measured at a number of measuring points, highest measured values are used for classifying the air quality index.

The technical solution is a web application that is integrated into the existing website of the Institute of Occupational Health Niš. Application is managed by an administrator. Users access the application by clicking on the "Environment and Health" field. On first accessing the application, users are required to register and create a username and password which they use for all subsequent access. On first access, the users are presented with a survey that includes information on general socio-demographic charac-

Table 1. Air quality classification

Air Quality Index					
Pollutant	Excellent	Good	Acceptable	Contaminated	Extremely Contaminated
SO ₂	do 50,0	50,1-75,0	75,1-125,0	125,1-187,5	above 187,5
NO ₂	do 42,5	42,6-60,0	60,1-85,0	85,1-125,0	above 125,0
PM ₁₀	do 25,0	25,1-35,0	35,1-50,0	50,1-75,0	above 75,0
CO	do 2500	2501-3500	3501-5000	5001-10000	above 10000
O ₃	do 60,0	60,1-85,0	85,1-120,0	120,1-180,0	above 180,0

teristics (age, sex, weight, height, smoking habits), and health status (chronic diseases, medication use, health services use, hospitalization).

Users are presented with the same survey every subsequent month of application use.

At the bottom of the survey is the “Forward” command for data recording. By entering this command the user is granted access to the application.

The application includes five web pages.

“Home” includes the application name, a brief description of the purpose of the application, and a warning that users must not modify their continuing therapy based only on the information and recommendations from this website without previously consulting their doctor. The “About” page gives information about the project name and participants.

At the top of the “Data” page are the values of meteorological factors and the concentration of pollutants in the air sorted by date, time and measuring points. Below these values are tables with the air quality index classes and the indices of heat or wind chill.

Below the tables is the information about how these three factors can affect the health, what their class values in relation to the level of health risk are, as well as information on specifically vulnerable population groups. Next are recommendations on ways to reduce or eliminate health risks.

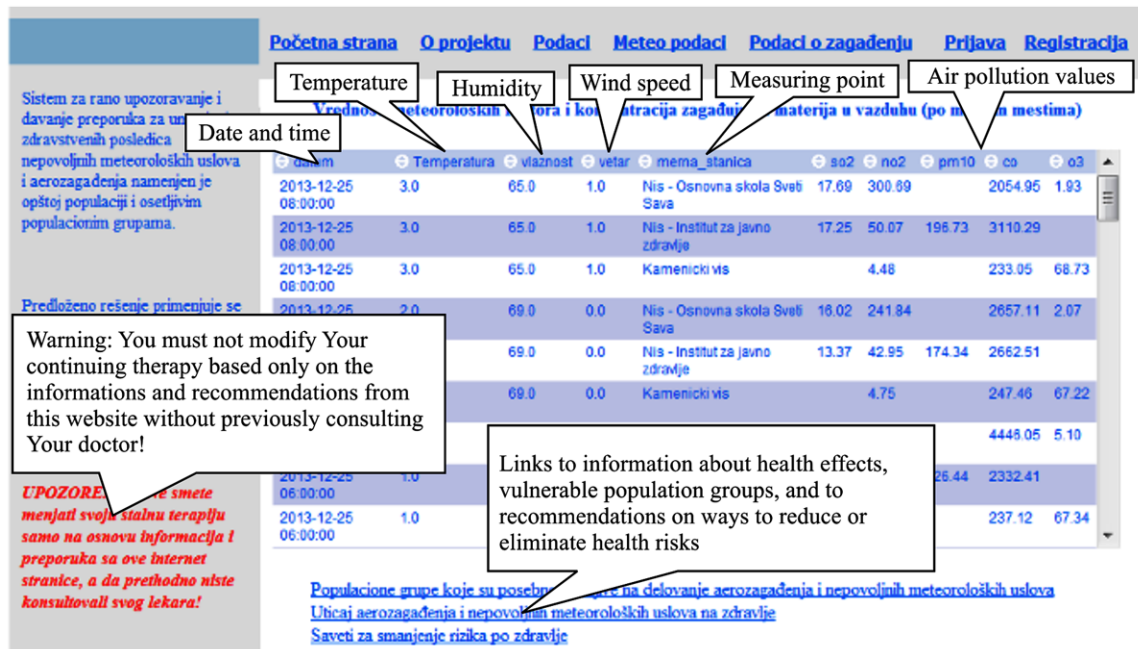

THE IMPACT OF AIR POLLUTION AND ADVERSE WEATHER CONDITIONS ON HEALTH

Air pollution and adverse weather conditions usually exert their negative impact on the health by worsening symptoms of pre-existing disease.

The biological mechanisms of air pollution effects include direct effects on the cardiovascular system, blood, lung receptors and indirect effects expressed through pulmonary oxidative stress and inflammatory responses. Direct effects may arise from the action of agents that can easily pass through the pulmonary epithelium into the circulation, such as gases, and the ultra-fine particles. Direct effects may contribute to the instability of vascular plaques, or initiate a cardiac arrhythmia. These effects of air pollution are the likely explanation for the occurrence of rapid (within hours) cardiovascular responses such as the increase in the number of acute myocardial infarction. Less acute (up to several days) and chronic indirect effects may occur due to oxidative stress or lung inflammation, which are caused by inhaled pollutants.

Warning System to Reduce Health Consequences of Extreme Weather Conditions

Figure 1. "Data" page

While at rest, the body temperature is around 37°C, and during physical exertion it can rise to 38-39°C without any harmful effects on health. In order to maintain the temperature within the physiological range it is necessary to create a balance between the heat generation and loss. Several mechanisms are involved in the regulation of body temperature, and the most important for heat loss are sweating and expansion of peripheral blood vessels, while the most important mechanisms for temperature increase are muscle tremors and the constriction of peripheral blood vessels. Both excessively increased and decreased temperatures act as stress factors for the organism, especially in individuals who already suffer from chronic diseases.

Population Groups that are Particularly Vulnerable to the Effect of Air Pollution and Adverse Weather Conditions

Population groups that are particularly vulnerable to the effect of air pollution are children, people over 65 years of age, people with chronic diseases of the cardiovascular or respiratory systems- especially asthma, emphysema, chronic bronchitis, heart insufficiency and coronary artery disease, as well as people of all ages who train or perform heavy physical labor in the environment (Faustini et al., 2012; Calderón-Garcidueñas et al., 2007; Curtis et al., 2006).

Population groups that are particularly sensitive to the action of excessive heat are: people over 65 years of age, people living alone, obese people, people with diabetes, people with chronic kidney disease, lung, cardiovascular, nervous and digestive system disease, as well as persons in therapy with diuretics, antipsychotics, antiparkinsonian drugs, antiepileptic drugs, and beta blockers (Kravchenko et al., 2013; Baccini et al., 2008).

Warning System to Reduce Health Consequences of Extreme Weather Conditions

Population groups that are particularly sensitive to the action of excessive cold are: children, people over 65 years of age, people with mental health problems, people with health disorders that affect thermoregulation (decreased thyroid function, malnutrition, stroke, severe arthritis, Parkinson's disease, trauma, spinal cord injuries, burns), diabetics, and people in therapy using antidepressants, antipsychotics and/or sedatives.

Tips for Reducing Health Risks

If the concentrations of air pollutants are elevated:

- Reduce or limit your outdoor activities, especially those that require physical effort.
- Avoid staying in locations that you know to contain sources of air pollution, such as heavy traffic roads.
- Take your therapy on a regular basis.
- Stop smoking tobacco.
- Heat:
 - Avoid exposure to sunlight or heat sources.
 - If possible, stay in an air-conditioned space.
 - If you do not have air conditioning during the hottest part of the day, dim your apartment, close the blinds and draw the curtains, and ensure good ventilation during the night.
 - Avoid strenuous physical activity outdoors.
 - Edit your schedule of sports training.
 - If possible, conduct business activities in air-conditioned space, and if it is not possible, take frequent breaks at work.
 - Drink plenty of water and natural fruit juices (avoid alcohol, coffee and soft drinks).
 - Wear loose clothing that permits the evaporation of sweat.
 - Wear a hat and use sunscreen (spf of at least 15).
 - Never leave children or pets unattended in a car.
 - Rest as much as possible.
 - Call or visit friends and neighbors who belong to the group of people who are particularly sensitive to the action of excessive heat.
- In cold weather:
 - Put on warm, multi-layered clothing.
 - If you go outside, put on a hat, gloves and scarf, clothing should be resistant to wind.
 - Keep your apartment/house warm, 21°C in the living room and the kids' rooms, 18°C in other rooms.
 - Be physically active.
 - Take plenty of hot food and drinks.
 - When the value of the wind chill index is lower than -18°C, shorten your outdoor activities or stop them completely.
 - Have yourself vaccinated against the flu on time.
 - Provide a small stash of drugs that you constantly use.

Warning System to Reduce Health Consequences of Extreme Weather Conditions

The “Weather Data” page contains the values of meteorological data per hour for the current day, obtained from the Hydrometeorological Institute, the heat or wind chill index values, depending on the air temperature, and the level of health risk.

The “Information on pollution” page contains concentrations of pollutants in the air, sorted by the place and time of measurement, as well as the value of air quality index. If any of the pollutants in a particular time and a particular place is not measured, the field remains blank.

Early warning systems for adverse health effects due to air pollution are the most developed in the United States, Canada, and Europe. There are few successful cases in Asia (Taiwan, China, Hong Kong, Korea, Japan and Thailand), and several in Latin America (Argentina, Brazil, and Mexico City), and only one in Africa (Cape Town, South Africa). Most existing systems focus on monitoring the concentration of pollutants in real time at the surface. Information on air quality is usually communicated via web services. The EPA provides e-mail alerts (EPA), but this service is available only in the United States. E-mail alerts are also provided by the Ministry of Environment, Ontario, Canada. The EPA information service provides information on air quality to its subscribers via e-mail, cell phone or pager, in real time, allowing them to take steps to protect their health in emergency situations. Forecasting is an essential component of the early warning system, and agencies such as the Agency for Environmental Protection of the USA, Belgium, Germany, and Canada provide forecasts, which are fundamental for early warning. (Grasso & Singh, 2011). The aim of these notifications is to help people adapt their behavior in situations of increased concentrations of some pollutants (eg, “do not go out”, “increase the use of medication in consultation with your doctor”, etc.) (Kelly et al., 2012)

Even if climatic factors are studied separately, they are mutually dependently connected, taking into account that many pollutants such as carbon dioxide are greenhouse gases and their increase leads to

Figure 2. “Weather data” page

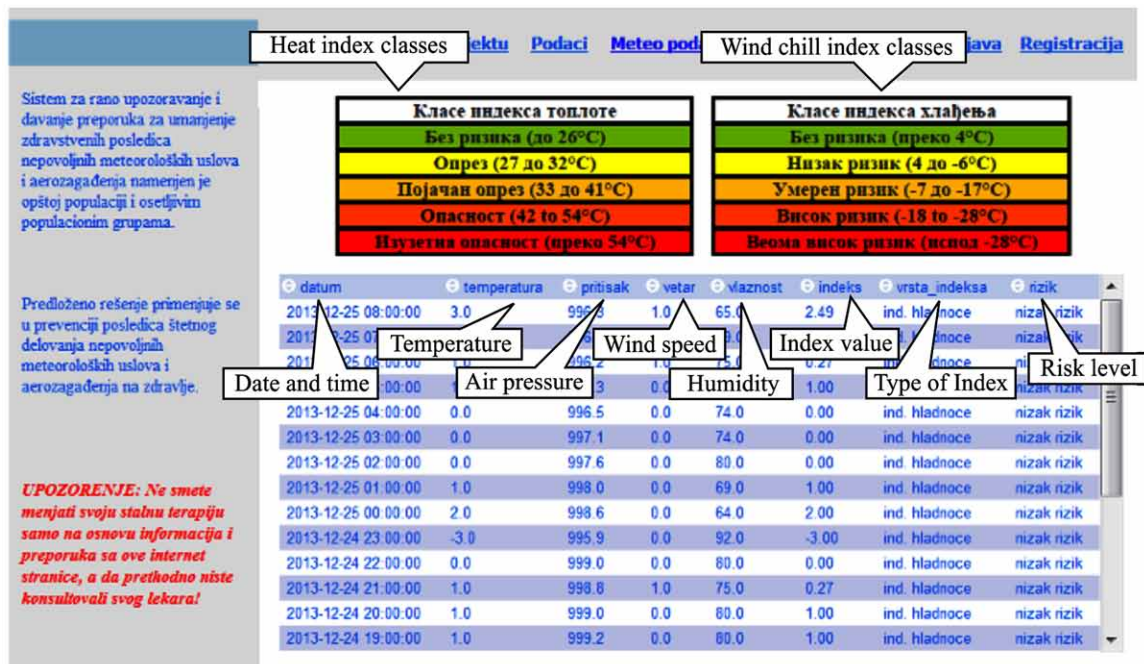

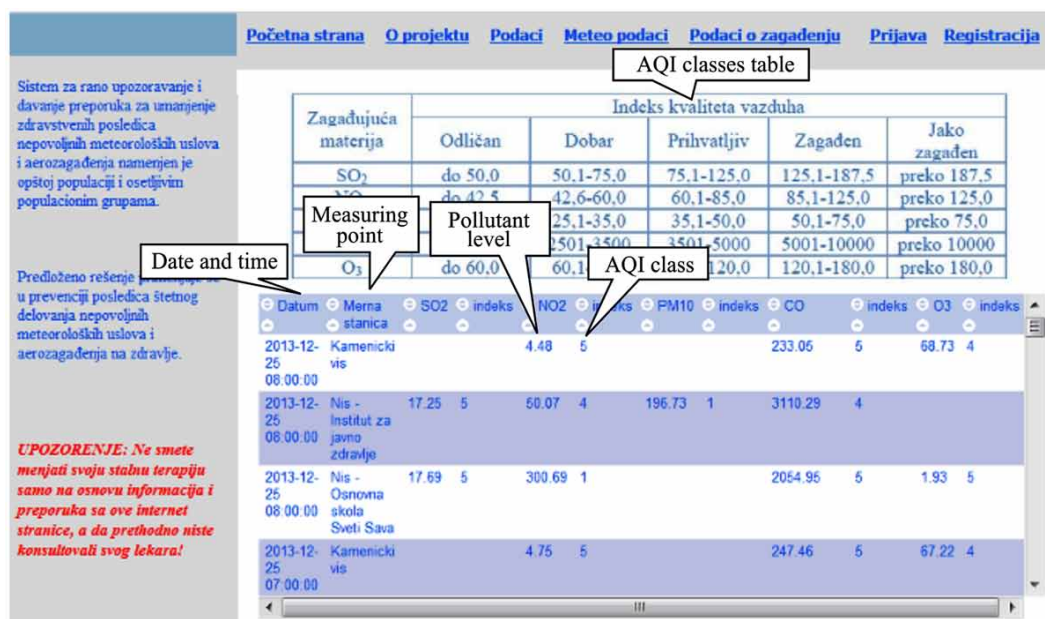

Figure 3. "Information on pollution" page

global warming and climate change (von Schneidemesser & Monks, 2013). Since the 2003 heat wave in France (National Institute of Public Health Surveillance, 2003) caused a significant increase in mortality of persons older than 75 years, a number of European countries has, as part of its public health policy, introduced plans, systems and guidelines for the purposes of prevention of adverse health effects caused by the heat waves. The European Commission has funded the EUROHEAT project, which aims to give guidance in public health actions in the event of adverse weather conditions, especially heat waves (Matthies & Menne, 2009)

The Government of Quebec has introduced a real-time integrated system for monitoring and tracking of extreme heat events as part of its Action Plan on Climate Change (2006-2012). That system is a component of a broader approach that will also monitor the public health impact of all types of extreme weather events. After conducting a detailed needs analysis, the National Institute of Public Health of Quebec has developed and implemented an integrated web application, at first applied only for heat waves. The system is available to health professionals through a secure web portal and provides access to the weather forecast and indicators (including mortality and hospitalization). The system was implemented and used during the summer of 2010, where it served as an important tool in decision-making during the heat wave in the province of Quebec. The next steps will be to provide access to the application to other groups of professionals who are involved in the prevention, monitoring and analysis of extreme weather events and their effects on the health of the community and the individual (Cheban et al., 2013).

A question is raised on the effectiveness of these systems in reducing heat wave related mortality. Toloo et al. (2013) have cited 15 studies that examined the efficiency of heat wave early warning systems. Six studies found that fewer people died during the heat waves after the implementation of the warning system, and there was less use of health care. One study also estimates that the costs of running the heat wave early warning system will cost the U.S. \$210,000, and that 117 lives were saved thanks to the

system. The remaining eight studies examined the behavior of the population in relation to the warning systems. Evidence suggests that the warning systems were efficient in reducing mortality and morbidity, but other factors that affect morbidity and mortality during heat waves must also be considered.

FUTURE RESEARCH DIRECTIONS

A database is formed from all the data from the questionnaires filled in by users, as well as data on meteorological factors and air pollution which, in addition to the user characteristics and the number of adverse health events also includes the value of the concentration of pollutants in the air, and the values of meteorological factors, which will be used to evaluate the effectiveness of the application and its further development. The number of physician visits, use of emergency medical services, as well as the number of hospitalizations before using the application and during its use will be compared. It is expected that the number of adverse health events during use of the application will significantly decrease. In addition, regression analysis will be used to examine how great is the impact of meteorological factors and air pollution on the number of adverse health events. Regression analysis will also be used to check if the class of heat and wind chill indices and air quality index are adequately defined in accordance with the findings which will be acquired during the implementation of the application, and appropriate limit value corrections will be performed.

CONCLUSION

Use of this system provides citizens with information about weather conditions and air pollution, how they can affect the health and how the general population and various vulnerable population groups can protect their health during periods of adverse weather conditions or increased levels of air pollution. Also, this system provides formation of a database on concentrations of pollutants in the air, the values of meteorological factors, as well as changes in the number of adverse health consequences of air pollution and meteorological factors in application users. This will allow the tracking of the solution efficiency, as well as a possible correction of limit values of meteorological factors and air pollution for certain classes of health risks.

KEY TERMS AND DEFINITIONS

Air Pollution: Air pollution is contamination of the indoor or outdoor environment by any chemical, physical or biological agent that modifies the natural characteristics of the atmosphere.

Early Warning System: Early warning system is any series of steps established to spot potential problems, and reduce their adverse effects.

Health: Health is a state of complete physical, mental and social well-being.

Heat Index: Heat index is a measurement of the air temperature in relation to the relative humidity, used as an indicator of the perceived temperature.

Wind Chill Index: Wind chill index is the perceived decrease in air temperature on exposed skin due to the flow of air. When the air temperature is below 5°C, the wind chill index is used as an indicator of the perceived temperature instead of the heat index.

ABSTRACT

In a context of intensification of international trade and travels, the transboundary spread of emerging human or animal pathogens represents a growing concern. One of the missions of the national veterinary services is to implement international epidemiological intelligence for a timely and accurate detection of emerging animal infectious diseases (EAID) worldwide, and take early actions to prevent their introduction on the national territory. For this purpose, an efficient use of the information published on the web is essential. The authors present a comprehensive method for identification of relevant associations between terms describing clinical signs and hosts to build queries to monitor the web for early detection of EAID. Using text and web mining approaches, they present statistical measures for automatic selection of relevant associations between terms. In addition, expert elicitation is used to highlight the most relevant terms and associations among those automatically selected. The authors assessed the performance of the combination of the automatic approach and expert elicitation to monitor the web for a list of selected animal pathogens.

1. INTRODUCTION

In recent years, the increased globalisation, movement of passengers and international trade has influenced the (re)emergence of new and exotic infectious diseases (Morens, Taubenberger, & Fauci, 2013). The traditional disease surveillance systems, organized via a multilevel health infrastructure, show delays in reporting disease outbreaks, starting from the first observation of clinical signs, laboratory confirmation until public communication (Chan et al., 2010). In consequence, the delays in reporting of disease outbreaks have themselves delayed the implementation of disease control measures, and thus influenced the spread of pathogens to uninfected territories (Khomenko et al., 2013).

As a complement to the traditional disease surveillance systems, several event-based surveillance systems (web monitoring systems) gather information about infectious disease outbreaks from automatically retrieved articles from the web (Collier et al., 2010; Freifeld, Mandl, Reis, & Brownstein, 2008; Steinberger, Fuat, Best, Von Etter & Yangarber, 2008). For this purpose, the current web monitoring systems use a specific vocabulary, such as names of diseases and clinical signs. However, it is not clear how these systems identify the vocabulary to mine the web, and especially for animal infectious diseases.

Innovative, data mining approaches have been successfully applied to clinical records in human medicine (Chapman, Dowling, & Wagner, 2004; Friedlin, Grannis, & Overhage, 2008) and to articles retrieved from the web, such as with the web monitoring systems HealthMap and BioCaster (Brownstein, Freifeld, Reis, & Mandl, 2008; Collier et al., 2008). However, the data mining approaches in animal health face challenges such as multiple vertebrate and possibly invertebrate (insects, ticks...) hosts and less formal vocabulary (Santamaria & Zimmerman, 2011; Smith-Akin, Bearden, Pittenger, & Bernstam, 2007). Indeed, a single pathogen agent can affect multiple animal hosts at the same time (cattle, sheep, goats, pigs) and can manifest with similar or different clinical signs. Furthermore, the clinical signs can vary from very typical, specific clinical signs (congenital malformations and deformations, blister-like sores on the skin and mucous membranes, haemorrhagic syndrome etc.) to less typical, non-specific clinical signs (fever, weakness, diarrhoea, etc.).

In this paper, we propose and evaluate a new method that combines text and web mining approaches to select relevant associations between terms describing hosts and clinical signs to build queries to mine the web and detect an emergence of an infectious animal disease outbreak. We focus on the new and exotic infectious animal diseases.

After the presentation of the related work in the next section, sections 3 and 4 present the framework of our method and the text and web mining approaches for identification of associations between terms describing hosts and clinical signs. Sections 5 and 6 consider the experiments and the results of the evaluations. Finally, in the last section we discuss this paper and present our future work.

2. RELATED WORK

The Argus system, hosted at Georgetown University Medical Centre (USA), uses a simple method to detect articles on the web, using search terms of multilingual disease names (Nelson et al., 2010; Nelson et al., 2012).

More complete, web search criteria are proposed by the HealthMap team, which include disease names (scientific and common), clinical signs, keywords, and phrases. The terms originate from a dictionary of pathogens (human, plant, and animal diseases) and geographic names (country, province, state, and city).

Identification of Associations between Clinical Signs and Hosts

HealthMap integrates outbreak data from multiple electronic sources, including news feed aggregators (e.g., Google News), expert curated accounts (e.g., ProMED-mail), multinational surveillance reports (e.g., Eurosurveillance), and validated official alerts e.g., from WHO and OIE (Brownstein, Freifeld, Reis, & Mandl, 2008).

To detect articles on the web (e.g., Google News), the International Biosurveillance System (IBIS) uses the knowledge of registered users of the system that propose the search terms themselves. Registered users can edit the search terms and add or edit the tags in the articles that are relevant to the search terms (Lyon et al., 2013).

The GPHIN system developed by the Public Health Agency of Canada, retrieves automatically articles from news feed aggregators (e.g., Al Bawaba and Factiva), based on search terms and Boolean expressions, updated regularly by experts (Keller et al., 2009). The automated system filters out duplicate articles and establishes relevance scores for articles based on a value assigned to each search term. The automated tool discards articles with a score below an established threshold value to a search term. The scanned, filtered and categorized articles are evaluated by GPHIN's human analysts before being shared with the users of the system (Mykhalovskiy & Weir, 2006).

Similarly, MediSys, the web monitoring system created by the Joint Research Centre of the European Commission, retrieves articles from a list of web pages and news-feed aggregators. The retrieval is based on a predefined multilingual terms for each disease included in the system using a list of weighted terms; and/or combination of terms, as proposed by experts. For example, the system retrieves an article and displays it in the disease category for dengue if the term “dengue” appears at least three times in the text. However, if the text of the web article includes a term (based on a list of irrelevant terms), such as the term “concert,” the article will not be retrieved. An article is also retrieved by the system if two combinations of search terms appear in the text, such as “dengue” and “outbreak” (Mantero, Belyaeva, & Linge, 2011).

The conceptual framework for the system BioCaster that has run from 2006 until 2012 was a multilingual ontology (Collier et al., 2007). The ontology was a structured public health vocabulary and relations of diseases, agents, clinical signs, syndromes and hosts. The BioCaster ontology adopted a thesaurus-like structure with synonym sets linking together terms across languages with similar meaning. Synonym sets used root terms. Root terms themselves were fully defined instances that provided bridges to external classification schemes and nomenclatures such as ICD10, MeSH, SNOMED CT and Wikipedia (Collier et al., 2010).

Zhang and Liu (2007) explored the detection of sentences containing disease outbreak information in ProMed-mail. They addressed the issue that the vocabulary used to report disease outbreaks overlaps with that used in other public health news, such as the treatment of diseases, and therefore search terms and text classifiers based on standard word features would not be effective in identifying disease outbreak articles. They used a dependency parser to identify sentence structures, and extracted verbs and adjectives directly modifying disease names as features. As additional features, they detected tense and negation status of verbs and extracted word *n*-grams (consecutive *n* words in text) and time terms (e.g., “today,” “three months ago,” etc.) from sentences (Torii et al., 2011).

Recently, Gesualdo et al., (2013) developed a minimally trained algorithm that exploits the abundance of health-related web pages to identify all jargon terms related to a specific technical term for avian influenza surveillance of Twitter. Then they translated an influenza case definition into a Boolean expression, with each clinical sign described by a technical term and all related jargon terms, as identified by the algorithm. Subsequently, they monitored tweets that reported a combination of clinical signs meeting the

case definition query and found a high correlation between the trend of their influenza-positive tweets and the trends identified by the US traditional avian influenza surveillance system.

Milinovich et al. (2014) found that the frequency of official notifications of exotic infectious diseases were correlated with a number of terms used as queries from the users on Google search engine. These terms varied from names of diseases or aetiological agent (“brucellosis, “Brucella”), colloquialisms (“flu,” “help”), clinical signs (“cough,” “cervical mucus”) or medications or general health or treatment related queries (“clinical signs of dengue,” “whooping cough treatment”) to environmental (“flash flood,” for leptospirosis) and behavioural vocabulary (“African tours,” for malaria). Similarly, in our previous work we showed that queries consisting in the name of the animal disease such as “African swine fever outbreak” or “ASF outbreak” retrieve new articles about African swine fever (ASF) outbreaks, rather than general queries such as “fever outbreak” (Anonymous, 2014).

3. OUR PROPOSED METHOD

The work presented in this paper is a part of the methodology that we currently develop for the purposes of the French epidemic intelligence team in animal health (VSI). Since its creation in 2013, the VSI team focuses in detection of outbreaks of new and exotic animal infectious diseases of potential threat to France. Our contribution is in the methodology for monitoring the web, as one of the sources of information for the VSI team, and especially:

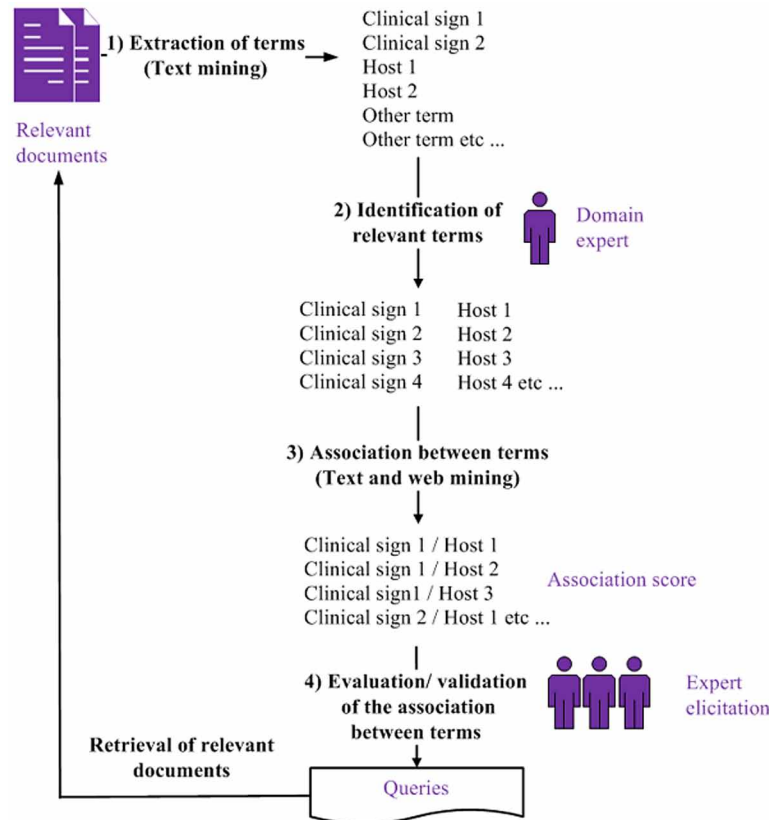

1. Automatic retrieval of documents based on search queries (queries);
2. Automatic classification of documents based on their content (relevant – disease outbreak documents and irrelevant – any other document);
3. Automatic extraction of information from relevant documents (name of a disease – if mentioned, date and location of an outbreak, affected hosts and clinical signs etc.); and
4. Evaluation of the process, using domain expert knowledge.

In this paper, we present our work related to the first step of the methodology for monitoring the web. To retrieve documents from the web, we use queries based on terms, such as disease names, for a known disease, but also associations between terms describing clinical signs and hosts, for a new or unknown disease. We explore the use of web and text mining techniques and domain expert knowledge to identify relevant associations between terms describing clinical signs and hosts that can permit detection of new relevant documents about disease outbreaks. More precisely, our method consists of four steps (Figure 1):

1. Extraction of terms from relevant documents, using a text mining approach;
2. Identification of terms describing hosts and clinical signs, using expert knowledge;
3. Association of terms describing hosts and clinical signs and calculation of statistical measures of association between terms, using text and web mining approaches; and
4. Evaluation of the relevance of the terms and the associations thereof, using expert elicitation.

Identification of Associations between Clinical Signs and Hosts

Figure 1. Workflow of the method for identification of relevant associations between terms describing hosts and clinical signs for monitoring disease emergence on the web

3.1. Extraction of Terms

A set of relevant (e.g., disease outbreak) documents for a certain disease serve as a basis for extraction of terms. Later, from each set of relevant documents, we automatically extract terms using *BioTex*¹, a tool that combines linguistic and statistic information adapted to biomedical area (Lossio Ventura et al., 2014). To select appropriate terms *BioTex* bases on two principles:

1. Implementation of a relevant combination of information retrieval techniques and statistical methods, e.g., term frequency - inverse document frequency (TF-IDF), OKAPI (a cross-platform and open-source set of components and applications that offer for localizing and translating documentation and software), or C-value measures;
2. Use of a list of syntactic structures of the terms that have been learnt with relevant sources, e.g., medical subject headings (MeSH). The terms extracted with *BioTex* can be either simple, one term (e.g., “pig”) or composed, multi-term (e.g., “domestic pig”) expressions.

3.2. Identification and Association of Terms

In this second step, a domain expert identifies the terms describing hosts and clinical signs that characterize an emergence of a certain disease. For this purpose, the domain expert selects the terms from the list resulting from the former step.

Next, using text mining and web mining approaches, we propose statistical measures for automatic selection of relevant associations between terms describing clinical signs and hosts. We detail this contribution in the section below.

3.3. Evaluation

Economopoulou et al. (2014) elicited experts to prioritize exotic infectious diseases of importance to the European Union. Mantero et al. (2011) used experts to identify keywords for the purposes of the MedISys web monitoring system of the European Commission. Expert elicitation was also adopted to evaluate the quality of different data mining approaches for identification of terminology for monitoring the web and for syndromic surveillance (Furrer et al., 2015; Steinberger et al., 2008). Therefore, we considered the expert elicitation as a necessary step for our method and we elicited a panel of domain experts to evaluate the level of relevance of the terms extracted with text mining as well as the associations thereof.

4. MEASURE OF THE ASSOCIATION BETWEEN TERMS

This section describes the data mining techniques that propose relevant associations between the terms describing hosts and clinical signs. This corresponds to the third step of our proposed method (see Figure 1).

4.1. Web Mining Approach

Pointwise Mutual Information and Information Retrieval (PMI-IR) is an algorithm using the AltaVista search engine to query the web to determine appropriate synonyms to a given query (Turney, 2001). For a given word, PMI-IR chooses a synonym among a given list. These selected terms correspond to the TOEFL questions. The aim is to identify the synonym that gives a better score. To obtain scores, PMI-IR uses several measures based on the proportion of documents where both terms are present on the web. Turney's formula is inspired from Mutual Information (Church & Hanks, 1990). Our work applies this principle. First, we propose D_{web} measures based on the Dice's coefficient. Other statistical measures like Mutual Information (MI_{web}) (Church & Hanks, 1990) and Cubic Mutual Information (CMI_{web}) (Nazar, Vivaldi, & Cabré, 2008; Vivaldi, Mâquez, & Rodríguez, 2001) can be associated with web mining techniques.

The D_{web} measure computes the relationship between terms describing hosts (h) and clinical signs (cs). In this context, we measure the number of pages containing the terms h and cs together (i.e. $hit(h \text{ AND } cs)$). We get this number of search pages with the search engine Exalead (<http://www.exalead.fr>). To calculate this association and the dependence of the terms, we also compute the number of pages where each term appears (i.e. $hit(h)$ and $hit(cs)$). The following formula defines D_{web} with AND operator:

Identification of Associations between Clinical Signs and Hosts

$$D_{Web}^{AND} = \frac{2 \times \text{hit}(h \text{ AND } cs)}{\text{hit}(h) + \text{hit}(cs)}$$

We chose Exalead because it offers the NEAR function like in Turney's approach (2001). NEAR is an operator that returns web pages where both terms h and cs are present in a 16-word window. We can adapt the previous formula with this new formula given below:

$$D_{Web}^{NEAR}(h, cs) = \frac{2 \times \text{hit}(h \text{ NEAR } cs)}{\text{hit}(h) + \text{hit}(cs)}$$

Moreover, we can use Mutual Information (MI) and Cubic Mutual Information (CMI) to estimate the dependency between h and cs :

$$MI_{Web}^{AND}(h, cs) = \frac{\text{hit}(h \text{ AND } cs)}{\text{hit}(h) \times \text{hit}(cs)}$$

$$CMI_{Web}^{AND}(h, cs) = \frac{\text{hit}^3(h \text{ AND } cs)}{\text{hit}(h) \times \text{hit}(cs)}$$

We can adapt these measures with the NEAR operator. The original MI measure (Church and Hanks, 1990) uses a logarithm (i.e. $\log_2 (P(x, y) / (P(x) P(y)))$). The logarithm function is strictly increasing. So, the application or not of logarithm function does not change the ranking of the terms. Also, it is worth noting that MI tends to extract rare and specific dependencies (Vivaldi, Màrquez, & Rodríguez, 2001).

In our approach, we do not use other web mining measures such as "Google Similarity Distance" (Cilibrasi & Vitanyi, 2007) that needs specific parameters, e.g., the total number of web pages indexed by search engines.

4.2. Text Mining Approach

The D , MI , and CMI statistical measures can be used with the text mining approach. In this context, the Dice measure (D) is defined as the number of times (i.e. nb function) where h and cs appear in the same context over the sum of the total number of times each one appears in the corpus for each disease. We can adapt the text mining context with other statistical measures (MI and CMI). In this case, the choice of the context is crucial. In our data, both terms h and cs are very rare in a given sentence so we use a larger context (i.e. an abstract or an article). To summarize, the following formulas give the text mining statistical measures:

$$D_{text}(h, cs) = \frac{2 \times nb(h \text{ AND } cs)}{nb(h) + nb(cs)}$$

$$MI_{text}(h, cs) = \frac{nb(h \text{ AND } cs)}{nb(h) \times nb(cs)}$$

$$CMI_{text}(h, cs) = \frac{nb^3(h \text{ AND } cs)}{nb(h) \times nb(cs)}$$

4.3. Combination of Text and Web Mining Approaches

Text mining and web mining approaches have a complementary behaviour. We apply text mining on specific texts in relation with each studied disease. Therefore, our global ranking function favours this type of approach. To overcome the case of rare associations, it is better to use a more global statistical measure calculated on the web, i.e. considering the web as a corpus. To take into account these principles, we propose a global measure called CMI_{global} . Based on our experiments (see following section) and the state-of-the-art review (Saneifar, Bonniol, Poncelet, & Roche, 2015; Vivaldi, Màrquez, & Rodríguez, 2001), the statistical measure CMI_{global} bases on the CMI criterion and the use of AND operator.

$$CMI_{global}(h, cs) = 1 + CMI_{text}(h, cs) \text{ if } CMI_{text}(h, cs) \neq 0 \text{ else } CMI_{Web}^{AND}(h, cs)$$

In this formula, the value 1 enables to favour the text mining value for the global ranking function (statistical measure) CMI_{global} . Table 1 shows examples of pairs of associations (hosts and clinical signs) for Bluetongue and Schmallenberg virus infection.

Table 1. Examples of ranked associations with CMI_{global}

Rank	Bluetongue clinical signs / hosts	Schmallenberg virus infection clinical signs / hosts
1	general clinical signs / pregnant ewes	stillborn bovine foetuses / bison
2	livestock deaths / sheep	aborted foetuses / sheep
3	embryonic death / cattle	deformed offspring / sheep
4	general clinical signs / sheep	stillborn bovine foetuses / deer
5	livestock deaths / cattle	aborted foetuses / cattle
6	livestock deaths / deer	deformed offspring / cattle
7	fever outbreak / sheep	stillborn bovine foetuses / calves
8	embryonic death / sheep	deformed offspring / lambs
9	fever outbreak / cattle	acute bronchopneumonia / bison
10	embryonic death / pregnant ewes	stillborn lambs / goat

5. EXPERIMENTS

5.1. Selection of Emerging Animal Infectious Diseases

For our experiments, we have chosen four animal infectious diseases of importance to animal health. These diseases have emerged in the last years in several countries in Europe and North Africa and they pose a risk of spread to other non-infected countries, including France.

African swine fever (ASF) is a highly contagious haemorrhagic viral disease of domestic and wild pigs. Typical clinical signs are high fever, loss of appetite, haemorrhages in the skin and internal organs, and death (Sánchez-Vizcaíno et al., 2013).

Foot-and-mouth disease (FMD) is a highly contagious viral disease of cattle, swine as well as sheep, goats, and other cloven-hoofed animals. Typical clinical signs are fever and blister-like sores on the tongue and lips, in the mouth, on the teats and between the hooves. The virus causes severe production losses and while the majority of affected animals recover, the virus often leaves them weakened and debilitated (Rodeia, 2008).

Bluetongue (BT) is a non-contagious, viral disease of domestic and wild ruminants transmitted by biting midges of the genus *Culicoides*. The clinical signs are most severe in sheep, resulting in weight loss, disruption in wool growth, and death (Wilson & Mellor, 2009).

In summer 2011, a new virus - Schmallenberg virus (SBV), appeared in The Netherlands and Germany. It quickly spread in many European countries. Affecting ruminants, it caused temporary, flu-like signs, with a short fever and drop in milk production, and sometimes abortion, stillbirth and severe foetal malformations (Wernike, Hoffmann, & Beer, 2013).

5.2. Textual Data

As sources of terms, we used a set of relevant documents (news articles and abstracts) for each of the studied diseases, which we manually retrieved in August and September 2014 from the Google search page and the PubMed database. We retrieved the news articles using the query in English-language “name of the disease” AND “outbreak” and we retrieved the abstracts using the query in English-language “name of the disease,” when present in the title or the body of the text. A relevant article described a disease outbreak event for each studied disease. A relevant abstract was indexed with the MeSH term “epidemiology,” and when not indexed, contained epidemiologic information for each studied disease. We used 181 news articles for ASF, 79 for BT, 84 for FMD, and 148 for SBV from Google and 45 abstracts for ASF, 116 for BT, 143 for FMD, and 53 for SBV from PubMed. The relevant documents principally covered topics about ASF outbreaks in Europe, FMD outbreaks in Northern Africa, BT outbreaks in the Balkans, and SBV outbreaks in Western Europe, for the period from 2011 to 2014.

5.3. Evaluation Protocol

5.3.1. Relevance of the Terms and the Associations Thereof

For each studied disease, we elicited a panel of domain experts (21 for ASF, 7 for FMD, 7 for BT, and 5 for SBV). Using an online questionnaire, the experts evaluated a representative number of terms ex-

Identification of Associations between Clinical Signs and Hosts

tracted with text mining that described clinical signs and hosts for each studied disease. Tables 2, 3, and 4 show details of the terms describing clinical signs and hosts.

For the studied disease, the experts evaluated the relevance (specificity) of the terms describing the clinical signs. The relevance of the clinical signs was:

Table 2. List of terms extracted with text mining, which described clinical signs and hosts that characterize a foot-and-mouth disease emergence. In bold are the terms proposed to the experts for evaluation

Clinical signs	Terms
General	production losses, low mortality
Mucous/ cutaneous	mucosal disease, papular stomatitis, swine vesicular disease, vesicular disease, vesicular stomatitis
Hosts	Terms
	cattle herds, wild boar, cattle and buffaloes, Bactrian camels, dairy cattle, beef cattle, cattle and pigs, pig farms, small ruminants, cattle farms, deer farm

Table 3. List of terms extracted with text mining, which described clinical signs and hosts that characterize a bluetongue emergence. In bold are the terms proposed to the experts for evaluation.

Clinical signs	Terms
General	livestock deaths, general clinical signs, onset of weakness, excess mortality, fever outbreak
Reproductive	embryonic death, reproductive disorders, occurrence of abortion
Hosts	Terms
	red deer, adult sheep, cattle herds, roe deer, cattle population, newborn calves, newborn dairy calves, dairy calves, dairy ewes, pregnant ewes, cattle and goats, small ruminants, cattle production, goat farms

Table 4. List of terms extracted with text mining, which described clinical signs and hosts that characterize a Schmallenberg virus emergence. In bold are the terms proposed to the experts for evaluation.

Clinical signs	Terms
Congenital malformations, deformations	congenital malformations, deformed lambs, malformed offspring, ovine congenital malformations, arthrogryposis hydranencephaly syndrome , severe foetal malformations, foetal malformations, vertebral malformations , severe congenital malformation, hydranencephaly syndrome, limb malformations , congenital malformation, malformed calves, severe congenital malformations , malformed lambs, malformed progeny, deformed offspring
Digestive	watery diarrhoea
General	nonspecific febrile syndrome, mild transient disease, febrile syndrome
Reproductive	perinatal death, premature birth, lamb losses, aborted foetuses, reproductive losses, enzootic outbreak of abortion , outbreak of abortion, stillborn bovine foetuses , substantial reproductive losses, stillborn lambs
Respiratory	acute bronchopneumonia
Hosts	Terms
	newborn calves, sheep holdings, cow herds, red deer , goat holdings, lambs and calves , kids and calves, adult dairy cows, cows and ewes, lambs and goats , adult cows, cattle herds, dairy cows, bovine foetuses, goat population, dairy cattle , sheep herds, small ruminants, bison population, European bison, fallow deer , bovine foetus, goat kids , goat farms, goat foetus, deer populations, sheep farm, cows and calves, sheep herd, sheep population, cattle farms, newborn lambs, small ruminant, cattle population

Identification of Associations between Clinical Signs and Hosts

1. Very low, when their occurrence was very unlikely to characterise the disease emergence;
2. Low, when they probably did not characterise the disease emergence;
3. Medium, when they possibly characterised the disease emergence;
4. High, when they very probably characterised the disease emergence; and
5. Very high, when they characterised in almost all cases the disease emergence.

Next, the experts noted the groups of clinical signs that are most likely to appear in the hosts during an emergence of the disease.

5.3.2. Precision of the Associations obtained with the Statistical Measures

After consideration of the evaluation made by the experts, for each studied disease and for the terms evaluated by the experts, we noted the relevant associations. For these purposes, we analysed the relevance of 36 associations for FMD, 42 associations for BT and 144 associations for SBV. Further, we analysed the precision for the first 20 highest ranked associations obtained with the statistical measures D_{Web}^{AND} , D_{Web}^{NEAR} , MI_{Web}^{AND} , MI_{Web}^{NEAR} , CMI_{Web}^{AND} , CMI_{Web}^{NEAR} , and CMI_{global} . The precision of ranking was the number of relevant associations from the 20 highest ranked associations obtained with the statistical measures.

The precision of retrieval was the number of returned relevant pages (first 10 pages) for the 20 highest ranked associations obtained with the statistical measures and when tested as queries (in Google news, period from 2011 to 2014). A relevant page (RP) was a page that covered disease related information, including disease outbreak information. For these purposes, we analysed the relevance of 587 web pages for FMD, 733 web pages for BT and 564 web pages for SBV.

6. RESULTS

In the present section, we analyse the results for FMD, BT and SBV. We discuss ASF elsewhere (Anonymous, 2014).

6.1. Relevance of the Terms and the Associations Thereof

Eighteen terms extracted with text mining described clinical signs and hosts that characterize a FMD emergence (Table 2). The experts evaluated 14 representative terms describing clinical signs and hosts. Two terms described general clinical signs (mortality, production losses) and five terms described mucous/ cutaneous clinical signs (vesicular and papular stomatitis, vesicular and mucosal disease, and swine vesicular disease). Seven terms described the hosts (cattle, small ruminants, buffaloes, pigs, wild boar, camels, and deer).

The majority of the experts (> 50%) evaluated the formation of vesicles as highly to very highly relevant; mucosal disease as medium to highly relevant, and production losses and formation of papules as medium relevant to characterise a FMD emergence (Figure 2). During a FMD emergence, the majority of the experts noted as relevant the apparition of mucous/ cutaneous clinical signs in cattle, small ruminants and pigs and the apparition of general clinical signs in cattle and pigs (Figure 3).

Identification of Associations between Clinical Signs and Hosts

Figure 2. Expert evaluation of the relevance of the terms describing clinical signs to characterize a foot-and-mouth disease emergence

Figure 3. Expert evaluation of the relevance between the terms describing hosts and clinical signs to characterize a foot-and-mouth disease emergence

Twenty - two terms extracted with text mining described clinical signs and hosts that characterize a BT emergence (Table 3). The experts evaluated 13 representative terms describing clinical signs and hosts. Four terms described general clinical signs (deaths, general clinical signs, weakness and fever) and two terms described reproductive clinical signs (embryonic death and abortion). Seven terms described the hosts (cattle, sheep, goats, ewes, calves, red deer and roe deer).

The majority of the experts (> 50%) evaluated the general clinical signs, including weakness, fever and mortality, the embryonic deaths and the abortions, as very low to low relevant to characterise a BT emergence (Figure 4). During a BT emergence, the majority of the experts noted as relevant the apparition of general and reproductive clinical signs in cattle and sheep (Figure 5).

Identification of Associations between Clinical Signs and Hosts

Figure 4. Expert evaluation of the relevance of the terms describing clinical signs to characterize a bluetongue emergence

Figure 5. Expert evaluation of the relevance between the terms describing hosts and clinical signs to characterize a bluetongue emergence

Sixty - six terms extracted with text mining described clinical signs and hosts that characterize a SBV emergence (Table 4). The experts evaluated 29 representative terms describing clinical signs and hosts. Seven terms described congenital malformations or deformations (arthrogryposis hydranencephaly syndrome, foetal malformations, vertebral malformations, severe congenital malformations, hydranencephaly syndrome, limb malformations, and deformed offspring). One term described digestive clinical signs (watery diarrhoea). Two terms described general clinical signs (nonspecific febrile syndrome, mild transient disease). Seven terms described reproductive, including postnatal clinical signs in new-born (perinatal death, premature birth, aborted foetuses, reproductive losses, enzootic outbreak of abortion,

stillborn bovine foetuses, stillborn lambs) and one term described respiratory clinical signs (acute bronchopneumonia). Nine terms described the SBV hosts (cows, goats, sheep, calves, and goat kids, lambs, bison, red deer and fallow deer).

The majority of the experts (> 50%) evaluated the congenital malformations and deformations as very highly relevant; the postnatal mortality and stillbirth as highly relevant; and the reproductive losses as medium relevant to characterize a SBV emergence (Figure 6). During an SBV emergence, the majority of the experts noted as relevant the apparition of congenital malformations and deformations and postnatal mortality and stillbirth in calves, kids and lambs, reproductive clinical signs in cattle, sheep and goats and digestive and general clinical signs in cattle (Figure 7).

6.2. Precision of the Associations Obtained with the Statistical Measures

Fourteen from 36 associations for FMD were relevant. The statistical measure CMI_{global} had the highest precision in ranking the relevant associations (12/ 20 associations), followed by CMI_{Web}^{AND} (11/ 20 associations) (Table 5). The precision of the relevant associations for FMD to retrieve relevant pages from the web for all statistical measures was > 0.92 (Table 6). From the relevant associations, the highest precision results to retrieve relevant pages from the web had the associations: vesicular stomatitis / cattle (10/ 10 pages), vesicular disease / cattle (9/ 10 pages), production losses / cattle (10/ 10 pages), and the associations: production losses / pigs (8/ 10 pages), vesicular disease / pigs (7/ 8 pages), and

Figure 6. Expert evaluation of the relevance of the terms describing clinical signs to characterize a Schmallenberg virus emergence

Identification of Associations between Clinical Signs and Hosts

Figure 7. Expert evaluation of the relevance of the terms describing hosts and clinical signs to characterize a Schmallenberg virus emergence

Table 5. Precision of ranking of the associations obtained with the statistical measures

Statistical measure	Foot-and-mouth disease	Bluetongue	Schmallenberg virus infection
D_{Web}^{AND}	0.40	0.25	0.45
D_{Web}^{NEAR}	0.40	0.40	0.50
MI_{Web}^{AND}	0.45	0.35	0.50
MI_{Web}^{NEAR}	0.45	0.35	0.40
CMI_{Web}^{AND}	0.55	0.25	0.60
CMI_{Web}^{NEAR}	0.50	0.35	0.40
CMI_{global}	0.60	0.30	0.50

vesicular stomatitis / pigs (3/ 4 pages). From the associations evaluated as less relevant, the highest precision had the associations: vesicular stomatitis / deer (10/ 10 pages), and vesicular disease / deer (4/ 4 pages).

Eleven from 42 associations for BT were relevant. The statistical measures had a precision for ranking the relevant associations < 0.4 with the highest precision for D_{Web}^{NEAR} (8/ 20 associations) (Table 5). The precision of the relevant associations to retrieve relevant pages from the web for all statistical measures was ≤ 0.1 (Table 6). From the relevant associations, the highest precision to retrieve relevant pages from the web had the associations: livestock deaths / cattle (2/ 10 pages). From the associations evaluated as less relevant, the highest precision to retrieve relevant pages from the web had the associations: embryonic death / cattle (10/ 10 pages), embryonic death / sheep (4/ 4 pages), fever outbreak / cattle (3/ 10 pages), and fever outbreak / sheep (2/ 10 pages).

Forty-five from 144 associations for SBV were relevant. The statistical measure CMI_{Web}^{AND} had the highest precision for ranking the relevant associations (12/ 20 associations) (Table 5). The precision of the relevant associations for SBV to retrieve relevant pages from the web was the highest for the associations obtained with the statistical measure CMI_{global} (precision of 0.4) (Table 6). From the relevant associations, the highest precision to retrieve relevant pages from the web had the associations: deformed offspring / lambs (6/ 6 pages), deformed offspring / calves (7/ 8 pages), and limb malformations / goat kids (3/ 3 pages). The associations: watery diarrhoea / cattle, and reproductive losses / cattle retrieved three relevant pages from seven pages. The associations: aborted foetuses / cattle, aborted foetuses / sheep, aborted foetuses / calves retrieved relevant pages with precision < 0.25. From the associations evaluated as less relevant, the highest precision results to retrieve relevant pages from the web had the associations: deformed offspring / sheep (8/ 10 pages) and deformed offspring / cattle (5/ 6 pages).

7. DISCUSSION AND FUTURE WORK

The work presented in this paper is part of the global methodology that we develop for the French epidemic intelligence team in animal health where we focus on monitoring the web to detect disease emergence (Arsevska et al., 2014). We currently have a list of more than twenty exotic diseases (including ASF, FMD, BT and SBV) and ten groups of clinical signs in five animal species.

In one of our previous works (Arsevska et al., 2014), we did experiments with data for African swine fever (ASF). We compared the predictive performance of (i) a Discriminative Multinomial Naïve Bayes (DMNB) algorithm and (ii) a Sequential Minimal Optimization (SMO) algorithm, using a 10-fold cross-validation method. Both classification algorithms reported good predictive performance for text documents about ASF, with precision, recall and F-score of 0.75 for DMNB, and precision, recall and F-score of 0.73 for SMO (Table 7). Similar results were obtained elsewhere (Conway et al., 2009; Freifeld et al., 2008; Zhang & Liu, 2007). In the future, we intend to use machine-learning techniques to extract other specific information from non-structured texts retrieved from the web, such as outbreak location, date, hosts, their numbers and clinical signs.

Table 6. Precision of document retrieval based on relevant associations obtained with the statistical measures

Statistical measure	Foot-and-mouth disease	Bluetongue	Schmallenberg virus infection
D_{Web}^{AND}	1.00	0.05	0.25
D_{Web}^{NEAR}	1.00	0.07	0.25
MI_{Web}^{AND}	1.00	0.10	0.21
MI_{Web}^{NEAR}	0.98	0.10	0.21
CMI_{Web}^{AND}	0.92	0.05	0.19
CMI_{Web}^{NEAR}	0.92	0.10	0.22
CMI_{global}	0.93	0.10	0.40

Table 7. Classification results for African swine fever documents

Classification algorithm		Naïve Bayes			Support Vector Machine		
Performance		Recall	Precision	F-score	Recall	Precision	F-score
Class	disease	0.72	0.77	0.74	0.66	0.68	0.67
	economy	0.48	0.53	0.50	0.49	0.73	0.58
	general	0.86	0.87	0.83	0.86	0.76	0.81
Average		0.75	0.75	0.75	0.73	0.73	0.73

In this paper, we explored the use of the data mining approaches to automatically extract relevant terms (clinical signs and hosts) from a corpus of relevant documents and to automatically select relevant associations (between clinical signs and hosts) for monitoring the web for disease emergence. We were mostly interested in the terms describing clinical signs and hosts for known exotic animal infectious diseases. Considering their specificity, we got a highest number of specific terms (clinical signs and hosts) for SBV. Indeed, the relevant documents used for extraction of SBV terms described in detail the emergence of the newly discovered pathogen. In contrast, we got a limited number of specific terms (clinical signs) for BT because the relevant documents described the consequences of this disease for animal productivity, reproduction and lifespan rather than the specific clinical signs.

The statistical measures varied in precision of the ranking of the relevant associations, as well as in precision of retrieval of relevant documents from the web. The highest precision of the ranking was obtained with the statistical measures for CMI_{Web}^{AND} (SBV: 0.6) and for CMI_{global} (FMD: 0.6). The highest precision results for the retrieval of relevant pages from the web were obtained from the relevant associations for CMI_{global} (FMD: 0.93), and the lowest for CMI_{global} (SBV: 0.4; BT: 0.1).

The precision was highly influenced by the criteria selected to note the relevance of each association. Indeed, each association was evaluated based on the experts' answers (taking into consideration the highest notes) but also the semantic context of the terms in the association. For example, for SBV, most experts evaluated the congenital malformations and deformations in offspring (lambs, calves, goat kids) as relevant to characterize a SBV emergence. Accordingly, the associations such as deformed offspring / lambs and deformed offspring / calves – noted as relevant, retrieved a high number of relevant pages from the web. However, the associations such as deformed offspring / cattle and deformed offspring / sheep – noted as less relevant, also retrieved a high number of relevant pages. As these associations were highly ranked with the statistical measures, we do not exclude their value to build queries. These observations provide evidence that the statistical measures used in this work are a valuable decision-supporting tool to facilitate the evaluation of the associations.

The two evaluations we conducted for the ranking and the retrieval of relevant web documents for BT did not exceed a precision higher than 0.4 and 0.1, respectively. One reason for these results was the evaluation by the experts of the terms describing clinical signs – as low specific to characterize a BT emergence (these evaluations correspond to what is known in the literature). This assertion was confirmed by the low performance of the relevant associations as queries. However, the associations that had the highest precision to retrieve relevant documents from the web, such as: fever outbreak / sheep and fever / outbreak / cattle, livestock deaths / cattle, embryonic death / cattle, embryonic death / sheep, corresponded to what was described in the relevant documents – source of terms. For example, the majority of the articles discussed the mortality and reproductive disorders in sheep, goats and cattle

for the 2014 BT epizootics in the Balkans, and the abstracts, discussed the BT clinical signs such as fever and weakness, reproductive disorders and abortions in ruminants.

The precision of our evaluations was also influenced by the number and type of associations used in the experiments. Indeed, in this first work, we only evaluated the representative associations proposed to the experts. In the future, we intend to evaluate all associations from all combinations of extracted terms (describing clinical signs and hosts). For example, we already evaluated 506 associations obtained with text mining for ASF, where the precision of ranking was 0.5 for CMI_{Web}^{AND} and 0.65 for CMI_{global} , and the average precision of retrieval of relevant documents from the web was > 0.83 .

The expert elicitation method allowed us to benefit from the common knowledge of many experts. Most experts agreed on the specificity of the terms for each studied disease, and these evaluations corresponded to what is found in the literature. The experts also proposed new terms important for our future work. For example, for BT they proposed associations such as buccal lesions and ulcers, facial oedemas, cyanosis of the tongue and hypersalivation, principally in sheep and cattle. For FMD they proposed associations, such as lameness and hypersalivation, mortality in young animals, along with vesicle and ulcer lesions of the hoofs, mouth, tongue, and udder, principally in cattle. The proposals by the experts for SBV and ASF corresponded to the extracted terms with the text mining. In future, we intend to evaluate the expert proposals as queries.

Finally, we intend to build queries using the following associations - obtained with text mining:

1. For FMD, production losses, vesicular stomatitis and vesicular disease in cattle and pigs;
2. For BT, deaths and fever in cattle and sheep; and
3. For SBV, malformations and deformations in goat kids, lambs and calves, including deformed offspring in cattle, sheep and goats, as well as reproductive losses and abortions in cattle, sheep and goats.

We consider that the combination of text and web mining approaches and expert knowledge enable to identify relevant associations between terms describing clinical signs and hosts that can improve the detection of infectious disease emergence on the web. Our method is generic and can have applications to both animal and public health.

ACKNOWLEDGMENT

Authors would like to thank the experts that participated in the elicitation. This work was funded by the French Ministry of Agriculture, Food and Forestry (MAAF), the French Agricultural Research Centre for International Development (CIRAD), and the SONGES Project (FEDER and Languedoc-Roussillon)².

Section 3

Utilization and Applications

This section discusses a variety of applications and opportunities available that can be considered by practitioners in developing viable and effective Public Health and Welfare programs and processes. This section includes 12 chapters that review topics from case studies to best practices and ongoing research. Further chapters discuss Public Health and Welfare in a variety of settings. Contributions included in this section provide excellent coverage of today's IT community and how research into Public Health and Welfare is impacting the social fabric of our present-day global village.

Chapter 27

An Investigation of the Application of New Media and Its Impact on Taiwan Health Communication

Ming Chuan University, Taiwan

ABSTRACT

Along with the rise of social networks and mobile media, health communication models also change with each passing day. Compared to traditional media, are the new media more effective to achieve the dissemination of health knowledge, or help people and patients to implement lifestyle adjustments? With the shift in modern lifestyles, social media have revolutionized health communication. The means and channels for health communication are now very diversified. In order to assess the influence of social media in health communication, this study analyzed the “1922 Prevention Expert”, a campaign launched by Taiwan’s Centers for Disease Control. In this study, the researchers collected data through interviews and a survey to investigate the use and outcomes of social media in health communication and explores how to use social media well in health communication.

1. INTRODUCTION

1.1. Research Background and Motive

Owing to the rapid advances in and popularity of mass media, the applications of new media have become more and more important. Based on historical contexts, people can clearly understand how

DOI: 10.4018/978-1-5225-1674-3.ch027

radio broadcast affected print media and television. As mass communication steps into the 21st century, accelerated technological advancements have brought about massive changes. The Internet has extensive applications, and displays ample evidence of the new media revolution. Therefore, computers and Internet will once again change the face of communication, from its form to its content. The sprouting of the Internet, multimedia, satellite broadcasting and broadband in our society can be traced back to the mid-1990s. Voice communication devices have also changed, from the old telegraph to landlines, followed by mobile phones and free Internet calls. The rise of personal entertainment (mp3 players and mobile phones) and personal Internet space (blogs and tweeting) show the shift in the way messages are moving and communicated across the world.

According to a survey on the use of broadband in Taiwan by Taiwan's Network Information Center, 16.95 million people had access to broadband in 2011, an increase of 730,000 people as compared to 2010's 16.22 million (Taiwan Network Information Center, 2011). The ever increasing number of Internet users shows the dependency of the modern generation on the Internet. This in turn spurs companies and corporate groups to invest resources into developing the Internet as a marketing platform and using mass communication media (e.g. official websites, official blogs etc.), for branding and customer communication. On the whole, communication has already developed from one-way to interactive, from mass to niche; the means and concepts of communication are evolving. As new media has gained users, it is now more than just a communication tool but also an important player influencing society. By many, it is viewed as the source for sharing knowledge, information, viewpoints, public opinion, emotions, and even rumors.

With the help of technological advancements, Social Networking Sites (SNS) are the new wave sweeping through the virtual world. SNS are basically web-based services, providing the means for users to build open or partially open personal information and a recommendation system linked to trust so as to share this information within a personal network (Boyd & Ellison, 2007). SNS provide users with a platform through which to interact over the Internet via instant messaging, forums etc. The interaction results in socialization and acts as a media; thus it is named social media. One of the most popular social media is Facebook. According to one online survey, Facebook had the most hits in the United States in 2010, surpassing even Google; it is also the most searched for keyword. Since June 2008, after Facebook launched its Chinese version, users increased immediately through the second half of 2009, a sharp incline in its membership. As of December 2011, Facebook users in Taiwan stood at 11.6 million, a staggering 71.92% of its total Internet population and 50.38% of Taiwan's overall population (Socialbakers, 2011). Statistics from InsightXplorer (2009) show a growth of 23.6% in Internet usage time from 2010 to 2011. Facebook accounted for most of the Internet usage time (27.01%) followed by Yahoo! (20.68%), Youtube (4.29%), Wretch (3.59%) and Google (2.58%). Facebook has shown a steady increase in Internet usage time, going from 17.77% in 2010 to 27.01% in 2011 (InsightXplorer, 2009). These statistics illustrate the changeover in mass media, especially the rise of social media websites.

As medicine and hygiene are fundamental to one's personal safety and health, the media being one of the most important sources of medical information has raised concern amongst public health and communication scholars. Many domestic and international research studies have shown that public health education through mass media has effectively changed health behaviors, lowering health risks and even death rates. Governments all over the world have worked the use of mass media into their annual budgets as a form of communication for health and disease information, thus raising awareness among people in order to achieve disease prevention and health promotion.

Along with the changing mass communication environment, health communications have become more dynamic. Information channels are more diverse and complicated than before, thereby increasing the difficulty in managing these channels. The benefits of media are that it is fast, effective and has wide coverage in terms of communication. In addition, the ability to use both the traditional media and new media well will be critical in achieving a high level of effective health communication. In this new digital era, managing public relations through social media has become essential and effective. This will help organizations to engage in two-way dialogue that includes the younger generation, media and social groups. Hence, as the use of social media, such as Facebook spreads, non-profit organizations, which are usually low on resources, are able to fully utilize the outreach provided by social media. With the above background in mind, this study aims to find out whether the new social media is more effective than traditional media in health communication. Besides, it also explores how social media to achieve effective health knowledge communication, thus helping the public and the patients to make behavior changes and bring about the well-being of society.

1.2. Research Objectives

Mass media is one of the most important communication channels for health-related information. According to some research, other than word-of-mouth to spread health information, mass media, especially news reports, are regarded as an important mechanism for health promotion (Hsu & Hu, 1998). With the shift in modern lifestyles, social media have revolutionized health communication. The means and channels for health communication are now very diversified. In order to assess the influence of social media in health communication, this study will analyze the “1922 Prevention Expert” campaign that was launched by Taiwan’s Centers for Disease Control. This study collected information through interviews and surveys to investigate the use and effectiveness of social media in health communication and explored how to use social media well in health communication.

Although the communication environment, as well as the healthcare system, in Taiwan differs from other countries in terms of policies; still, much importance is placed on health communication, just as in other countries. Despite seeing some results in health education and communication through the use of mass media in the country, there is a lack of systematic study on the effectiveness of social media for health communication. It is not only important, but also necessary, to understand how to best reach the target audience through the use of social media such as Facebook and to find out if such sites are achieving optimum results. This study aims to explore the:

1. Outreach and advantages among social media’s fan groups
2. Best evaluation of social media as a channel for health communication
3. Satisfaction factors among Internet users for social media
4. Willingness of Internet users to engage in re-diffusion

1.3. Research Subjects

Aside from medical personnel engaging in diffusion of health communication, mass media is also an important propaganda pipeline. The past research has shown that mass media, especially news reports, is viewed as an important mechanism for health promotion (Hsu & Hu, 1998). In the United States, health

and medical communication is divided into two large systems. The first one is for communication within the community itself and is formed by the medical community. This includes publishing in journals and writings by researchers, doctors and medical scholars. The other system is focused on communicating with the society beyond the medical community. This involves the use of mass media such as television, newspaper, magazines, radio, Internet, conferences, and brochures, etc to achieve health promotion and information dissemination.

In recent years, Taiwan's health institutions have placed greater emphasis on using media as a channel to communicate medical knowledge, providing healthcare information or explanation on medical procedures, or for marketing of certain medical procedures. These health institutions have learned from the service industry and have paid more attention to health communications and marketing. In 2009, the "1922 Prevention Expert" campaign was launched by Taiwan's Centers for Disease Control for H1N1 prevention education. Furthermore, it was a creative step in the use of social media for health communication in our country. This study chose to analyze "1922 Prevention Expert" in order to understand Internet users' reactions to social media being a health communication vehicle. The analysis will also assist to evaluate the effectiveness of the campaign, thus assessing the influence of social media on health communication.

2. LITERATURE REVIEW

2.1. Health Communication

The combination of health and communication can be traced back to 1970, starting in the United States, when communication scholars and heart surgeons began to use communication theories for public hygiene education and in long-term health promotion within a community. In attempts to apply concepts from social education to health communication, Jack Farquar made efforts to involve communication scholars to drive "Stanford Heart Disease Prevention Project" (SHDPP), which can be regarded as a milestone. Thereafter, researchers tapped the scientific research ability of Stanford to evaluate the influence of mass media and human diffusion of information on losing weight, cutting down on smoking, lowering of blood pressure and lowering of lipid indexes within a community. Due to this being the first project involving both communication scholars and medical experts; SHDPP was seen as the beginning of modern health communication in the U.S.. However, during the implementation of the SHDPP process, there was no such term as "health communication". Not until the mid-1970s did the International Communication Association (ICA) officially start to use the term "health communication" (Atkin and Marshall, 1996).

With regards to the definition of Health Communication, Rogers (1996) has mentioned an easy and widely accepted definition, that Health Communication is communication of humans in relation to health issues. Moreover, in order to communicate health-related issues, Rogers added four levels that form the core of health communication. These four levels comprise: intrapersonal, interpersonal, group and mass. The level of intrapersonal is about one's physical and mental health; interpersonal level is about doctor-patient and family relationships; group level is about hospital-patient relationship and medical staff training; and the mass level is about the relationship between an audience and media agenda-setting.

2.2. Internet and Health Communication

Before the emergence of the Internet, health inquiries mainly relied on hospitals, doctors or specialists organized for examination, treatment, nursing and applying of medicine. Predictably, this caused imbalanced doctor-patient relationships; the public must accept the doctor's diagnosis without discussing or questioning it. Since the Internet gained popularity, medical service structures are changing. Patients can obtain medical-related information through the Internet, thus increasing overall health knowledge, which in turn helps establish two-way communication and interaction with doctors. This is an enormous change: Patients can fully utilize medical information archives to obtain medical information, and are no longer ignorant and weak. According to survey results published in 2005 by the Pew Research Center, almost 80% of Americans used the Internet at least once a month to search health-related information. This was an increase of 25% from 55% in 2000. Among these 80%, the ratio of women was higher than men at 54%, and 34% of them college educated. The results indicated that 48% of the users were willing to act upon health suggestions given via the Internet and change their health habits. In addition, 92% were willing to refer to online health information while 81% felt that they learned new medical knowledge online. Besides, 47% of the people surveyed were willing to change existing health treatments based on suggestions found online; more importantly, 50% of the users used websites as their reference for consultation with doctors or as a second opinion (Pew Research Center, 2005).

Above research also shows that users regard medical websites as search tools. Almost 91% of the users used the Internet to check on disease-related information, with 26% of them checking on mental health information, 13% on weight loss and nutritional information and 9% checking about doctors, hospitals and drug information (Pew Research Center, 2005). Growing numbers of people accept health information gleaned from the net, and make it a part of medical consultation, thus producing a positive influence.

2.3. The Rise of Social Media

Recently, social networking sites are springing up plentifully; for this reason, it is important to understand what SNS exactly are? This study will use Facebook as an example. Facebook was established by Harvard student Mark Zuckerberg in 2004. Facebook's initial objective was to link up the different societies at Harvard. It became deeply loved by people; thence got the attention of schools and corporations. Since then, it has become one of the fastest growing SNS. Facebook not only combines lots of communication tools such as instant messaging, emails, blogs, file transfer and forum discussion, but has also developed gaming applications with other companies, such as Restaurant City, Happy Pets, etc. Users can interact with friends through these games, building relationships and expanding their network. Facebook can result a number of advantages, even the U.S. president, Barack Obama, used the site's networking well to win the 2012 election. In addition, lots of companies have set up fan pages to utilize the massive reach of a site such as Facebook to promote their marketing strategies, thus bringing in the fame and fortune. In past research, it was postulated that users mainly use SNS for information sharing and developing new relationships. Ridings et al. (2002) indicated that information sharing or exchange can be divided into giving of information and accepting of information. Other researchers feel that information sharing is divided two sectors, namely self-presentation and relationship maintenance, achieved through sharing of personal information such as photographs, real names, address, email, cell phone number, marital status, sexual orientation, nicknames etc. (Acquisti & Gross, 2006; Dwyer, 2007; Dwyer et al., 2007; Levin et al., 2008; Hoadley et al., 2009).

2.4. Social Media and Health Communication

Since the dramatic changes in the communication landscape brought about by Internet use and social media, it is critical to develop a better understanding of these technologies, applications, and their impact on health communication (Chou, Hunt, Beckjord, Moser, & Hesse, 2009). In the health communication community, there is a widespread assumption that recent advances in Internet technologies, such as social media, have changed the way and pattern of communication, including health-related communications (Gunther, 2008). Social networking sites have evolved from a preoccupation of high-school and university students to a mainstream form of social interaction that spans divisions of age, profession, and socioeconomic status. At many hospitals, medical students, residents, nurses, attending physicians, and service chiefs can be found linked to one another as active members of social networking sites (Jain, 2009).

The use of many forms of new media has become widespread among the U.S. and other countries (Abroms, Schiavo & Levebvre, 2008). Health professionals are making increasing use of social media (Thackeray, Neiger, Smith & Van Wagenen, 2012), while Facebook, Twitter, and MySpace are the most popular social media sites used for health promotion (Vyas, Landry, Schnider, Rojas, & Wood, 2012). Facebook not only holds a great potential for promoting health, but also breaks into the health domain (Zhang, He & Sang, 2013). It is mentioned that Facebook holds the potential to influence individuals' health behaviors by shaping their perceptions of social norms and the expectations that they set for themselves, or by improving their access to personally relevant information (Morris, Consolvo, Munson, Patrick, Tsai, & Kramer, 2011). Moreover, it is also indicated that social media sites serve as a growing source of health care information, while Facebook is the preferred source of health information for those who use social media sites for health purposes (Dolan, 2011; Park, Rodgers & Stemmle, 2011). In this regard, this study investigated the use and outcomes of social media in health communication and explored how to use social media in health communication.

2.5. 1922 Prevention Expert

The government sector in Taiwan officially first used social media as a promotional tool during the "1922 Prevention Expert" campaign. In the United States, top-ranked electronic government services use social media such as YouTube, Blog, MySpace, Facebook, Twitter, widgets etc. for their disease control centers to manage health information dissemination. Back in August 2009, this fresh and controversial method caught the attention of the American press, which influenced Taiwan to take a bold step in using social media as the channel for dissemination of H1N1 information. With the use of social media, "1922 Prevention Expert" established a semi-official platform to disseminate accurate and timely information for public reference; this represents a new kind of communication creativity. The Internet is filled with different sources, but the semi-official status of "1922 Prevention Expert" ensures information accuracy thus creating a chain of accurate information dissemination through its social media fans. H1N1 specially posed a threat to teenagers under 20 years of age. In order to prevent the infection from spreading, the organizers chose to use social media to publicize health information via a platform which is commonly used by the target group. The statistics of gender, age, fan growth, interaction, and use of other social networking websites in "1922 Prevention Expert" is shown in the following sub-sections.

Figure 1. “1922 prevention expert” Facebook gender and age statistics. Source: Taiwan’s Centers for Disease Control (April 2010).

2.5.1. Gender and Age

The ratio of male to female fans for this group is 4:6, with more than 700 females. Amongst the total fans, 54% are aged 25-34, with 620 more females than males in this sub-group; the age 18-24 group accounts for 20%, while 19% are 35-44 years old with male to female ratio at 1:1 in this age bracket. The main reason for the bigger group of 25-34 years old is their status as first time parents, who are thus paying more attention to prevention and vaccination; and in this group, as females are the main caretakers of children, thus the ratio tilted toward females. The other groups show more even ratios.

Figure 2. “1922 Prevention expert” Facebook fans’ growth chart. Source: Taiwan’s Centers for Disease Control (April 2010).

2.5.2. Facebook Fan Growth

After the “Influenza Prevention Expert” event in 2009, Facebook fan growth slowed due to Influenza Pandemic being under control, which influenced the felt need for related information. From January 1 2010, the number of fans increased by 7 daily, while the dropout rate held at 4, resulting in slight growth.

2.5.3. Facebook Interaction

From January 26 2010, Taiwan’s Centers for Disease Control reported a decrease in interaction as the second wave of the pandemic died down, thus a decrease in public attention to pandemic issues.

Figure 3. “1922 Prevention expert” Facebook interaction chart. Source: Taiwan’s Centers for Disease Control (April 2010).

Figure 4. “1922 Prevention expert” Plurk and Twitter new friends chart. Source: Taiwan’s Centers for Disease Control (April 2010).

2.5.4. Plurk and Twitter Fans

The levels of growth for Plurk and Twitter remained stable at 20-40 new friends per week during the period late 2009 through the first quarter of 2010.

Other than public relation strategies for promotion, health communication needs to develop new communication channels and tools to keep up with the trends. The power of social media cannot be ignored and need to understand how to utilize this power. As “1922 Prevention expert” is Taiwan’s first time to use social media to manage a public health threat: H1N1 pandemic, therefore, it can view this campaign as a benchmark for evaluation. As the H1N1 pandemic has died down, now the question is how effective can “1922 Prevention expert” be in spreading of information about all kinds of contactable disease. The above topics will be explored in this research.

3. RESEARCH METHOD

In this research, questionnaire and semi-structured interview were used for data collection. Descriptive statistics were calculated to analyze the data. The combination of qualitative and quantitative data presents effective evaluation results for the 1922 Prevention expert’s Facebook fan page.

3.1. Survey of Fans

This research conducted a survey of ‘1922 Prevention expert’ Facebook fans during January 2011 for one week. Below are the survey questions:

1. Have you ever interacted with 1922 Prevention expert before?
2. Are you satisfied with 1922 Prevention expert?
 - 2-1. What are your reasons for any dissatisfaction?
3. Are you willing to recommend 1922 Prevention expert’s page to friends?
4. Have you ever visited 1922 Prevention expert’s blog?
 - 4-1. If you have, are you satisfied with the content of the blog?
 - 4-2. What are your reasons for ant dissatisfaction?
5. Suggestions for content.

3.2. Interviews with Experts

In addition to the quantified survey mentioned above, this research also integrated quality viewpoints in order to avoid data under-representation. This involved examining the effectiveness of 1922 Prevention expert’s Facebook fan page through in-depth interview with experts on health prevention and health information.

Moreover, this study used semi-structured interviews with experts based on the experts’ prior knowledge in three sections. In descending order, these sections were: gathering experts’ opinions and determining any problems, finding the cause of the problems and possible solutions and proposing new ideas. To reach the most effective interview, the researchers interviewed 5 experts who are familiar with disease prevention knowledge, news and media to evaluate 1922 Prevention expert’s Facebook fan page.

The interview outline as follows:

1. What are the advantages and disadvantages of using social media for health communication?
2. Where do you obtain your knowledge on the current use of social media for health communication?
3. What are the main difficulties faced when using Facebook fan pages and why?
4. What are the advantages and impacts of using Facebook fan pages?
5. How can the effectiveness of using social media for health communication be evaluated?
6. Do you have any suggestions for using social media for health communication?

4. RESULTS

4.1. Survey Results

In this study, 378 survey forms were collected and the results are summarized as follows: 15.3% suggested a more lively and creative promotion channel, 9% suggested more lively methods; still another 7.6% wanted more concrete content. Three orientations were covered in the results, including promotion, execution, and content. In terms of promotion: (a). The quality of the promotion should be improved; (b). There should be more relevant activities; (c). Due to lack of relevant information, it must dissemination in daily life; (d). There should be advertisements in television, magazines or newspapers. In terms of execution: (a). The expression through animation is good; (b). There should be more use of animation; (c). Too many words are tiring on the eyes. However, cute animations will make people not only interested but also willing to visit and obtain related information. In terms of content: (a). There should be more examples for illustration e.g. How to improve home environment?

4.2. Interview Results

The researchers interviewed Taiwan's Centers for Disease Control public relations senior executives, staff, and the organizers of 1922 Prevention expert campaign.

Question 1: What are the advantages and disadvantages of using social media for health communication?

This question aims to understand the experts' opinions on health communication practices, besides exploring evaluation of the advantages and disadvantages of the application of social media and traditional media.

According to the interview, experts grasp the advantages and disadvantages of traditional media and social media quite clearly. Social networking media can spread the message of health information immediately, reach the target object, and save transmission costs, which are considered as important advantages. The advantages of traditional media have not been neglected: Traditional media has a certain reputation; therefore it is still regarded as a formal and reliable dissemination of information in the pipeline. Achieving a good combination of these media may maximize the dissemination effectiveness.

Question 2: Where do you obtain knowledge on the current use of social media for health communication?

This question is set to understand expert health communication practices in order to promote the application of social media in the current situation. One of the advantages of social networking is that it can be updated immediately; the content of popular sites is renewed almost every day. Experts reflected that this is an enormous challenge: To manage virtual community media well, the network should provide the user freshness, which requires frequent updates.

Question 3: What are the main difficulties faced when using Facebook fans pages and why?

On this topic, experts agree that the operation and management required for good page content requires a lot of creativity, manpower and time. One of the biggest challenges is that communication via Internet requires quick updates and immediacy. It is attractive, but also causes stress and difficulty if resources or manpower are limited.

Question 4: What are the advantages and impacts of the use of Facebook fan pages?

Experts pointed out that the differentiation of social networking sites is able to transcend the barriers of mainstream media. However, the mainstream media do not provide layout, but the immediacy of Facebook fans group offering some important health or medical information to the target audience has become an operational advantage. This information spread generated by the proliferation of sharing leads to effectiveness that is often beyond what was originally expected. In fact, according to the international marketing organization, Miniwatts, survey at the end of June 2011, Taiwan's Internet penetration rate of 70.0% is second only to North America's 78.3%. If the region regional statistic for the average online rate is valid for Taiwan, it has more Internet usage than Asia overall (23.8%), Europe (58.3%), Africa (11.4%), and Oceania (60.1%). Among the 12 major Asian countries, the penetration rate of China stands at number four, behind South Korea 80.9%, Japan 78.4% and Singapore 77.2%. As for growth rate, Taiwan's Council for Economic Planning and Development pointed out, that since 2000, Taiwan's Internet population has increased steadily, and from 6.26 million in 2000, to 16.15 million in 2011, increased about 1.6 times (Wang, 2011). That is to say, spread of healthcare information through the Internet cannot be neglected.

Question 5: How can the effectiveness of using social media for health communication be evaluated?

This question aims to understand the perspective of experts in health communication practices regarding promotion of the benefits of social media, and how to assess problems of effectiveness. They note that Facebook and YouTube systems provide a number of management tools for quantitative assessment. Social media has an important value in sharing experiences with people, enhancing users' awareness, goodwill, and trust. Reputation benefits may be intangible, but can be powerful in the long-term.

Question 6: Do you have any suggestions for the use of social media for health communication?

The experts generally agree with the positive benefits of social media for health communication, that it will continue to exert its influence.

5. CONCLUSION AND SUGGESTIONS

In this study, the researchers raised four questions: (1) In what situations is social media being used for health communication in Taiwan; (2) What is the status of its use; (3) How is the effectiveness of social media use in this context evaluated; and finally, (4) What is social media's impact on health communication. The first section summarizes the research results; the second section covers the findings arising from this research; the third section discusses the limitations of this research, and the last section presents suggestions made for future research.

5.1. Research Conclusions

This research regards that using social media as a creative channel for health communication has obtained the positive feedback from the participants. Besides, instead of using only traditional media, the government's willingness to develop interactive channels by using social media meets with positive reactions. According to the example of "1922 Prevention Expert," without any help from traditional media, this campaign still attracts users to join its fans page. Users can link with the campaign through all kinds of Internet-information sharing channels, such as search engines, recommendations from friends and family, BBS and forums etc, rather than from traditional media such as television and newspaper. Obviously, the difference between managing social networking sites and traditional media is that the users expect interaction and not just one-way dissemination of data. Most users are willing to spread information when they feel it is useful and they have interacted with it. Solis and Breakenridge (2009) mentioned that in the social media domain, dialogue is key; only active and passive listening can bring meaningful relationships. Based on the findings in this research, if Taiwan can combine different kinds of communication tools to satisfy different target audiences, then the country can build a new pattern for health communication, thus achieving a high level of health promotion and well-being for people.

Furthermore, the researchers discovered there is an information overload in this era; thus all industries exist symbiotically with communications. To get the best results out of this relationship depends on both parties respecting and understanding each other. Although the main focus of this research is on the use and impacts of social media, it is also indicated that effective health communication requires the knowledge of all communication tools, and each tool has its own pros and cons. For example, a televised message containing sounds and lighting effects, prompts immediate reactions from the audience, thus engaging them. For this reason, television is superior to newspaper or radio. However, if an influential radio message could be combined with television, it might be much more effective by increasing television media's impact. Nevertheless, print media (magazines, newspapers) are much better than voice media (radio) or visual media (television), especially when the information is complicated. That is to say, if we make good use of both traditional media's strength and social media's coverage and sharing abilities, health communication can spread broadly with great results and result in better well-being among people.

5.2. Research Limitations

Although this research is based on the examination of Internet users and experts, the '1922 Prevention Expert' campaign is unique in nature; it cannot represent the whole impact of social media on health communication. In addition, this research cannot indicate all levels of evaluation, therefore it is also limited to descriptive results of effectiveness. This study is biased towards the Centers of Disease Control,

as the expert participants may be affected by their status; so it does not represent a more complete and objective evaluation. If this line of research is carried on in the future, participants should be extended to the public or media.

5.3. Research Suggestions

According to this research, although “1922 Prevention Expert” can be regarded as milestone in using social media for health communication in Taiwan, there is much room for improvement. First of all, even although public policies are different from private sector marketing, policies can be executed with the essence of “Branding” and “Service”. Health communication should not just focus on building distinguishing features and service but also concentrate on branding and marketing strategies. The researchers in this study propose that health communication can identify the needs of users, and concentrate resources on building unique networks. Only in this way, can health communication stand out in this era of information overload.

In this study, the authors explored the effects on traditional media and social media, as both have advantages and disadvantages. However, social media is not a passing fad. Rather, it is actually symbolic of human’s need for information sharing and receiving. The government sector is more credible than other website hosts in disseminating health information. Thus, the government can establish a system to manage information and handle crises in a manner that eases the pressure in society. At the same time, policymakers and bureau directors must understand that the burden that comes with the social media is different from that related to traditional media.

Chapter 28

Extending Care Outside of the Hospital Walls: A Case of Value Creation through Synchronous Video Communication for Knowledge Exchange in Community Health Network

Jiban Khuntia

University of Colorado, USA

Mohan Tanniru

Oakland University, USA

John Zervos

Henry Ford Health System, USA

ABSTRACT

In healthcare settings knowledge exchange among important stakeholders such as doctors, family and patients, and other care providers is a critical imperative. However, such a community modelled approach is missing, limited in scope or its business value not well understood. In this study, the authors illustrate the value potential and subsequent development of a business model for knowledge exchange within the healthcare delivery model outside a hospital setting. Specifically, they illustrate how Synchronous Video Consultation with social media features, in a staged approach, can support knowledge exchange among a network of community health care professionals who address global health disparities and sustain this exchange through resource generation. The authors discuss the contributions and implications of the proposed framework towards value creation in a collaborative setting in general and suggest opportunities for future research.

DOI: 10.4018/978-1-5225-1674-3.ch028

INTRODUCTION

Community health information networks (CHIN) are fundamentally community and payer-centric means to healthcare prevention assessment; albeit with higher patient engagement through a collaborative support model. Two elements constitute a CHIN's foundation. First, a centralized knowledge platform and repository that contains individual level demographic, clinical, and eligibility information for a geographically defined community of stakeholder organizations (e.g. local agencies, payers, employers, and researchers). The stakeholder organizations are also consumers of the data for evaluation, diagnostic, or treatment activities and similar purposes (Rubin, 2003). Second, CHIN involves the use of a platform to enable both the community and patient to be actively engaged in the care delivery and management through collaboration, education and knowledge dissemination.

A number of CHIN models have shown success such as an Iowa based community health network (Japsen, 1996) and Wisconsin based community network (Payton & Brennan, 1999). Existing studies note that CHINs are emerging as successful in providing a platform for information collection, storage, archival and access (Vest & Gamm, 2010). Indeed, some CHINs have, over time, become regional health information organizations or health information exchanges (HIEs) and started supporting a wider community by efficiently providing information exchange services to participating stakeholders. The success of CHINs and later HIEs in the exchange of aggregate care related information has not translated into collaboration in support of care at an individual patient level. Hardly any successful CHINs today support collaboration among patients and care providers synchronously as and when needed in the continuity of care, especially when a patient is not within the confines of a hospital. While lack of trust in safeguarding patient information and limited or no financial incentives are partly to blame for not addressing patient care outside of the hospital, community can play an important role in addressing such care and leverage the best form CHIN efforts.

The role of community in support of pre and post-hospital care is critical for two reasons: First, although the current US healthcare delivery system (we call it as "inside hospital walls") is efficient and effective enough to provide "sick care", understanding its impact outside the hospital walls remains a challenge. For example, the current health system is not able to motivate a pre-diabetic patient to run a mile an hour or adhere to a diet control plan. Similarly, the current system does not provide emotional support to a cancer patient who has undergone chemotherapy with side effects that have a bearing on the physical and emotional state of the patient. A patient post-surgery may be able to reduce pain with pain-killers, but need avenues to discuss and get support for the emotional pain associated with the side-effect of the pain-killers or even the surgery itself. Similar examples reflect the type of emotional and cognitive states of patients, and disease management and treatment needs outside of a hospital will become critical if continuity of care is to become a key goal of CHINs. Hence, creating a platform to support a current patient (post-discharge) or a future patient (through prevention efforts) through community engagement is essential, if CHINs are to become relevant at an individual patient level.

As much as CHINs have a social objective to extend the care outside of the walls of the hospitals, there is no incentive in the current US healthcare to such extended care. As a result, many CHIN initiatives fail to sustain their work, specifically, after a period when the social objective faces the challenge of sponsorships or additional grants than the initial funding source. In this context, the avenue to generate revenue from operations or activities is crucial for the CHINs. Thus, as much as CHINs can shape their avenues of making money and plan their activities to meet the revenue generation goals, they will be able to go long way in providing service to the community. Studies have suggested that inappropri-

ate design of business models is a key explanation for the failure of the exchange platforms and similar entities (Gosain & Palmer, 2004). Following the same arguments, development of CHINs for patient level support outside the hospital need a business model that can be helpful to sustain the CHINs within their realm of social objectives. Else, like many other badly formulated entities, they will struggle to accrue revenue and sustain operations after the founding years. In general, 30 to 50 percent of new ventures reach a sustainable stage (Parker & Belghitar, 2006; Reynolds, 2007), with the failure rate being high for most of the social business ventures. A business model is fundamentally a roadmap that aligns a firm's technical potential with market-based revenue generation opportunities in order to realize an economic value (H. Chesbrough, 2007; Teece, 2010). For a venture with a social goal, achieving the economic value is difficult. Given the focus of CHINs is information exchange, prior studies note that aligning a set of services involved in an exchange-based business with revenue generating opportunities is extremely difficult and often leads to failures (Ganesh, Madanmohan, Seshadri, & Seshadri, 2004; Koch, 2002; Ray, Barney, & Muhanna, 2004). In other words, there is a significant gap in research on how to develop a successful business model to sustain the work of a CHIN (for a review, see Zott, Amit, & Massa, 2011), especially when such a network is set up to support the needs of a patient outside the hospital walls using participation from a number of community care providers.

In this paper, we will propose an IT-enabled business model for CHINs and discuss the use of a specific IT (synchronous video communication (SVC) with social media features embedded) in support of collaboration among a community of care providers outside a hospital in a global public health care domain. Next section will discuss prior research on the use of IT in support of knowledge exchanges within a CHIN and the characteristics of a business model that can support such exchanges. Section three discusses the research framework and section four discusses the methodology used to develop the IT artifact (SVC with Social Media) in stages to support the needs of a CHIN involved in global public health and the business model set up to sustain its operations. The last section provides an analysis on how such models can be extended to knowledge exchanges used in other settings and provides concluding comments and directions for future research.

LITERATURE REVIEW

CHIN models, designed to engage patients and community in support of patient care outside a hospital, have to support various types of IT-enabled knowledge sharing using a sustained business model. This section looks at prior research on the characteristics of knowledge sharing networks in health care and the nature of alignment needed if these networks are to support the goals of CHIN.

Knowledge Sharing and Networks in Healthcare

When it comes to knowledge exchange in community networks, the notion is conceptually new in healthcare system. Two challenges are involved in developing such a network. First, although knowledge exchanges existed in healthcare, such as doctors' offices, hospitals, and laboratories share patient information; but extending these exchanges to the community wide efforts is not seen previously. Second, non-digital forms of knowledge exchanges such as paper based, fax based or snail mails exist, but digital forms of knowledge exchange is a unique proposition in recent times. Nevertheless, digitized knowledge exchanges are common in other industries such as finance, banking, telecommunications and

airlines (Goldfarb, Pfarrer, & Kirsch, 2005). Learning from other industries and with the experience of accelerated adoption of health information technologies (HIT) in the United States healthcare (Agarwal, Gao, DesRoches, & Jha, 2010), digital knowledge exchanges with community wide involvement can potentially increase the value of HITs in increasing efficient and effective care delivery by health care organizations (Abraham & Junglas, 2011; Kohli & Kettinger, 2004; Menon, Lee, & Eldenburg, 2000). Indeed, in support of the argument that CHINs can enable such care delivery, more than 300 health exchanges in the US have surfaced in the last decade. At the same time, much like many business-to-business exchanges that emerged at the turn of the century, the health exchanges have been unable to construct the right business model, and led to several failures or non-sustainable businesses (Ganesh et al., 2004; Gosain & Palmer, 2004). CHINs are modelled to extend the concept of both physical and social media for community sharing of health information. In one perspective, CHINs are social media platform to generate, share, receive, and gather information and knowledge (Kamel Boulos & Wheeler, 2007; Kaplan & Haenlein, 2010). Social media are “a group of Internet-based applications that build on the ideological and technological foundations of Web 2.0, and allow the creation and exchange of user generated content” (Kaplan & Haenlein, 2010). For social media to be effective, the media selection and knowledge interaction framework has to support the CHIN stakeholders by enabling sharing of health care related information (Goffrnan, 1959; Short, Williams, & Christie, 1976).

Existing literature points to several limitations of social media for health care related communications. Moorhead et al (2013) points out that quality concerns, lack of reliability of information, and blurred lines between content producer and user are three major limitations. Beyond these limitations, the most important one is the “information overload” and “lack of validity of the information” as this poses a bigger challenge to the use of the social media for meaningful purposes (Adams, 2010a, 2010b). Lack of guidelines may lead to public not correctly applying information found online to their personal health situation, possibly leading to adverse health impact or consequences (Freeman & Chapman, 2007). There is limited evidence on the efficacy of online communities in their ability to support effective delivery of health related information to patients and positively impact people’s health (Colineau & Paris, 2010). All these contribute to providers not actively participating in online social health networking portals (Kim, 2009). In summary, if CHINs in health care are to be successful, they need to support a knowledge exchange architecture that can support multiple actors, playing multiple roles exchange knowledge in public and private mode, all in support of patient care outside a hospital.

Business Model and Community Health Networks

Several studies conclude that business models can be efficacious in defining new organizational structures, customer-centric value propositions, and competitive strategies. Table 1 provides a list of important studies around the concept of business models.

Value creation for customers has been variously alluded to as a ‘value proposition’, ‘creating value network’ or ‘value configuration’ frameworks (Johnson et al., 2008; Osterwalder et al., 2005). Some suggest that business models play a more significant role for entrepreneurial firms or initiatives in identifying and establishing organizational design, resource structures, value structures, and transitive structures; and creating opportunities for their value creation mechanisms (George & Bock, 2011; Teece, 2010).

Prior research suggests that some focal elements that need to be emphasized while designing a business model. First, studies emphasize that the revenue model is a central element in most prior work, albeit referred to with different labels such as revenue logic, capture value, profit formula or return for

(Chesbrough, 2007; Chesbrough & Rosenbloom, 2002)	Case studies and examples from corporations to demonstrate how business models can be helpful in capturing value from innovation.	<ul style="list-style-type: none"> • Business model as an construct that mediates the value creation process • Business model performs two important functions: value creation and value capture 	<ul style="list-style-type: none"> • Cost structure and profit potential • Competitive strategy • Target market • Revenue mechanism
(Amit & Zott, 2001)	Inductive data analysis from 59 American and European public traded corporations involved in e-business.	Business model depicts the content, structure, and governance of transactions designed so as to create value through the exploitation of business opportunities	<ul style="list-style-type: none"> • Transaction: content, structure and governance of transactions • Design of value chain

stakeholders (Chesbrough, 2007; Johnson et al., 2008; Magretta, 2002). Second, studies also converge on the notion that the structure of the firm that influences strategic decisions, choices and principles is a core element of the business model design, implementation, and execution process (George & Bock, 2011; Shafer et al., 2006; Tikkanen et al., 2005). Third, studies argue that to the degree that the business model is a reflection of the firm's core value propositions for customers, if configured appropriately, it can help the firm to achieve continued sustainability and satisfy the objectives of multiple stakeholders (Amit & Zott, 2001; Voelpel et al., 2005).

If a CHIN were to use an IT enabled platform to support patient care outside a hospital, such a platform has to be a strategic tool and help CHIN negotiate, coordinate and transact with the suppliers, partners, collaborators, and customers (i.e. support various types of knowledge exchanges). Further, the business models associated with CHINs have to make special efforts to seek alignment between IT and business, manage IT and health care environment dynamics, and look for niche positions to create value (Osterwalder & Pigneur, 2003; Osterwalder et al., 2005). The research question hence calls for the development of a business model around goals established by CHIN in support of patient care outside the hospital wall and select the right IT platform to support this goal.

RESEARCH FRAMEWORK

Synchronous Video Communication as the IT Platform for the CHIN Business Model

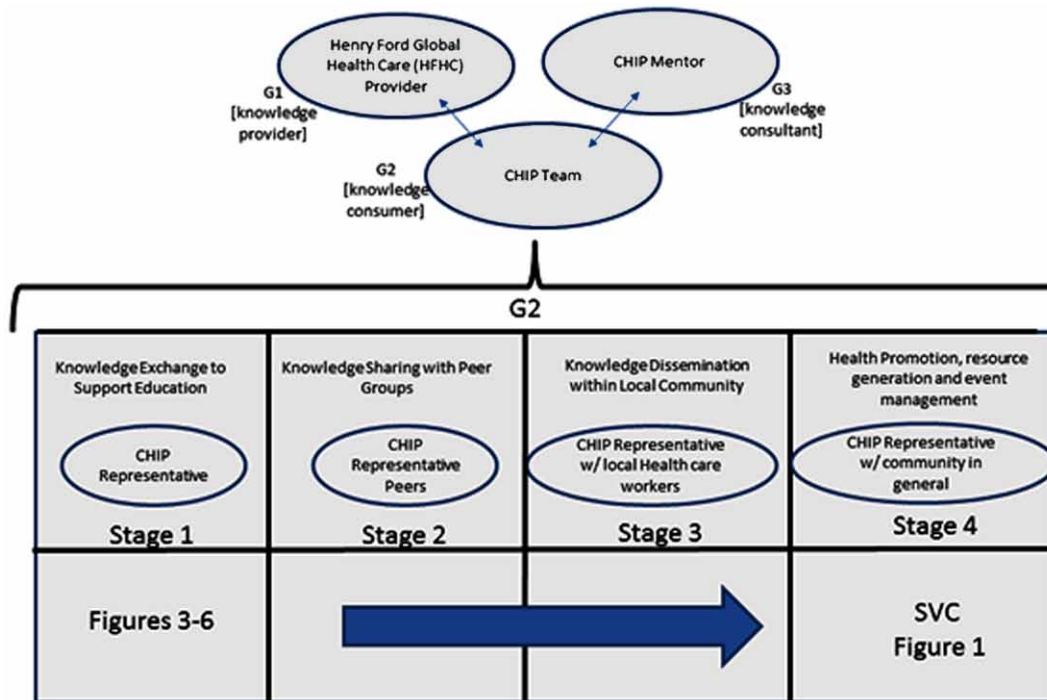

In existing information systems research, media synchronicity is defined as “the extent to which a communication environment encourages individuals to work together on the same activity, with the same information and at the same time; all to support shared focus.” (Dennis, Valacich, Speier, & Morris, 1998). Such a shared focus on patient care is highly relevant in the health care, especially when multiple community stakeholders outside the hospital are involved in support of patient care. As media synchronicity theory (Dennis, Fuller, & Valacich, 2008) proposes, to reach such a shared focus in a group setting two primary processes become important:

- **Conveyance:** The exchange of information. Here, not all participants need to agree on the meaning of the information or even focus on the same information at the same time. Low media synchronicity is generally preferred for the conveyance process;
- **Convergence:** The development of a shared meaning to information. Here, all participants must work together to establish the same meaning for shared information. High media synchronicity is generally preferred for the convergence process.

The synchronous video communication (SVC) that supports social media interactions for both conveyance and convergence is proposed here (see Figure 1) in support of knowledge exchanges needed to enhance shared focus as well as allow varied types of communication at different points of time among community care providers. There are a number of other technologies that can provide synchronous video communication services, albeit not within a social media platform oriented towards healthcare. Tools such as Skype, Voodoo, Google Chat with Video do facilitate multi-party video conferencing features. While it can be argued that social media users can always use these “external third party” solutions for synchronous communication; their use in a dynamic health care knowledge conversation context with privacy of conversations being paramount, is unclear. Either in a single patient-physician context, patient-patient context, or other combinations there-of, a well-integrated system that supports secure communication and knowledge sharing is important in today’s evolving health care settings. For these reasons, an SVC artifact, designed with social media communication support, will be used in support of this research. The technical design features of this artifact were discussed in Park et al. (2014). In this study, our scope is to focus on the use and implementation of the SVC artifact in the CHIN model, and highlight the role of business model to sustain the CHINs. Thus, this study differs from the earlier study in that the earlier study emphasizes on the SVC design as a technical artifact, and this paper uses the design framework for use in the case of global public health in stages, with the exploration of business models to sustain the efforts.

Next section will discuss the methodology used in this research to align the SVC enabled IT platform to support knowledge exchange goals of a CHIN being developed for patient care in a global public health domain.

Figure 1. Staged model for developing support for CHIP team members

RESEARCH METHODOLOGY

In this conceptual study, our research methodology is focused on the crafting parameters of an appropriate business model for CHIN-SVC framework and plausible validation methods. First we discuss an application enablement of the CHIN model in a global public health scenario, and use that specific case to establish the business model and value creation criteria for CHINs.

The Case of CHIN-M: Application of CHIN and SVC in Global Public Health

The CHIN Model (CHIN_M) supports a unique program called Community Health Innovator Program (CHIP), being developed by Henry Ford Global Health Initiative. CHIP empowers community leaders to identify health challenges and address these challenges through innovative local (“on-the-ground”) and global (“adaptable”) solutions. CHIP is grounded in the theory that homegrown health promotion has the most positive outcomes. Often, community residents are less supportive of reforms when they view them as being externally imposed (Parke & Fails, 2014). On the other hand, when health challenges are identified locally and CHIP leaders obtain the support of local communities to create innovative solutions, community residents are more likely to embrace health behavior interventions (Chambers, 1994). Therefore, by promoting local health innovations that provide low-cost health and social benefits to marginalized and vulnerable communities, CHIP proposes novel avenues for wider and more inclusive participation in global health strategy design.

Extending Care Outside of the Hospital Walls

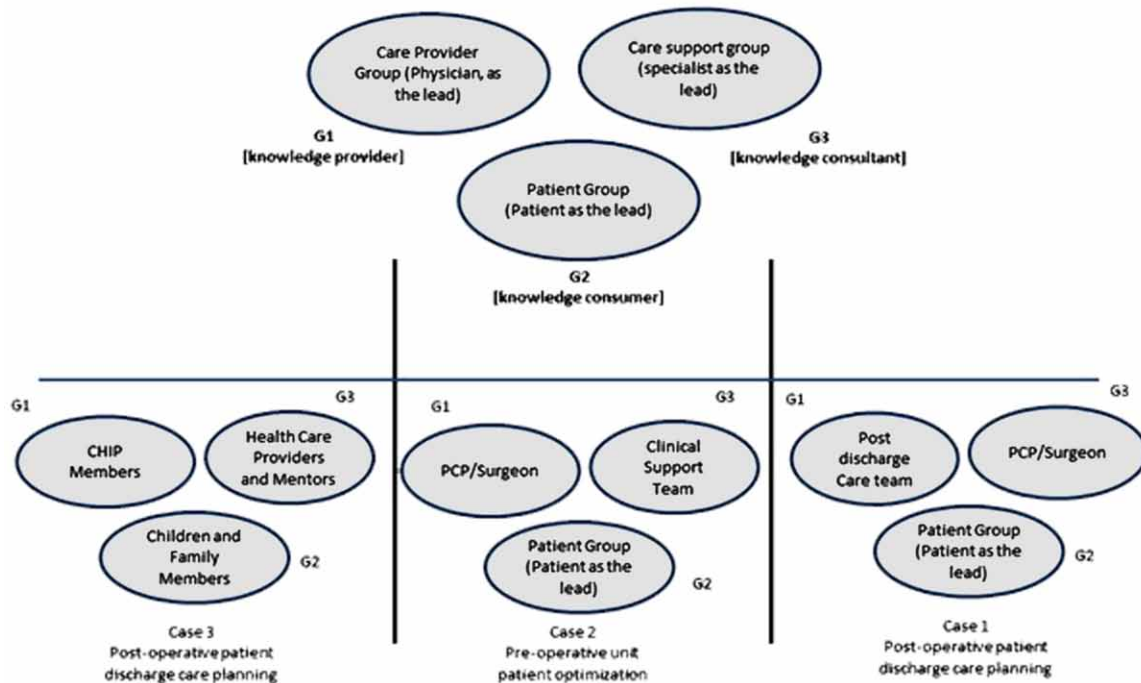

Through CHIN-M, CHIP leaders are equipped with the skills and tools necessary to work with and identify barriers to maximizing the effectiveness of community health workers, and develop locally-relevant interventions. In addition CHIN-M is designed to foster mentoring and professional networks, which enable both intra- and inter-national exchanges of information and strategies to address local health challenges. In low- and middle-income regions CHIP leaders frequently lack access to low-cost training, adequate technologies, funding initiatives, and multi-sectoral networks who are interested in facilitating and adopting social innovations. Current social innovation frameworks and incubators have varied outcomes, but often lack required inputs for success. The CHIP program was designed to address these current limitations and its structure evolved through a collaborative effort between the global health Program Team and an International Advisory Board (IAB), composed of practitioners, academics, and community members from Detroit, Haiti, Ghana, and Nepal. The IAB identified CHIP as an approach, which is needed, feasible, and can be integrated within local infrastructures.

CHIN-M brings together a variety of participants including: CHIP leaders, the Program Team, the International Advisory Board, Mentorship Teams, and Community Health Workers. The leaders are community-identified individuals who work with CHWs and utilize a range of skills (for example, skills in business, technology, health, education and community organization) to impact health outcomes for communities. The Program Team is an interdisciplinary global health team aided by its International Advisory Board. The multi-stakeholder Mentorship Teams are composed of in-country Mentors from academia, business, government, healthcare, and other disciplines as needed.

The CHIN-M is laid out in several stages (see Figure 2). Initially, the Program Team and International Advisory Board identify both Mentors and leaders in each country, as well as build curriculum for the leader trainings and launch a web portal and supported interactions using mobile technologies. Next, after receiving training and being linked with a Mentor, the CHIP leaders meet with CHWs to conduct a community health needs assessment and learn about barriers that the community health workers within that community experience. In the third stage, the leaders connect with the Program Team, the Mentor Team, and Innovators across sites, to engage with the community to innovate possible solutions to locally-identified barriers and health challenges. As we move to stage four, the Teams help connect CHIP leaders with tools to develop the health solutions and generate resources to successfully implement and sustain these solutions. In other words, the CHIN-M grows in sophistication from a simple knowledge exchange platform to knowledge interaction, knowledge sharing and lastly information broadcasting and knowledge dissemination, by leveraging the use of various IT-enabled discussion and other social medial platforms.

Details of the CHIN-M portal development are discussed in another study (Tanniru et al., 2015). The current state of this pilot effort is as follows: Two teams in Detroit and Haiti; after completion of the pilot, will evaluate the web portal through an iterative process. The central purpose of the pilot will be to test the functionality of the CHIP web portal and assess the feasibility of using this technology in both a developing country (Haiti) and a low-income region of the United States (Detroit). The web portal will be evaluated for: (1) Logistical issues for program implementation and participation; (2) Maximized accessibility for LMIC users; (3) Ease of website navigation; (4) Ease of accessing and downloading course content; (5) Usefulness of course content; (6) Usage of the web platform components; (7) Communication issues (e.g. between Innovators, Mentors and the Program Team); and (8) Similarities and differences in issues across sites. Based on feedback, the Stage 1 phase of the CHIP web portal will be completed and Stage 2 will begin. At the same time, the teams in other countries (Nepal, Ghana) will be provided access to the web portal for further evaluation of the technology as well as some of the

Figure 2. Knowledge exchange in three different case scenarios

process/work-flow challenges faced by the global community healthcare workers. It is anticipated that the successive stages of implementation and CHIP leader learning will continue in 2015.

In summary, by allowing increased communication among CHIP leaders across the globe, the CHIN-M will facilitate an exchange of ideas and comparison of solutions. Such a model has to be adaptable to meet local needs and develop a sustainable business model to address numerous global community health challenges, which is the discussed next.

Business Model and Value Creation for CHIN

The dominant value creation opportunity for the CHIN framework would be to leverage on the networked IT platform (e.g., SVC) and strategically design this platform to generate value. According to Chew and Gottschalk (2009), there are generally three value configurations: value shop, value chain and value net. Value shops are organizations designed to solve customer or client problems rather than creating value by producing output from an input of raw materials. A value chain is a chain of activities that a firm operating in a specific industry performs in order to deliver a valuable product or service. A value network describes social and technical resources within and between businesses that are connected by interactions that represent tangible and intangible deliverables. These deliverables take the form of knowledge or other intangibles and/or financial value. Value networks exhibit interdependence across entities, and may be external facing to include customers or recipients, intermediaries, stakeholders, complementary, open innovation networks and suppliers; or internal facing to focus on key activities, processes and relationships that cut across internal boundaries, such as order fulfillment, innovation, lead processing, or customer support. Value is created through exchange and the relationships between roles.

Extending Care Outside of the Hospital Walls

A cell phone company represent the value network concept where the users enter a contract with the company and immediately has access to all the value network of other customers of the phone company.

A CHIN is a value network as it is solely based on a network of relationships across a set of customers (patients) involving a set of stakeholders (e.g., hospitals, clinics, pharma), and channelizing the relational-efforts of the stakeholders to provide services that the customers use, through both stakeholder-customer and customer-customer interactions through the IT-enabled platform. As Johnson, Christensen, & Kagermann (2008) suggest, for an IT-enabled value network platform, value creation depends on the product or services offered, the revenue model, and the network of relationship through which value is created. Indeed, as reflected in Table 1, studies on business models have mainly focused on the issue of revenue models and value creation through customer engagement. Thus, although broadly, the concept of a business model includes all aspects of a company's approach to developing a profitable offering and delivering it to target customers; and might include a number of components depending on the context and circumstance where it is applied (Shafer et al., 2006). While there may be a number of factors that are important in the context of business models, what is pressing is how the CHINs can earn revenue within the limitations of a community-centric (e.g., social) service orientation is important puzzle. In this regard, the current study's focus on the sustainability of the CHIN-M model that inherently depends on CHIP leaders generating resources needed in support of various global public health challenges.

Product or service offered: In the case of the CHIN-M for global health, the customer focused value creation is the knowledge-centric exchanges between the community and its partners. A clear articulation of specific details on value proposition to various stakeholders, and a discussion of activities CHIP leaders are engaged to deliver this value is essential. In the early pilot, the community will be able to access the Global Health Initiative's section of Henry Ford Health System web site, search a program by either country or by sector (topic), and select the activities CHIP leaders are engaged in support of the program. For example, on Haiti and the country's need to provide vaccinations for Malaria, many activities have to be completed such as:

- Bring awareness to the locals (through radio advertisement, TV advertisement, fliers at schools, churches, hospitals, clinics, retirements homes, organizations, supermarkets, shopping centers, etc.);
- Attain buy-in support from the government and schools, in order to have them advertise on their webpage and to their contacts;
- Organize a social media platform to promote the vaccination (Facebook page, Twitter account, etc.);
- Attain a location to perform vaccinations (i.e. clinics, hospitals, community center, church, etc.);
- Obtain licensed nurses to administer the vaccination;
- Procure the vaccination and other materials required from citizens, local pharmacies, hospitals, clinics, and vaccine maker to provide/sponsor/donate vaccinations and other materials (i.e., bandages, band aids, sterile needles, gauze);
- Maintain records of those vaccinated in order to prevent double vaccination (i.e. computer, database, internet, computer literate workers, etc.);
- Ensure security protocols to keep patient data private.

Such a list will give the community information on how various activities will support a program of interest to them within a particular country.

Revenue model to sustain the community program: Revenues of CHIN can be generated in three possible ways. First, a subscription based model can help a community or house hold to support select set of activities discussed within a program. Second a transaction based model can discuss ways in which a patient or a donor can contribute resources in support of this activity. Some of this support can be in terms of time, talent or monetary resources. Third, a sponsorship model can help CHIP leaders solicit targeted resources from donor community, including those representing private foundations, government and community organizations or wealthy philanthropic community. While some of these programs may initially depend on grants and sponsorships, the sustainability of these programs need a business model that can generate appropriate revenues and resources to complete myriad set of activities associated with these programs.

It is anticipated that CHIP leaders are responsible for the development of a list of active programs available, resourced needed to fulfill the goal, and establish a countdown to reach the goal. CHIP leaders will be asked to establish a minimum donation and allow donors to contribute to a program financially as well as through other means (time, materials, and expertise) to successfully execute a program.

Building a network of relationships: CHIP leaders, with the web portal, develop a network of relationships with other CHIP leaders across the globe, mentors and health care providers. With the help of this network, the CHIP leaders will be able to tailor resources to specific programs. Since the community will be involved in all aspects of funding their programs, it will lead to stronger social connection between the community and public health programs. As community members see the value of working closely together, beneficiaries of select programs will in-turn become future donors and/or other resource contributors. As more citizens get engaged in their community programs, the stronger the motivation for the community as a whole to address the health care needs of their local citizens.

In summary, sustainable business model here call for a clear articulation of value, listing of activities that contribute to this value, and the engagement of multiple members of the community in support of these activities. The goal of CHIN-M is to make CHIP leaders motivate and engage the community in building these sustainable business models. Next section will discuss the potential role of such a community based approach to address continuity of patient care post-discharge from a hospital, and conclude with some future research directions.

ANALYSIS

In the previous section, we have seen how CHIP-like model can help develop regional solutions to continuity of care using both a community relationship network and a shared resource model. While this is just one instantiation of CHIN network using SVC platform, the concept of knowledge exchanges among different groups can be broadened. We can view three types of knowledge exchange among different stakeholder types: knowledge providers (G1), knowledge consumers (G2) and knowledge consultants or those with specific knowledge in support of complex decision making (G3) (see Figure 2). A patient/family is arguably the knowledge consumer and a physician is the knowledge provider. It is assumed that basic information/data is exchanged between the patient (e.g. medical history) and the physician (medical diagnosis). The special knowledge or expertise that a physician provides is pursued by the patient before or during the care delivery process. When the treatment decisions become complex, either a physician or a patient may consult the views of another expert (here we call them as knowledge consultants/community care providers post discharge).

Extending Care Outside of the Hospital Walls

Often the entities (patient, physician and consultant) extend to multiple members (e.g. patient may have family and support members as members of the knowledge consuming group) and physician and consultant may have their own groups to support their participation in the knowledge exchange. Such membership in groups is becoming more critical today given the evolving role of medical homes and specialist clinics where a patient may consult any available physician or specialist in the respective groups to answer an inquiry. The structure shown on top of Figure 2 can manifest itself in different forms for care related support.

Case 1 is a typical consultation post-treatment for a specific pain or medication related question (where often social media interactions are used), or as a part of a diagnosis of an illness based on a set of symptoms observed (where a physical visit to a clinic is often the frequently used approach). With many IT-enabled telemedicine/telehealth technologies becoming widely available, such consultation may develop a revenue stream if hospitals and insurance providers see this as a way to reduce expensive costs of hospital admission/readmission. In fact, states with many rural areas or areas that are urban but with limited transportation support, can start to see this type of exchanges as useful to reduce health care costs, especially those on Medicaid and Medicare.
